As shown in Table 3, there are two majors patterns in the clusters labeled 0 and 1. Both have an unbalanced number of check-ins and check-outs. The former has a large number of check-ins, implying geohashes as destinations, and the latter has a higher number of check-outs, representing origins. Clusters 7, 14, and 24 have an equal amount of check-ins and check-outs but include only data points between 4 -10 p.m. Each of the three represents a separate day: 7, 14, and 24 for Sunday, Monday, Tuesday respectively. The number of features is limited in this study. For future studies, income level and the number and the type of business in each geohash could give more details of subgroup mobility patterns.

Table 3: Summary of Clustering

Cluster Number	Number of data points
-1 (noise)	353
0	21971
1	7056
7	228
14	208
24	193

CONCLUSIONS

We have argued that pattern mining is essential to transportation professionals and decision-makers for improving customer satisfaction and asset utilization. We used the example of the Washington, D.C., dockless shared mobility data to show that knowledge from publicly available data could benefit public and private sectors to realize the strengths and weaknesses of shared mobility schemes and improve operational performance.

Contribution to Research

First, we extend the literature on mobility pattern mining by applying a new approach to understand hidden user commuting patterns. Both sequence mining and clustering demonstrate promising results for extracting meaningful and practical implications from users' mobility data.

Second, unlike the common approach of using transportation analysis zones (TAZ), zip codes, or parcel data, we tried the geohash concept to find patterns in different mobility resolution. This approach could benefit, not only shared-use mobility operators but also urban designers to understand parking patterns relative to building entry/exit doors, sidewalks, streets, etc.

Contribution to Practice

Our findings offer several insights for practitioners. This work investigates the spatial and temporal dimensions of dockless scooter/bike-share services in Washington, D.C. First, we suggest that time-dependent geohash would be the best option to find frequent users' mobility patterns. The results may lead to a cost-effective approach for rebalancing bike/scooters by operators. Different pricing strategies based on the findings would also help operators shift some of the rebalancing work to users. This would dramatically decrease labor for collecting vehicles scattered all-around blocks or at intersections.

Second, we emphasize the importance of users with similar mobility patterns by clustering them into various groups. Operators could apply different types of incentives to frequent users, or record number of accidents for each cluster and find out the groups with a high risk of injuries. City planners could impose traffic rules for different clusters to manage the interactions between shared mobility users and larger vehicles such as cars and transit buses.

Implications for future research

Though much of this analysis is limited to only two active dockless programs, the findings suggest that there are great opportunities to understand the mobility patterns of commuters by using machine learning techniques. Both sequence mining and clustering show promise as approaches for better analysis of hidden profiles in commuters' mobility. However, several improvements could yield better findings:

1. More cities with different spatial patterns could make mobility data available to researchers, transportation engineers, and city planners. The findings of these analyses may influence maintenance planning, infrastructure budgeting, and new development opportunities.
2. Trip surveys of commuters could help realize the true characteristics of clusters we found which may be beneficial to companies for determining pricing schemes, demand analysis, etc.
3. Given the sheer volume of data generated every second from these shared mobility systems, neural networks, especially recurrent neural network, could be used to build a model for predicting the next locations visited.
4. The results presented in this paper are not comprehensive enough because, as explained earlier, access to the spatial and temporal resolution of dockless shared mobility data in the United States is limited. Analyzing more data over a more extended period will provide additional insight. Future work will examine the impact of socioeconomic factors, compare these patterns to supplement or complement modes to dockless shared mobility alternatives.

ACKNOWLEDGMENT

We express our appreciation to Kenny Durell and the Coord Company for allowing us to download the initial dataset through their API for free.

Abstract

This paper discusses how R Python SPSS and SAS can be used to predict bank failures and the benefit that it would have to company's futures. By using stable forecasting, investors can predict the future bank failures. By using these software, organizations can govern the life cycles of their inquiries and be strategic in their in their future financial stability in the bank. We provide an example of how companies can calculate internal rate of return (IRR) and use this to determine future bank failures. This paper also discusses how each software can be used in different manners to determine future financial stability.

Keywords: Statistical Software Languages, Banking Research R, Python, Excel, SPSS, SAS

Introduction

R, Excel, SAS, SPSS and Python are five software programs designed to run statistical analyses and output graphics, can be used for banking research. R can run on any operating system, is open-source, and reflects many of the changing field preferences. It is also highly standardized. SAS is a paid software system that provides high performance analytics for banking research. Organizations can identify, investigate, and govern the life cycle of their inquiries. When it comes to data science one of the most common points of debate is R vs SAS vs Python vs Excel vs SPSS. It is a well-known fact that R, Python, Excel, SPSS and SAS are the most important five languages to be learned for data analysis.

When it comes to data science one of the most common points of debate is R vs SAS vs SPSS vs. Python. We should also include Excel, because, It does all of the functions that the other four programing languages provide. It is a well-known fact that R Python SPSS and SAS are the most important 4 programming languages to be learned for data analysis by data scientists. However, we can also utilize Excel, to perform most of the operations, especially the simple ones. Excel can be purchased when you purchase or download from Microsoft windows website.

In banking research, there are many software packages are being used including R, Python, SPSS.and SAS. Among these packages Python and R open source, free of charge software programming languages. However SAS and SPSS are paid for by licensing companies or universities. (C. Ozgur et.al 2017)

SAS Programming Language

It is a programming language where the input language common spreadsheets as input mechanisms to generate output based on the results of statistical analysis in the form of tables and graphs as RTF PDF, HTML documents. It is an expensive language that is not affordable by most data scientists. Unless the organization helps individuals with financial aid, they will not be able to use SAS. However, both R and Python are free of charge, they could be accessed by anyone, anywhere. This is a biggest advantage of to all data scientists for using both R and Python free of charge.

Classroom and Online Training for Certifications *https://www.edupristine.com/*

SPSS Programming Language

It is also a programming language where the input language common spreadsheets as input mechanisms to generate output based on the results of statistical analysis but the difference from SAS is that the programming language for SPSS is easier to learn and more similar to Excel. However, just like SAS, it is not free of charge. However, we are able to solve large scale problems. *https://www.edupristine.com/*

Python Programming Language

It is another programming language free of charge like R. It is another open source programming language, free to access by everyone. Its code is easier to learn than R or SAS. Python is easier programming language to learn than both. *https://www.edupristine.com/*

R Programming Language

R It is an open source programming language, free to access and pen to all to perform data analysis tasks. It is supported by the R Foundation for basically Statistical Computing. The R language is widely used among data miners for developing statistical software and data analysis. The source code for the R software environment is written primarily in C, FORTRAN, and R. Language R is freely available under the GNU General Public License and is pre-compiled binary versions that are provided for various operating systems. While R has a command line interface, there are several graphical front-ends also available.

Classroom and Online Training for Certifications *https://www.edupristine.com/*

Excel

It also can be used to solve simple problems that other's programs can solve. We can also utilize Excel, to perform most of the operations, especially the simple ones. Excel can be purchased when you purchase or download from Microsoft windows website.(Microsoft, 2019)

R in Finance

The software grew in popularity in response to the increasing overall demands on big data analytics and the need for programs which could handle massive data files. This changed how computational finance was done; the availability of a new and versatile tool is apt to reframe at least a portion of the discussions around calculation and application. Rickert (2014) notes that there were at least 70 separate finance packages available in 2014.

R's flexibility as a software means that it is fully able to perform the necessary tasks for financial analytics. There have been several programs written to facilitate the usage of R in such a setting; one of the most popular is jrvFinance (Trajanov, 2017). This package, alongside the standard tools of R and the bundle package Rmetrics (Trajanov, 2017), allows users to perform the necessary standard financial computations in the software. The largest advantage of this program is that it is set up to mimic the Excel format, allowing familiarity with the system. As Varma (2016) notes in his overview of the jrvFinance package, there are several specific commands to ensure that the correct operations are being performed.

JrvFinance specifically allows for the Internal Rate of Return (IRR) operations within R. Once loading R's syntax, the next step would be to load the package in the current R session (as packages are not stored from session to session). The syntax would be written as (where cf is the cash flow):

Internal Rate of Return: *irr(cf)*
(1)
Internal Rate of Return example: *irr(cf=c(-10, 3, 4, 5, 6))*
(2)

The example would compute an IRR of 0.2488813 for the cash flow specified in the function. The presented example is a fairly simple string of code to learn.

R's Growth and Comparison to Other Software

R's growth in the data analytics field has come to surpass SAS, SPSS, Stata, and MatLab, leading to an increase in job postings where applicants must know how to use R. The overall trend of R is observable in Figure 1, stated from Muenchen (2017).

SAS & R for banking and finance

Continuous innovation(https://www.sas.com en_ph/news/press-releases/2017/january/2016-financials.html)

Analysts named SAS a leader in predictive and advanced analytics, customer intelligence, data management, data integration and data quality. According to IDC, SAS holds a 31.6 percent share of the advanced and predictive analytics market.[2] SAS has also been recognized by industry analysts as a leader in fraud detection, risk and retail analytics. (Cary, 2017).

Maintaining this leadership is heavily dependent upon innovation. Year after year, SAS reinvests about twice the average of major technology firms into R&D – 26 percent in 2016. This unwavering commitment to innovation is behind the ground-breaking new SAS Viya technology – dubbed by analysts as changing the industry. SAS continues to introduce new innovation around this open and cloud-ready high-performance analytics and visualization platform – most recently with SAS Visual Investigator, which marries advanced analytics with dynamic and interactive visual workspaces. With it, organizations can identify, investigate and govern the entire life cycle of an investigation, search or inquiry. SAS plans to introduce even more to the SAS Viya family in the first quarter of 2017. (Cary, 2017).

Looking further ahead in 2017, SAS will continue innovation in its core focus areas, including analytics, visualization, data management, customer intelligence, risk and fraud. Additionally, SAS Viya, artificial intelligence, cloud and IoT will be strong investment areas for SAS. (Cary, 2017).

Forecasting Bank Failures

There has been major concern throughout economists that there will be a recession by 2020 in the United States. Specifically, a survey from J.P. Morgan found that 75 percent of ultra-high net worth investors predict that the US economy will fall into a recession by that time (Turak, 2018). Although there is concern regarding ultra-net investors, there is not as much concern in the realm of the banking industry. For instance, the International Monetary Fund recently upped its U.S. growth forecast for 2018 to 2,9 percent. This increase was caused by Tax Cuts and Job Acts that enlarged the federal spending package. Although this has present benefits, in the long run it is likely that the banks will not benefit from the tax cuts. (Turak, 2018).

DECISION SCIENCES INSTITUTE

An Obvious Basis for MTABS Analysis of 2x2 Cross-Tabulations that Doesn't Work

John R. Dickinson
University of Windsor
Email: MExperiences@bell.net

ABSTRACT

The chi-square test of independence attending cross-tabulations is among the most popular types of analysis in the social sciences. Recently, a system for measuring the reliability of that test, MTABS, has been developed. In construing MTABS a seemingly obvious basis for its progression–it is a form of sensitivity analysis–is directly apparent. That basis, however, is invalid. This study explains and demonstrates that invalidity.

KEYWORDS: MTABS, Cross-tabulation, Chi-square test of independence

INTRODUCTION

Cross-tabulation, often accompanied by the chi-square test of independence, is a mainstay of marketing research and research in the social sciences generally.

- "A cross-tabulation...is easily the most widely used data analysis technique in marketing research..." (Iacobucci & Churchill 2010, p. 362)
- "Perhaps the most common type of bivariate analysis in practice is the cross tabulation of two nominal variables." (Kinnear & Taylor 1991, p. 577)
- "Perhaps the most common of all uses of the χ^2 text is the test of whether an observed breakdown of frequencies in a 2 X 2 contingency table could have occurred under H_0. (Siegel 1956, p. 107)
- Of 20 types of statistical analysis published in major advertising journals from 1980 through 2010, cross-tabulation was the fourth most frequently used. (Yoo *et al.* 2015, p. 554)

MTABS (Moves To and Beyond Significance, Dickinson 2016, 2017) analysis is a complement to the usual chi-square hypothesis test of independence in a cross-tabulation. As a form of sensitivity analysis, its purpose is to provide a measure of the reliability of that statistical test.

From the original cross-tabulation, MTABS successively moves single observations between pairs of cells comprising the cross-tabulation. Moving TO significance, MTABS identifies the two cells where moving a single observation from one to the other achieves the greatest decrease in the p-value. With that move made, MTABS repeats the process for the revised cross-tabulation. The progression is the same for moving the p-value BEYOND significance, only the pair of cells identified is the one that achieves the greatest increase in the p-value.

From the p-value of the original cross-tabulation MTABS determines the number of observations that must be moved to achieve a p-value less than, say, 0.05 and the number of observations that must be moved to achieve a p-value greater than or equal to, say, 0.10.

α=0.05 and α=0.10 are traditional benchmarks for statistical hypothesis tests, though any levels specified by the researcher may be used.

SUM ELEMENT BASE

With that objective in mind, one might be inclined to think that the MTABS "to significance" progression would be made by shifting a single observation from the cell making the lowest contribution to the chi-square statistic to the cell making the highest contribution; it's obvious. The chi-square calculation is a sum and this "obvious" progression can be phrased as moving a single observation from the cell having the smallest sum element to the cell having the highest sum element. This "should" provide the maximum increase in the chi-square statistic value and, correspondingly, provide the maximum decrease in the p-value, i.e., the "to significance" direction.

But this "sum element" basis doesn't work. The reason is that with the movement of a single observation not only does the "from" cell count decrease and the "to" cell count increase, but also the row and column counts of both of those respective cells change. With this, the expected values in all cells in those rows and column change, not just the expected values in the "from" and "to" cells. So it is not necessarily the case that the "sum element" basis results in a regular (i.e., monotonic) increase (decrease) in the chi-square statistic value.

The purpose of this study is to recognize and demonstrate this invalidity for MTABS.

ACCOMPLISHING THE INTENDED MTABS PURPOSE

The sum element basis *may* work monotonically for both decreasing the p-value TO significance and increasing the p-value BEYOND significance. Such is the case, for example, for Bush & Leigh (1984, Table 3, p. 37, Prime Time National~Local x Traditional~Cable Networks) with original p-value 0.11001. And also the case for Murphy, Kangun, & Locander (1978, Exhibit 3, p. 64, Soft Drinks) having original p-value 0.00056. Substantially different original p-values, yet the sum elements basis succeeds in changing the p-value as intended.

SAME DATA BASE, OPPOSITE INTENDED p-VALUE CHANGE

As recorded above, the sum elements basis for moving observations *may* monotonically decrease the p-value TO significance and also *may* monotonically increase the p-value to BEYOND significance. This is in keeping with the intended purpose of MTABS. Such is the case with Lynn (1981, Table 2, p. 15, Marital Status) that relates newspaper readership to marital status.

Relating newspaper readership to education using that same data base (Table 4, p. 15, Education), however, in both TO and BEYOND the sum elements basis monotonically changes the p-value in the direction *opposite* that intended. In the latter cross-tabulation, the sum elements basis completely opposes the purpose of MTABS.

NONMONOTONICITY

The sum element basis toward significance moves observations from the cell with the lowest chi-square sum element to the cell with the highest element. Or toward insignificance from the cell having the highest sum element to the cell having the lowest. In neither direction is the effect necessarily monotonic. For two published cross-tabulations, Table 1 provides examples of this nonmonotonicity.

In Table 1 the direction of change in the p-value after each of 10 observation moves is denoted by ▼ for a decrease and by ▲ for an increase. As may be seen, in the "to"intended direction of change in the p-value, the p-value increases with the eighth and tenth observation moves. In the "beyond" intended direction, the first two observation moves using the sum element basis decrease, not increase, the p-value.

Table 1: Nonmonotonic Changes in p-Value

Intended Direction	Source	Original p-Value	Move 1-2-3-4-5-6-7-8-9-10
TO	Golan & Wanta (2001), Table 3, p. 254, Cut Taxes x Poll~Media	0.25858	▼-▼-▼-▼-▼-▼-▼-▲-▼-▲
BEYOND	Golan & Wanta (2001), Table 3, p. 254, Trust x Poll~Positive	0.02360	▼-▼-▲-▲-▲-▲-▲-▲-▲-▲

EFFICIENCY

Using the sum elements basis for Golan & Wanta (2001, Table 3, p. 254, Best Chance to Win x Poll~Positive Coverage) finds monotonically decreasing p-values for the TO significance direction and also monotonically increasing p-values for the BEYOND significance direction. For this particular application, the sum elements basis validly serves the purpose of MTABS.

In the TO significance direction, the sum elements basis takes 10 observation moves to achieve a p-value of 0.00504, still not less than 0.001. The MTABS approach, however, achieves a p-value of 0.00079 with the movement of just five observations. In the BEYOND significance direction, the sum elements basis takes 4 observation moves to achieve a p-value of 0.10061, just above one traditional benchmark for significance of $\alpha=0.10$. The MTABS approach exceeds that benchmark in only two moves ($p=0.115507$).

Beyond its demonstrable invalidity, it may be said, then, that the MTABS basis is more efficient than the sum elements basis.

THE STANDARDIZED RESIDUAL

The sum elements that are the focus of the present study do serve a purpose. Reynolds (1984, p. 22) suggests examining, "...each component of the chi square statistic...[to] indicate which categories of variables are most closely related." More prominent in the literature, though, is the standardized residual which is the square root of a given sum element. "The contribution of each cell to the Pearson chi-square statistic is printed in the table of **standardized residuals**. Chi-square is the sum of the squares of these." (SPSS 1999, p. 77, bold theirs) With this, the two statistics are perfectly nonlinearly correlated. The standardized residuals, then, suffer the same invalidities as the sum elements.

MTABS SUMMARY

As stated at the outset of this study, MTABS was developed to assess the reliability of the chi-square test of independence in cross-tabulations. The prescribed resultant of an MTABS analysis is to report:

- the chi-square p-value for the original table
- MTABS moves TO α=0.05 % (n)
- MTABS moves BEYOND α=0.10 % (n)

where n is the number of moved observations to decrease the p-value to less than 0.05 or to increase the p-value to greater than or equal to 0.10 and % is the number of such moved observations as a percent of the total number of observations. For the cross-tabulations cited herein, MTABS results are reported in Table 2.

Table 2: MTABS Summary for Cited Cross-Tabulations

Cross-Tabulation	**Original p-Value**	**To p-Value <0.05**	**To p-Value ≥0.10**
Bush & Leigh (1984, Table 3, p. 37, Prime Time National~Local x Traditional~Cable Networks)	0.110	0.385% (2)	n.a.
Golan & Wanta (2001, Table 3, p. 254, Best Chance to Win x Poll~Positive Coverage)	0.037	n.a.	1.389% (2)
Golan & Wanta (2001, Table 3, p. 254, Cut Taxes x Poll~Media)	0.259	1.843% (4)	n.a.
Golan & Wanta (2001, Table 3, p. 254, Trust x Poll~Positive Coverage)	0.024	n.a.	2.439% (2)
Lynn (1981, Table 2, p. 15, Marital Status)	0.014	n.a.	0.538% (8)
Lynn (1981, Table 2, p. 15, Education)	< 0.001	n.a.	3.146% (46)
Murphy, Kangun, & Locander (1978, Exhibit 3, p. 64, Soft Drinks)	0.001	n.a.	3.955% (7)

ABSTRACT

Crowdfunding platforms such as Kickstarter improve financial resource allocation efficiency and act as an essential part of financial innovation. Online crowdfunding platforms provide financing opportunities to a large group of individuals as well as organizations. In this study, we examine the effect of textual descriptions on each project's success rate. Specifically, we generate text-based models that utilize weighted and un-weighted term frequency measures respectively and evaluate their performance using multiple classifiers. We conduct experiments using real-world crowdfunding cases from Kickstarter.

KEYWORDS: Crowdfunding, Text analytics, Classification

INTRODUCTION

Crowdfunding is derived from the concept of crowdsourcing, which is defined as a way to harness the creative solutions of a distributed network of individuals. The first successful example of crowdfunding happened in 1997, when a British rock band took online donations to pay for a tour. Due to the development of online crowdfunding platforms and an increase in the types of crowdfunding projects, there has been an exponential increase in researchers' attention. Crowdfunding differs from traditional financing methods such as banking and venture capital investments mainly because it is designed to support specific and, in most cases, little projects or ideas by raising money from a crowd of people. Crowdfunding provides a revolutionary way to support creative ideas or projects in many industries, such as technology, art, crafts, publishing. With the current trend of online platforms, crowdfunding platforms lend themselves to the development of internet finance, which is a new form of financial activity that takes place primarily over the internet or any other internet protocol network. It is therefore an integration of modern finance and technology (Yang et al., 2018). Internet finance is characterized as the intersection of information technology, big data, and social networks. It improves the financial resource allocation efficiency by creating new avenues for finance in the network era. The combination with technology increases information transparency in the financial market as it relies on information technology to provide transaction information, as well as to coordinate and monitor the transactions. Big data also plays an important role by accelerating the competition and provide more transparent information which reduces the information asymmetry and uncertainty in investment returns.

Driven by trends of sharing and collaborative economy, and fueled by the internet and social media networks, new forms of fundraising and finance activities, based on collective intelligence, are growing. Crowdfunding is an open-market activity to gather financial resources from the public, which mostly takes place on internet-based platforms without standard financial intermediaries. It enables fundraisers to evade complicated regulatory requirements and reduce transaction costs by not requiring standard financial intermediaries (Mollick, 2014). Crowdfunding has many benefits due to its simpler and faster process compared to traditional means. It also serves as a platform for feedback and constructive ideas from the public, as well as a marketing strategy based on high accessibility to an extensive crowd of people.

A number of studies have been geared towards identifying factors that determine the success of crowdfunding projects (Etter et al., 2013; Greenberg et al., 2013; Mollick, 2014; Yuan et al., 2016). The focus has primarily been on structured attributes of projects such as, goal amount, duration of project, category of project, among others. However, the evaluation of unstructured attributes such as the 'blurb', a textual description of the project, is still an open challenge. The textual description is a pitch that presents the purpose and highlight of a project. We argue that unstructured attributes, in this case, the textual description of a project, contain messages pertinent to the success of a project. This research therefore aims to examine the predictive power of textual descriptions of each project's blurb on the project's success rate using text mining. For this study, we examine real-world cases scraped from Kickstarter. Kickstarter started in 2009 and is one of the biggest and most popular crowdfunding platforms on the internet. Similar to many other crowdfunding platforms, it aims to support individuals with small projects and creative ideas, in art, film, food, games, and others. The mechanism on Kickstarter is reward-based and All-or-Nothing. This means if a campaign does not achieve its' goal by the pre-determined deadline, it will not collect any funds. Therefore, the successful fulfillment of a funding goal is imperative for all projects. Our study extracts terms from the textual description and determine their frequency based on the following; (i) term frequency which focuses on high-frequency terms and (ii) td-idf which focuses on the reversed frequency of each term by identifying distinctive terms. In each case, we generate a feature-set in the form of a term matrix, which is used to predict the success rate of project.

Given only less than half of all launched campaigns reach their funding goal on the Kickstarter (Kickstarter), it is extremely important for fund seekers to know the factor(s) that potentially impact project outcomes. The proposed research approach poses potential benefit to entrepreneurs to identify the most influential textual features embedded in project descriptions in order to promote their projects better and improve chances of raising sufficient funds. This research makes the following contributions;

- We present a novel approach of analyzing unstructured features to predict crowdfunding success rate. Our proposed approach poses potential insights into the predictive power of using text analysis in crowdfunding success.
- We evaluate our proposed approach using multiple classification techniques in order to gain an understanding of suitable models for prediction.
- We conduct experiments using real-world crowdfunding cases from Kickstarter to demonstrate the effectiveness of our methods.

RELATED WORK

Crowdfunding Drivers: Crowdfunding is widely studied in many streams. Cumming et al. (2012) describe a French music crowdfunding start-up which is among the first studies of the crowdfunding. Mollick (2014) defines crowdfunding in an entrepreneurial context as a venture by drawing on small contributions from a large group of individuals using the internet characterized by an attempt to disrupt standard financial intermediation. Belleflamme et al. (2015) discuss various crowdfunding sectors and present a range of statistics on existing crowdfunding platforms. They also discuss the functioning of the crowdfunding platforms and the asymmetric information problems in the market. Duarte et al. (2012) examine the trust issue based on a P2P lending site built upon existing financial theories. Michels (2012) investigates the credibility issue in the crowdfunding market and finds that unverifiable disclosures influence the cost and activities in the lending. A group of scholars address the mechanisms in crowdfunding activities regarding possible factors that could influence the fundraising activities. In Ahlers et al. (2015), they focus on the effectiveness of signaling effects of some factors in the context of equity crowdfunding. Their study provides some empirical evidence that some information related to risks could be effective signals and can therefore strongly impact the probability of funding success. Colombo et al. (2015) study the early contributions on Kickstarter and find that internal social capital developed inside the crowdfunding community facilitates a self-reinforcing mechanism and fully mediated by the capital and backers collected in the campaign's early days.

Pattern Detection in Crowdfunding: Interestingly, there is a large body of literature describing the utilization of data mining techniques to analyze the behaviors and project characteristics on different platforms. Although crowdfunding websites such as Kickstarter and Indiegogo behave as online intermediary agents that allow project founders to quickly reach a large number of individual investors with minimal costs, initiators are not always guaranteed to reach their initial fundraising goals (Yuan et al., 2016). Studies about crowdfunding take on different perspectives. While some investigate from a participant or donor angle to check their motivation in participating in online crowdfunding activities (Gerber & Hui, 2013), others focus on project related characteristics that could lead to the success or failure of each fundraising project. In both cases, factors of most interest include number of backers, duration of the fundraising activity, or category of the project that requires funding among other structured features. On the other hand, this study addresses the gap in literature by utilizing data mining and focuses on the potential of unstructured features to characterize the success of projects.

DATA AND PRE-PROCESSING

For this study, we utilize data from Web Robots (Web Robots), which is a public data source. It provides scraped data from several sources including Kickstarter. Detailed data on projects is available on a monthly basis. The sample data used in this study is taken from a large pool of data that was last updated on March 14, 2019. In this data collection, all projects that are still alive on Kickstarter at the time the data is scraped are included. We download all posted projects on Kickstarter specific to the last updated timestamp. For purposes of this study, we randomly select several data files and end up with 37872 observations. According to the stats from Kickstarter (Kickstarter), there are more than 450000 projects launched so far. The raw scraped dataset includes 37 features. Many features are about identification information of scraped projects, for example, URLs about sources, creators' information, links of video, among others, which are not relevant to this study and we remove them. Our final set consists of five features. In table 1, we provide a summary of the features selected for this study.

The target feature or class label is "state", which is the status of the project at the time of data collection. Given that this study is targeted at investigating successful and failed projects, we eliminate any projects whose state is described as "canceled", "suspended" and "live". There are also several features with unstructured values generated as a result of raw data directly scraped from website. In order to preserve the identifying information of projects, we extract additional features such as category, category id, location, location id and project id. However, only the blurb and state are used during the prediction phase.

Table 1. Summary of Features and Descriptions

Feature	Description	Data Type
state	Outcome of project. Five states: successful, failed, canceled, live, suspended.	String
category	Project category in detail (e.g. Web, product design, accessories)	String
goal	Goal in dollars of project	Integer
blurb	Text description of project	String
location	Location of project (e.g. Los Angeles, London, New York)	String

Further data cleaning is applied to check for missing values and duplicate data. Following data cleaning, the selected sample consists of 34160 observations. In figure 1 we provide an overview of the rate per state for projects - successful versus failed.

Figure 1. Rate of Successful versus Failed Projects

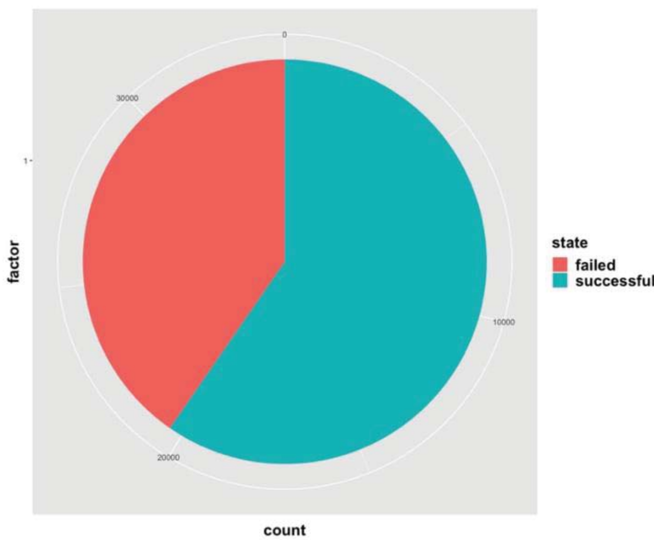

Figure 1 clearly shows that there are more successful cases in the selected sample. This can be attributed to the fact that most of the cases were still live. Nevertheless, it can also be argued that there is a rapid growth in successful projects in recent years given that Kickstarter has been around for 10 years.

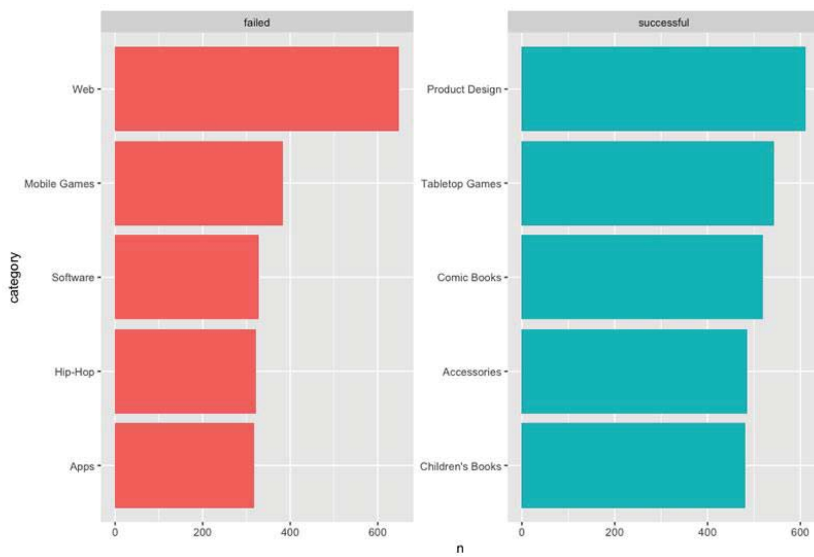
By drilling down into the various projects, the most frequent crowdfunding projects are web-based, followed by product design, accessories, and others. Additionally, most projects are located in Los Angeles, California. In figure 2. we provide a summary of the project counts based on the category and location.

Figure 2. Project Counts by Category and Location

```
        category_name          location_name
Web           :  777   Los Angeles  : 1569
Product Design:  612   London       : 1274
Accessories   :  556   New York     : 1225
Tabletop Games:  543   Chicago      :  636
Comic Books   :  520   San Francisco:  577
Apparel       :  499   Brooklyn     :  540
(Other)       :30653   (Other)      :28339
```

We extend our descriptive statistics to understand the distribution of successful and failed projects by category. As shown in figure 3, web-based, mobile games and software are predominant as the most failed categories in projects. While the most successful cases belong to product design, tabletop games, comic books, among others.

Figure 3. Distribution of Project State per Category

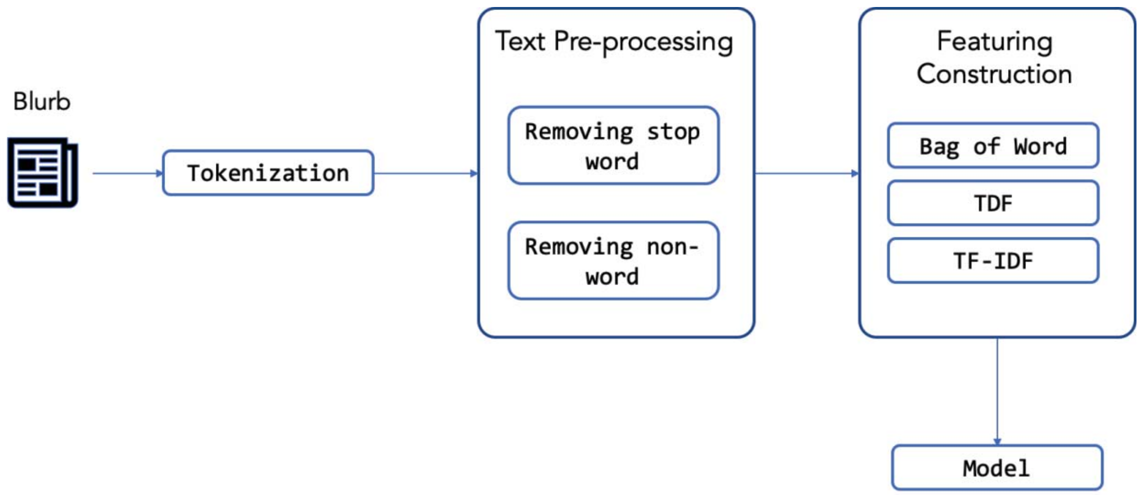


PREDICTION MODEL

Our focus in this research is the textual description, particularly the project blurb and trying to determine its impact on the funding goal. In order to conduct text analysis, we generate a text-based feature set from all project blurbs and then apply classification using state as the target feature. Feature extraction is an essential process for textual analysis (Ravisankar et al., 2011; Tsai & Hsiao, 2010; Yuan et al., 2016). In figure 4 we provide an overview of our proposed text mining approach.

First, we consider the blurb of each project as a document, then apply word segmentation to divide each English term. For this study, we only keep those descriptions in English and remove non-English (e.g. Japanese, French) descriptions due to limitations in the text handling process. We also remove stop words, numbers or other symbols. From that we construct a Document Term Matrix (DTM) using two methods: (1) term-document frequency (tdf) which is based on the frequency of each word in each document; (2) term frequency-inverse document frequency (tf-idf) which is the probability that combines within document-term frequency with the inverse of the expected document frequency in the collection (Amati & Rijsbergen, 2002). Simply put, tf-idf assigns a higher weight to those distinct words which appear less frequently across documents. Using a DTM generates a high dimensional space which often results into high sparsity. Therefore, we also remove sparse terms by limiting the sparsity level at 99%. Our objective is to compare the two matrix outcomes and their predictability on the success rate of projects.

Figure 4. Overview of Text Mining Process



Finally, we apply classification on the term feature sets respectively and using target label - state defined as successful or failed. Due to computational complexity, we only include up to 3000 observations during classification. We also apply data balancing between classes where successful and failed cases assigned a 55/45 ratio. This proportion is in line with the total sample scale as shown in figure 1. We apply k cross-validation using k = 5. In this study, we compare three classifiers, specifically, decision tree (C4.5), K-nearest neighbors and naïve Bayes, all of which are widely used in classification tasks. However, other classifiers are also applicable. For each classifier, we test both term matrices to evaluate their performance.

RESULTS

For model evaluation, we apply the several widely used metrics in classification tasks, specifically: Accuracy which measures the number of correctly classified instances, and precision and recall which measure the rate of true positive cases as a percentage of false positive and false negative instances respectively. In table 2, we provide a summary of the evaluation results for the selected classifiers based on with two different sample sizes, that is using 2000 and 3000 observations.

Table 2. Classification Metrics

	C4.5_TDF	C4.5_TF-IDF	KNN_TDF	KNN_TF-IDF	NB_TDF	NB_TF-IDF
Sample size=2000						
Accuracy	0.5555	0.5775	0.4625	0.5730	0.45	0.45
Precision=TP/(TP+FP)	0.5930	0.5734	1.0000	0.5670	NA	NA
Recall=TP/(TP+FN)	0.6145	0.9018	0.0236	0.9382	0	0
Sample size=3000						
Accuracy	0.5952	0.6032	0.4695	0.5732	0.45	0.45
Precision	0.6206	0.5918	0.9130	0.5724	NA	NA
Recall	0.6782	0.8964	0.0382	0.8836	0	0

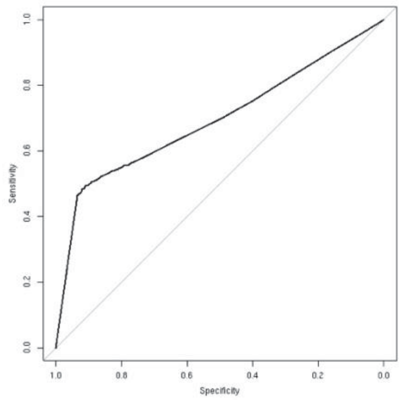
Our findings indicate that tf-idf outperforms tdf, particularly for C4.5 and KNN as indicated by slightly higher accuracy, and significantly higher recall values. The higher recall for tf-idf compared to tdf for both C4.5 and KNN indicates that measuring distinct terms using tf-idf generates a lower rate of false negatives. The overall performance of naïve Bayes is low across all evaluation metrics compared to other classifiers.

On the other hand, while accuracy and recall levels for C4.5 and KNN are higher in tf-idf cases, it is observed that precision levels are higher with tdf for both classifiers particularly for KNN with precision level is > 90% for tdf and < 60% for tf-idf in both sample sizes.

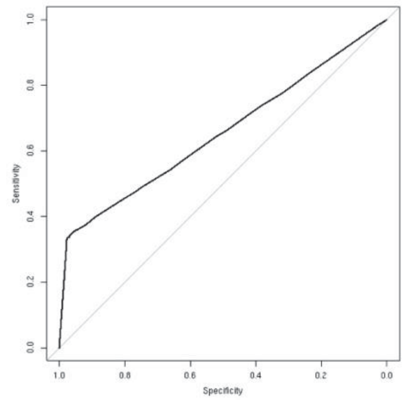
We also observe similar patterns in the receiver operating characteristic curves – area under the curve (ROC-AUC) showing a trade-off of the true positive rate (sensitivity) versus the false positive rate (specificity) at different thresholds. In figure 5a and 5b, our findings show an AUC of slightly more than 50% for all C4.5 and KNN classification except for KNN with tdf matrix.

Based on the prediction outcomes, we drill down to understand the terms utilized in the feature sets. As shown in figure 6, we present a word cloud generated for successful projects. Overall, it is observed that a lot of frequent words are related to the category of projects. Therefore, for future studies, we plan to apply controls on the inclusive terms in order to try to improve the purity of the text.

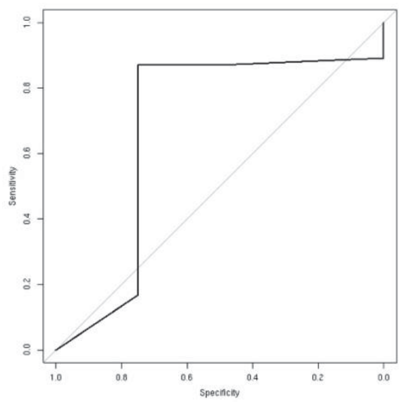
Figure 5a. ROC Curves for Sample Size of 2000



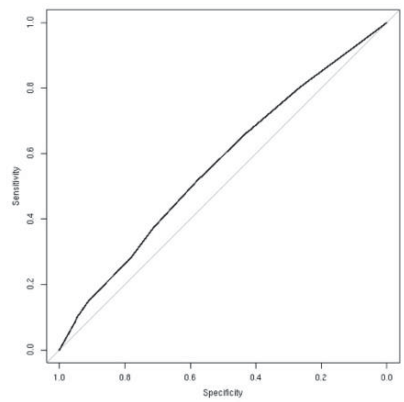
C4.5 TDF



C4.5 TF-IDF



KNN TDF



KNN TF-IDF

Figure 5b. ROC Curves for Sample Size of 3000

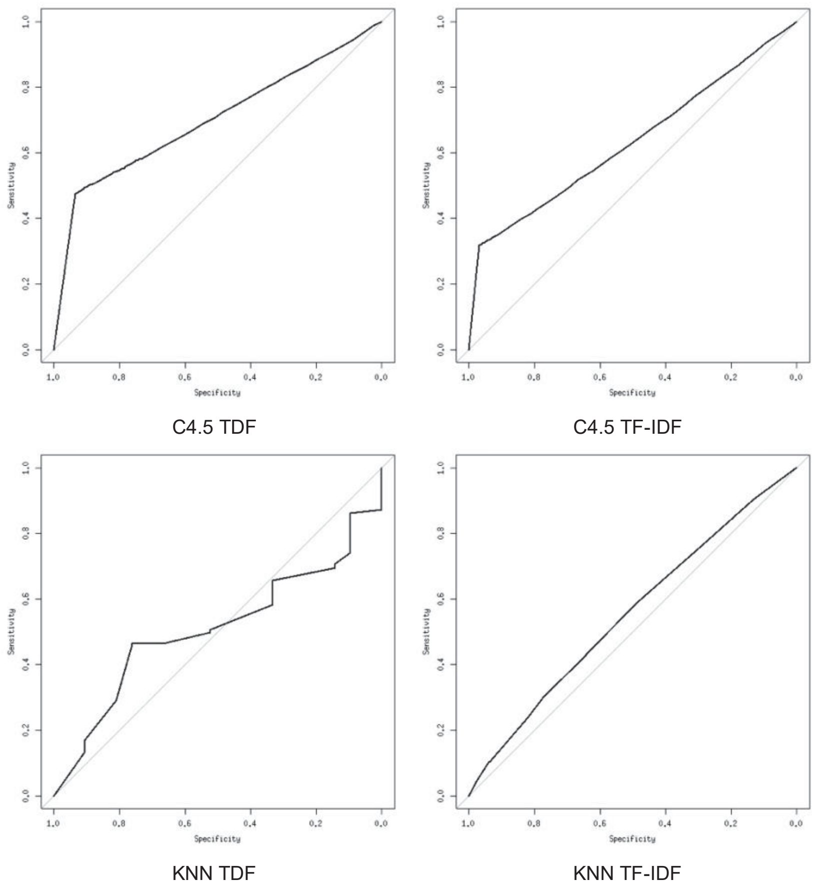


Figure 6. Word Cloud for Successful Projects

DISCUSSION AND FUTURE DIRECTIONS

This research is a preliminary study to utilize text-based descriptions to predict the success or failure of crowdfunding projects. Our findings show that text features predict the success of projects approximately 60% of the time. Furthermore, by comparing different classifiers and feature sets, we detect some interesting information pertaining to the model.

Given the limitations associated with this study such as focus on English terms, we plan to apply advanced text pre-processing methods to translate other languages and symbols. Our study has only been limited to 3000 instances. Therefore, we plan to apply distributed processing so can extend our methods to larger data samples. Additionally, we plan to combine structured and unstructured features in predicting project success in order to improve the robustness of the results in future studies.

Furthermore, given that the rate of fundraising for a project is driven by the will of the funder's feelings, it would be interesting to understand the sentiment included in the textual descriptions to determine if strong sentiments are expressed by the fundraisers and how this potentially influences project outcomes. On the other hand, a case-by-case analysis can be applied to understand why some cases supersede the goal. Other factors influencing the project outcomes in terms of different amounts could also help future fundraisers derive improved strategies on the crowdfunding platform. In the future, we also plan to explore ensemble learning in order to account for the diversity in how text is utilized.

Intellectual Property Theft
What are the Chinese stealing? How are they stealing it? What can we do about it?

Anita Reed
Texas A & M University – Corpus Christi
Email: anita.reed@tamucc.edu

William Harding
Texas A & M University – Corpus Christi (Retired)
Email: bharding_42@yahoo.com

ABSTRACT

We began this project by interviewing twelve Fortune 500 Companies. Most of these companies were very reluctant to directly share their experiences with IP theft. From their reactions, however, it was quite evident that all of these companies did have direct experience with some intellectual property (IP) theft issues. One company (referred to as Company X) proved to be very helpful in this study. Two other companies (referred to as Company Y and Z) offered some information. The information that we were able to collect is presented. First, in our paper, we define what IP theft is, and how it occurs. Next we discuss several examples of IP theft and the Chinese government's continuing support of it. Next we look at what some companies are doing to better protect themselves from IP theft. Finally, we look at what impact the U.S. trade tariffs and the trade talks are having, or not having, relative to Chinese IP theft.

Key Words: Intellectual property (IP), IP theft, forced IP transfers, copyrights and trade secrets, counterfeit goods, cloning, cybersecurity, proprietary knowledge, reverse engineering, trade tariffs, IP protection, No-spy agreements.

INTRODUCTION

Intellectual property (IP) is essentially any unique product of the human intellect that contains commercial value. Examples of IP are books, songs, movies, paintings, inventions, chemical formulas, computer software, etc. In the U.S. we have IP protection through: Trade secrets, trademarks, patents, and copyright laws. Trade secrets do not expire, but other companies can conceivably reverse engineer the formula or process. The advantage of a patent is that the U.S. government gives the patent owner the exclusive right to the IP, but the patent expires after 20 years. Patents are considered an unreliable way of protecting IP for software because the U.S. Patent Office has given out many bad/unreliable software patents that cannot hold up in court. Therefore, many times software is better protected in the U.S. through the Copyright laws. In the U.S. Trademarks can be registered and offer some protection from IP theft.

RESEARCH QUESTIONS AND METHODOLOGY

We are attempting to identify what kinds of IP are being stolen, and specifically what are the Chinese stealing. Additionally, identify what methods are commonly employed to steal IP, and what companies are doing to prevent IP theft. Our methodologies include: Interviewing 12 Fortune 500 companies, literature review, and current events in the news.

LITERATURE REVIEW

The Interviews

We interviewed twelve Fortune 500 Companies. They were very reluctant to directly identify specific cases of IP theft within their respective companies. Some of these companies were willing however, to talk about things that they were doing to help prevent IP Theft. We will discuss these examples later in this paper.

Annually, the US loses from $225 billion to $600 billion due to Chinese intellectual property theft. While not the only nation that steals intellectual property from the US, it is the main one. Some companies were infiltrated by Chinese spies who brought the information back to China, or they bribed insider employees. Theft is most prevalent; however, it is not the only way the Chinese are creating and selling similar products to those in the US. As much as 87% of seized counterfeit goods imported into the US were produced using reverse engineering of trademarked, patented, and copyrighted materials from many foreign companies. (Saady, 2018).

China's theft of intellectual property is encouraged by official Chinese policy and often involve active participation of government personnel. The theft of intellectual property includes fashion designs, pirated movies / video games, patent infringement, theft of proprietary software, and much more (Blair, 2017).

Since intellectual property helps the Chinese economy and thus, its government, the Chinese government, currently, does not plan on cracking down on most of these cases. In fact, intellectual property theft in China isn't illegal. When a US company wants to go into the Chinese market, they are faced with laws that force them to collaborate with Chinese companies in several key industries. This forces many companies to give their intellectual property to the Chinese. The Chinese realize that they need foreign technology companies, so they've created a means to legally obtain the information they want (Oviti, 2018). As of the writing of this paper, the U.S. government and the Chinese government are participating in Tariff/Trade talks. Hopefully, as a result of these talks, this situation can be improved. The Chinese do recognize the need for IP protection, especially for themselves.

Examples of Stealing/Cloning Techniques

The Beijing company Ninebot decided to market its own version of the two-wheeled self-balanced single-person vehicle after the debut of the pioneering technology by Segway in the US. The design is uncanny to that of the Segway which was marketed and sold in the US alongside its competitor. So Segway pursued an import ban on Ninebot for alleged stolen patents and design. It was thereafter that Ninebot outright bought Segway for a confidential amount (Ninebot, 2015). This is seen as a way of "quelling" the competition and silencing them after exploiting them. A second example happened when DuPont had its method of making a shimmering white color to its products, a chemical engineering problem that it invested a substantial amount of time and money. It was so successful that China sought after the process but for a quicker way to do it with less effort compared to the DuPont originator. So, they used a nationalized American citizen from their country to coerce former DuPont engineers to divulge their secret process. Eventually one of the DuPont engineers cracked, made a deal with China, and helped establish a factory with them that would take the color with DuPont's knowledge in tow. DuPont won their court case after seeking reparations, but ultimately lost the war as its trade secret it kept a lid on for making white was forever exposed to the world, ruining any market advantage (Lesperance, 2018).

A Chinese firm, Sinovel, "contracted with American Superconductor Corp. (AMSC) for more than $800 million in products and services to be used in wind turbines it manufactured" (Raymond, 2018). However, according to the same Reuters article, "Sinovel recruited Dejan Karabasevic, an employee of an AMSC unit, to join the Chinese company and to secretly copy information from AMSC's computer system, including the source code for the PM3000, part of its wind turbine control system". The code they stole was used in wind turbines they commissioned in Massachusetts. Following this, the American company AMSC lost over $1 billion and had to cut 700 jobs.

Several companies have suffered because their ideas have left their headquarters, boarded a plane and showed up in a different market, before the company could even decide on a launch date. One of the most recent IP Thefts was caught before it left the country. An ex-Apple employee, Xiaolang Zhang, was arrested at the airport by the FBI before attempting to board a flight to China. Zhang had worked as an engineer on a project developing self-driving cars. He's accused of stealing this information with plans of using it as a Chinese startup company called X Motors (Saady, 2018).

China has been thriving off stolen ideas for decades; this is nothing new. Outside of the tech industry the knock-off brand market in China is very well known and thriving to this day. China has stepped up and put in motion different tariffs and laws to better amend these detrimental blows to foreign companies. In 2017, China started a nationwide campaign to protect foreign firms' international property rights. The Ministry of Commerce says China is a developing country and doesn't have a perfect system to protect IP, acknowledging that there's much work to do…" (Bloomberg, 2018).

Huawei Technologies is a Chinese multinational conglomerate which specializes in telecommunications equipment, consumer electronics, and technology-based services and products. Huawei's smartphones tablets, etc. can be purchased from Sam's Club, Walmart, Amazon and many others. In 2014, T-Mobile filed a civil case against Huawei. Huawei was accused of stealing intellectual property related to a robot that T-Mobile used to diagnose quality control issues in mobile phones. A jury in Seattle found Huawei guilty in May 2017. In December 2018, Huawei CFO, Meng Wanzhou (the daughter of Huawei's founder), was arrested in Canada for extradition to the U.S. related to alleged violations of Iranian sanctions. (Wakabayashi, 2018). Canada now blames U.S. for the Huawei CFO arrest backlash that has left two Canadian citizens in Chinese prisons and a third Canadian citizen on death row. On December 11, 2018, President Trump told Reuters that he might intervene in Meng's case if it would help his trade war with China. "If I think it's good for the country, if I think it's good for what will be certainly the largest trade deal ever made – which is a very important thing – what's good for national security – I would certainly intervene if I thought it was necessary," the president said. In late January the U.S. Justice Department charged Meng and Huawei with conspiring to violate U.S. sanctions on Iran. On Friday, March 1, 2019 the department of Justice Canada officials issued an authority to proceed, formally commencing an extradition process in the case Ms. Meng Wanzhou. China, whose relations with Canada have deteriorated badly over the affair, denounced the decision and repeated previous demands for

Meng's release. Legal experts had predicted the liberal government of Prime Minister Justin Trudeau would give the go-ahead for extradition proceedings, given the close judicial relationship between Canada and the United States. It could be years though before Meng is ever sent to the United States, since Canada's slow-moving justice system allows many decisions to be appealed. Professor Wesley Wark of the University of Ottawa's Graduate School of Public and International Affairs said "the Canadians will take a beating throughout this whole process" from China. "I suspect the Trudeau government is desperately hoping that the Americans reach a deal with the Chinese," he said. Brock University professor Charles Burton, a former Canadian diplomat who had served two postings in China, said Beijing was likely to retaliate further. "They're not going to take this lying down… one shudders to think what the consequences could be," he told the Canadian Broadcasting Corp., saying Beijing might crack down on Canadian canola shipments or stop Chinese students from going to Canada. (Ljunggren, 2019)

Other news around the world: Huawei and fellow Chinese company ZTE were both banned from supplying 5G equipment to Australia's wireless network in August, 2018 on national security grounds. China's Huawei offered Berlin a "no-spy agreement" to address security concerns over the Chinese company's involvement in building Germany's next-generation 5G mobile infrastructure, a German magazine said. "We (Huawei) talked to the German Interior Ministry and said that we were ready to sign a no-spy agreement with the German government and to promise that Huawei will not install any backdoors in the networks," Wirtschaftswoche (of Germany) quoted Huawei Chief Executive Ren Zhengdei as saying. He called on the Chinese government to sign a similar no-spy-agreement and to adhere to European Union data protection laws. Germany last month set tougher criteria for vendors supplying network equipment, stopping short of singling out Huawei for special treatment and instead saying the same rules should apply to all vendors. (Alkousaa, 2019)

What some Companies are doing to prevent IP Theft

Intellectual property protection is crucial to any business. Complete secrecy and information block-outs seem to be the first line of defense. However, IT can play an important support role in protection. Cybersecurity measures must be implemented to protect proprietary knowledge stored in computer servers. Servers should be separated from outside networks and access privileges should be limited. The information should be encrypted, and network traffic should be monitored. Digital watermarking and time stamping can lace ownership rights into digital materials to help prove ownership in cases of litigation. Along with these typical cybersecurity measures, new technologies have led to new problems and new solutions. A new problem in copyright infringement is the availability of 3D printers. CAD files are shared online with printing information for patented products and designs. It is hard to track down the printers of these files, but companies should use web crawlers to find these CAD files to make sure their products do not end up being easily counterfeited (Wessing, 2017).

Corporations can only do so much to protect their copyrights and trade secrets. Educating the public to be conscious of the difference between a genuine product and a fake one, and the economic consequences of purchasing a fake, is one way that companies can combat this kind of theft. Most governments have had some type of intellectual property law on the books for years, which allows companies to use fear of prosecution as a deterrent. Governments around the world have begun writing laws specific to new circumstances that have arisen in the cyber-age. When state sanctioned theft occurs across nations there is not much a single company can do to stop a foreign company from profiting from the property they stole. As these cases have become more prevalent, the US Government is now taking a stand to back US companies in the fight again international intellectual property theft.

The following involves an interview with one manager at one Fortune 500 Company (who did not want to be quoted), which we will call Co. X: In a personal interview with manager James, of Co. X, He explained how they use a Hierarchy system to enact the principle of least privileges. Co. X uses an employee number to identify the privileges you have, the higher the number - the more privileges an employee possesses. They also require that all physical documents to be shredded. In addition, Co X utilizes a segmented network, not keeping all of their data in one location. In the event of a data breach, the compromised network is the only network accessible by the hacker thus minimizing the severity of damage to the company. James also explained that Co. X monitors their logs regularly. They monitor information being accessed as well as by whom. Co. X also requires that input devices such as USBs be restricted throughout all of their buildings. The interview with James was very informative on how a corporation handles the threat of intellectual property theft. Co. X has appropriate safe-guards in place for the biggest threat to a company's intellectual property, an insider. With least privilege access, persistent auditing, and encryption. This is one of the multitudes of contributing factors as to why Co. X has only a very few cases of IP theft.

Company "Y" uses several controls to limit their threat risk. They have 24-hour security officers and their security systems are monitored 24 hours a day, 365 days a year for signs of tampering or unauthorized logins. They also use encryption, a VPN, vulnerability testing as well as limiting their own employee's access to their systems.

Company "Z" requires all their employees and users sign off on an Intellectual Property Notice. The notice basically says that all the content, information and materials on their site, such as text, graphics, logos, images, data, software and other material is owned or licensed by Company "Z" is proprietary and protected by copyright, trademark, patent, and/or other intellectual property rights. Company "Z" grants only a limited use, and the user may not copy, reproduce, modify, remove, delete, add to, publish, transmit, transfer or sell any of this material.

What Impact are the Tariffs having?

As of March of 2018, the president of the United States—President Donald Trump—imposed strict tariffs on China in order to protect U.S. technology (Trump, 2018). While the tariffs were made as a case for fair trade and "to defend our industry and create a level playing field for the American worker", the tariffs are largely a response to Chinese firms and businesses that were stealing intellectual property from United States persons or businesses.

On CNBC the other day, Kevin O'Leary, a CNBC Contributor, present a "drain cleaning rod" that was invented and being sold by an American company. The device has been cloned and is being sold by other companies from foreign countries, but because of the Tariffs on Chinese imports, it is too expensive to buy the clones from China. So, this is one very small victory supporting U.S. Tariffs on China. However, our farmers and live-stock producers, that were selling many of their products to the Chinese, continue to lose billions of dollars in lost sales every day with the tariffs still in place. What effect this tariff war will eventually have on our trade policy with China, is anybody's guess. We are hopeful that as an outgrowth of these trade talks, our U.S. government will then be able to actively assist U.S. companies (large and small) to receive no-spy, no IP theft, and no invasion of privacy agreements with all other countries. It is the enforcement side of these potential agreements (especially with China) that U.S. companies will need the most help.

More Recent Developments

Recent developments have occurred that indicate the issue has not been resolved and continues to be in issue:

May 15: The Trump administration (via executive order) added the Chinese Company Huawei to the U.S. department of Commerce's "Entity List" (blacklist). This has had a large impact on U.S. companies such as Google, Intel and Qualcomm that were using Huawei's products. Most U.S. companies have publicly stated that they will obey the administration's order.

May 20: The Trump administration's Commerce Department issued a temporary license that will allow Huawei to maintain its current products (for existing customers). The license expires August 19, 2019.

May 23: President Trump has called Huawei "very dangerous," but said the U.S. is open to including the company as part of a future trade agreement between the U.S. and China.

May 28: Huawei filed a legal motion claiming the ban on their company working with other U.S.-based companies violates the U.S. Constitution.

May 31: China threatens to create its own "Entity List" (blacklist) to include American firms. Huawei ordered employees to cancel technical meetings with American contacts. Huawei also reportedly sent back American citizens who worked in research and development roles.

June 6: Huawei will build a 5G network for Russia's largest carrier.

June 7: Facebook will no longer allow Huawei to pre-install any of its apps on the company's smartphones. These apps include Facebook, Instagram, and WhatsApp, three of the most popular apps in the world. The ban only applies to phones that have not yet left the factory.

June 29: On the sidelines of the G20 summit in Osaka, Trump said "U.S. companies can sell their equipment to Huawei," without going into detail. "We're talking about equipment where there's no great national security problem with it," Trump continued. It's not clear what this means for now.

July 16: A bipartisan group of senators has introduced a bill, "The Defending America's 5G Future Act" that would effectively set the original Huawei blacklisting in stone. It would "codify" the executive order forbidding sales of telecom equipment to customers posing national security risks, and bar the removal of Huawei from the Commerce Department Entity List without an act of Congress.

August 15: Are the Hong Kong protests related to the US/China trade war? Maybe? In 1997, the Crown Colony of Hong Kong officially reverted to Chinese sovereignty, ending 156 years of British rule. Since then, Hong Kong has continued to enjoy more open trade commerce than mainland China. However, other basic freedoms and rights have been changed to conform to mainland China. In recent years the Hong Kong protests by its citizens continue. If the trade war is not settled, Hong Kong could also lose some of its open trade agreements with the U.S. As of the paper submission for publication date: The Trade War between the U.S. and China escalates from one retaliation to another, but some helpful tweets and comments also come about. The two might continue their trade talks in September. Huawei CFO Meng Wanzhou still resides in Canada and is still fighting extradition to the U.S.

RESEARCH CONCLUSIONS

IP theft is rampant and world-wide. Most IP theft is done through cloning, copying, and reengineering. In the past, the Chinese have not wasted their time or money on research and development. Mostly, they have found ways to just steal it, and with their government support. All twelve of the Fortune 500 companies that we interviewed have experienced IP Theft. Most of these companies were reluctant to share their experiences, but they are doing what they can to protect themselves. Many companies have learned that doing business with the Chinese is risky. Small American companies (especially) could use American government support in their fight against IP theft.

ABSTRACT

The organizational ability to react to cyber attacks recalls the concept of resilience. In order to provide a deep insight on how companies effectively introduce and implement cyber systems to enhance cyber resilience, a multiple case study analysis revealing interesting managerial implications is conducted.

KEYWORDS: Resilience, Cyber Security, Multiple Case Study

INTRODUCTION

Nowadays, according to complexity and level of digitalization of its business and to value offered to social and economic context, every organization has an IT system and the necessity of protecting its information and digitalized processes from fraud attempts and act of vandalism. These crimes, called cyber attacks, can be fronted by the implementation of a cyber resilient system.

The ability to react to these attacks recalls the concept of resilience, known in physics as the assumption of sustaining crashes without breaking. In management sciences, resilience is defined as the ability of an organization to adapt to unexpected disruptive changes or a trouble, for being able to continue the necessary operations both in expected condition and unexpected conditions (Wieland & Wallenburg, 2013).

Two features belong to a resilient system: (1) robustness against the predictable attacks and (2) ability to come back to a safe state if an attack has been successful, without regressing (Rogers *et al.*, 2016). This is the ability of the system to adapt, to reduce the probability of having to deal with sudden disturbances and having to resist their spread, maintaining control over structures and functions, and being ready to recover and respond with immediate and effective reactive plans to overwhelm the disturbance and restore to a robust state of operations.

The paper is organized as follows. The first section contains the literature review presenting the concepts of cyber security and resilience and the main stream of research for the cyber resilience: risk management process and resilience management process; further this section highlights the emerging research gap and defines the research question.
The third section (methods) presents the research methodology: a case studies analysis built thanks to the interviewing of cyber security managers: in this section the research protocol is detailed. The fourth section (results) contains the descriptive analysis of the cases and the last one (discussion and conclusion) discuss our results and report our conclusions, summarizing contributions and limitations of the research, together with possible future research directions.

LITERATURE REVIEW

Cyber Resilience

In the interconnected digital world, cyber resilience is a condition for continuous existence and competitive advantage, so the trend is towards adopting resilient strategies and operations to ensure success when operating in a hyper-connected system. Attention paid by companies to resilience is not only vital for the sustainability and growth of their business models but also a source of competitive advantage. In order to survive and guarantee longevity, companies must be constantly evolving, being able to adapt quickly, reacting to the ever-changing environment and, above all, they should have the ability to recover quickly from unforeseen events. Resilience of cyber-systems or cyber-physical systems is essential to maintain trust and privacy by mitigating security risks, protecting customers and providing them with better and safer services. Two features belong to a resilient system: (1) robustness against the predictable attacks and (2) ability to come back to a safe state if an attack has been successful, without regressing (Rogers *et al.*, 2016). This is the ability of the system to adapt, to reduce the probability of having to deal with sudden disturbances and having to resist their spread, maintaining control over structures and functions, and being ready to recover and respond with immediate and effective reactive plans to overwhelm the disturbance and restore to a robust state of operations.
Roege *et al.* (2017) propose a distinction between safety and resilience: the first one focusses on the protection of systems from threats or events, while the second one is the ability to prepare and adapt to changing conditions, to resist and to recover quickly from interruptions. In detail, resilience includes the ability to resist and recover from intentional attacks, accidents, threats and natural disasters.

Models for Cyber Resilience

Cyber resilience requires the integration of the risk management process and the resilience management process (Haimes, 2009; Collier *et al.*, 2014). Risk management selects and prioritizes potential measures to prevent or mitigate impacts, whereas resilience seeks to improve the system's inherent ability to respond to inevitable changes, both long and short, thus adopting a time perspective. “Improving a system’s resilience offers significant advantages in managing risk; improving the resilience of a system constitutes an integral part of the risk management process“ (Haimes, 2009: 500). “Successful implementation of these mechanisms will depend on the integration of risk- and resilience-based management in an adaptive framework” (Collier *et al*., 2014: 70). Indeed, a vision based on risk management focuses on prevention or protection against intrusions (avoiding risk) or on mitigating the negative consequences of an event. Differently, an approach based on resilience is concerned with ensuring the continuity of functions and critical services.

Several authors have proposed over the years methods for creating resilient systems for cyber security using a risk management process or a resilient management process.

Risk Management Process for Cyber Resilience

Katsumata *et al.* (2010) propose a proactive approach that builds protective and resilient mechanisms to provide greater assurance to the organizational information system. This approach is called Cyber Security Risk Management (CSRM). CSRM starts with the NIST methodology, which includes three processes: risk assessment, risk mitigation and monitoring/control, extending to a four-step process that includes an initial phase of risk management planning. The evaluation process establishes the risk baseline; the mitigation process uses a cost-benefit analysis to evaluate potential additional countermeasures that reduce risk; the CSRM risk monitoring and control process provides a method of "monitoring of identified risks, monitoring of residual risks, identification of new risks, execution of risk mitigation plans and assessment of their effectiveness". It also includes feedback cycles to allow a continuous process of risk assessment, mitigation and monitoring.
Steen and Aven (2011) in order to enhance resilience engineering, suggest the use of a risk perspective different from the most popular one. In this case probability is replaced by uncertainty. The (A, C; U) risk perspective in fact takes in consideration event A, consequence C and uncertainty U. Collier *et al*. (2013) in their risk-based cybersecurity framework show how risk-based standards can move beyond risk assessment to create systems that are more resilient to dynamic threats. According to Jensen (2015), cyber-resilience for the efficient functioning of the maritime industry should improve the risk management approach implemented by the introduction of the following guidelines: 1) informational campaigns directed at the maritime companies in terms of the cyber-risks they face; 2) pressure from customers who are made increasingly aware of the risk to their cargo in cases where maritime companies lack cyber-defenses; and finally 3) "cyber premiums" on insurance policies that reflect the degree to which maritime companies adhere to the voluntary guidelines.

Resilience Management Process for Cyber Resilience

Burstein *et al.* (2012) propose a model called STRATUS: strategic and tactical resiliency against threats to ubiquitous systems. This model uses an overload of computational resources to diagnose an attack, to quickly switch to calculated backup actions and predict downstream events by the attackers to make the functions resilient to those attacks. It uses an ontological model containing missions, components, vulnerability, reliability levels for hardware and software resources provided with attack tests, schemes of the attack plan for multi-stage attacks, host and cluster organization to think about how physical or network proximity can contribute to the possibility of vulnerability.
Linkov *et al.* (2013) designed the resilient matrix framework. In this matrix, the column indexes are the four stage life-cycle by the US National Academy of Sciences (NAS, 2012) i.e. plan/prepare, absorb, recover and adapt and the rows represent the four domains taken from Network-Centric Operations doctrine (Alberts, 2002) i.e. physical, information, cognitive and social. Cells in this matrix provide recommendation for resilience metrics. Linkov *et al.* (2013) provided these metrics.
Ferdinand (2015) studied how to build and to maintain a state of cyber resilience in organizations. The focus is on the organizational learning of the environment both internally and externally and the ability to exploit opportunities and manage threats in four moments: monitoring, analysis, decision-making and change. A structure with dynamic capabilities must

present both reactive capacities, necessary to respond to market changes, and proactive capacities that allow foreseeing and creating market changes. The combined use of dynamic capabilities, i.e. (1) ordinary defensive capabilities, (2) dynamic resilience capabilities and (3) extraordinary capabilities leads to increasing levels of maturity in the area of computer (cyber) resilience.

DiMase *et al.* (2015) propose the cyber physical systems security framework (CPSS). According to this framework, the following ten areas of concern enable an holistic analysis of the health status of the cyber-physical security: (1) Electronic and physical security, (2) Information assurance (IA) and data security, (3) Asset management and access control, (4) Life cycle and diminishing manufacturing sources and material shortages (DMSMS), (5) Anti-counterfeit and supply chain risk management (SCRM), (6) Software assurance and application security, (7) Forensics, prognostics, and recovery plans, (8) Track and trace, (9) Anti-malicious and anti-tamper, (10) Information sharing and reporting.

Boyes (2015) details the cyber security attributes that affect cyber resilience. They are divided in three main clusters: Information quality & validity system configuration (integrity, utility and authenticity); controlling access and system operations (confidentiality and possession) and continuity of operations safety personnel & assets (availability/reliability, safety and resilience).

Davis (2015) identifies factors affecting the ability of an acquirer to protect its information using a simplified supply chain model. These factors are (1) state cybersecurity requirements to suppliers using a common framework and language, (2) integrate cybersecurity into the acquirer procurement process (3) devote resource to investigate the makeup of the supply chain (i.e. which supplier organizations make up the supply chain), (4) understand how a supplier meets the acquirer's requirements when not using a common, shared, framework, and language, (5) identify acquirer information shared between the acquirer and its direct suppliers, and acquirer information shared between direct and indirect suppliers.

Sharkov (2016) shows the approach implemented in Bulgaria to design a roadmap for the cyber-security national strategy. The national strategy for Bulgarian cyber-security focus on two main aspects: the implementation of the so called "CIA triad" i.e. a triad for information security made by confidentiality, integrity and availability and the measurement of knowledge of risks and threats. Those two aspects allow the structuring of objectives and measures at three nested levels: information security, IT security and IT resilience. Threats, objectives and measures are outlined in three categories: "Known", "Unknown knowns" and "Unknown unknowns".

Tran *et al.* (2016) designed the Cyber Resilience Recovery Model (CRRM) to combat a zero-day malware attacks. The model provides insights into the strengths and weaknesses of current recovery processes and presents possible solutions for addressing changing cybersecurity threats.

Best practices as awareness trainings or the isolation of a machine infected with zero-day malware using the full containment method formatting and re-imaging a machine infected with zero day malware are indicated.

Rohmeyer *et al.* (2017) believe that complete cyber resilience tests, based on the principles of cyber war-gaming to involve all corporate domains, have the potential to increase knowledge, improve resilience and make its improvement measurable. Coordinated game events, discussion-based seminars and conferences, and special forums to support collaborative analysis of real-world events and emerging threats are also recommended.

Carayannis *et al.* (2019) outline the anatomy an ambidextrous approach to cyber security adopting a balanced scorecard, multistage approach under a 7Ps stage gate model (Patient, Persistent, Persevering, Proactive, Predictive, Preventive, and Preemptive). Such an approach "emphasizes the need to enable a complex, nonlinear, adaptive process of dynamic intangible

organizational assets, resources, and capabilities across a performance frontier” (p. 1) in order to enhance cyber resilience.
Caron (2019) highlights the potential of cyber-testing techniques in assessing the effectiveness of cyber-security controls and obtaining audit evidence.

Table 1: literature review

Author (year)	**Objective(s)**	**Approach**	**Output**
Katsumata *et al*. (2010)	To propose a proactive approach that builds protective and resilient mechanisms to provide greater assurance to the organizational information system.	Risk Management	Cyber Security Risk Management (CSRM).
Steen and Aven (2011)	To understand how risk can be assessed and treated to enhance resilience engineering.	Risk Management	The basic ideas of resilience engineering can be supported by the (A, C, U) risk perspective.
Collier *et al.* (2014)	Showing how risk-based standards can move beyond risk assessment to create systems that are more resilient to dynamic threats.	Risk Management	A risk-based cybersecurity framework
Jensen (2015)	Cyber-resilience for the efficient functioning of the maritime industry.	Risk Management	Three main tools are recommended: 1) informational campaigns 2) pressure from customers 3) "cyber premiums" on insurance policies
Bodeau and Graubart (2011)	To investigate how to evolve architectures, cyber resources, and operational processes to provide cost-effective cyber resiliency.	Resilience management	Cyber Resiliency Engineering Framework.
Burstein *et al.* *(*2012)	To diagnose an attack, to quickly switch to calculated backup actions and predict downstream events by the attackers to make the functions resilient to those attacks.	Resilience management	Strategic and tactical resiliency against threats to ubiquitous systems model (STRATUS).
Linkov *et al.* (2013)	To provide recommendations for resilience metrics.	Resilience management	Resilience Matrix Framework.
Linkov *et al.* (2013)	To provide the metrics recommended by Linkov *et al.* (2013).	Resilience management	Resilience Metrics.
Ferdinand (2015)	How to build and to maintain a state of cyber resilience in organizations.	Resilience management	The combined use of dynamic capabilities leads to increasing levels of maturity in the area of computer (cyber) resilience.
DiMase *et al.* (2015)	To provide a holistic analysis of the health status of the cyber-physical security.	Resilience management	Cyber Physical Systems Security Framework (CPSS).
Boyes (2015)	To detail the cyber security attributes that affect cyber resilience.	Resilience management	Three main clusters affecting cyber resilience are identified.
Davis (2015)	Building cyber-resilience into supply chains.	Resilience management	He identifies factors affecting the ability of an acquirer to protect its information using a simplified supply chain model.
Sharkov (2016)	To design a roadmap for the cyber-security national strategy.	Resilience management	The implementation of the so called "CIA triad" the measurement of knowledge of risks and threats: "Known", "Unknown knowns" and "Unknown unknowns".
Tran *et al.* (2016)	To combat a zero-day malware attacks.	Resilience management	Cyber Resilience Recovery Model (CRRM).
Rohmeyer *et al.* (2017)	To test Capability Effectiveness for Architectural Resiliency in Financial Systems.	Resilience management	Complete cyber resilience tests, based on the principles of cyber war-gaming to involve all corporate domains, have the

			potential to increase knowledge, improve resilience and make its improvement measurable.
Carayannis *et al.* (2019)	To outline the anatomy an ambidextrous approach to cyber security.	Resilience management	Multistage approach under a 7Ps stage gate model.
Caron (2019)	To highlight the potential of cyber-testing techniques in assessing the effectiveness of cyber-security controls and obtaining audit evidence.	Resilience management	Cyber-testing techniques are providing insight in the effectiveness of the actual implementation of cyber-security control and concise input for cyber-risk management and improvement recommendations.

Based on the theoretical background, the risk management approach resulted to be replaced by the adoption of a resilient management one in the most recent years. The second approach seems to be almost the evolution of the first one in order to enhance cyber resilience.

Research question

From the analysis of literature, some research gaps emerged. There are not yet enough studies focused on how to introduce and implement a cyber systems rather than specific practices and metrics to use. This limitation justifies our research that aims to provide a managerial approach in the implementation of a cyber resilient system. For this reason, our research question is:

How do companies effectively introduce and implement systems to enhance cyber security?

The following section describe in detail the methodology applied in order to answer this question.

METHODS

Research protocol

To answer the research question, we adopted the case study methodology to take into account the complex interrelation of variables characterizing the phenomenon of cyber security and its interrelationships with resilience. The case study is the preferred method to investigate an empirical topic by following a set of pre-specified rules and procedures; it allows a holistic and contextualized analysis, properly suited for exploratory research purposes, because it allows the identification of crucial variables while exploring a given phenomenon. In particular, this research employed a multiple case study design, because "it allows both an in-depth examination of each case and the identification of contingent variables that distinguish each case from the other" (Yin, 1984; Eisenhardt, 1989). Moreover, the essence of a case study is that it tries to illuminate a decision or a set of decisions: why they were taken, how they were implemented, and with what result (Schramm, 1971).
Even if cyber security can be considered as a (relatively) new topic, the existing theoretical background can be considered as a solid base upon which build and organize the research (Yin, 1984; Huberman and Miles, 2002). Given the above considerations, for this research there was no need of exploratory efforts with a grounded theory approach, and case studies have been designed as an inductive theory building effort, according to findings emerging from previous literature.

The approach of theory building is suitable to identify and describe key variables, linkages between them, and reasons behind these correlations.
Case studies have been designed in order to ensure a high quality of research and methodological rigor. In order to reduce possible biases, and to maximize validity and reliability, objective of the research was to diversify data collection methods and sources (Yin, 1984; Eisenhardt, 1989; Patton, 2002). Documentation included mainly primary data from semi-structured interviews, and the process of data collection for this first step of research required about 3 months.
The study involved three different cases, operating in different industries and involving different types of organizations. In this way, it has been possible to study different realities inside the same phenomenon. The chosen approach has been that of theoretical sampling (Eisenhardt, 1989; Eisenhardt and Graebner, 2007).
For each of the involved firms, we carried on a semi-structured interview with a high-level manager working in the field of IT and dealing with cyber security issues: the first part of the interview protocol has been focused on classifying firms and gathering more general data about the approach in building a cyber security system; the following sections of the interview protocol have been structured to investigate (1) *Organizational structure for cyber security, (2) Investments in cyber security (3) Risk management process for cyber security, (4) Risk analysis approach, (5) Definition of cyber resilience (6) Reactive/proactive approach against cyber attacks (7) How does the company introduce and implement cyber security systems.*
As already detailed, we selected the three cases to maximize the degree of information that could be extracted, privileging an all-encompassing view on the overall (cyber) risk management process. Given this aim, we selected three different cases that are: an international consultancy company (labelled as Case_1), a military center for cybernetic operations (Case_2) and a large Italian bank (Case_3).

Table 2: sample of cases selected

	Case_1	Case_2	Case_3
Country	U.K.	Italy	Italy
Industry	Consultancy	Military	Banking
Experience in Cyber Security	10 years	1 year	8 years
Number of employees[a]	200.000	300	89.000
Number of employees involved in Cyber Security	More than 100	More than 200	150
Cyber Security investment	1 mln €	NA	10 mln €
Key Informant	Cyber Security Manager	Military manager	Cyber Senior Analyst

a. Numbers of employees approximated

Case analysis was conducted following recommendations of Yin (1984), Eisenhardt (1989), McCutcheon and Meredith (1993), and Miles and Huberman (1994). Within-case analysis was conducted according to coding techniques (adapted from Strauss, 1987; Strauss and Corbin, 1990). Cross-case analysis was conducted according to Eisenhardt (1989), Runkel (1990), and Yin (1984), seeking matches, similarities, differences, and crossing variables, among cases, to maximize validity and generalizability of the study.

Criteria of internal validity, construct validity, external validity, and reliability were taken into account, according to Cook and Campbell (1979), Yin (1984), Eisenhardt and Graeber (2007), and are schematized in Table 2.

Table 3: validity and reliability of case studies

Characteristics	Criteria
Construct validity	• Review of transcriptions by co-authors and key informants • Explanation of data analysis procedures
Internal validity	• Research framework derived from literature
External validity	• Cross-case analysis (multiple case studies) • Rationale for cases selection: theoretical sampling
Reliability	• Adoption of an interview protocol • Development of a case study database

We performed a within-case analysis in order to test and verify the relevance of factors identified through literature analysis to understand their influence and capability of explaining cyber security's characteristics and the effects in enhancing organizational resilience.

RESULTS

The case studies enabled us to examine data at the micro level. Through these three cases we had the opportunity to analyzed data of real situations providing insights into the detailed opinion of the subjects of interest.
The different sectors analyzed allowed as to be more confident about the perceptions and recommendations common to the three interviewees.

The Multinational Consultancy Company and Cyber Security: Case 1

The first organization analyzed is a service company, a world leader in the strategic, legal and financial consulting market, where one of the cyber security managers of the Italy area was interviewed.
The interviewee was enrolled previously in a small company that dealt with facility management, holding the role of DB Administrator Junior, then in a large multinational company where he was able to approach the world of cyber security.

<u>Organizational structure for cyber security</u>

In this company, only in Italy, more than 100 employees are employed in cyber security. It is necessary, however, to make a distinction: on the one hand, there is a portion of the company that provides services to other companies and includes a hundred people who work with the interviewee; on the other hand, there is a team that deals with security for the company itself. In the second case, it is not merely an IT function but a security function, well structured, composed of a Cyber Information Security Office (CISO) that deals with the security of internal projects and with teams that are not very large, consisting in about 20 people.

Investments in cyber security

Within these three large areas, people are always the weak link in the cyber chain, and therefore there is a great need for investment in training and social engineering activities which, in the field of information security, is the study of a person's individual behavior to steal useful information. In order to strengthen the procedures and policies, on the other hand, we invest in writing rules and identifying rules to follow. And finally, the major investment in technology is the purchase of cutting-edge tools.
This company is ISO 27001 certified, which is the international standard in Europe for information security management.

Risk management process for cyber security

Among the six phases in which a risk management process is conventionally divided, the interviewee sustains that the company maintains missing a very important step: the first thing to do is the definition of the perimeter.

Risk analysis approach

Companies are large and this makes the risk analysis development difficult. Being unable to consider everything, the company considers for the risk analysis the processes that lead to a revenue, or the ones having a strong impact on the budget.
According to the interviewee, one of the most frequent errors is to look at security as a cost because it requires spending a lot of money without, however, any monetary returns.
Each year the Case_1 company invests about one million euros for the prevention of risks related to information security.

Definition of cyber resilience
An interesting observation expounded by the expert lies in the interpretation of resilience as the ability to not break down and therefore avoid economic losses, he talks about avoided damage rather than money earned.
The interviewee states that resilience does not consist in knowing how to protect oneself but in being able to deal positively with what happens. Do not get upset but know exactly what is lost and what still persists.

Reactive/proactive approach against cyber attack

Regarding the choice between a reactive and proactive approach against cyber-attacks, the interviewee claims that it is increasingly necessary to adopt a proactive approach.

The way the company introduces and implements cyber security systems

Recently, a series of initiatives gathered under the name of threat intelligence (which are going to mix with artificial intelligence) are taking place more and more in the cyber field. These are activities based on the concept of neural systems or systems that "learn". There are threat intelligence services and activities that help identifying new emerging threats day by day. These services are based on feed mechanisms that send a data stream and anticipate threats, starting from this intelligence analysis.

For some activities such as Vulnerability Assessment and Penetration Test, it is important to consult the CVSS catalogue (Common Vulnerability Scoring System) and to check if these vulnerabilities are exploitable i.e. if a hacker can pierce and enter the system via vulnerabilities. According to the interviewee, when cyber security attacks occur, it’s important that the critical infrastructure operators learn from the calamity and undertake actions in order to avoid similar situations.
Although intrusion detection systems and monitoring tools play a significant role in network security, among all the resources, the key resource is represented by human resources. The people who work within the company play the most delicate role because, having access to company data and privacy, they have the greatest responsibility. For this reason, a lot is invested in HR, allocating compulsory, online and frontal training paths with a teacher. Some of these are courses on specific topics, such as ad hoc courses on data protection. These provide information to employees about online security and social engineering, when users are connected to their workstations and access websites that could lead to potential cyber-attacks. Training programs are very often able to monitor users' progress.
The training is then tested with social engineering activities, that is, people are exposed to real receipts of false e-mails, attacks, and other simulations of attempts to extort sensitive data. These tests are done because often the possibility that, especially about online courses, people follow directions in a distracted way is underestimated. Of course, training courses will not avoid human errors but, if done correctly, they can increase awareness.
At the end of the interview, the manager was asked if he considered the company in which he works to be at the forefront, and the response was positive. In fact, they have four security operation center (SOC).

Future directions in cyber security

He also said that two paths are opening for the future in cyber: artificial intelligence and insurance.
About artificial intelligence the manager believes that we are going more and more towards a world in which man will give instructions and machines will learn. The new cyber trend will see hackers no longer attempting to puncture the system but badly instructing machines in doing it.
About insurance, the interviewee sustains that it is difficult to mitigate all the risks, so he highly recommends the development and the adoption of cyber risk insurances.

The Public Military Organization and Cyber Security: Case 2

The second interview was submitted to a cyber security manager operating in a military industry. His command deals with the protection of military networks and military information in Italy and abroad, where they have networks connected or are conducting some military actions.

Organizational structure for Cyber Security

The organization chart includes a command and staff area and an operational department, a training area and an experimental area. The mission of the Case_2 organization is cyber-defense and cyber-network-defense. Cyber defense is a static defense of the network, using monitoring systems that allow the company to observe the integrity and availability of data and networks on which they work. Cyber-network-defense, on the other hand, also includes the ability to perform Vulnerability Assessment (VA) Penetration Test (PT), i.e. the continuous verification of network efficiency and the search for vulnerabilities. The interviewer is a manager who has been working in the cyber defense sector for more than four years. He takes care of the organization, the management of human resources, the infostructure and infrastructure sector and takes care of all the educational and training activities of the personnel, which is around a few hundred people.

Investments in Cyber Security

The cyber environment has exploded over the past decades. In the last five years there has been a strong acceleration in that, above all the various european organizations, it has been ordered to adapt to those that are the dictates of the NIST and GDPR directives, regarding the protection of privacy. According to the key informant, creating a link between the academic world, the industrial world and other administrations, it is the best recipe for responding to cyber-attacks.

Risk Management Process for Cyber Security

Within a cyber risk management process, the six steps conventionally recognized in a risk management cycle are executed. It is an iterative process that, at the end of the risk mapping and after designing an action framework, dynamically restarted; creating a cycle that keeps threats under control. Each stage is assigned to a manager who, coordinating with the other sector managers, constantly monitors, possibly with the help of IT tools.
Through the analysis, the main answer to be obtained is the list of the priorities of the risks to be faced, with the related established response plans. This is because the attack surface is so wide that one cannot afford, not even as a nation, to establish countermeasures for any type of threat, as this would imply particularly high costs. Therefore, the first thing to do is to define which are the potential attacks for which it is valuable to take preventive measures and therefore, to draw a perimeter within which only the risks with greater priority assigned will fall.
The Case_2 organization has set up the main figures who must comply with what their duties and role require. Certainly, the problem arises in the case of small and medium-sized enterprises, when these do not have enough staff to dedicate to this purpose. In these cases, it is therefore necessary to proceed with an ad hoc investment program. Investing in cyber security, however, as well as being risky, often turns out to be very expensive.

Risk Analysis Approach

The best trade-off between costs, benefits and risks is for an economic approach to choices and decision-making activities. So, with protocols containing statistics, the real risks and the percentage of decisions to be taken must be addressed. The interviewee suggests that the salient point of each organization's policy should be to establish, even in agreement with the trade unions, clear rules that do not appear as simple regulatory dictates or prescriptions but rather are shared with employees. He claim that there is a need for creating a knowledge culture in which everyone must know why each policy has a reason to exist, so if the passwords must be of a certain type, if access via USB is not authorized, if it cannot be accessed during the weekend or during night hours to external systems from outside, the employee must be aware of the reason. It is mostly about establishing a continuous dialogue and a full sharing of objectives with the company.

Definition of Cyber Resilience

Resilience is a very structural and systemic concept, according to the interviewee. Even considering resilience as the ability to resume operations following a damage suffered, it must be considered that resilience can assume political, infrastructural, physical, logical and individual character. From the political point of view, resilience is the ability of the Nation to put in place policies that then allow all systems to resume functioning in unanimity. From an infrastructural point of view, system redundancy, whether infra-structural or info-structural, must exist.
We must not forget that internet was born in the ARPA (Advanced Research Projects Agency) as the ability to allow the various nodes to communicate in cases of nuclear war, to get information from EBI (European Bioinformatics Institute) ensuring the possibility of taking different paths. So, while the physical resilience is given by the redundancy of the systems, alternative A, B or C plans constitute the logical resilience since, given a failure or an inefficiency, we can still connect the various nodes though them. In this case, a great contribution could be made from the world of modeling and simulation, with those algorithms and data mining that allow us to automatically extract useful information from huge amounts of data and make them understand the correlations. Finally, resilience must be considered from an individual point of view. Resilience takes the cultural character of people and how the nation faces the issue of system security, so a large component is precisely the training of personnel, who must understand what their role is in the process of building computer resilience, in which man is certainly the weakest link. People must first be educated to protect themselves more, and this practically means being less superficial in generating passwords and not releasing, for example, their email to anyone. Resilience obviously also depends on the amount of investments that are made. Therefore, since cyber security is a "problem" of the Nation and many contributing actors are involved, procurement initiatives are necessary, thus acquiring technologies and material capacities, which are above all characterized by interoperability, that allow the various ministries to communicate. Surely all the aspects of anticipation, recovery, resistance, evolution, are necessary to build a resilient environment for cyber-attacks but we must start to build systems that are not only commercial off the shelf, that is, solutions that are given by the industrial world, and sometimes predominantly foreign, of which the main components are not known, but above all a system of national resilience must be structured that goes to look for those products that allow the Nation to have a precise control of the industrial solutions at the base.

Reactive/proactive approach against cyber attack

In order to be resilient, we cannot privilege a reactive approach or merely proactive approach, but it is above all the union of the two, a third approach that is the predictive prognostic approach, to ensure that there are capacities for resilience. The interviewee explains that he calls it “prognostic approach” because through the correlations of data it is possible to anticipate the arrival of a catastrophic event. Speaking of a reactive approach, the interviewee meant an attitude of the Nation that is ready to react in a very short time thanks to communication, to info - sharing and to industrial capabilities. However, the key informant sustains that Italy does not yet invest enough in a proactive component.

The way the company introduces and implements cyber security systems

According to the manager, the organization Case_2 focus on the artificial intelligence sector and should do it more allowing the systems to react automatically. With regards to monitoring technologies, the most advanced ones now rely on SIEM (System Incident Event Management) systems of all types, which can create the correlation between data and ranging from IBM to the

Firewall. The support of the human being is fundamental, that is, there must be a class of operators that really has awareness of the systems.
Without any doubt, the interviewee thinks the main factor is the "human" component. For this reason the activities on which Case_2 company invests the most are training, recruitment and above all development of retention that is the ability to retain people who bring value to the organization. The interviewee suggests that the education of the human system should start from schools. There is a need for education regarding the world of computer science starting from primary schools, in which basic concepts should be introduced with the primary aim of instilling curiosity, which is the basis of the growth and development of advanced studies. For training activities there is a need for cross-cultural systems, such as masters, training courses, and school activities. It would be a great benefit for the nation to have prepared people who can work in the various departments in a transparent manner and without additional costs.

Future directions in cyber security

The manager imagines that there will be another 5 or 10 years ahead in which it will be necessary to invest a lot. In the next five years he foresees that the major investment is dedicated to the retrofit of all ICT information systems; for the next ten years he also expects a lot to be invested in artificial intelligence and in secure by design. He concludes by saying that the serious mistakes that are still being made are above all that of not educating the national leadership and of entrusting the world of information technology only to a few very specialized young technicians, but who are unable to transfer the real criticality of this environment. So, the key points to which great importance must be attached will be the creation of a global and shared culture, the organization of events, conferences and awareness campaigns in order to educate policy makers and decision makers on this new reality that afflicts us.

The Multinational Banking services company and Cyber Security: Case 3

The third and last interview was submitted to a computer security consultant of one of the largest banking services companies in Italy (and in the world), which will be called Case_3. The interviewee is a senior analyst who has been dealing with computer security for about 7 years and for this reason he has had the opportunity to learn about many aspects of this area, including application security, or the security of online applications, infrastructure security, or security concerning computers and systems. It deals with defining what the mitigation actions downstream of a risk should be and what the costs are related to these actions.

Organizational structure for Cyber Security

CERT is the acronym of "Computer Emergency Response Team", it is a team designated to respond to security incidents in case of need. Usually, several levels of response are established: a team is in charge of the supervision, then real-time monitoring of all the corporate infrastructures, twenty-four hours a day, seven days a week and, when certain alarms occur that highlight problems, if the employees are not able to understand if it is indeed a real problem, a false positive or even a failed attempt, the CERT comes into play. Within this group there is a primary structure, the Security Operations Centre (SOC), from which monitoring and supervision activities are carried out, and a secondary structure that represents the real heart of CERT, corresponding to the second level of incident response, who is called to respond in cases of extreme necessity. Therefore, the CERT is specifically the body that oversees confirming the

occurrence of a real accident, and in this case indicates the countermeasures to be taken, or instead to ascertain whether it is an oversight of the system or a false positive. Incident management includes many aspects because, based on the type of accident, certain initiatives are taken rather than others.
Since the introduction of the GDPR (General Data Protection Regulation), the document already illustrated in the previous case study, there are certain areas and contexts in which there are constraints that require special attention. These are mandatory constraints and, if the threat is real and falls within a specific case, it is necessary to contact certain individuals who have been designated to receive the reports and evaluate with them whether to proceed with a publication for customers, in case the threat impacts on customers. The cyber environment is very large, and this means that the company uses a lot of resources in cyber security. It includes anti-fraud activities, intelligence and threat intelligence, prevention and protection teams, which serve to prevent and protect against threats in a preventive way. This constitutes a great gain for the company because, preventing threats rather than having to manage them when they are attacked, brings an advantage in terms of recovery costs. In this company, about 150 people doing cyber security are in different sites in Italy.

Investments in Cyber Security

It is very difficult to make an estimate on the volume of business because security does not consist only on the cyber one but includes a considerable part also of physical security. Investment is very high: about tens of millions of euros per year. Obviously, it depends on the type of organization, it will therefore be proportional to the business that the company provides and to the volume of users/customers that are managed: the greater the business volume of the company, the greater is the investment made to protect the business of the organization and its users.

Risk Management Process for Cyber Security

The cyber can be analyzed from different points of view: from the operational point of view, of the analyst, from that of processes and a whole part connected to governance.
Based on the cyber security that is analyzed, several risk management steps are performed. This way of acting is part of the risk management prevention phase.
There is a specific field related to cyber which is business continuity that gives a given company the possibility of being able to guarantee business continuity and, in a company like this in analysis, plays a fundamental role. In this regard, the company favors a proactive approach, despite it requires very high initial costs than the costs related to the reactive one.

Risk Analysis Approach

According to the interviewee, estimating costs related to a possible contingency is certainly the most effective way to react. For this reason, there are figures dedicated to prevention and protection that work on this aspect of proactivity: based on a problem that they have already experienced, they analyze what were the outcomes of accident to understand strengths and our weaknesses and go to study where we need to improve. After this analysis, they look for the right system to make an improvement in both qualitative and quantitative monitoring.

Definition of Cyber Resilience

For the key respondent of Case_3 company, resilience cannot be generalized, it must always be contextualized. In a cyber environment, adapting to change is very difficult because the change goes much faster than one can keep up with. The interviewee says that we need to know how to adapt to change based on the risks we face in this historic moment and defines resilience as the ability to stand up once fallen. In risk management context resilience is the intrinsic ability to change its functioning before, during and following a change or a disturbance, he says. This definition is well suited to the context under study as the cyber space is a field characterized by highly dynamic systems.

Reactive/proactive approach against cyber attack

The intent is to approach resilience in a dynamic way, but it is not always possible in the environment in which one finds oneself because sometimes there are constraints linked to certain business realities that could constitute obstacles for an incident response process, which should instead manage the occurrence of these issues. These difficulties often derive from another factor that must be considered, namely the fact that, within large companies, modifying processes is very difficult. What can be done, instead, is to intervene in operations by making changes that can be made even without modifying the process. This difference becomes important when it is not enough to change the approach to a problem, but it is necessary to change the way of approaching that problem.

The way the company introduces and implements cyber security systems

Within the IT world and, in general, companies that have many assets to monitor, protect and defend (meaning both physical and digital assets, both end points and servers, network devices such as routers, switches and all the pieces that allow the machines to communicate with each other), there are systems that collect the logs, or systems that maintain the computerized traces that these devices produce, thus allowing to store the information collected by the systems in the field, centralize them and aggregate them according to data models, to go then to model data based on the type of research you are going to do. These systems are called SIEM and today are indispensable for managing events of all kinds. They collect all the events that originate from the various devices and, starting from the evidences identified, they create an alarm system designed, developed, tested and then fielded. With this alarm system, trends are defined and analyzed so that the alarm is triggered whenever something is out of the baseline trend. The company Case_3 has an alarm that monitors whether an antivirus identifies specific files on the machines, and, in this case, an incident response process starts. The interviewee sustains that the weak link in modern computing and Cyber is man because he is the one who makes mistakes and introduces risks. In order to mitigate this aspect and train people, awareness campaigns are promoted. Often these campaigns are not very effective because of the availability of people, who should be ready to accept it. An effective way to enhance awareness consists in creating false attack vectors, simulations of the possible occurrence of certain conditions reported as anomalous. An example of simulation is the phishing campaign, that is a targeted attack aimed at a target group of people to steal data from them, and this means not just sensitive data but also personal data (name, surname, date of birth), from which it is possible to obtain the identity, or particular private data of interest for the hacker. A phishing simulation also allows to call users through customer service by pretending to be someone from the company staff and to have the information released. So, in practice, the phishing campaign consists in monitoring how many people fall into the trap to see if the awareness campaign has had an impact or not, because

what people aim to develop is the ability to recognize the possible attack vectors and have a complete picture of the company's perimeter of exposure.
The company in question, for the most part, carries out these activities internally but there are technologies that are still entrusted to third parties. There are very critical assets that must be managed internally and less sensitive assets that can be outsourced. Theoretically, if you have a working SIEM you can entrust the management of assets to third parties, monitor their progress remotely and make certain risk analyzes to understand what it is before contacting the manager. After the analysis, the manager is contacted for a comparison. Many appliances and software have already begun to exploit artificial intelligence, a part of computer science that allows machines to self-learn. This part of artificial intelligence is called "machine learning" and is already implemented by the company that uses this type of system. This is a very powerful technology but also very risky because, in managing a self-learning system, the biggest difficulty is being able to make it learn well and configure its learning.

Future directions in cyber security

Machine learning is certainly the future direction of this field; given that very rapidly a series of technologies are being created that can be managed by automated systems. However, the interviewee remains of the opinion that know-how and dynamism of the human beings are irreplaceable by artificial intelligence that can instead be introduced as a support, those the figure of the computer analyst has not to be eliminated. Currently, according to the interviewee's experience, the biggest mistake that can be made is cutting safety costs. Fortunately, this now happens less and less frequently because organizations have begun to understand the importance of safety, which is the pillar for the survival of any company and therefore one of the most important aspects on which to invest economic resources. A strong limitation is that security is often considered only as a cost and the real benefits are not realized. Another problem lies in the lack of sensitivity to content, both on the part of those who perform security-related activities, and on the part of those who benefit from it. It often happens that people within companies are hostile to security consultations because users may feel limited. But this is necessary to reduce their probability of making mistakes and to put them in situations of greater protection from possible attacks, preserving the reliability and integrity of the systems that the user uses. Cyber is increasingly becoming an instrument of attack and defence, a firearm that a state can focus on others and the serious thing is that the population does not yet have an awareness of the importance of data.

Findings

Table 4: Findings emerging from the multiple-case analysis

		Case_1 Consultancy	Case_2 Military	Case_3 Banking
Context	**Final Users**	External organizations	External organizations	Individuals
	Property	Private	Public	Private
	Critical structures/activities	No	Yes	Yes
	National Culture	UK and Italy	Italy	Italy
	Size (number of employees)	200.000	300.000	89.000
	Organizational Structure for Cyber Security	- Manager in charge of risk management and compliance - CISO + teams SOCS (20 people) - Risk Owner - Top Management	- Each stage is assigned to a different manager	- CERT - SOCS
	Investments amount	10 mln € per year	N.A.	10 mln € per year

				activities - Training
	Future directions	- Artificial intelligence - Cyber risk insurance	- Artificial intelligence - ICT information systems - Secure by design	- Artificial Intelligence - Know-how of human beings

DISCUSSION AND CONCLUSIONS

The case analyses revealed interesting insight regarding the existence of common practices to enhance cyber resilience.

What directly emerges from the presented cases is the great importance of intangible activities. Case_1 manager mentioned “social engineering activities” as a tool for the effective human resources training, while Case_3 manager talked about “phishing simulations” used to build organizational cyber resilience.

A considerable amount of people, handling vital information and data for the organization, still ignore how easily these information and data can be stolen: Case_2 and Case_3 directly highlighted “training activities” as an important investment to build resilience from cyber attacks.

There is however the need for developing more powerful tools: all the interviewees highlighted artificial intelligence as a future direction of investment. As a matter of fact, from both Case_1 and Case_3 emerged the relevance of “threat intelligence” as a current important investment.

Nevertheless, results of the study insistently point at stressing the importance of human dimension of cyber security: all the interviewees acknowledged that major threats come from oversights and lack of information on how to effectively manage information and communication means. As a matter of fact, tools like penetration tests can provide valuable results only if paired with investments in training to prevent erroneous behaviors.

Two key characteristics of organizational resilience, namely the analysis of historical trends and speed of recovery, maintain a critical role, just like in other risk management contexts.

Case_1 (consultancy) and Case_3 (banking) both are private organizations and the key interviews acknowledged the importance of investing into social engineering activities, e.g. phishing simulations, together with the development of threat intelligence.

Case_2 and Case_3 both deals with crucial data and information (security/military and banking): this brought interviewees to recognize the importance of SIEM system, together with training activities; at the same time, they highlighted the importance of recovery as a key dimension of resilience.

Case_1 and Case_2 both share similarities in the context, because their activities and interest toward cyber security involves also third parties. They stressed the importance of perimeter definition as a key step in risk management process together with the need of investing into IT tools like penetration tests and vulnerability assessments.

Indeed, findings showed that the introduction and implementation of security systems to enhance cyber resilience doesn’t necessarily involved the development of powerful IT tools, but rather it is made through investments in knowledge and training of human resources together with the introduction of artificial intelligence.

The above consideration brings to the formulation of the following proposition:

- ❖ Investments in learning of human resources (human resources training) and of machines (artificial intelligence solutions as machine learning) are the ways organizations introduce and implement security systems that enhance cyber resilience.

This proposition provides a double contribution, for both research and practice: it represents a new insight and direction for research on managerial aspects of cyber security and expresses also a guideline for managers willing to invest in security systems in order to enhance cyber resilience.
Indeed, this study identifies an organizational factor that plays an important role in building a resilient system for cyber security: learning. There is a need for introducing the culture of cyber security and the knowledge of its main aspects rather than the unaware adoption of high-tech tools and techniques.
However, the study has some limitations. First, the set of companies studied might be too small and future research is needed with a larger sample to confirm our findings: the above proposition must to be confirmed by a quantitative study using a survey methodology.
Secondly, the theoretical framework did not consider the nature of investments in cyber security, which do not provide a direct return and can be considered as sunk costs. Future research efforts should take into account this aspect to understand the overall willingness of company to invest in cyber security, given the highlighted drawback.

ACKNOWLEDGEMENT

This work is supported by the fund “Progetto di Eccellenza” of the Department of Computer Control and Management Engineering “Antonio Ruberti” of Sapienza University of Rome that has been assigned by the Italian Ministry of Education (MIUR) for being “Department of Excellence” in advanced training programs in the field of cybersecurity.

ABSTRACT

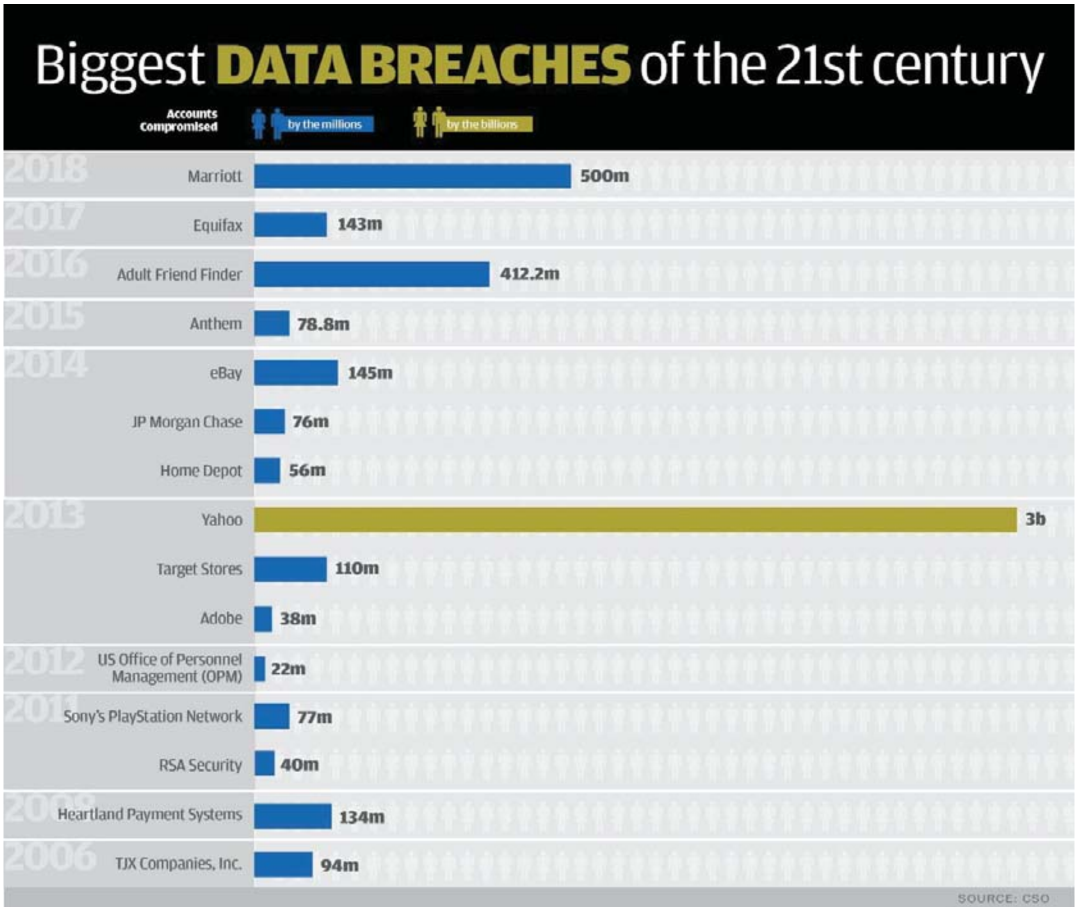
Decision Makers, aka Business Managers, control the budget without a good understanding of cybersecurity or the threats targeting their business. How can they adequately fund, staff and support a critical program without a good understanding of what the threats are and how the information they have is a desirable target for hackers and cyber criminals. This paper discusses the issues and suggests ways to address the risk and what is needed to keep up with, defend and recover from a cyber-attack.

Keywords: Cybersecurity, Decision Makers, Cyber-threats, Adversaries, Hackers, Cyber-criminals, Risk, Paradigm Change, Visibility, Detect, Contain, Remediate

INTRODUCTION

Historically, war has been waged on the ground and in the air through troops in combat. With the Internet and the growth of Internet connected devices, systems, homes, cars, etc., we have seen an increase of Nation States training cyber forces to attack other nations and individuals. It makes sense that the next world conflict or war will most likely include cyber warfare in some part, or in total. It is imperative that Decision Makers in companies or in government understand they can no longer leave everything cyber, including the understanding of cyber, to the IT or Information Security shops. It is critical that Decision Makers have a basic and beyond understanding of cybersecurity and how cyber-attacks can not only take down their network, but steal intellectual property; gain control of critical systems for ransom or nefarious purposes; be used as a launching point to attack other companies, governments or individuals, and cause serious financial and reputational loss, as well as impact the US critical infrastructure. It is not IF you will be attacked, it’s WHEN and how you quickly you detect an attack and mitigate it. Figure 1 is a compilation of some of the biggest data breaches and their reported losses, from 2006-2018 (Armerding, 2018). What they all have in common is the fact that their data was breached; what is not in common is the way they happened and the ways they could have been prevented. Much of this information is discussed in this paper.

Figure 1: Biggest Data Breaches of the 21st Century



TODAY'S THREATS

Attacks today are increasing in sophistication. We've seen them move from fairly simply scripted attacks to use of commodity malware and ransomware to custom backdoors put into networks with boot record (aka keys to the kingdom) malware that is so persistent it's difficult to remove. We've gone from the same type of malware spread throughout an organization to malware that dynamically morphs and changes as it spreads. We've gone from limited Command and Control takeovers that were typically limited to IP addresses and not Domain Name Resolution, to larger Command and Control infrastructures with more IP addresses and some use of Domain Name Resolution to taking advantage of legitimate sites for Command and Control.

We've seen disruption of services take place that has caused outages and the risk of ransomware to Internet of Things (IOT) increase. We've seen distortion of data and information happen, which has been used to spread misinformation. If you can't trust the integrity of the data because it's been compromised, or you don't know it's been compromised, what do you do?

Phishing attacks are fraudulent attempts to obtain sensitive information such as usernames, passwords and credit card details by disguising oneself as a trustworthy entity, typically in an email message. It often directs users to enter personal information at a fake website which looks very much like the legitimate site. These attacks are being used to obtain log-on information and credentials for home and office users, along with credit card information, financial information, health information, etc. (Fruhlinger, 2019). Phishing attacks are getting more sophisticated with the use of machine learning to gather information from social media, distribute fake and often times targeted messages (Goldberg, 2018).

Ransomware is still out there and being used repeatedly on those already ransomed. What many fail to realize is that once a ransom has been paid, the cyber-criminal normally has a full copy of all the information they want from your PC or network. Paying the ransom usually gets you or your company placed on a list on the Darknet of individuals and companies who have paid ransom, setting you up as a good place to be phished over and over again (Urbelis, 2017).

Cryptojacking is rising with the use of cyber-currency outside of the Darknet and criminal realms (Nadeau, 2018). Cryptojacking is a trend that involves cyber criminals hijacking home or work computers to look for, or “mine” cryptocurrency. Mining for cryptocurrency uses a lot of processing power, which is why is advantageous for the cyber-criminal to piggyback or use other systems to look for cryptocurrency. Cryptojacking runs in the background and causes serious performance issues to the infected computer or network.

Cyber-Physical attacks that use computers and their ability to interrupt or disable critical infrastructure such as cameras, traffic signals, the electrical grid, transportation, water treatment facilities, dams, and even military equipment is growing and is a new wave of warfare and terrorism. The threat to US weapon systems was brought to light in a NY Times article in October 2018 (Sanger & Broad, 2018).

THE GROWING THREATS AND WERE THEY ARE COMING FROM

The threat to IOT connected devices, medical equipment, cars (IOT connected and semi-automated), including law enforcement vehicles and medical records is growing.

Threats are coming from insiders, external partners and contractors, Internet connections, etc. That is why those in positions to make decisions, to allocate budgets and spending, need to realize how being under-protected in the cybersecurity realm can leave them wide open to attack, loss of data integrity, revenue and reputation, negligent and liable and many times out of a job. That lack of knowledge and commitment to cybersecurity can also lead to loss of life for those using a compromised or hacked device, system, weapon, vehicle, etc.

THE EXPENSE OF BEING ATTACKED

Cyber-attacks can cost involve cost of breach notification to customers; cost for credit insurance for customers; regulatory compliance (fines); public relations / crisis communications; attorney fees and litigation; cybersecurity improvements; and technical/forensic investigations, often times with law enforcement. Some of the lesser known costs can be insurance premium increases; increased cost which raises debt; operational disruption; loss of customers / strategic relationships; lost contracts resulting in lost revenue; devaluation of trade name /brand; loss of intellectual property.

UNDERSTANDING THE THREATS

The best way for those in decision making authority to understand the current cyber-threats is to become familiar with what the threats are, along with how mitigate them. The top 10 cyber-attacks are (Melnick, 2018):

1. Denial-of-Service (DoS) and distributed denial-of-service (DDoS) attacks, which include TCP Syn flood Attacks, Teardrop attack, Smurf attack, Ping of Death attack, and Botnets.
2. Man-in-the-Middle attack, which includes session hijacking, IP spoofing, and replay attacks.
3. Phishing and Spear-phishing attacks.
4. Drive-by attack
5. Password attack
6. SQL injection attack
7. Cross-site scripting (XSS) attack
8. Eavesdropping attack
9. Birthday attack
10. Malware attack

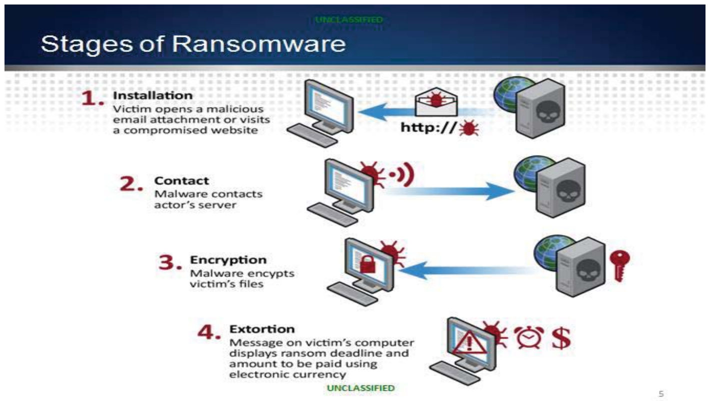
UNDERSTANDING THE TARGETS

Understanding the attacks along with who they target is important. DoS and DDoS attacks target the network and application infrastructure. Malware, zero-days and botnets target endpoint systems and servers. They try to obtain access to systems, create backdoors, and establish command and control over a large network of devices. SQL Injections and XSS attacks target databases (OWASP, 2019). Social and phishing attacks target individual users by doing a pre-attack recon eScience, building trust with fake social profiles, and then the initial infection. Password and configuration attacks target endpoint systems and servers. Their goal is initial penetration of a network or system, expansion of reach, and escalation of privileges to gain as much control possible. Smart or IOT connected device and mobile hacking targets mobile and embedded services. They are a new attack and entry point to enterprise networks. They gain access to user data through vulnerable mobile OS and applications.

Decision makers need to understand ransomware and how it works, along with the consequence of paying or not paying the ransom. Ransomware typically gets into a system or network when a user opens a malicious email, or visits an infected site, or clicks on an infected link. The malicious code is designed to crawl through the infected computer with the hope of gaining access to the network the computer is attached to. Once the ransomware has crawled the network and allowed the attacked to obtain files, confidential information, intellectual property, etc., the code executes and all or some of the files are encrypted. Then the extortion banner is displayed on the victim's computer telling them to pay the ransom in cyber currency by a certain deadline to unlock the files. Figure 2 illustrates this process.

What many do not understand is that the information has already been copied, stolen, compromised before the encryption takes place and the demand for ransom is issued. When the ransom is paid and the computer or network is unlocked, the attacker already has everything they want. Paying the ransom will unlock the data, but you can't be sure it hasn't been changed, altered or parts deleted. Additionally, paying the ransom gets the payee a place on a list for users or companies who paid ransom, setting them up to be targeted and held ransom again and again. It's better to have a solid, well tested back-up routine that you can use to recover from a ransom attack by wiping your systems and re-installing to the most recent back-up.

Figure 2: How Ransomware Works



THE ATTACKERS

Adversaries, cyber-criminals, hackers, attackers come in varying forms. There are groups with causes such as ALF, ELF, Peta, Anonymous, etc. who attack anyone they believe is a threat to, or against their cause. There are nation states such as China, Iran, North Korea, Eastern-Bloc Countries who target companies to steal intellectual property, plans (think defense contractors), weaponry or critical infrastructure systems or development, monetary targets (think banks, Fortune 100 companies, airline or just about anything you can think of. There are cyber-criminals who target individuals to steal personal information, financial credentials, and health information and credentials.

There are also the unintentional or intentional internal adversaries, your employees, their families or friends, external customers or partners that connect to your network using personal devices or using a company computer or device for personal use ignoring company policies and security.

WHAT IS A HACKER OR CYBER VILLIAN?

Hackers are a type of cyber villain who create and modify computer software and/or hardware, including computer programming, administration, and security-related items without authorization. They gain unauthorized access to computers or networks, often just for the challenge of it.

Non-Nation State Hackers or cyber-criminals typically fall into 4 categories: Black Hats, Gray Hats, White Hats and Suicide Hackers.

- Black Hats, aka Crackers, are individuals with extraordinary computing skills, who resort to malicious or destructive activities.

- White Hats are individuals professing hacking skills who use them for defensive purposes. They are also known as security analysts.
- Gray Hats are individuals who work offensively and defensively at times.
- Suicide Hackers are individuals who aim to bring down critical infrastructure for a "cause". The normally don't worry about facing jail time for their actions, believing the "cause" is greater than all.

There are also unintended cyber villains, which many call the Human Factor. Most companies are understaffed in the cybersecurity arena, which causes staff to do more with less people, causing mistakes to be made, or threats to be overlooked or missed. There is also the element that "stuff just happens". People take vacations, go to meetings, are out sick, etc. There is simply not enough time in a day for staff to do it all, which means they are not watching systems, reading logs, or correlating odd behavior on the network 24 x 7, or even 8 x 5. The world-wide shortage of cybersecurity professionals is the major reason behind this (Manpower, 2018).

ADDRESSING THE RISKS

Decision makers need to ensure the cyber risks are systematically addressed. To do this they should realize the risks. The global cost of cyber-crime in 2019 was estimated to reach $2 trillion US dollars (Juniper Research: Global Risk Reports). In 2016 the average cost of a cybersecurity breach is $4-7 million US dollars (Security Intelligence: 2016 Cost Data Breach Study) and it continues to grow in 2019. Theft of trade secrets/Intellectual Property (IPR) results in $749 billion to $2.2 trillion annually. Only 48% of breaches are caused by acts of malicious intent (IDG 2018).

Once you understand the risks and threats, you need to address them. First you must understand what you have. You cannot secure what you cannot see, or do not know about. Think about what you have in your organization and understand what it could mean to a hacker. Do you have intellectual property, confidential data, personally identifiable information, healthcare or medical information, top-secret plans or information, building and network diagrams that would provide someone to compromise you organization physically or through cyber, financial information, stock market projections or trading research or information, accounts receivables or ledger information that if changed would create financial ramifications, etc.? You should know how many ingress and egress (in and out) points there are on your network, how critical systems or information are protected and everything that resides on your network, systems and their patch levels, and who your users are. There should be a way to check the network and everything connected to it quickly with security solutions. You should be able to account for all users and ensure their access privileges are limited to need to know, and not accumulated from past positions within the organization.

DECISION MAKERS SHOULD…

It is critical to acknowledge that the cyber threat is real, all the way from the person who answers the phone to the CEO. Cybersecurity is the job of everyone who is in anyway connected.

Don't be fooled into thinking that just because you are compliant, you are secure. Compliance does not equal security. Security is a balance of control and visibility.

Penetration testing, also called pen testing or ethical hacking, “is the practice of testing a computer system, network or web application to find security vulnerabilities that an attacker could exploit. Penetration testing can be automated with software applications or performed manually. Either way, the process involves gathering information about the target before the test, identifying possible entry points, attempting to break in -- either virtually or for real -- and reporting back the findings” (TechTarget, 2018). Once a system has been updated, or a line of code changed, etc. there could be new holes opened up.

WAYS TO KEEP UP AND AHEAD OF THREATS

To stay ahead, or at least in step with attackers, you should continuously monitor your network. Often times, organizations fix high to medium vulnerabilities, leaving the low risk ones alone. Attackers are aware there is only so much time in a day, so they frequently look for low risk avenues to gain entrance. Use security solutions to do machine to machine analysis and human threat-hunters to review the data and make it contextual to your environment.

You should have solid security procedure policies, change control, full and incremental back-ups for data and critical systems that is tested regularly. You need an incident response and escalation plan that is practiced and kept up to date, along with training for all personnel.

CHANGE THE PARADIGM

Security tools by themselves are not the “magic bullet” that will solve all of your security problems. More cybersecurity professionals by themselves are not the answer either. It takes a combination of both to keep on top of cybersecurity.

Keep in mind, prevention is not enough. Tools fail or don’t see the whole picture. Individuals get re-tasked, are multi-tasking, are not reviewing logs continually, or just miss things. Relying on any of these solely can give you a false sense of security. All networks can be hacked if they are internet-facing. Visibility and quick threat detection and response is the key to preventing, minimizing and recovering from a cyber incident.

It’s time to change the paradigm! Going forward cybersecurity is all about:

- The time to detect
- The time to contain
- The time to remediate

If you don’t have the tools or the personnel to do cybersecurity, consider using a managed security service provider to fill the gaps. They normally have backgrounded staff with top level security clearances, along with the ability to monitor your network traffic round the clock. They can help the biggest security team, or the smallest fill in the gaps. The cost can be less than what you’d pay a lower-level cybersecurity analyst. A managed security service can help you identify and remediate the threats quickly, saving you time, money and reputation.

CONCLUSIONS

Regardless of the size of your company, or the industry you’re in, as a Decision Maker, it is your responsibility to ensure you have a good cybersecurity program, a secured network, and trained cybersecurity personnel. You may be the one that controls the budget, so it is imperative that you understand the problems and related risks.

ABSTRACT

Over the last decade, many MBA programs have added Business Analytics (BA) courses into their curriculum. Unlike most other disciplinary area courses that are somewhat similar in across MBA programs, BA courses tend to vary significantly in content and structure. Thus, very little systematic guidance is available to faculty who are considering developing a BA course. This paper presents a conceptual model of the data-driven decision-making process that was the foundational guide for the methodical development of a BA course and its implementation. Some implications of this model for development of BA courses for MBA programs are also presented.

KEYWORDS: Decision-making, Business Analytics, MBA, Course Development

INTRODUCTION

One could argue that analytics owes its origin to the Hindu-Arabic numeric system (that included zero – ninth century) for data and the development of scientific method and probabilities (17th through 19th century) for modeling as presented by Buchanan and O'Connell (2006). The first well documented use of data (numeric, temporal, and geographic) for decision making is the study of the cholera epidemic by John Snow in 1854 (Tufte, 1997). With the availability of computing to add to data and modeling, business analytics has become a strategic tool for decision making and competitive advantage in many organizations since the concept was introduced in the 2000's. Davenport & Harris (2007) defined analytics as "the extensive use of data, statistical and quantitative analysis, explanatory, and predictive models, and fact-based management to drive decisions and actions." Analytics helps to discover meaningful patterns, new and novel information, insights, and knowledge, in data. Business analytics (BA) has been defined to be "a special application/subset of analytics that leverage its tools, techniques, and principles to develop solutions to ever so complex business problems" (Delen and Ram, 2018, pg. 2).

Davenport and Patil (2012) identified that a huge shortage of analytically skilled employees, such as data scientists, is a serious challenge for organizations moving into data driven decision making economy. In a report for McKinsey, Manyika et al. (2011) projected that United States alone could face shortage of 140,000 to 190,000 people with deep analytical skills and 1.5 million managers and analysts well-versed in the use of analytics to make effective decisions by 2018. Many other authors also identified huge shortages of business analysts, data engineers & data scientists.

Since BA has become so important in organizations, universities took up the challenge of developing BA knowledge and skills among their graduates by introducing degree programs in BA and courses in BA in their graduate programs and this trend has exploded over the last decade. The number of universities offering graduate programs in BA and courses related to BA in their MBA programs have increased tremendously. According to Rappa (2014), there were nearly 60 programs that were offering advanced degree in analytics in 2014.

Initially, many business schools started converting their statistics, business intelligence, and management science courses into BA courses in their MBA programs. Faculty teaching these courses were assigned to develop and teach the newly introduced BA courses. Because of the lack of clear definition of BA at that time, the BA courses were heavily dependent on the background of the faculty who were assigned to teach these courses (Gorman & Klimberg, 2014). In the beginning, faculty assigned to teach BA courses could not depend on textbooks related to BA since there were none. Some faculty used customized books by putting together articles and cases from journals, and chapters from statistics, business intelligence, and management science books. Since then, publishers have started publishing books on BA authored by some of the faculty who were teaching the BA courses. This led to a wide variety of content in BA courses depending on the background of the faculty who were developing and teaching these courses. Some of the courses had statistics orientation whereas other courses had management science, decision sciences, Management Information Systems (MIS) and business intelligence orientation depending on the courses faculty developers were previously teaching.

Thus, the content of these BA courses were not consistent and were not based on any framework or model. New textbooks that were developed by the faculty who were teaching BA courses also had different orientation namely statistics, management science, MIS, and business intelligence. Some books cover descriptive, predictive, and prescriptive analytical models, whereas other books focus on descriptive and predictive analytical models only. Only few books evolved over time to cover topics based on the data mining models such as CRISP-DM (see Wirth and Hipp, 2000), SEMMA (see SAS, 2014), and KDD (see Brachman & Anand, 1996) models which grew as industry standards for developing data mining projects that define a set of sequential steps. Some schools decided to cover all types of analytics such as descriptive, predictive, and prescriptive analytics in one course and other schools decided to offer two courses with one course covering descriptive and predictive analytics and the next advanced BA course covering prescriptive and other advanced analytic topics such as big data and text analytics.

Due to the lack of systematic guidance in developing BA courses in MBA programs, a comprehensive process model could offer a solution. This model when used would lead to more consistency in course content and it would help in developing better targeted course materials. This would also make the process of course development more explicit. Since decision making is a journey, and not just a destination, the data-driven decision-making process should focus on the entire process of defining the right business problem, identifying and collecting the right data, analyzing the data with right methods, and interpreting the results and implementing the right solution to solve the problem effectively. That is the approach taken in this paper.

This paper focuses on the development of a graduate BA course for the MBA program based on a data-driven decision-making process model developed at a U.S. university by one of the co-authors. The approach to develop and teach the first BA course in the MBA program is entirely different compared to others, whose design was either driven by the background of the course developers or by the textbook they were using. The conceptual model of data driven decision making that shaped the design of an MBA course on Business Analytics will be discussed in detail. The process that was used in developing the course, the course content along with the assignments used, and the lessons learned from implementing the model will be presented in detail in the rest of the paper. Finally, implications of using the model for developing future courses in BA will be discussed.

REVIEW OF BUSINESS ANALYTICS CURRICULUM DESIGN LITERATURE

Over the past decade, universities have been responding to an increased demand for data analysis skills put forth by employers. As a result, institutions have been building analytics education and curricula, particularly in business-focused programs. During this time, the growth in analytics and related data science masters programs has been impressive. Most of these are MS in Analytics (MSA) or MS in Business Analytics (MSBA) programs (Institute for Advanced Analytics, 2019). Due to this growth in analytics programs, academic interest in studying various aspects of analytics infusion in business education has also increased. Some prior studies have examined business analytics coursework in universities, particularly programs offered by business programs and classified them by matriculation level, subject area coverage, topic coverage, and pedagogies employed (Sircar, 2009; Phelps and Szabat, 2017). Others have viewed analytics programs through the lens of industry needs, workforce requirements, and employment opportunities (Radovilsky, Hegde, Acharya, and Uma, 2018; Mamonov, Misra, and Jain, 2015; Turel and Kapoor, 2016) and appraised the maturity of such programs relative to their potential to fulfill presumed industry needs. Detailed surveys of faculty, industry professionals, and students interested in analytics have formed the basis of successive surveys conducted at the BI Congress meetings. These surveys yielded insights about curriculum design, content coverage, and a need for interdisciplinary collaborative engagement that have been documented in the studies by Wixom et al (2011, 2014). In the remainder of this section, a handful of studies on BA curriculum research is discussed briefly.

In an early exploratory study (Sircar, 2009), business analytics was posited to lie at the intersection of management science, statistics, and information technology (IT) – all of which have been offered in traditional business curricula, both at the graduate and undergraduate levels. The study found that only 7 among top 50 business schools offered a course on business analytics at the undergraduate level, while 5 others offered related coursework in which business analytics topics were expected to be covered. Sircar (2009) acknowledged that coursework in decision sciences, statistics, and IT has traditionally always been integral to business curricula; yet, the challenge was to consolidate important topics from these three areas in a coherent package that is either a standalone course in business analytics, or a BA minor or major.

Based on a survey of information systems faculty, industry professionals, and students, Wixom et al. (2011) recommended that universities must provide a broader range of analytics skills within analytics coursework and programs. The authors specifically recommended a broad, diverse range of topics for analytics coursework that includes business domain knowledge, research methods, statistics, data management, warehousing, and mining topics, quantitative analysis and operations research (OR), and systems analysis, design, and development. Recognizing that no single department within a specific unit, for example, a business school could offer such a diverse array of topics, Wixom et al. (2011) pointed to the need to adopt a more collaborative approach of curriculum development that spans multiple departments or academic units. In a subsequent survey-based study, Wixom et al. (2014) found that an interdisciplinary approach cutting across traditional disciplinary silos involving faculty from different departments and schools was on the rise for developing, offering, and teaching analytics and related coursework. Wixom et al. (2014) further found that such an approach was increasingly commonplace in MBA programs in which the introductory analytics courses were being taught by marketing faculty. A notable contribution of this study was the nuanced recommendation that analytics curricular offerings must be distinguished based on the audience – undergraduate versus graduate, and MS versus MBA. For MBA coursework and executive education in analytics, greater emphasis on business applications of analytics at the enterprise level was recommended. Analytical skills that enable students to interpret business data and make informed decisions, along with management aspects of analytics projects were recommended to be essential for MBA analytics curricula. Viewed together, the Wixom et al. (2011, 2014) studies are instructive and provide early clues about development of a foundational curriculum model that can guide the design of a BA core course for an MBA program.

Consistent with Wixom et al. (2014), Gorman and Klimberg (2014) also noted that a greater focus on technical knowledge marks a point of distinction of MS programs in analytics compared to MBA programs, even though both seem to emphasize skills training that is applicable in the workplace. Like Wixom et al (2014), Gorman and Klimberg (2014) also delineated subject area coverage of statistics, OR, and MIS topics in MS courses in analytics and found that among surveyed programs, half of the content cover statistics topics, while the other half is largely evenly split between OR and MIS topics. Only 4 of the 32 institutions included in the Gorman and Klimberg (2014) survey offered MBA concentrations in analytics, while a vast majority offered MS in analytics degrees, limiting insights on design of MBA coursework on analytics.

Among contemporary prior research on analytics curricula, especially as it relates to the development of a conceptual model for data-driven decision-making, the recent work by Gupta, Goul, and Dinter (2015) is notable for providing the first analytics model curriculum. Based on extensive survey and review of prior literature in analytics, Gupta et al. (2015) provided a taxonomy of analytics and business intelligence topic coverage for undergraduate, MS, and MBA coursework, based on knowledge and cognitive process dimensions. Reiterating Wixom et al. (2014), Gupta et al. (2015) argued that MBA coverage of analytics should predominantly focus on strategic applications of analytical tools and technologies to solve business problems to derive competitive advantage, while MS coverage should emphasize technical dimensions such as how to build and deploy analytics applications using BI and BA tools. Gupta et al. (2015) prescribed inclusion of topics such as introductory concepts, IT frameworks and use cases for analytics, evolution of analytics in the organization, enterprise performance management, human resources for BI and analytics, business processes as they relate to analytics, enterprise application areas, predictive analytics and data mining, visualization, ethics, advanced topics, etc. in an MBA BA course.

Overall, with the exception of Gupta et al. (2015), detailed, well-researched BA curriculum development guidance especially for analytics coursework in MBA programs is virtually absent.

Much of the prior work on analytics curriculum research has focused on MS in Analytics programs, consistent with the impressive growth in such programs. Yet, despite the increasing popularity of specialized MS programs, MBA programs offer a viable option for students interested in generalist business education to be exposed to analytics. As discussed earlier, in the absence of curriculum development guidance, analytics coursework design for MBA programs usually defaults to faculty with backgrounds in quantitatively oriented disciplines such as statistics, OR, industrial engineering, mathematics, and MIS, to name a few. Naturally, the course designer's academic, scholarly, and professional backgrounds are likely to bias course design. In addition, the absence of suitable teaching resources such as textbooks and case studies exacerbate the MBA analytics course designers' problems. Faculty end up designing courses based upon available textbooks that would otherwise be more suitable for MIS, OR, or business statistics coursework, or in some cases using textbooks that have been conveniently retitled to cater to the increasing demand of analytics coursework in business schools. This is neither desirable nor optimal, especially as the demand for skilled analysts continues to remain high in industry and is in fact predicted to grow.

Acknowledging that a single MBA course is hardly sufficient to produce a skilled analytics graduate, it nonetheless lays an important foundation for an aspiring analytics professional. A curriculum design model that is built around the quartet of problem definition, evaluation of data requirements, application of analytical techniques, culminating in interpretation of results and problem solution, not only places a greater focus on business applications of analytics, as deemed appropriate in prior studies (Wixom et al, 2011, 2014; Gupta et al, 2014), it aligns analytics course design with problem-solving needs of contemporary businesses and industry at large. In addition, such a curriculum design model could guide development of appropriate teaching resources, optimal selection of course designer, and potentially pave the path for redesign of MBA coursework in MIS, quantitative methods, and strategy leading to an MBA that can produce a well-rounded analytics professional.

In addition to reviewing prior BA curriculum design literature, a limited meta-analysis of syllabi of introductory Business Analytics (BA) courses in the MBA program from 16 different business schools/universities in the US was also conducted to better understand the design of existing introductory courses on business analytics in MBA programs. All 16 business schools are accredited by AACSB. All courses were 3-hour credit courses. All courses except for one course from a university in Texas had "Business Analytics" in the title of the course. Most of these courses did not have any pre-requisites except one that listed Business Statistics as pre-requisite for the BA course. The introductory BA course is required in the MBA programs in only 5 business schools whereas the other schools use them as electives. Only three courses were mentioned to be offered online.

Except for one business school, none of the BA courses were structured based on any conceptual model as per the syllabus. One school had structured their course on the CRISP-DM, six phase model. As far as the textbook is concerned, 8 schools required text book(s), one school was found to use a course reader made available in their book store, one school provides articles available online, and two schools have optional recommended books.

A variety of analytics software tools are being used in the BA courses by the business schools in their MBA program. Some are less technical than others which requires programming skills. Six schools use Excel, followed by two schools each uses XL Miner and R. Other schools are using JMP, SAS, SAS Enterprise Miner, Weka, Power BI, Rapid Miner, Risk, and Tableau.

From the content point of view, most of the schools cover descriptive, predictive, and prescriptive analytics in their courses. Eight schools cover descriptive analytics (average – 17% of the semester with a range from 12% to 40%); all 16 schools cover predictive analytics in their BA courses (average – 48% of the semester with a range from 25% to 80%); and only 5 schools cover prescriptive analytics (average – 9% of the semester with a range from 16% to 33%). This indicates a majority of BA courses cover descriptive and predictive analytics apart from some coverage on introduction to BA and Big Data.

This limited syllabus meta-analysis confirms that the BA course in many business schools do not follow any conceptual model and are either based on the text books they are using or the faculty's perception what should be covered in the introductory BA course. This also points to a need for a model for structured course development for BA courses in MBA programs.

The next section outlines a conceptual model of data-driven decision-making process as a guide for developing an introductory MBA core course in analytics.

APPROACH OF BUSINESS ANALYTICS COURSE DEVELOPMENT

Rationale for model

When faced with the task of developing a new course, it is common for faculty to search for existing courses elsewhere or conceptual models to guide them. This is no different with a business analytics (BA) course. One of the authors was tasked with development of a new introductory BA course for the MBA program early in 2018. This section details the process used for development and implementation of the course.

From the literature review, as presented in the previous section of this paper, it is clear that a single, commonly accepted, comprehensive model to guide development of BA courses does not exist. The development of our model is an attempt to fill this gap.

Data-driven decision-making process model: development

A typical decision making model starts off with a precise definition of a problem to be solved (or a decision to be made) and ends with a solution to the problem defined. For a data driven decision-making, there are three other activities that come in the middle – data, analysis, and results. This was the basis of our preliminary model. The roots for this model can thus be traced back to Dewey's model on decision making which was further structured/detailed by Simon (Dewey, 1910; Simon, 1977). The model was further refined with concepts from a variety of models – CRISP-DM, SEMMA, and KDD models.

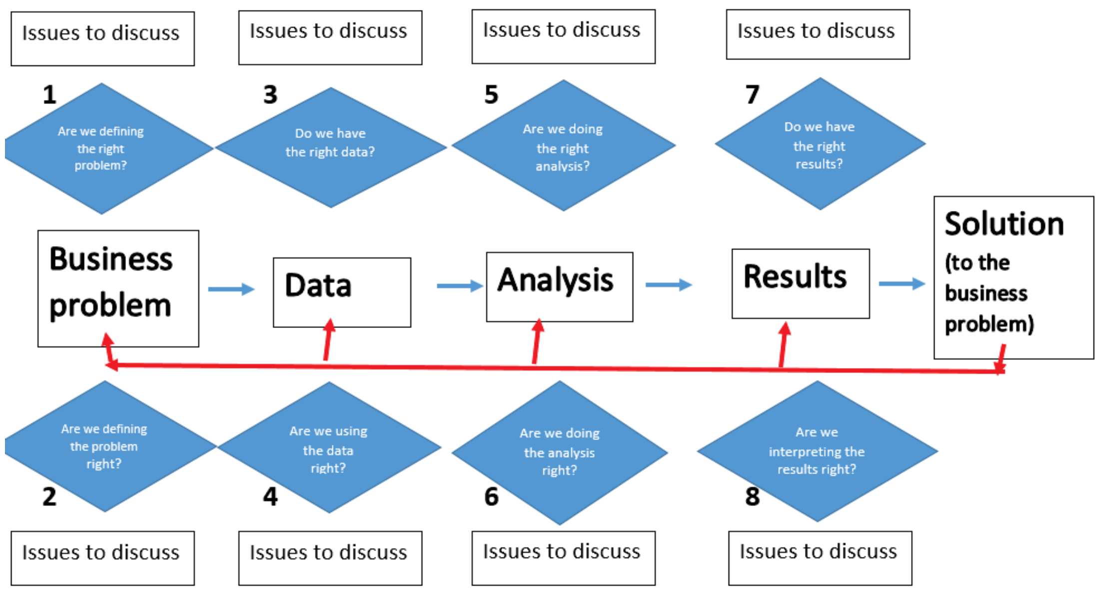
The model developed is presented in Figure 1. The model consists of the following:

- Five basic processes – defining the business problem, data, analysis, results, and solution to the stated problem
- Two sub-processes/activities for each of the first four basic processes (numbered 1 through 8 in the model) – the questions to be answered (or issues to be addressed) for each of these sub-processes are listed in Table 2.
- Connections between different processes/sub-processes.

The model thus developed maps well with Simon's decision making model. The mapping of our model with that from Simon is presented in Table 1:

Table 1: Mapping of Simon's decision making model with paper's conceptual model	
Simon's model	**Our model**
Intelligence (problem recognition/statement	Sub-processes 1 & 2 Sub-processes 3 through 6 & then 1 & 2 (Exploratory Data Analysis)
Design (generating alternative solutions)	Sub-processes 3 through 6
Choice (selecting the best solution)	Sub-processes 7 & 8 and then 1 & 2

Figure 1. Conceptual model of data driven decision-making process



The five basic processes are commonly approached in a sequential manner, in most problem solving situations. It is also Simon's argument that the three processes/phases (the intelligence, design, and choice) are followed in a sequential manner and within each phase there could still be the same three processes as each phase/process is explored. However, whenever we get stuck in any of the processes, we will most likely loopback to previous step(s) to continue the problem-solving process. For example, if we cannot get the data we need to solve the problem as stated in sub-activity 2, we may have to loop back to step 2 and redefine the problem so that appropriate data can be obtained to solve the problem. Also, in some cases, the decision making activity need not start with the first process. For example, in identifying a problem or an opportunity, we may do some exploratory data analysis (EDA) and, hence, the decision making process may start with data and proceed with the analysis processes sequentially and then loop back to problem statement. Thus, the model has the flexibility to be used in decision making contexts where exploratory or confirmatory data analysis is appropriate.

Table 2: Eight sub-processes – questions and related issues
1. Are we defining the right problem? a. How do we know we have defined the right problem? b. Who would know that?

c. Are there processes that would assure us a definition of the right problem?
2. Are we defining the problem right? a. How do we know we have defined the problem right? b. Who would know that? c. Have we clearly specified the boundaries of the problem? d. Have we understood "what is the problem" and "what is not the problem?" Have we stated them? e. Have we considered all assumptions made (whether implicit or explicit) and stated them? f. Are there processes that would assure us a definition of the problem right?
3. Do we have the right data? a. How do we know we have the right data? b. Have we defined all the variables needed? c. Have we coded the data correctly? d. Have we defined all the variables fully? e. Are there processes that would assure us a complete set of variables needed to address the problem defined? f. Are we collecting the specified data using proper methods? g. Have we used proper verification methods to assure good quality data?
4. Are we using the data right? a. Have we clearly classified the data into proper categories based on the measurement scale? (qualitative & quantitative, categorical & continuous, etc.) b. How are we handling missing values in the data set? c. How are we handling outliers? d. How are we handling incorrect data? e. Which variables will be transformed & which transformation technique is right?
5. Are we doing the right analysis? a. Do the analysis techniques match the data available? b. Would the results of the analyses address the problem defined in step 2?
6. Are we doing the analysis right? a. Have we transformed the data, if necessary, correctly? b. Have we specified the analysis fully and properly for the tool used? c. Are we using the right techniques to analyze the data? d. Are we using the intermediate results from the analysis to re-specify the model correctly for further analysis?
7. Do we have the right results? a. Have we verified the validity of the assumptions for the analysis techniques used? b. Have we asked for the right and complete outputs from the analyses?
8. Are we interpreting the results right? a. Are we interpreting the analysis results correctly? How would we assure this is happening? b. Do we need expertise from others to interpret the results?

For each of the first four basic processes, we can define two sub-activities. For example, when defining a business problem, we need to ensure that the right problem has been defined and also the problem has been defined right -- if we do not do this well, a type III error may occur, i.e., solving the wrong problem. The same structure also applies to data (having the right data versus using the data right – for example, the zip code data may be the right data, but using that data as quantitative will lead to wrong results), analysis (doing the right analysis versus doing the analysis right – doing the right analysis is a function of the data and the problem posed, but doing the analysis right is a function of the tools), and results (getting the right results versus interpreting the results right – for example, getting R^2 as a part of the regression analysis results is correct, but interpreting the value without paying attention to the "p" value would be inappropriate).

The connections between sub-activities and between some sub-activities and the first and last basic processes is also important for most problem solving situations. For example, the connection between (sub-activities) 4 and 5 is critical to understand. We may specify the data right, but fail to identify the right analysis to be done. We can see this in student work where quarter (with values assigned as 1, 2, 3, & 4) or zip codes are used in the analysis as quantitative variables.

Application of the model

Once the model is well understood and is deemed acceptable for course development, the focus will be on the following tasks:

1. Determining the depth of coverage for each aspect of the model (the processes and sub-processes) – this could differ depending on the philosophy of the designer of the course. For example, there may be courses where 10-20% the course time be spent on discussion of "data" and some other courses where the coverage may be only 5% of the course time. This also depends on the breadth and depth of students' preparation leading to this course.
2. Identifying and selecting the right course materials that map with the model – this could very well mean that a standard textbook may not be available. Using articles, from academic journals as well as from trade publications, articles that are classics (and possibly dated), and also current articles addressing relevant issues would be appropriate here.
3. Developing/selecting appropriate homework, case analyses, exams, and projects that map well with the model and with prior items 1 and 2. This could mean modifying existing materials (from textbooks) to match the model and its emphasis and also developing new materials as necessary.
4. Developing class discussion materials (like presentation materials) that map well with the model and addresses the questions raised in Table 2.
5. Choosing the right tools for analysis (like Excel, Minitab, SAS, Tableau, etc.)

The model can be used to develop any introductory BA course, in an MBA program, with different amount of focus on different aspects of analytics – descriptive, predictive, and prescriptive. We believe that the model may not change substantially in the near future, but different users could modify, add, or delete some questions raised in Table 2 to customize the model to their context and needs.

Implementation of the model

Our implementation context was a redesign of an "applied business statistics" course into an introductory analytics course in the MBA program. However, the model can be used to develop a new business analytics course in MBA programs. As the MBA program already had a "management science" course in the program, the focus of the new course was on descriptive and predictive analytics. This appears to be the case with most existing introductory business analytics courses in MBA programs as we have noted in the summary of the meta-analysis of syllabi. The designer was given complete freedom in forming the course and he exercised the freedom in making sure the content from the existing course did not have an undue influence on the new course. Though some topics overlap between the two courses, the emphasis shifted from "teaching business statistics" to "solving business problems using statistics." The new course was named "data driven decision-making" and all content (the breadth and depth) as per the model was specified before selecting the course materials (like books, articles, cases, etc.). Due to the design of the course, a traditional business statistics book or an available business analytics book was deemed to be unsuitable.

The main issue that had to be considered during the design/development of the course was the fact that many adjunct faculty would be teaching this course. Therefore, training was required to prepare them and make them comfortable teaching a radically different course compared to a traditional applied business statistics course that they were used to teaching. Also, new materials to suit the new course had to be developed – materials such as case studies, exams, projects, homework sets, etc. The materials were developed (or modified from existing materials) so that they can be mapped with the processes and sub-processes discussed in different sessions (again, with an emphasis on "solving business problems using statistical analysis" always in the forefront of discussion).

The course was offered in an eight-week format, one 4-hour session per week for eight weeks (with a stated expectation that students spend an average of 18 hours outside the classroom per week on the course). The course was offered for the first time in Nov-Dec 2018, when it was taught in both online and on-the-ground versions. The course will be taught again in May-June 2019. Some relevant parts of the syllabus developed – like course learning outcomes, reading materials, and course schedule/outline – are listed at the end of this paper.

LESSONS LEARNED AND IMPLICATIONS

Some lessons learned from the first delivery of the course – with experience of one of the authors, feedback from six adjunct faculty who taught the course and a little over 100 students are presented next.

- The model makes new course development considerably focused and straight forward.
    - It assisted the faculty involved in focused discussions on specific processes and sub-processes to be included in specific sessions. It helped faculty plan class sessions and spend appropriate amounts of time/emphasis on chosen topic areas. The model does not restrict academic freedom of faculty (in delivering the course) as long as they meet the course learning outcomes as stated.

- Students, in general, appreciate the business problem (or application) oriented focus of the course.
    - Many students specifically commented on the usefulness of the "solving business problems" focus and indicated that they have started using the concepts/tools at their place of work.
    - Students also had positive comments on the "practitioner oriented" reading materials (instead of boring academic materials).

- Do not overwhelm the students with reading materials – select/assign weekly materials that require reasonable number of hours to finish. Our students are expected to work outside the classroom an average of 18 hours per week/session. Providing "practitioner oriented" course materials, and having an emphasis on "solving business problems" makes the readings a bit more enjoyable and hence desist students from complaining about hours spent outside of course seat time per week.

- Do not overwhelm the students with too many analysis tools. We eased the students into using these tools with tutorials developed specifically for this course. Our students appreciated this extra help they received.

- Work closely with students needing extra help by providing them timely, appropriate and adequate tutorial help. As the course is fairly intense for most students, and as the course material is somewhat sequential in nature, it is important to diagnose the need for, and provide timely tutorial help to students who are having some difficulty with concepts, or tools in the course.

- A segment of students have difficulty connecting the five basic processes correctly. This was evident in the difficulty of some students with the project where they were required to pose a business problem and take it through an analytic solution. Thus, it is important to emphasize (in almost every session of the class – in our case just eight sessions) the seamless connections between the processes and sub-processes. It is best illustrated through business examples.

- As part of course assessment, a quiz as a part of the final exam was administered to all students. This consisted of six multiple choice questions – one question on problem solving process using hypothesis testing, one question on interpretation of a confidence interval estimation, and four questions of matching data with the right analysis (different types of data and different analyses). The assessment results are comparable with results from the original applied business statistics course that formed the basis for the new course. This assessment will help us with continuous improvement in the delivery of the course.
    - Anecdotal evidence volunteered by students indicate their clear happiness regarding the problem solving focus of the course and the usefulness of the course content. This is a very positive indication that the course was well received. It is very rare indeed when a student in a quantitative course voluntarily provides positive feedback!

The main implication for the course design using our model is to start with a simple design of the course (that does not overwhelm the students) and slowly add more content (i.e., readings, assignments, tools, etc.) over several deliveries of the course. In our program, this course is a pre-requisite course (and hence can be waived for students with a business degree). The diversity in the classroom is considerable with student age range of 22-55 years. This also results in considerable diversity in work experience. This will always be a challenge in course design/delivery. The implication we have discussed may be more or less severe depending on the composition of the student group.

Though the model may seem to indicate a sequential decision making process (as laid out), it is important to note there may be exceptions depending on the context. For example, in “big data” environments, the data already exists and hence the process starts with analysis (i.e., sub-process 5) and then eventually loop back to the “business problem” process. In other situations, regulatory requirements/standards, for example in healthcare environments, may constrain available data. This may again lead to starting with the “analysis” process of the model instead of the “business problem” process.

CONCLUSION

In this paper, we demonstrated how a conceptual model of the data driven decision-making process can guide in developing a graduate introductory BA course in the MBA program. This approach will help faculty in developing a BA course that is focused & consistent in course content. This well-defined data-driven decision-making process enables the faculty to break down complex problems into smaller steps that are easy for students to understand and master. This will also help students to get a clear grasp of the business problems to be solved. This can also help publishers develop BA books that are based on a standard and systematic process for BA. This should help faculty and publishers develop better course materials such as exercises, projects, cases, and discussion materials. The model presented in this paper is not rigid and provides flexibility to faculty teaching the BA course on the amount of time and coverage of topics in each phase of the data-driven decision-making process. The use of this model in refining the courses developed and in developing new courses will provide data for validation of the model/approach presented. Though the processes/sub-processes of the model developed are typically approached sequentially, it is important to note that exception to this is very much possible. An example of this could be the exploratory data analysis that could be used to identify problems. This would typically start with the “data” process and sub-processes 3 & 4, proceed with “analysis” process and sub-processes 5 & 6 and then loop back to “business problem” process.

APPENDIX

Course Learning Outcomes

Upon successful completion of this course, students will be able to:

1. Identify organizational opportunities for data-driven decision-making that create value.
2. Define each opportunity clearly and accurately, and articulate why your definition is right.
3. Specify the data needs for each opportunity identified, including its collection, and justify how that data is relevant for the context.
4. Identify and justify the right data analyses that could support decision-making in the context of the opportunity and data needs specified.
5. Perform relevant analyses using the right business analytics (BA) tools.
6. Effectively communicate the findings of the analyses performed to the decision maker(s).
7. Evaluate and articulate the value delivered by data-driven decision-making, for each opportunity identified.
8. Evaluate the ethical implications associated with BA use in organizations to assist decision making.

Course Schedule (Planned)

DAY/ DATE	TOPIC	TO DO (before you attend that session)	WORK DUE
1.	Introduction to the course: Decision-making (DM), data, patterns, and solution	**Read:** **Diez et al** -- Chapter 1, **Davenport et al** – Chapter 1 **Ayers** – Introduction & Chapter 1 **Articles:** 1-11 **Tufte** – pages 5-15 **Explore:** **Think and come prepared to discuss** sampling and data collection in your organization.	
2.	Uncertainty and patterns in uncertainty	**Read:** **Diez et al** -- Sections 2.1, 2.4, 2.5, 3.1, 3.4.1, & 3.5.2) **Davenport et al** – Chapter 2 **Ayers** – Chapter 2 **Articles:** 12 **Explore:** Excel capabilities related to descriptive statistics (functions & graphs) **Think and come prepared to discuss** how uncertainty is handled in your organization.	Homework set #1
3.	Data, variables, patterns, and analytics	**Read:** **Diez et al** -- Chapter 1 **Davenport et al** – Chapter 3 **Ayers** – Chapter 3 **Articles:** 13-19 **Tufte** – pages 16-31 **Explore:** Explore descriptive analytics features of Tableau **Think and come prepared to discuss** how patterns in data are explored in your organization.	Homework set #2
4.	One variable inference	**Read:** **Diez et al** – Sections 4.1 – 4.3 **Davenport et al** – None **Ayers** – Chapter 4 **Articles:** 20-27 **Explore:** Explore features related to today's topic in Excel **Think and come prepared to discuss** how inferences using data are made in your organization.	Homework set #3
5.	Two variables inference	**Read:** **Diez et al** – Sections 5.5, 6.4, & 7.1 **Davenport et al** – Chapter 4 **Ayers** – Chapter 5 **Articles:** 28-30 **Explore:** Explore features related to today's topic in Minitab **Think and come prepared to discuss** examples of single and multiple variable(s) inferences in your organization.	Take-home mid-term exam;
6.	Multiple variables inference	**Read:** **Diez et al** – Sections 8.1, 8.2, & 8.4 **Davenport et al** – Chapter 5 **Ayers** – Chapter 6 **Articles:** 31 **Explore:** Explore features related to today's topic in Minitab **Think and come prepared to discuss** how single and multiple variable(s) inferences are made in your organization..	Homework set #4
7.	Multiple variables inference	**Read:** **Diez et al** -- None **Davenport et al** – Chapter 6 **Ayers** – Chapter 7 **Articles:** 32-34 **Explore:** Explore features related to today's topic in Minitab **Think and come prepared to discuss** analytics use in your organization.	Homework set #5
8.	Ethical aspects of data-driven DM Project presentations.	**Read:** **Diez et al** -- None **Davenport et al** – Chapter 7 **Ayers** – Chapter 8 **Articles:** 35 **Explore:** **Think and come prepared to discuss** ethical and social aspects of analytics use in your organization.	Project presentations; Final exam (in-class)

Redesigning an Information System Survey Course for Online MBA Students

Teuta Cata

Northern Kentucky University

Email: catat@nku.edu

ABSTRACT

Business students don't find the benefit of an information systems course in the MBA curriculum. This study uses Bloom taxonomy to redesign testing of the concepts covered in an IS survey course by shifting from Remembering to Applying level as the best testing method for adult business professionals. Learning such IS concepts in isolation from their applications in business processes was the reason for the negative perception of why an IS course should be integrated in an MBA core curriculum.

KEYWORDS: Teaching MBA Students, Teaching IS Courses, Online MBA Teaching

INTRODUCTION

It is well known in the Information Systems community that business students have difficulty on grasping the concepts of an Information Systems course for several reasons: Such courses are survey ones, which cover a broad area of IT topics without going in depth in any of them. Students are facing the challenge of remembering all those concepts without understanding the difference between them since there is no depth in the coverage of such concepts. Furthermore, those concepts are changing very fast, as this is the nature of IT, and professors need to bring to class the updates, which are not included in the textbooks. The need to stay updated in the topics is a challenge for both faculty and students that adds more pressure on preparing for class exams (Dadashzadeh, 2018).

Teaching MIS survey courses to business students should be more than just lecture-oriented classes. Faculty should consider active learning approaches where they should integrate the lectures with hands-on activities, student participation in group projects, faculty – student collaborations to explain the concepts and their implications to business practices.

The value added of IT courses to an MBA program, has been the focus of many research projects over the years. Beachboard and Aytes (2011) identified the need than an IT course in the MBA program should focus on what strength and value the IT domain add to the education of an MBA student. The authors tested the perceptions of MBA students before and after taking the MIS class as part of their curriculum. Students' perceptions before taking the class were more towards the negative side, which reflects the well-known perception of an MIS course taken by business students. The authors redesigned the IT course content to include a consulting project that allowed students to use experience-based learning as a tool to see the connection between IT and the efficiency in business operations. This course redesign made a significant change on the students' perception after the class was over. Students saw the value of IT concepts in the preparation for them to become business executives in the future.

The research on how MIS concepts should be integrated in the MBA curriculum have changed over the years, since many MBA students have some IS related background from their undergraduate studies or work related experiences. Thouin et al (2018) investigated on how an MSIS program should be designed for students who have or not IT experience, the choice of curriculum, teaching instructions, and program selections. Students who have IT background prefer a program with high level of flexibility, more integrative approaches in teaching, working in groups, having guest lectures, and courses taught by adjunct professors who work full time in the industry. They prefer a program that has a mix information on both business and technology without having a heavy focus on IT.

While research conducted by Thouin et al (2018) suggests that students learn from each other while working on group projects with their peers, may not be necessary the case for accelerated online courses. A research on accelerated online MBA courses which are primarily 5 to 8 week classes', done by Favor and Kulp (2015), show that adult learners prefer to work alone rather than with other peers in groups. Despite students' perception, that working in groups enhances their learning on the subject matter, their preference is to work alone and pace themselves. Adult learners in accelerated degree programs get frustrated by waiting on others to communicate on the projects, align performance expectations on the tasks, managing and assigning workload within groups, etc. While it is very important to have several approaches on motivating learning in an online accelerated environment, learning from each other as much as learning from the faculty, group work is not suitable for such learners.

What Teaching and Testing Methods to Use for an Online MBA?

Teaching an online-accelerated MBA class is a much different teaching experience than to a regular MIS program in a traditional setting for a full semester (16-week). Faculty who teaches to such students must adjust their teaching goals, lectures, testing materials, in order to assess correctly the knowledge obtained by such adult learners.

A quasi-experiment study for an intensive online MBA program compared two different instructional approaches related to participation on online discussions. The Socratic questions used on the experimental group to lead students to critical thinking and deeper learning improved the online learning environment for that group of students (Strang, 2011). Group comparison analysis such as Anova and Mancova identified that academic quality was much higher when the Socratic questioning conversation theory was used. It is obvious that online MBA students learn better if they challenged to speak up and participate into an online discussion initiated by faculty. The downside of such methods is that faculty need to customize and participate in the online discussions which may be a time consuming approach if they teach large sections of online MBA classes.

The principal investigator of this study has changed the peer collaboration during the semester by having online discussions where students exchange readings, videos or personal professional experience related to the IS topics covered during that week. Such online discussions are found very informative and beneficial from such adult learners in the comments they make online or at the end while they evaluate the course.

Testing of the knowledge obtained from the weekly lectures is usually done by multiple choice questions quizzes, where questions come from a test bank prepared by the publishers. Such questions are drafted as "one size fits all", without taking in the consideration how adult learners prefer to understand the material and apply it in the business setting. There is a significant disconnect on what a student wants to learn and apply in the real world from an MIS textbook and what those multiple choice question quizzes suggest what a student should remember while learning. Those questions are very isolated from a business setting, ask specific details on definitions, and hardly motivate a student to see a value in that information.

Therefore the focus of this study is to understand who are the adult learners in an accelerated online MBA program, what kind of background they have in Information Systems (undergraduate or work related ones), and what will be the best way to motivate them learn Information Systems concepts which are necessary in the education of such business professionals.

Methodology to be Used in the Study:

This experimental study will include a pre-survey; experimental treatment, and course survey at the end of the 5-week course.

1. All students enrolled in the online 5-week MBA class of Intro in Information Systems will take a short survey where they are asked to share their background which will fall in three categories: have IS background from their undergraduate studies; have IS experience from their work experience; and have no IS experience at all.
2. Students will be randomly divided in two groups in Canvas: experimental and control groups.
    a. **Experimental group:** This group of students will have a mix of MCQ and short answer questions prepared by the faculty on how the concepts of that chapter applies into business processes. The short answer questions will be out of the some of the MCQ questions pool provided to the control group and transformed to short answer ones by the faculty who teaches the class. Students will be assessed on how concepts discussed in the chapters are related to business context. Such questions will require focusing on Understanding of the concepts and Applying them in the context of Information Systems domain, which is aligned with "Apply" level of Bloom Taxonomy. The nature of short answer questions for chapter will depend on what the chapter covers. Some chapters are more technical like the database, networking technologies chapter, etc. The short answers prepared for such technical chapters will be technical scenarios and how an MBA student can make a business decision based on the technical concepts covered on the chapter. Some of the chapters covered in the course are business oriented. Students will be asked to make a decision on what will be the best software to address that business need.
    b. **Control group:** 20 MCQ provided in the test bank will be used to test the students' understanding on the chapters. Such questions are usually testing definitions or specific details of such concepts. These questions are usually very specific and isolated from the business context where such technologies are implemented. Such questions belong to "Remembering" level on Blooms taxonomy, where they basically recall, memorize and list the concepts discuss in the chapters. Control group will have 20 questions and have 20 minutes to respond to them on Canvas.
3. Course and professor evaluations will be analyzed for both groups and will be compared to see if the perception about the course really adds value to an MBA student. The course survey for both groups will have more questions which will ask if students perceive the MIS course as a useful one in the MBA core classes; if this class will help them become a more successful business leader; and what kind of IS concepts they would be interested to learn more about.

Both groups are taught the same lectures from the faculty on how to relate IS concepts to a business context.

Analysis to be Used in this Study:

T-test, descriptive analysis and maybe text mining (if enough comments are shared on course evaluation at the end of semesters) will be used to see if there is any significant difference between control and experimental groups, among students with no IS backgrounds vs the ones who have previous IS backgrounds. These tests will help to understand what IS background the current MBA students have, what kind of learners they are (based on Blooms taxonomy) and what is the best way to teach an accelerated MBA course.

Contribution of this Study:

MBA program has become one of the most well attended graduate programs. The online format gives the students the opportunity to take classes when they can, and fit those classes into their busy life. Such students need to see that an MBA degree adds value in their education, and is relevant to their current work experience. Introduction to Information Systems class has been identified as a class that doesn't align very well with their educational goals. This misalignment is not so much a mental block that an MBA student may have towards concepts in IS domain, but how such information relates into their work experiences and educational expectations. Understanding what kind of IS background an MBA student has, designing a class that is challenging and interesting, is extremely important for a faculty who designs courses which make a graduate student to see the added value of his/her graduate education.

Mastering the onboarding challenge: The case of information processing in distributed ledgers in supply chains

Dominik Roeck
University of St.Gallen, Switzerland
Email: dominik.roeck@unisg.ch

Erik Hofmann
University of St.Gallen, Switzerland
Email: erik.hofmann@unisg.ch

ABSTRACT

Distributed ledger technology (DLT) is praised to process information across organizational boundaries and thus enhance supply chain transparency (SCT). However, as first pilots show, this improvement is no sure-fire success. This case study investigates what is needed to process information with DLT to enhance SCT by studying five DLT solutions in a single industry. The cases reveal that DLT requires information processing capabilities (IPCs) in form of processes, infrastructure and IT both on an organizational and interorganizational level. Thus, in order to process information with DLT, supply chain actors need to collaborate to enable smaller organizations make use of DLT.

KEYWORDS: Supply chain management, Information processing theory, Supply chain transparency, Distributed ledger technology, Supply chain collaboration

INTRODUCTION

The importance of supply chain transparency (SCT) is increasing for both practitioners and academics. Incidents of contaminated food on a daily basis, unethical work conditions, product recalls (Saberi *et al.*, 2018) or a billion-dollar diamond fraud in India (Subramanian, 2018) are just a few examples that depict the rising importance of SCT. For example, in 2018 media reported that an Indian diamond trader was able to fraud multiple banks with forged trade documents over a period of multiple years due to a lack of SCT. The affected banks were not able to match the trade documents with the corresponding diamond. Thus, leaving the opportunity to forge documents for stones that do not exist or finance trades multiple times. Moreover, this is not the only lack of transparency in the diamond industry as proofing provenance of diamonds remains challenging. Only lately has the Czech national collection revealed that the exhibited diamonds were faked glass imitations (Malm, 2018). In addition, the problem of conflict diamonds – diamonds that are mined in war zones, smuggled and unethical-mined diamonds increase the need for more SCT in the diamond industry. Although this is only one exemplary industry, it represents typical challenges in nowadays, globally distributed supply chains. For the actors within such supply chains, the lack of transparency results in uncertainties. Due to limited transparency, the actors cannot asses the product quality (e.g. the quality of the diamond) and its origin with certainty. This exposes them to risk that affects their operations, for example in case of bad product quality and consequently their reputation, for example when trade documents are forged. This is especially a challenge for an industry such as the gemstone and diamond industry. For hundreds of years, the industry was built on trust between transaction partners. Over all these years, the industry did not underwent significant change in the behavior of trading partners. Trust was always the replacement for the lack of transparency. It appeared as if the industry had already accepted that it lacks transparency. However, the latest incidents and the customer pressure pushed gemstone and diamond actors forward in their aspiration to improve transparency sooner than later. At the same time, distributed ledger technology (DLT) has emerged with promises to address the lack of transparency and consequently the resulting uncertainties. In supply chain management (SCM), both researchers (Rao *et al.*, 2017) and practitioners (Casey and Wong, 2017) see enormous potentials due to DLTs high level of availability, immutability of stored data, the frictionless distribution of data between network members and the reduced need for intermediaries (Beck and Müller-Bloch, 2017). Based on high availability, data immutability and data distribution, researchers indicate an improvement of SCT through the usage of DLT (Saberi *et al.*, 2018). In order to reduce the uncertainty within supply chains, organizations seek to enhance SCT. However, enhancing SCT greatly depends on the processing of information in supply chain networks. This requires that DLT-enhanced SCT solutions, and the organizations that use these solutions, process information successfully. While academics and practitioners have proclaimed the potential of DLT to improve SCT, they have paid little attention to the actual processing of information of DLT to enhance SCT. In particular, research lacks the understanding of the capabilities that are required to process information in DLT-enhanced SCT solutions in order to improve SCT. This understanding is substantial for DLT adoption and consequently the potential impact that DLT will have for SCT. This includes as well the aspect how these capabilities can be built up. Moreover, in order to understand this in the context it is necessary to study, why organizations seek to process information via DLT-enhanced SCT solutions, the driver for the need to process information. This paper wishes to address this research gap as it aims to study DLT-enhanced SCT solutions and their required capabilities to process information in DLT-enhanced SCT solutions. We address this research gap by the following three research questions:

Research question 1: What are the uncertainties that drive organizations to process information via DLT-enhanced SCT solutions?
Research question 2: What capabilities are required to process information in DLT-enhanced SCT solutions?
Research question 3: How can organizations build up these required capabilities?

In order to answer these questions, we draw on information processing theory (IPT), as it presents an appropriate theoretical lens to elaborate not only the needs to process information but also the required capabilities to do so and how they can be built up. By answering these questions, the paper contributes to practice as it helps managers to understand the information processing of DLT and to identify the required capabilities. Thereby, it supports managers' decisions for or against the technology and indicate needed capabilities. In addition, it contributes to theory by positioning SCT in IPT and applying it for DLT-enhanced SCT solutions. Thereby we expand IPT to an interorganizational setting.

LITERATURE REVIEW

Transparency in physical supply chains

SCT is not only a discussed topic in practice but also in academic literature (Morgan *et al.*, 2018) and since the turn of the millennium, more and more scholars turned their attention to the phenomenon of SCT. Scholars use the terminology of SCT to summarize visibility and traceability in supply chains. Creating visibility and traceability are understood as enablers to achieve SCT (Morgan *et al.*, 2018). Supply chain visibility is defined as "the ability of supply chain partners to access information related to operations of the entire supply chain, besides the activities in which they participate" (Tsanos *et al.*, 2014, p. 436). Daugherty *et al.* (2002) define traceability as an ability to track the current or historical movement of goods within the supply chain. In addition, SCT comprises different types of SCT mechanisms that are deployed to achieve visibility and traceability. Monitoring, tracking & tracing and proofing provenance in supply chains are types of such mechanisms. They enable organizations to gather and process information in supply chains. The variety of different SCT mechanisms illustrates the multi-facetted nature of the phenomenon SCT. In line with this nature of SCT, Morgan *et al.* (2018) developed a definition of SCT based on the contributions of Carter and Easton (2011) and Carter and Rogers (2008). "SCT involves reporting to and communicating with key stakeholders to provide traceability regarding the history of the product and visibility about current activities throughout the supply chain while also incorporating stakeholder feedback for supply chain improvement" (Morgan *et al.*, 2018, p. 960).

With the emergence of sustainable supply chains, SCT moved into the spotlight. As contemporary speed of communication reveals issues in a timely manner and to a large audience, firms benefit more from reporting and engaging actively with stakeholders (Carter and Rogers, 2008). This demonstrates that enhancing transparency on the origin of products is gaining in importance (Egels-Zandén and Hansson, 2016). By providing a proof of provenance of their products as well as their components, firms seek to identify risks associated with a product's origin or the involvement of specific parties within the supply chain (Maloni and Brown, 2006). Furthermore, when looking at the diamond industry, the case of the Czech National Museum demonstrates that fake diamonds are still present in the supply chain (Malm, 2018). Moreover, the end customers are likely to be laypersons. Thus, they have little expertise to assess the originality and quality of a diamond without the help of experts. A proof of provenance enables them to combat these challenges in two ways. First, a proof of provenance discloses the geographical origin of the diamond and indicates if stones are mined in conflict areas or under unethical work conditions (Cartier *et al.*, 2018). Second, a proof of provenance provides an evidence of the originality for buyers (Saberi *et al.*, 2018). However, despite technological advancement in geochemical, isotopic or spectroscopic methods, the identification of a diamond's origin is still limited (Cartier *et al.*, 2018) and so the industry turns towards establishing a chain of custody and certificates such as the Kimberley Process Certification Scheme (Responsible Jewellery Council, 2017). Thereby, the diamond industry follows a similar approach to other industries such as food (Maloni and Brown, 2006) or textile (Egels-Zandén and Hansson, 2016) that deploy paper-based certificates and labels. Yet, the solutions in the diamond industry are vulnerable to manipulations as the paper-based certificates can be forged. At the same time, paper-based processes enable only little visibility into the chain of custody, as documents and certificates are only in possession of a single actor in the supply chain. This gives rise to financial fraud in the industry as the verification of associated trade documents remains difficult (Linde *et al.*, 2018). However, paper-based trade documents still dominate global trade, even outside of the diamond supply chain (Casey and Wong, 2017). With digitization and the emergence of DLT, the ability to have a secure and timely exchange of trade documents caught the attention of numerous supply chain actors (Blossey *et al.*, 2019). IT is then deployed to reduce the lack of transparency and thereby mitigate the risk of manipulations of trade documents (Ivanov *et al.*, 2019).

Extant literature views IT usage in general as a helpful way to make upstream processes visible to downstream buyers. This includes the visibility of information on the scope and quality of processes. Therefore, buyers use monitoring as a SCT mechanism to gain visibility into external processes. Buying firms apply IT such as RFID systems to monitor external processes and their adherence to contractual agreements such as temperature in the food industry (Abad *et al.*, 2009). Aung and Chang (2014), for instance, developed an IT system for food traceability that allows buying companies to monitor suppliers' adherence to food processing standards and quality of production processes. More recently, scholars have identified the importance of IT to enhance SCT (Zhu *et al.*, 2018). Aside from established IT systems such as Electronic Data Interchange, the emergence of DLT raises high hopes to enhance SCT. The novel technology is praised for the immutability of data within the ledger which ensures a high level of data security (Nærland *et al.*, 2017). In addition, the technology is characterized by high availability of data guaranteed by decentralization (Beck *et al.*, 2016). Moreover, frictionless information distribution within the network enhances the level of data transparency (Beck and Müller-Bloch, 2017). Data security and transparency equip the technology to be applicable in the field with a low level of trust between transaction partners (Beck *et al.*, 2016). Consequently, the call for applying DLT in supply chains enjoys growing popularity among practitioners (Casey and Wong, 2017) and academics (Rao *et al.*, 2017). The technology is seen to improve SCT as it distributes and discloses information to all participating organizations within a DLT network. The immutability and high security of the technology allows to establish a single source of truth. Thus, managers and academic scholars alike see DLT as a technology that enables major improvement for SCT (Wang *et al.*, 2018). Wang *et al.* (2019) identify that twelve out of 14 experts see DLT as option to provide improved visibility and traceability in supply chains. However, there study reveals as well, that the majority of experts see substantial challenges for DLT in issues of collaboration, information sharing, interoperability as well as data (Wang *et al.*, 2019). Despite these challenges, numerous initiatives have started to introduce DLT to enhance SCT (Blossey *et al.*, 2019). Start-ups such as Provenance.org and Everledger.io have implemented several pilots to establish a DLT-based proof of provenance, allowing supply chain actors and end customers to trace back the origin of a product. In addition, established companies within supply chains such as Maersk or Walmart have joined forces with IT specialist IBM to set up a platform to digitize and exchange trade documents. While all of these initiatives aim at providing enhanced SCT with the use of DLT, these represent the main types of functionalities that can be found in practice. Namely, they are initiatives that enable a DLT-based proof of provenance and a DLT-based trade document registry.

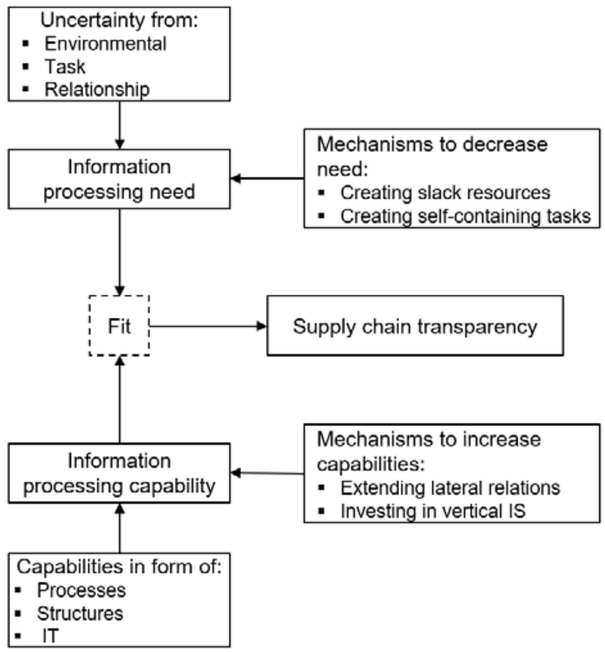
While several contributions have discussed these initiatives, the actual value of DLT for SCM and in particular for SCT and the key to overcome these challenges have not been empirically examined as of yet. Early contributions built on a conceptual approach without empirical evidence due to the novelty of the technology and so, two important aspects remain understudied. First, the adoption of the technology lacks empirical insights to guide practitioners in the technology adoption and associated decisions. Saberi *et al.* (2018) were one of the firsts to identify barriers for DLT adoption in sustainable supply chains, even though the study lacks empirical grounding. The second aspect is the value of DLT for SCM and the related phenomena such as SCT. While extant literature revealed substantial potentials, however, only a limited number of studies build their argumentation on proof of concepts (e.g. Beck and Müller-Bloch, 2017) or even pilot projects (e.g. Baruffaldi and Sternberg, 2018). Thus, more empirically grounded research is needed to guide practitioners for approaching DLT to enhance SCT. With the focus on DLT-enhanced SCT solutions, the most common application in nowadays supply chains (Wang *et al.*, 2019), the need is even larger as SCT in general is still understudied in supply chain management research (Wieland *et al.*, 2016). Nowadays, IT is gaining in importance as it supports SCT mechanisms to process information. For SCT, this processing of information is crucial, as it does not only entail the processing of information internally but also across organizations' boundaries. When analyzing the potential and challenges of novel ITs such as DLT, it is necessary to study the processing of information of these technologies. Therefore, we draw on IPT to study the information processing of DLT-enhanced SCT solutions.

Linking information processing theory to supply chain transparency

Galbraith (1974) introduced IPT, which is comprised of three key elements. These are the information processing need (IPN), the information processing capability (IPC) and the fit between both (Galbraith, 1974). As organizations are exposed to uncertainties that stem from their environment, their tasks and relationships, they have the need to process information in order to cope with uncertainty (Tushman and Nadler, 1978). Environment uncertainty are market and industry specific characteristics that arise from external factors that a company can't control (Premkumar *et al.*, 2005). Task uncertainty is related to the specific task an organization or department carries out while relationship uncertainty reflects the uncertainty that arises from the collaboration with external organizations or other internal departments that often have different goals and interests (Tushman and Nadler, 1978). In order to fulfill the need to process information, IPC in the form of processes, structures or IT are required (Bensaou and Venkatraman, 1995). Following IPT, organizations have to create a fit between IPN and IPC to cope with uncertainty and thus achieve improved performance (Tushman and Nadler, 1978). According to Galbraith (1974), organizations have two options to create the fit between IPN and IPC. They can deploy mechanisms to decrease the IPN such as creating slack or they deploy mechanisms that increase the IPC. Organizations select the mechanisms that are most effective in their setting to achieve the fit (Galbraith, 1974). While early scholars used IPT to study the design of organizations, Premkumar *et al.* (2005) expanded the scope of IPT to interorganizational studies. With their taxonomy, the authors demonstrated an approach to structure IPN and IPC in an interorganizational setting. Yet their focus is still the IPN and IPC of an individual organization. Moreover, Foerstl *et al.* (2018) study uncertainties in sustainable supply management and reveal that the fit between IPN and IPC depends upon the sustainability-related uncertainties that trigger the need. In their study, they use the buying firm as the unit of analysis, thus focusing on an individual organization again. While the mentioned studies observe supply chains, they all focus on a single organization within the supply chain. They disregard the interaction of supply chain partners and its impact on information processing within supply chains. However, SCT depends on the interaction of multiple supply chain partners (Carter and Rogers, 2008). Thus, SCT calls for information processing beyond the boundary of organizations within the supply chain (Zhu *et al.*, 2018).

Despite literatures' focus on individual organizations, IPT is well suited to be applied as a theoretical lens for SCT. Following IPT, a lack of transparency can cause uncertainty (Williams *et al.*, 2013). Thus, the IPN constitutes a need to process information in order to reduce the lack of transparency that causes the uncertainty. If mechanisms to reduce the IPN are costly such as creating slack (e.g. inventory) to deal with demand uncertainty, organizations decide to achieve the fit between IPN and IPC by deploying mechanisms to increase their IPC. Thus, they seek to enhance SCT by improving their IPC. SCT mechanisms are forms of extending lateral relations and investing in vertical information systems (IS). Figure 1 illustrates this positioning of SCT in IPT.

Figure 1: Positioning supply chain transparency in information processing theory



By this, SCT is a state that is reached by enhanced information processing which leads to improved supply chain performance. With their study, Williams *et al.* (2013) complement this notion. The authors apply IPT to model SCT by demand, supply and market visibility and operationalize performance by responsiveness. Their study reveals that internal integration is moderating the effect of SCT on responsiveness. This study demonstrates that SCT is not the sole cause for improved performance, which is taken into account in this paper. Drawing on IPT, Srinivasan and Swink (2015) explore that both demand and supply visibility are required for the development of analytics capability in an organization. Therefore, they put analytics capability in the focus. SCT is seen as a prerequisite for analytics capability. However, the authors confirm the positive effect of increased IPC for operational performance. Zhu *et al.* (2018) view analytics capabilities as enablers for SCT. The authors reveal that analytics capabilities have a positive effect on SCT. In our study, we combine the insights of Srinivasan and Swink (2015) and Zhu *et al.* (2018) and view SCT as an output of IPC and state that information is needed to fuel IPC, thus requiring visibility.

METHODOLOGY

Study design

The aim of this study is to contribute in three ways. First to help understanding DLT-enhanced SCT solutions. Second, to shed light into the drivers to deploy these solutions. Third, exploring the required capabilities to process information in these DLT-enhanced SCT solutions. Therefore, we chose to apply an inductive multiple case study design according to Yin (2017). We selected an inductive case study approach to generate mid-range theory from empirical data in the sense of Ketokivi and Choi (2014). As our research questions require an in-depth understanding of the studied phenomenon, case study research is well-suited to address these questions in detail (Ketokivi and Choi, 2014). Furthermore, the novelty of DLT use in general and specifically in SCM (Nærland *et al.*, 2017) and therewith the small number of observable units, call for a qualitative approach such as case study research (Eisenhardt, 1989). Alongside the study design, we drew on the seminal work of Galbraith (1974) and Premkumar *et al.* (2005) on IPT as our theoretical lens. The unit of analysis is the capability needed to process information in DLT-enhanced SCT solutions. Due to the variety of different DLT applications to enhance SCT (Blossey *et al.*, 2019), we decided to study the two major types that we have illustrated in sub-section “Transparency in physical supply chains”. Following this, our case study design is a multiple case design as illustrated in Table 1. The units of observation were five DLT pilots in the diamond industry that presented early pioneer implementations of the technology (Cartier *et al.*, 2018). We conducted fifteen semi-structured interviews of these five different DLT pilots over the timespan of 15 months. This period allowed us to analyze the drivers for DLT use, the needed IPCs and how firms can build these IPCs. The interviews lasted between 60 minutes to four hours. The interviews were conducted in English and German with interviewees in different positions such as CEOs, managing directors, heads of development and project managers. Furthermore, we conducted interviews with multiple organizations in the pilot to gather data from multiple angles. This included interviews with the technology providers, which developed the DLT solution or that developed identifying mechanisms. In addition, we conducted interviews with the user of these solutions as well as the initiators (in some cases they are at the same time the users). The interviews were conducted on site, Skype or via phone. Subsequently, we transcribed the interviews and sent the interviewees a copy for review to ensure correctness.

For our investigation we developed a conceptual framework as illustrated in Figure 1, drawing on IPT by Premkumar *et al.* (2005). The focus of our investigation was to uncover two aspects. First, we covered all four elements of IPT including IPN, IPC, the fit between both and the resulting improvement of SCT with our questions (see appendix) to gain an in depth understanding. Second, we paid special attention to the uncertainties and the IPC in the studied DLT pilots. These aspects were taken into account during case selection and data collection.

Case selection and sampling

For our study design, we sought to study multiple cases of DLT applications that aimed at providing more SCT by processing information with the use of DLT. We chose to select cases from only one industry in order to reach homogeneity of the objects under study. In particular, this is due the reason that different industries face different types of uncertainties (Zhu *et al.*, 2018). Following IPT, these would trigger different types of IPNs (Foerstl *et al.*, 2018) and would make it difficult to analyze the cases on a cross-case analysis. The diamond industry represented one of the first industries to implement multiple DLT pilots at this early stage (Cartier, Ali and Krzemnicki, 2018). After numerous fraudulent incidents (e.g. Malm, 2018; Subramanian, 2018) the processing of information along the supply chain (e.g. product’s origin) was gaining more importance in the diamond industry. Consequently, we defined the improvement of SCT in the diamond industry by the usage of DLT as the first selection criteria. As a second selection criteria, the DLT applications needed to represent a valid unit of observation according to Wüst and Gervais (2017) in order to avoid observing pointless uses of DLT. Furthermore, we decided to study only pilot implementations of DLT in the diamond industry to be able to observe perceived improvements of SCT, which constituted our third selection criteria. Following Eisenhardt (1989) and Seawright and Gerring (2008), our case selection followed a two-step sampling approach. In the first step, we selected cases within the diamond industry as well as with the same goal, namely to enhance SCT by the usage of DLT. In addition, all cases were initiated from experienced actors within the diamond supply chain that possess an in-depth understanding of the industry but were also characterized by an openness to adopt DLT as a novel technology in the field. By this, we established a homogenous base for our case study. In the second step, we selected cases from the initiating companies differing in mining and trade volume (big = 10 carat, medium = 5 to 10 carat or small = less than 5 carat) and in value steps within the diamond supply chain. Selecting cases from different volumes and value steps allows to include different perspectives form different market players. While companies with larger volume have a dominant market position in the diamond industry, smaller companies face different challenges. In addition, different value steps enabled to combine perspectives of mining companies, cutter and polisher as well as auditors. Our case study selection allows to uncover multiple factettes from different angles. This ensured a fuller picture of the entire supply chain and avoided making observations from a single perspective. Thereby, we were able to fulfill both objectives emphasized by Seawright and Gerring (2008). “(1) a representative sample and (2) useful variation on the dimensions of theoretical interest” (Seawright and Gerring, 2008, p. 296). Table 1 gives an overview of the five cases under study.

Table 1: Case overview

ID	**Type of functionalities**		**Interviewed organization**	**Interview partners**	**No. of interviews**
	DLT-based proof of provenance	**DLT-based trade document registry**			
1	x		Gemmology lab, technology provider	CEO; Managing Director; Head of R&D; Gemmologist Head of Sustainability	5
2	x	x	Mining company, technology provider	CEO; Business developer; Director of Communication	3
3	x		Mining company, technology provider	CEO; Communication Manager, Software developer	3
4		x	Industry interest group	Project Manager	2
5	x		Cutter, technology provider	CEO; Vice President & Head of Sustainability	2
Sum	4	2			12

Data collection

For the purpose of data collection, we designed a semi-structured interview protocol following Yin (2017). In the protocol, we defined our research questions (section “Introduction”) and theoretical framework (Figure 1), the data collection procedures, the questions we addressed in the interviews and a guide for the study report. Before collecting data, we applied the three defined selection criteria and followed our sampling approach. Therefore, we conducted desk research and combed press releases, blogs, webpages and industry magazines. Afterwards, we contacted the selected case organizations by sending out a brief description of our research project to the organizations. When the organizations agreed to be participants in our research project, we arranged an appointment for a first onsite interview or a Skype/telephone interview. We made sure to interview people that were not only involved in the pilots but also had different tasks within the pilot project to be able to both gather in-depth data and receive responses from multiple perspectives. Before conducting the interviews, we did a comprehensive research on the diamond industry, and on all pilots and involved organizations. Thereby, we collected data from websites, newspapers, conferences, and industry reports that we used both for preparation in beforehand and for data triangulation subsequently to the interviews. Afterwards, we conducted the interviews. When allowed, we recorded them electronically and made notes. When we were not able to make verbatim records, we took comprehensive notes. The records were transcribed and sent out to the interviewees for review.

Data analysis

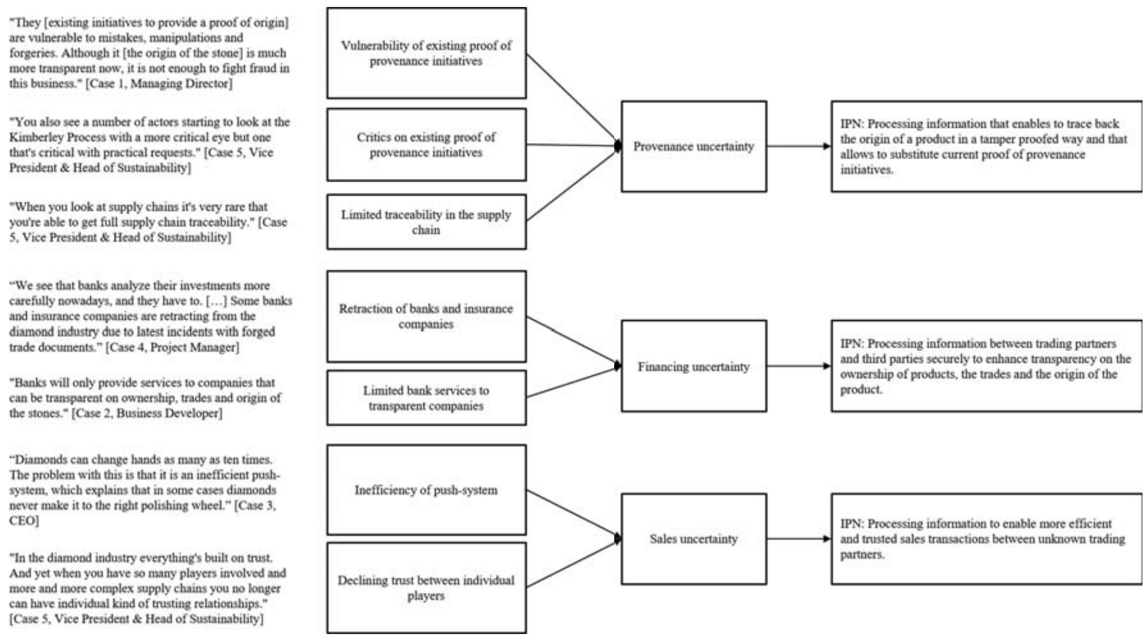
As reviewed above, the extant literature illustrates only few insights into the processing of information for gaining SCT with DLT. Thus, we applied an inductive approach (Eisenhardt, 1989). In line with Mantere and Ketokivi (2013) this approach enabled our inductive reasoning on a three-step journey. First, it helped us to understand the phenomenon of DLT-enhanced SCT in the diamond industry. Second, it allowed us to explain why and how DLT solutions were applied in the diamond supply chain to enhance SCT. Third, it enabled us to develop propositions to guide practitioners when seeking to apply DLT solutions to enhance SCT.
In line with grounded theory following Corbin and Strauss (1990), our data analysis included four steps. First, we conducted in vivo coding on all our transcripts and notes. This supported a deeper understanding and allowed us to identify emerging topics in our data. Herein we followed the approach of Gioia *et al.* (2013) that uses practitioners wording for the first codes with "informant-centric terms" (Gioia *et al.*, 2013, p. 18). As a second step, we created open codes based on our initial codes. With the support of the collected data and the data from additional sources, we were able to contextualize the emerging findings (Gioia *et al.*, 2013). Third, we consolidated the open codes into focused codes by inductive reasoning (Mantere and Ketokivi, 2013). In the following section, we present interview quotes and the corresponding focus codes. Finally, we identified the links of our focused codes to our theoretical framework and reduced the data in our focused codes (FC) that were not related to our framework.

RESULTS

The uncertainties that require more supply chain transparency

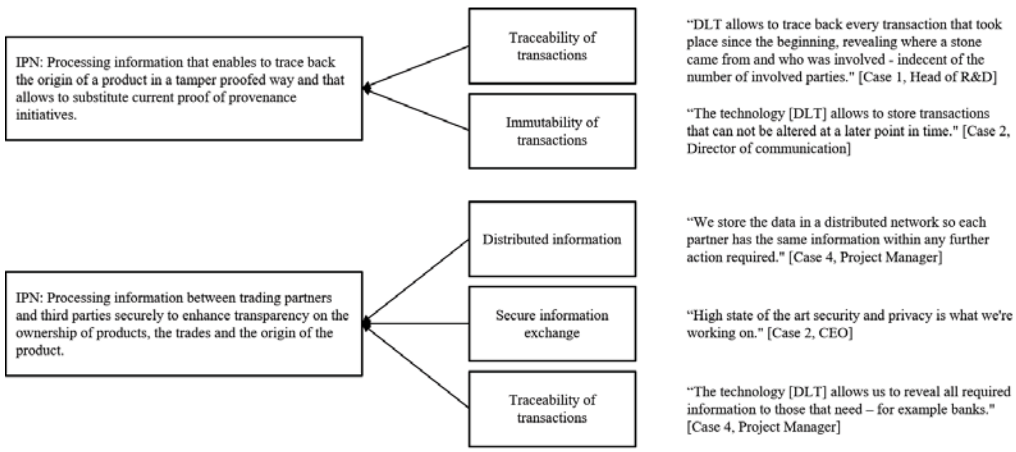
By revisiting the challenges of the diamond and gemstone supply chain from the introduction section, we go on to present the industry briefly and thereby derive the inherent uncertainties that bring to light the IPNs. Along a diamond's journey to the end customer it passes multiple actors from mining productions, to cutting and polishing on to jewelry manufacturing and retail sales (Linde *et al.*, 2018). Especially the gemstone industry is characterized by a large number of small mining facilities in rural and isolated areas. These are the four stages before a diamond or gemstone is sold to the end customer. However, the number of involved parties is much higher. Stones are typically traded multiple times before they make it to the next stage. In addition, these trades require substantial financing. Thus, banks and insurance companies are involved as well. Furthermore, from mine to ring, the stones travel thousands of kilometers, crossing a number of borders and with that require the involvement of customs authorities and additional third parties. With this increasing complexity, the supply chain lacks in transparency that result in incidents such as illustrated in the introduction. This lack of transparency causes uncertainties that characterize the diamond supply chain. Derived from our data, we identified three types of uncertainties: Provenance, financing and sales uncertainties. They create the need to process information between actors within the diamond supply chain. Consequently, these uncertainties result in IPNs, which we illustrate in Figure 2. While on the left side, we present selected statements form interviewees, we condense these to first level codes following the approach of Gioia *et al.* (2013). Based on these codes, we have identified the three types of uncertainties that drive organizations to process information.

Figure 2: Uncertainties that cause IPNs



Facing these IPNs, the initiating companies were attracted to the emerging technology DLT and its promise. As illustrated in Figure 3 the novel technology entails several characteristics that can be beneficial to process information within the diamond industry. These are illustrated in middle and are linked to the corresponding IPNs (on the left side). In summary, the technology enables to build DLT-enhanced SCT solutions that enable improved traceability while establishing a high level of security and immutability, which leads to increased trust, in an industry that is built on trust. Consequently, these initiating companies have developed DLT-enhanced SCT solutions that include two types of functionalities: DLT-enhanced proof of provenance and DLT-based trade document registry. Table 1 presents an allocation of these functionalities to the individual cases while sub-section "Transparency in physical supply chains" describes these functionalities.

Figure 3: IPNs and the corresponding DLT characteristics



Based on our analysis we made the following observation that addresses research question 1:

Observation 1: While organizations face uncertainties stemming from a lack of transparency, they initiate DLT-enhanced SCT solutions to increase transparency and rebuild trust within the supply chain.

The required IPCs in DLT-enhanced SCT solutions

In order to adopt and integrate these DLT-enhanced SCT solutions with their respective functionalities and thus process information successfully to cope with the uncertainties, organizations need to establish specific IPCs in form of processes, infrastructure and IT. These IPCs depend on the specific functionalities. In the following, we present the required IPCs by each functionality and link them to the IPNs.

<u>DLT-based proof of provenance</u>

In order for this functionality to enhance gapless product traceability and provide a proof of provenance, all involved actors have to provide information on their actions related to a specific diamond. Therefore, this functionality requires a wide range of IPCs illustrated in Table 2 from all involved actors. In order to match the IPN to trace back a products origin in a tamper proofed way, all organizations have to establish processes that they view as trusted for data entry and establish joint standards. Only by this, a gapless and trusted traceability can be achieved. Both capabilities are on an interorganizational level, as they require the joint agreement and adherence to these processes. Internally, the actors have to ensure adequate processes that enable this adherence and required infrastructure as well as IT that is necessary for processing the required information. A DLT-based proof of provenance requires to identify a diamond or gemstone in order to enter data to the corresponding diamond. Although there are multiple solutions in place, especially smaller actors may not have the required infrastructure and IT and thus have limited experience in processing the required information. Especially novel and more advanced procedures such as tagging and identifying diamonds and gemstones with nanoparticles that include DNA, are new to most of the actors in the gemstone and diamond industry. Hence, it requires to advanced technical capabilities. However, especially in the gemstone industry that includes a great number of small mining facilities, such advanced procedures will only be applied in a couple of years. Thus, it requires alternative procedures that enable to identify the stones more easily but still securely. Therefore, the involved actors have to establish common processes and standards to enable the integration of this solution for every player in the supply chain, no matter how advanced their technological capability is.

Table 2: IPCs for a DLT-based proof of provenance

IPCs	Cluster	Range	Cases
Capability to establish a process for data entry in DLT-solution that the entire supply chain accepts as trusted	Process	Interorganizational	1, 2, 5
Capability to comply (technologically) with required data standards and formats	Process	Interorganizational	1, 2, 3, 5
Capability to change established work process and incorporate data entry process for DLT-solution	Process	Organizational	1, 2, 3, 5
Expertise of employees to enable correct and timely data entry	Process	Organizational	1, 2, 3, 5
Technological expertise to handle instruments to read out identifiers of diamonds (e.g. nanoparticles)	Infrastructure	Organizational	1, 3, 5
Access to stable and secure internet for secure data entry	IT	Organizational	1, 2, 3

<u>DLT-based trade document registry</u>

In line with the previous functionality, a DLT-based trade document registry requires an interorganizational agreement on data entry and data standards in order to enable a solution that can be used by all parties. Within an organization, substantial change management capabilities have to be developed. As one interviewee stated:

> *“Well the diamond industry is still a 500 plus year old industry that has been based primarily on direct trading behaviors. But even as more people came to the industry and it didn't necessarily become more sophisticated.“* Vice President & Head of Sustainability

A DLT-based trade document registry addresses the IPN to process information securely, mostly in form of documents, between trading partners and banks. This processing of information across organizational boundaries is substantially changed, requiring all parties to buy in and comply with newly established processes. The functionality also requires the capability to enter and transfer the required information securely. A capability that all supply chain actors have to build up on their own but that is crucial for the entire supply chain.

Table 3: IPCs for a DLT-based trade document registry

IPCs	Cluster	Range	Cases
Capability to establish secure data entry process that is verified by all involved parties	Process	Interorganizational	2, 4
Capability to comply (technologically) with required data standards and formats	Process	Interorganizational	2, 4

Change management to enable the transfer from paper-based processes to DLT-based	Process	Organizational	2, 4
Expertise to enable secure data entry in DLT platform	IT	Organizational	2, 4

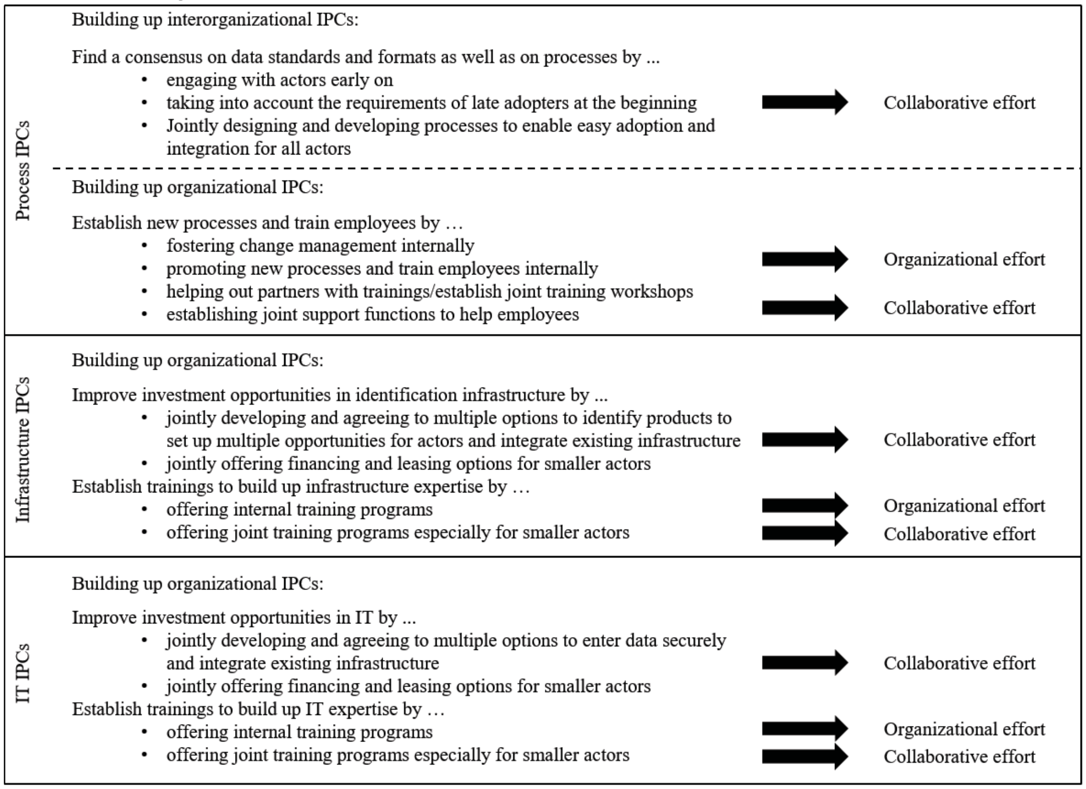
Observation 2: Adopting and integrating DLT-enhanced SCT solutions are joint initiatives that require interorganizational and organizational IPCs in form of processes, infrastructure and IT.

Existing literature (e.g. Zhu *et al.*, 2018) has focused on organizational IPCs, leaving interorganizational IPCs in the shadow. Drawing on the latest contributions of DLT in SCM, it becomes more obvious that DLTs are interorganizational solutions to process information between multiple organizations (Wang *et al.*, 2019). Hence, interorganizational IPCs are required.

Building up the required IPCs

In addition to identifying these IPCs, we have also interrogated the interviewees how they addressed these IPCs or how they will address them in the future. By this, we engaged in a vital dialogue that did also include reflections of interviewees and outlooks. In Figure 4 we summarized the insights from our case studies that reveals how organizations can build up the required IPCs to use and integrate DLT-enhanced SCT solutions. Our analysis reveals that interorganizational IPCs require a collaborative effort in order to build up these capabilities. E.g. this is the case for jointly establishing and agreeing to data standards and formats for data entry in the DLT-enhanced SCT solution. This also included to establish joined trainings and workshops that enable to share the experience and establish joint standards e.g. for the identification of stones and the uploading of data in the blockchain. This is especially crucial for smaller supply chain actors as in the gemstone industry. Bigger actors, associations and technical solution provider helped smaller actors with on-site trainings. Organizational IPCs, representing these IPCs that have to be built up by each party individually. They require the effort of each organization. This includes measurements to build up process, infrastructure and IT IPCs. However, our interview data disclosed that individual organizations should not be left alone with this task. This is especially crucial when the supply chain entails smaller actors that may not have the expertise or financial power to adopt and integrate these DLT-enhanced SCT solutions due to the required IPCs. Therefore, a collaborative effort can help them to build up the needed IPCs in form of processes, infrastructure and IT. Joint training programs, financial help for investments in infrastructure and IT as well as support functions are collaborative measurements that can help smaller actors to build up IPCs and therefore reduce the corresponding challenges. Especially in the gemstone industry, smaller players need the support of other supply chain partners to be able to adopt and integrate such DLT solutions. In some cases, the initiating firms have set up training programs online and onsite to build up the needed capabilities for tagging stones after mining.

Figure 4: Measures to build up process, infrastructure and IT IPCs



When analyzing how organizations can build up the required IPCs, we identified two additional observations that addresses research question 3.

Observation 3: DLT-enhanced SCT solutions require organizational effort but also collaborative effort to build up the required IPCs.

Observation 4: As DLT-enhanced SCT solutions require the adoption and integration of various actors within the supply chains, collaborative efforts can be adequate to help smaller organizations to build up the required IPCs.

Following IPT, DLT-enhanced SCT solutions are mechanism to increase information processing and constitute forms of extending lateral relations and investments in vertical IT.

DISCUSSION AND CONCLUSIONS

With our study, we contributed to practice in three ways. First, we have identified the uncertainties that drive organizations to process information via DLT-enhanced SCT solutions, a discussed phenomenon in the entire field of SCM. We did this by applying a case study approach in the diamond industry, an industry that has proven to be an early adopter of DLT in the field of SCM. Second, we have identified the IPCs that are required to process information via DLT-enhanced SCT solution and revealed that these IPCs are on an organizational but also

on an interorganizational level. Third, we have illustrated how organizations can build up the these IPCs. We have identified that both organizational as well as collaborative effort is needed, to adopt and integrate DLT-enhanced SCT solutions, as they require the adoption and integration of a variety of different supply chain actors. As our study was limited to the diamond and gemstone industry, these findings should lead to further research in other industries. This study reveals important learning for other industries that are characterized by similar structures with heterogenous actors along the supply chain with, strong variation of sales volumes, diverse technical and IT capabilities as well as infrastructure such as the food industry. As enhancing SCT involves processing information over multiple organizational boundaries, the findings are especially in the heterogenous setting important. They emphasize that DLT is not a intrafirm project but rather a interorganizational project, involving diverse actors that may need the help of other supply chain actors to master the onboarding challenges.
With our paper, we also contribute to theory by allocating the phenomenon of SCT in IPT. We identified DLT-enhanced SCT solutions as a form of investment in vertical IT to increase IPC and thus cope with uncertainty. While IPT was applied in the first contributions of SCT (e.g. Williams *et al.*, 2013), we extended IPT literature as we demonstrated that IPCs are to be found on an organizational and on an interorganizational level. Although several scholars have applied IPT in interorganizational settings (e.g. Zhu *et al.*, 2018), our contribution is the first to showcase interorganizational IPCs. Especially the collaboration to enable the adoption and integration of smaller supply chain actors illustrates how vital interorganizational IPCs are for DLT solutions. Extant literature has both dealt with adoption of interorganizational IS and IPT, yet literature has focused on the organization to study adoption and information processing. Our contribution emphasizes the need for collaboration to adopt, integrate and especially use DLT solutions. A finding that neither adoption literature nor IPT literature has taken into account up to now. Future research should address this gap and study the connection of collaboration and technology adoption as well as information processing.

Where to from here? Conceptualizing operating strategies for platforms and business ecosystems in smart manufacturing

Sabine Baumann
Jade University of Applied Sciences
Email: sabine.baumann@jade-hs.de

ABSTRACT

Smart manufacturing requires increasingly digitized production settings in order to achieve full flexibility of production environments to fulfil vastly individualized customer requests. Although future value-creation architectures will increasingly be designed and implemented through standardized technological platforms, the operating strategies for the necessary platforms and multi-industry business ecosystems are not yet well understood. This paper aims to mitigate these limitations by presenting the emerging research stream on platforms and business ecosystems. It illuminates the novelty and the usefulness of ecosystem-based approaches for production and operations management, to instigate a cumulative, interdisciplinary body of knowledge.

KEYWORDS: Industry 4.0, platforms, manufacturing industries, ecosystems, value creation networks

INTRODUCTION

Smart manufacturing or Industry 4.0 (I4.0) as it is known in Germany aims at fulfilling extremely individualized customer requests and moves away from predetermined supply chains towards highly flexible production environments. This flexibility challenges the role of the focal firm as coordinator and central decision maker in a production and supply network. Besides implementing the best real-time combination of actors for each individual order (Holweg & Helo, 2014, Stein et al., 2014) focal firms face managerial problems. The actors that contribute to the focal offer's value proposition increasingly operate via platforms and a growing number of complementary offers come from new partners outside the traditional industry settings (Gawer & Cusumano, 2014, Kapoor, 2018). These so-called business ecosystems bring their own set of rules and often ensuing loss of direct control for the focal firm over its production and supply network. In addition, the operating strategies for platforms and multi-industry business ecosystems are not well understood.

This paper aims to mitigate these limitations by presenting the emerging research stream on platforms and business ecosystems. It illuminates the novelty and the usefulness of ecosystem-based approaches for production and operations management in order to instigate a cumulative, interdisciplinary body of knowledge. The author investigates the key concepts in research on platforms and business ecosystems in strategic management and in operations and production management literature and their relationship with established perspectives of value chains and of production and supply networks. Grounded in this analysis the author derives elements and constructs for a cumulative concept for operations and production management on platforms and business ecosystems for I4.0 settings.

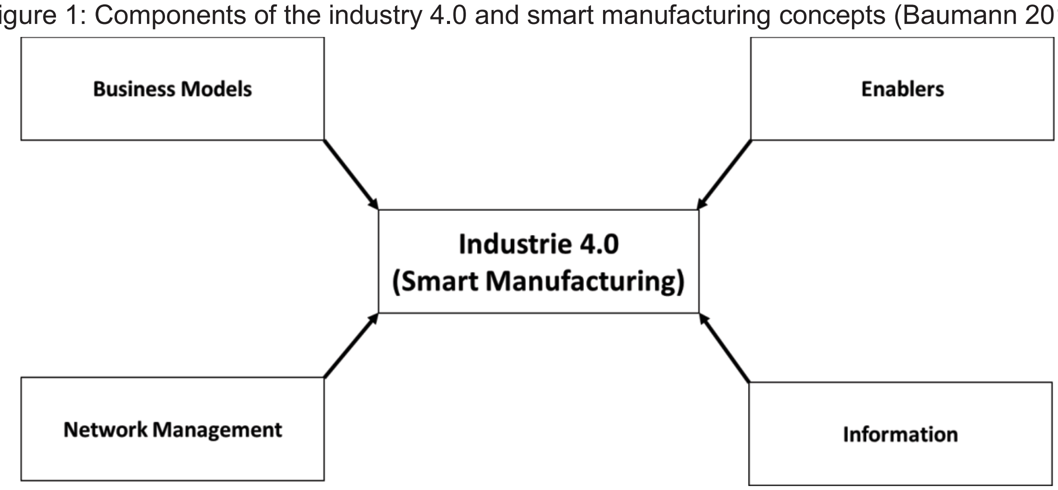
The paper is organized as follows: the first section provides a brief description of the I4.0 concept. The following method section presents information on the design and implementation of the literature review of operations and production management and strategic management research. The main part of the paper depicts the key concepts of the emerging research stream on platforms and business ecosystems and how they relate to established perspectives of value chains and of production and supply networks. Finally, the elements and constructs for a cumulative concept for operations and production management on platforms and business ecosystems are being derived for I4.0 settings. The paper closes with a conclusion and an outlook on future research.

LITERATURE REVIEW

The Concept of Smart manufacturing/Industry 4.0

The German government coined the term Industrie 4.0 (industry 4.0) in their High-Tech Strategy Action Plan 2020 that addresses the increasing global competition on product quality and production costs faced by the German manufacturing industry. Nevertheless, even before the launch German manufacturing companies had started to exploit emerging technologies such as digitalization, the internet of things (IoT), internet of services (IoS) or cyber-physical systems (CPS) in search of new digital business models.
Although the concept Industry 4.0 is now widely discussed, neither academia nor practice has arrived at a generally accepted definition of what the concept comprises in terms of the actual objectives, the relevant technologies, or the applicability for different industrial sectors. Following Baumann (2018) this paper defines industry 4.0 as a concept in which companies, machines, devices and computers cooperate through digital technologies in horizontal and vertical networks to manufacture highly-individualized products. By connecting plants, equipment, machines, products and workpieces through information and communication technologies (ICT) into cyber-physical systems these networks continuously share information in real-time" (p. 2). The term smart manufacturing will be used interchangeably with I4.0 in this paper as it expresses the same ideas.
The I4.0 concept can be captured into four components: business models, enablers, information, and network management (see figure 1), which are briefly explained (see Baumann 2018 and the literature mentioned there for a more detailed description).

Figure 1: Components of the industry 4.0 and smart manufacturing concepts (Baumann 2018)



Business Models
I4.0 business models either address cost reductions or capturing new business opportunities such as innovative products and services. The majority of new digital business models is based on data analytics, for example predictive maintenance. Extended models move to service offers where the customer pays for equipment use, but no longer buys the equipment. From a cost reduction perspective I4.0 increases production flexibility and adaptiveness, speeds up reaction times or improves overall effectiveness of manufacturing equipment.

Network Management
The best real-time combination of actors regarding objectives such as timing, cost, quality levels, etc. for each individual order can only be achieved through extended vertical, horizontal, and lateral collaborations. Actors face a trade-off between installing efficient production and supply networks for particular products while being flexible enough to be part of alternative networks for required product differentiations. Furthermore, the role of the focal firm as principal coordinator becomes increasingly decentralized in I4.0 settings (see also the discussion of business ecosystems below).

Enablers
I4.0 grounds in a variety of enablers, such as *Cyber-physical systems (CPS), Internet of Things (IoT), Internet of Services (IoS),* and *Smart factory. CPS* connect computation with physical processes, so in manufacturing CPS refers to monitoring and controlling the processes via computer networks (through the use of multiple sensors, actuators, control processing units, and communication devices) and synchronising information related to the shop floor. Manufacturing execution systems (MES) link enterprise resource planning (ERP), production planning and control (PPC), and the actual shop floor to integrate all network participants. Thus, MES allow the shop-floor to become a marketplace where the allocation of capacity is self-coordinated with multi-agent systems. In *IoT* settings (physical) things connect to the internet with the use of RFID tags, sensors, actuators, or small computers. These “smart things” interact with each other and cooperate with their neighbouring ‘smart’ components in order to reach common goals. *IoS* makes services available through web technologies or software as a service (SaaS) and allows companies and consumers to access to the resources and service functions of another party. The idea of the *Smart factory* proposes a decentralised production network comprised of human beings, machines and resources. Digital connectivity enables an automated and self-optimised production and delivery free of human interventions or the customary central steering entity. Advanced data analytics derived from the operations of these connected systems provides decision support to both machines and humans.

Information
I4.0 grounds in extensive data collection, (big) data analytics and the implementation of efficient decision support and data-based self-coordination systems. The processes within the information processing chain in I4.0 systems also need to be evaluated from the perspective of value added by these processes, i.e. a detailed analysis of their accompanying value architectures in order to compare value propositions of competing I4.0 solutions (Wunck & Baumann, 2017).

DESIGN/METHODOLOGY/APPROACH

A content-analysis-based literature review is being completed, in which an inductive and multi-level coding procedure is applied on >120 articles on platforms and business ecosystems, spanning the literature in production and operations management and strategic management. The following section shares the key tenets in research on platforms and business ecosystems in strategic management and in operations and production management literature and how they relate to established perspectives of value chains and of production and supply networks.

FINDINGS

Cooperation and Value Creation Scenarios

The cooperation of companies, machines, and computers through digital technologies is central to the provision of individualised products and services in I4.0 settings. These collaborations are realized by integrating technical and organisational processes into order-based value creation architectures that include all actors that contribute to the focal offer's user value proposition. Central elements of these value creation architectures are platforms and business ecosystems which are introduced in the following section.

Platforms

The concept of platforms is being discussed differently in economic (e.g., Rochet & Tirole, 2003 or Cennamo & Santalo, 2013) and engineering (e.g, Meyer et al., 1997 or Jiao, Simpson & Siddique, 2007) research. Economics investigates transactions on platform markets between different customer groups as well as the influence of network effects on competition. In contrast, engineering research regards platforms as technological designs that help firms generate modular product innovations (Brax et al., 2017; Gawer, 2014; Sköld & Karlsson, 2012). Engineers interpret platforms as technological architectures that have been specifically developed (including their interfaces) so that their components can be utilised systematically across different products of a product family. Design and usage of these platforms allow for economies of scope in product development and production. Consequently, implemented platforms bear permanent structures while changes occur for newly developed or redeveloped modules, in order to achieve economies of scope through platform-based product development (Gawer, 2014; Jiao, Simpson & Siddique, 2007; Sköld & Karlsson, 2012).
In economic models platform competition is driven through the adoption of a platform through multiple user groups who themselves are being compelled through network effects. In the relevant literature network effects are distinguished into direct and indirect effects. Direct (or horizontal) network effects emerge through changes in the number of users of a platform (or a technology or a particular product): the higher the number of users, the higher the value for the users. Indirect (or vertical) network effects arise when the benefit of the platform (or technology or product) is not determined by the usage, but is determined by applications or complementary products that are based on or leveraged through the platform. Consequently, the influence on value is not determined by a direct relationship, but through a vertical network of interdependent complementary goods. It follows that it is not single products or components of the network that generate the value, but instead value is created through an inherent interdependency of the demand of two or more user groups. This mutual interdependency of two or more market sides in turn produces a self-supporting feedback loop (Hagiu & Wright, 2015; McIntyre & Srinivasan, 2017).
From the perspective of economic theory, value creation of platform relies on connecting user groups that would otherwise not be linked and could not transact with each other. The price settings of the platform operator coordinate these user groups. Developing the optimal price menu therefore is one of the central problems of platform management. Prices need to be set such that they motivate users from the relevant groups to participate and transact on the platform. Specifically, attracting an increasing number of users from multiple user groups

creates benefits for both the platform participants (increased value) and the platform operator (increased profits) because of the indirect network effects. This means that network effects are an essential attribute of platforms as they reflect the exogenous demand dependencies of different user groups and consequently shape platform competition. Thus, the economic perspective addresses the question under which conditions platforms could become dominant and or even drive out all other platforms in a „Winner-takes-all" rivalry (Eisenmann, Parker & van Alstyne, 2006; Rochet & Tirole, 2003).

<u>Business ecosystems</u>

Digitization not only provides data to develop new data-driven business models, but also requires collaborations with companies that have not been part of the traditional supply chain of an industry. Through these collaborations so-called Business Ecosystems emerge, i.e. company networks that link incumbents from different industries and on horizontal, vertical, and/or vertical level. Simply put a business ecosystem comprises the set of partners that contribute to the value promise of the focal firm (focal offer). The focal offer can consist of a product and/or service that has been created with or without a platform-based architecture. The biological term ecosystem conveys the mutual interdependency of the partners that together operate as a combined system. In addition the analogy suggests that the partners in a business ecosystem may well come from different industries and that the system persistently changes over time: partners compete with each other, new partners join and others leave the system, connections between ecosystem partners change (Kapoor, 2018).

Business ecosystem participants mutually influence each other because of simultaneously existing interdependencies and complementarities. Interdependencies between partners arise through the combination of their offers within the system architecture in the production of the final product and/or service. Opposed to that complementarities emerge because the combination of the partners' offers provides or increases value for the user/consumer. Economics investigates for how companies can survive competition in business ecosystems given these interdependencies and complementarities (e.g., Adner & Kapoor, 2010); Baldwin & Woodard, 2011); Hannah & Eisenhardt, 2017; Jacobides, Cennamo & Gawer, 2018 or Pierce, 2009).

The business ecosystems perspective differs from long-established concepts such as the value chain and the supply chain regarding focus and also the subject of investigation. Porter's value chain centers on the focal firm and investigates how the focal firm can derive competitive advantage in a specific market through organising its value creation activities to achieve cost leadership or differentiation (Porter, 1996). Supply chain research studies the efficient design and coordination of object flows (goods, information, values) along all stages of a supply chain through which a product is manufactured and then distributed to the final customers (MacCarthy et al., 2016). In particular, it investigates coordination problems in buyer-supplier-relationships along the entire supply chain (Pullman & Dillard, 2010). As the supply chain typically involves different companies, supply chain research consequently extends its emphasis beyond the focal firm. Compared to business ecosystems supply chain investigations do not consider complementarities of demand and the structure of interdependencies (Kapoor, 2018; Kapoor & Lee, 2013).

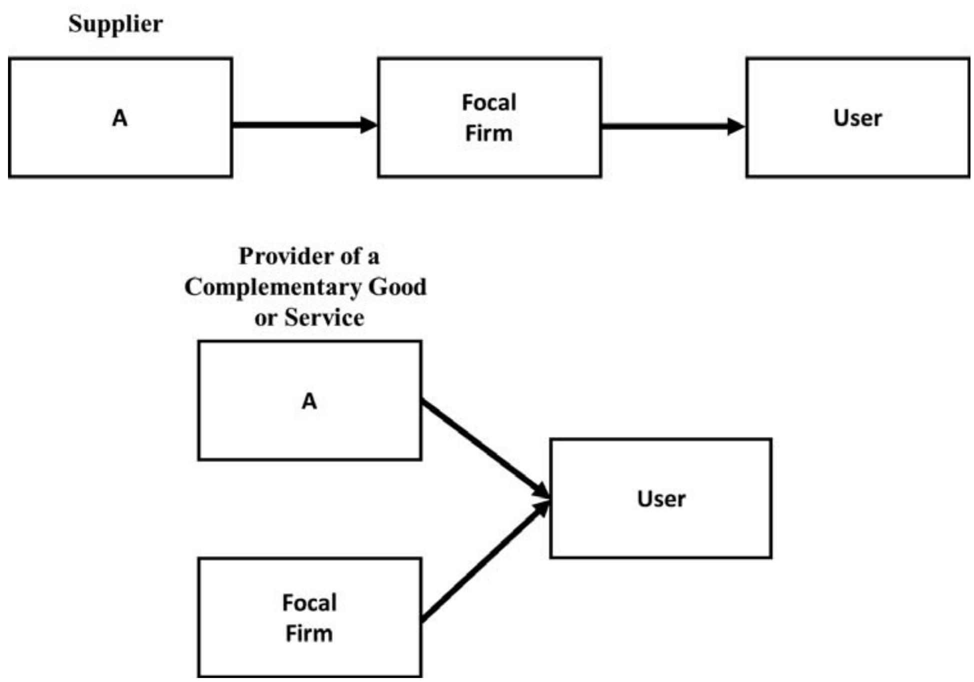
Management of value creation architectures in industry 4.0

The management of value creation architectures in I4.0 comes with a number of challenges. Particularly relevant are the integration of technological platforms, coordinating partners in business ecosystems with complementary offers and dealing with bottlenecks.

Bottlenecks
Bottlenecks can occur in any system that consists of more than one component. They limit the performance of the entire system (dominance of the minimum sector). Accordingly, partners in business ecosystems can constrain the performance and growth of the focal firm’s offer due to their output, capacities or incurred costs. Similarly, interactions between components can be determined through the technological architecture such that improvements in the performance of one partner reduce or balance weaknesses of another partner and vice versa. Identifying and dealing with bottlenecks that result from technological innovations or business models therefore is one of the central problems of business ecosystem management. Besides developing value creation architectures with reduced bottleneck effects business ecosystem management concerns resource allocations between and mutual support of business ecosystem partners in order to resolve bottleneck situations (Adner & Kapoor, 2016; Kapoor, 2018).

Partners with complementary products and services
Providers of complementary products and services (complements) are central to business ecosystems, because they increase the value of the focal firm’s offer (e.g., smartphone apps or infrastructure for charging electric vehicles). The function of the complements differs depending on how they contribute to the focal offer. A strict complementarity between two goods exists, if the goods have no usage value without each other (e.g. razor and blade). A super-modular complementarity describes a relationship where an increase in complements (availability, performance) increases the value of the focal offer (e.g., smartphone and number of apps, or electric vehicles and charging stations). Furthermore, complements can be generic or specialised regarding the focal offer (Jacobides, Cennamo & Gawer, 2018).

Figure 2: Roles in business ecosystems: supplier vs. provider of complementary goods (based on Kapoor, 2018)



The interdependency between providers of complementary products and services at the market level differs from that between a focal firm and its suppliers in the context of a supply chain. The latter concerns a sequential supply-side interdependency determined by the focal firm who decides how the supplied product or service is integrated into the focal offer. In the case of a complementary product or service offer (at the market level) the users of the focal offer decide on the integration of complementary offers. Figure 2 visualises the difference.

Compared to managing traditional supplier relationships the focal firm faces much higher operational challenges in business ecosystems. Relationships with suppliers are typically steered via bilateral contract-based formal mechanisms that regulate amounts, timing, and prices of supplies. Opposed to that the relationship with providers of complements concerns establishing multi-lateral alignment of offers with all relevant partners in the business ecosystem. This alignment relationship is about ensuring successful joint value creation (e.g. standards of cooperation, roles in business models) and the consecutive value appropriation across the partners, including rules to resolve conflict. In addition, the function of the complementary offer (strict, super-modular) poses significant alignment challenges, in order for the focal firm's value promise to be actually realised (Kapoor, 2018).

Platforms

Many value creation architectures organise the offer of complementary products and services via a central platform architecture. It is important to note that the management of product-based and platform-based business ecosystems differs considerably. Platform-based ecosystems are being orchestrated by the platform owner, who designs the platform architecture and determines the rules of participation. As such the platform owner also decides on the alignment structures with providers of complementary goods and services. In contrast, the rules in product-based business ecosystems are being determined jointly by the product company and the providers of complements.

In platform-based ecosystems the owner also defines the interface of the platform architecture through which providers of complements can access the platform as well as any changes over time (e.g., enhanced platform generation). Since every platform has its own specific interfaces providers of complements have to invest for their participation. They also have to decide in how many platform they want to participate (single- vs. multi-homing). Multi-homing provides them with a higher number of market opportunities, but increases costs through the necessary product adaptations for each platform. From the platform operator's perspective increased multi-homing reduces the relative value of their platform compared to competitors (Eisenmann, Parker & van Alstyne, 2006; Kapoor, 2018).

Product-based business ecosystems contain a single-sided market transaction between the focal product firm and the user. Platform-based ecosystems, however, relate to two- or multi-sided markets, on which the platform company interacts with complement providers and users that influence each other's platform benefits through mutual network effects (Rochet & Tirole, 2006). This multi-sided market interaction is a critical aspect of the necessary alignment structure, because it has to be designed such that it reinforces the platform value proposition through adequate price setting and subsidies (Rochet & Tirole, 2006, Rochet & Tirole, 2003; Eisenmann, Parker & van Alstyne, 2011).

In the context of I4.0 companies are expected to be able to develop and provide highly individualised products and service as participants of a value creation architecture. Depending on the order requirements the value creation architecture is assembled from a set of possible actors (Baumann, 2018). That means the architectures typically differ for different orders. Ecosystem participants therefore have to take a number of strategic decisions. As focal firms they have to determine, for example, the structural design of the value creation architecture, the composition of the business ecosystem and which parts of the value creation they want to cover themselves (Kapoor, 2018; Pierce, 2009). Providers of complementary goods and services have different roles depending on whether they participate in product- or platform-based ecosystems. Their opportunities are limited by required technologies and necessary funds as well as their market position. Small and medium-sized enterprises (SME) in particular have to ensure that they are part of competitive value creation architectures, while competing successfully for orders in the business ecosystem. They face a trade-off between differentiation (unique selling proposition) and efficiency (e.g., cost minimisation, resource allocation). An increased degree of differentiation may allow for a higher share of value appropriation, but at the same time limits potential inclusion in a large number of value creation architectures. A higher standardisation improves connectivity, but with the danger of being easily replaceable (Baumann, Eulenstein & Wunck, 2017).

CONCLUSION

The purpose of this paper was to shed light on the evolution and current state of platform and business ecosystems concepts in the literature and to synthesize the strategic management and the operations and production management perspectives into a multifaceted view for I4.0 settings. The concepts were derived through a content-analysis-based literature review on platforms and business ecosystems, spanning literature in production and operations management and strategic management. It was found that the number of studies in operations and production literature on business ecosystems is still low, while strategic management research is more advanced in their discussions. However, the latter often lacks the application perspective which is offered by the dynamic I4.0 settings. Exploring the ecosystem perspective in different research fields therefore facilitates to explain firms' manufacturing and supply strategies and to evaluate outcomes in I4.0 settings through the lens of complementarities and interdependencies. By identifying and defining key elements and constructs the paper proposes a first draft for a platform and business ecosystem framework for extending future production and operations management research.

Collaborations of companies, machines, and computers through digital technologies are central elements of I4.0. This cooperation is implelented through so-called business ecosystems, i.e. sets of actors that contribute to the focal offer's user value proposition. The ecosystem perspective explicitly links supply-side and demand-side of focal offers and also considers contributions from multiple industries. It relates to traditional views of managing production and supply networks though investigating interdependencies between actors, because their offers are connected within a system-level architecture. In addition, it simultaneously considers complementarities between actors whose respective offers help to create or enhance the user value proposition. Consequently, interdependencies embody structural relationships between offers through their value contributions and the way changes in one offer affect the value contribution of other offers, whereas complementarities represent an economic value creation relationship between offers endorsed by the user.

Nevertheless, business ecosystems incur a number of operational challenges. For I4.0 settings the integration of technological platforms, coordinating partners in business ecosystems with complementary offers and dealing with bottlenecks are of particular relevance. These subjects must be tackled on the level of the value creation activities, the perspectives of the different actors and the structure of the business ecosystem. Therefore additional research both in the production and operations management and the strategic management fields is required on three levels: the focal offer (innovation, technology), the focal firm and the business ecosystem.

ABSTRACT

We model a network congestion management problem of an online-service-provider (OSP) that uses bandwidth throttling as a tool, and show that it is optimal for the OSP to throttle the demand whenever it reaches a threshold level and downgrade the service-speed by a fixed factor while the throttling is employed. Our numerical simulations suggest that it is always optimal for OSPs to induce negative (demand) growth rates during throttling to reduce unfavorable future demand. Moreover, our comparative statics analysis explains how OSPs should handle user demand with higher growth rates and volatility, and service networks that face higher demand fluctuations.

KEYWORDS: Server/Network congestion management, Bandwidth throttling, Stochastic optimal control.

1. INTRODUCTION

Demand for bandwidth exceeds the capacity of networks [Within the context of this paper, 'server' and 'network' can be treated as the same. Thus, we use these two words interchangeably throughout the paper.] during peak demand periods/points, sometimes leading to severe network congestion which generally triggers user backlash towards the online-service-providers (OSPs). For example, in June 2016, a large number of users (several hundred thousand) who were trying to watch the famous HBO drama *Game of Thrones* online, triggered network congestion resulting in more than 15,000 users being denied network access (Hecht 2016). Thereafter, HBO issued an apology and promised to avoid a repeat of the event. In another incident in 2017, due to a server crash at the Foxtel streaming service (an OSP in Australia), the users were again left without access to the same HBO drama series (The Guardian 2017). Foxtel issued the following statement:

"We are devastated that due to unprecedented demand, we are experiencing problems with our online services this evening. Obviously, this comes at a time when so many of our users are wanting to watch the first episode of Season 7 of Game of Thrones".

Users were not happy with Foxtel's network management and criticized the OSP's inability to prepare for the high demand. It is evident that Foxtel had no clear strategy to avoid service interruptions in this situation.

Network congestion usually occurs when a large number of users access the network at the same time or when some users consume a very large amount of network capacity, during busy periods such as peak usage times or planned network maintenance (AT&T.com 2018).

Bandwidth throttling is a commonly used intervention by most OSPs that involves an intentional reduction in bandwidth (speed) whenever network/server congestion occurs. Throttling helps OSPs to preserve the network resources by regulating the traffic that goes through their network, minimizing potential bandwidth congestion and server crashes. Such an intervention is necessary due to a limit on network resources, such as bandwidth capacity in terms of speed, number of servers, and volume of data transfer, etc.

Although the practice of bandwidth throttling has been considered somewhat controversial and unethical [A recent article by Stevens (2018) in the New York Times, reported that Verizon throttled the data connection for firefighters in California, when the firefighters were in the midst of a massive wildfire operation. The chief of the Santa Clara County Fire Department, Anthony Bowden, indicated that Verizon's bandwidth throttling interfered with the ability of the firefighters to function effectively in their operations. In the interest of public safety, the technology department at the Fire Department requested Verizon to remove throttling, however, Verizon recommended the department to switch to a different (more expensive) internet plan that would limit throttling. At a later time, Verizon announced a new plan for the first responders which has no restrictions and have priority access, at a discounted price (VOA.com 2018).] (Krämer et al. 2012, Kourandi et al. 2015, Easley et al. 2018), it is however widely used by most OSPs as a part of their congestion management policy (O'Donoghue 2014). In their defense, OSPs argue that throttling helps to maintain the service quality for all their users, instead of allowing a few users with disproportionately high usage, to negatively impact the experience of other users in a shared network. OSPs such as *Verizon* for cellular and broadband internet, *Spectrum* for broadband internet, *Xfinity* for digital cable TV and broadband internet etc., are known to employ bandwidth throttling policies and these are usually stated in their terms of service. For example, Verizon.com (2018) states on its website:

"On certain plans, we may prioritize your 4G LTE data behind other traffic. If the cell site you are connected to begins experiencing high demand during the duration of your session, your 4G LTE data speeds may be slower than the other traffic's. Once the demand on the site lessens, or if you connect to a different site not experiencing high demand, your speed will return to normal. Any such network management practices will be disclosed in the descriptions of impacted plans.".

Moreover, Spectrum.net (2018) assures its users of the benefits of its network congestion management policies as follows.

"We monitor our network at all times to ensure the highest quality service. During periods of congestion, we employ certain network management principles ('congestion management') to maintain quality of service for all users, rather than allowing a few users with disproportionately high usage to impact the experience of others. While times of congestion are rare, it's important to us that all of our users experience exceptional service at all times."

While server congestion management via bandwidth throttling has been widely used over the last decade in the industry, this topic has been largely neglected in the academic literature. To the best our knowledge, this is the first analytical study that aims at achieving an optimal throttling mechanism for server congestion management when user demand is stochastic.

We model a server congestion management problem as a stochastic (impulse) control problem. The demand of the OSP is modeled as a continuous stochastic—geometric Brownian—process. The OSP can momentarily use demand throttling (i.e., speed reduction) as a tool to regulate demand. This demand throttling procedure involves costs in both the fixed and proportional forms. Moreover, the dynamics of the demand during throttling is assumed to be different in order to capture the reactions from the users as they experience inferior delivery speeds during throttling; this change in demand dynamics is modeled using another stochastic process of which the growth rate is governed by the intensity of throttling. The cost of maintaining demand is assumed to be a quadratic function of the level of demand (i.e., convex and increasing). The objective of the OSP is to minimize the total expected discounted cost of maintaining, and throttling demand. Within this setting, we show that the optimal strategy is to throttle the demand whenever it reaches a threshold level and downgrade the speed by a fixed factor every time throttling is employed. In other words, we show that the optimal strategy is to follow a simple threshold level policy.

A dynamic programming approach is employed to solve our stochastic control problem. We first derive the Quasi-Variational Inequality (QVI) associated with this optimization problem. We then prove, using a verification theorem, that a solution of the QVI coincides with the optimal (minimal) cost of the original problem. While we can only numerically validate the existence and uniqueness of the proposed optimal throttling strategy, we also provide the conditions under which our proposed solution solves the QVI associated with the original problem.

Our numerical study reveals that OSPs should be more patient while applying throttling on user demand with higher growth rates and volatility, and the intensity of throttling for such demands should be higher. Moreover, we find that service networks that face higher demand fluctuations (or volatility) during throttling should be subjected to throttling with lower intensities but applied more frequently. Another finding of our work is that it is always optimal for OSPs to induce negative growth rates while throttling is in place. This result is interesting as OSPs exploit users' willingness to exit the server due to inferior service experience during throttling. Thus, OSPs may use throttling not only to regulate the current demand but also to reduce unfavorable future demand. Furthermore, our numerical study emphasizes the importance of analyzing the trade-off between internal and external non-monetary cost factors (such as the one-time cost of damaging the OSP's public reputation and the cost of damaging the goodwill of current users etc.) and provides guidelines for making decisions on throttling intensities under different scenarios.

The rest of the paper is organized as follows: A section with related literature is provided next. Our demand throttling model and its solution using the QVI approach are presented in Sections 3 and 4, respectively. Section 5 is devoted to a comprehensive numerical study with comparative statics analysis; it also expounds on the implications of the numerical results. We discuss how congestion management with limited capacity is contained within our setting as well as other important implications of our work in Section 6. Section 7 concludes our work with directions for future research and a short summary. Additional simulation results and proofs are provided in appendices.

2. RELATED LITERATURE

We first discuss the stream of literature on network congestion management and then briefly review the related literature on impulse control theory at the end of this section.

The impact of large-scale demand surges resulting in network congestion on web servers and online networks has been extensively studied in computer science, systems science, and other related engineering streams. A few examples of such studies include Stavrou et al. (2004), Deshpande et al. (2007), Kim et al. (2015), and Tada et al. (2017). These studies mainly focus on different engineering mechanism designs to make the OSP resilient and/or prone to network congestion. Our paper focuses on an optimal demand throttling mechanism that reduces the risks associated with network congestion and manages demand during congestion while keeping non-monetary costs associated with throttling at a minimal level. Thus, our contribution lies more on the (operational) policy making domain. This is a very important but largely neglected area of research at the interface between information systems (IS) and operations management (OM).

One important feature of our model is that OSPs treat all users equally when throttling is employed. In other words, our throttling policy is non-discriminatory, that is, it obeys the principle of *network (net) neutrality*. In contrast, a vast majority of the extant literature on network (congestion) management policies focuses on non-neutral policies, where OSPs may provide preferential treatment of certain web-traffic on their networks and may charge a premium for that. Guo et al. (2013) explored the net neutrality issue from both supply (content provider) and demand (customer) sides. One of the key results in their study is that OSPs generally prefer non-neutral network management policies. However, such non-neutral network management policies may not always lead to decrease in customer welfare. From a modeling perspective, they model two different classes of customers based on their usage—heavy and light—who incur a cost (disutility) due to congestion. Thus, they capture the difference in demand levels based on congestion. They assume that customer arrivals are Poisson, whereas, we model aggregate customer demand as a geometric Brownian process. In another study, Guo and Easley (2016) examine the impact on content innovation in the context of net neutrality when customers may experience network congestion. An important result in their study is that a higher level of content generation by providers can also lead to an increase in network congestion. This an important implication for OSPs (e.g., Foxtel) who are looking to mitigate network congestion when there are new offerings by their content providers (e.g., HBO).

Feuillet et al. (2014) study the complex interaction between different classes of stochastic demand. They define classes as *stable* and *unstable*, where these classes depict different user types based on their network usage—low (stable) usage and heavy (unstable) usage. Further, they assume that these classes obtain bandwidth proportional to their incoming demand from the moment of the initial surge until the demand reaches its equilibrium. They use the asymptotic behavior of the unstable class to derive important qualitative insights on how bandwidth allocation affects the overall network performance. In another study, Cho et al. (2016) develop an analytical model using game-theory to analyze the effects of subsidizing internet access for users. They find that the *equilibrium* network management choice of subsidizing the users depends on market conditions, such as the revenue rates of the content providers and the cost to consumers. While these studies, as well as ours, consider congestion management problems in a broader sense, the focus of our study is different.

In a more recent paper, Jordan (2017) studied *zero-rating* program and associated (bandwidth) throttling policies for open internet networks. The zero-rating program has been offered by several OSPs in the United States where some specific network traffic is not included in a user's usage-based pricing policy. These programs are often accompanied by bandwidth throttling (T-Mobile Binge On 2018), where once the user reaches a certain threshold, their network speed is reduced by the OSP as per their contract. Jordan (2017) discussed in detail the no-throttling rule, introduced by Federal Communications Commission (FCC), that provides protection to users against OSP's discriminatory practices that inhibit the delivery of particular content, applications, or services to a user. However, it is important to note that the existing throttling strategies are criticized due to their discriminatory nature. On the other hand, our study focuses on optimal non-discriminatory throttling strategies.

Easley et al. (2018) discuss and categorize key issues and corresponding trade-offs in the context of the debates on net neutrality. Bandwidth throttling is one of the key issues discussed in their paper which is concerned with a *gatekeeper* (OSP) at the infrastructure level that controls and regulates the demand flow in the network. This control can happen at various levels, such as the origin of data, at the software level, hardware level, last-mile to the user, etc. They present several network management tools such as *packet discrimination* including OSP-driven bandwidth throttling, OSP-driven prioritizing of certain network protocols, content-provider driven packet discrimination, content-providers paying the OSPs to lift the data cap for their consumers (zero-rating programs), etc. Furthermore, their study discusses ways of preserving net-neutrality using data caps without discrimination. While we also do not discriminate against users in our setting, we use the aggregate-level bandwidth throttling as opposed to the individual-level data caps.

There is a second stream of literature that investigates how incentivizing users to change their behavior in consuming online services help to mitigate network congestion. Incentive schemes are used as demand management tools employing pricing to shape customer demand and help OSPs to tackle congestion. Dyaberi et al. (2012) conduct experiments with different incentive (pricing) schemes for cellular internet services. They found that users changed their network usage due to economic incentives and disincentives; specifically, users reduce their consumption more due to incentives as compared to disincentives. More recently, De et al. (2017) study quality of service (QoS) based pricing schemes to induce content sharing by end-users in peer-to-peer (P2P) networks. They develop a game-theory based model to study the changes in QoS measures based on the network size as OSPs evolve. For instance, their study indicates that for small networks, higher upload capacity can induce content sharing, however, the opposite is true when the network is large. Zheng et al. (2018) study the change in user behavior due to different pricing policies (unlimited, prepaid, and usage-based) used by different internet service providers (ISPs). They developed a deterministic as well as a stochastic model to capture this user behavior which maximizes a user's net utility from using the ISP's service. They derived analytical and numerical results for an ISP that maximizes its profit based on this specific user behavior without capturing bandwidth throttling. Although we do not consider any explicit incentive scheme in our setting, one could view throttling as a form of disincentive from a service user's standpoint.

We conclude our review on network congestion management highlighting several other notable papers. Anthony and Chung (2013) propose a speed-selection mechanism that allows users to choose different speeds for their data, that helps to limit throttling without increasing the costs for the OSP or without using pricing to manage demand. They show that by adopting this mechanism, the throttling factor can be lowered which reduces the aggregate user dissatisfaction. Li et al. (2017) develop a tool 'lib erate' that can help users to expose the network management policies used by OSPs and then help them to efficiently avoid such measures; they also discuss different throttling policies used by OSPs including AT&T and T-Mobile. In a P2P network setting, Johar et al. (2011) study how customers share content when they experience congestion under three broad categories—total delay, jitter and proportion of packets lost—and argue that successfully managing network congestion can improve end-user performance and may decrease costs for OSPs. In another study, Krämer et al. (2012) explore the allocation problem of existing network capacity through different QoS tiers offered by OSPs for prioritizing the network traffic. Their results indicate that QoS tiering can be more efficient in the short-run as well as long-run because of incentives due to increased demand leading to increased expenditure on infrastructure. Notably, Krämer et al. (2012) assume that the average user demand for service is constant and does not depend on network congestion or OSP's sensitivity to the congestion, whereas, we capture the difference in average user demand before and during the congestion (throttling) period.

Overall, from the extant literature and observed practices of network congestion by OSPs, there is no doubt that bandwidth throttling is a critically important congestion management tool for OSPs. However, research on optimal bandwidth throttling mechanisms is limited or nonexistent. As such, this paper aims to fill this important gap in the literature. To the best our knowledge, this is the first analytical study that aims at achieving an optimal non-discriminatory throttling mechanism for bandwidth when user demand is stochastic. We next briefly review the related literature on stochastic (impulse) control models.

We formulate our congestion management problem as a stochastic impulse control model and use the dynamic programming (DP) approach to solve the problem; this classical DP approach is commonly referred as the Quasi-Variational Inequality (QVI) approach in the literature (Bensoussan and Lions 1984). This celebrated method has been used extensively in the literature (Constantinides and Richard 1978, Sulem 1986, Presman and Sethi 2006, Cadenillas et al. 2010, Yamazaki 2017, etc.). In particular, Harrison et al. (1993), Korn (1997), Ormeci et al. (2008), Feng and Muthuraman (2010), Dai and Yao (2013a,b), Mitchell et al. (2014), Wu and Chao (2014), Muthuraman et al. (2015) and He et al. (2017) use the QVI approach when the underlying stochastic process follows a Brownian process, whereas Cadenillas and Zapatero (1999, 2000), Lumley and Zervos (2001), Ohnishi and Tsujimura (2006), Bensoussan et al. (2012), and Bensoussan and Chevalier-Roignant (2019) employ the QVI approach when the underlying process specifically follows a geometric Brownian process, as in our setting. We also refer our readers to Ivanov et al. (2018) and Dolgui et al. (2019) for state-of-the-art applications of control theory in the context of Industry 4.0 and digitalization.

While all these seminal papers use the QVI approach as a common tool, their model formulations and underlying applications are different; moreover, each article has its own merit in terms of use of the technique and managerial insights. In a similar spirit, we apply the QVI approach to solve a problem at the interface of IS and OM for the first time. Even among the models that use a geometric Brownian process as the underlying process, our model has several distinct features. First, rather than intervening only at the stopping times, we allow intervention (or throttling) over a random period of time which we call the *throttling period*. Second, the dynamics of the underlying process is allowed to be different during this throttling period and the corresponding dynamics depend on the throttling factor associated with each throttling period. Finally, the effective-demand (process) is only a fraction of the underlying process during the throttling period. These features clearly distinguish our model from the extant models. The model that is somewhat closest to ours is that of Bensoussan et al. (2012). Specifically, these authors also use a different stochastic process (over a period called *market reaction period*) to capture market reactions to central bank interventions in the foreign exchange market. However, they apply the impulsive type of (instantaneous) interventions while the throttling is applied over a period of time in our setting. In addition, the dynamics of the underlying process during the throttling period is governed by the intensity of the intervention (i.e., throttling factor) in our setting whereas the corresponding dynamics during the market reaction period of Bensoussan et al. (2012) is entirely governed by exogenous parameters. Consequently, our model is novel, and our work contributes to the extant literature on both the IS-OM interface and stochastic control theory.

3. DEMAND THROTTLING MODEL

Our model focuses on an online service provider (OSP) that tries to keep its demand for bandwidth below a certain threshold level to avoid server/network congestion. We assume that the demand (aggregate bandwidth usage) follows a geometric Brownian process. Formally, let $(\Omega, \mathcal{F}, P)$ be a probability space equipped with an information set (filtration) $\{\mathcal{F}_t\}_{t\geq 0}$ generated by a 1-dimensional Brownian process $B(t)$. Then, the demand process $X(t)$ at time t, when there is no throttling (control), is the solution of the following stochastic differential equation (SDE):

$$dX(t) = \mu X(t)dt + \sigma X(t)dB(t), \tag{1}$$

where μ is the growth rate, $\sigma > 0$ is the volatility parameter of demand, and $X(0) = x > 0$.

OSP manages demand by throttling it for a random period of time. Throughout the throttling period, OSP slows down its service (or bandwidth speed) so that each user experiences a slower speed. Mathematically, service speed will be multiplied by a *fixed* fraction ρ, where $0 \leq \rho < 1$, in this period. For example, if $\rho = 70\%$, then each user receives only 70% of the speed that he/she received before throttling is employed. At the end of this period, the speed will be reinstated. Moreover, the intensity of throttling is represented by $\gamma := (1 - \rho)$ and γ will be referred to as *throttling factor (intensity)* hereafter.

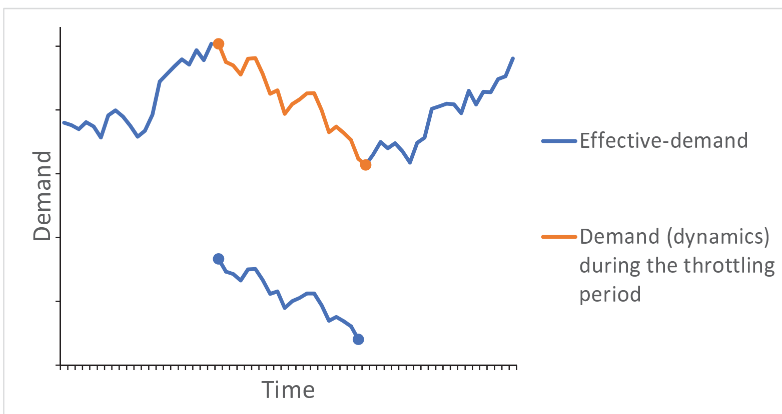
We now turn our attention to the aggregate demand and its dynamics during the throttling period. Due to the lack of speed in this period, multiple users (especially, the users who are more sensitive to the speed) may decide to stop using the service network temporarily; in extreme cases, some users may switch to different service providers permanently because of their inferior service experience [When Verizon throttled the data connection for firefighters in California, the Fire Department relied on other agencies for their internet service and firefighters used their personal internet devices, and finally, the department switched to a more expensive data plan to avoid throttling (Stevens 2018). It is also reported that, as a result of throttling, users switch to other network carriers including using Wi-Fi instead of cellphone internet, or using a mobile hotspot of another user, or in extreme cases users abandon the service intermittently (Hildenbrand 2017).]. Thus, the dynamics of the demand process should switch during the throttling period. Moreover, recognizing that the rate of exiting the service should be proportional to throttling factor γ, we assume that the demand follows the process $\tilde{X}$ during the throttling period and its dynamics is governed by the following SDE:

$$d\tilde{X}(t) = (\mu - \tilde{\mu}\gamma)\tilde{X}(t)dt + \tilde{\sigma}\tilde{X}(t)dB(t), \tag{2}$$

where $\tilde{\mu} > 0$ and $\tilde{\sigma} > 0$ are constants. Here, $\tilde{\sigma}$ represents the volatility of demand during the throttling period, whereas $\tilde{\mu}_g := (\mu - \tilde{\mu}\gamma)$ is the growth rate of demand. Our selection of the growth rate $\tilde{\mu}_g$, with the assumption $\mu < \tilde{\mu}$, allows us to have both the positive and negative growth rates for the demand during the throttling period. We consider two cases for discussion—$\mu \leq 0$ and $\mu > 0$. If $\mu \leq 0$, then it is clearly seen that $\tilde{\mu}_g \leq \mu < 0$. Thus, the growth rate of the demand during the throttling period is negative and lower than that of pre-throttling demand; moreover, the magnitude of the negative demand is proportional to γ. This is clearly expected at any level of throttling when $\mu \leq 0$. However, if $\mu > 0$, then the growth rate $\tilde{\mu}_g$ during the throttling period could either be positive or negative depending on the intensity of throttling. Specifically, $\tilde{\mu}_g > 0$ if $\mu/\tilde{\mu} > \gamma$, and $\tilde{\mu}_g < 0$ if $\mu/\tilde{\mu} < \gamma$. Thus, the growth rate changes its direction only if the intensity of throttling exceeds the threshold of $\mu/\tilde{\mu}$.

While the dynamics of the demand is governed by $\tilde{X}$ during the throttling period, the effective (aggregate) demand during this period is $\rho\tilde{X}$ and this will be the (total) bandwidth usage during the throttling period. Figure 1 illustrates the demand and effective-demand around a throttling period. The figure highlights two important features of our model. First, the demand dynamics during the throttling period is different as users experience slower speeds and the corresponding dynamics depend on the throttling factor (see also (2)). Second, the effective-demand (or true usage) during the throttling period is only a fraction of the demand during that period. These features somewhat distinguish our model from the extant impulse control models (*cf.* Cadenillas and Zapatero 1999, Lumley and Zervos 2001, Ohnishi and Tsujimura 2006, Bensoussan et al. 2012, Bensoussan and Chevalier-Roignant 2019). Finally, note that the demand dynamics reverts to the original dynamics given in (1) at the end of the throttling period. However, the demand process evolves from the level of demand at the end of the throttling period under the reinstated speed; in order to compute this starting level of demand, one should multiply the effective-demand at the end of the throttling period by $(1-\gamma)^{-1}$ (or, equivalently by ρ^{-1}). We have mathematically defined these in the sequel (see the system (3)-(5)).

Figure 1: Effective-demand during the throttling period



Despite the fact that demand throttling is employed over a period of time, we refer to the starting instance of the throttling period as the *throttling time* throughout this article. OSP decides on the times $\{\tau_n\}_n$ at which to initiate demand throttling and also on the throttling intensities (factors) $\{\gamma_n\}_n$. Formally, we can define OSP's throttling policy as an impulse control.

Definition 1. *OSP's throttling policy is a double sequence* $\nu = (\tau_1, \tau_2, \ldots, \tau_i, \ldots; \gamma_1, \gamma_2, \ldots, \gamma_i, \ldots)$, *where* $\tau_1 < \tau_2 < \cdots$ *are* $\mathcal{F}_t$*-stopping times (the throttling times) and* $\gamma_1, \gamma_2, \ldots$ *are the corresponding throttling factors (intensities) employed over the throttling periods initiated at these times such that each* γ_i *is* $\mathcal{F}_{\tau_i}$*-measurable.*

As we noted above, demand throttling is applied over the entire throttling period although the throttling is initiated as an impulse at each throttling time. This feature of our throttling (impulse-control) policy is novel and distinguishes our policy from the classical frameworks in Bensoussan and Lions (1984), Øksendal and Sulem (2007), etc.

Now, let $X_x(t)$ (resp., $\tilde{X}_x(t)$) denote the demand process $X(t)$ (resp., $\tilde{X}(t)$) with $X(0) = x$ (resp., $\tilde{X}(0) = x$). Moreover, we denote the duration of the i-th throttling period by T_i; and assume that T_i's are independent and identically distributed, and has the distribution function F_T. (Later in the paper, we further assume that T_i's are also independent of $B(t)$, and hence independent of the demand processes.) Then, if we apply a throttling policy $\nu = (\tau_1, \tau_2, ..., \tau_i, ...; \gamma_1, \gamma_2, ..., \gamma_i, ...)$ to the demand process $X_x(t)$, the corresponding throttled (or controlled) demand process $X_x^{(\nu)}(t)$ can be defined by

$$X_x^{(\nu)}(t) = X_x(t)\ ;\ 0 \le t < \tau_1, \tag{3}$$

$$X_x^{(\nu)}(t) = (1-\gamma_i)\tilde{X}_{X_x^{(\nu)}(\tau_i -)}(t) \text{ for } \tau_i \le t \le \tau_i + T_i\ ;\ i = 1, 2, ..., \tag{4}$$

$$X_x^{(\nu)}(t) = X_{(1-\gamma_i)^{-1}X_x^{(\nu)}(\tau_i + T_i)}(t) \text{ for } \tau_i + T_i < t < \tau_{i+1}\ ;\ i = 1, 2, ... \tag{5}$$

Equation (3) above means that the throttled demand process simply follows the original demand process (1) until the first throttling time τ_1. OSP initiates each throttling period and throttles demand according to equation (4). At each τ_i, as soon as throttling is applied, the dynamics of the demand process switches to $\tilde{X}$; while this new process $\tilde{X}$ evolves from the level of demand just before throttling (i.e., $X_x^{(\nu)}(\tau_i -)$), OSP's effective demand of this period is derived as in (4). In particular, equation (4) assures that each user receives only $(1-\gamma_i)$ percentage of the original speed throughout the throttling period. At the end of the throttling period (i.e., $t = \tau_i + T_i$), OSP reinstates the original speed by multiplying the current speed by $(1-\gamma_i)^{-1}$. This results in a change in dynamics as well as a change in the level of demand as indicated in (5). Specifically, the post throttling period demand evolves from the initial level of $(1-\gamma_i)^{-1}X_x^{(\nu)}(\tau_i + T_i)$ according to the original demand dynamics in (1) until the next throttling time.

To capture the qualitative factors associated with this problem, we have incorporated a running cost and a throttling cost in our model. The running cost is assumed to be a quadratic function of the level of demand x. We denote this cost by $f(\cdot)$ with $f(x) := \beta x^2$ for some $\beta > 0$. This cost is motivated by the potential risks associated with server congestion; these risks include, but not limited to, server crashes, queueing delay, packet loss and the blocking of new connections. Note that, as the level of demand increases, so does the risk associated with congestion. Moreover, the marginal risk of having congestion should be increasing as the level of demand increases. Consequently, the running cost associated with the server congestion should be convex. Notwithstanding, we assume the specific form of $f(x)$ above to simplify the analysis.

Next, we assume that the cost of throttling is $K + c\,\zeta$, where K and c are positive constants and $\zeta > 0$ is the immediate change (drop) in the level of effective-demand at the launch of throttling; for example, if the effective-demand instantly drops down from level y to ρy when throttling is initiated, then $\zeta := (1-\rho)y = \gamma y$. Here, ζ is the size of the immediate impact of throttling. The costs associated with throttling is driven by qualitative features of our problem. Note that frequent demand throttling is not encouraged in practice as throttling immediately frustrate users (irrespective of the intensity of throttling) and that significantly hurts the public reputation of the OSP each time throttling is initiated. One way to incorporate these infrequent throttling in our model is to consider a fixed cost associated with throttling; this part of the throttling cost does not depend on the intensity of throttling. On the other hand, demand throttling with higher intensities should frustrates users more compared to relatively lower intensities; thus, the throttling cost should also include a cost that is proportional to the intensity of throttling.

The objective of the risk-neutral OSP is to minimize the total expected discounted future costs of managing congestion via demand throttling. For a given discount rate $r > 0$, an initial demand level $x > 0$ and a throttling policy ν, we can define this (cost) objective as below.

$$C^{(\nu)}(x) := \mathbb{E}\left[\int_0^\infty e^{-rt} f(X_x^{(\nu)}(t))dt + \sum_{i=1}^{\infty} e^{-r\tau_i}\left\{K + c\gamma_i X_x^{(\nu)}(\tau_i -)\right\}\right]. \tag{6}$$

For a given x, we are interested in the minimizer(s) of $C^{(\nu)}(x)$ over a set of admissible class of throttling policies which we denote by $\mathcal{V}$ and define as follows:

Definition 2. *The set $\mathcal{V}$ of throttling policies is called admissible, if for all $x > 0$, $\nu \in \mathcal{V}$,*
(i) a unique solution $X_x^{(\nu)}(t)$, $t \geq 0$, of the system (3)–(5) exists,
(ii) $\lim_{i\to\infty} \tau_i = \infty$ a.s.,
(iii) $E\left[\int_0^\infty e^{-rt} f(X_x^{(\nu)}(t))dt\right] < \infty$,
(iv) $E\left[\sum_{i=1}^\infty e^{-r\tau_i}\left\{K + c\gamma_i X_x^{(\nu)}(\tau_i -)\right\}\right] < \infty$,
(v) $\gamma_i \in (0, 1]$, for $i = 1, 2, ...$, and
(vi) $\tau_{i+1} - \tau_i \geq T_i$, for $i = 1, 2, ...$

While conditions (i)-(iv) above are quite common in the literature (*cf.* Chapter 6 of Øksendal and Sulem (2007)), it will be clear in the sequel that some of these conditions can be replaced by simple sufficient conditions; for example, condition (iii) is implied by $(r - \sigma^2 - 2\mu) > 0$. Moreover, condition (v) is necessary for a meaningful analysis in our setting. Condition (vi), however, is somewhat uncommon and has been imposed only in impulse control models with random reaction periods (*cf.* Bensoussan et al. 2012, Perera et al. 2018). This condition implies that OSP waits until the current throttling period is over before implementing the next throttling period. We believe that this assumption is reasonable for our application. For example, if there is a chance of exceeding a certain threshold again while the throttling is in place, then the optimal decision under the current policy would have been to throttle by a larger factor; furthermore, it makes perfect sense for an OSP to wait and study the impact of the current throttling period before implementing a new throttling. This restriction is also supported by the fact that fixed costs associated with throttling is large enough so that frequent throttling is not economical. We recognize that, under a more general class of admissible policies, it is theoretically feasible to have scenarios where the next throttling time lands within the current throttling period. However, considering our application and for mathematical simplicity, we assume that $\tau_{i+1} - \tau_i \geq T_i$ for all i.

Finally, let Φ denote the value function (optimal minimal cost) of our congestion management problem, i.e., for all $x > 0$,

$$\Phi(x) = \inf\left\{C^{(\nu)}(x); \nu \in \mathcal{V}\right\} = C^{(\nu^*)}(x),$$

where ν^* is the minimizer of $C^{(\nu)}(x)$ over $\mathcal{V}$. The analysis of the value function Φ is not trivial. Therefore, in the next section, we convert this dynamic optimization problem into a set of point-wise optimization problems using the dynamic programming approach. This classical approach is referred to as the QVI approach in the literature (Bensoussan and Lions 1984).

4. QUASI-VARIATIONAL INEQUALITY AND ITS SOLUTION

The derivation of the QVI associated with our demand throttling model is standard. Thus, we will be brief and only present the essential steps in the derivation. In our setting, at any given state x, the OSP can either choose to throttle (optimally) or stay put. If the OSP chooses either of these alternatives immediately and thereafter follow the optimal (feasible [Note that OSP has to wait until the immediate throttling period is over before initiating another throttling period. Thus, if OSP has chosen to throttle immediately, then any policy that has a throttling time within the immediate throttling period will not be feasible.]) throttling policy, then the cost of the alternative policy should be no less than that of the 'optimal' policy which is $\Phi(x)$. Let us consider each of these scenarios separately. First, consider the case where the OSP starts throttling immediately with intensity γ and then follows the optimal policy starting with the state $\tilde{X}_x(T)$, which is the state at the end of the immediate throttling period. The cost of this policy is

$$K + c\gamma x + \int_0^\infty \mathbb{E}\left[\int_0^T e^{-rs} f\left((1-\gamma)\tilde{X}_x(s)\right) ds + e^{-rT}\Phi\left(\tilde{X}_x(T)\right)\Big| T = t\right] dF_T(t).$$

The first two terms of the above cost expression represent the throttling cost which consists of a fixed cost K and a proportional cost $c\gamma x$. The first part of the final term is the running cost during the throttling period which is governed by the effective-demand level $(1-\gamma)\tilde{X}_x$. The second part of the final term is the cost of following the optimal policy, starting with the state $\tilde{X}_x(T)$, at the end of the throttling period. If the OSP chooses this immediate throttling decision optimally over $\gamma \in (0, 1]$, then the corresponding cost can be written as

$$\inf\left\{K + c\gamma x + \int_0^\infty \mathbb{E}\left[\int_0^T e^{-rs} f\left((1-\gamma)\tilde{X}_x(s)\right) ds + e^{-rT}\Phi\left(\tilde{X}_x(T)\right)\Big| T = t\right] dF_T(t)\ ;\ \gamma \in (0,1]\right\}. \tag{7}$$

The cost expression in (7) is referred to as the *minimum cost operator* in the literature (Øksendal and Sulem 2007) and we denote it by $\mathcal{M}\Phi(x)$. As we explained above, the cost of this alternative policy should be no less than that of the optimal policy. Thus, we have $\Phi(x) \le \mathcal{M}\Phi(x)$.

Our minimum cost operator is distinct from the standard literature (Bensoussan and Lions 1984, Øksendal and Sulem 2007). In particular, we have included a throttling period where no additional control is allowed. Moreover, the dynamics of the demand process is governed by a different process during this period. With the change in demand dynamics during the throttling period, our model is akin to the impulse control model with random reaction periods (ICRRP) proposed by Bensoussan et al. (2012). However, our model has two distinct features. First, it uses the effective-demand as the underlying stochastic process throughout the throttling period; in other words, the controller applies the impulse throughout the throttling period. Second, the dynamics of the $\tilde{X}$ process depends on the value of γ which is the intensity of throttling.

Next, we consider the other alternative policy where the OSP stays put (without throttling) for a short duration of length $\varepsilon > 0$ and then follows the optimal throttling policy starting with the state $X_x(\varepsilon)$. It is easily seen that the cost of this alternative policy is

$$\mathbb{E}\left[\int_0^\varepsilon e^{-rt} f(X_x(t))dt + e^{-r\varepsilon}\Phi(X_x(\varepsilon))\right].$$

From our intuitive argument at the beginning of this section, or from the principle of optimality (Bellman 1957), we know that the cost above should be no less than the optimal cost $\Phi(x)$, for any $x > 0$. Therefore, for any $\varepsilon > 0$, we have

$$\Phi(x) \leq \mathbb{E}\left[\int_0^{\varepsilon} e^{-rt} f(X_x(t))dt + e^{-r\varepsilon}\Phi(X_x(\varepsilon))\right].$$

Dividing both sides of the above expression by ε and rearranging the terms, we obtain

$$\frac{\mathbb{E}\left[e^{-r\varepsilon}\Phi(X_x(\varepsilon))\right] - \Phi(x)}{\varepsilon} + \frac{\mathbb{E}\left[\int_0^{\varepsilon} e^{-rt} f(X_x(t))dt\right]}{\varepsilon} \geq 0.$$

Now, letting $\varepsilon \to 0$, we derive $A\Phi(x) + f(x) \geq 0$, where

$$\begin{aligned} A\Phi(x) &:= \lim_{\varepsilon \to 0} \frac{\mathbb{E}\left[e^{-r\varepsilon}\Phi(X_x(\varepsilon))\right] - \Phi(x)}{\varepsilon} \\ &= \mu x \frac{\partial \Phi(x)}{\partial x} + \frac{1}{2}\sigma^2 x^2 \frac{\partial^2 \Phi(x)}{\partial x^2} - r\Phi(x). \end{aligned}$$

Here, the differential operator A is defined on the set of twice continuously differentiable functions.

Finally, note that at any initial level of demand $x > 0$, the OSP can either choose to throttle (optimally) or stay put. Therefore, one of the weak inequalities from $\Phi(x) \leq \mathcal{M}\Phi(x)$ and $A\Phi(x) + f(x) \geq 0$ should be strict whereas the other is an equality. Thus, we should also have the following complementary slackness condition:

$$[A\Phi(x) + f(x)]\,[\Phi(x) - \mathcal{M}\Phi(x)] = 0\,.$$

We summarize the QVI associated with the value function of our problem in the proposition below.

Proposition 1 (QVI)**.** *For a given $x > 0$, the value function $\Phi(x)$ of our congestion management problem, which is assumed to be continuously differentiable [We only need $\Phi(\cdot)$ to be continuously differentiable in order to approximate it by a sequence of twice continuously differentiable functions using a well-known approximation result (cf. Appendix D of Øksendal 2003).], satisfies the following QVI:*

$$\begin{aligned} \Phi(x) &\leq \mathcal{M}\Phi(x), \\ A\Phi(x) + f(x) &\geq 0, \\ [A\Phi(x) + f(x)]\,[\Phi(x) - \mathcal{M}\Phi(x)] &= 0\,. \end{aligned}$$

A solution of the QVI above divides the interval $[0, \infty)$ into two disjoint regions—a continuation (non-throttling) region, $\mathbb{C} = \{x : \Phi(x) < \mathcal{M}\Phi(x)$ and $A\Phi(x) + f(x) = 0\}$, and a throttling region, $\mathbb{I} = \{x : \Phi(x) = \mathcal{M}\Phi(x)$ and $A\Phi(x) + f(x) > 0\}$. While OSP does not need to take any action when the demand is strictly inside the continuation region, throttling should be initiated as soon as the level of demand reaches the boundary of the continuation region provided there is no ongoing throttling.

The rest of this section will be dedicated to the solution of the QVI. However, it should be noted that one needs to verify that a solution of the QVI indeed coincides with the original value function Φ. This requires a standard verification argument which we have presented in Appendix A for the sake of completeness.

Before we turn our attention to the solution of the problem, we derive an important identity. It is well-known that the solution of (1) is given by

$$X_x(t) = x\ \exp\left\{(\mu - \frac{1}{2}\sigma^2)t + \sigma B(t)\right\}.$$

Then, using the exponential moments of the process, it follows that, for $q \in \mathbb{R}$,

$$\mathbb{E}\left[(X_x(t))^q\right] = x^q \exp\left\{\left[\left(\mu - \frac{1}{2}\sigma^2\right) q + \frac{1}{2}\sigma^2 q^2\right] t\right\}. \tag{8}$$

A similar identity holds for $\tilde{X}$ process, i.e.,

$$\mathbb{E}\left[(\tilde{X}_x(t))^q\right] = x^q \exp\left\{\left[\left((\mu - \tilde{\mu}\gamma) - \frac{1}{2}\tilde{\sigma}^2\right) q + \frac{1}{2}\tilde{\sigma}^2 q^2\right] t\right\}. \tag{9}$$

Next, we conjecture that the solution of the QVI associated with our congestion management problem is a policy governed by a positive threshold U and a control factor Υ, where $0 < \Upsilon \leq 1$; the optimal strategy is to initiate a throttling period with intensity Υ whenever the level of demand reaches the threshold U outside a throttling period. The continuation (non-throttling) and throttling regions are $(0, U)$ and $[U, \infty)$, respectively. One could view the proposed policy as a modified version of the classical control-band policy where the optimal policy is to bring down the state process to level $u := (1 - \Upsilon)U$ whenever it reaches a threshold level $U > 0$. However, our policy is distinct in that the demand throttling is applied over a period of time as oppose to an instantaneous (impulsive) control.

We now follow standard techniques to find the optimal cost and policy parameters. Note that, using the techniques of Boyce and Prima (1997), we can solve $A\Phi(x) + f(x) = 0$ for $x \in (0, U)$, and show that

$$\Phi(x) = ax^{\alpha_1} + bx^{\alpha_2} + \left(\frac{\beta}{r - \sigma^2 - 2\mu}\right) x^2,$$

where $\alpha_1 := \frac{\frac{1}{2}\sigma^2 - \mu + \sqrt{\left(\mu - \frac{\sigma^2}{2}\right)^2 + 2\sigma^2 r}}{\sigma^2}$, $\alpha_2 := \frac{\frac{1}{2}\sigma^2 - \mu - \sqrt{\left(\mu - \frac{\sigma^2}{2}\right)^2 + 2\sigma^2 r}}{\sigma^2}$, and a and b are constants to be determined. Observe that $\Phi(x)$ above should be no greater than the cost of no throttling policy for any $x \in (0, U)$. From (6), we can compute the cost of no throttling policy (denoted by $C^{(0)}(x)$) as follows:

$$\begin{aligned} C^{(0)}(x) &= \mathbb{E}\left[\int_0^\infty e^{-rt} f(X_x^{(\nu)}(t))dt\right] \\ &= \int_0^\infty e^{-rt}\beta\, \mathbb{E}\left[(X_x^{(\nu)}(t))^2\right] dt \\ &= \int_0^\infty \beta\, e^{-rt} x^2 e^{(2\mu+\sigma^2)t} dt \\ &= \left(\frac{\beta}{r - \sigma^2 - 2\mu}\right) x^2, \end{aligned}$$

where the third equality is due to (8). Moreover, from (iii) of Definition 2, we can deduce that $(r - \sigma^2 - 2\mu) > 0$. Therefore, we have

$$0 \leq ax^{\alpha_1} + bx^{\alpha_2} + \left(\frac{\beta}{r - \sigma^2 - 2\mu}\right) x^2 \leq \left(\frac{\beta}{r - \sigma^2 - 2\mu}\right) x^2, \tag{10}$$

for any $x \in (0, U)$. Note from their definitions that $\alpha_1 > 0$ and $\alpha_2 < 0$. Now, letting $x \to 0$ in the inequality on the right-hand side of (10), we deduce that $b \leq 0$; however, taking the limit $x \to 0$ in the inequality on the left-hand side of (10), we conclude that $b = 0$. Then, it is easily seen that $a \leq 0$. Consequently, for $x \in (0, U)$,

$$\Phi(x) = ax^{\alpha_1} + \left(\frac{\beta}{r - \sigma^2 - 2\mu}\right) x^2. \tag{11}$$

We now turn our attention to the throttling region $[U, \infty)$, where $\Phi(x) = \mathcal{M}\Phi(x)$. In order to compute $\mathcal{M}\Phi(x)$ explicitly and for analytical tractability, we assume that T follows an exponential distribution with rate $\lambda > 0$ (or mean λ^{-1}), i.e., $F_T(t) = 1 - e^{\lambda t}$ for $t > 0$. This assumption is reasonable in our setting. In particular, observe that $Prob(T > t_0) < 0.0025 \approx 0$ for $t_0 > 6/\lambda$. Thus, the probability of throttling for a longer period is very low under the exponential distribution. Since no additional throttling is allowed during a throttling period, short-lived throttling periods are desirable for our setting.

Now, define

$$R(x,\gamma) := \int_0^\infty \mathbb{E}\left[\int_0^T e^{-rs} f((1-\gamma)\tilde{X}_x(s))ds + e^{-rT}\Phi(\tilde{X}_x(T)) \middle| T = t\right] dF_T(t).$$

Then, using (9) and (11), it can be shown (see Appendix B) that

$$\begin{aligned} R(x,\gamma) = {} & \frac{\beta(1-\gamma)^2 x^2}{[r + \lambda - 2(\mu - \tilde{\mu}\gamma) - \tilde{\sigma}^2]} + \frac{a\lambda x^{\alpha_1}}{[r + \lambda - (\mu - \tilde{\mu}\gamma)\alpha_1 + \frac{1}{2}\tilde{\sigma}^2\alpha_1(\alpha_1 - 1)]} \\ & + \frac{\beta\lambda x^2}{(r - \sigma^2 - 2\mu)[r + \lambda - 2(\mu - \tilde{\mu}\gamma) - \tilde{\sigma}^2]}. \end{aligned}$$

Consequently, we have

$$\Phi(x) = \begin{cases} ax^{\alpha_1} + \left(\frac{\beta}{r-\sigma^2-2\mu}\right) x^2, & \text{if } x \in (0, U), \\ K + c\Upsilon x + R(U, \Upsilon), & \text{if } x \in [U, \infty). \end{cases} \tag{12}$$

Using standard 'principle of smooth fit' at the boundary U of the continuation region, we derive the following two equations

$$aU^{\alpha_1} + \left(\frac{\beta}{r - \sigma^2 - 2\mu}\right) U^2 = K + c\Upsilon U + R(U, \Upsilon), \text{ and} \tag{13}$$

$$a\alpha_1 U^{\alpha_1 - 1} + \left(\frac{2\beta}{r - \sigma^2 - 2\mu}\right) U = c\Upsilon. \tag{14}$$

Moreover, we know that the function $G(\gamma) := K + c\gamma U + R(U, \gamma)$ should be minimized at $\gamma = \Upsilon$. Then, using the first order condition $G'(\gamma) = 0$, we derive

$$\frac{\partial}{\partial\gamma} R(U, \gamma) \mid_{\gamma=\Upsilon} = -cU. \tag{15}$$

We need to solve the non-linear system (13)-(15) to compute the values of U, Υ and a. The parameters U and Υ uniquely determine our optimal policy. While it is customary to prove that there exists a unique solution for the non-linear system (13)-(15), we now briefly explain why it is not feasible to prove this result analytically in our case.

The existence and uniqueness of a solution for a non-linear system such as ours have been studied in the extant literature whenever it is analytically feasible to do so (Constantinides and Richard 1978, Øksendal 1999, Ohnishi and Tsujimura 2006, Perera and Buckley 2017, and the references therein); otherwise, the authors rely on numerical results (Cadenillas and Zapatero 1999). In particular, Ohnishi and Tsujimura (2006) employ techniques from Øksendal (1999) to prove the existence and uniqueness of a solution for a system when the underlying stochastic process follows a geometric Brownian process, as in our case. One common theme among all of these proofs is the 'separability' of the policy parameters in the system [For example, in Ohnishi and Tsujimura (2006), for a given $A_1 < 0$, parameters b and β are separable in equation (3.26) of the system (3.26)-(3.28).]. However, in our system (13)-(15), for a given $a < 0$, parameters U and Υ are not separable in both (13) and (15); this is because the growth rate during the throttling period depends on Υ. Consequently, it is not feasible to analytically prove the existence and uniqueness of a solution for our system. Therefore, we rely on extensive numerical simulations to address the issues of existence and uniqueness. Fortunately, as will be seen in Section 5, our computer program produces consistent and meaningful solutions for our system (13)-(15) under all feasible scenarios even though we occasionally had to impose obvious constraints such as the positivity of Υ.

Before we present our numerical results, we provide the conditions under which a solution Φ of the system (12)-(15) solves the QVI defined in Proposition 1. The proof of this result is presented in Appendix C.

Proposition 2. *Let Φ be a continuously differentiable solution of* (12)-(15) *such that*

$$U > \frac{-(\mu - r)c\Upsilon + \left\{(\mu - r)^2 c^2 \Upsilon^2 + 4\beta r[K + R(U, \Upsilon)]\right\}^{\frac{1}{2}}}{2\beta} \tag{16}$$

and

$$\Phi(x) < K + \inf_{0<\gamma\leq 1} \{cx\gamma + R(x, \gamma)\}, \tag{17}$$

for $x \in (0, U)$. Then, Φ is a solution to the QVI defined in Proposition 1.

5. NUMERICAL SIMULATIONS AND THEIR IMPLICATIONS

We use Newton's method to solve the non-linear system (13)-(15) in MATLAB [`https://www.mathworks.com/help/optim/ug/fsolve.html`]. Considering the admissibility constraints, convergence, existence, and uniqueness of the optimal solutions, we use the following parameters in our baseline model: $\mu = 0.01$, $\sigma = 0.10$, $\tilde{\sigma} = 0.15$, $\tilde{\mu} = 0.02$, $\beta = 1.0$, $r = 0.06$, $c = 2.0$, $K = 20$ and $\lambda = 0.5$. Using our MATLAB program, we derive the numerical approximations (rounded to three decimal places) for U, Υ, and a as:

$$U = 3.178, \ \Upsilon = 0.735, \ a = -6.944.$$

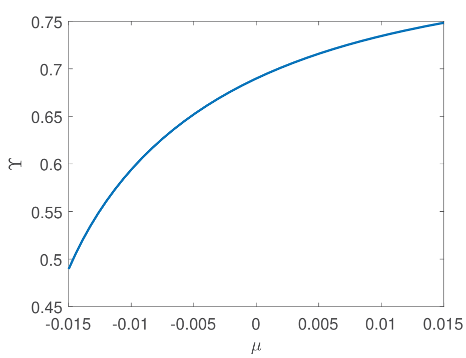
The inbuilt function *fsolve* in MATLAB also provides the range of errors for the system (13)-(15) and it is easy to verify that the conditions in the system of equations are satisfied within the default tolerance limit of 1×10^{-3} for the function. We obtain the square root of the sum of the square of errors in the three equations, viz. (13)-(15), as $2.15 \times e^{-19} \ll 1 \times 10^{-3}$.

The above numerical solution suggests that the OSP should start throttling the demand when it reaches the level $U = 3.178$. Moreover, intensity $\Upsilon = 0.735$ implies that the speed of delivery should be reduced by 73.5% during the throttling period.

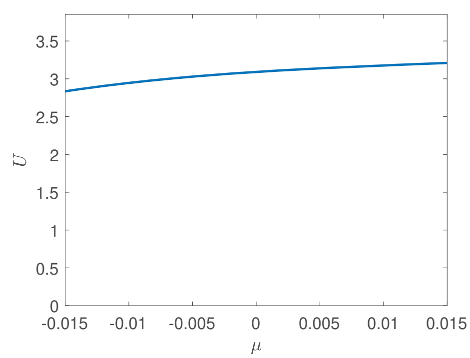
One of the main advantages of our efficient MATLAB program is that we can use it to solve multiple instances of the problem, and thereby, perform a comparative statics analysis to derive some interesting operational and managerial implications. In our comparative statics analysis, we use the parameters from the baseline case described above and change one parameter at a time to study the impact of the change in that parameter. The rest of this section is devoted to this comparative statics analysis.

5.1 The Impact of Change in the Growth Rate and Volatility of Unthrottled Demand

Figure 2(a) indicates that the throttling factor increases as μ increases. This means that, in order to alleviate higher growth rates, OSPs should employ severe throttling. It should also be noted from Figure 2(b) that U is slightly increasing in μ implying that the OSP will be somewhat patient before taking such severe actions against higher growth rates that can lead to network congestion.



(a) Υ versus μ



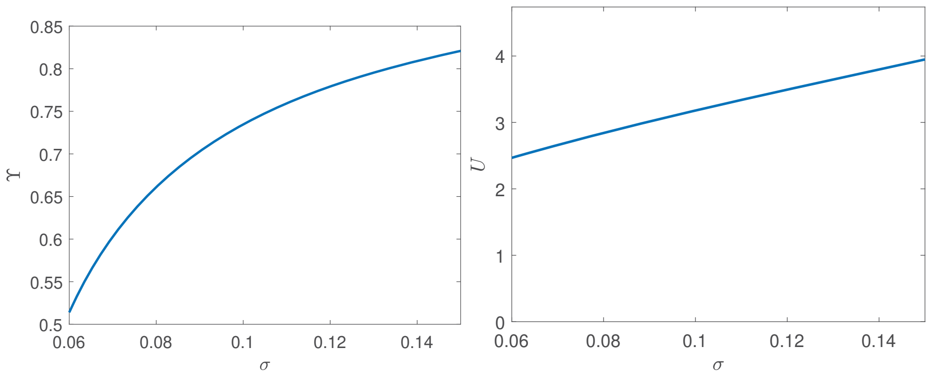
(b) U versus μ

Figure 2: Optimal throttling factor and threshold level as μ increases.

It is evident from Figure 3 that the impact of an increase in volatility, σ is similar to an increase in μ. In both of these cases, we also notice that the throttling factor is concave and increasing in the respective parameters. Thus, the marginal impact of throttling increases with its intensity.

5.2 The Impact of Change in the Dynamics of Demand during Throttling Period

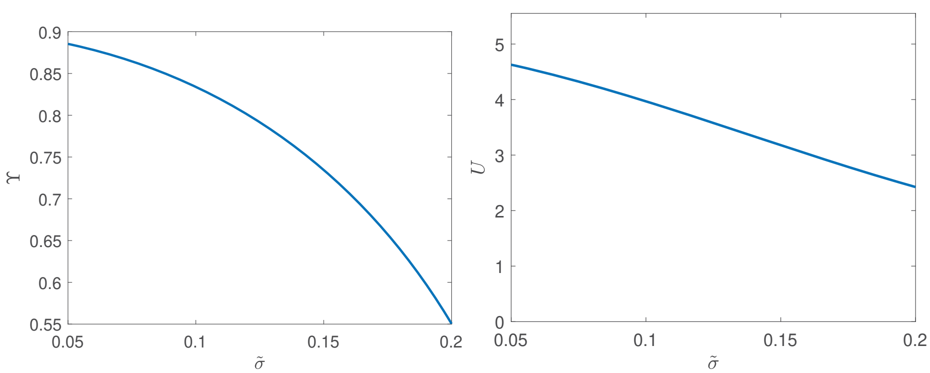
During the throttling period, the demand is driven by two parameters $\tilde{\mu}$ and $\tilde{\sigma}$. Figure 4 indicates that both Υ and U are decreasing in $\tilde{\sigma}$. From the impulse control literature (*cf.* Cadenillas and Zapatero 1999, Cadenillas et al. 2010), we know that, the OSP should wait longer to throttle



(a) Υ versus σ (b) U versus σ

Figure 3: Optimal throttling factor and threshold level as σ increases.

(intervene) as the volatility increases; moreover, the throttling factor is expected to be increasing in volatility. This is also what we observed in Section 5.1. In comparison with that traditional intuition, our observation sounds somewhat counter-intuitive and it is worth pursuing further discussion.

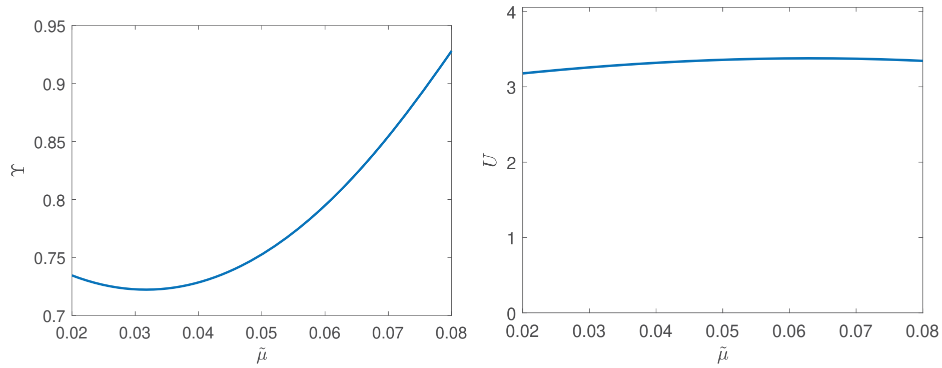


(a) Υ versus $\tilde{\sigma}$ (b) U versus $\tilde{\sigma}$

Figure 4: Optimal throttling factor and threshold level as $\tilde{\sigma}$ increases.

In our setting, $\tilde{\sigma}$ represents the volatility of the throttled demand. Thus, a higher value of $\tilde{\sigma}$ implies that users are more sensitive to throttling. If the OSP knows that its users are very sensitive to throttling, then it would lessen the strength of throttling; this indirectly forces the OSP to throttle more frequently implying a lower value of U. Finally, this observation is consistent with our model in which the sensitivity of users to throttling depends on the strength of throttling as opposed to the frequency of throttling.

We now turn our attention to $\tilde{\mu}$. While the value of U is fairly stable as a function of $\tilde{\mu}$ (see Figure 5(b)), the throttling factor is initially decreasing and then increasing as a function of $\tilde{\mu}$ (see 5(a)). However, it should be noted that the growth rate of the demand process (2) during the throttling period is $\mu - \tilde{\mu}\Upsilon$. From Figure 6, it is easily seen that the optimal throttling factor is selected such that this growth rate is negative and decreasing in $\tilde{\mu}$. Thus, optimal throttling not only helps the OSP to manage demand during the throttling period, it also helps the OSP to force out more reactive users (with a larger $\tilde{\mu}$) from its service.



(a) Υ versus $\tilde{\mu}$ (b) U versus $\tilde{\mu}$

Figure 5: Optimal throttling factor and threshold level as $\tilde{\mu}$ increases.

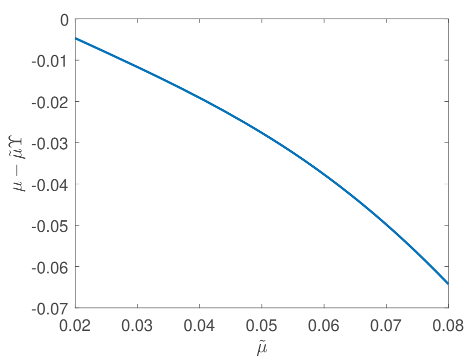


Figure 6: The growth rate of the demand during the throttling period as a function of $\tilde{\mu}$.

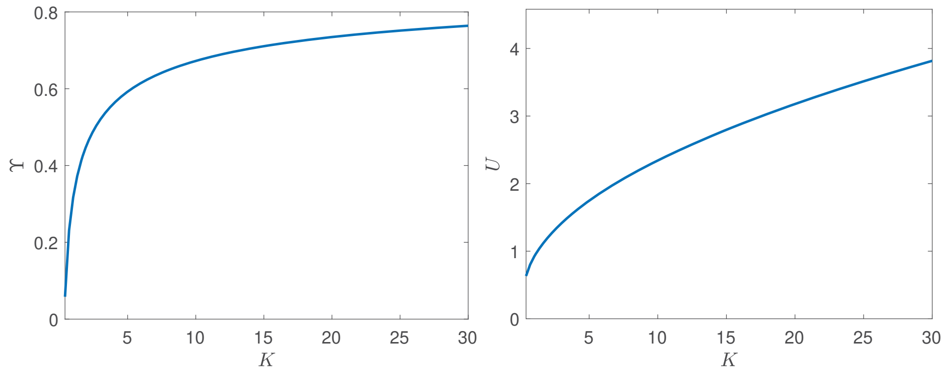
5.3 The Impact of Change in Cost Parameters and Discount Rate

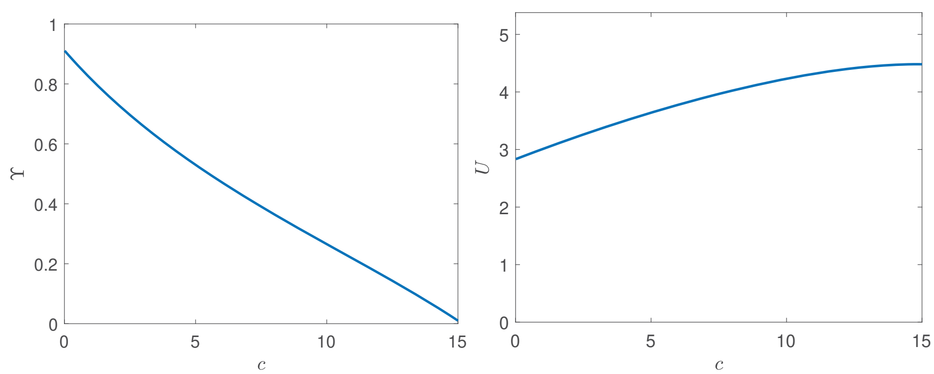
These results are parallel with the extant literature (*cf.* Bensoussan et al. 2012, Cadenillas et al. 2010, Cadenillas and Zapatero 1999, 2000) while their interpretations are different. First, we note from Figure 7 that both Υ and U are increasing in K. This means that it is optimal for the OSP to wait longer if the fixed cost is higher and then employ a stronger throttling. This fixed cost represents one-time costs such as cost of damaging the reputation of the OSP. Thus, it makes perfect sense for the OSP to wait and then apply stronger throttling if this fixed cost is higher. Conversely, the proportional cost parameter c, in general, represents the direct cost associated with the impact of throttling intensity on the current users negative experience due to throttling. Thus, for a larger value of c, the OSP should employ throttling with less intensity and be patient before throttling again. This phenomenon is clearly illustrated in Figure 8.

The cost of maintaining the demand should be higher for a larger value of β at a given level of demand. Thus, for a larger value of β, we expect a smaller U and a higher Υ. This is exactly what we observe in Figure 9. As we explained in our model, the cost of maintaining accommodates for the potential risks associated with the server congestion. Therefore, the higher



(a) Υ versus K (b) U versus K

Figure 7: Optimal throttling factor and threshold level as K increases.



(a) Υ versus c (b) U versus c

Figure 8: Optimal throttling factor and threshold level as c increases.

the value of β, the higher the risk; this is exactly why OSPs impose severe and more frequent throttling for larger values of β as a *risk-minimizing strategy*. In Section 6.2, we explain how we can use this observation to handle congestion management problems with capacity limitations.

Finally, the discount rate r basically represents the inflation rate. Thus, when the value of r increases, discounted future cost of throttling becomes cheaper. Hence, it is optimal for OSP to postpone throttling (see Figure 10(b)). Moreover, the intensity of these delayed throttling will be slightly less (see Figure 10(a)).

6. DISCUSSION AND ADDITIONAL REMARKS

6.1 Long-term Effect of Demand Throttling

From Figure 6, we noticed that the growth rate of the demand during the throttling period (i.e., $\tilde{\mu}_g = \mu - \tilde{\mu}\Upsilon$) is negative. We further investigated this phenomenon using an extensive numerical study, and our study confirmed that $\tilde{\mu}_g < 0$ always holds at the *optimum*. We have presented a

part of our results in Table 1 below and included a comprehensive summary of other simulation results in Appendix D. Therefore, as suggested by our numerical study, it is optimal for the OSP to implement throttling so that the growth rate during the throttling period is negative. (Recall that from (2), it is feasible to have a positive growth rate during the throttling period.) Thus, OSP uses demand throttling not only to manage the congestion while throttling is in place, but also to force away unhealthy future demand from the system.

Table 1: Value of $-\tilde{\mu}_g$ (rounded to three decimal places) for different values of μ and $\tilde{\mu}$.

$\mu \downarrow \quad \tilde{\mu} \rightarrow$	0.02	0.04	0.06	0.08
-0.01	0.022	0.032	0.049	0.080
0.00	0.014	0.027	0.046	0.073
0.01	0.004	0.010	0.011	0.011

6.2 Incorporating Capacity Constraints

The capacity of a server is limited, and the risks associated with congestion is higher when the usage is higher and closer to the capacity. While our demand throttling model in Section 3 does not handle capacity directly, the capacity is incorporated in our definition of the maintenance cost. As we explained earlier, our maintenance cost represents the costs associated with risks such as server crashing risk, queueing delay risk, packet loss risk and the risk of blocking of new connections. If the capacity is lower, then the cost associated with these risks should be higher implying a higher value of β; moreover, infinite capacity does not mean zero risk either. For example, one could assume that

$$\beta(C) := \kappa_1 + \kappa_2/\eta(C), \tag{18}$$

where κ_1 and κ_2 are some constants such that $\beta(C) > 0$, and $\eta(\cdot)$ is a non-negative increasing function of C. However, for applications, properly estimating a closed-form expression such as the one in (18) could be challenging. Moreover, mathematical analysis of such an explicit formulation will be more intricate without adding further insights. Nevertheless, it should be noted that if the capacity C of the server is known, then one could incorporate the capacity as a constraint to our congestion management problem through β. We illustrate this idea by using a simple example.

Consider our baseline model introduced at the beginning of Section 5 with capacity C. We also redefine β as a function of capacity via $\beta(C) := 15/(C + 1)$. Thus, using the notation of (18) above, we have $\kappa_1 = 0$, $\kappa_2 = 15$ and $\eta(C) = C + 1$. Since $C = -1 + 15/\beta$ (with $\beta < 15$) decreases as β increases, from Figure 9(a), we can deduce that the throttling intensity Υ must be higher with tighter capacities. Moreover, Figure 11 compares optimal threshold (U) values with the corresponding capacities at each value of β; it is easily seen from the figure that it is optimal to stay below and follow the trajectory of the capacity in our setting.

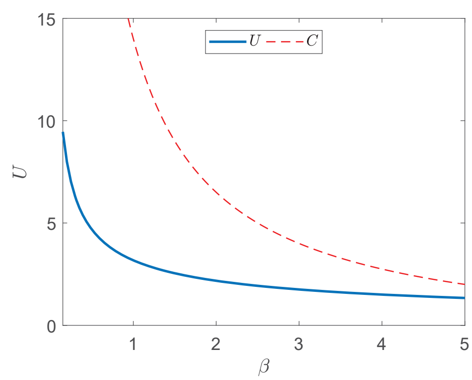

Figure 11: Optimal threshold values (U) with corresponding capacity constraints (C).

6.3 Trade-off Between Internal and External Costs

We also know, from Section 5.3, that higher fixed or proportional throttling costs always imply waiting longer before throttling. However, the throttling factor is increasing in K and decreasing in c. Thus, if the fixed cost is relatively higher than the proportional cost, then the optimal throttling factor should be higher. Consequently, whenever factors corresponding to fixed costs outweigh those associated with proportional costs, throttling should be stronger. For example, if the one-time cost of damaging the OSP's reputation outweighs the 'non-monetary' cost of making its current users unhappy, then the OSP should prefer throttling with higher intensities. Here, we should notice that factors associated with the fixed cost are *external* and do not have a direct connection with the user-experience of the current customers, whereas the proportional cost is *internal* and directly impacts the user-experience. In summary, our results suggest that the OSP should carefully evaluate the trade-offs between these external and internal costs, and the factors associated with these costs while making their throttling decisions.

7. CONCLUSION AND FURTHER DIRECTIONS

We have modeled a congestion management problem of an online service provider (OSP) as a stochastic impulse control problem and proved that the optimal strategy is to initiate throttling of a fixed intensity for a period of time whenever demand reaches a certain threshold. In particular, we have incorporated users' reactions to throttling in our model. Our numerical results suggest that service providers should employ users' willingness to exit the service, as a result of throttling, to regulate the future demand by always imposing negative growth rates during the throttling periods. This is the first stochastic model that handles the congestion management problem of an online service provider while preserving net-neutrality.

OSPs in some industries including energy distribution, cloud services, and video streaming (Fukuda et al. 2018, Deng et al. 2018, Dede et al. 2018, respectively) are more vulnerable to bulk and sporadic demand. Moreover, this type of demand could cause crashing more often than regular demand. To capture the dynamics of such demand, one could use a geometric jump diffusion process as the underlying stochastic process. While our analysis may be extended to handle this scenario, the corresponding analysis would be more intricate and will be a challenging problem for future research.

Although bandwidth throttling applies to OSPs only, demand throttling is a commonly observed practice in other businesses. For example, energy companies use programs such as 'Peak Power Saver'® (`https://peakpowersavers.com/`) program to manage their demand during the peak times in summer and winter (Consumers Energy 2018). Recently, under their Peak Power Savers® programs, Consumers Energy offered their customer $25 VISA gift card plus annual bill credit worth more than $30 for signing up for their 'AC Peak Cycling program'. When a customer signs up for this program, Consumers Energy installs a switch on (or near) the outside central air conditioning unit of the customer's household free of charge. On select summer weekdays during peak energy demand, the switch will be activated—reducing the output of the AC unit by a certain percentage for a short period of time. Our framework could be adopted to model this electricity throttling problem and other similar applications in the future. Thus, the scope of applications of our model is indeed broad.

A. VERIFICATION THEOREM AND ITS PROOF

A verification theorem for our congestion management problem is presented here. We first need to define the QVI-control associated with the QVI.

Definition 3 (QVI-control)**.** *Let ϕ be a solution of the QVI presented in Proposition 1 and*

$$M(\phi, y, \gamma) := K + c\gamma y + \int_0^\infty \mathbb{E}\left[\int_0^T e^{-rs} f\left((1-\gamma)\tilde{X}_y(s)\right) ds + e^{-rT}\phi\left(\tilde{X}_y(T)\right)\Big| T = t\right] dF_T(t).$$

Then, the QVI-control $\hat{\nu} = (\hat{\tau}_1, \hat{\tau}_2, \dots, \hat{\tau}_i, \dots; \hat{\gamma}_1, \hat{\gamma}_2, \dots, \hat{\gamma}_i, \dots)$ (when it exists) is inductively defined by

$$\begin{aligned} \hat{\tau}_0 &= 0, \\ \hat{\tau}_{i+1} &= \inf\{t > \hat{\tau}_i + T_i; X_x^{(\hat{\nu}_i)}(t-) \notin \mathbb{C}\}, \text{ and} \\ \hat{\gamma}_{i+1} &= \arg\inf\left\{M(\phi, X_x^{(\hat{\nu}_i)}(\hat{\tau}_{i+1}-), \gamma);\ \gamma \in (0,1]\right\}, \end{aligned}$$

where $X_x^{(\hat{\nu}_i)}$ is the result of applying $\hat{u}_i = (\hat{\tau}_1, \hat{\tau}_2, \dots, \hat{\tau}_i; \hat{\gamma}_1, \hat{\gamma}_2, \dots, \hat{\gamma}_i)$ to X_x.

Theorem 1 (Verification Theorem)**.** *Suppose that a solution of the QVI given in Proposition 1 also has continuous second order derivatives on $(0,\infty) \setminus \{x_0\}$ for some $x_0 > 0$, and the second order derivatives of ϕ are locally bounded near $x = x_0$. Moreover, assume that for $x > 0$, we have*

(I) QVI-control $\hat{\nu}$ corresponding to ϕ is admissible,
(II) $\lim_{t\to\infty} E\left[e^{-rt}\phi\left(X_x^{(\hat{\nu})}(t)\right)\right] = 0$,
(III) $\{\phi(X_x^{(\hat{\nu})}(\tau));\ \tau$ is a stopping time$\}$ is uniformly integrable, and
(IV) $\hat{\gamma} = \arg\inf\{M(\phi, x, \gamma);\ \gamma \in (0,1]\}$ is a Borel measurable selection,
then $\phi(x) = \Phi(x)$ and $\hat{\nu} = \nu^*$ for all $x > 0$.

Proof: Since $\phi \in C^1$ with continuous second order derivatives on $(0,\infty) \setminus \{x_0\}$ and the second order derivatives of ϕ are locally bounded near $x = x_0$, using a well-known approximation result (*cf.* Appendix D of Øksendal 2003), we can simply assume that $\phi \in C^2$ throughout our proof. Now, let

$$\phi_d\left(X_x^{(\hat{\nu})}(s)\right) := e^{-rs}\phi\left(X_x^{(\hat{\nu})}(s)\right)$$

for $s \geq 0$. Then, since T_i is independent of $X_x^{(\hat{\nu})}$ for $i \geq 1$, we have

$$E\left[\phi_d\left(X_x^{(\hat{\nu})}(\tau_i + T_i)\right)\Big| T_i = t\right] = E\left[\phi_d\left(X_x^{(\hat{\nu})}(\tau_i + t)\right)\right], \tag{19}$$

where $t \geq 0$.

We use the Itô's formula (Øksendal 2003) to derive an expression for the right-hand side of (19). First, consider

$$g(s, X_x^{(\hat{\nu})}(s)) := e^{-rs}\phi\left(X_x^{(\hat{\nu})}(s)\right) = \phi_d\left(X_x^{(\hat{\nu})}(s)\right)$$

and note that $g(s,y)$ is C^1 w.r.t. $s \geq 0$ (i.e., for $y > 0$, $g(\cdot, y)$ is continuous on $[0,\infty)$ with continuous first order derivatives) and C^2 w.r.t. $y > 0$ (i.e., for $s \geq 0$, $g(s,\cdot)$ is continuous on $(0,\infty)$

with continuous second order derivatives). Thus, we can apply the Itô's formula for g from τ_i to $\tau_i + t$, and obtain [Note that, from τ_j to $\tau_j + t$, the effective-process $X^{(\hat{\nu})}$ follows $(1 - \gamma_j)\tilde{X}$.]

$$\begin{aligned}\phi_d\left(X_x^{(\hat{\nu})}(\tau_i + t)\right) &= \phi_d\left(X_x^{(\hat{\nu})}(\tau_i)\right) - r\int_{\tau_i}^{\tau_i+t} \phi_d\left(X_x^{(\hat{\nu})}(s)\right) ds \\ &+ \int_{\tau_i}^{\tau_i+t} \frac{\partial \phi_d}{\partial x}\left(X_x^{(\hat{\nu})}(s)\right)[(\mu - \tilde{\mu}\gamma_i)ds + \tilde{\sigma} dB(s)] \\ &+ \frac{1}{2}\tilde{\sigma}^2 \int_{\tau_i}^{\tau_i+t} \frac{\partial^2 \phi_d}{\partial x^2}\left(X_x^{(\hat{\nu})}(s)\right) ds. \qquad (20)\end{aligned}$$

For $x > 0$, we define the differential operator $\tilde{A}$ for the i-th throttling period as follows:

$$\tilde{A}\phi_d(x) := (\mu - \tilde{\mu}\gamma_i)\frac{\partial \phi_d}{\partial x}(x) + \frac{1}{2}\tilde{\sigma}^2\frac{\partial^2 \phi_d}{\partial x^2}(x) - r\phi_d(x).$$

Then, from (20), we deduce that

$$\begin{aligned}\phi_d\left(X_x^{(\hat{\nu})}(\tau_i + t)\right) &= \phi_d\left(X_x^{(\hat{\nu})}(\tau_i)\right) + \tilde{\sigma}\int_{\tau_i}^{\tau_i+t} \frac{\partial \phi_d}{\partial x}\left(X_x^{(\hat{\nu})}(t)\right) dB(s) \\ &+ \int_{\tau_i}^{\tau_i+t} \tilde{A}\phi_d\left(X_x^{(\hat{\nu})}(s)\right) ds. \qquad (21)\end{aligned}$$

Since $E\left[\int_{\tau_i}^{\tau_i+t} \frac{\partial \phi_d}{\partial x}\left(X^{(\hat{\nu})}(t)\right) dB(s)\right] = 0$, taking the expectation of both sides of (21), we have

$$E\left[\phi_d\left(X_x^{(\hat{\nu})}(\tau_i + t)\right)\right] = E\left[\phi_d\left(X_x^{(\hat{\nu})}(\tau_i)\right)\right] + E\left[\int_{\tau_i}^{\tau_i+t} \tilde{A}\phi_d\left(X_x^{(\hat{\nu})}(s)\right) ds\right]. \qquad (22)$$

Using a similar argument from $\tau_j + t$ to τ_{i+1}, we can derive an expression for $E\left[\phi_d\left(X_x^{(\hat{\nu})}(\tau_{i+1}-)\right)\right]$. Here, it must be noted that the process $X^{(\hat{\nu})}$ follows the original process X from $\tau_j + t$ to τ_{i+1}. Consequently, we can easily derive that

$$E\left[\phi_d\left(X_x^{(\hat{\nu})}(\tau_{i+1}-)\right)\right] = E\left[\phi_d\left(X_x^{(\hat{\nu})}(\tau_i + t)\right)\right] + E\left[\int_{\tau_i+t}^{\tau_{i+1}} A\phi_d\left(X_x^{(\hat{\nu})}(s)\right) ds\right]. \qquad (23)$$

Combining (22) and (23) yields

$$\begin{aligned}&E[\phi_d\left(X_x^{(\hat{\nu})}(\tau_i)\right) - \phi_d\left(X_x^{(\hat{\nu})}(\tau_{i+1}-)\right)] = \\ &\qquad - E\left[\int_{\tau_i}^{\tau_i+t} \tilde{A}\phi_d\left(X_x^{(\hat{\nu})}(s)\right) ds\right] - E\left[\int_{\tau_i+t}^{\tau_{i+1}} A\phi_d\left(X_x^{(\hat{\nu})}(s)\right) ds\right].\end{aligned}$$

Summing the above equation from $i = 1$ to $i = n$, we get

$$\begin{aligned}&\sum_{i=1}^{n} E[\phi_d\left(X_x^{(\hat{\nu})}(\tau_i)\right) - \phi_d\left(X_x^{(\hat{\nu})}(\tau_{i+1}-)\right)] = \\ &\qquad - E\left[\sum_{i=1}^{n}\int_{\tau_i}^{\tau_i+t} \tilde{A}\phi_d\left(X_x^{(\hat{\nu})}(s)\right) ds\right] - E\left[\sum_{i=1}^{n}\int_{\tau_i+t}^{\tau_{i+1}} A\phi_d\left(X_x^{(\hat{\nu})}(s)\right) ds\right]. \qquad (24)\end{aligned}$$

Applying an argument similar to that leading up to (22), it can be easily shown that

$$E\left[\phi_d\left(X_x^{(\hat{\nu})}(\tau_1-)\right)\right] = E\left[\phi_d\left(X_x^{(\hat{\nu})}(0)\right)\right] + E\left[\int_0^{\tau_1} A\phi_d\left(X_x^{(\hat{\nu})}(s)\right)ds\right].$$

However, since $E[\phi_d\left(X_x^{(\hat{\nu})}(0)\right)] = E[e^{-r(0)}\phi(X_x^{(\hat{\nu})}(0))] = E[\phi(x)] = \phi(x)$, we deduce that

$$E\left[\phi_d\left(X_x^{(\hat{\nu})}(\tau_1-)\right)\right] = \phi(x) + E\left[\int_0^{\tau_1} A\phi_d\left(X_x^{(\hat{\nu})}(s)\right)ds\right]. \tag{25}$$

Combining (24) and (25), and rearranging the terms yield the following equation.

$$\begin{aligned}\phi(x) \quad &+ \quad \sum_{i=1}^{m} E\left[\phi_d(X_x^{(\hat{\nu})}(\tau_i)) - \phi_d\left(X_x^{(\hat{\nu})}(\tau_{i+1}-)\right)\right] - E\left[\phi_d\left(X_x^{(\hat{\nu})}(\tau_1-)\right)\right] \\ &= \quad -E\left[\sum_{i=1}^{m}\int_{\tau_i}^{\tau_i+t}\tilde{A}\phi_d\left(X_x^{(\hat{\nu})}(s)\right)ds\right] - E\left[\int_0^{\tau_1} A\phi_d\left(X_x^{(\hat{\nu})}(s)\right)ds\right] \\ &\qquad -E\left[\sum_{i=1}^{m}\int_{\tau_i+t}^{\tau_{i+1}} A\phi_d\left(X_x^{(\hat{\nu})}(s)\right)ds\right].\end{aligned}$$

Equivalently, we have

$$\begin{aligned}\phi(x) \quad &+ \quad \sum_{i=1}^{m} E\left[\phi_d(X_x^{(\hat{\nu})}(\tau_i)) - \phi_d(X_x^{(\hat{\nu})}(\tau_i-))\right] - E\left[\phi_d(X_x^{(\hat{\nu})}(\tau_{m+1}-))\right] \\ &= \quad -E\left[\sum_{i=1}^{m}\int_{\tau_i}^{\tau_i+t}\tilde{A}\phi_d\left(X_x^{(\hat{\nu})}(s)\right)ds\right] - E\left[\int_0^{\tau_1} A\phi_d\left(X_x^{(\hat{\nu})}(s)\right)ds\right] \\ &\qquad -E\left[\sum_{i=1}^{m}\int_{\tau_i+t}^{\tau_{i+1}} A\phi_d\left(X_x^{(\hat{\nu})}(s)\right)ds\right].\end{aligned} \tag{26}$$

Next, observe that the throttled process $\{X_x^{(\hat{\nu})}(s) : s \geq 0\}$ stays either within the continuation region $\mathbb{C}$ or on its boundary. Thus, for all $s \geq 0$, we have

$$f(X_x^{(\hat{\nu})}(s)) + A\phi(X_x^{(\hat{\nu})}(s)) = 0.$$

Multiplying the above equation by e^{-rs}, we obtain

$$f_d(X_x^{(\hat{\nu})}(s)) + A\phi_d(X_x^{(\hat{\nu})}(s)) = 0,$$

where $f_d(X^{(\hat{\nu})}(s)) = e^{-rs}f(X^{(\hat{\nu})}(s))$. Substituting this in (26) yields

$$\begin{aligned}\phi(x) \quad &+ \quad \sum_{i=1}^{m} E\left[\phi_d(X_x^{(\hat{\nu})}(\tau_i)) - \phi_d(X_x^{(\hat{\nu})}(\tau_i-))\right] - E\left[\phi_d(X_x^{(\hat{\nu})}(\tau_{m+1}-))\right] \\ &= \quad -E\left[\sum_{i=1}^{m}\int_{\tau_i}^{\tau_i+t}\tilde{A}\phi_d\left(X_x^{(\hat{\nu})}(s)\right)ds\right] + E\left[\int_0^{\tau_1} f_d\left(X_x^{(\hat{\nu})}(s)\right)ds\right] \\ &\qquad +E\left[\sum_{i=1}^{m}\int_{\tau_i+t}^{\tau_{i+1}} f_d\left(X_x^{(\hat{\nu})}(s)\right)ds\right].\end{aligned} \tag{27}$$

From Condition (IV) and the definitions of $\mathcal{M}$ and $\hat{\nu}$, it follows that

$$\mathcal{M}\phi(X_x^{(\hat{\nu})}(\tau_i-)) = K + c\gamma_i X_x^{(\hat{\nu})}(\tau_i-) + \int_0^\infty \mathbb{E}\left[\int_0^t e^{-rs} f\left((1-\gamma_i)\tilde{X}_{X_x^{(\hat{\nu})}(\tau_i-)}(s)\right) ds + e^{-rt}\phi\left(\tilde{X}_{X_x^{(\hat{\nu})}(\tau_i-)}(t)\right)\right] dF_T(t)$$

Rearranging the right-hand side, we get

$$\begin{aligned}\mathcal{M}\phi(X_x^{(\hat{\nu})}(\tau_i-)) &= K + c\gamma_i X_x^{(\hat{\nu})}(\tau_i-) \\ &\quad + \int_0^\infty \left\{\int_0^t e^{-rs}\mathbb{E}\left[f\left((1-\gamma_i)\tilde{X}_{X_x^{(\hat{\nu})}(\tau_i-)}(s)\right)\right] ds\right\} dF_T(t) \\ &\quad + \int_0^\infty \mathbb{E}\left[e^{-rt}\phi\left(\tilde{X}_{X_x^{(\hat{\nu})}(\tau_i-)}(t)\right)\right] dF_T(t).\end{aligned} \tag{28}$$

We next derive alternative expressions for the last two terms of (28). For this, note that $X_x^{(\hat{\nu})}(s) = (1-\gamma_i)\tilde{X}_{X_x^{(\hat{\nu})}(\tau_i-)}(s)$ for $\tau_i \le s \le \tau_i + t$. Then,

$$\begin{aligned}&\int_0^\infty \left\{\int_0^t e^{-rs}\mathbb{E}\left[f\left((1-\gamma_i)\tilde{X}_{X_x^{(\hat{\nu})}(\tau_i-)}(s)\right)\right] ds\right\} dF_T(t) \\ &= \int_0^\infty \left\{\int_0^t e^{-rs} E\left[f\left(X_x^{(\hat{\nu})}(\tau_i+s)\right)\Big|\,\mathcal{F}_{\tau_i}\right] ds\right\} dF_T(t) \\ &= \int_0^\infty E\left[\int_0^t e^{-rs} f\left(X_x^{(\hat{\nu})}(\tau_i+s)\right) ds\Big|\mathcal{F}_{\tau_i}\right] dF_T(t) \\ &= \int_0^\infty e^{r\tau_i} E\left[\int_{\tau_i}^{\tau_i+t} f_d\left(X_x^{(\hat{\nu})}(s)\right) ds\Big|\mathcal{F}_{\tau_i}\right] dF_T(t),\end{aligned} \tag{29}$$

where the first equality above is due to the strong Markov property and the last equality is due to the $\mathcal{F}_{\tau_i}$-measurability of $e^{r\tau_i}$. Moreover, note that $X_x^{(\hat{\nu})}(s) = \tilde{X}_{X_x^{(\hat{\nu})}(\tau_i-)}(s)$ when $s = \tau_i + t$. Then, using the strong Markov property again, we obtain

$$\begin{aligned}\int_0^\infty \mathbb{E}\left[e^{-rt}\phi\left(\tilde{X}_{X_x^{(\hat{\nu})}(\tau_i-)}(t)\right)\right] dF_T(t) &= \int_0^\infty E\left[e^{-rt}\phi\left(\tilde{X}_{X_x^{(\hat{\nu})}(\tau_i-)}(\tau_i+t)\right)\Big|\,\mathcal{F}_{\tau_i}\right] dF_T(t) \\ &= \int_0^\infty E\left[e^{-rt}\phi\left(X_x^{(\hat{\nu})}(\tau_i+t)\right)\Big|\,\mathcal{F}_{\tau_i}\right] dF_T(t).\end{aligned} \tag{30}$$

Substituting the alternative expressions derived in (29)-(30) into (28), and multiplying the resulting equation by $e^{-r\tau_i}$ yields

$$\begin{aligned}\mathcal{M}\phi_d(X_x^{(\hat{\nu})}(\tau_i-)) &= e^{-r\tau_i}\left\{K + c\gamma_i X_x^{(\hat{\nu})}(\tau_i-)\right\} \\ &\quad + \int_0^\infty E\left[\int_{\tau_i}^{\tau_i+t} f_d\left(X_x^{(\hat{\nu})}(s)\right) ds\Big|\mathcal{F}_{\tau_i}\right] dF_T(t) \\ &\quad + \int_0^\infty E\left[\phi_d\left(X_x^{(\hat{\nu})}(\tau_i+t)\right)\Big|\,\mathcal{F}_{\tau_i}\right] dF_T(t).\end{aligned} \tag{31}$$

To derive an alternative expression for the last part of the above equation, we take the conditional expectation of the both sides of (21) and obtain that

$$\begin{aligned}E\left[\phi_d\left(X_x^{(\hat{\nu})}(\tau_i+t)\right)\Big|\,\mathcal{F}_{\tau_i}\right] &= E\left[\phi_d\left(X_x^{(\hat{\nu})}(\tau_i)\right)\Big|\,\mathcal{F}_{\tau_i}\right] + \tilde{\sigma}E\left[\int_{\tau_i}^{\tau_i+t}\frac{\partial\phi_d}{\partial x}\left(X_x^{(\hat{\nu})}(t)\right) dB(s)\Big|\mathcal{F}_{\tau_i}\right] \\ &\quad + E\left[\int_{\tau_i}^{\tau_i+t}\tilde{A}\phi_d\left(X_x^{(\hat{\nu})}(s)\right) ds\Big|\mathcal{F}_{\tau_i}\right].\end{aligned}$$

Since $\phi_d\left(X_x^{(\hat{\nu})}(\tau_i)\right)$ is $\mathcal{F}_{\tau_i}$-measurable and $E\left[\int_{\tau_i}^{\tau_i+t}\frac{\partial\phi_d}{\partial x}\left(X_x^{(\hat{\nu})}(t)\right)dB(s)\Big|\mathcal{F}_{\tau_i}\right]=0$, we deduce that

$$E\left[\phi_d\left(X_x^{(\hat{\nu})}(\tau_i+t)\right)\Big|\,\mathcal{F}_{\tau_i}\right]=\phi_d\left(X_x^{(\hat{\nu})}(\tau_i)\right)+E\left[\int_{\tau_i}^{\tau_i+t}\tilde{A}\phi_d\left(X_x^{(\hat{\nu})}(s)\right)ds\Big|\mathcal{F}_{\tau_i}\right].$$

Integrating the above equation with respect to the probability measure induced by T on $[0,\infty)$, and substituting the resulting equation in (31) yields

$$\begin{aligned}\mathcal{M}\phi_d(X_x^{(\hat{\nu})}(\tau_i-))=e^{-r\tau_i}&\left\{K+c\gamma_i X_x^{(\hat{\nu})}(\tau_i-)\right\}\\&+\int_0^\infty E\left[\int_{\tau_i}^{\tau_i+t}f_d\left(X_x^{(\hat{\nu})}(s)\right)ds\Big|\mathcal{F}_{\tau_i}\right]dF_T(t)\\&+\phi_d\left(X_x^{(\hat{\nu})}(\tau_i)\right)+\int_0^\infty E\left[\int_{\tau_i}^{\tau_i+t}\tilde{A}\phi_d\left(X_x^{(\hat{\nu})}(s)\right)ds\Big|\mathcal{F}_{\tau_i}\right]dF_T(t).\end{aligned}$$

Subtracting $\phi_d(X_x^{(\hat{\nu})}(\tau_i-))$ from the both sides of the above equation and rearranging, we have

$$\begin{aligned}\phi_d\left(X_x^{(\hat{\nu})}(\tau_i)\right)-\phi_d(X_x^{(\hat{\nu})}(\tau_i-))&=\mathcal{M}\phi_d(X_x^{(\hat{\nu})}(\tau_i-))-\phi_d(X_x^{(\hat{\nu})}(\tau_i-))\\&-e^{-r\tau_i}\left\{K+c\gamma_i X_x^{(\hat{\nu})}(\tau_i-)\right\}\\&-\int_0^\infty E\left[\int_{\tau_i}^{\tau_i+t}f_d\left(X_x^{(\hat{\nu})}(s)\right)ds\Big|\mathcal{F}_{\tau_i}\right]dF_T(t)\\&-\int_0^\infty E\left[\int_{\tau_i}^{\tau_i+t}\tilde{A}\phi_d\left(X_x^{(\hat{\nu})}(s)\right)ds\Big|\mathcal{F}_{\tau_i}\right]dF_T(t).\end{aligned}$$

Now taking expectation and applying the double expectation formula, it can be deduced that

$$\begin{aligned}E\left[\phi_d\left(X_x^{(\hat{\nu})}(\tau_i)\right)-\phi_d(X_x^{(\hat{\nu})}(\tau_i-))\right]&=E\left[\mathcal{M}\phi_d(X_x^{(\hat{\nu})}(\tau_i-))-\phi_d(X_x^{(\hat{\nu})}(\tau_i-))\right]\\&-E\left[e^{-r\tau_i}\left\{K+c\gamma_i X_x^{(\hat{\nu})}(\tau_i-)\right\}\right]\\&-\int_0^\infty E\left[\int_{\tau_i}^{\tau_i+t}f_d\left(X_x^{(\hat{\nu})}(s)\right)ds\right]dF_T(t)\\&-\int_0^\infty E\left[\int_{\tau_i}^{\tau_i+t}\tilde{A}\phi_d\left(X_x^{(\hat{\nu})}(s)\right)ds\right]dF_T(t).\end{aligned}$$

Moreover, since $E\left[\mathcal{M}\phi_d(X_x^{(\hat{\nu})}(\tau_i-))-\phi_d(X_x^{(\hat{\nu})}(\tau_i-))\right]=0$ on the boundary of the throttling region, we have

$$\begin{aligned}E\left[\phi_d\left(X_x^{(\hat{\nu})}(\tau_i)\right)-\phi_d(X_x^{(\hat{\nu})}(\tau_i-))\right]&=-E\left[e^{-r\tau_i}\left\{K+c\gamma_i X_x^{(\hat{\nu})}(\tau_i-)\right\}\right]\\&-\int_0^\infty E\left[\int_{\tau_i}^{\tau_i+t}f_d\left(X_x^{(\hat{\nu})}(s)\right)ds\right]dF_T(t)\\&-\int_0^\infty E\left[\int_{\tau_i}^{\tau_i+t}\tilde{A}\phi_d\left(X_x^{(\hat{\nu})}(s)\right)ds\right]dF_T(t).\end{aligned}$$

Finally, replacing the expression inside the second term on the left-hand side of (27) by the above expression and simplifying, we get

$$\phi(x) = E\left[\int_0^{\tau_{m+1}} e^{-rs} f(X_x^{(\hat{\nu})}(s))ds + \sum_{i=1}^{m} e^{-r\tau_i}\left\{K + c\gamma_i X_x^{(\hat{\nu})}(\tau_i-)\right\}\right] + E\left[e^{-r\tau_{m+1}}\phi(X_x^{(\hat{\nu})}(\tau_{m+1}-))\right].$$

Note that, Condition (II) implies that $E\left[e^{-r\tau_{m+1}}\phi(X_x^{(\hat{\nu})}(\tau_{m+1}-))\right] \to 0$ as $m \to \infty$. Thus, letting $m \to \infty$ in the above equation yields

$$\phi(x) = E\left[\int_0^{\infty} e^{-rs} f(X_x^{(\hat{\nu})}(s))ds + \sum_{i=1}^{\infty} e^{-r\tau_i}\left\{K + c\gamma_i X_x^{(\hat{\nu})}(\tau_i-)\right\}\right] = C^{(\hat{\nu})}(x).$$

Hence, $\phi(x) = \Phi(x)$ and $u^* = \hat{\nu}$. □

B. DERIVATION OF $R(X)$

Let

$$R(x;t) := \mathbb{E}\left[\int_0^t e^{-rs} f((1-\gamma)\tilde{X}_x(s))ds + e^{-rt}\Phi(\tilde{X}_x(t))\right],$$

then $R(x,\gamma) = \int_0^\infty R(x;t)\lambda e^{-\lambda t}dt$. We first compute $R(x;t)$:

$$\begin{aligned} R(x;t) &= \mathbb{E}\left[\int_0^t e^{-rs} f((1-\gamma)\tilde{X}_x(s))ds + e^{-rt}\Phi(\tilde{X}_x(t))\right] \\ &= \int_0^t e^{-rs}\mathbb{E}\left[f((1-\gamma)\tilde{X}_x(s))\right]ds + e^{-rt}\mathbb{E}\left[\Phi(\tilde{X}_x(t))\right] \\ &= \int_0^t e^{-rs}\mathbb{E}\left[\beta\left((1-\gamma)\tilde{X}_x(s)\right)^2\right]ds + e^{-rt}\mathbb{E}\left[a\tilde{X}_x(t)^{\alpha_1} + \left(\frac{\beta}{r-\sigma^2-2\mu}\right)\tilde{X}_x(t)^2\right] \\ &= \beta(1-\gamma)^2\int_0^t e^{-rs}\mathbb{E}\left[\tilde{X}_x(s)^2\right]ds + ae^{-rt}\mathbb{E}\left[\tilde{X}_x(t)^{\alpha_1}\right] + e^{-rT}\left(\frac{\beta}{r-\sigma^2-2\mu}\right)\mathbb{E}\left[\tilde{X}_x(t)^2\right] \end{aligned}$$

Now by applying (9), we get

$$\begin{aligned} R(x;t) &= \beta(1-\gamma)^2\int_0^t e^{-rs}x^2 e^{(2(\mu-\tilde{\mu}\gamma)+\tilde{\sigma}^2)s}ds + ae^{-rt}x^{\alpha_1}e^{\left((\mu-\tilde{\mu}\gamma)\alpha_1+\frac{1}{2}\tilde{\sigma}^2\alpha_1(\alpha_1-1)\right)t} \\ &\quad + e^{-rt}\left(\frac{\beta}{r-\sigma^2-2\mu}\right)x^2 e^{(2(\mu-\tilde{\mu}\gamma)+\tilde{\sigma}^2)t} \\ &= \beta(1-\gamma)^2x^2\int_0^t e^{-\left(r-2(\mu-\tilde{\mu}\gamma)-\tilde{\sigma}^2\right)s}ds + ax^{\alpha_1}e^{-\left(r-(\mu-\tilde{\mu}\gamma)\alpha_1+\frac{1}{2}\tilde{\sigma}^2\alpha_1(\alpha_1-1)\right)t} \\ &\quad + \left(\frac{\beta x^2}{r-\sigma^2-2\mu}\right)e^{-(r-2(\mu-\tilde{\mu}\gamma)-\tilde{\sigma}^2)t} \\ &= \beta(1-\gamma)^2x^2\frac{\left[1-e^{-\left(r-2(\mu-\tilde{\mu}\gamma)-\tilde{\sigma}^2\right)t}\right]}{[r-2(\mu-\tilde{\mu}\gamma)-\tilde{\sigma}^2]} + ax^{\alpha_1}e^{-\left(r-(\mu-\tilde{\mu}\gamma)\alpha_1+\frac{1}{2}\tilde{\sigma}^2\alpha_1(\alpha_1-1)\right)t} \\ &\quad + \left(\frac{\beta x^2}{r-\sigma^2-2\mu}\right)e^{-(r-2(\mu-\tilde{\mu}\gamma)-\tilde{\sigma}^2)t}, \end{aligned}$$

where the last equality hold with $\left(r - 2(\mu - \tilde{\mu}\gamma) - \tilde{\sigma}^2\right) > 0$.

Finally, we can compute $R(x, \gamma)$ as follows:

$$\begin{aligned}
R(x,\gamma) &= \int_0^\infty R(x;t)\lambda e^{-\lambda t} dt \\
&= \int_0^\infty \beta(1-\gamma)^2 x^2 \frac{\left[1 - e^{-\left(r-2(\mu-\tilde{\mu}\gamma)-\tilde{\sigma}^2\right)t}\right]}{[r - 2(\mu-\tilde{\mu}\gamma) - \tilde{\sigma}^2]} \lambda e^{-\lambda t} dt \\
&\quad + \int_0^\infty a x^{\alpha_1} e^{-\left(r-(\mu-\tilde{\mu}\gamma)\alpha_1 + \frac{1}{2}\tilde{\sigma}^2\alpha_1(\alpha_1-1)\right)t} \lambda e^{-\lambda t} dt \\
&\qquad + \int_0^\infty \left(\frac{\beta x^2}{r - \sigma^2 - 2\mu}\right) e^{-(r-2(\mu-\tilde{\mu}\gamma)-\tilde{\sigma}^2)t} \lambda e^{-\lambda t} dt \\
&= \frac{\beta\lambda(1-\gamma)^2 x^2}{[r - 2(\mu-\tilde{\mu}\gamma) - \tilde{\sigma}^2]} \int_0^\infty \left[e^{-\lambda t} - e^{-\left(r+\lambda-2(\mu-\tilde{\mu}\gamma)-\tilde{\sigma}^2\right)t}\right] dt \\
&\quad + a\lambda x^{\alpha_1} \int_0^\infty e^{-\left(r+\lambda-(\mu-\tilde{\mu}\gamma)\alpha_1 + \frac{1}{2}\tilde{\sigma}^2\alpha_1(\alpha_1-1)\right)t} dt \\
&\qquad + \left(\frac{\beta\lambda x^2}{r - \sigma^2 - 2\mu}\right) \int_0^\infty e^{-(r+\lambda-2(\mu-\tilde{\mu}\gamma)-\tilde{\sigma}^2)t} dt \\
&= \frac{\beta(1-\gamma)^2 x^2}{[r + \lambda - 2(\mu-\tilde{\mu}\gamma) - \tilde{\sigma}^2]} + \frac{a\lambda x^{\alpha_1}}{[r + \lambda - (\mu-\tilde{\mu}\gamma)\alpha_1 + \frac{1}{2}\tilde{\sigma}^2\alpha_1(\alpha_1-1)]} \\
&\qquad + \frac{\beta\lambda x^2}{(r - \sigma^2 - 2\mu)[r + \lambda - 2(\mu-\tilde{\mu}\gamma) - \tilde{\sigma}^2]},
\end{aligned}$$

where the last equality hold with $[r + \lambda - (\mu - \tilde{\mu}\gamma)\alpha_1 + \frac{1}{2}\tilde{\sigma}^2\alpha_1(\alpha_1 - 1)] > 0$.

C. PROOF OF PROPOSITION 2

Let $x > 0$ and consider a continuously differentiable solution $\Phi(x)$ of (12)-(15). Then, under the given conditions, we need to prove that (i) $A\Phi(x) + f(x) = 0$ and $\Phi(x) < \mathcal{M}\Phi(x)$ whenever $x \in (0, U)$, and (ii) $A\Phi(x) + f(x) > 0$ and $\Phi(x) = \mathcal{M}\Phi(x)$ whenever $x \in [U, \infty)$.

We first prove (i). For this, note that $\Phi(x)$ is derived from the equation $A\Phi(x) + f(x) = 0$ for $x \in (0, U)$. Thus, we only need to verify that $\Phi(x) < \mathcal{M}\Phi(x)$ for $x \in (0, U)$, which is also implied immediately by Condition (17).

Next for (ii), note that for $x \in [U, \infty)$, $\Phi(x)$ is derived such that $\Phi(x) = \mathcal{M}\Phi(x)$. Thus, we only need to validate that $A\Phi(x) + f(x) > 0$ for $x \in [U, \infty)$. We conclude the proof with this required step. Note that for $x \in [U, \infty)$, we have

$$\begin{aligned}
A\Phi(x) + f(x) &= \mu x \frac{\partial \Phi(x)}{\partial x} + \frac{1}{2}\sigma^2 x^2 \frac{\partial^2 \Phi(x)}{\partial x^2} - r\Phi(x) + f(x) \\
&= \mu x c\Upsilon - r\left(K + c\Upsilon x + R(U, \Upsilon)\right) + \beta x^2 \\
&= \beta x^2 + (\mu - r)c\Upsilon x - r[K + R(U, \Upsilon)].
\end{aligned}$$

Thus, $A\Phi(x) + f(x)$ is a convex and quadratic function of x; moreover, the value of this function at

$x = 0$ is negative. Therefore, $A\Phi(x) + f(x)$ should be clearly positive for all $x > x_0$, where

$$x_0 := \frac{-(\mu - r)c\Upsilon + \{(\mu - r)^2 c^2 \Upsilon^2 + 4\beta r[K + R(U, \Upsilon)]\}^{\frac{1}{2}}}{2\beta}$$

is the positive root of $A\Phi(x) + f(x) = 0$. Condition (16) yields that $x_0 < U$. Consequently, $x_0 < U \leq x$ and we have the desired result. □

D. NUMERICAL SIMULATIONS TO VALIDATE $-\tilde{\mu}_G > 0$.

Behavioral Finance and the Architecture of the Asset Management Industry

Michel Verlaine
Michel.verlaine@icn-artem.com

ABSTRACT

The standard portfolio approach assumes that investors maximize Expected Utility functions and that the Markowitz Mean-Variance Standard Portfolio Optimization approach can be applied. Behavioral Research, however, indicates that investors' behavior with respect to risk or uncertainty is not consistent with EU. Notably, decision makers transform probabilities. Most of the academic literature integrating those aspects, however, focuses on so-called financial market anomalies but does not focus on the structural impact those behavioral aspects might have, notably in terms of industrial organization of the asset management industry. This paper analyzes the industrial organization of the asset management industry and argues that the architecture of the asset management industry is inconsistent with the standard EU framework. The origin of the industrial organization of the asset management industry stems from the convexity of the Flow-performance relationship, which is due to Prospect Theory effects. The convexity of the Flow-performance relationship explains the inflation of Mutual Funds and Fund families, a phenomenon inconsistent with the Mutual Fund Separation Theorem..

KEYWORDS:: Portfolio Choice, Behavior under Uncertainty, Behavioral Industrial Organization.

JEL classification: G11, D82, N2.

INTRODUCTION

Most of the academic literature in Behavioral Finance focuses on so-called financial market anomalies that cannot be explained by the standard rationality assumptions in Economics. An extensive literature has been developed over the last two decades. (Benartzi & Thaler, 2003) provide a somewhat older survey and a more recent account of the literature can be found in (Benartzi, 2018). As the reader of those surveys will readily notice, those surveys exclusively analyze the impact of deviations from rationality on asset markets. In a sense, this literature analyzes how behavioral aspects generate financial market anomalies. More recently, a new literature called Behavioral Corporate Finance has been developed. (Malmendier, 2018) surveys this literature and points out that until recently research on the impact of behavioral aspects on Corporate Finance decisions has been very low. Yet, recently, research on Behavioral Corporate Finance has become a strong sub-field.

Strangely, the academic research that focuses on the industrial organization of the asset management industry is weak or nearly non-existent. This is a pity as the understanding of the value chain of the financial industry is important to understand its Business Models, notably how they evolve through time and adapt to technological factors (FinTech) and behavioral shifts of stakeholders. With the growth of the AM Industry, the understanding of those value chains and eventual relocation strategies of sub-units of Financial Institutions has become even more relevant and eventually important for political decision makers. What we call the Architecture of Finance is the way the finance industry is structured with its different financial institutions. We thus distinguish different institutions such as Banks, Insurance companies, different types of funds (Mutual Funds, Alternative Investment funds) as well as the emergence of new intermediary structures such as Shadow Banks. The evolutionary process of those institutions can be analyzed through technological and behavioral aspects. A similar approach has been developed for financial markets. (Lo, 2017) has put forward the Adaptive Markets Hypothesis in comparison to the Efficient Markets Hypothesis. The idea is to analyze Financial Markets movements through evolutionary and adaptive mechanisms of “institutional traders” rather than rational and individual investors.

The underlying idea is that in order to understand the existence and the transformations of this Architecture we need to add frictions such as asymmetry of information, cognitive frictions and regulatory frictions. The latter, however, can be seen as derived from the two first types of frictions. Indeed, financial regulation exists in order to protect economic agents against others exploiting “irrationalities” and situations of asymmetry of information.

We are, here, interested in the “Architecture of the Asset Management Industry” an account of which in relation to behavioral aspects is provided in (Verlaine, 2016). Of central importance to understand why behavioral aspects matter to explain the Architecture of Finance is the Mutual Fund Separation Theorem (Tobin, 1958) and its questioning, namely the Asset Allocation Puzzle. Indeed, the Mutual Fund Separation Theorem states that “rational” investors with similar information sets should invest in a risky portfolio and mix this portfolio with the risk free asset. It means that whatever the risk aversions of investors, they should hold similar risky portfolios. This is a very strong prediction and it can be viewed as some kind of Modigliani-Miller Theorem for the Asset Management Industry, indicating what we should observe in a frictionless equilibrium. Basically, if we were to analyze the asset allocations of investors we should observe relatively balanced risky portfolios or funds combined with investments in non-risky investments, let’s say government bonds. This is not what we observe. Most small investors hold non-diversified portfolios of a few stocks. But recommendations of asset management firms as well are not in line with the Mutual Fund Separation Theorem (MFST). (Canner et al, 1997) were the first to document the inconsistency between asset allocation recommendations of investment advisors for different risk profiles of investors. This phenomenon is called the Asset Allocation Puzzle. Frictions such as background risk and transaction costs might explain some deviations from the MFST but are insufficient to explain the empirical differences. Strangely, not much has been published on that phenomenon.

The Mutual Fund Separation Theorem is not only important as a guide, and some professionals might say a bad guide, for portfolio construction. It is also a major building block of general equilibrium financial market models such as the Capital Asset Pricing Models and it hence also has an impact on valuation models in Corporate Finance. As far as equilibrium asset pricing is concerned, there has been some elaboration by adding further frictions to the CAPM model (Fama & French, 1993). The fundamental portfolio choice approach and its implications for the finance industry, however, have not been questioned. Recently, (Markowitz, 2014) analyzed the conditions for the Mean-Variance approach to portfolio choice. He points out that most Expected utility functions support Mean-Variance optimization but that models with probability weighting do not support Mean-Variance optimization. Empirical evidence on individual behavior indicates that most individuals act according to Prospect theory (Bruhin et al, 2010); Wakker, 2010). This implies that they are loss averse and transform observed probability distributions. Some tentative approaches to portfolio optimization have been developed notably by (Shefrin & Statman, 2000), but they are not very operational. Recent publications in operational research indicate an interest in decision-theoretic approaches, ambiguity and risk management (Borgonovo & Marinacci, 2015;

Borgonovo et al, 2018; Cerreia-Voglio et al, 2013). A first attempt to apply those concepts to the Fund Industry can be found in (Verlaine, 2018).

Focusing more on the industrial organization of the Asset Management Industry, the first attempt to analyze fund vehicles rather than individual investors seems (Berk & Green, 2004). Their approach, however, is based on standard neoclassical assumptions of rationality. The core element is the flow-performance relationship which indicates the sensitivity of in- and out-flows of the Fund as a function of abnormal performance. This abnormal performance is typically measured with the Carhart 4-factor model and for sophisticated investors the relationship should be linear. The neoclassical assumption is that costs in percentage should decrease with AUM, but alpha as well and faster. There hence exists an industry equilibrium where funds attract in-flows as long as alpha is higher than the fees, until the fees are equal to the alpha. The cross-section data of investment funds should thus indicate a positive relationship between alpha and fees, where in the long run equilibrium abnormal performance after fees is 0. The US data, however, indicates that the relationship between fees and alpha is negative. Funds with lower performance have higher fees (Gil-Basu & Ruiz-Verdu, 2009).

The flow-performance relationship is of central importance to understand that phenomenon. Indeed, the flow-performance relationship is not linear as presumed by neo-classical economic theory but non-linear and more or less convex. This means that inflows are much more sensitive to good performance than outflows to bad performance. This phenomenon can be linked to behavioral aspects such as the asymmetric behavior with respect to gains and losses implicit in Prospect Theory. This non-linearity is of central importance as it provides an explanation of the multitude of funds and families of funds, an empirical fact inconsistent with the MFST. Asset Management firms facing a convex flow-performance relationship can launch a family of funds that ex-ante have similar return profiles. As the realized returns ex-post will differ, the funds can then promote the best performing fund which then attracts higher inflows.

The paper is organized as follows. Section I presents the Investor Behavior and the portfolio delegation issues that go with it. Section II then analyses the relationship between fees and fund performance. The observed fee anomaly then leads us to analyse the impact of the Board composition on the fee setting process in Section III. Section IV focuses on the behavioral aspects behind the convexity of the flow-performance relationship. Section V analyses whether the distribution channels could have an impact on the fee-performance anomaly. Section VI and VII analyze the impact on the outsourcing and internalization. Finally, Section VIII explains how the behavioral features that lead to convex flow-performance relationships can be exploited within fund families.

INVESTOR BEHAVIOUR AND PORTFOLIO DELEGATION ISSUES

Standard Markowitz portfolio theory presumes that investors are EU maximizers with a concave Bernouilli utility function. The decision theoretic and behavioral economics literature, however, highlights that most individuals' behavior is not consistent with the EU hypothesis. Recent experimental evidence is provided in (Bruhin et al, 2010). (Kahneman & Tversky, 1979; 1992), document that individuals evaluate gains and losses with respect to a subjective reference level. Their so-called value function is concave on gains and convex on losses. Moreover, investors are strongly averse to losses. This has led to the following well-known specification:

$$v(w-\overline{w}) = \begin{cases} (w-\overline{w})^{\alpha} & if \quad w \geq \overline{w} \\ -\lambda(w-\overline{w})^{\beta} & if \quad w < \overline{w} \end{cases} \tag{1}$$

Where w and $\overline{w}$ respectively denote the realized wealth and the subjective reference wealth level. λ is the loss aversion parameter and is typically calibrated to 2.25. α and β are generally calibrated to 0.88.

Investors also transform observed probabilities and the way these probabilities are distorted is well-documented (Tversky & Wakker, 1995; Wakker, 2010; Prelec, 1998). Investors typically apply inverse S-shaped functions, called probability weighting functions, to the cumulative probability distribution. Recent research indicates that such behavior could stem from a kind of ambiguity aversion. Frameworks to treat ambiguity have been developed by (Gilboa & Schmeidler, 1989; Schmeidler, 1989). Those authors suggest that DMs maximize EU under the worst case scenario given sets of probability distributions. (Schmeidler, 1989) shows that relaxations of the independence axiom lead to a preference representation with respect to a non-additive set measure. This model is known as the Choquet Expected Utility (CEU) model. (Ghirardato et al, 2004) suggest to model behavior in the face of ambiguity with a weighted $(\alpha, 1-\alpha)$ combination of the worst and the best scenarios. This has led to the $\alpha - MEU$ approach where α is interpreted as a parameter of ambiguity aversion. Recently, (Amarante, 2009) shows that $\alpha - MEU$ can be mapped on CEU representations. Finally, a last dimension that is often forgotten in the literature, is that DMs also typically consider prospects in different mental accounts. This opens the door for multiple investment styles and funds. This provides an explanation of the asset Allocation Puzzle (Canner et al, 1997). The academic literature, however, has faced difficulties to integrate those behavioral aspects into an operational portfolio optimization framework.

(Shefrin & Statman, 2000) develop a portfolio optimization approach that is consistent with empirically documented behavior. They argue that there are three dimensions that matter for the DM: *potential*, *aspiration* and *security*. *Aspiration* indicates the level of wealth expected or desired by the DM. *Security* refers to the desire to limit losses with respect to the aspiration level. Finally, *potential* indicates that DMs want to invest a fraction in assets that have a very small probability of very high payoffs such as lottery tickets. This is in line with the well-documented fact that DMs buy insurance as well as lottery tickets. The three dimensions are linked to different behavioral aspects of prospect theory. Besides behavioral aspects, institutional features are also important to take into account and are actually conditioned by behavioral features. (Verlaine, 2016) provides a detailed analysis of this topic. (Polkovnichenko & Zhao, 2013) show that the risk neutral probability distribution implicit in option prices is consistent with probability weighting behavior. They estimate parameters for the (Prelec, 1998) probability weighting function. (Polkovnichenko, et al, 2018) show that those probability weighting features can explain the demand for active funds. This thus rationalizes the delegation of asset management to active asset managers and opens the door for information economics and principal-agent problems in asset management.

As argued in (Verlaine, 2018), the optimal contracts with the asset managers bear a close relationship with the risk management of the fund and behavioral aspects thus also influence the optimal contract. (Stracca, 2005) surveys the delegation issues in portfolio management. The delegation problem is typically modelled through a Principal-Agent relationship. The investor is the Principal and the Agent is the Asset Manager. The portfolio delegation literature focuses on contractual issues. In a first step, the investors face a set of Managers and have to select the good ones that have the skills to generate outperformance. In a second step, the contract and the compensation rules have to incentivize the Manager to spend maximal effort to generate outperformance. The investors are thus supposed to structure the contract in such a way that 3 conditions be respected. First, the managers with superior skills are selected. Second, the contract incentivizes the Asset Manager to generate risk-adjusted outperformance once the contract is signed. Finally, the risk-sharing between the investor and the Asset Manager should also be optimal.

Formally, the maximization problem takes the following form.
In the first order the Principal maximizes his expected utility given by :

$$\begin{aligned} &Max_f\, EU((1+R)-f(R)) \\ &with\, R = w(S(e))R_p \end{aligned} \tag{2}$$

He thus maximizes expected utility of gross return minus the fees. But in order to hire a manager he also needs to be sure that the expected utility of the return is higher than what he gets if he simply invests in a passively managed fund. Hence, the following participation constraint has to hold:

$$EU(1+R-f(R)) \geq EU(1+R_u) \tag{3}$$

So basically, the EU of the gross net of fees return has to be higher than what the investor gets when he invests in an Exchange Traded Funds, for instance.
The manager also maximizes utility and faces a participation contraint.

$$e, w(S) = \arg\max\left[EU(f(R)) - h(e)\right] \tag{4}$$

So the manager chooses an optimal effort level and portfolio combination so that he maximizes EU of fees perceived minus his disutility of effort *h(e)*. However, the following participation constraint

$$EU(f(R)-h(e)) \geq U^* \tag{5}$$

indicates that he is only working for the investors if the expected utility of the fee minus disutility of effort is higher than the utility he gets in another job.
Different fee functions have been suggested, but they all face the drawback that, due to the fact that there is no direct relationship between effort spent by the manager and portfolio return, it is extremely difficult to make sure the manager spends effort and that the returns are due to luck or hidden risks. Basically, there are two types of contracts, linear and non-linear, which we analyse below.

The linear compensation contract takes the following form:

$$\begin{aligned} &f(R) = C + B(R-b) \\ &with\ C, B > 0 \end{aligned} \tag{6}$$

b is a subjective benchmark that is known in advance and it can be either stochastic or fixed. A behavioral approach implies the evaluation of this subjective benchmark for a prospect theory type decision maker and then the choice of an investment fund benchmark that has the same expected return. Typically Mutual Funds are benchmarked with a stochastic market based benchmark, generally given by an index that reflects the strategy of the fund. Hedge Funds, however, are mostly benchmarked with an absolute target which is given by the Hurdle rate. Hedge Funds often also have so-called High-water mark clauses which specify that past losses with respect to the benchmark have to be made up before the variable fees are paid. As shown by (Brown & Goetzmann, 2003) this creates path dependent option like features which are difficult to analyse within this framework. Within the linear contract framework, a higher B induces the manager to spend more effort but also to take more risk which will increase the required flat payment C.

In the standard agency setting, there is a trade-off between risk sharing and effort inducement. However, in a portfolio delegation framework this kind of contract is insufficient to induce the manager to work harder as the manager has complete control over his response to signals (his information). This result is known as the 'irrelevance result'. This result holds irrespective of whether the contract contains a benchmark. A benchmark, unless it is the optimal conditional portfolio, is a distorting factor.

The non-linear compensation contract has also been suggested as an optimal compensation rule:

$$f(R) = C + B(R-b)^2 \quad with \;\; C, B > 0 \tag{7}$$

Here, compensation depends in a quadratic way on the relative performance compared to a benchmark. It can induce the manager to undertake more effort. However, if the manager is allowed to respond to the signal in a nonlinear way, the 'irrelevance result' still holds. Hence, restrictions have to be imposed on the manager's trading set. This is an interesting result in terms of industry regulation.
Finally, linear vs. non-linear asymmetric contracts

$$f(R) = \begin{cases} \mathrm{C + B(R - b)} \;\; \text{if} \;\; \mathrm{R > b} \\ \quad 0 \;\; \text{if} \qquad\quad \mathrm{R < b} \end{cases} \tag{8}$$

Symmetric contracts penalize negative outcomes in the same way as they reward positive outcomes, while for convex contracts the marginal reward is higher the better the performance compared to a benchmark. The "irrelevance result" and the fact that restrictions on the trading set have to be imposed rationalizes the recourse to risk management and risk limits. The Board's responsibility in terms of risk management is thus to select a benchmark that is in line with the risk profile of the fund and determine the risk limit or limits of the fund or positions. The foregoing developments imply that the Board has to develop a top-down approach to the risk management and measurement.

The function of the benchmark is also to distinguish performance related to systematic risk factors from performance due to superior selection skills. From an operational viewpoint, the role of the benchmark is also to control the deviation of the portfolio with respect to the benchmark. As pointed out in (CMRA, 2008), the main risk is that the performance will fall short of the benchmark. Finally, benchmarks are also often used to compare fund performance to the benchmark. Correct benchmarking is an issue and (Sensoy, 2009) suggests that approximately 35% of benchmarks are not in line with the risk profile of the fund.

Deviations from the benchmark are typically controlled through the trading error variance (TEV). This is in line with the quadratic compensation rule above. If we apply the expectation operator to the quadratic compensation rule we get:

$$\begin{aligned} E[f(R)] &= C + BE\left[(R-b)^2\right] \\ &= C + B \times TEV \end{aligned} \tag{9}$$

And the compensation thus depends on the TEV. Even though this approach is quite used in practice, the TEV evaluates positive and negative deviations from the benchmark in the same way.
The next sections focus on the different features of the asset management industry highlighting the behavioral and contractual features that seem inconsistent with the standard neoclassical EU assumptions.

ANALYSIS OF THE RELATIONSHIP BETWEEN FEES AND PERFORMANCE

In principle, there should be a positive relationship between before-fee performance and fees in the fund industry. According to some recent research, however, the relationship is negative (Gil-Bazu, & Ruiz-Verdu, 2009). It might be worthwhile highlighting that Fund management fees are typically computed as a fixed percentage of the value of AUM. These fees, together with other operating costs, such as custodian, administration, accounting, registration and transfer agent fees, comprise the fund's expenses. Expenses are usually expressed as a percentage of AUM known as the expense ratio. Fees paid to brokers in the course of the trading activity are detracted from the fund's assets but are not included in the fund's assets. Distribution fees also matter but, in general, they are included in the operating expenses. Funds often charge "loads", which are one time fees that are used to pay distribution. The "loads" are paid at the time of purchasing ("front-end loads") or redeeming ("back-end loads" or "deferred sales charge") fund shares and are computed as the fraction of the amount invested. Since 1980, funds may charge so-called "12b-1 fees", which are included in the expense ratio. Since 1990, many funds offer multiple share classes with different combinations of "loads" and "12b-1 fees" (f.i. high front-end loads and low annual 12b-1 fees or vice-versa).

In order to analyse the relationship between performance and fees, (Gil-Bazu, & Ruiz-Verdu, 2009) focus on a specific Mutual Fund sample. First, all funds that cannot be described as diversified domestic equity mutual funds are excluded from the sample. Second, observations with extreme values for returns and expenses are also removed from the sample (outliers). Finally, to ensure that results are not driven by differences between index and actively managed funds or between institutional and retail funds, passively managed (index) and institutional funds are excluded from the sample.

As the aim of the board members should be to care about shareholders' interests, Fund Governance issues matter for the fee setting process. The measure of the board quality is the sum of four equally weighted components that measure:

- The degree to which the board has taken action "in cases where the fund clearly has not served investors well".
- The significance of independent director's investments in the fund.
- Whether the board is "overseeing so many funds that it may compromise the ability to diligently protect interests of shareholders".
- The proportion of independent directors.

The authors are interested in comparing before-fee risk-adjusted performance to fees. In order to determine that performance, a model is needed. Different models could be used, but market standard has become the (Carhart, 1997) 4-factor or (Fama & French, 1993) 3-factor model. Carhart's model is used extensively as it encompasses the Fama-French model. The specification is the following:

$$r_{it} = \alpha_i + \beta_{rm,i} rm_t + \beta_{hml,i} hml_t + \beta_{smb,i} smb_t + \beta_{pr1y,i} pr1y_t + \varepsilon_{it} \tag{10}$$

Where smb and hml denote returns on portfolios that proxy for common risk factors associated with size and book-to-market, respectively. The term pr1yt is the return difference between stocks with high and low returns in the previous year. This term accounts for passive momentum strategies. r_{it} is the fund's before-expense return in month t in excess of the 30-day risk-free interest rate. The alpha is supposed to capture the fund's before-fee risk adjusted performance.

Suppose that this model were a good approximation for the data generating mechanism. What should be the fees of the funds in equilibrium? Well, in the absence of frictions, all funds should earn zero expected after-fee risk-adjusted returns. Otherwise, there would be excess demand for funds with positive after-fee risk-adjusted return (Berk & Green, 2004). Thus, if investors knew the fund alphas, in equilibrium we should observe $\alpha_i = f_i \ \forall_i$ and there should thus exist an approximately linear relationship of slope 1 between fees and alphas. If investors do not know the alphas then the equilibrium relationship takes the form of an expectation: $E(\alpha_i) = f_i \ \forall_i$.

What are the equilibrium adjustment mechanisms in place? Equilibrium in the MF market can be achieved through fee adjustments if funds with higher expected before-fee risk-adjusted returns increase their fees or underperforming funds lower theirs. (Berk & Green, 2004) show that in the market for MF's, market clearing can also be via quantity adjustments. If there are decreasing returns to scale in fund management, then flows of money into funds that are expected to perform better will reduce these funds' expected performance until after-fee expected returns are equalized across all funds in equilibrium. The equilibrium will require that expected after-fee risk-adjusted returns be zero for all funds and that there exists a linear relationship of slope 1 between fees and before-fee performance. In order to test this assumption, fund fees and before-fee risk-adjusted performance is regressed by pooled OLS regression:

$$\hat{\alpha}_{it} = \delta_{0t} + \delta_1 f_{it} + \varepsilon_{it},\ i = 1, \dots, N,\ t = 1, \dots, T \tag{11}$$

Where f_{it} is the fund's expense ratio expressed as a fraction of fund's assets. Alpha is the risk-adjusted before-fee performance measured according to Carhart's 4-factor model.

The results of the estimation indicate a slope coefficient that is between -1 and -0.5 and the null hypothesis of a unit slope is strongly rejected. This result is in stark contrast with the equilibrium predicted in a frictionless economy. In a market with frictions, however, we might observe deviations from unit slope and it is difficult to forecast whether the slope should be higher or lower. Managers should generate positive alpha and could over- or under-compensate for their respective performance. It might also be plausible that there exists no relationship between fees and alphas, which would lead to the slope being 0. However, the slope being negative, it suggests that worse-performing funds charge higher fees. It might be that the results are partly due to estimation errors. There might be estimation errors in the Carhart regression and these estimation errors might impact the estimates of the (alpha, fee) regression. (Gil-Bazo & Ruiz-Verdu, 2009) show by non-parametric techniques that the relationship is negative and robust to extreme cases. Moreover, it holds over different sub-periods.

The relationship warrants some explanations. There are 3 potential types of explanations:

- Cost-based explanations
- Strategic explanations
- Fund Governance explanations

Cost-based explanations:

Fees might simply reflect operating costs of the fund and low-operating cost funds might have high before-fee risk-adjusted performance. This would thus explain the negative relationship. Two rationales are suggested. First, economies of scale might lead to lower operating costs for larger funds and performance persistence might lead to better performing funds becoming larger. Second, better management skills might lead to better investment decisions and efficient management of fund operations.

Strategic explanations:

The relationship might be the result of some strategic fee setting.

First, (Christofferson & Musto, 2002) argue that fund's investors differ in their performance sensitivity. Also, funds with bad performance history face out-flows and mainly stay with performance insensitive investors. In order to compensate for losses, they might increase fees which would lead to a negative relationship between risk-adjusted performance and fees.

Second, (Gil-Bazo & Ruiz-Verdu, 2008) argue that competition in a market with asymmetric information might lead to an equilibrium in which funds with higher return expectations reduce their fees up to the point where they price lower return expectation funds out of the performance sensitive share of the market. Moreover, as the fee is a fraction of AUM and as the expected value increase is higher for "good" funds, they can expect a value increase in fees. "Bad" funds will then raise fees in order to extract rents from performance insensitive investors.

Third, low-performing funds might face higher marketing and distribution costs. Insensitive investors are less sensitive to marketing material and the costs and time spent to convince them to invest in the fund might be higher. Moreover, distributors might ask for a premium for the extra-effort and eventual reputation risk they face.

Fund Governance:

The strategic explanation implicitly assumed that fees are set by the management company, but fund fees are negotiated with the board of directors. The latter have the fiduciary duty to make sure that the fees are in line with the added value they provide investors. There are some conflicts of interest, however, as the board members are selected by the management company. The directors interests might thus be more aligned with that of the management company than with investors. It can be expected that boards of better governed funds might ensure that fees are in line with value added. It means that the relationship between performance and fees should be positive or flatter for good-governed funds.

To test the different suggested explanations the fees are regressed against fund characteristics, flow-to-performance sensitivity and performance. Fund fees are assumed to linearly depend on a vector x_{t-1} of variables supposed to determine fund operating costs, the performance sensitivity of fund flows, S_t, and the fund's expected before-fee performance in period t, α_t.

$$f_{it} = \gamma' x_{it-1} + \lambda_S S_{it} + \lambda_S \alpha_{it} + v_{it} \tag{12}$$

With $E(v_{it}) = 0 \;\; and \;\; \sigma_v^2 = c$

Most of the variables are only available on a yearly basis and *t* thus refers to years. The following variables are supposed to impact the operating costs of the fund:

- Size: defined as the log of the year-end total NAV
- Age: computed as the log of the fund's years since inception
- Volatility: The standard deviation of log returns
- Reported annual turnover
- Investment objectives: represented through dummies

In order to test whether the negative relationship between performance and fees stems from the omission of the variables determining operational costs, the above- mentioned relation is first estimated without the performance sensitivity. The results indicate that the coefficient on alpha does not change sign and is still negative (-14.65) and thus cost-based arguments cannot explain why fees and performance are negatively related. The relationship is then re-estimated with the performance-sensitivity variable. The latter is highly significant and this seems to confirm that funds strategically exploit a low elasticity of demand with respect to performance to increase their fees. However, the coefficient on alpha is still negative and this is thus not sufficient to explain why underperforming funds have higher fees. Does fund governance have an influence on the fee structure? In order to test this assumption, the regression is implemented for different governance-rated sub-groups. The results indicate that better-governed funds resist the attempts to exploit performance-insensitivities of investors, as the relationship between performance and fees is flatter. This leads us to the question of the impact of the board structure on fees.

THE IMPACT OF THE BOARD STRUCTURE ON FEES

It is interesting to focus more in detail on the fee-setting process. Note that the fees have to be approved by the Board and the latter might thus have an impact on the % of fees charged to service providers. (Tufano & Sevick, 1997) analyse the relationship between Board composition and fees in more detail. As in any business, Boards are legally charged with the protection of shareholders' interests. In the fund business, this implies that they have to negotiate and approve the contracts with the management company, the distributor and other eventual service providers. Note, however, that in the fund industry there is a major specificity that is non-existent in other businesses. Indeed, the shareholder structure can rapidly change with different investors investing and redeeming their shares on a daily basis. Moreover, many funds are launched by fund sponsors, firms that manage and distribute a whole set of funds called fund families. Those sponsors typically choose the dependent as well as the independent board members (directors) at the inception of the fund. Those board members often sit in different funds of the fund family. Such a constellation might lead to conflicts of interest as the board members might not be representative of the shareholders when the shareholder structure of the fund changes.

A simple example will help illustrate the problem. Assume that a sponsor launches a fund by putting 10 Mio $ in the fund in order to kick-start it. At the same time the sponsor selects the board members. At inception, as the sponsor is also the only investor (shareholder), the interests of the sponsor, the Board and the shareholders are aligned. Now, assume that new investors step in and that the fund grows to 100 Mio $ AUM. Those investors are not affiliated with the sponsor but the board composition is still the same as at inception. Potential conflicts of interest might arise as for most of the shareholders, lower fees are in their interest, whereas for the fund sponsor it might be interesting to increase fees in order to increase income. As board members might be dependent on the compensation provided by the sponsor, notably on other funds distributed by the sponsor, they might align their interests with the ones of the sponsor.

In order to evaluate this potential governance issue, (Tufano & Sevick, 1997) analyse a sample of US open-end mutual funds which account for 69% of all US open-end mutual fund assets. The following characteristics of mutual fund boards are analysed:

- Board size
- The fraction of independent directors in the board
- The number of boards on which a board member represents a particular sponsor
- The compensation of the board members

In the US, the regulator requires that a certain percentage (around 40%) of fund board members are not affiliated with the sponsor, underwriter or broker. Also, amongst other responsibilities the fund directors are legally responsible to

- Evaluate and approve contracts and fees with the fund sponsor, the distributor and other service providers.
- Select the accountants
- Oversee the compliance of the securities transactions
- Check the NAV valuation process

We focus, here, on the responsibilities that are the most relevant from the economic viewpoint. The rationality and the asymmetry of information play a major role. If investors were well-informed and rational, they would disinvest of funds that are not well-governed and that have high fees compared to their performance. However, investors are subject to many cognitive frictions and there exist many layers of informational asymmetry.

In the respective dataset analysed by the authors, the average board has approximately 9 members with about 6 independent members. Still, there is considerable variation amongst boards and all funds have more independent directors than what is required by the regulator. On average directors sit on 16 boards within a fund family and, in principle, work exclusively for one fund sponsor. In order to evaluate the effect of board concentration, Tufano and Sevick measure the so-called independent director's asset share. It is calculated by dividing the assets under oversight by the board member, by the total assets under management by the sponsor. For instance, if total AUM of the sponsor amount to 100 Mio $ and the board member sits on 4 boards of funds having 20 Mio $ AUM, then the asset share of the board member is 0.8.

This measure is then used to calculate the board and sponsor concentration measures. The board concentration measures the fraction of assets overseen by a typical board and sponsor concentration the average fraction overseen by the average director of the sponsor. In the respective sample, the average sponsor concentration is 0.8. Nevertheless, there is strong variation amongst fund sponsors as the average concentration shifts between 0.1 and 1! A typical independent director earns around 60,000$ and is compensated through different board memberships provided by one sponsor. As already mentioned, he is thus partly dependent on the sponsor's decision to renew his board membership.

The question is whether and how this will impact the level of fees. Still, fund fees might be impacted by other factors as well. The following factors are known to impact the level of fees.

- Economies of scale which might exist at the fund and sponsor level. There is evidence (Figure 3 to Figure 6 in the Appendix) that fund costs in percentage decrease with AUM. At the fund family level there might exist synergies in terms of research.
- The age of the fund. The literature documents a relationship between age and fees, even though the mechanisms are not clear yet.
- Performance. In Principle a positive relationship could be expected, but empirically the relationship seems negative.
- Investment styles. As Figure 7 indicates, total production costs differ for different kinds of Funds.
- The distribution channel might impact fees as the cost of marketing the fund varies for different investment vehicles.

Those variables are typically used to statistically isolate their impact on fees independently of board governance issues. After careful analysis, Tufano and Sevick find economies of scale at the fund as well as the sponsor level. They also find a positive relationship between fund age and fees, which might be explained by more experienced funds charging higher fees. We know already that there is no or a negative relationship between performance and fees. After isolating all those factors, the authors find out that board structure matters. Notably, larger boards charge higher fees, whereas for a given size, boards with a higher fraction of independent directors charge lower fees. The share of assets overseen by independent directors is also negatively related with fees. The funds whose independent directors sit on many boards of the sponsor have lower fees.

BEHAVIOURAL ASPECTS OF THE FLOW-PERFORMANCE RELATIONSHIP AND MARKET SHARES

From the foregoing section, it is evident that the Flow-performance relationship plays a major role for the (Berke & Green, 2004)) rational adjustment mechanisms to work. As the Flow-Performance relationship is not linear, the so-called rational industry equilibrium is unlikely to be realized. In order to better understand the industry adjustment mechanisms it is thus important to better understand the behavioural aspects underpinning the Flow-performance relationship. A first explanation that comes to mind is that the relationship could be explained by the Kahneman-Tversky Prospect Theory Framework. More recently, some authors have also analysed learning effects to explain the empirically observed convexity of the Flow-Performance relationship.

In a recent paper, (Chang et al, 2016) analyse how the Flow-Performance relationship could be related to the so-called disposition effect. One of the largely documented phenomena in Behavioural Finance is the disposition effect (Shefrin & Statman, 1985). Individual investors tend to sell winning stocks but stick (too long at least) to losing stocks. Even though the phenomenon seems well-documented there doesn't seem to exist a commonly accepted explanation. (Chang et al, 2016) suggest an explanation together with a clever approach to test it through the analysis of selling and buying decisions of stocks and funds. They first note that the disposition effect is reversed in the case of funds as investors have a greater tendency to sell losing funds and invest in good performing funds. As already alluded to earlier, this is evident from the performance-flow relationship, even though the relationship is not linear but convex. More generally, this positive relationship seems to hold for existing as well as new investors.

The above-mentioned authors note that the disposition effect can be explained with Festinger's Cognitive Dissonance effect (Festinger, 1957). Cognitive Dissonance typically arises when a Decision Maker takes decisions that are inconsistent with its self-image. For instance, for an investor to make losses on his investment is inconsistent with his self-image of being a good investor. The point is that as the long as the investor doesn't sell the asset which is losing in value, the losses are not realized and he can still convince himself that this is a short term dip and the market is wrong! This, let's say subjective conviction, thus enables him not to take the negative blow to his self-image. Cognitive Dissonance hence rationalizes the aversion for realized losses and the tendency to realize gains, the latter providing a positive blow to the self-image.

If we consider the fund industry, however, investments are typically delegated to a manager. This relationship is analysed through the Principal-Agent model. The investor (the Principal) can thus blame the manager (the Agent) if the performance is not good and/or the fund loses in value. In the case of a delegated investment there is thus no cognitive dissonance involved on the side of the investor. Those insights lead the authors to the following predictions.

- Non-delegated assets will exhibit a disposition effect and delegated assets display a lesser or reverse disposition effect. This difference is stemming from behavioural biases.
- If investor's cognitive dissonance is strong, it leads to a larger disposition effect in non-delegated assets and a larger reverse disposition effect in delegated assets (funds). Inversely for low levels of cognitive dissonance.
- For investors that focus more on the fund manager's role, the reverse disposition effect is stronger.

(Chang et al, 2016) analyse the (Barber & Odean, 2000) individual investor trading data and come up with the following three stylized facts.

- The disposition effect in stocks and the reverse disposition effect for funds is observable for the same investors at the same time.
- Across asset classes, a positive disposition effect is observed for non-delegated assets whereas a reverse disposition effect is observed for delegated assets.
- Passive funds, namely index funds, display a small positive disposition effect.

In a recent paper, (Khorana & Servaes, 2012) analyse Market Shares in the fund industry through the degree of competition and fees. The two main mechanisms of price competition at work are:

- The response of the investor to fund fees
- The way economies of scale feed into a reduction of fees

Recall that in the rational (Berk & Green, 2004) framework, expected abnormal performance should be equalized with fees across funds. Even performance of skilled managers, in equilibrium, should respect this condition as inflows will increase AUM and abnormal performance will decrease with AUM till the condition is fulfilled. Second, it is well-known that the performance-flow relationship is non-linear (Lynch & Musto, 2003) and this leads to a situation where AUM can be increased by launching a set of funds whose future performance is random, but where some by chance will outperform. Figure 9 in the Appendix illustrates the idea .
4 funds are randomly launched (the blue arrows) and the probability distribution, represented in green, is the same for all the funds. Their future random performance realization will be one of the points on the performance axis. Due to the convexity of the Flow -Performance relationship this leads to a non-linear impact on inflows.

This, let's say anomaly, creates incentives for fund sponsors to inflate their product offerings, apart from any product innovation. The demand-side mechanism that might explain the creation of differentiated products is narrow framing. This mechanism might actually lead to product innovation by the fund family, even though such differentiation is difficult to reconcile with the Efficient Market Hypothesis and Rational Expected Utility maximization. Anyway, it is important to

distinguish product innovation through differentiation and the random launch of funds that might not even have different investment styles. Another interesting question is how marketing and distribution fees impact the market share. As Figure 1 and 2 in the Appendix show, distribution costs cover approximately 60-70% of total costs of European Equity Funds.
Finally, should the fund family specialize in specific strategies or should it diversify the fund family. Diversification of the fund family enables investors to more easily diversify whereas specializing in an investment style might lead to higher risk-adjusted performance. Both might lead to an increase in market share.

In the dataset analysed by (Khorana & Servaes, 2012), the number of fund families increases from 134 to 584 from 1976 till 2009. During the same time, the average family increased the mean number of funds offered from 2.87 to 19.61! Fund families also seem to have become less focused in terms of investment objectives. The industry has become slightly more fragmented, but fees as a percentage of AUM have increased. Empirical results indicate that price competition is at play as funds that significantly increase fees subsequently observe a significant decrease in market share. As far as the effect of performance on market share is concerned, its effect is mainly mediated through the presence of a top 5% performing fund in the fund family. The authors measure that the presence of a top 5% fund in a given family leads to an increase of market share of 42%.

The diversity of product offerings also has a bigger impact in terms of market share than the focus on specific investment styles. The innovation of new products, which is measured through the launch of new funds typically has a positive impact on the market share. The opening of a new fund leads to an increase in the market share of 8.6%. The effect, however, decreases with higher levels of innovation.

INCENTIVES TO GENERATE FUND PERFORMANCE AND THE DISTRIBUTION CHANNELS

Recent research also points to the fact that the distribution channels might have an impact on fund performance, in the sense that funds distributed through more intermediaries perform less. Basically, if funds are sold directly to investors they face more incentives to perform than if they are sold through brokers. Let's focus more in detail on the process.
Typically, standard retail funds that are sold to non-sophisticated investors can be classified into two broad categories:

- Unbundled Portfolio Management Services without involvement of investment advice
- Bundled Portfolio management and investment advice

In most advanced economies, at least 50% of mutual fund shareholders keep an ongoing relationship with financial advisors. Surveys indicate that quite many investors value face to face contact and a trust relationship with an investment advisor. A recent paper even indicates that investment advisors can be viewed as Money Doctors (Gennaioli et al. 2015)) in the sense that they help investors feel more safe about their investments and thus the latter feel safe in taking more risks. Investors using full brokerage services also seem to be less experienced (Chalmers & Reuter, 2012).

This potentially leads to differences in competition within two market segments, namely the direct-sold and the broker-sold channels. The broker-sold segment, in principle, should be less subject to competitive pressure as the investors are less experienced and less likely to grasp the difference between raw returns and risk adjusted returns. This leads (Del Guercio & Reuter, 2016) to the assumption that inflows of broker-sold retail funds should be less sensitive to alpha. They classify funds as direct-sold or broker-sold when at least 75% of their assets are sold through share classes focussing on that segment.

As the fund industry is typically structured around fund families it is important to understand how fund families market their funds. They might use different channels for different funds and/or different customers. The authors use the (Del Gercio et al, 2010) approach to evaluate the fraction of assets each family distributes through the respective channels. Most Mutual Fund Families mainly focus on one of both distribution channels and are quite specialized. A few distinguishing features can be observed across market segments.

- There are more actively managed funds in the broker-sold segment
- The average broker-sold fund manages fewer assets
- Broker-sold funds have significantly fewer assets.
- Broker-sold funds have higher average expense ratios, more or less equivalent to 12b-1 fees.
- Average monthly after-fee returns of broker-sold funds underperforms those of direct-sold funds.

In order to understand those facts, the Performance-flow relationship is of highest importance. Remember that as AM fees are fixed, the revenues of the Asset Manager increase with the inflow to the fund. Basically, Investment Funds are in competition to attract inflows. As investors in the broker-sold segment are less sophisticated, they are likely to focus on raw returns rather than on different estimates of alpha. Del Guercio and Reuter thus test for difference in performance-flow relationships between the direct and broker-sold segment. They use data on US domestic equity funds from January 1993 till December 2004. They indeed find that fund flows in the direct-segment channel are significantly more sensitive the risk-adjusted returns than fund flows in the broker-sold channel. The estimates imply that a standard deviation in alpha leads to an increase in inflows over the next year of 6.18% in the direct-sold segment, whereas as the increase of inflows is only 0.59% in the broker-sold segment.

In order to evaluate the impact in terms of revenue consider the following example. To make things straightforward to calculate. Imagine that the AUM are 1bn $ and the AM fees make up 1% of AUM. For the direct sold fund, the increase in inflows would be 61.8 million $ whereas for the broker sold fund it would be 5.9 million $ only. The increase in revenue from fees would be 618,000 $ for the direct sold funds and 59000$ for the broker-sold funds. The incentives to hire teams and invest in technology are thus much weaker for broker-sold funds. If at all, the incentives to generate alpha are much lower in the broker-sold segment. Conversely, broker-sold funds have incentives to increase exposure to systematic risk as non-sophisticated investors are focussing on raw returns.

Del Guercio and Reuter’s research indeed indicates that direct-sold funds exhibit higher after-fee risk-adjusted returns. The difference is approximately 10 basis points per month and increases to approximately 17 bps for small-cap funds. The authors suggest the difference between more balanced and small-cap funds can be viewed as an indication of more active management. They test this assumption more formally through the (Kacperczyk et al, 2008) return gap measure. The latter measures the difference between the fund’s actual gross return and the gross return implied by the fund’s lagged reported holdings. The authors find that a great part of the differences in performance can be explained through more active management as measured through the return gap. For the overall sample, the difference in return gap between direct-sold and broker-sold funds is approximately 6% and for small cap-funds it is approximately 12%. In order to evaluate whether direct sold funds are more actively managed the authors also use the (Cremers & Petajisto, 2009) active share measure. The latter is the fraction of fund *i*'s assets that have to be traded to obtain a portfolio that mirrors fund *i*'s benchmark. Evidence points out that direct-sold funds are more actively managed than broker-sold funds. The differences in returns between direct-sold and broker-sold funds is much higher for more actively managed small-cap funds. What about systematic risk exposures such as beta? In principle, broker-sold fund managers have a higher temptation to increase systematic risk as their investors are more sensitive to raw returns. Indeed, broker-sold funds seem to have higher betas than direct-sold funds.

Another issue concerns the number of different styles provided by fund families. In principle this fund variety is inconsistent with the standard rationality paradigm of Expected Utility maximization and the Mutual Fund Separation Theorem but can be explained within the Behavioural Economics framework, notably through Mental Accounting. There is evidence that quite many investors value "one-stop shopping" in the sense that they prefer to invest in a large fund family which offers a variety of investment styles. However, (Ciccorello et al, 2006) indicate that this convenience costs investors through lower risk-adjusted returns. According to (Massa, 2003), such lower performance is the result of diseconomies of scope in the generation of fund variety and fund performance. Given the greater sensitivity to risk-adjusted performance of investors in the direct-sold channel, it can be expected that the families will offer a narrow range of investment styles. Indeed, the study indicates that direct-sold funds offer on average 2.2 different Morningstar styles whereas broker-sold funds offer 3.5. Families specializing in direct-sold funds are also more specialized by investment styles than broker-sold funds. Direct-sold funds thus take better organizational decisions in order to generate risk-adjusted performance for investors.

A further well-documented fact is that funds outsourced to subadvisors are less performant (on a risk-adjusted basis). They should thus be less attractive for direct-sold funds. Indeed, broker-sold funds are much more likely to delegate to a subadvisor. The research indicates that around 22% of broker-sold funds are delegated to subadvisors as compared to 12% for direct-sold funds. These results are thus consistent with the theoretical prediction that families concentrating in providing direct-sold funds do not increase the scope of offered styles at the cost of risk-adjusted performance, conversely to broker-sold funds.

OUTSOURCING OF MUTUAL FUND MANAGEMENT: RISKS AND PERFORMANCE

Most of the investors delegate the management of their wealth to intermediaries that manage investment funds. Hence, from 1980 to 2007, the percentage of American households owning mutual funds rose from 5.7 to 43.6% (Investment Company Institute, 2007). The fraction of total equity owned by those investment vehicles has been increasing steadily and has recently increased to 32.4% by the end of 2007 (French, 2008). The fact that those investments are delegated to third parties leads to an agency problem. In that respect, the optimal compensation rules have received a lot of attention (Stracca, 2005). The role of the organizational structure, however, has not received that much attention. A paper by (Chen et al, 2010) analyzes how outsourcing of the fund management may impact managerial incentives and thus the performance of investment funds.

Although, in many cases the management company and the investment advisor are one unit, there are situations where the management of the fund is outsourced to an external investment advisor. The latter is then not involved in the operational day to day work and distribution. The management company retains the marketing and distribution fees and the external advisor obtains the pure management or advisory fees. In principle, the board of directors of the management company then monitors the fund's activities and risks. The Management company can at any time close down the fund or replace the investment advisor. The latter can either advise or manage funds. It is worthwhile noting that the investor typically does not know that the management is outsourced. The question is whether the outsourcing of the fund impacts the performance and, if, for what reason? (Chen et al, 2010) study the impact of fund outsourcing and consider a fund to be outsourced if one of the investment advisors is not affiliated with the Management Company.

An emerging literature also analyzes the influence of mutual fund families on mutual funds. In that respect, investors seem to choose a fund family first and then invest in one of the funds of the fund family (Massa, 2003). This, let's say behavioral bias, leads fund families to offer a greater degree of product differentiation. This excessive degree of product differentiation is actually a puzzle for the standard finance theory as the risk aversion of the investor should not influence the composition of the risky portfolio. This fact is known in the literature as the asset allocation puzzle (Canner *et al,* 1997). Of course, this product differentiation can, at least, partly be explained by behavioral aspects. (Gasper et al, 2006) note that fund families might subsidize the performance of a favorable fund in the family at the expense of another fund. What is worth highlighting, here, is that the organizational structure of the fund industry matters. Even though, this might seem evident for any practitioner, it has not been addressed by academics, except by (Chen et al, 2004). The fundamental issue is the boundary of the firm in a multi-task agency framework such as the one in (Holmstrom & Milgrom, 1991). How does the nature of the organization, notably the degree of integration, impact performance?

(Chen et al, 2010) aim at analyzing the performance of outsourced funds, they first analyze whether outsourced funds significantly differ from in-house funds in terms of characteristics. In their respective dataset, they distinguish outsourced funds by the fact that the investment advisor's name differs from that of the family complex. They identify roughly 56% of fund-year observations as being in-house managed and 44% as being outsourced. Some funds might be unidentified. Basically, there is a growing trend toward more outsourcing, but the degree of outsourcing does not seem to depend on the investment style that is followed. Note, also, that the number of funds has more than doubled from 1994 to 2007, which again is difficult to reconcile with the standard rationality paradigm in Finance. Figure 10 in the Appendix reports the characteristics of the fund families analyzed by (Chen et al, 2010).

The number of families has increased from 1994 to 2000, to slightly decrease afterwards. This goes together with a rather similar increase and decrease in the number of funds per family, a topic that would be interesting to analyze in more detail. Still, the average number of funds per family is roughly 8. The percentage of families that outsource to some degree is around 43 with again the same peak around the years 2000-2004. Interestingly, the average fraction of funds outsourced has increased steadily. The last column indicates the concentration in their respective investment styles of the families of funds. The table indicates that fund families specialize and follow the styles in which they have expertise.

Let's focus for a moment on the characteristics of the Mutual Funds in the sample. The expense ratios as a fraction of the year-end total net assets (TNA) do not differ from in-house funds and amount to approximately 1.3%. Fund turnover, which is defined as the minimum of purchases and sales over average TNA for the respective calendar year, is around 87.6% for in-house funds and 81.4% for outsourced funds. This doesn't seem to be a significant difference. Yet, outsourced funds tend to be somewhat younger and the total load they charge is somewhat lower. Fund in- and out-flows also do not depend on the outsourcing status. This seems quite straightforward as the typical investor doesn't know whether the fund is outsourced or not. Note that as smaller funds are more likely to be outsourced, it is important to adjust for fund size when analyzing performance.

In order to get a grasp of the performance as a function of risk factors, the authors benchmark fund performance using the famous Carhart 4-factor model (Carhart, 1997). As we already know, the latter is a combination of the Fama-French 3-factor model and the momentum factor discovered by (Jegadeesh & Titman, 1993). The authors also add two other factors: 1) The Morgan Stanley Capital International Index (MSCI) return covering Europe, Australia and Far East, 2) the Lehmann Aggregate Bond Index (LABI) return. Each month funds are then sorted into two respective portfolios dependent on whether they are outsourced or managed in-house. Equity funds are also sorted from non-equity funds as their return drivers differ. Funds are then sorted as a function of TNA, in order to isolate the effect due to the size of the fund. The time series of monthly returns is then used to estimate factor loadings. Figure 10 in the appendix provides an overview of the results.

Interestingly, the factor loadings are more or less the same for out-sourced and in-house funds. Outsourced funds, however, have smaller alphas accounting for around 60-80 basis points (bps) per annum lower than in-house funds. Here, it is noteworthy to highlight that the average alpha for in-house funds is already negative. As fund performance might be correlated with other observable fund characteristics, the authors also provide a regression between fund performance, outsourcing indicators as well as other characteristics supposed to eliminate other effects. They are the so-called control variables. The regression methodology is the one suggested by Fama and McBeth (1973). The regression specification takes the following form:

$$FUNDRET_{i,t} = \mu + \phi OUTSOURCED_{i,t-1} + \gamma X_{i,t-1} + \varepsilon_{i,t} \tag{13}$$

Where $FUNDRET_{i,t}$is the alpha of the fund *i* in month *t* adjusted by the typical Carhart and Fama-French factor adjustments. $OUTSOURCED_{i,t-1}$ is an indicator variable that indicates whether or not the fund is outsourced. The set of control variables in $X_{i,t-1}$ consist of the following: size, expense ratio, age, total load, flows.

Outsourcing has a negatively statistically significant impact on performance, whatever the benchmark adjustments used. The underperformance of outsourced funds compared to other funds is between 40 and 60 basis points per year. A few questions arise. How does performance differ for in-house and outsourced funds when the funds belong to the same family? Furthermore, does fund performance of an investment advisor differ when he manages on his own behalf rather than for an outsourced fund. (Chen et al, 2010) test this assumption by first testing whether the number of funds in the family impacts the probability to outsource. They find a positive impact using logistic regressions. If this impact is included as variable in the regression discussed above, the negative impact on performance of outsourcing is even stronger. Outsourcing reduces performances by 1.03% to 1.64% per year!

Theories of the firm (Holmstrom, 1999)) suggest that outsourced funds, not being under the direct control of the family, should face stronger incentives. First, the probability of closure following poor past performance should be higher. Second, risk taking should be monitored more closely than for in-house funds. The authors analyze the sensitivity of fund closures to past performance. This is typically done with the following logit regression specification:

$$Prob\left(Closed_{i,t} = 1\right) = \Lambda\left(\mu + \lambda Z_{i,t+1}\right) \tag{14}$$

Where $Closed_{i,t}$ is a dummy variable that takes value 1 if fund *i* is closed in year *t* and 0 otherwise. $\Lambda(.)$ is the logistic cumulative distribution function and is the vector of coefficients multiplied by the vector of fund characteristics. A fund is considered closed if it does not have the full set of twelve month returns. The fund characteristics are the standard ones considered above but an indicator whether the fund is outsourced and whether it is in its model style is added.

The aim is to test the (Chevalier & Ellison, 1999) hypothesis which leads to expect that fund closures are more sensitive to poor past performance for outsourced funds than for in-house funds. Indeed, the results indicate that the odds for an outsourced fund to be closed are much higher than for an in-house managed fund. Still, other types of factors might impact the results. For instance, outsourced funds are smaller and younger and thus face steeper incentives due to those characteristics. Even after controlling for those characteristics, econometric evidence still indicates that outsourcing leads to steeper incentives.

Contractual theories also predict that families should more closely monitor the risk taking of outsourced funds. Risk–taking deviation measures are suggested in (Chevalier & Ellison, 1999). The first variable if the deviation of the fund's beta from the average beta of funds in the same class. (Chen et al, 2010) calculate beta's using six factor models. The beta deviation risk measure is then calculated by taking the square-root of total squared deviations from the style means of the factor loadings. The second measure is the idiosyncratic risk calculated from the 6-factor model. The authors than re-estimate the probability to close with the risk-taking variables included and risk-taking is more penalized for outsourced funds. This also leads to less risk-taking from outsourced funds.

INTERNATIONALIZATION AND OUTSOURCING OF MUTUAL FUND MANAGEMENT

In a recent paper (Chuprinin et al, 2015) analyze outsourcing in a more international framework. Their approach is based on a distinction between two types of fund management status and they distinguish:

- Funds that are managed and marketed by the same financial group, called in-house.
- Funds managed on behalf of other financial groups called outsourced.

Basically, the management company is supposed to perform the management of the portfolio and the fund family the distribution and marketing of the fund. For in-house managed funds, the management company and the fund family are thus the same. The authors analyze so-called open-end actively managed equity funds from 2001 till 2008.

In order to detect outsourced funds, the difference in reporting between two datasets is exploited. One dataset, namely FactSheet/LionShare report the management company and the financial group that manages the fund, whereas the other dataset, Morningstar Direct, report the fund families of each respective fund. If the fund family in the second dataset differs from the financial group disclosed in the first dataset, the fund is diagnosed as outsourced. Other sources are then checked to verify that the supposedly outsourced fund is not managed by a subordinated structure. This leads to an indicator (dummy) variable that can be used in an asset pricing model to evaluate the impact of outsourcing. The asset pricing model used by the authors is the standard Carhart 4-factor model, but they also add a specification with an added liquidity risk factor based on the Amihud (2002) concept of illiquidity. Country-specific illiquidity risk factors are based on the methodology of (Liang & Wei, 2012). As usual, abnormal performance is measured by comparing the excess gross return to the one forecasted by the asset pricing model. However, in order to distinguish fund performance related to outsourcing from performance stemming from other characteristics, the following standard control variables are added:

- FundSize which is measured through the log of the fund's TNA
- MgmtCompanySize as the log of 1 plus the TNA of all funds excluding fund *j*.
- Expenses as the annual expense ratio of fund *j*.
- Fund Age which is the time since inception
- Past Retrun which is the last 12 month return
- Volatility measured trough the SD of the returns over the last 12 months
- Shareclasses, namely the number of share classes in the respective fund
- Inst Shareclass, indicating whether the fund had a share class open to only Institutinal Share holders.

Broadly speaking a quarter of funds is outsourced and different sources such as (Chen et al, 2013) and (Del Guercio & Reuter, 2014) seem to broadly accord with that number. The characteristics of the control variables also seem to be consistent with those of foregoing studies. (Chuprinin et al, 2015) analyse differences in performance as a function of whether the fund is outsourced or not. The impact of outsourcing is measured through a dummy variable and the following panel regression is implemented.

$$Performance_{j,t} = \beta_1 Outsourced_{j,t} + \beta_2 Controls_{j,t} + \alpha_t + \alpha_S(+\alpha_m) + \varepsilon_{j,t} \qquad (15)$$

Where the *j* indexes the funds, $Outsourced_{j,t}$ is the dummy variable and $Controls_{j,t}$ are the control variables discussed earlier. $\alpha_t,\ \alpha_S\ and\ \alpha_m$ indicate time, style and management company fixed effects.

Estimates indicate that outsourced funds underperform in-house funds by approximately 7 bps per month if we compare performance with the Carhart 4-factor model. On an annual basis this makes up approximately 84 bps and corresponds to approximately 57% of fund's annual expenses. Investment companies thus seem to treat their in-house funds more favourably than the outsourced funds they manage.

What are the mechanisms that might lead to such preferential treatment?
Two broad mechanisms are suggested in the literature:

- The strategic allocation of IPO stocks or the privileged use of information for in-house funds
- Cross-trading activity between in-house and outsourced funds

Let's focus on the IPO allocation, a mechanism already documented in (Gaspar et al, 2006). As management companies have long-term relationships with underwriters, they potentially have information about interesting IPO stocks. Moreover, IPO stocks often outperform at the beginning, a phenomenon known as the IPO Puzzle. It is highly likely that management companies might allocate IPOs to their in-house funds rather than their co-managed outsourced funds. In order to evaluate the impact of IPO allocations, the authors measure the weight of IPOs in the respective in-house and outsourced funds. The differences between those weights indicates that outsourced funds are allocated approximately 44% fewer IPO stocks than in-house funds. The preferential treatment due to IPO allocations seems to explain around a third of the return gap between funds of different status.

Is there any favouritism in terms of exploited investment opportunities?
Suppose that a management company has some information about future potential stock movements. The question is whether it is exploiting these opportunities systematically for in-house funds. This is checked by estimating the correlation between buy and sell positions at time *t* and

future stock returns between *t* and *t+1*. For quarterly data, the correlation between buy trades and future stock returns is around 35% larger for in-house funds, confirming the assumption that the best investment opportunities are mostly allocated to in-house funds.

Last but not least, let's consider cross-trading between affiliated funds. (Gaspar et al, 2006) discuss how cross-trading can affect performance either through favourite prices between affiliated funds (instead of through exchanges) or liquidity provision in case of distress. According to (Chuprini et al, 2015) the cross trading between affiliated funds is twice higher than the unconditional cross trading (between unrelated funds). Moreover, the cross trading is especially higher during times when funds are distressed.

Here the (Holmstrom & Milgrom, 1987) Principal-Agent model can be applied, where the fund family is viewed as the Principal and the Management Company the Agent. The question is whether outsourced funds just get treated less favourable than in-house funds or whether preferential treatment can be seen as incentive provision by the Principal. The first assumption is called the "inferior product hypothesis", the second the "incentive hypothesis". Moral Hazard plays a key role and the eventual degree of Moral Hazard is directly related to the monitoring ability of the Principal and the bargaining power of the Agent. The mechanisms are the following: If the Principal cannot adequately monitor, the Agent is shirking and the former has to provide a preferential treatment to the Agent. Second, the more market power the Agent has, the more bargaining power he has to get a preferential treatment. The authors measure monitoring ability through the use of a common language by the Principal and the Agent. Note that the country location of the Principal and the Agent matter in this case. Bargaining power of the Agent is measured through the market share of the subcontractor firm in the outsourcing market.

(Chuprinin et al, 2015) develop the following empirical approach to discriminate between both hypotheses. First, they note that the task of managing in-house and outsourced funds is complementary. Indeed, the agent acting as a subadvisor can use his skills and investment research to manage other in-house funds. This is the spillover effect and this positive effect increases with the number of in-house fund managed by the subcontractor. Given that the positive spillover effect increases, the preferential treatment should be less under the "incentive hypothesis" for subcontractors having a higher fraction of in-house funds. Inversely, the "inferior product" hypothesis predicts that for subcontractors having a higher fraction of in-house funds, the latter are more important and this raises their preferential treatment. A more extreme version of the "inferior product" hypothesis leads to profit reallocation between in-house and outsourced funds. If that were the case, we should observe negative contemporaneous correlations between the two types of funds. Basically, superior performance of in-house funds is subsidized by outsourced funds. Under the incentive hypothesis however, preferential treatment can be seen as a kind of in-kind compensation with the tacit agreement of the Principal and contemporaneous returns between the two types of funds should be positively correlated. Finally, preferential treatment can be seen as a substitute for subadvisory fees. The incentive hypothesis entails a positive relationship between subadvisory fees and outsourced performance. .Moreover, the relationship between affiliated in-house and outsourced funds is expected to be negative.

The results are the following.

- Fund families that share a common language with the management perform better and the difference is about 2.5% per year! The impact is event stronger if we focus on cross-border relationships between fund families and management companies. This might be related to higher information asymmetry due to cultural and geographical distance.

- The market power is measured through the market share of the respective management company in the outsourcing segment of a respective style. More exactly, the ratio of aggregate TNA of outsourced funds run by the management company in a given style to the total TNA of all outsourced funds in that given style. When a management company has a higher market share in a given outsourced investment style, the preferential treatment tends to be higher. A one standard deviation increase in market power approximately lowers the performance of outsourced funds by 1.8% per year.
- If we measure the fraction of outsourced funds as the ratio of the aggregate TNA of outsourced funds run by the management company to the aggregate TNA of all funds run by the management company, there is a negative relationship between the performance gap and the fraction of own account activity of the management company.
- Superior performance of in-house funds is not associated with contemporaneous poor performance of affiliated outsourced funds. Subadvisory fees bear a positive relationship with outsourced fund performance. A percentage point increase of subadvisory fees goes together with a 2% performance increase. Broadly, the results suggest that preferential treatment and subadvisory fees are substitutes.

Liquidity Provision in Fund Families

The fund industry is typically structured around so-called fund families. Fund sponsors then launch a few types of funds available to investors. Two arguments can be suggested to explain this fact. First, from a demand-side perspective, different kinds of investors have different kinds of tastes. Second, from an industry supply-side perspective, it might be interesting for a sponsor to launch a few funds, which maximizes the chance that one particular fund has outstanding abnormal performance. It is well know that this fund then attracts huge inflows. Indeed, the non-linearity of the inflow/outflow relationship as a function of performance is well documented in the literature. Good abnormal performance has a high impact on inflows, whereas under normal market circumstances, fund outflows are not very reactive to bad performance. This leads to a convex flow relationship with respect to performance.

Still, the supply-side as well as the demand-side explanation implies a relaxation of the standard behavioral paradigm in financial economics. Standard rationality postulates have to be relaxed. This doesn’t mean that investors are necessarily irrational, but rather that they are less rational or rational in a different way, than suggested by standard textbooks. For instance, they could be inattentive or evolutionary rational. For recent contributions on evolutionary rationality the reader can consult (Lo ,2017) and (Smith, 2009). The deviations with respect to full rationality, however, are potential weaknesses that can be exploited by financial decision makers. As already mentioned, fund families potentially exploit such weaknesses by launching a whole set of funds. They thus exploit individuals’ cognitive biases with respect to probabilities. But fund sponsors might exploit investors in other different ways.

In that sense, a recent research paper by (Bhattacharya et al, 2012) analyze whether fund families provide insurance to other funds belonging to the same family. Fund families are typically organized as a collection of legally independent entities sponsored by a management company. From a legal perspective, the different investment vehicles are different legal vehicles. The temptation, however, is strong to provide insurance to funds that are facing redemptions due to bad performance. Better performing funds would thus provide insurance to less performing funds, at the cost of well performing funds’ shareholders. (Bhattacharya et al, 2012) examine the assumption by analyzing the so-called affiliated funds of funds, the latter being funds that only invest in other funds in the fund family.

Funds in families that have affiliated funds of mutual funds (AFoMFs) have two groups of investors: the AFoMFs and the outside investors. In order to understand how and if the family provides insurance, we have to distinguish the flows. The total flow to each fund *j* in family *k* during period *t* is measured in the standard way.

$$Flow_{j,k,t}^{Total} = TNA_{j,t} - TNA_{j,t-1} * \left(1 + r_{j,t}\right) \tag{16}$$

r is the net of fees return. Note that the equation presumes that the cash flows arrive at the end of the respective period. In order to isolate the impact of the AFoMFs on fund flows, the authors calculated the change in the number of shares held by AFoMF *i* in fund *j* multiplied by the Net Asset Value (NAV) of fund *j*. If the values are aggregated for all AFoMFs within the respective family, we get the total flow going from the family to fund *j*.

$$Flow_{j,k,t}^{AFoMF} = \sum_{i=1}^{n_k} \Delta shares_{i,j,t} * NAV_{j,t} \tag{17}$$

Where $n_k$is the numver of AFoMFs in family *k*. Delta shares is the change in the number of shares of fund *j* held by AFoMF *I* between date t-1 and t. The flow from outsiders can now be calculated by removing the flow of AFoMFS from te total flow:

$$Flow_{j,k,t}^{Outside} = Flow_{j,k,t}^{Total} - Flow_{j,k,t}^{AFoMF} \tag{18}$$

Funds can now be sorted in each family into deciles according the outside flows. Funds in the lowest decile 1 are considered distressed and experience severe redemption requests. Decile calculations are adjusted each period. For each decile, the authors calculate the average flows from AFoMFs (scaled by TNA) and the fraction of their positions. Figure 11 in the Appendix indicates the flows analyzed by (Battacharya *et al,* 2012).

The dashed line divides the funds into positive and negative flow subgroups. It is clear from the Figure that, generally, there is a positive relationship between outside flows and AFoMF flows. For the decile of distressed funds this is not the case anymore and Figure 11 provides first evidence that AFoMFs invest in distressed funds.

The authors also implement an econometric analysis to evaluate a model consistent with (Ellison, 1997; Sirri & Tufano, 1998; Dela Guercio & Tkac, 2002). In those models, the flow performance relationship is positive even though non-linear. In order to test the impact of funds being distressed, they add an indicator variable for the first decile. In general, outside flows have a positive impact on AFoMF flows, except for the first decile, as indicated by the sum of beta1 and beta2. This is clear indication that AFoMFs provide liquidity to distressed funds. Yet, if AFoMFs provide support to funds facing liquidity problems, this behavior should not be observed for funds that are less in need of liquidity support.

Some might argue that the flow movements are a result of asset allocation decisions. Imagine that the asset class value has decreased below target value, then an asset manager will have to inject inflows to keep the target weight. To test this assumption (Bhattacharya et al, 2012) construct an "asset allocation" variable which is defined as the difference between the weight of the AFoMFs in the asset class of fund *j* at the beginning of the respective portfolio period and the target rate. The target weight is presumed equal to the average weight over time. A regression analysis using this variable indicates, even though somewhat significant, does not remove the strong impact of liquidity provision. What kind of funds does the family help? According to (Gaspar et al, 2006) fund families strategies tend to help high value or high fee funds in order to maximize total revenue. This seems rational in the sense that star funds attract flows to other funds of the family as well (Nanda et al, 2000). Is the liquidity provision really beneficial to the respective funds? In order to test this assumption, the following approach developed in (Edelen, 1999) is used. Fund alphas, either determined by a Carhart 4-factor model or a (Fung & Hsieh, 2004) 7-factor model, are regressed with the following specification:

$$\alpha_{j,t} = \beta_0 + \beta_1 * I_{j,t} + \beta_2 * I_{j,t} * Flow_{j,t}^{AFoMF} + controls + \varepsilon_{j,t} \quad (19)$$

Where $\alpha_j$denotes the abnormal performance of fund j, $Flow_{j,t}^{AFoMF}$is the flow that fund j receives from the AFoMFs in its family. I_j is an indicator that takes value 1 if fund is distressed. The control variables are diverse standard control variables used in this literature. The results indicate that $\beta_1$is significantly negative and amounts to -0.0009. This means that, indeed, huge redemptions have a negative impact on performance. This is probably due to costly fire sales. β_2, however, is statistically significant and positive which implies that AFoMF flows are counteracting the negative impact on performance. The estimated $\beta_2$equals 0.0481 and a 1% increase in AFoMF flow during a stress period lowers the negative impact by 4.8 bps.

CONCLUSION

The industrial organization of the fund industry differs a lot from the standard portfolio theory predictions. The Mutual Fund Separation Theorem suggests that most investors would hold diversified portfolios and that fund industry would consist of big diversified funds. The Behavioral Finance literature mostly focuses on market and pricing anomalies but does not analyze the industrial organization of the fund industry. The common thread of the paper is that behavioral aspects explain the origin of the complexity of the fund industry. More broadly, there is a need for a kind of industrial organization of the finance sector based on behavioral aspects.

ABSTRACT

This article's main objective is to identify the relationship between the reduction of the basic interest rate in Brazil (represented by Selic) and the management of results in banks. For the development of this analysis, this study utilizes a specific accrual model to estimate what portion of loan loss provisions (LLPs) can be managed by banks. The results of our survey reveal that when the Selic rate has been low, Brazilian banks have increased their use of discretionary loan loss provision (LLP) accruals, thus reducing their overall earnings from credit operations.

KEYWORDS: Earnings Management, Loan Loss Provisions and Interest Rate.

INTRODUCTION

In light of Accounting Choice Theory, exogenous factors may encourage banking organization managers to display opportunistic behavior. In this conception, considering that incentives in terms of practices related to earnings management may be derived from the external environment, where regulatory policy, contracts and capital markets may exert an influence (Watts & Zimmerman, 1978). Studies have already found, for example, that the earnings management is related to economic development (Riahi-Belkaoui, 2004; Baatour & Othman, 2016) and the quality of auditing (Tendeloo & Vanstraelen, 2008). On the other hand, given the wide range of external variables that can influence decisions related to accounting procedures, there still remain gaps in the literature that need to be explored. One of these concerns low Selic rates which, given this rate's relevance to Brazilian economic policy, as well as its impact on the banking spread, may encourage the management of bank earnings.

In Brazil, the Selic (Special Settlement and Custody System) represents a basic interest rate practiced in the economy, being used as reference for loans and financial investments. Part of the mandatory bank deposits, as well as some Brazilian public debt securities, are remunerated by this indicator. For this reason, interest rates applied by financial institutions are parameterized by the Selic rate.

The Selic rate plays a fundamental role in the macroeconomic sphere and is published for monetary policy purposes. This has been true ever since the adoption of inflation targets in 1999, in which decisions related to this indicator came to influence the money supply and, as a result, investment, consumption and production. It should be emphasized, however, that this prerogative is only possible due to the relationship that exists between the Selic rate and bank credit, which in turn, according to Carvalho (2005), is a mechanism for the transmission of monetary policy. In this mechanism, changes in the macro rate affect production through credit, inducing changes in banking reserves which can be driven by expansionary or contractionary monetary policy. In other words, depending on how it is applied through changes in the Selic rate, there will be a change in the operational volumes experienced by banking institutions. Due to this macroeconomic influence, changes in the Selic rate, in addition to affecting issues related to monetary policy, also affect the operational volume of entities that participate in financial intermediation.

Based on these macroeconomic influences on banking credit, it is assumed as a consequence that changes in the prime interest rate can also influence the results of financial institutions. Studies of this subject have found that the prime interest rate appears to be one of the determinants of earnings (Demirgüç-Kunt & Huizinga, 1999). In addition, it has been noted that alterations in this indicator are statistically related to the growth in the earnings of institutions linked to financial intermediation (Ho & Saunders, 1981; Saunders & Schumacher, 2000). Or in other words, it has been concluded that macroeconomic oscillations of interest rates directly influence banking margins in the granting of credit.

However, even though this empiric evidence assumes that alterations in the Selic rate have the potential to influence the reported earnings of financial institutions, there still have been no studies that make it possible to infer their capacity to encourage opportunistic management of the reporting of banking assets. In studies of the management of financial institutions conducted by Zendersky (2005), Santos (2007) and Dantas, Medeiros, Galdi and Costa (2012), the Selic rate was employed as the only control instrument in their statistical models. In general, however, few studies have sought to identify macroeconomic factors that may encourage the practice of earnings management (Almeida, Lopes & Corrar, 2011; Rodrigues, 2013). To Watts (1992), decisions related to accounting choices are influenced by economic issues, which indicates the need to explore these instigating factors which may lead to opportunistic behavior on the part of managers.

Based on these considerations, as well as the theoretical gap regarding the influence of the prime interest rate on the making of accounting decisions, we have formulated the following research question: **what is the relationship between a low Selic rate and earnings management in Brazilian banks?** Based on this question, this study seeks to analyze the relationship between low Selic rates and the use of discretionary LLP accruals. To do this, we have used a specific accrual approach based on the existing literature. To perform these tests, we use accounting data from financial institutions in the Brazilian market between the first quarter of 2010 through the third quarter of 2017 which have been classified as commercial and multiple banks and credit unions.

LITERATURE REVIEW

Earnings Management in Banks

In the banking sector, studies have identified asset accounting which offer the manager discretion, making it possible to manage earnings in an opportunistic manner. In this sphere, loan loss provisions (LLPs) play a prominent role. This type of accounting has been tested statistically rendering results that testify to its use in the manipulation of accounting reports.

The findings of McNichols and Wilson (1988) obtained results that make it possible to make inferences about the use of LLPs in earnings management. The study examined American companies that used large LLPs in relation to the profits they obtained. To capture evidence of earnings management, the authors used a specific accrual approach which later was used in other studies (Zendersky, 2005; Lobo & Yang, 2001). To estimate the non-discretionary portion of an LLP, the author used the initial balance of the LLP, the losses during period t and the losses during period t + 1. The results were significant, suggesting the use of these accruals in earnings management.

Lobo and Yang (2001) also deal with the use of accounting choices related to LLP reporting. To perform their statistical tests, the authors used time series regressions, obtaining three results: significant evidence in terms of income smoothing practices; the sign and coefficient were better specified by time series for each bank; and banks managed their earnings to conform with regulatory capital requirements.

The findings of Kanagaretnam, Lobo and Mathieu (2003) suggest that the discretionary nature of LLPs is used to smooth income. To do this, the authors divided financial institutions into groups, discriminating them based on their pre-income tax and pre-LLP earnings. The evidence indicates that these organizations increased their LLPs during good times to reduce their published earnings, thus “saving” earnings for subsequent financial reports.

Curcio, Simone and Gallo (2016) found that banks which were subject to stress tests by a supervisory authority demonstrated a greater propensity for smoothing income. To reach this conclusion, the authors developed a study of financial institutions that were operating in Europe during the financial crisis. The results revealed exogenous stimuli which could affect the decisions made by managers in terms of loan loss provisions (LLPs).

Moyer (1990), in turn, found that earnings management practices were used to conform with regulatory capital requirements. The author pointed out that in the United States, banks that do not fulfill these minimum capital requirements receive larger fines, which influences institutional earnings. Within this context, the author found evidence that suggests that LLPs and assets were being used to manipulate earnings to meet capital adequacy norms.

However, Beatty, Ke and Petroni (1999) sought to identify evidence of the existence of differences between discretionary bank accounting between public and private banks. The authors identified indices of smoothing income for banks that are listed on the stock exchange. They observed that private financial institutions, with earnings that were close to zero, were more likely to report losses than public financial institutions. This evidence suggests that financial institutions which are listed on the stock exchange have a greater incentive to report market gains.

To Tomy (2018), earnings management in banks can be useful in inhibiting new competitors from entering the market. The author argues that community banks increase their provisions for questionable credit in order to appear less profitable. The statistical evidence found helped reinforce the hypothesis put forward in this study.

Within the Brazilian context and using a specific accrual approach, Zendersky (2005) identified that the discretionary portions of LLPs are used by financial conglomerates in Brazil to manage earnings. To give greater robustness to the results found through his employed methodology, the author also performed tests with an alternative stage model. The results found in the two methodologies were not divergent, and thus corroborated his findings.

Goulart (2007) analyzed the fifty largest banks operating in Brazil between June 2002 and December 2006 in order to identify income smoothing practices. After performing statistical tests, he found evidence that banks were managing earnings through LLPs, which were the result of derivatives and revenues positively adjusted on the stock market. The results also make it possible to infer that according to the metric utilized, the LLP is the most often used instrument to manage bank earnings.

Prime Interest Rate and Bank Earnings

There is evidence that the prime interest rate is related to the bank spread. In Demirguç-Kunt and Huizinga's study (1999), for example, the authors sought to identify factors related to the bank margins practiced in financial intermediation. Based on a sample that included banks from 80 countries, it found a significant relationship between the macro rate and the bank spread, suggesting that banks demand greater margins in countries with higher interest rates. In Brazil, a study by Afanasieff, Lhacer and Nakane (2002) revealed that the factors that present the greatest explanatory power in terms of the bank spread are macroeconomic variables, represented by the Selic rate and the GDP. Studies by Jiang, Tang and Law (2003) and Dick (1999) also presented empirical evidence which observed that increasing interest rates resulted in elevated bank earnings. Based on these studies, it was found that the macro rate established in a country influenced the margins demanded by banks.

It should be emphasized that some studies have found an elevated financial margin in more underdeveloped nations. To Claeys and Vander Vennet (2008), this condition is a measure to compensate for exposure to risks due to scenarios characterized by greater instability. In an analysis of the earnings of financial intermediaries in some countries in Latin America, Brock and Suarez (2000) stated that macroeconomic uncertainty as well as the financial reserves in these countries are reflected in the practices of elevated banking earnings.

Another justification for the inclusion of the Selic as an indicator of the bank spread is interest rate risk. Oreiro, Paula, Silva and Ono (2006) explain that this risk associated with banking activity occurs due to the chance that the remuneration of the credit portfolio will not be sufficient to cover a positive oscillation in the prime interest rate, resulting in losses for the organization. This being so, they suggest that even with a low interest rate policy, the uncertainties associated with macro-instability may lead institutions to maintain an elevated bank spread to cover macroeconomic uncertainty.

In addition to these considerations in terms of the makeup of the bank spread, some studies deal with the passing on of interest rate increases by financial institutions. To Castro and Melo (2010), in pricing bank loans, Brazilian financial institutions respond more quickly to increases in the Selic rate than to decreases. Hannan and Berger (1991) have found that American banks display greater rigidity in relation to passing along interest rate hikes in terms of fundraising costs. That being so, this evidence suggests that in function of the velocity of the passing on of changes in the macro prime interest rate to the market, banks end up obtaining positive results, because they pass along these changes to financial applications, but delay reducing interest rates for financial loans. In this way, it is suggested that a decrease in the Selic rate produces positive effects on bank earnings.

However, it should also be noted that considerable oscillations in the Selic rate can also be reflected in bank spreads. This hypothesis was tested in the studies of Ho and Saunders (1981), which identified that volatility in the macroeconomic interest rate has an impact on bank margins. Saunders and Schumacker (2000), in turn, using a similar approach, investigated this relationship in six European countries and the United States and observed that a 1% variation in the prime interest rate generated a growth of 0.2% in the margin of financial intermediation practiced by banks. The authors suggested that volatility in the macro rate influences banks' net margin on interest rates, and that policy directives that seek to inhibit abrupt oscillations can have a positive effect on reducing bank spreads.

Nonetheless, considering positive factors in terms of the growth of institutional earnings from credit operations, opportunistic behavior by managers is expected in trying to reduce current earnings, transferring a portion of the earnings to subsequent periods. In this strategy, at a certain level of earnings it is considered appropriate to "store" earnings for more difficult periods (Paulo, 2007). Based on this assumption, it is expected that banks will increase their use of discretionary

LLP accruals, reducing bank earnings when the Selic rate is low. This is why we have established the following test hypothesis

> *H0a – There is a positive relationship between lower Selic rates and discretionary LLP accruals.*

METHODOLOGY

Delimitation of the Period and the Sample

The time period for this study spans from 2010 to September 2017. This initial restriction is based on the publication of BACEN Resolutions 3786/09 and 3853/10, which determined that financial institutions need to publish consolidated accounting records beginning in 2010, based on international standards emitted by the International Accounting Standards Board (IASB). The convergence of these standards makes a better comparison of these records possible, which should yield a greater homogeneity in the standards of the data collected, which explains the restriction determined in terms of the beginning of our collection period for the accounting information used in this study.

The delimitation of the period also serves as a parameter for the selection of the institutions examined in this study. Therefore, we initially defined the population examined in this study as financial institutions operating in Brazil which are classified as commercial banks, multiple banks with commercial operations, or credit unions that are not members of a conglomerate. A non-representative sample was selected from these institutions based on the information available from the BACEN.

In addition, to arrive at a representative sample for this study, we also used the criterion of the availability of accounting information, in order to make the operationalization of the employed model viable. Given this, of the 99 financial institutions that constitute this universe, we excluded 32 of them because they did not possess data for the variables under examination which thus left us with a sample of 67 banks. This selection, according to the accounting data published by BACEN, is representative of this larger universe, given that this group performed 99.36% of its credit operations and possessed 98.14% of its total assets. That being so, this sample is appropriate in terms of the established objectives.

Analytical Model

The operationalization of the current study was carried out by applying a statistical model in two stages. This methodology consists of first estimating discretionary accruals through the use of a statistical equation. The results of this equation were used as the dependent variable of a second equation to test the study's hypothesis. It should be emphasized that this methodological approach has been widely applied in both the national (Santos, 2007; Zendersky, 2005; Dantas *et al*., 2012), and international literature (McNichols & Wilson, 1988; Lobo & Yang, 2001; Beaver & Engel, 1996). The results of these studies have been discussed in the course of this research and support the methodology which we have adopted to test this study's hypotheses.

In terms of the first stage, we have opted to estimate accruals by focusing on identifying practices that indicate the management of earnings through specific accounting. To McNichols (2000), this methodology is an alternative to aggregate accumulations, and has the advantage of making it possible to identify key factors that influence accruals. Martinez (2001) points out another advantage which would be the chance to develop a model more appropriate for the problem under examination. Nonetheless, the author warns that this depends on the clarity of the accumulation which can be used to manage earnings.

In this sense, to address this condition, we have estimated accruals for loan loss provisions (LLP). To Beatty, Ke and Petroni (2002), this figure is one of the most manipulated areas of bank earnings. Corroborating the authors' inference, various studies in the literature have found evidence of the management of earnings through this accumulation (Mcnichols & Wilson, 1988; Moyer, 1990; Beaver & Engel, 1996; Lobo & Yang, 2001; Goulart, 2007; Santos, 2007; Zendersky, 2005). These findings suggest that this choice has the potential to meet the needs of this study.
In light of these considerations, we first estimated LLP accruals through Equation 1, whose structure is based on models that have already been used in other studies (Beaver & Engel, 1996; Lobo & Yang, 2001; Kanagaretnam *et al.*, 2003; Zendersky, 2005)

$$LLP_{it} = \beta_0 + \beta_1 CO_{it} + \beta_2 LLP_{it-1} + \beta_6 RCO_{it} + \varepsilon_{it} \qquad (1)$$

in which:
i = Bank
t = Period
LLP_{it}= Total LLP accruals.
CO_{it} = Credit operations.
LLP_{it-1}= LLPs during the previous period.
RCO_{it}= Revenues from credit operations.
ε_{it}= Standard error, which represents the discretionary portion of the LLP.

With the results of the equations used in the first stage, we will begin the procedure that seeks to test this study's hypothesis. To do this, we will use the 2 model, whose structure is represented below.

$$DLLP_{it} = \beta_0 + \beta_1 LWSEL_{it} + \beta_2 ROA_{it} + \beta_3 SIZ_{it} + \beta_4 PUB_{it} + \beta_5 BAS_{it} + \beta_6 PTC_{it} + \mu_{it} \qquad (2)$$

in which:
$DLLP$= Discretionary LLP Accruals
$LWSEL_{it}$ = Low Selic rate.
ROA_{it}= Return on assets.
SIZ_{it}= Variable which represents size.
PUB_{it}= Variable which indicates whether a bank is public or private
BAS_{it}= Basel Index
PTC_{it}= Companies that are publicly traded on the BM&F Bovespa stock market

The above mentioned model also makes it possible to test income smoothing practices performed by financial institutions in our sample. The confirmation of these practices is dependent on the statistical significance of the variable ROA_{it}, with positive parameters for Equation 2. Concerning their signs, we would like to emphasize that the expectation is justified by LLPs producing a reduction in accounted earnings. In this manner, a positive coefficient for the employed variable is interpreted as a smoothing of income, where in the face of elevated earnings, managers broaden the utilization of the discretionary portion of this figure.
In terms of the validity of the models, we have used tests designed to verify whether they meet our statistical assumptions. To do this, we confirmed the normality of the results of the equations, diagnosing multi-collinearity through the Variation Inflation Factor (VIF), homoscedasticity through White's test, and autocorrelation through the Durbin Watson test. These procedures give the inferences made greater robustness in terms of our results.

Variables Used

In Equation 1, the dependent variable represents the value listed as an LLP in the Earnings Statement. This value which is used as an estimate of discretionary accruals has been employed as a proxy for the management of earnings, and has also been used in other studies (McNichols & Wilson, 1988; Beaver & Engel, 1996; Lobo & Yang, 2001; Zendersky, 2005).

In terms of explanatory variables, the balance of credit operations (CO_{it}), registered as assets in financial institutions, was also used in the model. To Beaver and Engel (1996), credit operations from previous quarters also represent a risk to the financial institution, which suggests that an increase in the credit portfolio should follow the direction of LLPs. The findings of Kim and Kross (1998) confirm this expectation, revealing a positive coefficient in the correlation between these variables. That being so, it is expected that this explanatory variable will present a positive parameter in the employed regression model.

In relation to the variable LLP_{it-1}, which represents the initial balance of the LLP balance, which reduces assets, we would expect a positive relationship with the dependent variable. Lobo and Yang (2001) suppose that if a bank presents an elevated history of LLPs, it is less likely that the non-discretionary portion of this provision will be elevated in this period, due to the functioning of regulatory bodies, which will find it strange to have an increase in these provisions. However, the positive relationship observed in the model used by the authors contradicted this supposition, making them adherents to the arguments of Wahlen (1994), who suggests that the data presented by LLPs is used by investors to formulate future expectations. In Brazil, Zenderski's study (2005) also perceived a positive relationship between these two variables. This is why, we expect a positive coefficient for this explanatory variable.

The third variable of the equation (RCO), which represents the revenues from financial intermediation in credit operations registered in the earnings statement, is intended to express a bank's elevated exposure to risk. According to the banking regulations emitted by the National Monetary Board through Resolution 2682/99, banks are required to classify credit operations by order of increasing risk, with reviews being required in only a few special cases, such as, for example, a default on credit granted. In this manner, we suggest that the greatest impact of LLP expenses comes from operations that are contracted during the period, a fact that justifies the utilization of this variable in this model. In addition, it is expected that the presented coefficient will be positive, because according to previously realized studies (Lobo & Yang, 2001; Kanagaretnam, Lobo, & Mathieu, 2003; Tomy, 2018), where an elevated exposure to risk has been found through the credit portfolio, a positive relationship has been obtained.

In terms of Model 2, the $LWSEL_{it}$ is designed to test this study's hypothesis. To operationalize it, we use a dummy variable, using 1 for quarters which demonstrated low values for this Brazilian economic indicator and 0 for other cases. The information related to the Selic rate was obtained directly from the Central Bank website, employing the last rate before each quarter's close. Nonetheless, it is expected that this variable will be positive in Equation 2, keeping in mind the expectation that a decrease in this variable will have a positive influence on bank earnings.

In terms of the ROA_{it} variable, which represents the return on total assets, it was obtained by dividing net profits by the total assets registered at the beginning of the quarter. As mentioned in the previous section, this variable is intended to capture income smoothing practices employed by financial institution managers. To Kanagaretnam *et al.* (2001), banks tend to elevate the discretionary elements of LLPs in favorable times, economizing earnings to be later used in times of trouble. In line with the expectation mentioned by the authors, it is expected that this variable will be positively correlated with the discretionary portion of the LLP.

To represent the size of the financial institutions used in this statistical model, we use the SIZ_{it} variable which is obtained through the natural logarithm of the total assets. It is expected that this variable will be significant in the proposed model, indicating that the size of banking institutions influences earnings management practices. According to Curcio et al (2016), we would expect a positive coefficient for this variable.

We also have employed the PUB_{it} variable in this statistical model in order to distinguish public from private banks. To do this, we have operationalized this indicator through a dummy variable, using 1 for public banks and 0 for other types. In Santos (2007), even though there were no expectations in terms of the sign of this coefficient, this variable presented positive parameters and statistical significance. Nonetheless, it should be emphasized that the theoretical basis for this is still too incipient to indicate prospects for the sign of this variable.
The BAS_{it} variable was used to capture the relationship that exists between the need to conform to the regulatory capital requirements instituted through the Basel Accord and earnings management practices. In this sense, we have used a similar approach to that used by Shieves and Dahl (2003), in which they divided financial institutions into quartiles, using the Basel Index as a criterion for this stratification. In this manner, the first quartile selected the banks with the lowest indices of complying with regulatory capital requirements. To operationalize this segmentation of the statistical model, we used a dummy variable, with a value of 1 indicating organizations in the first quartile and 0 for the others. A negative relationship for this variable is expected in Equation 2, because the institutions with the greatest prominence in non-compliance with this regulatory parameter hypothetically would be more likely to reduce the use of the discretionary portion of accruals, as suggested by studies of Shieves and Dahl (2003) and Santos (2007).
The model also uses the control variable PTC_{it} in order to capture a possible relationship between companies that are publicly traded on the Brazilian stock market and earnings management. To Beatty *et al.* (1999), private companies are more likely to report smaller losses as compared to publicly traded companies. A possible justification suggested by the authors would be less asymmetry of information between the owners and managers of private banks, since contracts signed between these parties rarely are defined in terms of benchmarks. In relation to these arguments, it is expected that publicly traded companies will exhibit greater use of discretionary accruals. To operationalize the use of this indicator, we have used a binary variable, with a value of 1 used for companies which are publicly traded on the stock market and 0 for private companies.
Finally, we would like to mention that to verify the normality of the indicators used in these regressions, the variables LLP_{it}, CO_{it}, LLP_{it-1}, RCO_{it} and ROA_{it} were scaled by the amount of total assets at the beginning of quarter t (At_{it-1}). A summary of all the variables, their operationalization and their expected relationships is displayed in Text Table 1.

Variable	Operationalization	Expected relationship
LLP_{it}	$\frac{LLP_{it}}{At_{it-1}}$	
CO_{it}	$\frac{CO_{it}}{At_{it-1}}$	Positive (Beaver and Engel, 1996; Kim and Kross, 1998)
LLP_{it-1}	$\frac{LLP_{it-1}}{At_{it-1}}$	Positive (Lobo and Yang, 2001; Zendersky, 2005)
RCO_{it}	$\frac{RCO_{it}}{At_{it-1}}$	Positive (Lobo & Yang, 2001; Kanagaretnam, Lobo & Mathieu, 2003; Tomy, 2018)
$LWSEL_{it}$	Dummy variable: 1 for low and 0 for other cases	Positive

		(Ho & Saunders, 1981; Saunders & Schumacher, 2000)
ROA_{it}	$\frac{NR_{it}}{At_{it-1}}$	Positive (Kanagaretnam *et al.* , 2003)
SIZ_{it}	InTA	Positive (Curcio, Simone, Gallo, 2016)
PUB_{it}	Dummy variable: 1 for public banks and 0 for others	? (Santos, 2007)
BAS_{it}	Dummy variable: 1 for first quartile and 0 for others	Negative (2) / (Shrieve & Dahl, 2003; Santos, 2007)
PTC_{it}	Dummy variable: 1 for publicly traded institutions and 0 for others	Positive (Beatty, Ke & Petroni, 1999)

Text Table 1. Variables Used
Note: LLP_{it} is the expense associated with doubtful loan loss provisions; CO_{it} is the balance of portfolio credit operations; LLP_{it-1} is the balance for doubtful loan loss provisions at the beginning of the quarter, which reduces the assets; RCO_{it} is total revenues from credit operations; $LWSEL_{it}$ represents a low Selic rate; ROA_{it} indicates the return on assets; SIZ_{it} is the natural logarithm of total assets; PUB_{it} indicates 1 for banks with public participation and 0 for others; BAS_{it} indicates 1 for banks in the first quartile (which consists of the worst banks in terms of the Basel Indices) and 0 for others; PTC_{it} for banks with stocks that are traded publicly on the BM&F Bovespa stock market and 0 for others; At_{it-1} represents total assets at the beginning of the quarter.

RESULTS

The information pertinent to the descriptive statistics and the normality tests of the variables used in the study is described in Table 1. Below are listed the averages, medians and standard deviations for the variables employed in Models 1 and 2.

Table 1:
Descriptive Statistics of the Variables Used

	Average	**Median**	**Standard Deviation**	**Jarque Bera Test**	
				Coefficient	**p-value**
Panel A – LLP					
LLP_{it}	-0.0067	-0.0033	0.0137	261022.3	0.0000
CO_{it}	0.3573	0.3598	0.2362	61.3262	0.0000
LLP_{it-1}	-0.0204	-0.0152	0.0249	67394.43	0.0000

RCO_{it}	0.0286	0.0206	0.0285	3086.853	0.0000
Panel B - DLLP					
SIZ_{it}	15.3254	15.2450	2.4264	47.7882	0.0000
ROA_{it}	0.0014	0.0034	0.0239	1061199	0.0000

Where: LLP_{it} is the expense for doubtful loan loss provisions; CO_{it} is the balance of the credit operation portfolio; LLP_{it-1} is the balance of the doubtful loan loss provisions at the beginning of the quarter, which reduces the assets; RCO_{it} represents the revenues from credit operations; ROA_{it} is the return on assets; SIZ_{it} is the natural logarithm of total assets

The Jarque-Bera test was used to test the normality of the variables employed in the statistical models. The results described in the table above indicate a rejection of the normality of the variables.

Nonetheless, to apply this panel data to Equation 2, the Ordinary Least Square model was first used (OLS). Based on these results, autocorrelation, homoscedasticity and multicollinearity tests were realized. The results are displayed in Table 2.

Table 2:
Results of the Estimates of Discretionary Accruals

	OLS	**OLS with robust standard error**	**Random Effect (robust standard errors)**

Source: Study results

Looking at the presented results, note that the Durbin-Watson test, as well as the White test presented p-values below 0.05, revealing problems of autocorrelation and heteroscedasticity. In light of this, it was necessary to use robust standard errors. In terms of diagnosing multicollinearity, the statistical measure VIF (*variance inflation factor*) presented values less than or equal to 1.9413 for the variables of Equation 1. Thus, we can see that there is an absence of problems in terms of multicollinearity, because the estimated values are less than 3 (Wooldridge, 2002).

After testing our statistical assumptions, the Chow, Breusch-Pagan and Hausman tests were performed to identify the most appropriate model for the proposed equation. The Chow test, which is designed to compare the OLS model with the fixed effect model, presented a low p-value, which rejects the null hypothesis that the OLS model is appropriate, and thus validates the alternative hypothesis of the existence of fixed effects. To test whether the OLS model is more appropriate than the random effect model, Breusch-Pagan's LM test was performed and it presented a low p-value, contradicting the null hypothesis that the OLS model is appropriate. Finally, the Hausman test compared the appropriateness of the random effects model with the fixed effects model, and the result of 0.2625 did not contradict the null hypothesis that the random effects model is consistent. That being so, the tests indicate that the random effects panel model is more consistent for Equation 1, which thus guided the realization of the regression, whose results are presented in Table 3.

The equation presents an adjusted R^2 of 0.3016. This determinant coefficient indicates that the variables employed in the model explain 30.416% of the doubtful loan loss provisions (LLPs). The results of this regression were used as a proxy for Equation 2 (DLLPs).

In terms of the explanatory variables employed in Model 1, it may be observed that CO_{it} presents a positive coefficient at a 1% level of significance. In keeping with the findings of Beaver and Engel (1996) and Kim and Kross (1998), this result which the banks use for the balance of their portfolio credit operations is a measurement of risk that is reflected in the LLP figures reported.

In relation to the explanatory variable LLP_{it-1}, a positive relationship was observed with a significance level of 1%. This is in keeping with the findings of Lobo and Yang (2001), which suggests that the balance of LLPs serves as a parameter for future reported LLP figures, as suggested by Wahlen (1994).

The RCO_{it}, which represents credit operations that originated during the quarter, results in a negative coefficient using this regression with a 1% level of significance. This result would contradict the initial expectation based on the findings of Beaver and Engel (1996) and Tomy (2018). A possible justification for this relationship is in the improvement of the credit portfolio of Brazilian financial institutions, which could be a consequence of economic factors or greater rigor in granting credit. The results of Beaver and Engel (1996), even though they found a positive relationship, observed that the increments of the credit portfolio presented a negative relationship. The authors suggest that this fact occurred due to several banking regulations which were implemented in the United States during the 1980s, which led to a greater concern about the quality of credit, and which resulted in greater scrutiny by bank examiners. In the case of Brazil, the reasons for this negative relationship are not within the scope of that work, which represents a limitation to this study.

Analysis of Earnings Management

After estimating the discretionary accruals through Equation 1, models from Equation 2 were used to test the hypothesis of the present study. To do this, the OLS regression model was used to test its statistical assumptions in terms of autocorrelation, heteroscedasticity and multicollinearity.

Table 3 displays the results generated by the tests realized on Equation 2. For the Durbin-Watson test, the result was a p-value less than 0.05, which validates the alternative hypothesis of autocorrelation, violating the statistical assumption. The White test in turn presented a value below 0.05, which thus rejected the null hypothesis of an absence of heteroscedasticity. In terms of the results generated by the VIF statistic, no multicollinearity problems were detected, because the values presented were less than 3 (Wooldridge, 2002). In light of the violation of the assumptions of autocorrelation and heteroscedasticity, robust standard errors were used, whose results are also presented in Table 3.

Table 3:
Results of the Regression – Second Stage

Note: ***, ** and * levels of significance of 1%, 5% and 10%.

Source: Study data

After testing the statistical assumptions, the panel data was diagnosed to determine the correct type of balanced panel data regression. In terms of Chow's test, we may observe the statistical significance of the tested model (p-value < 0.05), which validates the alternative hypothesis of the existence of fixed effects. Breusch-Pagan's LM test also produced significant results which validates the alternative hypothesis of the existence of random effects. To compare the appropriateness of the random effect and fixed effect models, the Hausman test was performed, which generated significant results only for Equation 2, and did not reject the null hypothesis of the existence of fixed effects. Thus, based on the performed tests, the regression was conducted using fixed effect panel data.

The results of the regression of the equation are reported in Table 3, with the determinant coefficients (adjusted R^2) of the 2 Model explaining 5.96% of discretionary LLP accruals. It should be emphasized that its low explanatory power is a possible consequence of having a two-stage model, which as Zendersky remembers (2005), absorbs all of the heterogeneity of the transversal data. In Brazil, for example, Zendersky (2005) presented a model that explains 5% of the discretionary portion of the LLP. Meanwhile the model proposed by Dantas *et al.* (2012), explains 13.8% of the discretionary accruals of stock earnings. In the international sphere, in the studies of Beaver and Engel (1996), the equation used in the second stage to explain the discretionary portion of the LLP between the period from 1977 to 1984 resulted in a determinant coefficient of 11%. Thus, this suggests that the low determinant coefficient found in the study does not discredit the findings of the proposed model.

In terms of the results found in Equation 2, the most notable are the positive and statistically significant parameters (p-value<0.05) of the variable that represents a low Selic rate ($LWSEL_{it}$), which thus does not reject H0. These results are consistent with the initially defined expectation, which was traced in consonance with the allusions made based on the studies of Demirgüç-Kunt and Huizinga (1999), Ho and Saunders (1981), Saunders and Schumacher (2000) and Hannan and Berger (1991). It has therefore been verified that during times of economic stimulus, when there are low prime interest rates, financial institutions are increasing their use of discretionary LLP accruals, in order to reduce bank earnings during the period, saving them for future use.

It may further be observed, that in the model employed to explain discretionary LLP accruals (2), that the ROA_{it} variable presents a negative coefficient and a significant value (p-value<0.05). These findings suggest that banks raise the manageable portion of LLPs when they have lower earnings, which therefore does not confirm the hypothesis of income smoothing. Thus, the intentional reduction of these results, based on the statistical evidence, is not being realized to minimize the volatility of the results over the long term. The studies of Ahmed *et al.* (1999), also obtained similar parameters to these variables, which are not in line with the presented literature. The authors argue that the discrepancy in these findings is due to the difference in the sample period utilized. Wall and Koch (2000) in turn, agree with these justifications remembering that banks are subject to auditing procedures that can change the focus of managers during any given period. Nonetheless, the fact that income smoothing has not been found to occur does not contradict the hypothesis that banks manage earnings to “save” profits, because according to Martinez (2001) there is also the “*big bath”* explanation, whose applicability is beyond the scope of the present study.

CONCLUSION

This study seeks to analyze the relationship that exists between a low Selic rate and earnings management practiced by banks that operate in Brazil. This purpose was mainly motivated by historical data that demonstrates that when there have been lower Selic rates ever since this has become an indicator for economic policy. In addition, theoretical evidence argues that this macro-change can positively influence bank earnings. In light of this scenario, it has been suggested that managers use discretionary accounting to reduce earnings, saving them for later times of difficulty.

To achieve this objective, as well as test this study’s hypotheses, we have used a representative sample of Brazilian banks, classified as commercial banks, multiple banks with commercial operations, and credit unions that do not belong to conglomerates. The criterion used to select the sample was the availability of the information necessary to operationalize the econometric model during the period ranging from January 2010 to September 2017.

In terms of earnings management, we have opted to use the specific accruals model, electing to use reported LLPs to estimate the portion that can be managed by banks. These equations have been constructed based on theoretical fundamentals which justify the use of the explanatory variables. To verify the robustness of the model, we have employed tests designed to address statistical assumptions. Based on these criteria, we have determined that the estimates related to the discretionary portion of these figures can appropriately be used as proxies for earnings management.

Given the estimates of the discretionary portion of LLPs obtained in the first stage, we used these results in a second equation to test this study's hypothesis. We also used the ROA variable to verify the use of income smoothing practices by managers. The model also considers other explanatory variables which represent the size of the financial institution, whether it is publicly or privately controlled, Basel indicators, and whether they are publicly traded on the BM&F Bovespa stock market.

The reported earnings, when this last model is used, reveal that decreases in the prime interest rate are related to the utilization of the discretionary portion of LLPs. This evidence testifies to the importance of macroeconomic changes in the business climate, and includes elements that make it possible to infer whether exogenous factors can influence managers in terms of opportunistic behavior regarding accounting choices.

This statistical evidence suggests that bank managers are reducing earnings using discretionary elements of LLPs during economic times when Selic rates are low. This finding is consistent with our initial expectation which was based on allusions to studies that reported the influence of the prime interest rate on bank earnings (Ho & Saunders, 1981; Saunders & Schumacher, 2000; Hannan & Berger, 1991). In other words, considering that low interest rates are propitious for achieving greater earnings through financial intermediation, it was expected that managers would have a tendency to exhibit opportunistic behavior, increasing expenses to reduce reported quarterly gains to be later used in subsequent years. The results for this first stage offered aspects that confirmed this behavior.

However, this practice of income smoothing was not perceived statistically in the model that was used to explain discretionary LLP accruals. The negative relationship between the variable used to express the return on assets and earnings management suggest that banks are reducing their earnings even when this indicator is decreasing. These statistical parameters have already been perceived in the literature (Ahmed *et al*., 1999) and have been justified as a limitation of the sample period. In addition, this situation does not contradict the hypothesis of earnings management designed to "save" earnings.

Based on this evidence, this study contributes to the existing literature by offering findings regarding the use of discretionary accounting to perform earnings management. These findings confirm the need of normative elements that seek to restrain practices that seek to report opportunistic and therefore asymmetric information. In addition, in line with Accounting Choice Theory, these findings offer evidence of factors outside organizations that can influence manager decision making. Nonetheless, we would like to emphasize the relevance of policy decisions concerning low Selic rates, which in addition to influencing macroeconomic issues, have been statistically revealed to have the power to instigate opportunistic behavior on the part of business managers. That being so, we consider the evidence described throughout this study to be relevant to the existing literature.

In terms of this study's limitations, the period of analysis stands out, given that it only addresses low rates between 2010 and 2017 for the reasons mentioned above. In addition, the sample used is limited only to Brazilian commercial banks and does not encompass other economic activities. There are also limitations in terms of the econometric model utilized, which can present a non-discretionary portion of the total accumulations within the error term used to express discretionary accruals.

Finally, in terms of future research, we would recommend that other periods of low Selic rates be tested in order to provide new scientific evidence related to the influence of economic indicators on earnings management. In addition, other samples can be used to test earnings management in other economic sectors.

ABSTRACT

This paper investigates the relationship between the prominence of information technology (IT) firms and US unemployment. We operationalize IT firm prominence as four industry sectors, each of which is measured in two ways relative to the overall economy: firm counts and market capitalizations. Applying covariance-based structural equation modeling to a dataset spanning from 1970Q4 to 2018Q1, we found small overall significant relationships between the relative importance of IT firms and national unemployment using two measurement types. The preponderance of our findings suggested that contrary to popular belief, IT prominence increased in the US economy as the unemployment rate dropped.

KEYWORDS: IT firms, unemployment, market capitalization, structural equation modeling

INTRODUCTION

Although the current unemployment rate remains extremely low in the US, recent articles in the popular press continue to alarm readers that information technology (IT) adoption eliminates jobs (Feldstein, 2018; Whitehouse & Rojanasakul, 2017; Williams, 2017; Gardels, 2018). Further, writers fear the effect could exacerbate macro-economic unemployment in the next economic downturn, which experts view as inevitable (Miles, 2019).

Technological unemployment, referring to the loss of jobs caused by technological innovation, concerns a large population of the U.S. Many workers are worried they may lose their jobs due to robotics or artificial intelligence as modern society progresses. A 2018 report by McKinsey Global Institute forecasts that one-third of American workers will be replaced by automation by 2030. The institute predicts that among 60% of occupations, at least 30% of work activities will be automated. While organizations embrace and enjoy advanced technology, IT generating firms continue to proliferate. IT firms are making use of diverse technologies to improve the organizational efficiency, competitive advantage, and public image (Dery et al., 2017) of non-IT firms. As an example, Apple demonstrates innovation using IT to grow significantly in the market

(Templeton et al., 2018). However, economic anxiety persists in the US despite the deployment of world-class technology throughout the country. This macro-economic phenomenon has not yet been examined by Information Systems (IS) researchers. Based on this discussion, we believe it is better to illuminate how IT firms and unemployment have historically fluctuated through several important economic cycles in the US. To address this gap, our first research question is:

Research Question 1: How does relative IT firm prominence and unemployment change during known economic periods of recession and expansion?

Hardware, services, trades, and telecommunications are four representative sectors of IT industry recent years. We are interested in these specific industries and their influence on unemployment. Using each subsector will produce specific findings that offer greater insight into the relationship between IT firm prominence and national unemployment. Hence, our second research question is:

Research Question 2: How do specific IT industries (hardware, services, trades, and telecommunications) influence unemployment?

We start examining the first question by graphing the interrelationships among two measures of IT firm prominence (counts and market capitalizations) and the unemployment rate. To answer the second question, we classify IT firms into four sectors – hardware, services, trades, and telecommunications, then construct two models for measuring the casual relationships. Specifically, we explore how market capitalizations generated by the four IT industries influence the unemployment rate and how IT firm counts in the four IT industries affect the unemployment rate. We believe the findings may shed new light on the impact of the relative size of IT firms on national unemployment from an economic perspective.

This paper begins by reviewing the theoretical background of IT firms and the influence of the relative prominence of IT firms on the unemployment rate. The methodology is presented in the next section, including the applied analysis technique, data, and analysis process. Finally, we present and discuss our results, followed by concluding remarks in the last section.

BACKGROUND

The economic impact of unemployment has been widely studied by researchers. Okun's law (Okun, 1962) points out that an increasing unemployment rate negatively influences a country's GDP (Prachowny, 1993) and labor (e.g., weekly hours). The unemployment rate is also a good single indicator of economic health. When the unemployed lose wages, it results in less contribution to the economy in terms of less purchasing power and taxable income. Thus, unemployment plays a significant role in overall economic health.

Technological Innovation and National Unemployment

The link between technology and unemployment has been discussed often in the last century. Despite concerns in the popular press, empirical studies are mixed concerning the relationship between technological change and unemployment. This relationship is complex, since technological progress is known to simultaneously eliminate and create jobs (Aghion & Howitt, 1998). Some empirical studies show that "positive technology shocks" improve employment

(Trehan, 2003, p. 13). Others contradict that assessment (Gali, 1999) and it is believed that technology negatively affects less educated employees the most (Rotman, 2017).

Modern economic theorists reason that the cyclical nature of unemployment is driven by technological obsolescence and innovation (Manuelli, 2000). In this vein, periods of unemployment are believed to be initiated by employers adjusting to technological obsolescence. As older technologies become obsolete, firms will either 1) update technology and retrain workers or 2) eliminate relevant jobs. In this way, technological progress causes the knowledge embodied in a job to become obsolete (Mortensen and Pissarides (1998). The decision to update or eliminate workers is effected by the cost of technology adoption. The Internet is a form of technological advancement that is known to greatly lower the cost of employer and worker job searches (Gomme, 1998). This makes migration in the labor market more efficient and timely, theoretically improving the labor situation long term.

IT Firms and National Unemployment

The significant role of IT in the global economy has been widely recognized (Porter, 2000). The unique capabilities of IT-generating firms to create value through digital disruption strategies (Templeton et al., 2018) is shown in the extraordinary market valuations of Alphabet, Microsoft, Amazon, Facebook, and others. The deployment of the products and services of these companies throughout the global marketplace also suggest their profound economic influences (Picardo, 2018). The value creating strategies most associated with IT firms are known to be R&D investment (Jha & Bose, 2016), outsourcing (Wickramasinghe & Jayaweera, 2011), mergers and acquisitions (Chang & Cho, 2017), and data analytics (Chen et al., 2015). Despite the success of these strategies, IT firms have been scarcely studied as objects of scientific experimentation. Consequently, there is very little available literature on the relationship between IT firm phenomena and national unemployment.

Given IT firms base their wealth on digital innovation, they are useful representations of the extent of technological revolution occurring in the national economy (Greenwood & Jovanovic, 1999; Hobijn & Jovanvic, 2001). The performance of IT firms are known to affect the U.S economy (Deutsch, 2018; Jorgenson et al, 2016), including the labor market. The literature supports two basic ways to assess the presence of IT firms in the US economy. First, firm asset values drive labor demand (Phelps, 1994). However, the relationship between firm value and unemployment is unclear. For example, Manuelli (2000) suggested firm technology improvements reduce market values, which in turn cause firms to reduce investment and hiring. Second, IT firm counts may drive unemployment. Manuelli (2000) explains that when firm market valuations are low, new firms are less willing to enter the market because existing technology is becoming obsolete. Thus, we expect both measurement types to be reasonable paths for assessing the IT firm-unemployment relationship.

IT Industries and National Unemployment

Our study splits the IT economy into four industry sectors. Figure 1 shows that the IT subsectors (hardware, services, trades, and telecommunications) defined in Templeton et al. (2018) are a substantial component of the U.S. economy. Despite their prominence, virtually no existing literature addresses these IT industries.

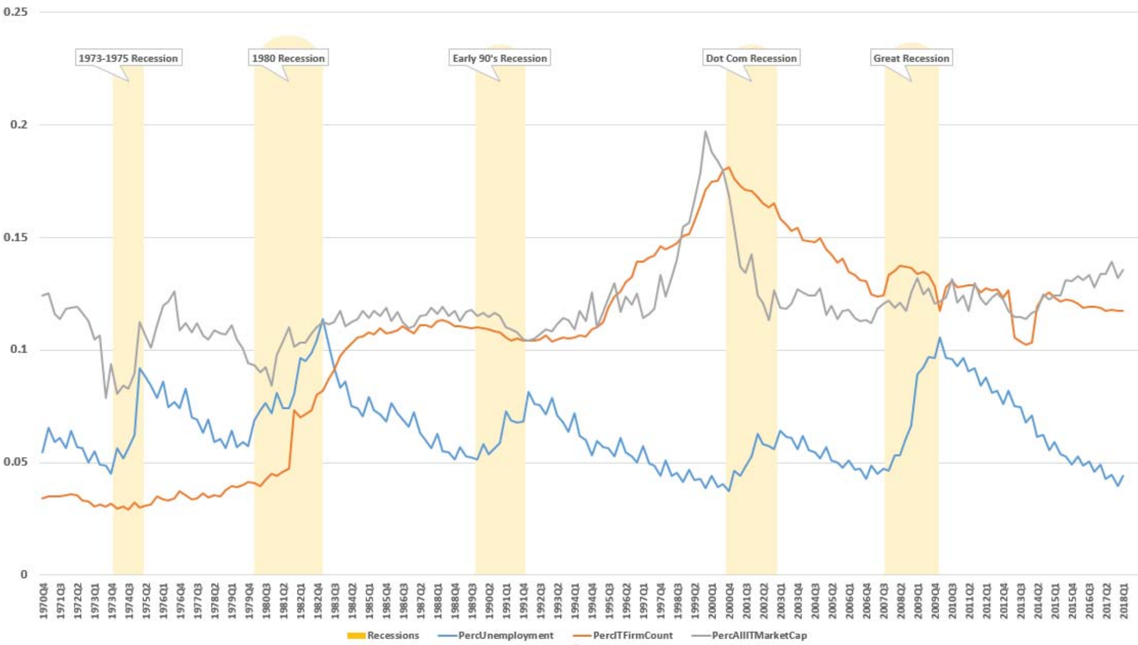
The hardware IT sector includes firms that manufacture computer, telephone, television, and other communications equipment. Discussions of automation and robotics are relevant to this subsector. The threat of process automation to employment has been a prominent social issue over the last half-century (Davenport & Kirby, 2015; Miller, 1964). According to studies, the linkn between IT hardware and unemployment is confounding and complex. Robotics are believed to increase organizational unemployment rates by replacing workers from a variety of occupations (Fortunati et al., 2015). Therefore, experts believe robotics contribute to labor uncertainty (Frick, 2014) and decrease unemployment (Sorells, 2018). Schwitter (1965) argued that computer hardware has had a minor effect on the unemployment rate. Aside from its labor consequences, automation also fulfills employees' needs in ways that may not be reflected in economic indicators (Diebold, 1953). Technological advancement is believed to cause a substitution of capital for labor (Falatoonzadeh & Safarzadeh, 2017) in ways that cannot readily be measured. IT services include programming services, computer processing, and developed systems. Writers and researchers are usually referring to this sector when discussing the effects of artificial intelligence (AI) on unemployment. For instance, Rotman (2017) warns that labor issues should be considered while enjoying the benefits brought by artificial intelligence. IT-enabled service innovations are known to save labor costs in organizations (Seifer, 1971). For example, technical advancement allows self-servicing such that customers make transactions online without assistance. Organizations are known to apply IT to reduce reliance on scarce and expensive skills (Miles, 1993).

IT trades include the wholesale and retail sales of digital devices and software. The relationship between IT trades and unemployment also remains obscure. While Borjas, Freeman, and Katz (1991) found a small negative relationship between trade and labor conditions at the national level, they ignored the role of computing. Results concerning computer equipment may be differentiated from other economic phenomena due to Moore's Law (Moore, 1965). While this uniqueness has been demonstrated in studies (Sachs & Shatz, 1994), nothing has been done to isolate country-specific computer trades and unemployment. Morin (2014) explains that as computers become cheaper than labor, they become more in demand. The computer displacement of routine work occurs rapidly as the economy enters recessions and these jobs are not replaced during expansions. However, the world has not experienced continuously increasing unemployment due to falling computing costs.

The telecommunications IT sector includes firms involved in radio, telephone, messaging, and other communications. The literature regarding this sector is mixed concerning its relationship with unemployment. Investment within the telecommunications sector presumably leads to economic growth (Zahra et al., 2008). However, Czernich (2014) could not confirm their results that the diffusion of broadband internet is associated with lower unemployment rates in Germany. Montgomery and Benbasat (1983) advocated using telecommunications to reduce white collar labor costs, although they did not test this association.

Practically all publicized concerns about the negative economic effects of IT on unemployment ignore surges in influence among IT firms. We could not find any article investigating the link between the relative prominence of IT firms in society and macro-economic unemployment. For these reasons, we empirically investigate this relationship in the US.

Figure 1: The Relative Prominence of IT firms and Unemployment (1970Q4 – 2018Q1)[1]



[1]Marked recessions in Figure 1 are based on prominently understood US economic recessions. We defined the timeframes for each, only for the purpose of charting, by estimated each recessionary period. The low points in unemployment marked the starts of recessions and the high points marked recessionary finishes.

METHODLOGY

Data

All IT firm data was collected from the *Compustat – Capital IQ* database component of the *Wharton Research Database Service (WRDS)*. To capture the largest and reliable sample frame, the study utilized a quarterly timeframe spanning quarter 4 of 1970 until quarter 1 of 2018. We used multiple measures of IT firms to gauge their prominence in the US economy: 1) aggregated market capitalization and 2) IT firm count. We calculated these values within each of four IT sectors: hardware, services, trades, and telecommunications. Within each sector-quarter, we divided each aggregated IT firm measure by the same for all firms to arrive at relative scores. This provided eight measurement options (relative count and capitalization measures for each of the four IT sectors) for assessing the relationship between IT economic prominence and national unemployment. We collected the US non-seasonally adjusted unemployment rate from the Federal Reserve Economic Database (FRED). We divided this value by 100 in order to standarize with other study measures. Table 1 displays the descriptive statistics for each study variable.

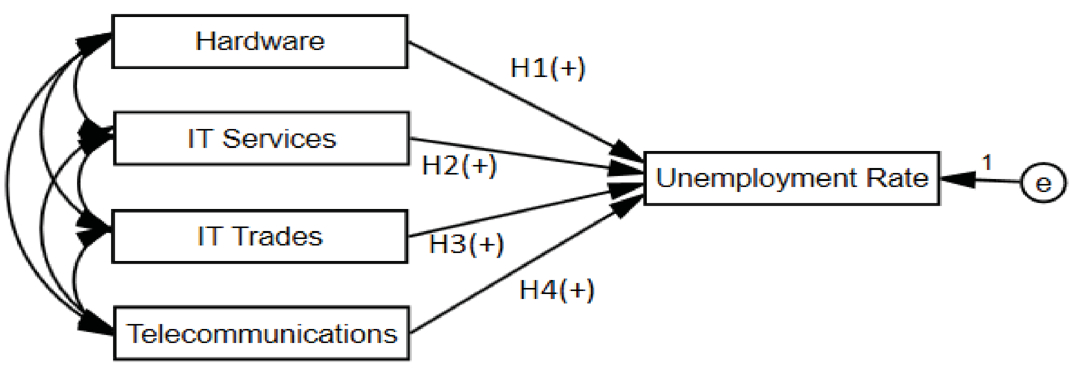
Table 1: Study Variables

Variable Name	**n**	**μ**	**Σ**
Unemployment Rate (%)	190	0.06	0.02
Relative Market Capitalization			
Hardware	190	0.03	0.00
Telecommunications	190	0.05	0.01
Trades	190	0.00	0.00
Services	190	0.05	0.01
Relative Firm Count			
Hardware	190	0.03	0.00
Telecommunications	190	0.02	0.01
Trades	190	0.00	0.00
Services	190	0.03	0.01

Procedures

We used Excel 2016, SPSS 25, and Amos 25 for all analyses. We used covariance-based structural equation modeling (SEM) to test hypotheses associated with RQ2 (concerned with the link between IT subsector prominence scores and unemployment). Figure 2 illustrates the path diagram used to test the relationships between each of the four industry sectors and unemployment. This model was tested using two bases for measurement: relative market capitalization and relative firm count.

Figure 2: Research Model



RESULTS

RQ1 is concerned with how economic recessions effected aggregated measures of IT firm prominence and unemployment. Figure 1 illustrates the relative stability of these IT firm economic measures, their behavior during and between five prominent recessions[1], and their relationship with national unemployment. For example, the graph indicates that the relative prominence of IT firms (using both measures) was at its peak in 2000, just prior to the Dot Com Recession. Further, it shows an unclear relationship between both IT firm prominence omnibus measures and unemployment. While unemployment rates are clearly cyclical over time, there does not appear to be a pattern for IT firm promenence in both boom and bust economic periods. This is true using both IT firm count and market capitalization data. This data justifies further empirical work on this evidence.

Pursuant to RQ2, we found that the relative aggregate market capitalizations of IT industry sectors explained 18.1% (Adjusted R^2) of the national unemployment rate. Further, we found support for three of the four hypotheses (see Table 2, Panel A). All tests produced negative critical ratios, indicating that unemployment decreases as the prominence of IT firms increases. This, and especially the consistent pattern in three significant sectors (hardware, trades, and services), suggests that IT firm health improves the labor situation at the national level. Further, these indicators are adequately independent influences on the overall economy. RQ2 results also indicate that IT firm counts explain 14.2% of the national unemployment rate. The analysis elicited support for two of four hypotheses (see Table 2, Panel B). Consistent with results pertaining to H4a, findings for H4b suggested a negative relationship between IT services prominence and unemployment. However, contrary to all other significant findings, the path for H1b showed a positive relationship between IT hardware firm prominence and unemployment. Thus, this isolated finding generally supported the idea that IT causes unemployment.

Table 2: Market Capitalization in Four IT Industries and Unemployment Rate

Panel A: Using IT Firm Market Capitalization

Hyp	Test	Estimate	S.E.	C.R.	P
H1a	Hardware Market Cap→ Unemployment	-.481	.155	-3.102	.002
H2a	Telecom Market Cap→ Unemployment	-.087	.098	-.889	.374
H3a	IT Trades Market Cap→ Unemployment	-16.922	4.972	-3.403	***
H4a	IT Services Market Cap→ Unemployment	-.232	.096	-2.413	.016

Panel B: Using IT Firm Counts

Hyp	Test	Estimate	S.E.	C.R.	P
H1b	Hardware Firm Count → Unemployment	.833	.182	4.575	***
H2b	Telecom Firm Count → Unemployment	-.173	.096	-1.795	.073
H3b	IT Trades Firm Count → Unemployment	1.820	1.498	1.214	.225
H4b	IT Services Firm Count → Unemployment	-.906	.186	-4.870	***

DISCUSSION

Results concerning RQ1, concerned with observing the interplay between study variables during economic recessions and expansions, reveal insights about how IT firms interact with the overall economy. Importantly, it reveals that IT firm prominence is a stable and sensible economic indicator. The phenomenon, introduce in this study, is reliable over a timeframe spanning several decades. Further, we show that unemployment is a demonstrably cyclical economic indicator that correlates well with known economic peaks and troughs.

Pursuant to RQ2, which involves four hypotheses concerning relationships between IT firm prominence and unemployment, we found mostly consistent results. One basic interpretation from this result is that IT firms influence the U.S economy in diverse ways that affect overall employment opportunities (Jorgenson et al, 2016). Our results provided evidence that illuminates how four IT sectors uniquely effected unemployment. As research using novel economic concepts and measures, the findings promote the inducement of new economic theory applicable to IT firms.

Proponents of the belief that IT causes unemployment may be bolstered by our finding that the prominence of the hardware sector (assessed using firm counts) positively influences national unemployment (H1b). That is, as the sector grows in firms, the labor situation is harmed and vice versa. This could very well be due to robotics, which are widely feared in the popular press for this reason. On the other hand, this test resulted in a negative significant relationship when using market capitalization data (H1a). However, popularly held notions about the overall effects of IT on unemployment were challenged by the preponderance of our findings. As we discussed earlier, robotics or automation may be one of the possible reasons. This finding suggests it may be beneficial to train employees to have updated skills (Davenport & Kirby, 2015).

Interestingly, the prominence of the telecommunications sector was insignificant as a predictor of unemployment. This is consistent with prior questions about whether efficiency in telecommunications technology affected unemployment (Runhaar & Lafferty, 2009). By contrast, the number of trades firms, unlike the market capitalization, does not influence the unemployment rate. Therefore, the economic aspects of IT trades deployment show the mixed results in this paper. Policymakers can take advantage of our findings to make better decisions to steer the economy and counter unemployment. Last, the count of IT services firms helps with the unemployment rate, aligning with the result of its market capitalization.

CONCLUSIONS

This paper presents a study assessing the relationship between IT and unemployment at the national level. Using structural equation modeling (SEM) path analysis applied to 47 years, we found support for five out of eight hypotheses tested. However, four of our significant hypotheses diverged from a long history of publicized fears claiming IT causes unemployment. Given the temporal and industrial spans of this study, it is useful to revisit one of the direst warnings about communication systems in the last century in *Harvard Business Review*:

> *"It is perfectly clear that this will produce an unemployment situation, in comparison with which the present recession and even the depression of the thirties will seem a pleasant joke. This depression will ruin many industries -- possibly even the factories that have taken advantage of the new potentialities" (Wiener, 1954).*

Broad speculations such as these have been debunked by the last half century of experience, in addition to our findings. Our study reveals that it is more realistic to say there is a relationship between the influence of IT in society and unemployment, but the relationship is not profound, and is complex. In fact, most of our significant findings indicate that when IT firms are most influential, the labor market improves. Both our data (see Figure 1) and our findings reveal that the public should largely absolve IT firms and their customers further blame for job losses.

A few limitations should be recognized when interpreting the research findings. First, we used two variables to assess the relative prominence of IT firms and a single variable to assess the national unemployment rate. More perspectives on both measures would be more convincing while testing our hypotheses. For Instance, the US economy is very complex and is monitored using hundreds of diverse metrics. Second, the prominence of IT firms may very well effect other economic factors, such as wages (Helpman et al., 2010) and the growth of gross domestic product. Control variables may also be used to achieve more rigorous results. For these reasons, future research may incorporate additional indicators to extend our tested models. The association between the economic prominence of telecommunications on productivity would make interesting future research. In light of our finding that hardware firm count may potentially increase national unemployment, we suggest researchers uncover and use more specific data about this relationship.

ABSTRACT

The purpose of this paper is to analyze how working capital is allocated in supply chain networks. It investigates working capital fluctuations along supply chain networks. Inter-organizational network data was collected by snowball sampling in Bloomberg Terminal's database. The results suggest the existence of a financial spillover effect in the supply chain network and a mechanism that transmits working capital burden from customers to suppliers. Interestingly, the financial spillover effect is "reset" in the midstream section of supply chain networks where cash-rich companies provide liquidity to its supply chain partners. Similarly, inter-firm collaboration through the adoption of supply chain finance (SCF) solutions may reduce the cascading spillover reactions – the financial bullwhip effect – and stabilize a supply chain. network.

KEYWORDS: Working capital management, Financial spillover effects, Network theory, Snowball sampling, Supply chain finance

INTRODUCTION

Working capital is a measure of liquidity as it involves, by definition, all short-term items on the balance sheet. Consequently, net working capital might be interpreted as the liquidity that ensures continuity of a firms operations. Optimizing working capital has imminent benefits: First, it lowers capital requirements and releases liquidity (Deloof, 2003). Second, it reduces cost of capital (Knauer & Wöhrmann, 2013; Wöhrmann, 2012). Third, good working capital management (WCM) reduces financial and operational risks as a high proportion of business failures are due to poor decisions concerning the working capital of the firm (Smith, 1980). Working capital therefore is not only important from a finance perspective, but also from a logistics management perspective (Farris & Hutchinson, 2003). With respect to the latter, working capital is crucial in measuring supply chain management improvements and process efficiency (Farris & Hutchison, 2002). Companies usually do not improve liquidity management before reaching crisis condition or the verge of bankruptcy (Cole, 1991; Enqvist et al., 2014; Wöhrmann, 2012). This may have devastating consequences for an entire supply chain, because according to Wagner, Bode and Koziol (2009) default dependencies among suppliers exist. The difficulty of managing working capital stems from the inherent risk-return trade-off. "[…] too much investments in this area ties up liquidity that could be used more efficiently elsewhere" (Ek & Guerin, 2011). Conversely, too little investments in working capital might cause stock-outs and thus may alienate customers and suppliers. Furthermore, the traditional firm-individual approach to working capital management falls short in recognizing supply-chain

related inter-firm dependencies (Hofmann & Kotzab, 2010). It is decisive for decision makers to consider the following two lines of argumentation. First, companies no longer compete as stand-alone entities, but rather as integrated supply chains and second, managing working capital detached from a firms supply chain partners might no longer be the most efficient solution (Daugherty et al., 2006; Christopher, 2005). Supporting these statements, Protopappa-Sieke and Seifert (2017) and Viskari and Kärri (2012) both found significant benefits of collaborative WCM within the supply chain. Grosse-Ruyken, Wagner and Jonke (2011) suggested that shortening CCC in the entire supply chain increases the performance of a focal firm. In addition, Hofmann and Kotzab (2010) and Randall and Farris (2009) show optimization approaches for working capital management in a network context.
However, existing research is insufficient due to various reasons. First, the potential of network thinking similar to the interpretation in lean material supply chain management or JIT has not yet been quantitatively evaluated from a working capital perspective. In particular, the knowledge about financial spillover effects between companies in supply chain networks is very limited. Second, past studies in general conventionalized supply chains as linear systems of sequential relationships. However, a company's financial working capital relationships take place in an extended supply chain network beyond immediate dyadic relationships, which a linear model fails to capture. Third, current literature about working capital investigates companies as stand-alone entities. Conceptual studies have pointed towards a more holistic approach in WCM. However, only few quantitative studies exist that take into consideration that working capital is not only pivotal for the efficient management of an individual company but also greatly impact its extended supply chain network. The present paper addresses aforementioned gaps by analyzing working capital from a supply-chain-oriented perspective. In particular, the following overall research questions are examined:

RQ1: How is working capital allocated in supply chain networks?
RQ2: How does working capital fluctuate along supply chain networks?

This paper addresses the shortcomings in previous research attempts as follows: First, the paper at hand chooses a novel approach by analyzing working capital in supply chain networks from a social network perspective. It therefore bridges several literature streams from the working capital, supply chain/logistics and social network theory literature. Second, it established an understanding of how the presence of liquid companies with access to outside finance may break the cascading effect of financial spillover effects in supply chain networks (Serrano et al., 2018; Gropp, 2013). Third, it contributes to financial literature that deals with the effects of supplier-customer interactions by exploring supply chains in terms of financial contagions. Fourth, it provides practitioners with valuable hints on how supply chain networks can be stabilized to the benefit of all involved players through better working capital coordination (e.g. with the help of supply chain finance solutions). It extends current research and pushes towards a more holistic perspective on working capital management
The remainder of the paper is organized as follows. First, the theoretical background and hypotheses are presented. Second, the methodology and data analysis approach of the explorative supply chain network analysis are outlined. This includes the method for approximating supply chain network tiers and the statistical methods used to derive conclusions from observations in the dataset. Third, the results of the different analyses are presented. Fourth, the results of the data analysis are discussed and both theoretical and practical implications are provided.

THEORETICAL BACKGROUND AND HYPOTHESIS DEVELOPMENT

A multitude of studies have analyzed working capital levels across numerous settings and varying scopes of analysis. In particular, differences amongst industries and geographies have been investigated comprehensively. For example, Hawawini et al. (1986) investigated whether the working capital requirement to sales ratio (i.e., CCC) is different among industries. The results indicate a significant industry effect on firm's investment in working capital over the examined periods covered. They argue that this industry effect exists partly due to similar technologies, processes and managerial efficiency. Similarly, Filbeck and Krueger (2005) found significant differences between industries regarding the working capital measures. In line with these observations, Weinraub and Visscher (1998) found relative differences in working capital policies between industries. The latter further propose that these differences persist over an extended period. Similarly, Ng et al. (1999) found that while credit terms vary widely across industries, only little variation within industries exists.
These studies are of great value because they improve our understanding about differences in working capital levels across distinct settings and therefore varying explanatory variables, in particular industry and countries. However, from a modelling perspective they are limited as they are not conducted in the setting of multiple supply chain relationships. Supply management research have used the complex system perspective as a theoretical basis to describe supply networks (e.g., Choi, Dooley, & Rungtusanatham, 2001; Kim, 2009; Pathak, Day, Nair, Sawaya, & Kristal, 2007; Surana, Kumara, Greaves, & Raghavan, 2005). This supply chain-related studies used both simulation models (e.g., Kim, 2009; Pathak et al., 2007) and real-world supply networks (e.g., Choi & Hong, 2002; Jarillo & Stevenson, 1991). Choi and Hong (2002), for example, study a sample of three complete networks from the automotive industry to conceptually analyze the structure of supply networks in this industry. Losbichler and Rothböck (2008) conducted a working capital study on 6,925 European companies over the period 1995–2004. By applying a supply chain network perspective on working capital they found that some industries were able to reduce CCC by up to 31.6 days, whereas in others the CCC increased by up to 59.9 days. In particular, car manufacturers were able to improve CCC on the expense of other companies in industries such as logistic providers and metal goods manufacturers that were faced with an increase in CCC. Another example is the study of Lorentz et al. (2016), who examined the effect of the business cycle on net trade credit including its components in different supply chain network tiers. They found that net trade credit decreases in further upstream tiers. Additionally, they found that period-to-period changes in accounts receivable and accounts payable are greater further up the supply chain. A similar mechanism was found by Chen (2012) who analyzed payment terms of project contractors, project owners, specialist contractors and suppliers. Against the background of these results our first hypothesis, addressing the level of working capital in supply chain networks, reads as follows:

H1: *Average CCC levels increase in companies located further upstream a supply chain network.*

While working capital-related papers using network theory are scarce, there exist various studies analyzing working capital-related spillover effects in customer-supplier relations. Regarding the inventory management component of WCM the most important spillover effect is known as the bullwhip effect (Chen & Lee, 2017). The bullwhip effect describes how the distortion of demand information in a supply chain amplifies demand variance as it moves from consumption point up the supply chain to layers of suppliers. The phenomenon arises when supply chain members place orders with a large variance to actual sales (demand distortion). The demand variation amplifies as it propagates to further upstream companies (Lee, Padmanabhan, & Whang, 1997). Several studies analyzed these spillover effects, highlighting that a bullwhip effect exists in a supply chain (e.g., Chen, Liao, & Kuo, 2013; Lee et al., 1997;

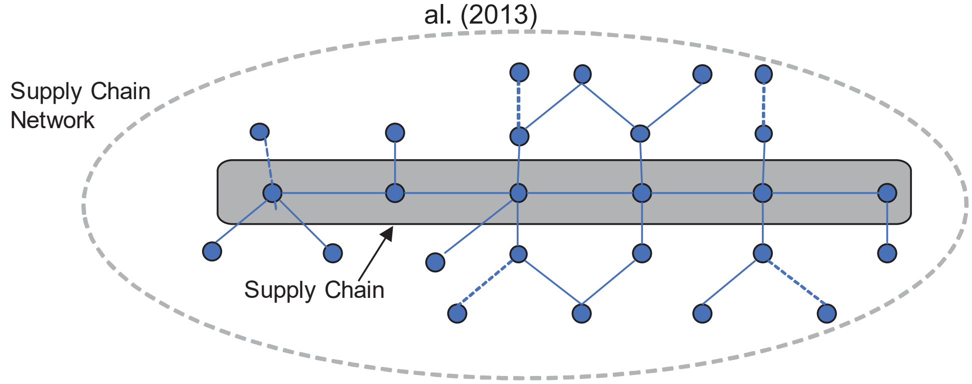
Lee, So, & Tang, 2000; Osadchiy, Gaur, & Seshadri, 2011). Only a few considered a supply network (e.g., Mizgier, Wagner, & Holyst, 2012; Ouyang & Li, 2010; Wangphanich, Kara, & Kayis, 2010).
Regarding the financial components of WCM a similar phenomenon is known as "financial contagion". It refers "to the increased likelihood of a firm defaulting to its suppliers as a result of its customers' defaults on trade credit" (Serrano, Olivio, & Kraiselburd, 2018). This suggests "not only that payments to suppliers are subject to variability, but also that variability is somehow transmitted upstream". Studies were conducted to analyze how this risk spreads from a single company to an industry. Serrano et al. (2018) showed that for strongly coupled relationships, the decision of a company not only affects the firm but also its suppliers. They confirm that large, liquid firms with access to outside finance ("deep pockets") have a reducing effect on the propagation of risk in a supply chain (Serrano et al., 2018). Similarly, Boissay and Gropp's (2013) results indicated that a credit-constrained firm facing a liquidity shock partly absorbs this shock and partly passes it on to suppliers. The liquidity shocks are transmitted through trade credit chains until a "deep pocket" fully absorbs the shock. Hence, firms with access to outside finance provide liquidity to the supply chain through maturity extensions on trade credit and by paying trade debits on time. Trade credit default chains might be seen as a mechanism that reallocates liquidity from deep pockets to small, credit-constrained firms. Boissay and Gropp (2013) interpret this mechanism as liquidity insurance through trade credit which is supplied by all types of companies to their customers. Also, small and credit-constrained firms can afford insuring their customer, because they are themselves insured by their suppliers. However, only deep pockets are able to inject fresh liquidity into the supply chain. Consequently, by extending maturities on trade credit supplier do not only "relax the financial constraints faced by their customers but also ultimately their customers' customers and other firms they may not have direct business relationships with". Chen et al. (2013) explore internal liquidity risk and financial bullwhip effects on corporate bond yield spreads along supply chain counterparties. Tangsucheeva and Prabhu (2013) introduce the financial (cash flow) bullwhip measured by the ratio of CCC variance over demand variance. Using simulation, they find "that increasing variability increases inventory and cash flow bullwhip along with lead time". Since the amplified order is higher than the actual demand, products remain in inventory and thereby cause higher inventory cost. Additionally, the company will also encounter higher opportunity- and financial cost as well as elevated levels of working capital. Itzkowitz (2013) showed that a supplier's cash holding increases as the importance of the relationship increases. This is argued to be a precaution against the additional operating risk by having an important customer. Kale and Shahrur (2007) show that lower debt level induces supplier and customer to make relationship-specific investments. Further, they indicate that companies have higher debt levels when customer or suppliers have higher bargaining power (bargaining role of debt). In line with these findings, Chu (2012) find decreasing firm leverage as the degree of competition between suppliers decreases. Oliveira, Kadapakkam, and Beyhaghi (2017) find that suppliers to distressed customers "increase their financing leverage to fortify their bargaining power". Against this background the second hypothesis, addressing the working capital variability and potential financial spillover effects in supply chain networks, reads as follows:

H2: *CCC variability increase in companies located further upstream a supply chain network.*

METHODOLOGY

Applying a supply chain network model, it is important to be clear about the distinction between a "supply network" and a "supply chain". A supply chain in general describes the extended network of dyadic exchange relationships that must exist for the creation of a product or service that is supplied to a final customer (Cox, Sanderson, & Watson, 2001). Hence, a supply chain is traditionally captured by a dyadic model that arranges suppliers and customers in a linear fashion. However, a dyadic perspective is limited in order to understand a company's working capital financing relationships as these depend on an extended network beyond immediate dyadic relationships. Kim et al. (2011) define a supply network as a firm's supply network that consists of ties to its immediate suppliers and customers, and ties between them and their immediate suppliers and customers, and so on. In this paper this definition is followed and illustrated in Figure 1.

Figure 1: Supply chain and supply network: a diagrammatical representation; Source: Rogers et al. (2013)



Data Source

All data used for this paper were downloaded from the Bloomberg Terminal database in November 2018. Bloomberg provides various information on supplier-customer relationships. Each relationship is categorized by cost type for the customer: cost of goods sold (COGS), capital expenditure (CAPEX), research and development (R&D) and selling, general and administrative expenses (SG&A). Bloomberg quantifies the relationship value if possible. For these "quantified" relationships, Bloomberg specifies percent revenue and percent cost. Revenue percent represents what the central company gets from is customer and cost percent represents what gets incurred by this customer.

Sampling Procedure and Data Collection

The supplier-customer relationship data were collected through snowball sampling. This is usually the preferred method for sampling network structures (Robins, 2015). Vogt and Johnson (2011) define snowball sampling as a technique for finding research subjects. One subject (ego) gives the researcher the name of another subject (alter), who in turn provides the name of a third, and so on. The ego initiating the snowball sample is called "seed". The snowball sampling approach is particularly useful for analyzing financial spillover effects as it can provide a better understanding about a topic for which little information is available (Griffiths et al., 1993). Further, large sample sizes and replication of results are likely to strengthen the level of generalization (Griffiths et al., 1993). According to Robins (2015) recent statistical models for social networks have demonstrated that estimated effects from a snowball sample can be consistent with the entire network structure. For the analysis in this paper the manufacturing company Hewlett Packard as part of the high-tech industry was chosen as the seed company. As Bloomberg's early data collection on supply chain information focused on the high-tech sector it is expected that this sector has a better supply chain coverage compared to other

sectors. Further, it deemed important to choose a company with (at least) 20 suppliers and 20 customers in the Bloomberg database. Fewer companies in the first wave would restrict the sample size of the next waves and render it impossible to come up with an extensive snowball sample.
After choosing HPE US Equity as the seed, four waves were sampled. In each wave a maximum of 20 suppliers and 20 customers were sampled per company of the previous wave (ego). This theoretically results in of maximum 2,560,000 (=1,280,000*2) alters in the last wave. However, due to lack of data (non-reporting, private company, government etc.), concentrated markets, loops or “beginning/end” of the supply chain the snowball sampling provided a total of 1,386,652 (=485,029+901,623) alters in the last wave. An overview of the sampled raw data is given in Table 1.

Table 1: Raw network sample; number of egos and alters per wave (including duplicates)

	Theoretically (per side)		**Downstream: effective**		**Upstream: effective**	
Wave	**Egos**	**Alters/no. dyads**	**Egos**	**Alters/no. dyads**	**Egos**	**Alters/no. dyads**
1	(HPE US Equity) 1	20	1	20	1	20
2	20	800	20	701	20	773
3	800	32,000	701	18,610	773	26,937
4	32,000	1,280,000	18,610	485,029	26,937	901,623

To clean the raw data, the following actions were conducted:

(1) removal of duplicate relationships;
(2) exclusion of all cost types other than COGS;
(3) removal of percent cost relation;
(4) removal of unquantified relationships;
(5) removal of isolated companies.

During the data cleansing all relationships with cost types other than COGS were excluded. This is motivated by the focus of the present paper on working capital relationships. In line with Itzkowitz (2013), this paper uses percent revenue as the measure for relationship importance. Revenue percentages are from a supplier perspective and represent material flow in a network (from node: supplier, to node: customer). Furthermore, only quantified relationships were considered in order to assign an importance to supplier-customer links. Lastly, companies that were no longer connected to the main cluster due to the data cleansing were removed. This process lead to a data set of 5,853 companies connected by 29,253 directed nodes. After collecting the network data, relevant financial working capital data for the represented companies were collected. In particular, data on accounts payable, accounts receivable, inventory, sales, sector (2-digit), industry group (4-digit), industry (6-digit), sub-industry (8-digit), Standard & Poor’s (S&P) long-term credit rating, Moody’s long-term credit rating, country origin and private indicator was collected. Data cleansing was performed again after collecting the financial data. All firms that had incomplete records in a metric necessary to calculate the working capital measures were removed from the sample (Baños-Caballero et al., 2014; Deloof, 2003). Further, all companies in the financial sector (2-digit GICS: Financials) and all real estate investment trusts (6-digit GICS: REITs) were removed because of the nature of their business (Deloof, 2003). Finally, the above data cleaning lead to companies isolated from the giant network, which were also eliminated. Table 2 gives a summary of the data cleaning. The final data set consists of 3,956 firms. Also note that DIH, DPO and DSO were winsorized at the 5% and 95% level to deal with outliers (Baños-Caballero et al., 2014; Deloof, 2003).

Table 2: Summary of data cleansing after retrieving company-specific data

Data cleansing	Number of companies
Number of initial companies	5,853
missing data	1,855
Financials (GICS 2-digit) and REITs (GICS 8-digit)	8
Isolated companies (due to above actions)	34
Final sample	**3,956**

Data Analysis Method

Table 3 provides an overview of the data analysis approach and sketches the structure of the following sections. The columns represent the supply chain approximation methods. The rows show the structure of the analysis by CCC levels and CCC variability. The analysis of the absolute working capital levels is applied to two different subsamples (complete sample and “subsample 10”). Subsample 10 is a more restricted sample and consist only of companies that are connected by an edge weight of 10 or more. The variability analysis is conducted on the complete sample with two measures. For each measure the analysis is divided into credit rating groups. The analyses were conducted with Gephi 0.9.2 and UCINET 6.645. Gephi was used to visualize the network and to calculate the network statistics. UCINET was used to perform the permutation tests.

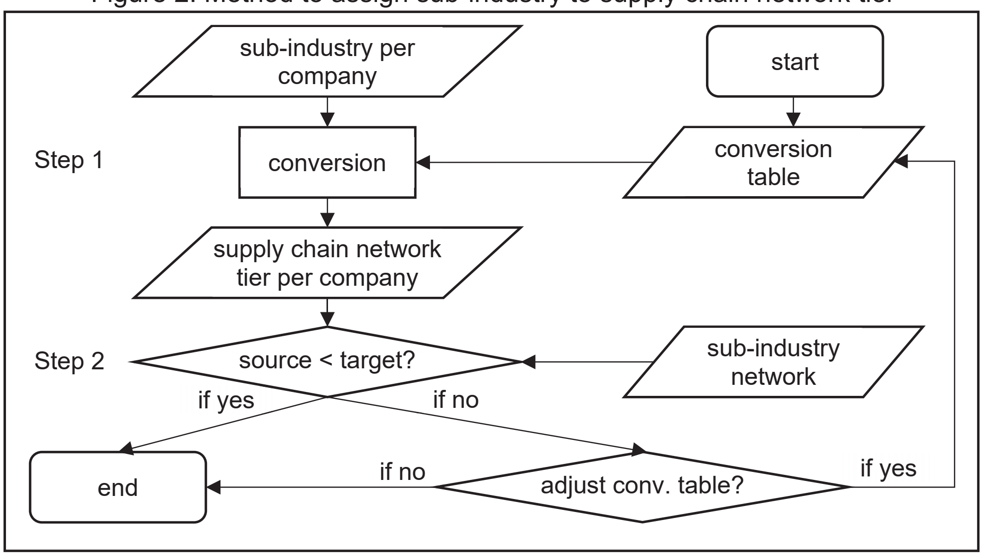
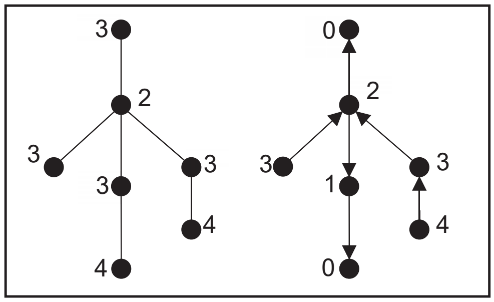
In order to determine how working capital is allocated in supply chain networks two different approaches are applied. Scholars such as Lind et al. (2012), Brandenburg (2016), Losbichler and Rothböck (2008) or Lorentz et al. (2016) used industries to divide a set of companies into different supply chain network tiers. The present paper applies this approach and labels it as the “existent approach” (see column 2 in table 3). The assignment of an industry to supply chain network tier is subjective as many different industries and products are present in the analyzed network. The process illustrated in Figure 2 was chosen to reduce subjectivity of the assignments. In the first step, a conversion table was created where the sub-industries (8-digit GICS) were assigned supply chain network tiers. The supply chain network tiers are retailer (Ret), distributor (Dist), product producers (Prod), component manufacturers (Comp), primary manufacturing (Prim) and raw material (Raw) in downstream to upstream order. The descriptions of the GICS classification were used to achieve the best possible allocation (Maitland & Gandhi, 2018). Integrated companies, consultants, service providers, energy providers, and transportation companies were assigned to the group “integrated companies” (Int) as these create value throughout the supply chain. Companies for which Bloomberg provided no values were assigned to the “not classified” group (NC). With this conversion table the corresponding supply chain network tier was assigned to each company. In the second step, the subjective assignments were checked and corrected if necessary. In particular, a sub-industry network based on the original network was created. For each relationship the sub-industry of the source node and the sub-industry of the target node were taken to form an edge list by sub-industries. Duplicate edges were merged by summing up their edge weights. Thereafter, the conversion was checked. If source and target tier did not match logical product flow it was further assessed. In the assessment connections to other industries of source and target were considered together with the edge weight. If deemed reasonable, the conversion table was adjusted to match major product flow.

Figure 2: Method to assign sub-industry to supply chain network tier



The second analysis approach incorporates the location of a company in the network instead of the industry. This approach is called the “network approach” (see column 2 in table 3). In particular, an eccentricity measure is used to group the companies, thereby, incorporating the network perspective into the analysis. The eccentricity of a graph is a distance measure. Distance is thereby defined as follows: If G has a u, v-path, then the distance from u to v, written [···] d(u, v), is the least length of a u, v-path. If G has no such path, then d(u, v) = ∞” (West, 2001). The eccentricity of a vertex u, written e(u), is maxv∈V(G)d(u, v) (West, 2001). Hence, the eccentricity e(v) of a vertex v is the distance between v and a vertex farthest from v. Figure 3 illustrates the eccentricity measure in both a directed and an undirected network. In a material flow network, vertices with an eccentricity of 0 can be interpreted as the furthest downstream as the material cannot flow any further. A high eccentricity on the other hand, means that the product has (potentially many nodes left before reaching the final customer. Therefore, a node with a high eccentricity is expected to be further upstream. In this interpretation, eccentricity represents the tier distance from the end-customer. The directed network in Figure 3 (right-hand side) illustrates this argument.

Figure 3: Graph eccentricities in an undirected (left) and directed network (right)



Statistical analysis

The analysis of working capital within the supply chain network is conducted with ANOVA (analysis of variance). However, as standard statistical tests make assumptions, which are violated by network data, a viable approach for statistical tests on a network sample is introduced. Models studying the distribution of ties or randomized tests are suitable for networks. In particular, this paper applies permutational tests for the analysis of CCC levels in the supply chain network. The general logic of permutation test in the network context is that one wants to compare the observed correlation against the distribution of correlations that one could obtain if the two variables were in fact independent of each other (Borgatti et al., 2018). The permutation test calculates all ways the experiment could have come out with actual independent scores. Then, the proportion of all assignments yielding a correlation as large as the one actually observed are counted. This value represents the “p-value” or significance of the test (Borgatti et al., 2018). The number of permutations of N objects grows very quickly with N, therefore enumerating all possible permutations is not feasible and a sample from all permutations is taken. Typically, a large sample, such as 20000 permutations is used (Borgatti et al., 2018). According to Good (2005) permutation tests rely on the assumption of exchangeability. Thereby, exchangeable means independent, identically distributed observations as well as dependent normally distributed random variables. Further, it is also a necessary condition for the application of any statistical test. Thus, permutational tests are a suitable method to identify potential differences in average working capital levels in supply chain networks. The null hypothesis for an ANOVA is presented in Equation (1), where µk represents average CCC in group k. Contrary, Equation (2) represents the alternative hypothesis.

H_0: $$\mu_1 = \mu_2 = \mu_3 = \cdots = \mu_k \quad (1)$$

H_1: Means are not all equal; at least one $\mu_i \neq \mu_j$ (2)

ANOVA is an omnibus test and as such does not indicate between which groups the statistically significant difference exists. Therefore, if the null hypothesis of the ANOVA is rejected, post-hoc permutation t-tests are necessary to identify which groups are significantly different. Equation (3) presents the null hypothesis of a t-test and Equation (4) is the alternative hypothesis of a t-test, where µk represents average CCC in group k.

H_0 $$\mu_1 = \mu_2 \quad (3)$$

H_1 $$\mu_1 \neq \mu_2 \quad (4)$$

These post-hoc tests raise the concern of alpha inflation or the multiple comparison problem. The problem arises when multiple tests are performed on the same data. Each of these tests has its own alpha. If multiple tests are performed, the cumulative error for all these tests is going to be higher than the initially set alpha (Shaffer, 1995). To mitigate this problem, alpha-adjustment procedures were developed. In particular, permutational t-tests with a subsequent manual Benjamini-Hochberg procedure and Bonferroni method were performed (Shaffer, 1995; Benjamini & Hochberg 1995).

The working capital variability in the network is analyzed based on two measures. First, analogous to Lorentz et al. (2016) the CCC changes between two consecutive periods are compared. Second, in style of the cash flow bullwhip theory by Tangsucheeva and Prabhu (2013) the working capital variability between the groups is measured by the ratio in Equation (5).

$$\text{Working capital variability (WCVar)} = \frac{\mathrm{Var(CCC)}}{\mathrm{Var(Sales)}} \tag{5}$$

The formula scales working capital fluctuations by the variance of actual sales. A relatively high ratio indicates that the variability in working capital is higher than in sales. Consequently, a firm may find it more difficult to manage working capital and may incur higher cost (Tangsucheeva & Prabhu, 2013). To control for outliers, values more than three standard deviations higher than the average were removed. The cash flow bullwhip effect represents fluctuations that occur due to seasonality and other short-term effects (Chen & Lee, 2017). The bullwhip effect may, therefore, not be adequately captured by yearly accounting data. Nevertheless, with reference to the “working capital wave” of Lorentz et al. (2016) and Chen’s (2012) theory the variability of CCC along the supply chain network is analyzed.

The analysis of CCC variability is performed on three company groups. Boissay and Gropp (2013) suggested that firms with access to outside finance (“deep pockets”) absorb the cascading effect of payment default chains. Therefore, the analysis is conducted on three credit rating groups: investment grade group, speculative-grade group and not rated group (NR) (Moody’s Investor Services, 2019; Standard & Poor’s Financial Services, 2018). The assignment to the three groups is according to the S&P long-term credit rating as of end of 2017. If a company was not rated by S&P but by Moody’s, the rating of Moody’s was used. In case Bloomberg did not provide a rating of either S&P or Moody’s, the company was assigned to the not rated group together with all companies that were listed as “not rated” in Bloomberg.

RESULTS

Descriptive Statistics

The complete supply chain network consists of 3,956 nodes that are interconnected through 19,328 edges (Table 4). Subsample 10 consists of about 15% of the nodes and 3.6% of all edges of the complete sample. The elimination of edges is also seen in the average degree, which represents the number of adjacent edges to the average node (Borgatti et al., 2018). The average degree in the complete sample is about 4.9 and 1.2 in Subsample 10. Further, average-weighted degree, which is based on the number of edges but scaled by the edge weight, is lowest in the complete sample (Newman, 2001).

The network diameter, describing the longest of all shortest paths in a network, decreases as lower weighted edges are eliminated. In the complete network the diameter has 20 edges and in the Subsample 10 only 3 edges. On the other hand, radius is defined as the shortest path between all pairs of nodes (= minimum eccentricity). The radius is zero for in the complete

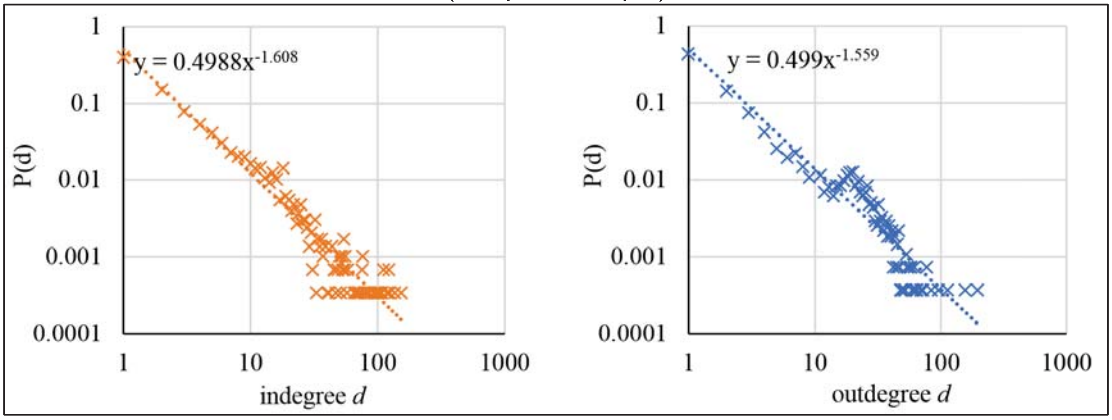
sample and in all subsamples. This indicates that at least one node has no outgoing edge. The average path length describes the average number of steps along the shortest paths for all possible pairs of network nodes. In the complete sample the measure is with about 5.3 steps much lower than the network diameter. For Subsample 10 it is 1.2 steps, respectively (Chartrand & Tian, 1997).
Graph density describes the number of ties in the network, expressed as a proportion of the number possible (Borgatti et al., 2018). The measure is slightly higher in Subsample 10 compared to the complete sample. Similarly, the average clustering coefficient is a measure for the average probability that "if A is related to B and B is related to C then there would be a relationship from A to C" (Borgatti et al., 2018). This value is highest in the complete sample.

Table 4: Network metrics

Metrics	**Complete**	**Weight 10**
Nodes	3,956	599
Edges	19,328	707
Directed	True	True
Average degree	4.886	1.18
Average weighted degree	12.676	28.064
Network diameter	20	3
Radius	0	0
Average path length	5.346	1.229
Graph density	0.001	0.002
Average clustering coefficient	0.050	0.009

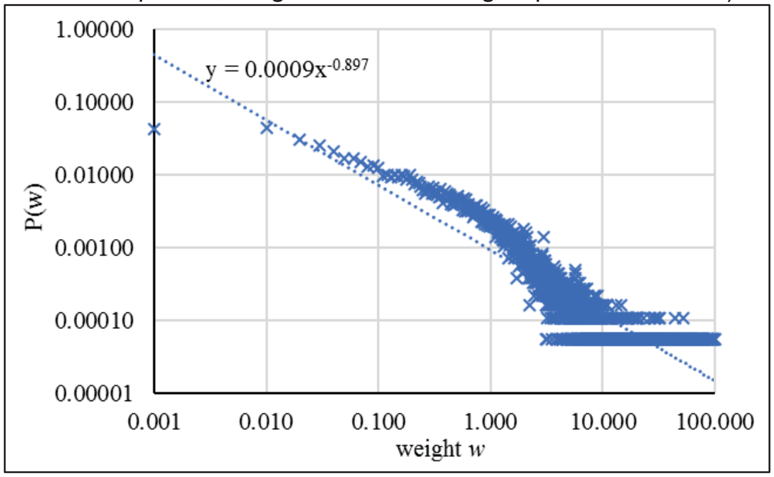
Figure 4 illustrates the connectivity distribution in the complete sample for indegree and outdegree edges. The top left point in the indegree plot indicates that a company has an indegree equal to 1 with a probability of 0.4 (i.e., 1,177 companies). The vertical lines on the bottom, right corners occur because only few companies have these relatively high degrees. If the connectivity distribution follows power law, the distribution would be following a linear line in the log-log plot. The dashed line represents the fitted power law curve. Thus, many nodes with a low degree and only a few nodes with a high degree are present in the network. Similarly, many nodes are connected by a relatively thin arrow indicating a relatively low edge weight.

Figure 4: Indegree distribution (left) and outdegree distribution (right), both on a log-log plot (complete sample)



Analog for edge weights, if the distribution follows power law, the distribution would be allocated in a linear fashion. Figure 5 depicts the edge weights in a log-log plot. The weights were rounded to two decimal places, weights of 0.005 or less were grouped in the 0.001 bin. Hence, the point on the top left indicates a probability of 0.04 that a company has a weight of 0.001 or less. The horizontal lines in the bottom right corner indicate large fluctuation in the tail for large degrees.

Figure 5: Edge weight distribution on a log-log plot (complete sample; weights rounded to two decimal places, weights below 0.005 grouped in 0.001 bin)



The descriptive statistics for the working capital measures are summarized in Table 5. Both, the mean CCC and the median CCC are highest in the complete sample at about 72 days and 64 days respectively. In the Subsample 10 the mean is at about 62 days and the median at 87 days. The difference between the means and medians as well as the values for skewness and kurtosis indicate not normally distributed samples.

Table 5: Working capital descriptive statistics, complete sample and subsamples

	mean	min	max	SD	25th %ile	median	75th %ile	kurtosis	skewness
Complete sample									
CCC	71.6	–99.1	374.6	56.7	33.7	63.5	100.3	1.829	0.982
DSO	66.8	1.2	251.5	45.4	37.1	58.4	85.7	3.262	1.508
DPO	42.4	9.3	101.1	24.9	23.3	37.1	56.9	–0.121	0.801
DIH	47.3	0.8	132.4	34.8	21.5	41.3	65.4	0.133	0.84
Subsample 10									
CCC	65.2	–84.8	282.7	43.3	37.0	56.8	87.3	1.881	1.019
DSO	64.6	1.2	251.5	32.9	43.7	58.1	78.5	4.846	1.633
DPO	41.8	9.3	101.1	21.5	25.4	39.0	54.5	0.232	0.731
DIH	42.4	0.8	132.4	28.1	24.6	37.6	54.4	1.820	1.204

CCC Level Results

The working capital allocation within the supply chain network was analyzed with two different grouping approaches: the “existent approach” and the “network approach”. Each analysis was performed on the complete sample and Subsample 10. For each combination of approach and subsample an ANOVA was calculated and, if necessary, post-hoc t-tests were performed. In the following, only the most important statistics of each analysis are presented. Regarding the post-hoc t-tests it is important to notice that the p-values presented in this paper cannot be blindly compared to an alpha of 5%, for example. The tests must be corrected for alpha inflation as explained previously. Each table showing the p-values for the t-tests indicates by a superscript which value is significant according to the Benjamini-Hochberg procedure (indicated by the superscript “a”) and the Bonferroni procedure (indicated by the superscript “b”). Thereby an alpha level of 0.05 is assumed.

<u>Existent Approach</u>

Figure 6 depicts the network graph of the complete sample with the nodes colored according to the respective supply chain tier. The node size is scaled by average CCC of each company over the entire observation period.

Figure 6: Network graph complete sample grouped by the existing approach (node size scaled by average CCC over all periods; edge size scaled by edge weight; node coloring by supply chain network tier, not classified and integrated companies colored the same)

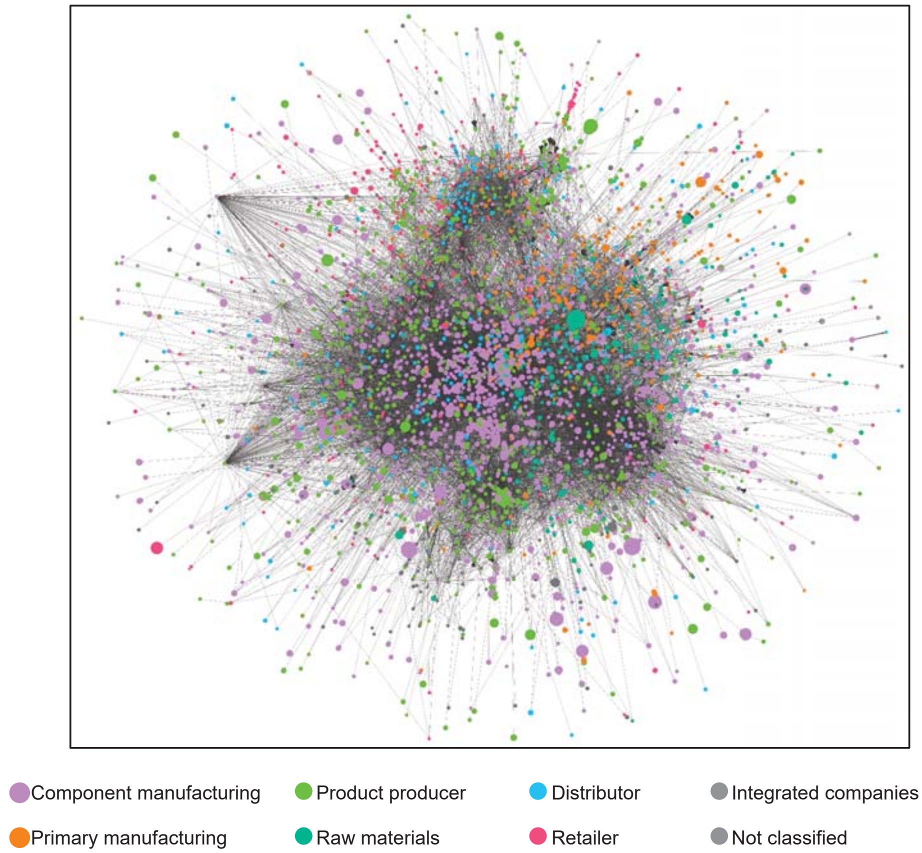


Figure 7 illustrates the average CCC per supply chain network tier and year of the complete sample. The average CCC increases between retailer (31 days average over all periods), distributor (53 days), product producer (83 days) and component manufacturers (88 days). Further up in the supply chain network, primary manufacturing (68 days) and raw materials (74 days) have both lower average CCC than product producers and component manufacturers. The black bar in Figure 7, between the raw-materials and integrated-companies groups, indicates the upstream end of the supply chain. Integrated companies and not classified companies provide services throughout the supply chain.

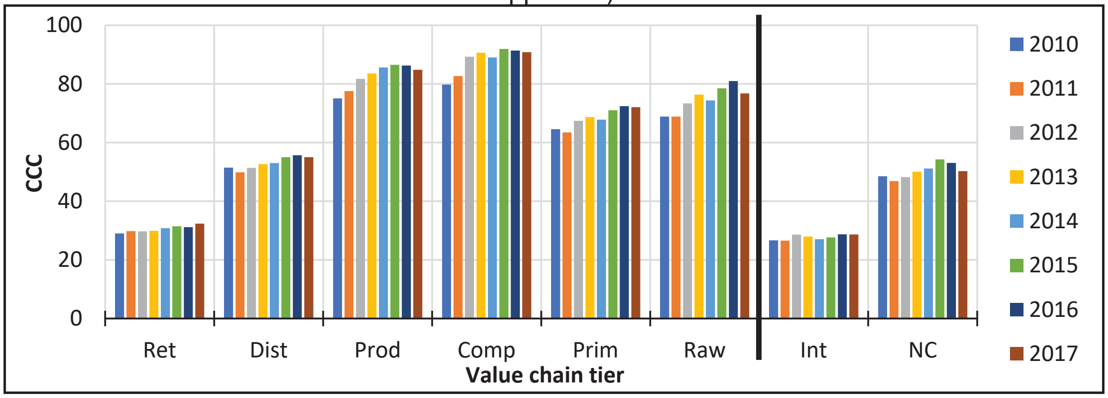
Figure 7: Average CCC per supply chain network tier and year (complete sample, existing approach)



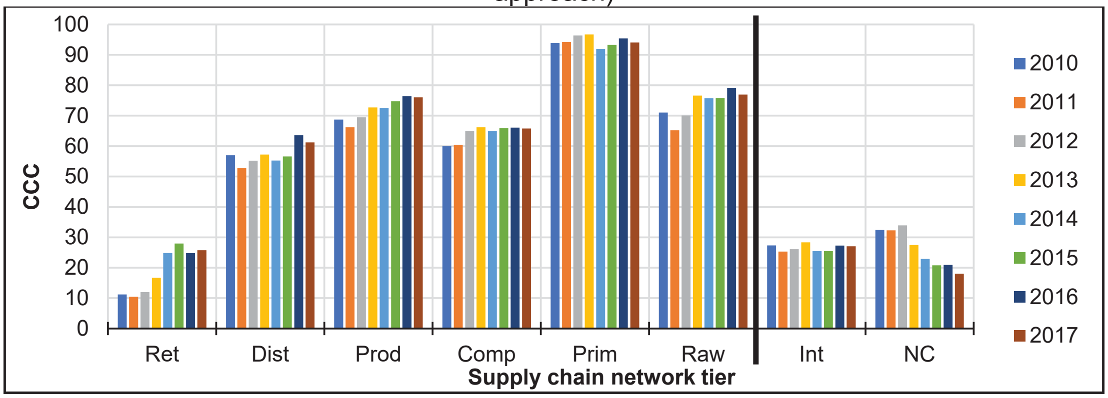
A permutational ANOVA was calculated to determine whether the average CCC is different between the groups. The results indicate that the average CCC in the supply chain network tiers are significantly different at the p<.001 level, [F(7, 31624)= 723.8016, p=0.000]. Therefore, the H0 must be rejected and post-hoc pairwise comparisons performed.
Table 6 shows the p-values of the pairwise t-tests. Only the not classified group and distributors are not significantly different at the alpha level of .05. The average CCC in the retail group is not significantly different to the integrated group after the correction by the Bonferroni method. All other possible combinations are significantly different at the .05 alpha level after Benjamini-Hochberg procedure and Bonferroni method. Qualitatively the same results hold true within the Subsample 10.

Table 6: P-values of pairwise t-test (complete sample, existing approach)

	Ret	Dist	Prod	Comp	Prim	Raw	Int	NC
Ret								
Dist	0.0000[a,b]							
Prod	0.0000[a,b]	0.0000[a,b]						
Comp	0.0000[a,b]	0.0000[a,b]	0.0000[a,b]					
Prim	0.0000[a,b]	0.0000[a,b]	0.0000[a,b]	0.0000[a,b]				
Raw	0.0000[a,b]	0.0000[a,b]	0.0000[a,b]	0.0001[a,b]	0.0001[a,b]			
Int	0.0259[a]	0.0000[a,b]	0.0000[a,b]	0.0000[a,b]	0.0000[a,b]	0.0000[a,b]		
NC	0.0000[a,b]	0.2015	0.0000[a,b]	0.0000[a,b]	0.0000[a,b]	0.0000[a,b]	0.0000[a,b]	

Figure 8 shows the results from the Subsample 10. The average CCC over all periods increases from retailer to product producer. Retailers have an average CCC over all observation periods of 19 days. For distributors the average CCC is 57 days and for product producers the measure peaks at about 72 days. The CCC is at about 64 days on average for the component manufacturers. The average CCC of primary manufacturers is highest with 94 days. Raw material producers have an average CCC of 73 days. Integrated companies and the unclassified groups have an average CCC of 27 days and 20 days, respectively.

Figure 8: Average CCC per supply chain network tier and year (Subsample 10, existing approach)



The permutation ANOVA to determine whether the average CCC is different between the groups is significant at the p<.001 level [F(4, 8571)= 31.0974, p=0.000]. Therefore, H1 must be rejected and the groups further analyzed in post-hoc tests. Table 7 presents the p-values of the post-hoc t-test. The results indicate that the average CCC of retailers is not significantly different to both the unclassified group and integrated companies. Further, the average CCC of integrated companies and the not classified group is not found to be significantly different. H0 cannot be accepted for the combination raw material producers and product producers. The average CCC of all other possible combinations was found to be significantly different at the .05 alpha level after both corrections for alpha inflation. The results regarding the p-values of the post-hoc t-test indicate that the average CCC of retailers is not significantly different to both the unclassified group and integrated companies.

Table 7: P-values of pairwise t-test (complete sample, network approach)

Network Approach

Figure 9 visualizes the results of the network approach. Again, companies are colored by eccentricity group. The node size is scaled by average CCC of the particular company.

Figure 9: Graph complete sample grouped by the network approach (node size scaled by average CCC over all periods; edge size scaled by edge weight; node coloring by aggregated eccentricity groups)

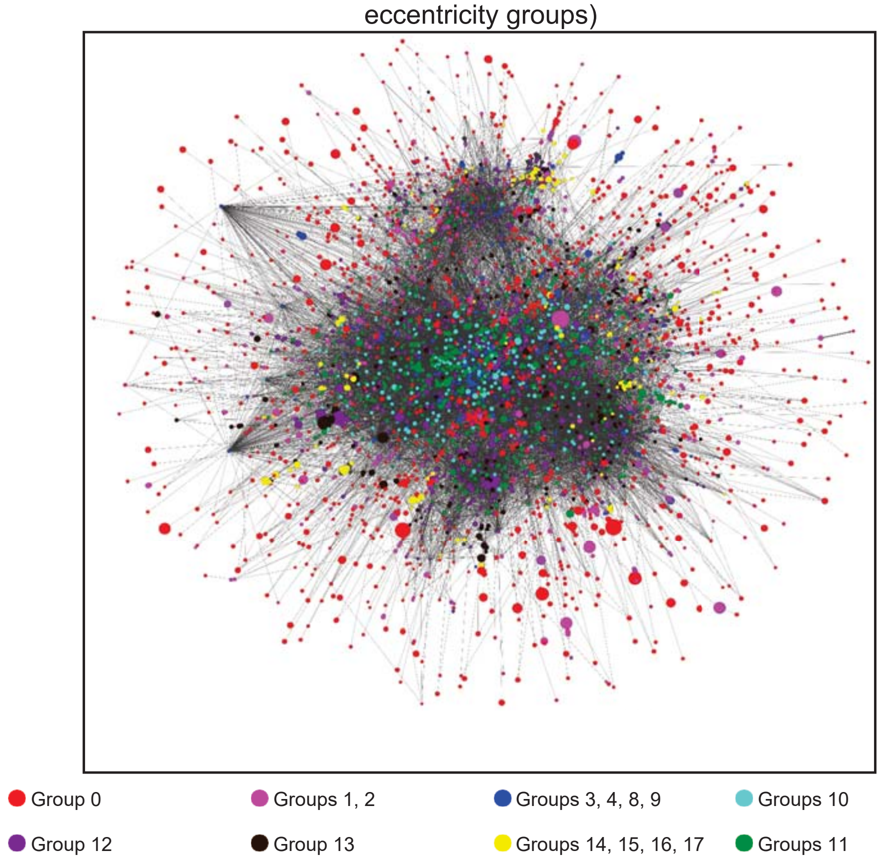

Figure 10 illustrates the development of average CCC of the 16 eccentricity groups in the complete sample. The average CCC over the entire period increases from about 69 days in group 0 to about 82 days in group 4. Thereafter the average CCC over all periods seems to decrease again to about 69 days in group 10. Further upstream, the measure stabilizes between 70 and 75 days until group 15. In group 16 the average CCC reaches a peak at about 84 days. In group 17 the measure is at about 58 days on the minimum for all groups. Group 18 has the highest average CCC of all groups with about 105 days.

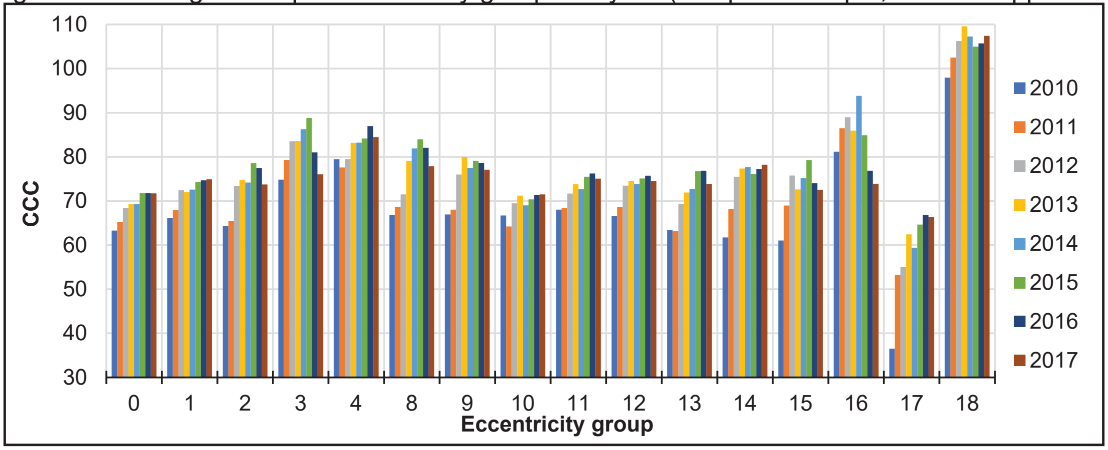
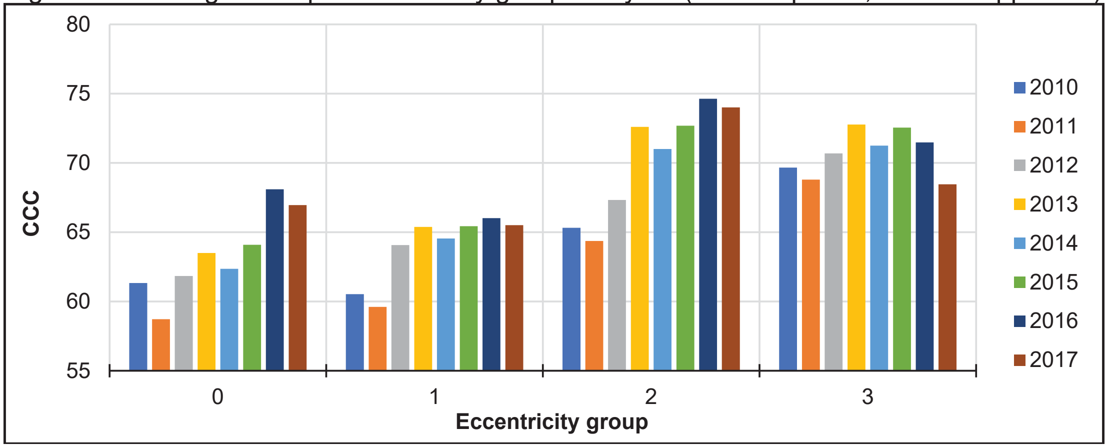
Figure 10: Average CCC per eccentricity group and year (complete sample, network approach)



The results of the permutation ANOVA revealed a significant difference of average CCC between the groups at the p<.001 level, [F(15, 31616) = 10.207, p=0.000]. Post-hoc permutation t-tests were facilitated to determine which eccentricity groups are significantly different. Table 7 summarizes the p-values for the post-hoc t-tests. H0 cannot be rejected for the tests of group 0 with Groups 2, 8, 10, 13, 15 and 17. Further, the average CCC in group 1 is found to be significantly different to the average CCC of Group 0, 3, 4, 16, 17 and 18. Group 2, however, is only significantly different to groups 16, 17 and 18. Groups 3 and 4 are both significantly different to the following groups: 0, 1, 10, 11, 12, 13, 17 and 18. Groups 8 and 9 are both significantly different to groups 10, 17 and 18. Additionally, group 9 is found to be different to group 0. These interpretations correspond to the Benjamini-Hochberg procedure or an alpha level of .05. According to the Bonferroni method fewer groups are significantly different.

Figure 11 shows the average CCC per eccentricity group in each period for Subsample 10. Group 0 has the lowest average CCC over all periods with about 63 days. In group 1 the measure is slightly higher at 64 days. Group 2 and group 3 have the highest CCC at an average of 70 days and 71 days, respectively. The permutation ANOVA to detect differences in the average CCC of the groups was significant at the p<.001 level, [F(3, 4788)= 6.0666, p=0.0007].

Figure 11: Average CCC per eccentricity group and year (Subsample 10, network approach)



The post-hoc t-tests suggest that the mean CCC of both group 0 and group 1 is significantly different to the average CCC of group 2 after the Benjamini-Hochberg procedure and Bonferroni method. For all other combinations H0 cannot be rejected at the .05 significance level (see Table 8).

CCC Variability Results

The variability of average CCC is analyzed by two measures. First, by the year-on-year CCC changes and, second, by the WCVar ratio. Further, each analysis is grouped by company rating. As in the analysis of working capital allocation the results are first presented for both the existing approach and network approach.

Existing Approach

Figure 12 shows the delta CCC for the companies by the example of the speculative-grade group. Figure 12 indicates that the year-on-year CCC changes of the speculative-grade group, the two most downstream tiers have relatively low delta CCC. This, however, increases in the further upstream groups. In the product producer group there was a more than 5-days increase between 2011 and 2012. Between the same periods the increase was even larger in the component manufacturer group. Raw material also experienced a pronounced increase 2011–2012. Similarly, for the period 2016–2017, a decrease in the CCC was observed in the product producer tier with decreasing values in further upstream tiers. The integrated-companies group shows relatively low delta CCC values.

Figure 12: Changes in CCC during the observation period (speculative grade-rated group, existing approach)

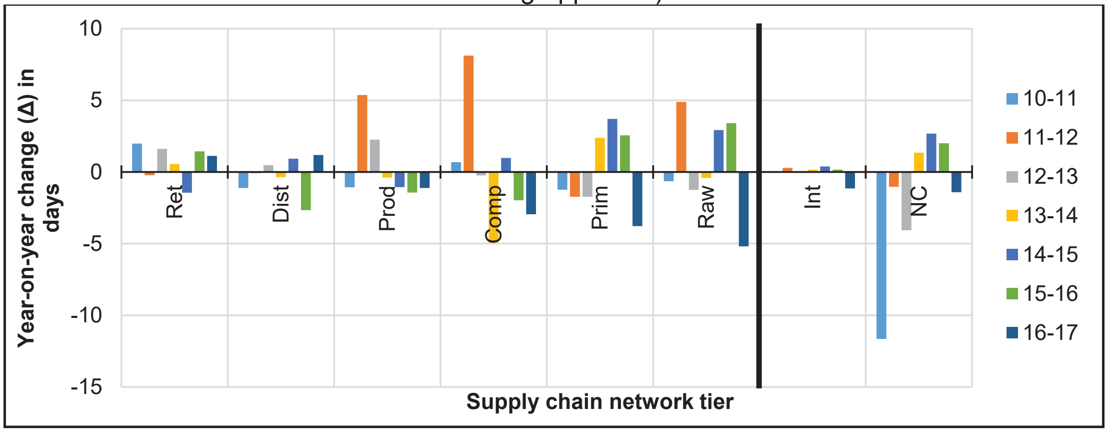

Figure 13 depicts the average WCVar ratio in each supply chain network tier on a log scale. The line illustrates the average ratio in all credit rating groups. The total measure is relatively low in the retail and distribution tiers before rising to a peak in the product producer tier. In the component manufacturer tier the measure is slightly lower than the peak. Thereafter, in the primary manufacturing tier the measure declines, only to increase again in the most upstream tier. Integrated companies and companies that were not classified have relatively low ratios. The bars in Figure 13 illustrate the level of the ratio for different rating groups. The variation seems to mainly come from the not rated companies. The values for the investment grade-rated companies are below the other two groups but show the same trend as the total measure.

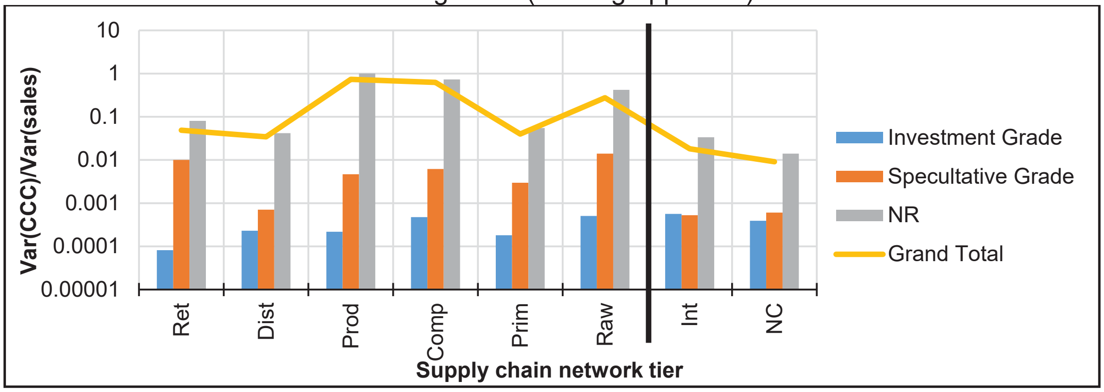
Figure 13: Working capital variability ratio per supply chain network tier and credit rating group on a log scale (existing approach)



Network Approach

Figure 14 presents the changes for the companies in the speculative-grade group (similar results were obtained in the other groups). The year-on-year average CCC changes are smallest in the two most downstream groups. Further midstream, in eccentricities 2–9, the changes were more pronounced. In eccentricities 10–13 the changes were slightly lower, especially the changes between 2011 and 2012 were higher than the other year-on-year deltas in these groups. Further upstream the changes become relatively large. Figure 30 depicts the

CCC changes in the not rated group. These show a similar trend as the investment grade and speculative-grade groups: low values in the most downstream groups, followed by more pronounced changes in eccentricities 2–9, lower deltas in eccentricities 10–13 and another increasing trend until eccentricity group 17.

Figure 14: Changes in CCC during the observation period (speculative-grade-rated group, network approach)

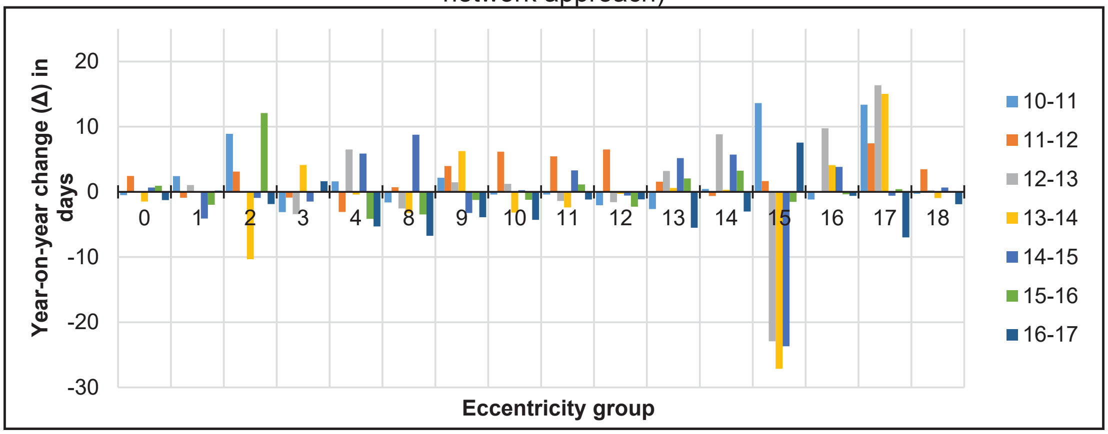


Figure 15 depicts the average WCVar ratio grouped by the network approach. In the two most downstream groups, the ratio is similar to the groups 13 and 14. It reaches a peak in group 2 and decreases again for group 3. In eccentricity 4 the measure reaches again a local peak but below the peaks in group 2 and group 11. Thereafter, the measure is relatively low until eccentricity 10. The bars in Figure 15 show the average WCVar ratio by credit rating group. The figure indicates that the main part of the variation stems from the not rated group. The values of this group closely follow the total values. The values for the speculative-grade group are generally between the not rated group and the investment grade group. The values of all groups seem to follow a similar trend as the total variation.

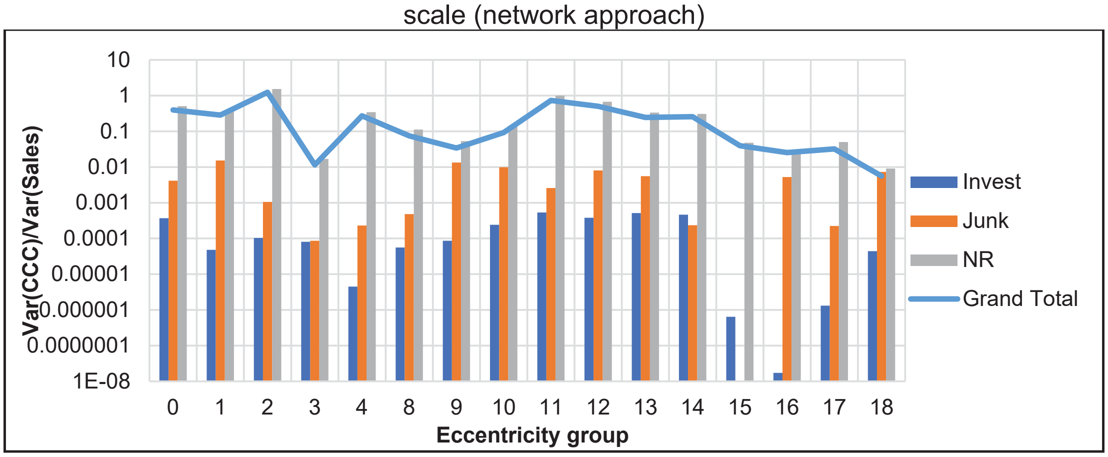
Figure 15: Working capital variability ratio per eccentricity group and credit rating group on a log scale (network approach)



DISCUSSION

Methodological

The network description showed that both connectivity distribution and edge weight distribution follow power law. The distributions are truncated for very high degrees and very high edge weights. According to Albert and Barabási (2002) this characteristic is found in many large real-world networks. The truncation indicates a limit to never ending growth (Amaral, Scala, Barthelemy, & Stanley, 2000). Despite having an exponential tail these distributions are significantly different to a random graph which follows a Poisson distribution. Barabási and Albert (1999) argue that a power law connectivity distribution is the consequence of network growth under preferential attachment. That is, new nodes preferentially attach to already well-connected nodes in a growing network. A consequence of preferential attachment is the formation of hub nodes and a “fit-gets-richer” phenomenon. This phenomenon occurs when in a supply chain system new firms attach to incumbent firms that are considered profitable, sizable and of use for the new entrant. The concept is similar to the first mover advantage but assumes heterogeneity of firms and includes the firm’s fitness. There is usually a limit to never ending growth, leading to the exponential cut-off and preventing a fit-gets-richer phenomenon from inexorably occurring. In a material flow network reasons for such a cut-off are, for example, the finite size of marketplaces, final consumer demand or production capacity (Hearnshaw & Wilson, 2013). Hearnshaw and Wilson (2013), therefore, reason that scale-free networks are typically found in competitive markets. Conversely, a “star network” where a large number of peripheral nodes group around a single hub could “represent an inefficient monopolistic market or a highly vertically integrated supply chain”. According to Hearnshaw and Wilson (2013) hub nodes are important in supply chain networks in that they are analogous to channel leaders. They control performance and provide supply chain wide coordination (Human & Provan, 2000; Jarillo, 1988). It might be argued that complex modern supply chains prevent authoritative, centralized structures. Still, Cowan and Jonard (2007) found that channel leaders can exert their influence, provide opportunities and motivation for other firms to align to the objectives of the leader. Achrol and Kotler (1999) state that supply chains are unlikely to coordinate, self-organize and lower transaction costs without channel leaders. These findings must be put into the perspective of the sampling method used. The degree bias in snowball sampling indicates that highly connected nodes (i.e., hub nodes) are more likely to be included (Illenberger et al., 2011). Hence, it is expected that the actual distribution shows a stronger truncation. Similarly to the connectivity distribution, the present paper finds a truncated power law distribution for edge weights. Many real-world networks have edge weights distribution that follow power law, that is, a few highly weighted connections and many lowly weighted relationships (Onnela et al., 2007). Hence, most firms have only a few critical suppliers. Hearnshaw and Wilson (2013) state that firms who have tightly coupled exchange relationships are more likely to improve their fitness compared to firms that continue with arms-length transactions.

To sum up, the supply chain network used for this paper follows the same characteristics that are found in efficient real-world networks from various disciplines: a small-world character like random graphs but unusually large clustering coefficient combined with a power law connectivity distribution as well as a power law relationship weights distribution (Albert & Barabási, 2002; Hearnshaw & Wilson, 2013). A characteristic of such a network is its resilience to disruptions and consequently its relative stability compared to random networks. Albert and Barabási (2002) argue that “hub nodes provide the network resilience against random disturbances. This is because a random disturbance event is more likely to impact a peripheral node that has few connections”. Conversely, if a hub node is impacted by disturbance the efficient network is more vulnerable than the random structure.

Content-related Implications

The analyses within the existing approach showed that the pattern of working capital allocation in the different tiers was similar across the subsamples. The retail tier and the integrated group have the lowest working capital levels in all samples. Further upstream from the retail tier, the average CCC increases and reaches a peak in the product producer or component manufacturer tier (midstream section) depending on the sample. After this peak a sharp drop in the measure is observed but it recovers again towards the upstream section. Comparing the average CCC levels between the different subsamples indicates that the CCC levels decrease as the edge weight increases. Hence, companies with stronger relationships seem to have lower average CCC. Within the network approach the difference of average CCC between the groups is not as pronounced compared to the existing approach. However, in the complete sample a similar trend in average CCC was found as in the existing approach. The average CCC in the eccentricity groups is increasing in the most downstream groups, hitting a peak in middle eccentricity groups. Overall the results suggest that the hypothesis of increasing average CCC, the further upstream a company is located, is only partly true. There are two “peaks” in the average CCC trend for the average supply chain underlying this paper with a “reset” in the midstream section.

In the existing approach the delta CCC was lowest in the most downstream group. However, between midstream tiers and upstream tiers the delta CCC did not seem to increase further. The WCVar ratio, however, increased again towards to most upstream tier showing two peaks. Further, in both variability measures the better rated groups showed lower values for both measures.

Theoretical Implications

The above presented findings are in line with existing research. Lorentz et al. (2016) found a lower net-trade-credit (i.e., subtracting DSO from DPO) for further upstream companies. This suggests an increasing CCC in further upstream companies when DIH is constant in all tiers. Further, Lorentz et al. (2016) indicated that period-on-period delta DSO and delta DPO appear larger further upstream explaining it by the relative power of the companies. While Lorentz et al. (2016) found a “working capital wave” for net trade credit and its components, the present paper suggests the existence of such a “working capital wave” for the CCC measure. In particular, the results suggest that there might be two consecutive working capital waves in a supply chain. The reason for these two waves can be traced back to highly liquid companies with access to outside finance (“deep pockets”) interrupt the wave from cascading further upstream. Boissay and Gropp (2013) and Serrano et al. (2018) have shown that the propagation of payment variability (i.e., financial contagion) is mitigated by supply chain members with solid financial statements. Conversely, “weak” financial statements amplified the effect (Serrano et al., 2018). Similarly, Shenoy and Williams (2017) found that companies with better access to bank liquidity offer more trade credit to customers. Serrano et al. (2018) argue that “deep pockets” decouple the supply chain in terms of financial contagion. A “double working capital wave” is further in line with the findings of Losbichler and Rothböck (2008). They suggested that in a supply chain the leading branch, i.e. a company with a high bargaining power, can reduce its working capital burden more than its suppliers and customers. Hence, the CCC level and possibly also the variability of CCC may not steadily increase between downstream and upstream tiers. Cash-rich companies might be able to break this pattern thanks to their bargaining power. Hence, the finding that the working capital of a firm is not only driven by firm specific factors but also the composition of the supply chain network. In this light, the paper at hand underlines the

importance of collaboration between companies to reduce negative material and financial spillover effects. Through the better coordination of working capital, companies can reduce cost, improve resilience to shocks and therewith increase the competitiveness of supply chain networks (Hofmann & Kotzab, 2010; Protopappa-Sieke & Seifert, 2017). For example, by adopting supply chain finance solutions such as reverse factoring as they have the potential to reduce the cascading effect in the supply chain networks like “deep pocket” companies.
One main reason for high working capitals in upstream supply chain networks can be traced back to the inventory bullwhip effect (Luo & Shang, 2012; Tangsucheeva & Prabhu, 2013). The spread of the amplified order and the actual demand results in products remaining in inventory for an extended period (Tangsucheeva & Prabhu, 2013). In the same vein, the amplified orders require more capital in the upstream stage to make the inventory payments (Luo & Shang, 2012). Accordingly, a reduction of the material bullwhip effect would reduce the working capital burden for upstream companies. Lee et al. (1997) give three ways to reduce the inventory bullwhip effect: information sharing, channel alignment and operational efficiency. These approaches all require inter-organizational coordination. Large inventories could also be financed through inventory financing where a financial institution provides a loan against collateralized inventory (Zhao & Huchzermeier, 2018).

Practical Implications

A supply-chain-wide coordination is necessary to tackle the working capital burdens of further upstream companies. Through coordination and an increased awareness for consequences of actions in a crisis, practitioners can stabilize to the benefit of all involved parties. This paper showed that similar patterns existed regardless of the relationship strength. Therefore, the key message for practitioners here is that collaboration with important supply chain partners should be approached first. This would improve the working capital situation of partners that contribute most to a product. Cash rich companies should take on the responsibility of pushing towards this goal. Because they can exert their influence on other firms to align to the objectives and reach a supply-chain-wide coordination (Hearnshaw & Wilson, 2013). Further, channel leaders provide resilience to an efficient network and, thus, their “fitness” should be improved (Albert, Jeong, & Barabási, 2000).
Practitioners can reduce CCC variability and financial contagion in supply chain networks with innovative financing solutions (Luo & Shang, 2012). Reverse factoring for example, aligns the cash flow and the product flow to some extent, thereby, reducing the impact of cash flow variability. This is line with Caniato et al. (2016) who found that companies use reverse factoring “with the main purpose of reducing bankruptcy risk in the upstream supply chain”. Another solution is dynamic discounting, improves the working capital situation for the companies within the sampled networks (Zhao & Huchzermeier, 2018).
The observed increasing average CCC along the supply chain poses a challenge to affected companies. They must be able to finance the higher working capital burden and withstand its variability. Attempts to reduce this cascading effect in CCC can be addressed on all of its components.

CONCLUSION

The aim of the present study was to analyze working capital from a network perspective. Previous research incorporated the network perspective into working capital analysis by approximating supply chains by industry. The present study extends previous research by applying social network analysis in the context of working capital management. The results of the empirical analysis revealed a “double working capital wave” in the network. Existing literature suggests increasing working capital levels and working capital variability in further upstream tiers. This study supports these findings but finds that the existence of liquid companies with access to outside finance may break the cascading effect. Therefore, the working capital increases in further upstream companies until reaching a "deep pocket". The "deep pocket" provides liquidity and, thus, the cascade restarts.

The originality of this research lies in its attempt to apply a social network perspective to the concept of supply chain-oriented working capital management. It therewith enables an integrated view on the topic by bridging several literature streams from the working capital, logistics/supply chain and social network theory. The paper at hand additionally establishes an understanding of how the presence of liquid companies with access to outside finance may interrupt the financial spillover effects in supply chain networks. Moreover, it complements existing financial management literature that focuses on the effects of supplier-customer interactions by including a thorough investigation of financial spillover effects in a supply chain environment. Finally, it provides valuable insights to both researchers as well as practitioners on how better working capital coordination in a supply chain network can benefit all players involved. This may be achieved, inter alia, through the usage of supply chain finance (SCF) solutions.

It can be argued that the main limitation of this paper lies in the snowball sampling approach, which is known to be prone for conceptual and methodological biases. Examples include the selection bias, degree bias and status homophily (Illenberger et al., 2012). Another limitation from this paper arises from the usage of yearly accounting data. This restricts the analysis of potential cash flow bullwhip effects, which are known to occur in short time intervals. Future research could address the methodical limitations arising from snowball sampling by using more seed companies or applying alternative methods (e.g., Kirchherr & Charles, 2018). In addition, the decomposition of the CCC into its components would be interesting and possibility yield a more differentiated analysis. Regarding the variability of CCC within supply chain networks it is further desirable to analyze the existence of a financial bullwhip effect on a real-world sample.

Patient Hospital Satisfaction Ratings on Social Media versus HCAHPS Survey Scores

ABSTRACT

We demonstrate that hospital satisfaction ratings expressed by patients freely on social media are positively related to the patient experience of care domain score that CMS calculates based on the HCAHPS surveys. We suggest that hospital leaders can know about their patient experiences by frequently tapping into social media.
Keywords: HCAHPS surveys; patient hospital satisfaction rating; patient experience of care score; social media.

INTRODUCTION

The last few years have seen a fundamental transformation of the modern U.S. hospital. A lot of consolidation efforts and changing margins have led to hospitals incorporating principles and practice from other business sectors, perhaps more than ever before. As more hospital executives run their hospitals like traditional businesses, one area of renewed focus is patient satisfaction in the quest to become more patient-centric. While always a point of emphasis, hospitals have recently begun to take note of the attention given to initiatives around customer satisfaction and retention in other service industries. Companies with high customer satisfaction scores enjoy a wide range of tangible economic benefits including increased sales, greater profitability and lower customer turnover (Heskett, 1987; Heskett, Jones, Loveman, Sasser, & Schlesinger, 1994; Heskett, Sasser, & Schlesinger, 1997).

The internet has made soliciting the opinions of customers easier than ever before as a result of advancements in Web 2.0 technologies and the development of websites built around online customer reviews. Many organizations, in particular manufacturing and retail service organizations, have been quick to embrace online customer reviews as a new way of truly understanding their customer grievances, thereby leading to their needs and wants. These organizations realize that in the age of social media, customers have a much louder voice and the ability to influence large segments of an organization's customer base (Brodalski, 2011; Holt, 2016; Killian & McManus, 2015). It is not uncommon to see many service organizations go to great lengths and provide significant incentives to solicit customer comments from organizations. However, despite these advantages and an espoused interest in improving patient satisfaction scores, many hospitals lag behind other service organizations in their use of new and emerging data resources and technology (Acohido, 2013; Hernandez, Machacz, & Robinson, 2015; Landi, 2018; Sullivan, 2018). As a result, investment in online customer reviews have been largely overlooked by U.S. hospitals.

The primary reason for this is that U.S. hospitals have for quite some time now relied on industry-specific customer feedback mechanisms—the Hospital Consumer Assessment of Healthcare Providers and Systems (HCAHPS) survey and other tools (Cahill & Wang, 2012).

These standardized surveys are designed to capture key aspects of the patient experience relevant for regulatory requirements and key aspects of health outcomes. While HCAHPS surveys serve a valuable function within the hospital organizations, they are limited when compared with online customer reviews. First, an important consideration is the cost and requisite resources needed to administer HCAHPS. With online customer reviews, customers provide all of the information and are completely in charge of what they say with all the customer reviews. Thus, the onus of data creation and management is placed on the customer and the site collating the reviews such as Yelp or Healthgrades.

A second advantage of online customer reviews is their timeliness. While HCAHPS undeniably provide quality data, there is a significant lag time between patient interaction and HCAHPS reporting (Ranard et al., 2016). In today's hospital environment, many organizations should not be willing to wait so long to see the impact of their changing initiatives, especially when other data resources are available. This is especially true in the case of mergers and acquisitions, when hospitals move into new areas where patient feedback about the organizational transformation is crucial and may even adversely affect patient experience (V. Ho & Hamilton, 2000). Online customer reviews offer an almost instantaneous way for patients to share their feelings and experiences with the hospital organization.

A third difference between online customer reviews and hospital managed feedback mechanisms is the lack of constraints on customer interaction (Ranard et al., 2016). Authors of online customer reviews are free to deal with any topics that they choose, without the constraining influence inherent in all standardized survey instruments. Such freedom of response even extends to the online review authors themselves. Online customer reviews may even capture long-tail populations (Brynjolfsson, Hu, & Smith, 2006) totally untouched by HCAHPS, in the form of reviews authored by extended family members, caregivers or other individuals only tangentially related to patient interaction.

Our study attempts to highlight the value of online customer reviews by examining their usefulness as a metric of gauging hospital interactions. We use online review data from Yelp.com, one of the largest and most comprehensive online customer review websites today in an attempt to answer the research question: *do patient hospital satisfaction ratings on social media such as Yelp provide similar information as HCAHPS surveys?* Results from our study demonstrate that they do in several ways. We show that online customer reviews are useful for predicting some of the similar indicators of patient experience as calculated with the HCAHPS survey data. At the same time, we also control for the different hospital types thereby showing that while there may be challenges in soliciting customer data for certain hospitals, its importance lies undiminished for any type of hospital.

The remainder of our paper is organized as follows. First, we discuss the extant literature on patient satisfaction, the scant literature backing the use of social media in healthcare and introduce our hypothesis. Second, we describe the methods and procedures followed for data collection. Third, we elaborate the results of the study and discuss the findings. Finally, we note the limitations of the study and end with a discussion on practice implications and future directions.

LITERATURE REVIEW AND HYPOTHESIS

In healthcare and marketing literature, patient satisfaction is widely accepted as a multi-dimensional concept, based on a relationship between patient experiences and expectations (Sixma, Kerssens, Campen, & Peters, 1998). In one of the early works on patient satisfaction, Pascoe (1983) defined patient satisfaction as: "…the health care recipient's reaction to salient aspects of the context, process, and result of their service experiences… (pp. 189)." He noted that satisfaction consists of a "…cognitively based evaluation or grading of directly-received services including structure, process, and outcome of services… and an affectively based response to the structure, process, and outcome of services…(pp. 189)". Similar to customers of any service, most patients have some expectations of the health service in their mind when they visit a hospital. Patients evaluate the healthcare service actually received at the hospital against their expectations to form their overall impression about the service; and some of them choose to express their dissatisfaction or happiness later on social media such as Yelp.

In the U.S. healthcare system, typically, individual patient satisfaction has generally been obtained from a few random patients at every hospital by the HCAHPS surveys and aggregated to the hospital level to calculate the hospital's patient experience of care domain score. Once a hospital or its survey vendor submits the HCAHPS survey data to the data warehouse for the hospital inpatient quality reporting program, CMS cleans the submitted data by removing incomplete surveys, surveys from ineligible patients and calculates the "top-box" raw score for the nine HCAHPS measures that are used in the Hospital value-based purchasing (VBP)—Patient Experience of Care Domain. CMS applies the patient-mix adjustment for each of the nine HCAHPS measures used in Hospital VBP to obtain unrounded patient-mix adjusted scores. After performing more intermediate steps including survey mode adjustment for each of the nine HCAHPS measures used in Hospital VBP, CMS calculates the Unweighted Patient Experience of Care Domain Score (out of 100) for each hospital by summing the hospital's HCAHPS base score (0-80) and HCAHPS consistency score (0-20).

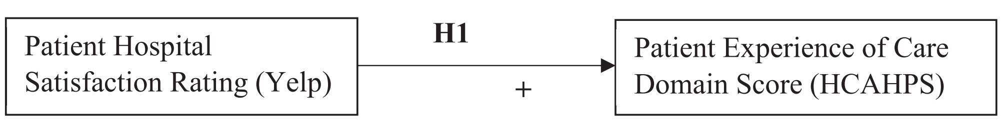
These established methods for capturing patient satisfaction have significant merits, yet online customer reviews also have a long history of successfully capturing these types of opinions across many different areas of the economy including retail and hospitality (Chevalier & Mayzlin, 2006; Liu & Park, 2015). Moreover, the few studies on use of social media use in healthcare (Church & Chakraborty, 2018; Ranard et al., 2016) have identified positive effects of social media use by patients. Social media can aid patients (Smailhodzic, Hooijsma, Boonstra, & Langley, 2016) by giving them the ability to read more about the disease/ailment and complement the information provided by healthcare professionals (Rupert et al., 2014) and also by providing psychosocial support (Y.-X. Ho, O'Connor, & Mulvaney, 2014). Use of social media by patients can also aid healthcare professionals by providing them a tool to become more responsive to patients' concerns thereby helping efforts for brand building and improved service delivery (Li, 2010; Williams, 2011) all of which ultimately strengthen the hospital's market position (McCaughey et al., 2014; Williams, 2011). However, as highlighted above, these social media sources are still not widely used in healthcare; at least not in a major way in U.S. hospitals.

Based on the conceptualization of patient satisfaction and the extant literature on the usefulness of social media ratings in healthcare (Church & Chakraborty, 2018; Greaves et al., 2014, 2012; Lagu, Goff, Hannon, Shatz, & Lindenauer, 2013; Ranard et al., 2016) we argue that information similar to HCAHPS ratings can be obtained from free social media websites such as Yelp. Therefore, we hypothesize:

H1: Patient hospital satisfaction rating obtained from Yelp is positively related to the patient experience of care score obtained from HCAHPS surveys.

Figure 1 depicts our research model. In the next sections, we discuss the methods used in the evaluation and testing of this hypothesis.

FIGURE 1: Research Model



METHODS

Procedure

We collected all available hospital reviews (24,313 reviews of 397 hospitals) from the commercial Yelp website (www.yelp.com) that were posted by patients/kin over a period spanning 11 years (9-May-2005 to 23-Jun-2016). Consistent with other studies, we avoided any hospitals that had reviews flagged as being suspicious or fake. Yelp ensures that review content is genuine and provides a notification if a business is accused of having reviews that have been faked or purchased by the organization. No reviews flagged as potentially fake were included in the sample. We also eliminated hospitals with less than 10 reviews so as to include only those hospitals which had a good presence among the Yelp reviewers. We matched up the hospital names and address information with CMS' 2016 Hospital Compare database. From CMS' database, two hospital attributes were also collected and dummy coded: (a) hospital type that had the following values: Acute Care Hospitals (1), Children's (2) and Critical Access Hospitals (3); and (b) hospital ownership that had the following values: Proprietary (1), Government-Federal (2), Government-Hospital District or Authority (3), Government-Local (4), Government-State (5), Physician (6), Voluntary non-profit-Church (7), Voluntary non-profit-Other (8), and Voluntary non-profit-Private (9).

We removed hospital reviews if they did not have either of the study variables; 26 hospitals did not have their average hospital star rating reported on Yelp while another 2 hospitals did not have the overall star rating reported in the CMS' Hospital Compare database. All 28 reviews were removed, leaving a final sample of 359 U.S. hospital level records which we used for our analyses.

Variables

Yelp calculates the average of all the star ratings (1 through 5) given by patients/kin for each hospital and displays it along with other hospital meta-data. We denoted the average hospital star rating given by patients/kin as the *patient hospital satisfaction*. Next, the two dummy coded variables taken from CMS—hospital type and the hospital ownership were used as controls in the hospital-level regression. We also used a Yelp meta-data—the actual number of review records available for each hospital—as a control in our regression because a greater number of positive or negative reviews for a hospital could have biased the overall Yelp-calculated patient hospital satisfaction ratings.

From the HCAHPS survey data, we used the unweighted patient experience of care dimension score for each hospital taken from the 2016 Hospital Compare database as our variable *patient experience of care*. We also used the recently introduced CMS' overall hospital star rating (CMS, 2016) to represent the *hospital quality performance*. CMS (2016) uses an elaborate methodology using 57 items from the HCAHPS survey grouped into seven subcategories, and is therefore appropriate for our use as a reflection of overall hospital quality.

RESULTS

All descriptive statistics including Pearson correlations among the variables in the study are indicated in Table 1. Our findings noted in Table 1, indicate a strong significant correlation between patient hospital satisfaction (collected from Yelp) and patient experience of care domain score (obtained from HCAHPS surveys), and also between patient hospital satisfaction and CMS overall hospital quality scores.

TABLE 1: Descriptive Statistics

		Mean	Std. Dev.	1	2
1	Patient Experience of Care (HCAHPS)	27.46	14.74		
2	Patient Hospital Satisfaction (Yelp)	2.82	0.60	0.51**	
3	Hospital Quality Performance (CMS)	2.90	0.95	0.55**	0.36**
4	Hospital Type	1	0.05		
5	Hospital Ownership	2.70	1.81		
6	Merged	1.93	0.26		
7	Number of Reviews	61.17	46.76		

Notes. n = 359 hospitals. **p < 0.01 (2-tailed). Model 1 (n = 359 reviews) with only controls; Model 2 with the predictor (n = 359 reviews). Pearson Correlations are reported. **p < 0.001.

Next, we performed an OLS regression with patient hospital satisfaction obtained from Yelp as the predictor and the patient experience of care domain scores obtained from HCAHPS as the criterion. Based on extant healthcare literature we introduced a few controls as these variables have been known to affect healthcare studies: the hospital type, the hospital ownership (Dobrzykowski, McFadden, & Vonderembse, 2016; Sharma, Chandrasekaran, Boyer, & McDermott, 2016; Wani & Malhotra, 2018) and number of online reviews received by the hospital (Ranard et al., 2016) and the dummy-coded merger indicator (1 = merged, 2 = not merged). None of the controls turned out to be significant. Our findings noted in Table 2, indicate a significant coefficient of patient hospital satisfaction predicting the patient experience of care thereby lending support to our hypothesis H1.

TABLE 2: OLS Regression Results

Variables / Model	**1**	**2**
Controls		
Hospital Type	-0.05	-0.05
Hospital Ownership	0.08	0.01
Merged	0.03	0.04
Number of Reviews	-0.02	-0.06
Predictors		
Patient Hospital Satisfaction	-	0.52**
R^2	0.01	0.27
Adjusted R^2	-0.00	0.26
ΔR^2		0.26

Notes*. Patient experience of care is the dependent variable. Model 1 (n = 359 reviews) with only controls; Model 2 with the predictor (n = 359 reviews). Standardized beta weights are reported. **p < 0.001.*

DISCUSSION

In this paper we investigated whether hospital satisfaction ratings obtained from social media sites such as Yelp can provide similar information to that obtained from HCAHPS ratings of hospitals. Support for our hypothesis demonstrates that freely-expressed patient hospital satisfaction ratings on social media sites such as Yelp are valuable. Our results show that the patient hospital satisfaction ratings from Yelp can predict the patient experience of care domain scores obtained through the HCAHPS surveys annually; and are also positively and significantly correlated to the overall hospital quality performance scores given by CMS. In so doing, we suggest that frequently checking hospital ratings from social media such as Yelp may provide hospital leaders an alternative to the long wait for the annually available HCAHPS survey results.

There are several disadvantages of the HCAHPS data collection process, and when the ratings are disclosed to each a participating hospital. First, each year on an average it takes quite a few months of actual survey on the part of the vendor to randomly collect the data from patients, collate and clean the data and get it ready for national level average calculations. Invariably, hospitals get to see their overall scores, and more specifically their patient experience of care scores almost a year from the time the data collection first began. Now, in the world of changing customer perceptions and even their feedback, a year may be too long a time. Yelp ratings, on the other hand, are freely available to anyone and they are constantly updated such that the scores are accurate at any time.

Second, hospitals enrolled in the value-based purchasing program (VBP), are now reimbursed their share of Medicare and Medicaid expenses or penalized based on their overall hospital score that is based on the HCAHPS ratings/data. Thus, hospitals leaders are generally apprehensive of the overall ratings published by CMS, which are all based on these HCAHPS data collection. Our study shows that Yelp ratings provide almost similar information, and hence could help hospital leaders know in advance, the overall CMS ratings that they are likely to receive. In that sense, Yelp ratings may help hospital leaders have a pre-emptive method to know their overall CMS ratings and could allow them to plan for their future steps better.

Like all studies, this study too has a few limitations. In this study we calculated the unweighted patient experience of care domain score for each hospital by summing the hospital’s HCAHPS base score (0-80) and HCAHPS consistency score (0-20). We demonstrate that patient hospital satisfaction ratings are positively and significantly correlated with overall hospital quality performance scores given by CMS. Nevertheless, we used the patient experience of care domain score as our criterion variable and not the overall CMS hospital quality performance score given by CMS each year because Yelp hospital ratings being satisfaction ratings of the patients/kin after all, we believe that Yelp ratings should be able to provide similar information as the patient experience score part of the data collected from HCAHPS. There are other dimensions too in the overall CMS hospital quality performance scores given each year but, in this paper, we argue that the patient experience domain scores being a very important part of the overall hospital score determined by CMS, hospital leaders would do well to keep a tab on Yelp scores and comments given by patients on free social media sites to gauge how their hospital is performing on the patient experience domain.

Another limitation of our study is that we have relied upon patient/kin comments expressed freely on only one social media website (Yelp). An avenue for future research involves collecting more patient comments from other popular social media websites such as *Healthgrades*, *Twitter* and *Facebook* as patients like other service customers are known to express their anguish on these social media sites too. We believe that patients freely express both their dissatisfaction and even happiness with on social media websites primarily because in the current US healthcare system, there are not too many avenues to express their comments and describe their experiences (Lagu et al., 2013). As we have demonstrated in this study, hospital leaders are able to obtain similar information that they routinely obtain from HCAHPS in a much easier manner and on a more frequent basis from social media websites.

Another future opportunity worth investigating is the difference in patient comments between merged hospitals and regular hospitals that have not consolidated. In our study, we had only a few hospitals that had merged during these 10 years; thus, our merged indicator as a control turned out to be insignificant. Future studies could specifically investigate if patient experiences improve after a merger or consolidation, as expressed by patients freely on social media for the hospital.

In closing, we would like to reiterate that patient hospital satisfaction ratings given freely on social media websites such as Yelp may provide a rich pool of up-to-date information about patient experiences in the hospital. As review sites continue to grow and proliferate in coming years, patient review data could provide an avenue for hospital leaders to know the areas for improvement at much greater frequency than waiting for the annual overall CMS scores obtained from CMS that are collected through the HCAHPS survey. In this manner, social media sites such as Yelp may help hospitals ultimately become more patient-centric.

Reviewers Ranking as a Variable in Value Creation: Health Care Case

Ahmed Gomaa

ABSTRACT

Users of healthcare services are providing online reviews of the services received from the healthcare providers. Positive patient reviews are likely to attract more patients and repeat visits. Health care providers are aware that a shift in the patient selection mechanism is taking place. One problem is the valuation of online reviews. This paper proposes a new algorithm that ranks each reviewer by weighting the type of feedback they provide for service providers to provide an economic valuation for the reviewers and their reviews. The algorithms calculate an Eigenvector and generate a weight for the reviews and the reviewers.

KEYWORDS: reviewers ranking, value creation, patient online reviews.

INTRODUCTION

Increasingly, more and more people are using Internet to select a service provider or a product. Online reviews have become a de-facto standard for all services providers. A majority of the consumers are expected to lookup a service provider or a product and find online reviews from prior users posted on sites like Facebook, google review, yelp, Amazon or even the providers web sites. Online reviews impact a purchase decision (Mudambi & Schuff, 2010); (Huang, Burtch, Hong, & Polma, 2016) and the absence of any online reviews will create a negative impression about the service provider or product.

This paper presents a new ranking algorithm for authors of health providers reviews to allow the economic valuation of the authors of the online reviews and their posted reviews. This research attempts to rank the reviewers of the healthcare providers, and their reviews, to assess the economic value of each reviewer. This paper models the value of the online reviewers of medical professionals by building on the **BiRank** ranking algorithm (He, Gao, Kan, & Wang, 2017)

The weighting is for the “Authority” or "contribution to," the online community, and “Hub” or "engagement with," the online community as well as the user’s interaction level with the reviews. The "Authority" variables are the summation of the A) number of reviews, and B) Stars rating left for the provider. The user’s interaction is the number of views and comments the reviews collected. Those variables help creating an "Authority Weight" for the reviewer. Another weight, the "Hub weight" is calculated based on the summation of A) the number of reactions and B) comments to other reviews. All variables are represented as a binary matrix to be able to calculate the corresponding Eigenvector and generate a weight for the reviews based on those variables. As shown in the demonstration results, the advantage of calculating the reviewer weight in this fashion is that it allows the reviewer weight to impact the reviews ranking even if that reviewer submitted review did not receive any positive feedback yet from the community. The algorithm weight the reviewer based on her prior interactions. The algorithm variables are selected based on two datasets. First, the data available from Medicare.gov which provide information about groups, individual physicians, and other clinicians currently enrolled in Medicare. Second, is from Yelp dataset, which provides a subset of business, along with the stored attributes.

LITERATURE REVIEW

In recent years, researchers started to show growing interest in the relationship between online reviews and the selection of healthcare providers. Some of this research is in Table 1:

Table 1: Research summary

Author	Year	Title	Finding
Luca and Vats (HBR)	2013	Digitizing Doctor Demand: The Impact of Online Reviews on Doctor Choice	Established a relationship between online and the healthcare provider selection
Patel and, Brombach (MISQ)	2016	Patient Engagement: Digital self-scheduling set to explode in healthcare over the next five years	By the end of 2019, 64% of patients will book appointments digitally, delivering $3.2 billion in value and a competitive boost for health systems
Goh, Gao, and Agarwal (MISQ)	2016	The Creation of Social Value: Can an Online Health Community Reduce Rural-Urban Health Disparities?	Rural areas generate value from consuming the content created by urban areas, thus establishing the fact that a value is transferable from one area to another due to the reviews.
Xu, Armony, and Ghose, (Management Science – under review)	2017	The Interplay between Online Reviews and Physician Demand: An Empirical Investigation"	Physician demand increase up to 7.24% from positive online reviews, the patient utility function increases up to 5.01% - thus establishing a monetary valuation of the online reviews
Lu and Rui (Management Science)	2017	Can We Trust Online Physician Ratings? Evidence from Cardiac Surgeons in Florida	Patients could trust the online ratings of physicians

Currently, there are several ranking algorithms that have proven to be effective. The common denominator across those algorithms is modeling the problem into a binary matrix of ones and zeros, and through an iterative process, the algorithm generates an eigenvector with the rank of the different components. PageRank developed by Google in 1998 (Page, Brin, Motwani, & Winograd, 1998), used it by modeling the web in a matrix of links, where one is an incoming link, and zero presents no link. The HITS algorithm (Kleinberg, 1999) presented both incoming links and outgoing links as matrixes and also used eigenvectors to rank the webpage. BiRank, developed in 2017, is an empirically superior algorithm (He, Gao, Kan, & Wang, 2017). It modeled as factors the time, current popularity of pages, and current influence of users. The algorithm is superior in predicting the level of popularity of a particular item with those three variables, time, item popularity, and user influence. In specific, BiRank algorithm has three hypotheses, 1) *Temporal Factor*. If an item has received many comments recently, it is more likely to be famous soon. More recent comments are a salient signal that more users focused on the item recently. 2) Item *Current Popularity*. If an item has already been widespread, it is likely to garner more views in the future. Popularity is partially affected by the existing visual interfaces of Web 2.0 systems: the more views an item has, the more likely it will be promoted to users.3) *User Social Influence*. If the users commenting on an item are more influential than uncommenting users, the item is more likely to receive more views in the future. It is important to note that BiRank is drastically different from PageRank and HITS. BiRank model users and their interactions and how that impact the popularity of the item, while the other two models model the webpage links. The fundamental difference lies within the information flow. As a result, PageRank and HITS will always rank popular websites like espn.com, CNN.com or FOXNews.com highly, while BiRank, given the influence of a celebrity like Michele Obama, her new page will be ranked high regardless of the website she decides to use too.

The BiRank algorithm includes the following variables/ equations.

$$w_{ij} = \delta^{a(t_0 - t_{ij}) + b} \tag{1}$$

The Weight w from user i to object *j* is a function of the time it was provided. In other words, the older the comment is, the less valuable it is.

$$u_i^0 = \frac{\log(1 + g_i)}{\sum_{k=1}^{|U|} \log(1 + g_k)} \tag{2}$$

$$p_j^0 = \frac{\log v_j}{\sum_{k=1}^{|P|} \log v_k} \tag{3}$$

u stands for user i, and the user influence is a function of the g, which is the number of a friend that user has. The *p* stands for a post, page or object, and its value is a function of *v* which is the number of comments that page or object received.

Figure1: BiRank Algorithm (He, Gao, Kan, & Wang, 2017)

Algorithm 1. The Iterative BiRank Algorithm

Input: Weight matrix W, query vector $\mathbf{p}^0, \mathbf{u}^0$, and hyper-parameters α, β;

Output: Ranking vectors $\mathbf{p}, \mathbf{u}$;

Symmetrically normalize W:$S = D_u^{-\frac{1}{2}} W D_p^{-\frac{1}{2}}$;

Randomly initialize $\mathbf{p}$ and $\mathbf{u}$;

while Stopping criteria is not met **do**

$\quad \mathbf{p} \leftarrow \alpha S^T \mathbf{u} + (1-\alpha)\mathbf{p}^0$;

$\quad \mathbf{u} \leftarrow \beta S \mathbf{p} + (1-\beta)\mathbf{u}^0$;

end

return $\mathbf{p}$ and $\mathbf{u}$

BiRank Algorithm in figure 1 presents how to calculate the rank of a particular page; the input is the weight matrix, which represents the comment and likes on a specific object, an initial random rank for the post or object *p* and an initial random rank for the user. The algorithm continues its iterations until *p* and *u* converges that is *p*, and *u* stop changing with further iterations. At this point, the algorithm finalizes the rank for the objects and the users.

ACCOUNTING FOR PATIENTS SPECIFIC CONDITIONS WITHIN THE BIRANK ALGORITHM

The paper applies “patients review” to the BiRank algorithm. First, the hypotheses are adjusted as follows:

H1. *Temporal Factor*: If a review received many comments recently, the author of the review is more likely to be popular in the short term. More recent comments are a salient signal that more Patients focused on the recent reviews.
H2. *User’s Social Influence*: If the users reviewing the physicians are more influential than others, the Physician is more likely to receive more views in the future. Interaction includes commenting, liking another comment, or commenting on another comment.
H3. *Item Current Popularity*: If a review is already viewed as helpful, it is likely to garner more patients to trust it in the future.

It is important to note that the variables and the equations remain the same, but the semantics of the variables are different. For instance, in H1, the algorithm accounts for the time of ALL interactions, not only the comments. Furthermore, in H2, the user influence is not only by friends but also by the level of interaction and engagement with others within the community. Also, in H3, the object represents the health provider review itself as a step to evaluate the reviewer value.

ALGORITHM

We need to consider the effect of user influence on ranking physicians. We define a user influence matrix U whose elements indicate how many times a user has contributed or engaged with a review. This should contribute to the reputation score of the review.

As mentioned before, the *p* represents the post, in this paper context, the physician current popularity, and *u* represent the user social influence. In step 5, the customized algorithm represents u^0 with the equation $u^o = c^0 x e^0$

$$\mathbf{p} \leftarrow \alpha S^T \mathbf{u} + (1-\alpha)\mathbf{p}^0; \tag{4}$$
$$\mathbf{u} \leftarrow \beta S \mathbf{p} + (1-\beta)\mathbf{u}^0 \tag{5}$$

Here the initial value the user influence is not her friends as in BiRank, but instead the importance of the user contribution and engagement to the system. The new algorithm starts assuming that all users are fully contributing and fully engaged with a perfect score. The new algorithm multiplies the transpose of both vectors to get the initial U value

$c^0 = [1.1.1.....1]^T$ (6)
vector indicates the score of contribution given to the community, number of check-ins, and stars

$e^0 = [1.1.1.....1]^T$ (7)
vector indicates the number of engagements: (likes) and comments back

To get the *U* value, the customized algorithm uses the generated *P* in step 4 and plug in the values in equation 5.

The *U* score in step 5 is calculated based on the number of contributions, and Engagement, both presented as matrixes

C_{ij}, number of contributions: reviews, number of check-ins, and number of stars
E_{ij} number of engagements: (likes) and comments back
$u^0 = C^T c + E^T e$ (8)

WEIGHTS ON CONTRIBUTIONS AND ENGAGEMENT

The "Authority weight" represents Authors of online reviews contributions and is based on
A) number of reviews,
B) Stars rating left for the provider.

The “Hub weight” represents Authors of online reviews engagement and is calculated based on
A) the number of reactions and
B) comments to other reviews.
Both variables are creating the reviewer influence level

So far, the paper modeled the authors rank by using the amount of engagement and contribution to the community instead of using the number of friends as a point of reference. The resulting ranked authors of reviews lead to ranking reviews. The algorithm output will be ranked reviews, based on the reviewers’ level of engagement and contribution. The reviews are first classified into eight separate aspects according to Medicare classification, namely,

1. Getting timely care, appointments, and information.
2. Between-visit communication.
3. Attention to patient medication cost.

4. How well clinicians communicate.
5. Patients' rating of clinicians.
6. Health promotion and education.
7. Courteous and helpful office staff.
8. Clinicians are working together for patient care.

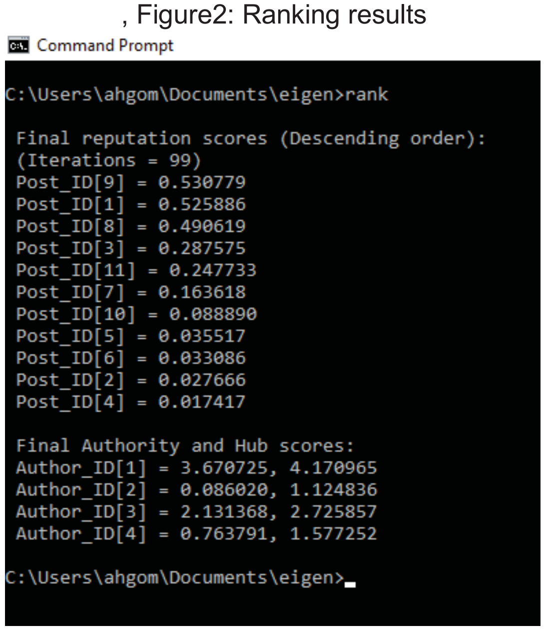
The paper ranks the reviewers based on the aspects they are reviewing a physician. Natural language processing allows for the classification of each review in one or more aspect, in addition to any other aspects presented in the Yelp reviews. In other words, for each identified aspect, related reviews are grouped and ranked based on the review popularity, reviewers influence and the temporal dimension.

IMPLEMENTATION DISCUSSION

For demonstration purposes, the implementation assumes the same time of review in one aspect. In the algorithm implementation, assume there are 4 reviewers addressing one identified aspect, which is attention to patient medication cost. All reviewers provided their reviews at the same time period. The four reviewers provided 11 reviews, and are interacting with each other's reviews. The Appendix presents the data used to generate the ranking of the reviews along with each reviewer rank as a hub and an authority to reflect the reviewer level of engagement and contribution to the community. The algorithm output shows that review 9, written by Author 3, is the most relevant review to the community, given the author of the review rank in terms of contribution and engagement. Author 1 is the most influential reviewer within the community, as she is the one the majority of the community interact with her posts. It is worth noting that post 1, written by Author 1 has a higher ranking than post 8 written by Author 3 due to the difference in the author authority and hub rank.

Accordingly, the algorithm allows for ranking reviews based on the reviewer influence, and the item popularity. The time of the review impacts the final ranking. Figure 2 shows the results of the algorithm. The results converge after 99 iterations. The levels of contributions, engagement and user interactions is presented in the Appendix.

, Figure2: Ranking results



ECONOMIC VALUE

Recent research suggests that there is an economic value from the online reviews of healthcare providers. The objective of exchanging the economic value with an online health community economy is to disseminate knowledge from the ecosystem point of view. In an attempt to formalize the ecosystem, it is essential to articulate the reviewers' economy variables in exchange. The reader of the reviews is trading their time and attention, in return, they are receiving the collective wisdom of the masses, and as a byproduct, the service providers are increasing their utility function, and the reviews readers book appointments with them more than the non-reviewed service providers. This paper uses the reviewer/patient engagement and contribution, and the health care provider reviews popularity to create a value function, where the patient generates value based on his effort (online reviews). According to the literature, the provider benefits from such engagement up to 7%, and the other system users benefit up to 5%. If a reservation system generates $250,000 per day, the benefits for the system to have a higher booking due to relevant reviews would be 7% daily or $17,500 per day. It might make sense to provide monetary compensation for the reviewers as a function of the value added they provide

$$ValueCreation_i^t = \frac{f(u_i^{(t)})}{\sum_{n \in all} f(u_n^{(t)})} \text{ x } income^t \tag{9}$$

The Value Creation is reviewer $\boldsymbol{i}$'s value creation in time $\boldsymbol{t}$. Income is the total income that may be distributed by the system to the community in time $\boldsymbol{t}$. $\boldsymbol{u}$ is the user influence score in time $\boldsymbol{t}$. $\boldsymbol{f}(.)$ is a reward function that controls the effect of change.

CONCLUSION

The paper presents a model to help incentivize online contributors in the form of reviews, where more compensation is delivered when more meaningful/sustainable contributions are provided. First, the paper identified an empirically tested superior ranking algorithm and modeled the patients' characteristics using the same methodology in the identified algorithm. The new algorithm defines the user influence as a result of the user contribution and engagement in addition to the importance of the reviews as viewed by the community. The algorithm implementation demonstrates the impact of the reviewer authority on the rank of the review. Second, the paper presents a value creation function based on the user influence, where each user is compensated based on her rank, which is derived from her engagement and contribution to the community, and the popularity of the physicians she is reviewing. To incentivize commentators, a financial model needs to pay the reviewer based on their impact. Future work includes automating the reviewers' compensation by presenting the knowledge created and disseminated in a blockchain ledger. Knowledge transactions may be recorded on a public ledger, similar to blockchain. The more usable the reviewer knowledge, the more transaction it generates. According to the paper model of value creation, it leads to more booking to the system in general, even if negative reviews exist. This is because the compensation is based on the quality and influence of the review, not the sentiment of the reviewers. An additional area of future research is to combine the temporal dimension with the spatial dimension of the patients using the build in mobile sensors to validate the physician popularity based on the number of signals detected in large medical buildings.

Managing Product Complexity to Create More Effective Innovation Outcomes: A Comprehensive Examination of Coordination Mechanisms

Ryan Skiver
University of Wisconsin Oshkosh
Email: Skiverr@uwosh.edu

ABSTRACT

Literature suggests that product complexity has the potential to lead to greater profits if the complexity is managed effectively (Kekre & Srinivasan, 1990). Yet firms with higher levels of product complexity experience profit margins that are on average 3 percent lower than firms that do not have high product complexity (Hoole, 2006). Coordination Mechanisms should be put into place to manage the strain caused by product complexity. The results showed product complexity in two dimensions (multiplicity and relatedness) could create better innovative outcomes (Blue Ocean and Red Ocean) with coordination mechanisms in place.

KEYWORDS: Product complexity, coordination mechanisms, Blue ocean innovation, Red ocean innovation, survey research

INTRODUCTION

Product complexity has been increasing over the past couple decades due to customer demand for new technologies and customized products. Firms must adopt these differentiated products to continue thriving in today's customer-driven market. Literature suggests that added product complexity has the potential to lead to greater profits if the complexity is managed effectively (Kekre & Srinivasan, 1990; Meeker, Parikh, & Jhaveri, 2009; Meyer & Mugge, 2001). Yet firms with higher levels of product complexity experience profit margins that are on average three percent lower than firms that do not have high product complexity (Bozarth, Warsing, Flynn, & Flynn, 2009; Hoole, 2006). Firms with greater product complexity typically do have higher revenue growth, but have lower margins (profits). A key imperative is to find ways of more efficiently managing complexity. Literature has shown that managing product complexity effectively poses great difficulty in coordinating complex systems and aligning product complexity with strategic goals (Jacobs & Swink, 2011). This research was structured to find management techniques in product complex environments that would render gains in profits instead of profit losses.

LITERATURE REVIEW

Product complexity (and factors that cause complexity), strategy, and innovation have all been studied vastly in literature. This research put all of the areas together to create a model of successful innovation in a high complexity environment. There is a growing need to create multiple products that cater to individual needs (Jacobs, 2007; Lawton, 2007). However, there is a growing paradox associated with product complexity. Product complexity can create greater profits if the complexity is managed effectively (Meeker et al., 2009; Meyer & Mugge, 2001). At the same time, higher profits are not seen in highly complex industries (Bozarth et al., 2009; Hoole, 2006). This is due to a lack of strategic management of the complexity issues (Hoole, 2006). This research examined this paradox in detail and explored strategies using coordination mechanisms to alleviate the strain from complexity and to create more successful outcomes for firms in complex environments. Concurrently, innovation is necessary for a firm's survival (Steencamp, Hofstede, & Wedel, 1999). This research explores the link between complexity and innovation in the following sections and shows that innovation is an outcome of product complexity. This research also explores the literature on coordination mechanisms and combines this stream of literature with highly complex industry and innovation outcomes. The research then shows that certain coordination mechanisms can relieve the strain from complexity and at the same time create better outcomes in terms of both new and existing market innovation. Complexity, strategy, and innovation relationships are shown in Table 1 below.

Table 1: Complexity, Strategy, and Innovation: A Vital Relationship

Key Business Challenges	**Key Research Issues**	**Reference**
Complexity Challenges: Increasingly firms face complexity challenges that arise from diverse aspects including technological, environmental, and social factors. Firms need to understand these challenges and focus on how they can manage them successfully.	(1) Assess the source of complexity at firm and industry level; (2) Understand how firms manage the increasing level of complexity to add values to customers and to stay competitive.	Lawton, 2007; Meeker et al., 2009; Meyer & Mugge, 2001
Strategic Responses: A single firm cannot handle complexity challenges alone. Complexity challenges require organization-wide, purpose-driven efforts over a long-term horizon.	(1) Firms strategically engage employees, customers, and suppliers to create more effective outcomes in a complex environment; (2) Firms operationally involve employees, customers, and suppliers to create more effective innovation results.	Ashkenas et al., 2002; Bozarth et al., 2009
Innovation Outcomes: Complex problems and issues require innovative problem definition and solving and deploying processes that involve effective translation of challenges into valuable outcomes.	(1) Complexity challenges require new and different approaches (i.e., innovation); (2) Innovation is the lifeblood of the firm; (3) Outstanding innovation is often the result of adopting new perspectives, implementing different processes, and pursuing high value-reward outcomes.	Pellissier, 2012; Sivadas & Dwyer, 2000; Steencamp et al., 1999

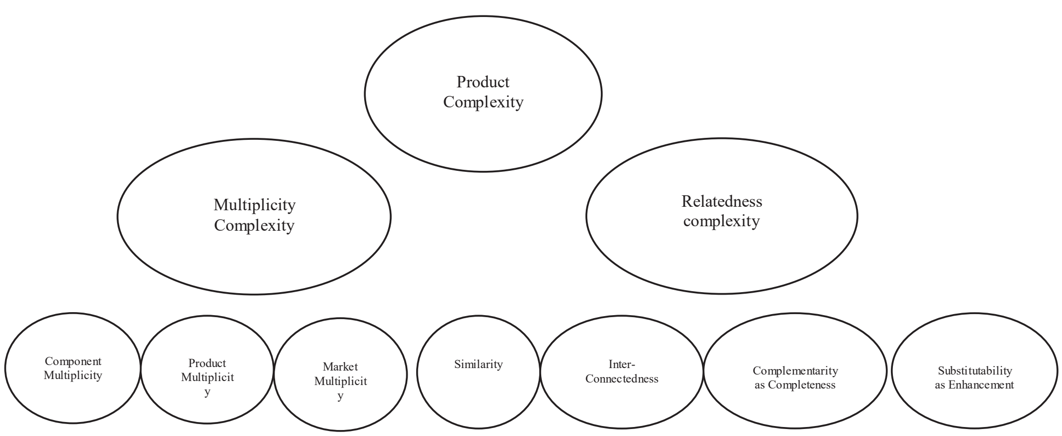
Table 1: Complexity challenges are significant and strategic responses are required. Firms that manage complexity well also show high levels of innovation outcome success.

This review will continue to explain the following three main areas of study: product complexity, the product complexity link to innovation outcomes, and coordination mechanisms to reduce strain caused by product complexity. This review provides a better understanding of the subject area and the reason for linking all the concepts together with theory. To understand what drives product complexity, we must first understand complexity challenges and what innovation is to discover how product complexity and innovation connect.

Complexity challenges. Increasingly, firms face complexity challenges that arise from diverse aspects including technological, environmental, and social factors (Lawton, 2007). Firms need to understand these challenges and to focus on how they can manage successfully (Meeker et al., 2009; Meyer & Mugge, 2001). This research aimed to accomplish two outcomes: (1) Explore the relationship between product complexity and innovation outcomes, and (2) Understand how firms manage the increasing level of complexity to add value to customers and to stay competitive with innovative products. To accomplish these three goals we must first understand the relationship between product complexity and innovation outcomes.

Product complexity dimensions. This research on product complexity built on the workings of Jacobs (2007) by expanding on the areas of multiplicity and relatedness. A greater understanding was obtained by dividing multiplicity into three dimensions: component, product, and market. This is because products can cause complexity for a firm due to many different products, many different components inside the products, and many different markets. By dividing multiplicity up into categories, this research attempted to gain a better understanding of the complexity of these three areas. Although the three dimensions of relatedness (similarity, interconnectedness, and complementarity) all fit the purpose of this research, a clearer understanding of complexity could be gained only if complementarity was divided into separate categories such as complementarity as completeness and substitutability as enhancement. In the previous literature complementarity complexity was all linked into one dimension. This research has found that complementarity is add-on product; however, add-on products can either be necessary for a product to function or unnecessary to enhance a product. For this reason to clarify this issues complementarity was divided into complementarity as completeness and substitutability as enhancement. Product complexity is quite complicated but by looking at product complexity in terms of the dimensions of multiplicity and relatedness, complexity can be captured in a specific, researchable way. The dimensions of product complexity are show below in Figure 1.

Figure 1: Dimensions of Product Complexity



Strategic coordination: a crucial role for coordination. Complexity challenges require responses from firms. Coordination is "the organization of the different elements of a complex body or activity so as to enable them to work together effectively" (Webster, 1964 p. 502). Therefore, coordination mechanisms are defined as the sustainable system-wide efforts that coordinate diverse business processes, functions, and people for the purpose of product development. The role of coordination mechanisms is to translate organizational resources into new ways of problem solving and value creation for customers in the form of products/services that increase value to the customers. Involvement and collaboration of employees, customers, and suppliers have been shown to have many advantages for the firm involved (Ashkenas et al., 2002; Cross, Yan, & Louis, 2000; Devanna & Tichy, 1990; Kerr & Ulrich, 1995). This collaboration has been studied extensively in the innovation literature (Powell, Koput, & Smith-Doerr, 1996; Shan, Walker, & Kogut, 1994). These authors have performed empirical tests and have shown that collaboration between: functional units, hierarchical levels, suppliers, and customers was positively related to new product development success both in financial performance and output of new products (Powell et al., 1996; Shan et al., 1994). The financial aspect is due to the close feedback from consumers so products that are necessary are being created. As the consumer demands greater complexity and newer products, coordination mechanisms will need to be in place to allow for more successful product creation. The success of new products is due to the collaboration between functional units, hierarchical levels, suppliers, and customers, allowing for products that are desired in the market at faster speeds and without technical problems.

Boundaryless organizations. **"**Boundaryless organizations" is the strategy of forming coordination mechanisms between firms and employees, customers, and suppliers. These coordination mechanisms allow for increased speed, clearer information, better decisions, etc. (Ashkenas et al., 2002). The idea of "boundaryless organizations" was created in 1988 inside General Electric by former CEO Jack Welch. The idea was to reduce bureaucracy, shorten cycle times, and increase capabilities for change (Ashkenas et al., 2002). A group of consultants that included Ashkenas, Jick, Ulrich, and Kerr created a blueprint for the term now known as boundaryless organizations (first coined in 1990). By 1992 global linkages were added and Kerr, Jick, and Ulrich began adding details to the complete the concept. They created a paradigm shift from describing successful businesses using old factors of size, role clarity, specialization, and control to using new success factors of speed, flexibility, integration, and innovation. The final concept consisted of four areas (included in Table 3 below) [modified from (Ashkenas et al., 2002).

Table 2: Types of Boundaries

Boundary Type	**Brief Summary**	**Description**	**Reference**
Vertical Boundaries	The various layers between the floor and ceiling of the organization.	Separate people by hierarchical levels, title, status, and rank.	Ashkenas et al., 2002; Devanna & Tichy, 1990
Horizontal Boundaries	The internal walls.	Separate people in organizations by function, business unit, product group, or division.	Ashkenas et al., 2002; Devanna & Tichy, 1990
External Boundaries	The external walls.	Divide companies from their suppliers,	Ashkenas et al., 2002; Cross et

		customers, communities, and other external constituencies.	al., 2000; Kerr & Ulrich, 1995
Geographic Boundaries	The cultural walls.	Include aspects of the other three but are applied over time and space, often across different cultures.	Ashkenas et al., 2002; Cross et al., 2000

Ashkenas et al. (2002) was amended to create Table 2 above. These changes were made to encompass the scope of product complexity and to focus on areas of product complexity and innovation to create working coordination mechanisms that could be used within a firm. For the purpose of this research, vertical, horizontal, upstream, and downstream boundaries covered the necessary scope of the coordination needed in product complex environments. Also because the area of focus for this research was primarily national, the instances of geographic boundaries from Ashkenas et al. (2002) that dealt with coordination between countries were excluded or changed to the appropriate coordination area vertical, horizontal, upstream, or downstream.

Innovation outcomes. Innovations and new product development are the lifeblood of any firm (Steencamp et al., 1999). To remain successful over long periods, firms must be ambidextrous in creating new market products (products that create new markets) through modular and radical innovation, and must upgrade existing market products (products that are new but do not form new markets) through architectural and incremental innovations. The management of radical and modular (new market innovation) poses a unique set of challenges for managers. It is a long and investment intensive process, marked by set-backs and unpleasant surprises, with no guarantee of success (Lynn, Morone, & Paulson, 1996). Success in the competitive environment involves exploitation of a firm's existing capabilities, whereas survival in a complex environment involves exploration for new capabilities at the same time (Levinthal & March, 1993; March, 1991).

With rapid increases in technology over the past thirty years, the environment has becoming more and more complex (Lawton, 2007). This brings an added importance to the exploration or new technology factor. In the literature there have been two main types of exploration of new market products—radical and modular innovation (Henderson & Clark, 1990). Yet, firms still experience significant failure rates when trying to implement new technologies (Sivadas & Dwyer, 2000). This research continues below with a review of the literature on innovation to put a better perspective on innovation and its relationship to product complexity.

This research viewed product complexity in terms of multiplicity and relatedness complexity. Product complexity and innovation go hand in hand (Pellissier, 2012). Multiplicity has three dimensions (component, product, and market) has four dimensions (simplicity, interconnectedness, complementarity as completeness, and substitutability as enhancement) discussed in the previous section that attribute to product complexity. These dimensions cause firms to introduce new products and thus create innovation in the firm. To fully understand product complexity we must understand innovation and how innovation is created from product complexity. These will be explained in the upcoming sections, but first a clear understanding of innovation must be developed from the literature to understand this relationship and to discover ways to manage complexity properly.

Contingency theory. Contingency theory was used to describe the different strategies needed for different levels of product complexity and why successful product complexity requires various coordination mechanisms. To understand the linkages of product complexity to coordination mechanisms, it was essential to investigate contingency theory further. Contingency theory links the characteristics of the organization (i.e., technology and strategy) to complexity, where different strategies are necessary to control the outcome of a changing system (Donaldson, 2001). This research explored strategies to deal with one type of system, a product complex system. Burns and Stalker (1961) stated that different kinds of management systems are appropriate to different kinds of technical environments. In other words, the same system cannot be used universally. Instead, technological complexity forces the use of different systems, depending on the conditions. Chandler (1962) stated that structure follows strategy in organizations. The firm creates a strategy based on what they hope to accomplish. The strategy is based on objectives, long-term goals, and allocation of resources. Different strategies create different needs; therefore, organizational structure will evolve to accommodate those needs.

A firm focuses on creating products that it controls and does not focus on products that are impossible to control (Lawrence & Lorsch, 1967). Contingency theory literature has shown that a fit between internal structure and the external environment must be obtained for maximized performance (Lawrence & Lorsch, 1967). If the strategy were changed due to external conditions, this would allow for better performance. Galbraith (1977) discussed contingency theory from the perspective of information processing in organizations by developing an information-processing model to explain the relationship between the information processing needs of a firm and the structural mechanisms that can address those needs. He argued that the ability of an organization to coordinate its activities successfully depends on how effectively and efficiently it can process the amount of information needed to be processed. This effective processing is done by reducing the need for information processing or by increasing the capacity to process the information. In other words, an information processing mechanism, or capability, should match the firm's information processing needs. Mintzberg (1981) stated that organizational success is matching or fitting the parts and characteristics of organizational structures to one another. This research focused on fitting strategy to practices based on varying levels of product complexity. A further explanation of contingency theory is provided below in Table 3. Table 3 demonstrates the key findings from contingency theory literature as applied in this research.

Table 3: Contingency Theory Time Frame

Key findings	**Literature Source**
Structures follow strategy in organizations	Burns & Stalker, 1961
Different kinds of management systems are appropriate to different kinds of technical environments	Chandler, 1962
Organization must establish a "fit" between its internal structure and its external environment	Lawrence & Lorsch, 1967
The ability of an organization to successfully coordinate its activities depends on how effectively and efficiently it can process the amount of information needed to be processed	Galbraith, 1977

The key to organizational success is matching or fitting the parts and characteristics of organizational structures to one another	Mintzberg, 1981
Appropriate fit between strategy and environment results in superior performance	Miller, 1988

Systems theory. In organizations systems consist of people, structures, and processes that work together to make an organization healthy or unhealthy (Ackoff, 1978; Bailey, 1994; Bánáthy, 1996; Bausch, 2001; Buckley, 1967; Capra, 1997). Systems thinking has been defined as an approach to problem solving, by viewing problems as parts of an overall system (Davidson, 1983; François, 1999; Gorelik, 1975). Firms are not judged solely by being in the market. Instead, they are judged by what they achieve in terms of outcomes (François, 1999). One firm alone cannot handle complexity; therefore, system resources (employees, customers, and suppliers) are needed to create the most successful outcomes (Davidson, 1983; Gorelik, 1975). Systems thinking is not one simple concept, but rather a set of habits or mechanisms within a framework that is based on the belief that the parts of a system can best be understood in the context of relationships with each other and with other systems, rather than in isolation (Checkland, 1981, 1997; Churchman, 1968, 1971). Product complexity challenges can be handled by an organizational system network to allow an organization to achieve improved outcomes.

What is the rationale for multiplicity and relatedness? Complexity theory details that single items are not complex; it is the number of different items or the interaction of the items that form complexity (Anderson, 1999; Brown & Eisenhardt, 1997). Because of this complexity, there is a great importance in understanding the multiplicity and the relatedness of products.

Social exchange theory. Social exchange theory is a social, psychological, and sociological perspective that explains social change and stability as a process of negotiated exchanges between parties (Befu, 1977; Cook & Emerson, 1978; Ekeh, 1974). Social exchange theory posits that all human relationships are formed by the use of a subjective cost-benefit analysis and the comparison of alternatives (Miller, 2005; Roloff, 1981; West & Turner, 2007; Zafirovski, 2005). Another part of social exchange theory is structuralism, which describes the benefits of coordination or why employees, customers, and suppliers would want to coordinate to form a network.

Why are coordination mechanisms the key strategic response? Systems theory and social exchange theory have demonstrated that one firm alone cannot handle complexity; therefore, resource coordination (between employees, customers, and suppliers) in the entire system is needed (Checkland, 1981, 1997; Churchman, 1968, 1971). Systems theory also explains why coordination mechanisms are needed due to the valuable outcomes attained by all parties involved in network coordination (Miller, 2005; West & Turner, 2007). Thus, how firms coordinate employees, customers, and suppliers is important strategically to success in a firm.

Product multiplicity complexity. Jacobs (2007) defined multiplicity as enumeration of items. This research extended that definition to ask the question, “the enumeration of what items?” The literature has shown that multiplicity exists not only in the sheer number of skus but also in the number of components within the product, the number of products themselves (skus), and the number of markets in which the firm participates (Baldwin & Clark, 2000; Daft, 1983; Gupta & Krishnan, 1999; Novak & Eppinger, 2001; Ramdas, 2003; Scott, 1992).

Component multiplicity. Component multiplicity is the enumeration of components within a portfolio (Gupta & Krishnan, 1999; Ramdas, 2003). Different products contain different numbers of components. Books are for the most part very low in component complexity, whereas cell phones and computers may contain thousands of component parts and thus are very component complex. Firms must deal with this type of complexity to create the necessary products for the consumer.

Product multiplicity. Product multiplicity is the enumeration of products within a portfolio (Baldwin & Clark, 2000; Novak & Eppinger, 2001). A small firm may specialize in one product, but this is usually not the case for long. Soon there are new generations of the product or product spinoffs to generate more revenue for the firm. Markets for most products are not infinite, so firms search for ways to gain valuable market share. This is done by generating new products.

Market multiplicity. Market multiplicity is the enumeration of markets within a portfolio (Daft, 1983; Scott, 1992). As a firm grows larger, it looks outside its current market to new markets to earn revenue. The more markets it enters, the more complex its environment becomes and the more difficult to control the need for new products becomes. This adds to the product complexity of a firm.

Product relatedness complexity. Relatedness of elements is formed by three subcomponents identified from the research on complexity. They are similarity, interconnectedness, and complementarity (Jacobs, 2007). Similarity is the sharing of product architectures in the terms of a platform or module (Fixson, 2005; Novak & Eppinger, 2001). Interconnectedness is the sharing or interaction of components to make the product function when one component needs another component to function (Griffin, 1997a, 1997b; Kaski & Heikkila, 2002). The final dimension is complementarity, which occurs when one product requires another aftermarket product (Jacobs, 2007; Tatikonda & Stock, 2003). Examples are a Blu-ray player and a Blu-ray disc, mp4 and digital audio/video, etc. The original product requires additional products for the original product to function.

Similarity. Similarity is the extent to which a product shares characteristics such as part geometries or components, fulfilling the same strategic role in the portfolio as a prior product but allowing for customization through replacement of components or modules. (Fixson, 2005; Novak & Eppinger, 2001). Customization includes modifying the appearance of presentation objects or editing their attribute values by selecting among a set of predefined configuration options (Morch, 1997). Customization can be accomplished by the company during production or after the initial purchase by the consumer. For example, the consumer may purchase a car with power windows or a premium sound system. The car itself has not changed, yet the modules of the power windows or a premium sound system give the consumers more options and differentiation than found in the original product (the car). In this case, product differentiation exists, but the differentiation is easier to produce because different products use similar platforms and modules.

Interconnectedness. Interconnectedness is a connection via an interface (Jacobs, 2007). When component parts require additional component parts to communicate or to fulfill their role in a product, there will be high interconnectedness (Griffin, 1997a, 1997b; Kaski & Heikkila, 2002). There are many products that have connected components, where if one fails, the entire unit will fail. This interconnectedness makes the product much more complex by relying on every component to function without failure.

Complementarity as completeness. Complexity as completeness is the extent to which other aftermarket products need to be purchased by the end user to obtain the intended use of the original purchased product (Jacobs, 2007; Tatikonda & Stock, 2003). One product adds value to another that otherwise would be less valuable. An example of this is computer software. It is dependent on a computer to function. The way to test for complementarity as completeness is to determine if the original product works out of the box or if it is dependent on a second product purchase to work as its designers intended. Complementarity as completeness requires a great deal of technology for a product to function.

Substitutability as enhancement. Substitutability as enhancement is the extent to which other aftermarket products can be purchased by the end user to create enhanced benefits from the original purchased product. One product adds value to another product by enhancing the original product, making the original product more valuable to the consumer. An example of this is a cell phone case. A consumer may purchase a case and screen protector for a smart phone through the retailer. This purchase adds to the complexity of the product by adding on more components to the original product. The cell phone could function fine on its own without the case; however, the case provides extra features such as waterproofing and damage protection, which create greater value for the original product. The way to test for substitutability as enhancement is to determine if the original product works out of the box and could later be enhanced by extra component purchases.

Coordination mechanisms. Coordination is, “the organization of the different elements of a complex body or activity so as to enable them to work together effectively” (Webster, 1964, p. 502). We therefore define coordination mechanisms as the sustainable system-wide efforts that coordinate diverse business processes, functions, and people for the purpose of product development. Involvement and collaboration of the employees, customers, and suppliers provide many advantages for the firm involved (Ashkenas et al., 2002; Cross et al., 2000; Devanna & Tichy, 1990; Kerr & Ulrich, 1995; Roh, Hong, & Park, 2008). This collaboration of networks has been studied extensively in the complexity and innovation literature (Powell et al., 1996; Shan et al., 1994). There have been empirical tests discussed in the previous literature that showed the important relationship between networks and new product development success in financial performance and output of new products (Powell et al., 1996; Shan et al., 1994). The financial aspect is due to the close feedback from consumers, which leads to the firm creating only products that are needed and demanded by the consumer. As the consumer demands greater complexity and newer products, coordination mechanisms will need to be in place to allow for more successful product creation. The output of new product creation is due to the collaboration between functional units, allowing for the product to be created without serious setbacks (Hong, Doll, Nahm, & Li, 2004; Hong et al., 2011).

Vertical coordination. Vertical coordination is bringing together employees and the firm as one unit (Ashkenas et al., 2002; Devanna & Tichy, 1990). This collaboration creates a free flow of information and tears down the bureaucracy. Boundaryless organizations focus more on who has the useful ideas than on who has rank. The boundaryless concept also allows decisions to be made quickly, increases information sharing, increases innovation research, and increases speed and flexibility (Ashkenas et al., 2002). The idea is that when employees are free to experiment and to think for themselves, they will be more creative and the company will create new, innovative products. Firms with fluid job descriptions, loose organization charts, high communication, and few rules may be conducive to innovation because they free developers from constraints, allowing them to change flexibly and to create novel ideas (March, 1981; Peters, 1994).

Horizontal coordination. Horizontal coordination is bringing together the firm's functional units as one unit (Ashkenas et al., 2002; Devanna & Tichy, 1990). This collaboration creates a free flow of information among departments. Boundaryless organizations focus more on who has the useful ideas than on who has authority. The boundaryless concept also allows decisions to be made quickly, increases information sharing, increases innovation research, and increases speed and flexibility (Ashkenas et al., 2002). Firms with fluid job descriptions, loose organization charts, high communication, and few rules may be conducive to innovation because they free developers from constraints, allowing them to change flexibly and to create novel ideas (March, 1981; Peters, 1994).

Upstream coordination. Upstream coordination is bringing together suppliers and the firm as one unit (Ashkenas et al., 2002; Kerr & Ulrich, 1995). This collaboration allows firms to reduce cost and to increase flexibility by working as a single unit rather than as several separate entities. Due to increasing complexity, one firm can no longer do everything; so instead it must concentrate on core competencies and focused missions (Ashkenas et al., 2002; Jin & Hong, 2007; Kerr & Ulrich, 1995). Both the firm and the supplier could gain by creating necessary products and working out a financial situation where both will profit (Ashkenas et al., 2002; Youn, Hong, & Nahm, 2008). This collaboration also could increase innovation if ideas are shared cross-organizationally. Communication allows other intelligent minds to see the problem and to find a solution to benefit all parties.

Downstream coordination. Downstream coordination is bringing together customers and the firm as one unit (Cross et al., 2000). Customer needs change at an increasing rate. By involving the customer, the firm can be more informed about the customer's likes, dislikes, needs, and wants (Ashkenas et al., 2002; Cross et al., 2000). This relationship with the customer also fosters innovative outcomes by leading the firm to create products that it otherwise might not have thought of offering in both existing and new markets (Ashkenas et al., 2002; Jeong & Hong, 2007).

Blue Ocean innovation offerings performance. Kim and Mauborgne (2005) created the concept of Blue Ocean and Red Ocean innovation. These terms were used to highlight the importance of innovation in both forms (new market as well as existing market). Blue Ocean innovation offerings are defined as product and service offerings with new innovation(s) that target new markets. Blue Ocean refers to the creation of products that create a new market. Based on the previous literature, we further distinguished new market innovation as either modular or radical innovation. Both new and existing innovations are necessary; yet many efforts to understand ways to improve the success rates of these innovations have failed. This research incorporated product complexity and innovation along with coordination mechanisms to study the success outcomes of firms that use these mechanisms in a complex environment.

Red Ocean innovation offerings performance. As mentioned previously, Kim and Mauborgne (2005) created the concept of Blue Ocean and Red Ocean innovation. These terms were used to highlight the importance of innovation in both forms (new market as well as existing market). Red Ocean innovation offerings are defined as multigenerations of products and services that include new innovation(s) in existing and growing markets. Using the previous literature, we divided existing markets further into whether they used architectural or incremental innovations. Both new and existing innovations are necessary, yet many efforts to understand ways to improve the success rates of these innovations have failed. This research incorporated product complexity and innovation along with coordination mechanisms to study the success outcomes of firms that use these mechanisms in a complex environment.

Table 4: Constructs, Definition, Key Variables, and Literature Base

Constructs and Definition	Key Variables	Definition	Items	Literature Base
Product multiplicity complexity A design state resulting from the multiplicity of product architectural elements.	Component multiplicity	The enumeration (i.e., sheer number) of components and parts received from suppliers, and parts and components to be added through transformation processes.	1) Our firm's products contain a large number of components? 2) Our firm's products contain a large number of component variants? 3) Our firm's product part list is large?	Gupta & Krishnan, 1999; Jacobs, 2007; Ramdas, 2003
	Product multiplicity	The enumeration (i.e., sheer number) of product lines that a firm offers to customers.	1) Our firm produces a large number of product variants? 2) Our firm produces a large number of products? 3) Our firm produces many SKUs?	Baldwin & Clark, 2000; Novak & Eppinger, 2001
	Market multiplicity	The enumeration (i.e., sheer number) of customer segments (i.e., local, regional, national, and global) that a firm targets and serves.	1) Our firm serves different markets for our products? 2) Our firm serves different geographic locations? 3) Our firm serves different customer segments?	Daft, 1983; Scott, 1992

Table 8 Continued: Constructs, Definition, Key Variables, and Literature Base

Constructs and Definition	Key Variables	Definition	Items	Literature Base
Product relatedness complexity A design state resulting from the relatedness among product architectural elements.	Similarity	The extent to which a product shares characteristics such as part geometries or components, fulfilling the same strategic role in the portfolio as a prior product but allowing for customization through replacement of components or modules.	1) Our products contain exchangeable parts? 2) Our products' parts are customized in-house? 3) Our products are mass-customized?	Fixson, 2005; Jacobs, 2007; Novak & Eppinger, 2001
	Inter-connectedness	The extent to which components are joined to each other within a product to form a completed product that adds value to the customer by allowing aftermarket customization with additional purchases.	1) Our components are highly networked *within* the product? 2) Our components are networked to allow for aftermarket customization of our products *without* additional purchases? 3) Our components are interconnected within the product?	Griffin, 1997a, 1997b; Kaski & Heikkila, 2002
	Complementarity as completeness	The extent to which other aftermarket product(s) need to be purchased by the end user to obtain the intended use of the original purchased product.	1) Our products require other product purchases for the full intended use of the product? 2) Our products are complementary to other product purchases?	Jacobs, 2007; Tatikonda & Stock, 2003

			3) Additional product purchases are necessary for our products? 4) Our products need additional aftermarket purchases?

HYPOTHESES/MODEL

Development of Hypothesis 1 and 1A. Because complexity is dynamic and changing, in complex environment more products will be created. These products will be new market products (i.e., Blue Ocean innovation) (Pellissier, 2012). Innovation is the lifeblood of a firm (Steencamp et al., 1999). Yet, half of the innovations fail to achieve successful revenue (Sivadas & Dwyer, 2000). Systems theory and social exchange theory have been used to explain the reason coordination mechanisms have led to more successful innovative outcomes given high multiplicity complexity. Product complexity and innovation challenges can be handled by organizational system networks (Ackoff, 1978; Ash, 1992; Bánáthy, 1991, 1992, 1996, 1997; Checkland, 1981, 1997). Several strategies can link employees, customers, and suppliers to create a more effective innovation system network (Ashkenas et al., 2002). In other words, strategies can create better innovation outcomes. Effective strategies are accomplished through building appropriate system networks. These system networks are the firm's resources of vertical/horizontal (employees), downstream (customers), and upstream (suppliers). These system networks provide the information and collaboration to manage innovation effectively and to create successful innovative outcomes in new markets by creating new knowledge and improving the information flow needed in the firm.

Vertical and horizontal coordination allow for employees to address problems quickly and to change in a complex fast-moving environment (Ashkenas et al., 2002; Devanna & Tichy, 1990). Vertical and horizontal coordination cut down the bureaucracy and speed up decisions to allow success in this type of environment. Vertical and horizontal coordination can empower employees to create a more effective innovation system network (Ashkenas et al., 2002). This system network can provide the information and collaboration to manage innovation effectively and to create successful innovative outcomes in new markets by creating new knowledge and improving the information flow in the firm.

Downstream coordination allows for customers to communicate problems, needs, and changes in a complex fast-moving environment (Ashkenas et al., 2002; Kerr & Ulrich, 1995). Downstream coordination forms collaboration with customers to create a more effective innovation system network (Ashkenas et al., 2002). This system network can provide the information and collaboration to manage innovation effectively and to create successful innovative outcomes in new markets through creating new knowledge.

Upstream coordination allows for suppliers to collaborate in creation, to avoid bottlenecks, and to speed up product development in a complex fast-moving environment (Ashkenas et al., 2002; Cross et al., 2000). Upstream coordination creates collaboration with suppliers to generate a more effective innovation system network (Ashkenas et al., 2002). This system network can provide the information and collaboration to manage innovation effectively and to create successful innovative outcomes in new markets through creating new knowledge. Therefore:

Hypothesis 1:
Coordination mechanisms moderate the relationship between product relatedness complexity and Blue Ocean innovation offerings performance.

Hypothesis 1A:
Coordination mechanisms moderate the relationship between product multiplicity complexity and Blue Ocean innovation offerings performance.

Development of Hypothesis 2 and 2A. Because complexity is dynamic and changing, in complex environments, more products will be created. These products will be existing market products (Red Ocean innovation) (Pellissier, 2012). Innovation is the lifeblood of a firm (Steencamp et al., 1999). Yet, half of the innovations fail to achieve successful revenue (Sivadas & Dwyer, 2000). Systems theory and social exchange theory have explained the reason coordination mechanisms have led to more successful innovative outcomes during high relatedness complexity. Product complexity and innovation challenges can be handled by organizational system networks (Ackoff, 1978; Ash, 1992; Bánáthy, 1991, 1992, 1996, 1997; Checkland, 1981, 1997). Several strategies can link employees, customers, and suppliers to create a more effective innovation system network (Ashkenas et al., 2002). In other words, strategies can create better innovation outcomes. This is accomplished as specified through system networks. These system networks are the firm's resources of vertical (employees), downstream (customers), and upstream (suppliers). These system networks provide the information and collaboration to manage innovation effectively and to create successful innovative outcomes in existing markets by providing knowledge of ways to advance current products in the firm.

Vertical and horizontal coordination allow for employees to address problems quickly and to make changes in a complex fast-moving environment (Ashkenas et al., 2002; Devanna & Tichy, 1990). Vertical and horizontal coordination cut down the bureaucracy and speed up decisions to allow success in this type of environment. Vertical and horizontal coordination can empower employees to create a more effective innovation system network (Ashkenas et al., 2002). This system network can provide the information and collaboration to manage innovation effectively and to create successful innovative outcomes in existing markets by creating knowledge of issues and advancement to current products in the firm.

Downstream coordination allows for customers to communicate problems, needs, and changes in a complex fast-moving environment (Ashkenas et al., 2002; Kerr & Ulrich, 1995). Downstream coordination creates collaboration with customers to generate a more effective innovation system network (Ashkenas et al., 2002). This system network can provide the information and collaboration to manage innovation effectively and to create successful innovative outcomes in existing markets by creating knowledge of issues and advancement to current products in the firm.

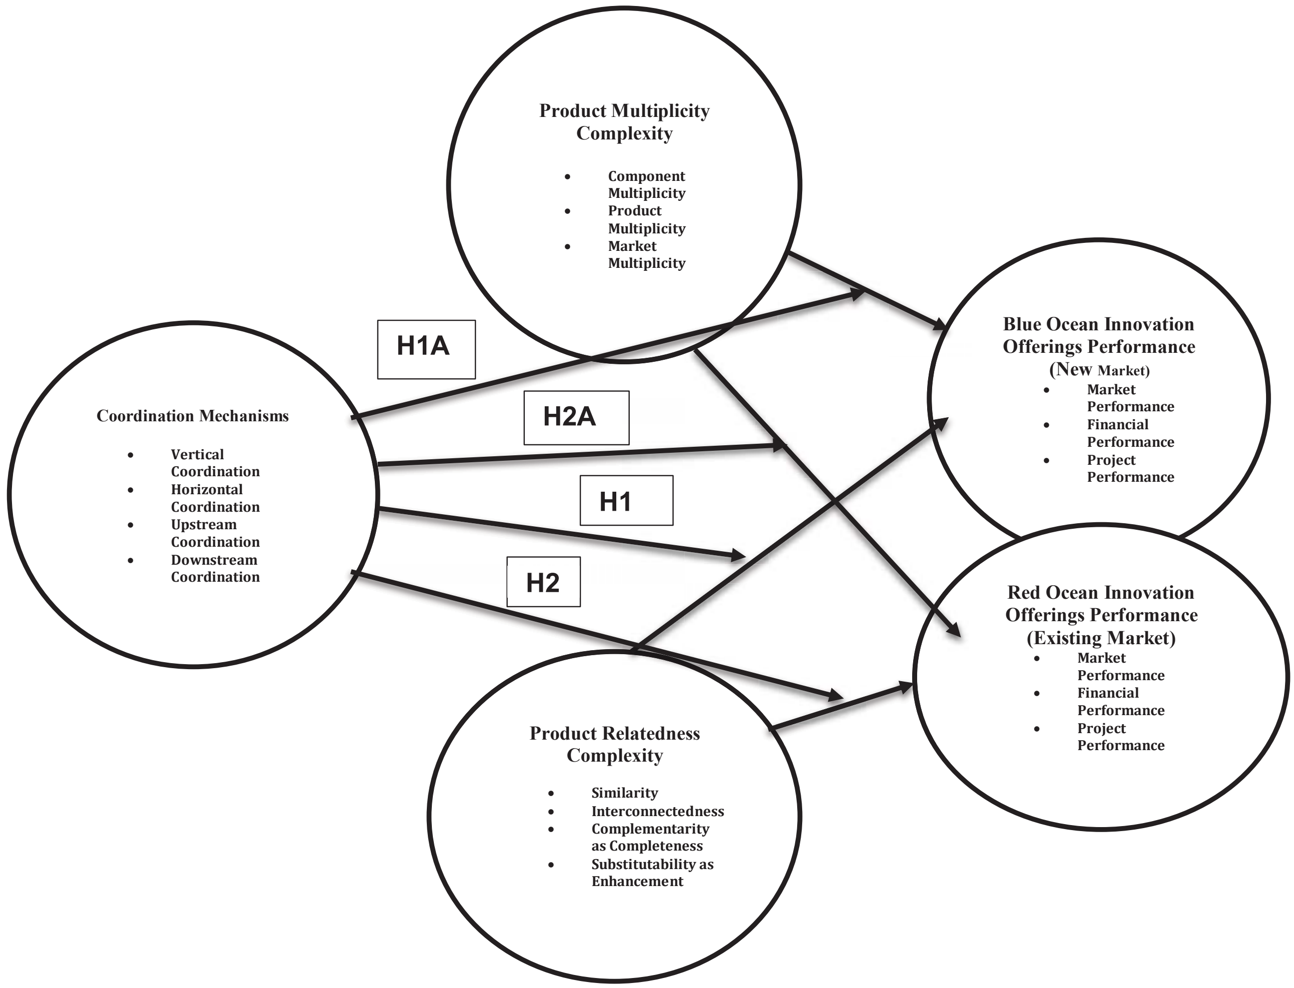
Upstream coordination allows for suppliers to collaborate in creation, to avoid bottlenecks, and to speed up product development in a complex fast-moving environment (Ashkenas et al., 2002; Cross et al., 2000). Upstream coordination creates collaboration with suppliers to generate a more effective innovation system network (Ashkenas et al., 2002). This system network can provide the information and collaboration to manage innovation effectively and to create successful innovative outcomes in existing markets by creating knowledge of issues and advancement to current products in the firm. Therefore:

Hypothesis 2:
Coordination mechanisms moderate the relationship between product relatedness complexity and Red Ocean innovation offerings performance.

Hypothesis 2A:
Coordination mechanisms moderate the relationship between product multiplicity complexity and Red Ocean innovation offerings performance.

Model

Figure 2: Model



METHODOLODGY

Testing the proposed hypotheses required a large representative sample. A cross-sectional field survey method was employed to meet the sample size requirement to provide an adequate level of statistical power (Gatignon & Xuereb, 1997; Iyer, 2001). The development and administration of surveys was done following Dillman's (1991, 2000) Tailored Design Method, which is often regarded as the standard for mail surveys. The Tailored Design Method (TDM) involves five elements for achieving high response rates: 1) a respondent-friendly questionnaire, 2) the use of four contacts by first-class mail, with an additional 'special' contact (e.g. certified mail or a telephone call), 3) the use of return envelopes with real first-class stamps, 4) personalized correspondence, and 5) a token financial incentive sent with the survey request. The questionnaires were emailed, faxed, or mailed as desired by the respondent (see next paragraph).

The survey was designed to be respondent friendly—not too long, with easily read terms and mostly Likert-type scales. The survey was prepared online, however, the respondents also were given an option to receive a mailed hard copy or a faxed copy of the survey. The questionnaires that were mailed were mailed with a postage-paid return envelope. Cover letters and questionnaires that were faxed were faxed with a return fax number listed. All letters were specifically addressed to the name of the firm's executive (i.e., CEO, VP of R&D, Director of Product Development, etc.) explaining the purpose of the survey. The survey cover page also included a nondisclosure agreement, indicating that the responses would be treated confidentially (no firm names would be used in this research) and that the data would be used for research purposes only. Appeals were used to highlight the importance of each response and of the research. Respondents who completed questionnaires were entered into a drawing as an incentive to participate and to increase the response rate.

Data collection involved a sequence of contacts that consisted of phone calls, faxes, and/or emails from late April to mid-August 2013. Phone calls were made to each of the 750 potential subjects to: 1) Verify that the information was correct (position of the key respondent), 2) Solicit participation and notify the key respondent about the survey, and 3) Ask the preferred method for survey delivery (i.e., email address, fax number, or mailing address) for the respondents.

Product multiplicity complexity model fit. Convergent validity and reliability for product multiplicity complexity: The nine items for product multiplicity complexity and their coded names are listed in Table 5. AVE and Cronbach's α values (for reliability testing) for the final measurement model are displayed following each dimension's name. Model fit statistical values of goodness of fit (GFI, AGFI, RMR, CFI, and NFI) are shown in the table under model fit. All of the model fit values and the AVE values shown in the table signified acceptable convergent validity for each dimension of the construct. The CFA of the product multiplicity complexity from AMOS is shown in Figure 3.

Table 5: Model Fit for Product Multiplicity Complexity

Coded Name	**Item**	**Model Fit**
	Component (Final AVE=.80, α=.92)	
PMCC1	Our firm's products contain a large number of components?	GFI= 0.973 AGFI= 0.915 RMR= 0.011 CFI= 0.980 NFI= 0.979
PMCC2	Our firm's products contain a large number of component variants?	
PMCC3	Our firm's product part list is large?	
	Product (Final AVE=.74, α=.88)	
PMCP1	Our firm produces a large number of product variants?	GFI= 0.964 AGFI= 0.928 RMR= 0.022 CFI= 0.985 NFI= 0.983
PMCP2	Our firm produces a large number of products?	
PMCP3	Our firm produces many Skus?	
	Market (Final AVE=.70, α=.83)	
PMCM1	Our firm serves different markets for our products?	GFI= 0.970 AGFI= 0.930 RMR= 0.018 CFI= 0.992 NFI= 0.991
PMCM2	Our firm serves different geographic locations?	
PMCM3	Our firm serves different customer segments?	

Discriminant validity for product multiplicity complexity: Table 6 displays the results of the single-factor/two-factor (pairwise) X^2 tests for discriminant validity. The differences in chi- squared values for each pair of dimensions were all statistically significant at $p < 0.001$ ($df = 1$, critical value = 12.485), offering appropriate evidence of discriminant validity.

Product relatedness complexity model fit. Convergent validity and reliability for product relatedness complexity: The fifteen items for product relatedness complexity and their coded names are listed in Table 7. AVE and Cronbach‘s α values (for reliability testing) for the final measurement model are displayed following each dimension’s name. Model fit statistical values of goodness of fit (GFI, AGFI, RMR, CFI, and NFI) are shown in the table under model fit. All of the model fit values and the AVE values shown in the table signified acceptable convergent validity for each dimension of the construct. Three items were deleted: PRCC4, PRCSE3, and PRCSE5. After a re-evaluation of the definitions and a review of the literature, these items were found to be ambiguous and to not fit the scope of this study. Because they did not fit the scope of this study, and due to the higher values for model fit (GFI, AGFI, RMR, CFI, and NFI) when deleted, these three items were deleted. The CFA of the product relatedness complexity from AMOS is shown in Figure 4.

Table 7: Model Fit for Product Relatedness Complexity

Coded Name	Item	Model Fit
Similarity (Final AVE=.69 α=.87)		
PRCS1	Our products contain exchangeable parts?	GFI= 0.944 AGFI= 0.901 RMR= 0.031 CFI= 0.934 NFI= 0.928

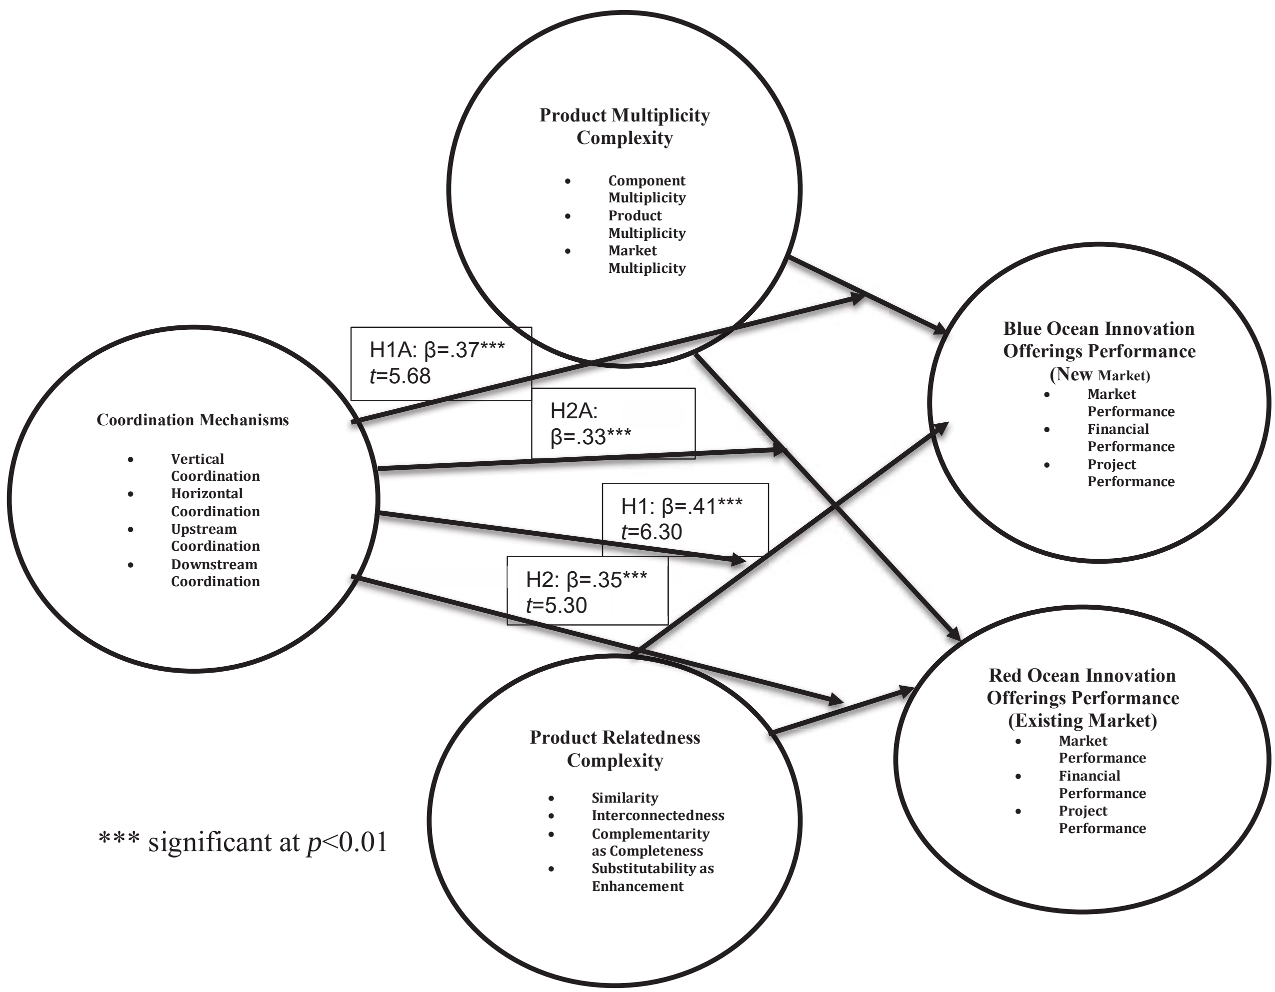
RESULTS

Figure 8 Model Results



The model indicated that under conditions where coordination mechanisms were used to manage product complexity, outcomes were higher than in firms where coordination mechanisms were not used. Use of these coordination mechanisms led to better innovation performance outcomes (Blue Ocean and Red Ocean) under the conditions of high product complexity (multiplicity and relatedness) in Hypotheses 1, 1A, 2, and 2A. To sum up this model, firms need to use coordination mechanisms to manage product complexity to create successful innovation outcomes that create overall success for the firms.

Table 15: Structural Model Results

Hypothesis	**Relationship**	**Beta (β)**	**Hypothesis Supported**	***t*-Statistic (t)**	R^2
Hypothesis 1	**CM *PRC Moderates BOOP**	**.41***	**Yes**	**6.30**	**.39**
Hypothesis 2	**CM *PRC Moderates ROOP**	**.35***	**Yes**	**5.30**	**.37**
Hypothesis 1A	**CM *PMC Moderates BOOP**	**.37***	**Yes**	**5.68**	**.39**
Hypothesis 2A	**CM *PMC Moderates ROOP**	**.33***	**Yes**	**4.84**	**.37**

DISCUSSION AND CONCLUSIONS

Hypothesis 1 and 1A Supported The hypotheses were tested and found to be statistically significant at a $p < 0.01$ level, with β =.41, $t = 6.30$, and $R^2 = .39$ for hypothesis 1 and β =.37, $t = 5.68$, and $R^2 = .39$ for hypothesis 1A indicating a good amount of variance explained by the model. This indicates that coordination mechanisms moderate the relationship between product complexity and supply chain performance measured by Blue Ocean innovation offerings performance. This means that the coordination mechanisms support and enhance the long-term objectives and goals of firms in high product complexity environments. In particular, if a firm is dealing with multiple products from relatedness complexity, it should use these coordination mechanisms to create products that provide better Blue Ocean performance. Because complexity is dynamic and changing, in complex environment more products will be created. These products will be in terms of new market products (Blue Ocean innovation) (Pellissier, 2012). Innovation is the lifeblood of a firm (Steencamp et al., 1999). Yet, half of the innovations fail to achieve successful revenue (Sivadas & Dwyer, 2000). Systems theory and social exchange theory have been used to explain the reason that coordination mechanisms lead to more successful innovative outcomes given high multiplicity complexity. Product complexity and innovation challenges can be handled by organizational system networks (Ackoff, 1978; Ash, 1992; Bánáthy, 1991, 1992, 1996, 1997; Checkland, 1981, 1997). Several strategies can link employees, customers, and suppliers to create a more effective innovation system network (Ashkenas et al., 2002). In other words, strategies can create better innovation outcomes. Better innovation outcomes are accomplished as specified through system networks. These system networks are the firm's resources of vertical/horizontal (employees), downstream (customers), and upstream (suppliers). These system networks provide the information and collaboration to manage innovation effectively to create successful innovative outcomes in new markets by creating new knowledge and improving the information flow within the firm.

Hypothesis 2 and 2A: Supported

The hypotheses were tested and found to be statistically significant at a $p < 0.01$ level, with $\beta = .35$, $t = 5.30$, and $R^2 = .37$ for hypothesis 2 and $\beta = .33$, $t = 4.84$, and $R^2 = .37$ for yypothesis 2A indicating a good amount of variance explained by the model. This indicates that coordination mechanisms moderate the relationship between product complexity and supply chain performance measured by Red Ocean innovation offerings performance. This means that the coordination mechanisms support and enhance the long-term objectives and goals of firms in high product complexity environments. In particular, if a firm is dealing with multiple products from relatedness complexity, it should use these coordination mechanisms to create products that provide better Red Ocean performance. When relatedness complexity is very dynamic, many components and products are being created at a very rapid pace. Firms that do not manage complexity properly lose profits (Hoole, 2006). Yet, when firms properly manage complexity, they are expected to produce successful returns (Meeker et al., 2009; Meyer & Mugge, 2001). According to contingency theory, strategies need to change in different external contexts for success (Miller, 1988). Therefore, different strategies must be applied in different contexts. In this research, product complexity strategies have been presented as coordination mechanisms, which will be more effective at managing product complexity than current methods are. These coordination mechanisms can decrease the strain from product complexity to create successful outcomes (Burns & Stalker, 1961; Miller, 1988; Mintzberg, 1979). Complexity increases the strain between employees, customers, and suppliers due to rapid changing (Jacobs, 2007). Several coordination mechanisms can link employees, customers, and suppliers to create more effective outcomes in complex environments (Ashkenas et al., 2002; Bozarth et al., 2009). Similarity, interconnectedness, and complementarity complexity create a dynamic environment that can cause strain between employees, customers and suppliers. Collaboration allows a firm to be more productive by making better choices regarding the components needed (Ashkenas et al., 2002; Kerr and Ulrich, 1995; Cross et al., 2000; Devanna and Tichy, 1990). Coordination mechanisms help align who, what, why, and where in the organization to provide success through knowledge and information (Ashkenas et al., 2002; Cross et al., 2000; Devanna and Tichy, 1990; Kerr & Ulrich, 1995). In the same manner, the coordination of employees, customers, and suppliers can help firms manage similarity complexity, interconnectedness complexity, and complementarity complexity.

DISCUSSION/ CONCLUSION

This research provided several advances to the area of product complexity in both the academic and managerial fields. First, this research provided evidence that market conditions lead to a need for more complex products. This product complex environment will continue to limit a firm's profits if it does manage effectively. Thus, this research showed ways to relieve the strain from product complexity by providing coordination mechanisms to deal effectively with product complexity to create better outcomes. This research also explored the drivers of complexity, thereby creating a clearer understanding of the origin of complexity.

Second, a major contribution of this research has been the development of a reliable instrument and clear definitions that supports future research in the area of product complexity. Product complexity was identified and clear definitions and examples were produced, as well as an instrument to measure product complexity. Twenty one variables for product complexity (9 for Product multiplicity complexity and 12 for product relatedness complexity) were developed to measure product complexity and the relationship to innovation and coordination mechanisms. This research provided future researchers a better understanding of complexity and thus provided a means by which to research complexity deeper in the future. This enables researchers to further explore product complexity, which has been receiving increasing attention, but is still in need of more empirical research.

Second, a theoretical knowledge integration framework is provided that identifies product complexity, coordination mechanism, and Blue and Red Ocean innovations (market performance of projects). The key to success is coordination mechanisms which can effectively create Blue and Red Ocean innovations in highly product complex environment. Much more has to be learned about the linkages to types of coordination mechanisms on type of product complexities. This research provides a framework that will be beneficial for future study of product complexity. The use of the proposed constructs allows researchers to formulate and test numerous hypotheses. Other constructs may be added or modified in the future to further examine other connections or more detailed hypotheses.

Forth, this research also provided a valuable benchmarking tools for product development executives to assess the extent of their coordination mechanism in product complex environments. This means that in highly complex environments, firms could employ the benchmark of vertical, horizontal, upstream, and downstream coordination researched in this research to alleviate the strain and potential performance losses, possibly saving firms millions of dollars. Because complexity is growing, it must be managed appropriately; thus, mechanisms must be put into place to alleviate the strain from complexity. This research provided this possible benchmark tool on how to achieve this and how to be successful in product innovation under complex environments. Without using these coordination mechanisms, firms will not be as effective in creating successful innovation performance.

Finally, this research was an empirical research of coordination mechanism effect on product complexity in multiple different industries. The data was received from 208 firms from managers and executives that specialize in product development. This research adopted a sound methodology, which resulted in more precise measurement of underlying constructs of product complexity and examined the mechanisms that affect Blue Ocean and Red Ocean outcomes including overall performance.

Abstract

Automated Guided Vehicle (AGV) is one of the advanced equipment designed to move materials in manufacturing facilities. AGVs are mainly classified based on their layouts. This paper studies AVGs system in Tandem Layout by using a quadratic mathematical model to determine the optimal station layout and AGV load capacity in each cell. The optimization model presented in this study contains a quadratic function of several variables that makes the problem NP-hard. Therefore, a Simulated Annealing (SA) algorithm is proposed to solve the model in a timely manner. The numerical example shows that the exact solving time, an alternative solver, increases exponentially by increasing problem's size while the proposed SA algorithm slightly changes and results in better solutions.

KEYWORDS: Material handling system, AGV, multiple-load, Simulated annealing

INTRODUCTION

An efficient transportation system not only improves performance and increase the flexibility of a system but eventually results in reducing final product or service cost, production time and pollution [1]–[3]. The transportation could perform outside of a manufacturing plant which is related to supply chain logistic [4]–[6] or could be part of material flow in a manufacturing system. An efficient material flow network design can reduce material flow costs by 20% [7].

One of the most advanced material handle system in the manufacturing environment is Automated Guided Vehicle. AGVs are driverless vehicle that transfer parts between stations. The application of the AGVs was first developed during the late 20th when it was used for repeating transportation tasks in areas, such as warehouses, production lines, container terminals and external (underground) transportation systems[8].

AGVs transfer materials by following a wire guide-path. Designing an efficient guide path can improve the navigation process and performance of the system. The AGV guide path configurations were discussed in literature, which are Conventional/Traditional, Tandem, Single loop, Bi-directional shortest path and Segmented flow[9]. This paper focuses on tandem configuration which is proposed by [10]. In this configuration, stations are divided into non-overlapping zones where one AGV serves the demands in a cell. Transfer between zones is possible by defining the transfer point. This configuration was studied in the several researches because of the following advantages [11]:

- Simple control strategy by applying one AGV in each zone
- Removing collisions and traffic problems
- Finding optimal facilities' locations in each work station
- Developing a group technology (GT) system
- Increasing flexibility due to changes in the number of work stations and changes in the production planning
- Simplifying production processes in each loop

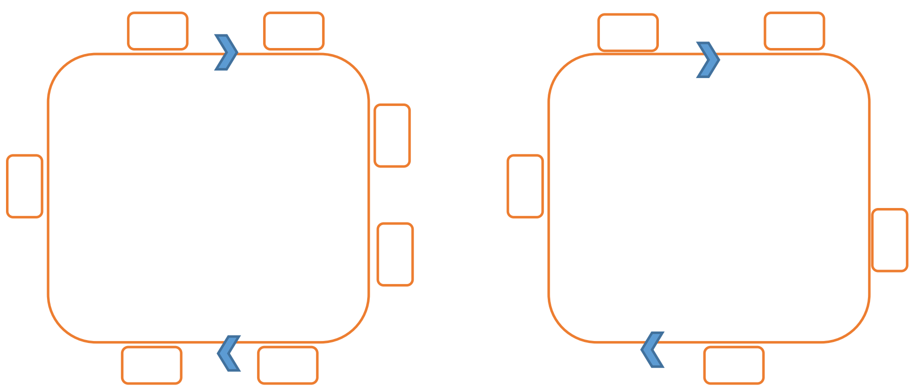

FIGURE 1: TANDEM CONFIGURATION AS PROPOSED BY [10].

There are many articles on dividing station into non-overlapping zones [9], [11]–[18]. These researches focus on balancing workload in different zones by minimizing the maximum work load or considering balancing strategy (see [11] for details). In addition, since the problem is binary quadratic assignment by nature, it is classified as NP-hard problem. Since, finding the optimal solution for large size problem is not possible using exact methods in timely manner[19], authors developed heuristic or metaheuristic algorithms to find optimal or near optimal answers in an efficient time.

After selecting AGV as the material handling system, AGV's capacity should be calculated [8]. In simulation studies conducted by [20] and [21], indicated that increasing load capacity will reduce the AGV fleet size and also will decrease the average throughput time. This paper significantly considers multiple load AGVs in modeling, this configuration was rarely considered in previous studies [8].

The first research that suggested a tandem AGV system with multi-load AGVs was [22]. They initially determined the subsets of workstations solving a travel salesman problem, then they applied a Markov chain model to calculate the AGV utilization in each partitioned subset, from which the final subsets of workstations were determined. Finally, they used simulation to validate their proposed methodology. In another study, [16], proposed a design methodology for multiple loads AGV in tandem layout. Their objective is to achieve the workload-balance between vehicles of different loops and the trade-off between the load-carrying capacity of a vehicle and its work capacity.

The present paper proposes a mathematical model to design a multiple-load AGV handling system in tandem configuration by considering balancing strategy. A metaheuristic algorithm is developed to solve the optimization model as the problem is NP-hard. Also a numerical example is provided to assess the efficiency of the algorithm and optimal results.

The rest of paper arranges as follow: in section 0 a detail problem statement will be presented. The parameters, variables and the mathematical model are included in this section. In section 0, a simulated annealing algorithm is developed to solve the proposed mathematical model. In section 0, set of illustrative examples are presented to solve the proposed model san Meta heuristic algorithm. Finally result analysis and validation concluded in this research.

MATHEMATICAL MODEL

Problem and notations

This paper presumes a system that AGVs are performing transportation task on bi-directional path in each cell, where at least two stations are in each cell. Each station is only allowed to assign to one cell, where one AGV serves as material handling facility. Empty transportations are not considered and the number of cells is the input variable.

The goal is to classify stations into non-overlapping loops in order to minimize both inter and intra loops transportation by considering multiple load AGV. A balancing strategy is used in this paper which was first proposed by [11]. The following notation represents indexes and variables that are utilized in the mathematical formulation.

- i(k): define i(k)th station;
- j(l): define j(l)th cell;
- p: define AGV capacity;

Please note that f_{ik} is number of transported loads between two stations.

The decision variables in the optimization problem are binary as follow:

x_{ij}: Equal to 1 if station i assigns to cell j else equal to zero.

y_{jp}: Equal to 1 if AGV with P capacity assigns to cell j else equal to zero.

The control parameters listed below are used to establish values, lower and upper bounds for constraints in the formulation:

w_p: Performance coefficient of AGV with P capacity;

f_{ik}: Flow between station k to i;

f_i: Flow from different station to station i ($\sum_k f_{ik}$);

T: The time that AGV is available;-

t_i: Mean loading, unloading and process time on part in ith station;

t_j': Bottleneck time in jth station;

N: Total number of predefined loop;

$\acute{\eta}, \eta$: Upper and lower bound of flow coefficient;

λ_p: Penalty of selecting AGV with P capacity;

n: Number of stations;

Proposed model

Based on the above notations and assumptions Model I can be formulated as follow:

Model I

(1) $$\text{Min } Z = \underbrace{\sum_{j=1}^{N}\sum_{l=1}^{N}\left(\frac{\sum_{i=1}^{n}\sum_{k=1}^{n} f_{ik}x_{ij}x_{kl}}{\sum_{p=1}^{m} y_{jp}w_p}\right)}_{i\neq k, j=l} + \underbrace{\sum_{i=1}^{n}\sum_{j=1}^{N}\sum_{k=1}^{n}\sum_{l=1}^{N} f_{ik}x_{ij}x_{kl}}_{i\neq k, j\neq l} + \sum_{j=1}^{N}\sum_{p=1}^{m} y_{jp}w_p\lambda_p$$

Subject to:

(2) $$\sum_{j=1}^{N} x_{ij} = 1 \quad i = 1,2,3 \dots, n$$

(3) $$\sum_{p=1}^{m} y_{jp} = 1 \qquad j = 1,2,3 \dots, N$$

(4) $$\sum_{i=1}^{n} x_{ij} \geq 2 \qquad j = 1,2,3 \dots, N$$

(5) $$\eta\left(\frac{\underbrace{\sum_{i=1}^{n}\sum_{j=1}^{N}\sum_{k=1}^{n}\sum_{l=1}^{N} f_{ik}x_{ij}x_{kl}}_{i\neq k}\times\sum_{p=1}^{m} y_{jp}w_p}{\sum_{j=1}^{N}\sum_{p=1}^{m} y_{jp}w_p}\right) \leq \underbrace{\sum_{i=1}^{n}\sum_{k=1}^{n} f_{ik}x_{ij}x_{kj}}_{i\neq k} \qquad \varphi=1,2,3 \dots, N$$

(6) $$\acute{\eta}\left(\frac{\underbrace{\sum_{i=1}^{n}\sum_{j=1}^{N}\sum_{k=1}^{n}\sum_{l=1}^{N} f_{ik}x_{ij}x_{kl}}_{i\neq k}\times\sum_{p=1}^{m} y_{jp}w_p}{\sum_{j=1}^{N}\sum_{p=1}^{m} y_{jp}w_p}\right) \geq \underbrace{\sum_{i=1}^{n}\sum_{k=1}^{n} f_{ik}x_{ij}x_{kj}}_{i\neq k} \qquad \varphi=1,2,3 \dots, N$$

(7) $$t_j' = \max_i\{f_i t_i x_{ij}\} \qquad \varphi=1,2,3..,N$$

(8) $\sum_{i=1}^{n} x_{ij} \leq \frac{T\sum_{p=1}^{m} y_{jp} w_p}{t_j}$ φ=1,2,3,..,N

(9) $x_{ij} \in \{0,1\}$ $\forall$ i, j

(10) $y_{jp} \in \{0,1\}$ $\forall$ i, j

(11) $\boldsymbol{\eta} = \frac{1}{N} - \Delta$ $\boldsymbol{\acute{\eta}} = \frac{1}{N} + \Delta$

(12) Where , $0 \leq \Delta \leq \frac{1}{N}$

Equation (1) is the objective function that minimizes internal transportation (by considering load capacity), inter loop transportations and the penalty cost which is proportional to AGV capacity. Constraints (2) and (3) ensure that each station is assigned to one loop and in each loop there is only one AGV. Constraint (4) ensures that at least 2 stations are in each loop. Constraints (5) and (6) balance the work load based on the work capacity by defining η and ή. Equation (7) finds the bottleneck station in each loop. Constraint (8) assesses the feasibility of serving stations in loops by considering AGV capacity and bottleneck station, and constraints (9) and (10) enforce the binary constraint on decision variables. Equations (11) and (12) show that works are distributed based on the number of loops. Δ is defined to avoid impossibility of assigning exact number of work load to each loop (see [11] and [18] details).

Model I is a nonlinear binary mathematical programming model for multiple-load AGV system in Tandem configuration. In next the subsection, the objective function is modified to have more efficient solving procedure.

Modifying objective function

The first step is to simplify the mathematical model by linearizing the decision variables;

(1) $z_{ijkl} = x_{ij} \times x_{kl}$

The modification is done by adding decision variable z_{ijkl} to model and its necessary constraints.

Model II

(2) $$\mathrm{Min}\ Z = \underbrace{\sum_{j=1}^{N} \sum_{l=1}^{N} \left(\frac{\sum_{i=1}^{n} \sum_{k=1}^{n} f_{ik} z_{ijkl}}{\sum_{p=1}^{m} y_{jp} w_p} \right)}_{i \neq k, j=l} + \underbrace{\sum_{i=1}^{n} \sum_{j=1}^{N} \sum_{k=1}^{n} \sum_{l=1}^{N} f_{ik} z_{ijkl}}_{i \neq k, j \neq l} + \sum_{j=1}^{N} \sum_{p=1}^{m} y_{jp} w_p \lambda_p$$

(2) $\sum_{j=1}^{N} x_{ij} = 1$ $i = 1,2,3 \ldots, n$

(3) $\sum_{p=1}^{m} y_{jp} = 1$ $j = 1,2,3 \ldots, N$

(4) $\sum_{i=1}^{n} x_{ij} \geq 2 \quad j = 1,2,3 \dots, N$

(3) $\eta\left(\frac{\underbrace{\sum_{i=1}^{n}\sum_{j=1}^{N}\sum_{k=1}^{n}\sum_{l=1}^{N} f_{ik} z_{ijkl}}_{i\neq k} \times \sum_{p=1}^{m} y_{jp} w_p}{\sum_{j=1}^{N}\sum_{p=1}^{m} y_{jp} w_p}\right) \leq \underbrace{\sum_{i=1}^{n}\sum_{k=1}^{n} f_{ik} z_{ijkj}}_{i\neq k} \quad j=1,2,3 \dots, N$

(4) $\acute{\eta}\left(\frac{\underbrace{\sum_{i=1}^{n}\sum_{j=1}^{N}\sum_{k=1}^{n}\sum_{l=1}^{N} f_{ik} z_{ijkl}}_{i\neq k} \times \sum_{p=1}^{m} y_{jp} w_p}{\sum_{j=1}^{N}\sum_{p=1}^{m} y_{jp} w_p}\right) \geq \underbrace{\sum_{i=1}^{n}\sum_{k=1}^{n} f_{ik} z_{ijkj}}_{i\neq k} \quad j=1,2,3 \dots, N$

(7) $\acute{t}_j = \max_i \{f_i t_i x_{ij}\} \quad j=1,2,3..,N$

(8) $\sum_{i=1}^{n} x_{ij} \leq \frac{T\sum_{p=1}^{m} y_{jp} w_p}{\acute{t}_j} \quad j=1,2,3,..,N$

(5) $x_{ij} + x_{kl} - 2z_{ijkl} \geq 0 \quad \forall\, i, j, k, l$

(6) $\sum_{i=1}^{n}\sum_{j=1}^{N}\sum_{k=1}^{n}\sum_{l=1}^{N} z_{ijkl} = \frac{n(n-1)}{2} \quad k > i$

(9) $x_{ij} \epsilon \{0,1\} \quad \forall\, i, j$

(10) $y_{jp} \epsilon \{0,1\} \quad \forall\, i, j$

(7) $z_{ijkl} \epsilon \{0,1\} \quad \forall\, i, j, k, l$

As it is mentioned, according to [23] constraints (5) and (6) are necessary for linearization.

The Lagrangian relaxation approach proposed by [24] is applied to relax some constraints, in this approach constraints which are hard to become feasible are rewritten. Consider Y as an objective function and $g_i(x)$ as constraints:

$\text{Min } Y = f(x)$

(8) S.t:

$g_i(x) \leq b_i, \forall i$

To remove inequality constraints and rewrite them in objective function the following change is made:

(9) $\min y = \{f(x) + rk(x)\}$

In above mentioned equation *r* is penalty coefficient and *k(x)* is penalty function;

(10) $k(x) = \sum_{i=1}^{m} \max\{(g_i(x) - b_i), 0\}^2$

Now problem (8), (9) are equivalent. The same modification will be made for constraints (4) and (8). Therefore the final objective function is formulated as Model III.

Model III

$$\begin{aligned}
\operatorname{Min} Z = &\underbrace{\sum_{j=1}^{N}\sum_{l=1}^{N}\left(\frac{\sum_{i=1}^{n}\sum_{k=1}^{n} f_{ik} z_{ijkl}}{\sum_{p=1}^{m} y_{jp} w_p}\right)}_{i\neq k,\, j=l} + \underbrace{\sum_{i=1}^{n}\sum_{j=1}^{N}\sum_{k=1}^{n}\sum_{l=1}^{N} f_{ik} z_{ijkl}}_{i\neq k,\, j\neq l} + \sum_{j=1}^{N}\sum_{p=1}^{m} y_{jp} w_p \lambda_p \\
&+ r\sum_{j=1}^{N}\left(\operatorname{Max}\left[\left\{\eta\left(\frac{\underbrace{\sum_{i=1}^{n}\sum_{j=1}^{N}\sum_{k=1}^{n}\sum_{l=1}^{N} f_{ik} z_{ijkl}}_{i\neq k} \times \sum_{p=1}^{m} y_{jp} w_p}{\sum_{j=1}^{N}\sum_{p=1}^{m} y_{jp} w_p}\right)\right.\right.\right. \\
&\left.\left. - \underbrace{\sum_{i=1}^{n}\sum_{k=1}^{n} f_{ik} z_{ijkj}}_{i\neq k}\right\}, 0\right]^2 \\
&+ \operatorname{Max}\left[\left\{\underbrace{\sum_{i=1}^{n}\sum_{k=1}^{n} f_{ik} z_{ijkj}}_{i\neq k} - \eta\left(\frac{\underbrace{\sum_{i=1}^{n}\sum_{j=1}^{N}\sum_{k=1}^{n}\sum_{l=1}^{N} f_{ik} z_{ijkl}}_{i\neq k} \times \sum_{p=1}^{m} y_{jp} w_p}{\sum_{j=1}^{N}\sum_{p=1}^{m} y_{jp} w_p}\right)\right\}, 0\right]^2 \\
&\left. + \max\left[\left\{\sum_{i=1}^{n} x_{ij} \frac{T\sum_{p=1}^{m} y_{jp} w_p}{\acute{t}_j}\right\}, 0\right]^2\right)
\end{aligned}$$

Note that constraints (2), (3), (4), (7), (9), (5), (6) and (7) remain unchanged.

SIMULATED ANNEALING ALGORITHM

As can be seen from model formulation the proposed optimization model is a quadratic problem which is classified as NP-hard problem, thus simulated algorithm could be efficient to solve this problem in a timely manner. Simulated Annealing (SA) algorithm proposed by [25] is a metaheuristic algorithm to approximate global solutions. Algorithm 1 clarifies the algorithm steps clearly:

Algorithm 1:

Input: Cooling schedule.

s = s_0; /∗ Generation of the initial solution ∗/

T = β* f(s_0); /∗ Starting temperature ∗/

Repeat

Repeat /∗ At a fixed temperature ∗/

Generate a random neighbor s′ ;

ΔE = f (s′) − f (s) ;

If ΔE ⩽ 0 **Then** s = s′ /∗ Accept the neighbor solution ∗/

Else Accept s′ with a probability $e^{-\Delta E/T}$;

Until Equilibrium condition

/∗ e.g. a given number of iterations executed at each temperature T∗/

T = α*T; /∗ Temperature update ∗/

Until Stopping criteria satisfied /∗ e.g. T < T_{min}∗/

Output: Best solution found.

This is a probabilistic algorithm that avoids trapping in local optimum by accepting worse solutions. In this paper, by progressing in solution procedure, the rejection gets harder and the proposed SA reaches to one of the local optimum solutions.

The proposed algorithm starts with initial temperature T_0 which is calculated by the multiplying the initial solution (s_0) objective function to equalization coefficient (β). In the next step, the algorithm generate a random feasible solution, this process is explained in section generating neighborhood, if the generated solution answer gets better than the previous one, the answer will be accepted. Otherwise, the proposed algorithm generates a random probability λ and checks the following equation$\lambda \geq e^{-\frac{\Delta E}{T}}$, if the inequality satisfies then the worse answer is accepted otherwise it will be rejected. This algorithm iterates until termination criteria meets, which can be final temperature or optimal solution. The necessary parameters of the algorithms are tuned using [11] which are as follows:

TABLE I. SA's algorithm parameters

α	β	iteration
0.98	0.5	20

Initial solution

The solution structure is defined based on problem, which is a three rows matrix; the first row introduces the name of the station, the second row presents the loop name, where the above station is assigned, and the last row presents the type of AGV in that loop. TABLE II. depicts solution structure in which stations 1, 4 and 5 are in loop 1 that means they are served by single load AGV and the rest of stations are in loop 2 and served by three load AGV.

TABLE II. Solution structure

Station	1	2	3	4	5	6
Loop	1	2	2	1	1	2
AGV capacity	1	3	3	1	1	3

Generating neighborhood

The proposed algorithm first select a station and randomly assigns the station to a new loop, then revises the third row and select the best type AGV assignment. As an example in Figure II, stations 1, 4 and 5 are in loop 1 where an AGV with 1 load capacity is working, and station 2,3 and 6 are in loop 2 where a two load AGV doing transportation job. At first step station 4 will move to loop 2. The next happen in Figure III, where loop one AGV capacity will be the same but the second loop AGV capacity increase to three.

Station	1	2	3	4	5	6
Loop	1	2	2	1	1	2
AGV capacity	1	2	2	1	1	2

Station	1	2	3	4	5	6
Loop	1	2	2	2	1	2
AGV capacity	1	2	2	2	1	2

FIGURE II. First step of generating neighborhood

Station	1	2	3	4	5	6
Loop	1	2	2	2	1	2
AGV capacity	1	2	2	2	1	2

Station	1	2	3	4	5	6
Loop	1	2	2	2	1	2
AGV capacity	1	3	3	3	1	3

FIGURE III. Second step of generating neighborhood

Termination criteria

The proposed SA algorithm stops searching for solution when one of the termination criteria is satisfied;

1. Objective worsening (reaching optimal solution)
2. Iteration limit (final temperature)

In next section, we use some illustrative examples to check and validate the proposed simulated annealing algorithm.

NUMERICAL EXAMPLE

To validate the performance of the presented mathematical model and SA algorithm five numerical examples with different dimensions are tested (See TABLE III. For details). These examples are used in [11] as well.

TABLE III. Numerical examples parameters

instances	Parameters					
	n	N	η	η´	t	T
P1	6	2	0.25	0.75	{1,1,1,1,1,1}	2000
P2	7	2	0.2	0.8	{2,1,5,1,3,1,1}	1000
P3	8	2	0.25	0.75	{2,1,5,1,3,1,1,3}	4000
P4	9	2	0.2	0.8	{2,1,5,1,3,1,1,3,4}	4000
P5	10	2	0.15	0.85	1 ∀ i	5000
P6	12	3	0.09	0.57	1 ∀ i	5000

To conduct result analysis, three parameters should be defined which are w_p, r and λ. w_p is the performance coefficient of AGV with type P. This coefficient does not have a linear relationship with AGV's capacity so variation in loading and unloading policy can make difference. To determine this coefficient a uniform distribution is used for determining AGV capacity. The performance coefficient is 1 for AGV with one load capacity, AGV with 2 load capacity can have value in between [1.5, 2] and value for AGV with 3 load capacity could be a random number between [2.3, 3] [16]. After calculation, these values for AGV with 2 and 3 load capacity are 1.8 and 2.65 respectively. Parameter λ which is a penalty associated to increasing AGV capacity, and *r* which is Lagrangian relaxation are considered as 1.

According to above information and TABLE III. , the result analysis is as follows:

TABLE IV. Results of p1-p5 by λ=1

	GAMS	Time	Best SA	Max deviation	Mean Time	Enumeration
P1	901.82	3	901.82	0	24.1	901.82
P2	126.8	5	126.8	0	16.4	126.8
P3	181.77	25	178.39	0	19.7	178.39
P4	2337.65	50	2254.6	0	29	2254.6
P5	2948.77	67	2769.7	118.5	26	2769.7
P6	*	*	4725.9	38	29	4709.7

- STOP AFTER 2400 SECONDS

Enumeration presents the optimal solution of the problems. As TABLE IV. represents, by increasing the problem size, the complexity of the problem will increase and it may cause in trapping to local optimum. The GAMS solver trapped in local optimum after solving the first 2 problems. It was not able to solve P6 after limited time and stopped. While the proposed SA algorithm in the present paper solved first 4 problems in short time and reached to the global optimum. It also successfully solved *p5* in 26 seconds and found a local optimum for example *P6*. Even though increasing the size of problem increased the complexity, but the proposed algorithm could successfully solve the problems more effectively limited time.

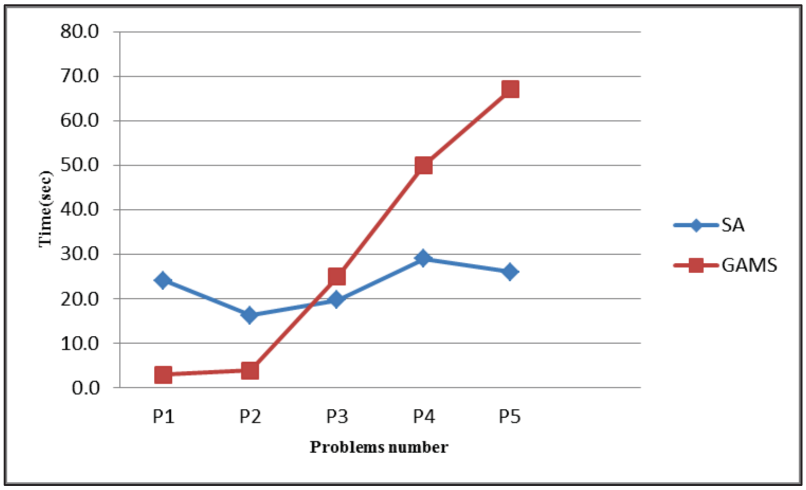

FIGURE IV. Analyze p1-p5 solving time

Figure IV indicates that increasing the size of problem will increase the complexity and GAMS solving time growing exponentially but the proposed SA algorithm solving time shows slight fluctuation. Figure V also compares the set of best results for both solving algorithms. As it is shown, in problem P4 and P5 the SA algorithm found a better solution comparing to GAMS.

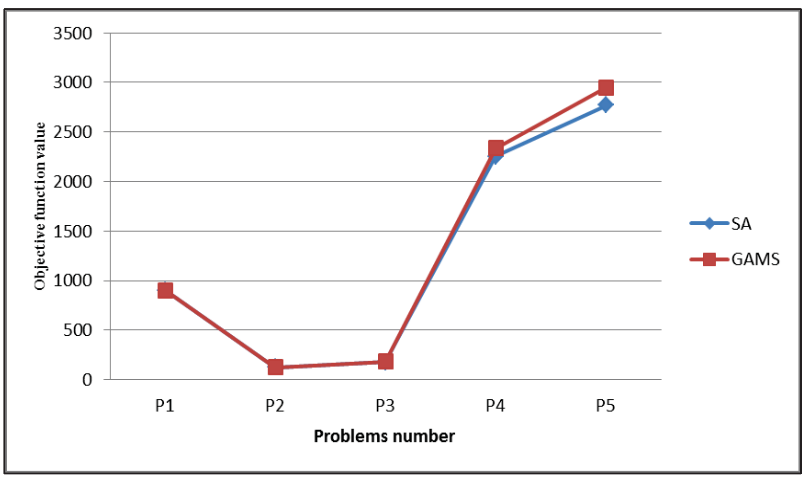

FIGURE V. Analyze p1-p5 solving time

CONCLUSION

This paper mainly focuses on modeling multiple load AGVs and conducts a review on the related literature which indicated that few number of researches have been done on this topic. Researches mentioned that multiple load AGVs cause decrease in average throughput time and fleet size, so this paper proposed a non-linear integer mathematical programming model for multiple-load AGV in tandem configuration. A simulated annealing algorithm was proposed to solve the problem in efficient time. Result analysis section reveals that increasing the problems dimension significantly increases the GAMS solving time, however the proposed SA algorithm solves the problem in short time and generates better solutions. In future research a new approach for modeling multiple loads AGV can be considered which minimizes the travel time and loading waiting time.

ABSTRACT

The overall process of Risk Management (RM) is to identify, analyze and monitor risks as well as to design and implement risk treatments. For this paper, we focus on and review the characteristics of a set of specialized computer-based systems, Decision-Making Support Systems (DMSS), which is a valuable tool for supporting RM processes within the context of Project Management. We report six illustrative application examples of DMSS in the Project Risk Management (PRM) domain and develop two extended and adapted DMSS models for PRM factors and phases. Along the process, a theoretical mapping framework between the generic decision-making processes and PRM processes is identified and depicted. We have also developed an integrated application framework for applying relevant DMSS tools and capabilities to the specific PRM sub-processes. Our aim is to provide a well-structured introduction to DMSS tools to efficiently and effectively facilitate PRM. We also aim to apply a linkage, creating awareness for project and risk managers of the usefulness and value of a variety of DMSS tools.

INTRODUCTION

The world has seen an increase of large complex projects that involve vast amounts of time, money and resources. The fast development of technology and global competition are among the significant reasons that project management (PM) is getting more attention (Schwalbe, 2016). The success parameters for any project named the triple constraints are on-time completion, completion within a specified budget and completion with satisfying performance. The main barriers for achievement are the changes in the project environment and when the problem multiplies with the size of the project because uncertainties in project outcomes increase (Dey, 2001; 2010).

To better understand, identify, and analyze such uncertainties and more effectively mitigate their potential negative consequences, the field of Risk Management (RM) has emerged in the last 40 years. RM refers to anticipating the occurrence of potential negative events, estimating effects and elaborating and implementing suitable actions against them. RM methods are used in several relevant fields such as project management (Raz and Michael, 2001), financial investments (Aebi et al., 2012), hazards management (Liu et al., 2016) and business continuity management (Torabi et al., 2014) among others.

In this paper, we focus on the field of Project Risk Management (PRM) within the context of RM and investigate how an integrated decision-making support approach could facilitate more efficient and effective PRM. Specifically, we introduce and review the characteristics of a set of specialized computer-based systems named Decision-Making Support Systems (DMSS) as valuable tools for supporting PRM. We aim to provide a concise but well-structured overview of DMSS tools and the PRM process, and its application linkage for creating awareness in project managers and risk managers alike of the usefulness and value of DMSS tools.

A REVIEW OF PRM PROCESS

PRM is the overall process to identify, analyze and monitor risks as well as to design and implement risk response strategies, including analyzing and monitoring risks throughout the life cycle of a project (NIST, 2002; Schwalbe, 2016). PRM is a field of study and practice established and matured in the last 40 years with the overall aim to conceptualize, assess and manage risks. The concept of risk has been defined in several qualitative and quantitative forms, but all of them share the notion of an undesirable uncertainty event which would cause damage on humans and/or assets valued by humans (Aven, 2016).

According to Raz and Michael (2001), RM is an essential process that accompanies the entire project life cycle throughout the planning, execution, control and completion phases. In particular, it was found that banks with adequate governance structures on RM had a better performance than those with weak governance structures (Idem, 2001). Highlighted, are the usefulness of the RM process for addressing natural hazards such as earthquakes, hurricanes, volcanic eruption, river flood, and landslide among others (Liu et al., 2016). According to our research, there are classifications of hazard interactions for complementing the current Multi-Hazard Risk Assessment method (Marzocchi et al., 2009). There is support for the implicit and required utilization of RM techniques as well as of the Business Impact Analysis (BIA) one, as part of the Business Continuity Management (BCM) process with the aim to increase the business organizational resilience after disruptions caused by the realization of risks (Torabi et al., 2014). Torabi et al. (2014) elaborated a comprehensive BIA framework supported with multi-attribute decision making (MADM) methods based on the notion of the concept risk appetite defined as “the amount of risk that an organization is willing to pursue or retain” (Idem, 2014; p. 314).

A RM process usually covers three sub-processes: Risk Assessment, Risk Mitigation, and Risk Evaluation (NIST, 2002). An updated concept of RM in the context of information technology standards (NIST, 2012) covers the following phases: Risk Framing, Risk Assessment, Risk Responses, and Risk Monitoring. Both traditional and updated concepts can be mapped as follows: the traditional Risk Assessment sub-process includes updated Risk Framing and Assessment sub-processes; the traditional Risk Mitigation sub-process corresponding to updated Risk Responses and the traditional Risk Evaluation sub-processes corresponding to Risk Monitoring.

The purpose of the Risk Framing sub-process is to establish the high-level organizational context for implementing the right level, no under or over one, of a RM process (NIST, 2012). A RM strategy is delineated, and decisional boundaries are established. A high-level analysis of the organizational context including priorities, assumptions, trade-offs, as well as selection of risk approaches, models and methods are established. In particular, a Risk Model is a core operational concept because it defines the specific elements to be included in the analysis of risks and their interrelationships. In NIST (2002; 2012) the expected elements are: threats; sources of threats; threats scenarios; threats shifting; assets vulnerabilities; severities of vulnerabilities; likelihood of threat exploitation on vulnerabilities; harm impact on assets; likelihood of occurrence of harm impact; final organizational risk as the product of the harm impact and its likelihood of occurrence and risk uncertainty level. This first sub-process is critical to establish a formal RM process in the organization and is executed as a preparation sub-process for the next one of Risk Assessment.

The purpose of the Risk Assessment sub-process (NIST, 2002; 2012) is to determine the specific organizational risks through the detailed analysis of threats, vulnerabilities, impacts, likelihoods and uncertainties (i.e., by using the agreed Risk Model). Qualitative, quantitative or hybrid models are used for specific and agreed RM approaches along with method and type analysis. This sub-process can be considered the core essential sub-process because a wrong analysis of organizational risks will lead to failed actions and countermeasures for risk treatments with potentially severe economic and organizational impacts. In some cases, the harm can also have an impact on human beings; thus, this sub-process becomes essentially critical.

The next sub-process is Risk Mitigation/Risk Responses (NIST, 2002; 2012). Its purpose can be stated as "*prioritizing, evaluating, and implementing the appropriate risk-reducing controls recommended from the risk assessment process*" (NIST, 2002; p. 27) for each organizational risk must be developed, evaluated and implemented for the selected alternative courses of action for coping with the risk with the organizational risk strategy (NIST, 2012). This third sub-process is also very important because it is usually economically impractical or impossible to eliminate organizational risks; thus, adequate and economically viable countermeasures must be proposed and implemented. (NIST, 2002; 2012). The risk mitigations countermeasures can be one of the following ones according to NIST (2002): 1) risk acceptance; 2) risk avoidance; 3) risk limitation; 4) risk planning; 5) risk acknowledgement and research treatment and 6) risk transference. Naturally, every organization must be treated with different risk mitigation actions based on economic and impact analysis.

The final sub-process is Risk Evaluation/Risk Monitoring (NIST, 2002; 2012). The purpose of this sub-process is to conduct ongoing evaluation and monitoring of the implemented risk mitigation countermeasures, as well as to watch over organizational and external changes that may reduce the effectiveness of the current mitigation actions. In this sub-process, the compliance or adherence analysis to best RM practices and external regulations is conducted.

Table 1: PRM Process and Sub-Processes Profile

SUB-PROCESS	INPUTS	TASKS	OUTPUTS
Risk Assessment / Risk Framing	• Risk Context (assumptions, constraints, priorities and tradeoffs, tolerance and uncertainty levels)	• Identify the purpose of the assessment • Identify the scope of the assessment • Identify the assumptions and constraints associated with the assessment • Identify the sources of information to be used as inputs to the assessment • Identify the risk model and analytic approaches to be employed during the assessment	• Risk management strategy • Risk assessment methodology (risk steps, risk model, assessment approach, and analysis approach).
Risk Assessment / Risk Assessment	• Inventory of assets • History of attacks • Data from intelligence on attacks • Reports from prior Risk Assessments • Current Controls • Security Requirements • Threats-Sources Profiles • Criticality of assets	• Identify threat sources that are relevant to organizations • Identify threat events that could be produced by those sources • Identify vulnerabilities within organizations that could be exploited by threat sources • Determine the likelihood of identified threat sources • Determine the adverse impacts to organizational operations and assets • Determine information security risks including any uncertainties associated with the risk determinations	• System boundaries • List of Threats-Sources • List of Potential Vulnerabilities • Current and Potential Controls • Likelihood Rating • Impact Rating • Risks and Risks Levels • Recommended Controls
Risk Mitigation / Risk Responses	• Risk Assessment Report	• Prioritize actions • Evaluate recommended control actions • Conduct Cost-Benefit analysis • Select control • Assign responsibility • Develop a safeguard implementation plan • Implement selected controls	• Actions ranking from High to Low • List of possible Controls • Cost-Benefit Analysis • Selected Controls • List of Responsible Persons • Safeguard Implementation Plan • Residual Risks
Risk Evaluation / Risk Monitoring	• Risk Assessment Report • Risk Mitigation / Responses Report • Risk Management Regulations • Best Practices on Risk Management Reports	• Determine the ongoing effectiveness of risk responses • Identify risk-impacting changes to organizational assets and the environments • Conduct audit evaluations • Trace Risk Management best practices and new regulations	• Risk Evaluation / Monitoring Report

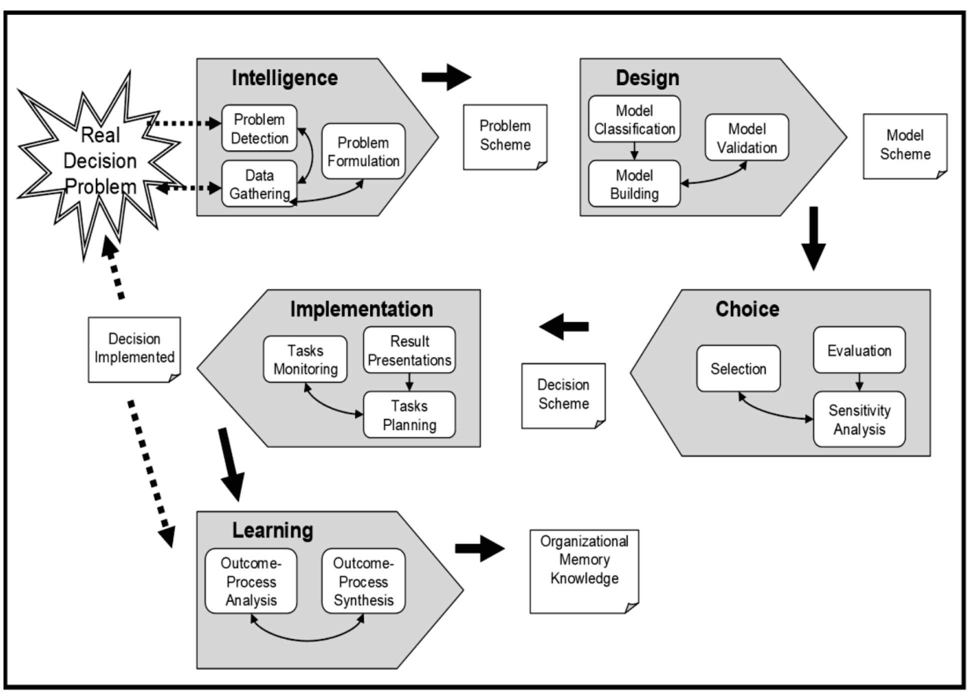
Table 1: PRM Process and Sub-Processes Profile, summarizes the essential characteristics of the RM sub-processes as reported in the consulted sources (NIST, 2002; 2012).

A REVIEW OF DECISION-MAKING PROCESS AND DECISION-MAKING SUPPORT SYSTEMS (DMSS) IN THE PROJECT MANAGEMENT DOMAIN

Decision-Making Support Systems (DMSS) are computer-based systems designed to support some or all phases of a decision-making process (Forgionne et al., 2000). A high-level generic decision-making process (Forgionne et al., 2000; Mora et al., 2014) can be defined as a managerial process of five phases: *intelligence, design, choice, implementation* and *learning*.

In the *intelligence* phase, the decision maker gains a fundamental understanding and acquisition of the general information needed to address the organization's problems or opportunities. In the *design* phase, the decision maker develops a specific and precise model that can be used to systematically examine the discovered problem or opportunity. Using the explicit model to logically evaluate the specified alternatives and to generate recommended actions constitute the ensuing *choice* phase. During the subsequent *implementation* phase, the decision maker ponders the analyses and recommendations, weighs the consequences, gains sufficient confidence in the decision, and implements a final decision. In the final *learning* phase, the decision maker or decision team reviews the process and outcomes with learning purposes (e.g., for reinforcing good practices and discouraging bad ones). Figure 1: A high-level generic decision-making process, illustrates this high-level generic decision-making process with their phases, inputs, and outputs (Mora et al., 2014).

Figure 1: A High-Level Generic Decision-Making Process



DMSS tools have evolved during these last 45 years (Shim et al., 2002). We report the existence of classic and modern DMSS (Forgionne et al., 2005). Classic DMSS are Decision Support Systems (DSS), Executive Information Systems (EIS), and Expert Systems/Knowledge-based Systems (ES/KBS). Modern DMSS are Data Warehouse-based Business Intelligence tools (DW/BI) and Data Mining-based and Business Analytics DMSS (DM/BA), and intelligent DMSS (i-DMSS).

Decision Support Systems (DSS)
According to Sprague (1980) "*… a DSS is an interactive computer-based system which help decision makers utilizing data and quantitative models to solve semi-structured problems*". A DSS offers the following capabilities: what-if scenario analysis, goal-seeking analysis, and sensitivity variables analysis. A DSS is usually used by staff personnel in the organizations, top managers and executive decisions makers. A survey of DSS applications pointed out that the main areas of use are production/operation, marketing, finance and strategic management (Eom & Kim, 2006). An interesting fact is that the underlying model which was quantitative in nature, either deterministic or stochastic have shifted to a hybrid nature (i.e., quantitative and qualitative). Qualitative models are now based on artificial intelligence techniques. Literature reports successful cases of the use of DSS (Sprague & Carlson, 1982; Eom & Kim, 2006).

Executive Information Systems (EIS)
An Executive Information Systems (EIS) according to Rockart and Tracy (1982) *"… is a computer-based system which let to access a common core of data covering key internal and external business variables by time and by business unit*". They discovered in the early '80s that some top executives (i.e., CEO's, CFO's, etc.) were using special information systems, which allowed them to monitor and track key performance indicators of the company.

Afterward, they coined the term EIS. The capabilities typical of EIS are access to summarized information as internal and external key performance indicators usually presented as graph and text-tables displays; analysis through drill-down, roll-up, slice and dice and pivoting operations, and networking communications to bulletin boards. The literature also reports successful cases of EIS usage (Watson et al., 1991; Elam & Leidner, 1995; Rainer & Watson, 1995).

Expert Systems/Knowledge-based Systems (ES/KBS)
According to several researchers in the field, ES/KBS is a computer-based system that exhibits, in a specific domain, a high degree of expertise in problem-solving that is comparable to that of a human expert (Feigenbaum et al., 1988; Liebowitz, 1990). An ES/KBS contains three main components: a knowledge base specialized in a specific domain, an inference algorithm, and a user interface. Two types of problems are usually addressed: classification (e.g., diagnosing, repairing, prediction, interpretation, monitoring and control) or construction (e.g., scheduling, configuration, planning or designing). An ES/KBS offers the following capabilities: intelligent advice, qualitative reasoning, problem-solving assistance, and explanation of advice. Successful cases of ES/KBS are reported from several sources (Feingenbaum et al., 1988; Eom, 1993). The difference between an ES and a KBS is that the former contains the knowledge of a recognized expert in the field and the second contains only knowledge valuable for the organization.

Data Warehouse-based and Business Intelligence Tools (DW/BI)
A data warehouse is a specialized organizational macro database composed usually by a large number of dimensions and usually containing a vast quantity of records (Wixom and Watson,

2001). It is defined as "*subject-oriented, integrated, time-invariant, non-updatable collection of data used to support management decision-making processes and business intelligence*" (March & Hevner, 2007; p. 1031). A data warehouse is the organizational repository of relevant data sets which can be exploited through computer-based systems named Business Intelligence (BI) tools. BI tools aim to support BI activities in an organization refers to the environment and organization relevant data. These tools scan the data for interpretation applying organizational knowledge and producing intelligence (interpreted information useful for a specific organizational context) (March & Hevner, 2007). BI tools emerged as the evolution of EIS (Adam & Pomerol, 2002) by the progress of information technologies to reach all organizational levels in addition to the top management level addressed for EIS; thus, provide the same capabilities. However, they are released to end-users through the concept of dashboards. Dashboards are systems that present a control display of the main indicators of interest for a decision-maker, and the name comes as an analogy of the car dashboards for drivers.

Similar to classic DMSS, DW/BI tools have provided several benefits to users such as: a better understanding of the decision context, increase decision-making productivity, positive change on how people perform tasks, effective decision support, improved on-line analytical processing; availability of high quality/accurate/secure data; high payback and low-cost access (Wixom & Watson, 2001; March & Hevner, 2007; Ramamurthy et al., 2008).

Data Mining and Business Analytics Tools (DM/BA)
These DMSS are based on the application of classic and modern statistical algorithms and heuristic intelligent - both numeric and logical- techniques which discover useful internal relationships among usually a vast quantity of heterogenous sources of data mainly for classification and prediction purposes (Davenport, 2006; Delen & Demirkan, 2013; Watson, 2014). Data Mining (also called Knowledge Discovery in Databases) emerged from the artificial intelligence research community (Fayyad et al., 1996) with the aim to cope with the massive quantity of heterogeneous sources of data available for the availability and convergence of new information and communication technologies (i.e., extensive use of internet, cloud computing, social web tools, RFID devices, mobile phones and tablets, and so on). This technological availability also enabled the convergence of advanced visual-oriented tools including data mining techniques and other data visualization ones in the concept of analytics. Analytics covers a set of statistical and intelligent heuristics algorithms for exploring, analyzing and visualizing huge quantities of heterogeneous sources of data.

According to Delen and Demirkan (2013) and Watson (2013), analytics can be classified in Descriptive, Predictive, and Prescriptive types. Descriptive Analytics refers to the already well-known reporting, OLAP, dashboards/scorecards, and data visualization techniques (i.e., DW/BI DMSS tools). Predictive Analytics covers techniques such as regression analysis, machine learning, and neural networks to elaborate forecasts. Finally, Prescriptive Analytics includes techniques including optimization modeling, simulation modeling, multi-criteria decision modeling, expert systems, and group support systems to obtain optimal or satisfactory solutions (i.e., decisional courses of action) on complex problems.

Intelligent and Integrated DMSS (i-DMSS)
These types of DMSS emerged from the need to combine the capabilities of a single DMSS (i.e., a DSS, an EIS or an ES/KBS) and add human-like intelligent capabilities to normal DMSS. Several research efforts were conducted for this aim.

Turban and Watkins (1986) proposed to integrate DSS and ES/KBS for adding the qualitative modeling capabilities of an ES/KBS to enhance a DSS. Delong and Rockart (1986) proposed the integration of a DSS with an EIS to add analytical capabilities to EIS and to extend the time frame of analysis from past and present to future forecasted data. Elam and Konsynski (1987) developed the prototypes to improve the management model modules of DSS by using intelligent techniques. Turban and Watson (1989), Forgionne (1991) and Forgionne and Kohli (1996) posed the integration of DSS, EIS and ES/KBS. The main aim was to support all the phases of the decision-making processes that stand-alone systems are unable to do. Turban and Watson (1989), and Forgionne (1991) developed a conceptual model proposing how this integration could be developed. Forgionne and Kohli (1996), based on this model, developed an intelligent integrated DMSS and tested its effectiveness and efficiency versus stand-alone systems in an experimental setting. King (1992) suggested the addition of why-analysis to traditional DSS. Why-analysis consists of explanation facilities in quantitative models to track how a numerical variable in the model reached a particular value. Klein and Methie (1990) suggested this integration to access data and knowledge bases in order to effectively support decision makers in complex and ill-structured tasks. Finally, Turban and Aronson (1998) surveyed the potential usage of other intelligent-based technologies including Genetic Algorithms, Fuzzy Logic Systems, Neural Networks, Case-Based Reasoning, and Knowledge-Management Systems. Most modern efforts are oriented to ontology-based systems at present (Chandrasekaran et al., 1999) as instances of these integrations, foundations and successful cases of intelligent DMSS were reported (Gupta et al., 2005)

Classic and modern DMSS have been widely used in organizations because when they are successfully implemented, they provide benefits such as: improved organizational performance, better decision quality, improved communication, enhanced mental models, amplified analytical skills of decision-makers, and reduced decision times among others (Turban & Aronson, 1998; Forgionne & Kohli, 2000; Eom & Kim, 2006; March & Hevner, 2007; Davenport, 2006; Delen & Demirkan, 2013; Watson, 2014). Table 2: Decision-Making Process vs. DMSS Capabilities by DMSS Type, summarizes the main capabilities provided by the different types of DMSS tools regarding the phases conducted in a generic Decision-Making process.

Hence, we propose that classic and modern DMSS can be very adequate tools for supporting a RM process in all domains of application. However, the design and utilization of DMSS, in general, are not seamless organizational paths despite the benefits of deploying them. Technical and organizational challenges must be addressed and solved for achieving a successful DMSS design, building and implementation (Setzerkon et al., 2002; Mora et al., 2013).

Table 2: Decision-Making Process vs. DMSS Capabilities by DMSS Type

DECISION-MAKING PROCESS PHASE	DSS	EIS	ES/KBS	DW/BI	DM/BA
INTELLIGENCE	-	Drill-Down, Roll-Out, Pivoting, Executive Dashboards on Data warehouses	Conceptual knowledge stored and logical inferences for analysis and synthesis tasks	Drill-Down, Roll-Out, Pivoting, Visual Reporting, Multiple Dashboards on Data warehouses	Descriptive Analytics for reporting and visualizing past facts
DESIGN	-	-		-	Predictive Analytics for exploring and elaborating forecasts models
CHOICE	What-if, Goal-Seeking, Sensitivity Analysis on Quantitative Models	-		-	Prescriptive Analytics for searching optimal or satisfactory solutions on Quantitative Models
IMPLEMENTATION	-	Drill-Down, Roll-Out, Pivoting, Executive Dashboards on Data warehouses		Drill-Down, Roll-Out, Pivoting, Visual Reporting, Multiple Dashboards on Data warehouses	Descriptive Analytics for reporting and visualizing past facts
LEARNING	-	-		-	Predictive Analytics for exploring and elaborating predictive models

THE UTILIZATION OF DMSS IN PROJECT RISK MANAGEMENT - SIX ILLUSTRATIVE CASES

In this section, six illustrative application examples of DMSS tools in the PRM domain are reported and summarized in Table 3: Case Studies of Project Risk Management Applications. Based on the comprehensive review, two extended and adapted DMSS models for project risks factors and phases are developed and presented thereafter.

Table 3: Case Studies of Project Risk Management Applications

Authors	Publication Date	Industry Area	Brief Description
Meyer et al.	1992	Underwriting life insurance	Linkage between business strategy and development of large-scale expert systems in the context of project selection and evolution
Dey	2001	A cross-country petroleum pipeline project	A quantitative approach to through analytic hierarchy process and decision tree analysis
Ngai, & Wat	2005	E-commerce (EC) development projects	A Web-based prototype fuzzy decision support system is designed and developed
Dey	2010	Oil pipeline construction project	Integrated framework using AHP and risk map for managing project risks
Fang & Marle	2012	A project of staging a musical show in Paris, France	An integrated DSS framework and simulation-based model
Choi et al.	2016	Industrial-based business systems, and operational risk management	Challenges and opportunities of big data analytics in industrial systems

Areas such as life insurance are driven by business strategy to provide fast, accurate decisions as a competitive advantage. Meyer et al. (1992) diagnosed the flow of information and the process of deciding on life insurance underwriting and found signification opportunities to improve the decision-making process. They evaluated two expert systems at two companies, John Hancock and Lincoln National. John Hancock approved 43% of applications within 24 hours, reducing expenses and permitting underwriters to focus on more complex cases. Lincoln

National formed a new organizational unit and a product that could be sold to other insurance companies. Both expert systems support the companies' strategic plans.

Dey (2001) utilized a quantitative approach of DMSS that incorporates AHP and decision tree analysis for PRM. Some examples of RM and uncertainty that affect projects are size of the project, the complexity of the project, the speed of project's constructions, the location of the project, lack of experience relating to the project, external factors that are beyond human control, external causes which limit resources availability, and the project's degree of unfamiliarity. To address all the complexity in PRM, using a case application of a cross-country petroleum pipeline project in India, Dey (2001) developed a project management model that enables the project management team to establish strong and adequate relationships among all the phases of the project. Some of the benefits of the project management model developed are: (1) to help forecast project achievement to build confidence of project team; (2) to help to make decision objectively with the help of reliable and accurate database; (3) to provide accurate and adequate information for effective and efficient project management; (4) to provide formal risk management method to help to manage projects relating to time, cost, and quality; (4) to help establish close co-operation among top executives and members of project teams; (5) to help identify all risk factors; (6) to help determine and compute the probability and severity of all risk factors; (7) to generate various alternative responses with cost implications for quantifying risks and (8) to derive monetary values for each alternative in a decision tree framework.

Ngai and Wat (2005) discussed a fuzzy decision support system (FDSS) that was a web-based prototype designed and developed to assist e-commerce project managers in identifying potential risk factors and the corresponding project risks. Evaluators can use the risk evaluation checklist and linguistic terms to evaluate the risk level by using a proposed risk analysis model incorporated into the FDSS. Although the results of an evaluation showed that the prototype performed to expectations, further research is needed to develop different ‘‘weightings’’ for different evaluators.

Dey (2010) used AHP to identify project level risks and select the least risky project. The method is applied to a cross-country oil pipeline project in western India comparing four pipeline routes. Dey attempted to capture both business risks and operational risks as determined by a team of experts. The author noted that although the method is tedious and time-consuming, the combined AHP and risk map is a useful technique for risk analysis and potential response planning.

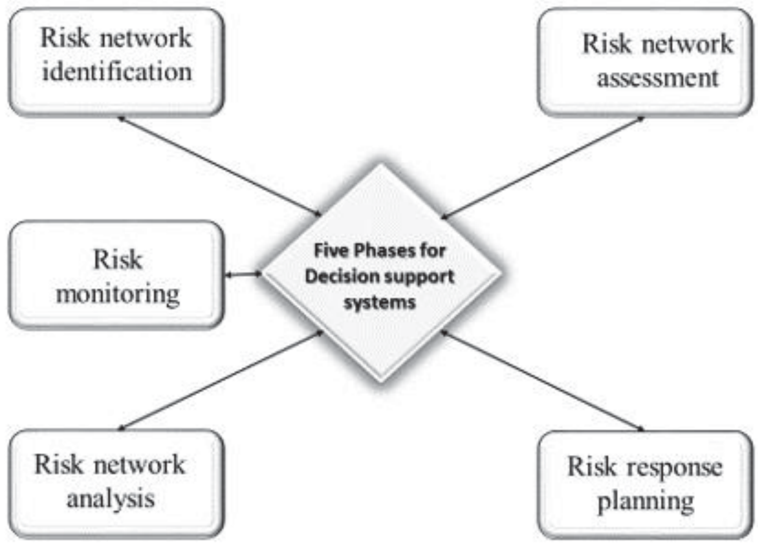
Fang and Marle (2012) argued that to effectively and efficiently manage the complexly interrelated risks associated with a project, that the DMSS should be able to integrate the multiple dimensions of risks (i.e., probability and impact) and to bring the modeling of risk interaction into the PRM process. They discussed that a simulation-based risk network model (i.e., integrated DMSS framework) for decision support in PRM should include these five phases: (1) risk network identification; (2) risk network assessment; (3) risk network analysis; (4) risk response planning and (5) risk monitoring and control. Some of the main advantages of the integrated DMSS framework are: (1) to re-evaluate risks; (2) to priorities risks; (3) to suggest and test mitigation actions and (4) to support top management in making better decisions relating to risks response actions.

Choi et al. (2016) discussed challenges in applying big data analytics to business applications. The authors presented an extensive references list and review of the literature to conclude that there is a myriad of opportunities; however, there are also significant challenges including cost, value, data quality and systems security in industrial system projects.

Based on the preceding discussions and comprehensive literature review of DMSS in PRM, we extend the earlier research work by developing the DMSS models for project risk factors as shown in Figure 3: DMSS model for project risk management phases. The arrows in Figure 2: DMSS model for project risk factors, posits that decision support systems must adapt to all its stakeholders and risks. The arrows in Figure 3 are also multidirectional and indicate that project managers and top management should have the skills, tools, and resources to adapt to all the risks as shown.

Figure 2: DMSS model for project risk factors

Figure 3: DMSS model for project risk management phases



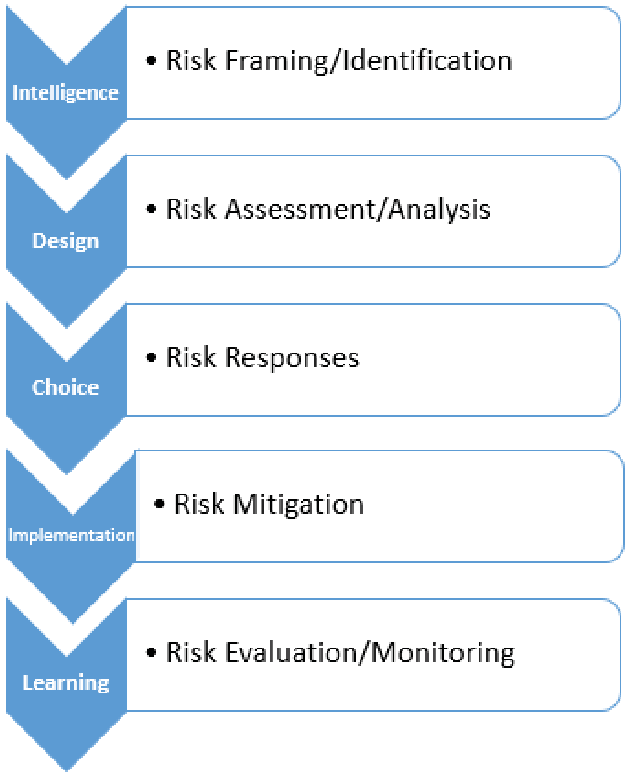
Figures 2 and 3 models address the limitations of current models relating to modeling complexity in PRM. In addition, the extended and adapted DMSS models provide insights and understanding to project managers and top management on how to effectively and efficiently manage project risks. The models also provide insights to project managers and top management on criteria to consider when developing or selecting DMSS tools that objectively measure the different kinds of project risks that exist in project development and assessments. The models enable project managers to save time in project processes relating to designing risk response plans, reducing the cost of dealing with contingencies and assessing and weighing all the risks that are associated with a specific project. Proactive RM can be achieved if project managers have the skills, tools, and resources to adapt and adjust to all the risks as illustrated in Figures 2 and 3.

Figures 2 and 3 equip project managers with the skills, tools, and structural procedure on a robust model to analyze and control project risks. The extended and adapted DMSS models encourage project managers and experts to actively participate in the entire process of DMSS to adapt to the different kinds of risks that exist and understand the relationship among these risks during decision support in PRM. Some of the benefits of the extended and adapted DMSS models are: (1) help to identify; refine and prioritize risks; (2) help to re-assign risk ownership; (3) help to provide effective and efficient mitigation strategies and actions and (4) help to adapt to the different kinds of risks that exist in the dynamic project environment.

DISCUSSIONS AND IMPLICATIONS ON THE LINKAGE BETWEEN DMSS AND RISK MANAGEMENT

In the previous sections, we have summarized the main concepts and characteristics of the RM process, reviewed the types and characteristics of DMSS tools, reported six illustrative application examples of DMSS tools in the PRM domain, and extended the current DMSS models for project risk factors and phases. We also identified the theoretical as well as practical linkages between the DMSS and RM processes. Figure 4: The theoretical mapping framework below illustrates the theoretical mapping framework between the generic decision-making processes and RM processes in the context of information technology standards.

Figure 4: The theoretical mapping framework



As illustrated in Figure 4, the essential risk management process and its sub-processes can be naturally mapped to the established generic decision-making process and the five phases therein. For instance, the *intelligence* phase of the generic decision-making process, when mapped to the essential risk management sub-process of Risk Framing, involves acquiring risk relevant contextual information and identifying possible risks in the identified organizational and/or project context. Next, in the *design* phase of the generic decision-making process, which is mapped to the essential risk management sub-process of Risk Assessment, decision makers or managers would identify or develop a relevant risk model to analyze and assess the identified risks in terms of their probabilities and consequences. Following that, generating recommended actions and responses and putting that into final decisions and strategies correspond to the *choice* phase and *implementation* phase respectively of the generic decision-making process, which is mapped to the essential risk management sub-process of Risk Responses and Risk Mitigation. Finally, in the *learning* phase of the generic decision-making process, which is mapped to the essential risk management sub-process of Risk Evaluation and Monitoring, decision makers or managers review, evaluate, and monitor the process and outcomes of implemented risk mitigation strategies for future organizational learning purpose.

Accordingly, DMSS, which are designed to support some or all phases of a decision-making process, can be considered as valuable and pertinent tools for supporting a Risk Management process. Table 4*:* The application framework of applying DMSS to Risk Management *sub*-processes, illustrates the application framework of applying relevant DMSS tools and capabilities to the specific RM sub-processes.

Table 4: The application framework of applying DMSS to PRM sub-processes

Risk Management Sub-Process	Main Tasks	Suggested DMSS Tools	Relevant DMSS Capabilities
Risk Assessment / Risk Framing	• Establish the high-level organizational context and decisional boundaries for Risk Management	• EIS • ES/KBS • DW/BI • DM/BA	• Drill-Down, Roll-Out, Pivoting, & Executive Dashboards • Visual, interactive, & real-time Reporting • Descriptive Analytics for reporting and visualizing
Risk Assessment / Risk Analysis	• Determine the specific organizational risks through the detailed analysis of threats, vulnerabilities, impacts, likelihoods and uncertainties	• ES/KBS • DM/BA	• Intelligent advice, qualitative reasoning, problem-solving assistance, and logical inferences • Predictive Analytics for exploring and elaborating forecasts models
Risk Mitigation / Risk Responses	• Prioritize, evaluate, and implement the appropriate risk-reducing controls recommended from the risk assessment process	• DSS • EIS • ES/KBS • DW/BI • DM/BA	• What-if, Goal-Seeking, Sensitivity Analysis on Quantitative Models • Prescriptive Analytics for searching optimal or satisfactory solutions on Quantitative Models
Risk Evaluation / Risk Monitoring	• Conduct an ongoing evaluation and monitoring of the implemented risk mitigation countermeasures, and watch over organizational and external changes	• ES/KBS • DM/BA	• Intelligent advice, qualitative reasoning, problem-solving assistance, and explanation of advices • Predictive Analytics for exploring and elaborating predictive models

From an applied perspective, executives and decision makers of worldwide organizations are facing challenges of effective PRM in the current era, and they look for practical DMSS solutions that can help them better identify, assess, mitigate, and monitor organizational risks. This integrative review paper adds to this body of knowledge and helps facilitate additional research and practical endeavors. An integrated and well-structured introduction to and review of the DMSS tools and PRM process were presented. Based on the richness and variety of such applications and research findings, we can present the following recommendations and cautions to executives and decision makers interested in applying relevant DMSS tools to managing organizational risks:

- All industry fields face the challenges of effective and efficient PRM and both the classic and modern DMSS solutions can help them better identify, assess, mitigate, and monitor organizational risks.
- To effectively address the PRM challenges, the classic DMSS solutions need to be equipped with modern and advanced techniques depending on the involved data types, sources, structures, constraints, priorities, uncertainty levels, and other organizational characteristics.
- Practitioners across different industries can utilize the presented application framework to adopt or develop the appropriate DMSS techniques and solutions to reduce risks and derive the intended benefits of making well informed decisions and risk strategies.
- Big data brings a new culture and way of decision making and PRM. Besides technical challenges, managerial challenges of DMSS for risk management in the current era must be addressed to reap the full benefits of that transition.

Hence, our study reveals that the PRM process has experienced drastic changes in its execution by organizations, its theoretical conceptualization by researchers and its practical implications in the current era. The main shift on the PRM process can be stated as an evolution from traditional analytical and statistical techniques with structured data sets in highly predictable and cooperative business environment, to data-driven discovery and highly proactive and creative decision-making utilizing modern and advanced analytical techniques with unstructured and massive data sources to cope with a highly dynamic global business environment in the current era.

CONCLUSIONS ON CONTRIBUTIONS, LIMITATIONS, TRENDS, AND OPEN CHALLENGES

Risk management has become a vital theme in both academia and practice over the past several decades (Wu et al., 2014). It refers to the overall process to identify, analyze and monitor risks as well as the design and implementation of risk strategies to identify risks. In this article, we have introduced and reviewed the characteristics of a set of DMSS as valuable tools for supporting the RM process. We have also reported and analyzed six illustrative application examples of DMSS in the PRM domain. Two extended and adapted DMSS models were developed and presented for project risk factors and phases based on the comprehensive literature review. We have also identified theoretical as well as practical linkages between the DMSS and PRM processes. A theoretical mapping framework between the generic decision-making processes and PRM processes was identified and depicted. In addition, we have developed an integrated application framework for applying relevant DMSS tools and capabilities to the specific PRM sub-processes.

This study also elicits a set of practical recommendations for executives, project managers and decision makers in organizations worldwide. Interpreting RM literature and applying a rich body of knowledge for business practitioners is of great importance. Currently, PM is gaining more attention due to technology and global competition. Successful projects have a greater number of on-time completions, stay within budget and customers are satisfied with the performance for the project. The main barriers to the achievement of completed projects are the changes in the project environment. Challenges may multiply with the size of the project as uncertainties. Given the significance and complexity of PRM and big data phenomenon, we encourage continued research in this area. It is necessary to investigate and establish advanced and updated conceptualizations including frameworks to comprehend this complex yet critical subject.

ABSTRACT

The need to consistently advance with environmentally sustainable practices in today's businesses is crucial. Businesses are demanded to be more environmentally sustainable every day. Our goal is to provide a review of common drivers, barriers and other similarities important to the future of implementing sustainability by small and medium sized enterprises. We investigated patterns in drivers and barriers to obtain the most recent trends by carefully examining 122 studies from 53 different journals published from 2013 to 2019. This meta-analysis can serve as guidelines to gain some insights and knowledge on sustainability strategies in small and medium sized businesses in order to produce a more sustainable and successful future for SMEs as well as evaluates research gaps for future studies.

KEYWORDS

SMEs, Small and Medium Enterprises, Barriers to Sustainability, Sustainability Drivers, Green Practices, Environmental Sustainability, Business Environment, Eco-Friendly

INTRODUCTION

Concerns over the environment have increased over the years, with the 2020 US election coming there are conversations among candidates on plans of enacting new legislation to help the environment. From afar, we might think that pollution exists from large corporations;

however, research shows that SMEs make up 90% of worldwide businesses and are reported to be responsible for about 70% of the global pollution (Tutterow, 2014; Langwell et al., 2014). Large businesses only contribute to around 30% of the pollution in the world today; they are far more qualified than SMEs to achieve environmental sustainability (Aghelie, 2017). SMEs lack experience, data, financial resources and the technical expertise to go green compared to their larger counterparts (Ghazilla et al., 2015). SMEs vary widely in the makeup of the business and commitment to going green (Parker et al., 2009). For example, the issue is that a good environmental plan that would work for a small farm in France would not be sufficient for a machine shop in the United States. Not just the size or make-up of an SME affects a good environmental plan, but it also needs to investigate environmental factors such as the economy and the government policies and regulations. An SME in underdeveloped or transition economies will have a different set of barriers than an SME in a developed country (Silajdzic et al., 2015). Transitional economies, for example, don't have government regulations like developed economies. Their educational institutions don't have the knowledge of green practices and the businesses themselves tend to only worry about profit because of the high failure rates of SMEs in their transitional economies (Silajdzic et al., 2015). Therefore, it would be left to assume that the research on SMEs going green needs to be specific to each of the variables of an SME operates within (Parker et al., 2009). Parker et al.'s (2009) indicates that all the research they found was vague and did not concentrate on the vast array of different SMEs. Now their research has hit the ten-year mark of reviewed journals on environmental sustainability in SMEs, we aim to get the most up to date trends in this research area.

A meta-analysis is a research process in which researchers systematically merge the findings of other independent studies using both qualitative and quantitative data from those studies. We used various meta-analysis studies such as Johnson & Schaltegger (2015) and Parker et al.'s (2009) in order to identify where they left off in their studies and where we should pick up. This meta-analysis is similar to Parker et al.'s(2009) as we found our research could build off of theirs and produce an updated version covering broader ideas.We used a systematic review and searched for studies published in high credibility and ranked journals. As part of our data extraction, we categorized the reviewed studies based on their research questions, methodology, sample size, conclusion and focus of the study. We reviewed many articles and those of best relevance were picked out and cross examined with each other to analyze patterns.

LITERATURE REVIEW

SMEs are important to focus on as larger businesses seem to have more resources, such as capital, knowledge, and technology to adjust and drive their business to become more environmentally sustainable. SMEs, on the other hand, face many barriers that are difficult to overcome. SMEs today have increasing demands from stakeholders that want more transparency and accountability from them about what they are doing to expand environmental sustainability. and accountability from them about what they are doing to expand environmental sustainability.

In Parker et al.'s study (2009), 50 peer-reviewed journal articles were analyzed using a deductive thematic approach in being selected for their study. They then analyzed the summaries and grouped the SME types and interventions based on the themes which emerged. Parker et al. (2009) categorized the data based on the method, countries and the size of the SMEs by employees. They found that a majority of the studies were from the Europeans. They also examined the drivers and barriers of sustainability in SMEs from these articles. They concluded it was naive to rely on the extremes of voluntary environmental agreements or regulation and legislation to engage SMEs in environmental improvement. Better yet, intervention strategies to assist SMEs to engage in environmental improvement need to be holistic and designed for the specific category of SME being targeted. They argued that a properly coordinated and mixed strategy intervention approach is likely to be more successful in engaging SMEs.

Albertini (2013) conducted a meta-analysis in which she focused on integrating prior research studying their relationship of environmental management and financial performance of businesses. Albertini (2013) investigated 52 studies over a 35-year period that confirms a positive relationship between environmental performance and financial performance. Moderators' analysis reveals that the relationship is significantly influenced by the environmental and financial performance measures, the regional differences, the activity sector and the duration of the sustainability practices. After discussing the theoretical and managerial implications, Albertini's (2013) meta-analysis tried to answer the question: "When and how does it pay to be green?" Using theories like Accounting-based indicators the results showed that financial performances are positively correlated with environmental management.

Johnson & Schaltegger (2015) conducted another meta-analysis focusing on sustainability management tools for SMEs. Their literature review was guided by specific questions such as: What sustainability management tools, including tools for corporate social responsibility and tools for environmental management, have been designed for and are applicable to SMEs? Their data collection was based on thematic analysis and included an explanation of how many articles were searched and were relevant. They also collected data on what journals these credible articles were from as well as where they were from geographically. Their results consist of explaining four particular areas of investigation, including the overview of proposed tools, the reasons for implementation, the barriers for implementation, and the key facilitating criteria to improve applicability of tools in SMEs.

Lastly, Alvarez et al. (2018) focused on strictly barriers to sustainability in small and medium enterprises. Their method was to analyze the top most cited studies. They were able to find 46 top most cited articles in helping them analyze the top barriers faced by small and medium sized enterprises when starting initiatives for environmental sustainability. They were able to find a total of 175 barriers to entry into environmental sustainability (Álvarez et al., 2018). The barriers that were the most frequent which showed up in 13 articles were lack of resources, high initial capital cost in implementing sustainability, which showed up 11 times and the third most frequent was lack of expertise which appeared in 9 papers. They also found that the countries with the highest amount of research publications that recalled barriers to sustainability for SMEs are United Kingdom, Germany, Italy, Malaysia, and Romania.

Common drivers known to date that promote sustainability in small businesses include financial gains, government regulations, resources, and other benefits. One of the most distinct factors in driving sustainable entrepreneurship were behavioral factors or habits that seem to be the norm within a business. Tur-Porcar et al. (2018) demonstrated that behavioral factors which are motivation, lifestyle, and metacognition scored 49.59% compared to environmental/surroundings at 6.55%, human relations 13.6% and business factors at 30.26%. They focused on the hierarchical design of the key factors that influence entrepreneurial sustainability. Their study sampled nine experts from three distinct professional areas: academia, business, and government. The results reflected that half the reasons why businesses go green is due to behavioral factors (Tur-Porcar et al., 2018). Other drivers that encourage sustainable acts include economic, external pressures and the role of personal values (Aboelmaged, 2018). The results underline that external pressures and entrepreneurs' attitudes are the most important predictors of environmental proactivity both for small and micro firms (Testa et al., 2016). In addition, the need for a fit between personal and professional values was essential in underpinning respondents' engagement with climate change and encouraging a sense of personal responsibility (Williams & Schaefer, 2013). William & Schaefer's (2013) study explored nine in-depth interviews with SME managers in the East of England between March and May 2009.

Other studies found that managers' environmental responsibility is the most important driver of environmental behavior (Shahlan et al., 2018; Iraldo et al., 2017). Top management and stakeholder pressure is a major influence in a business going green. A major conclusion in Pinget et al. 's (2015) study suggests that environmental regulation has a positive effect on the probability of adopting environmental impact (EI) practices. Firms that are conscious of their environmental impact are more actively adopting environmental solutions. Environmental stewardship was able to influence the firm's behavior (Hamann et al., 2016). Hamann et al. (2016) also found that managers' environmental responsibility is the most important driver of environmental behavior. They also showed that a clear and direct influence and the most significant drivers of going green are first local, national and international regulations and stakeholders, such as managers and employees. Their data collection consists of South African wine firms and 55 survey respondents.

Social responsibility and pro –environmental organizational culture and organizational support were found to have significant impacts on company's green initiative as well (Loke et al., 2014). Loke et al. (2014) hand delivered questionnaires to a sample of 1000 randomly selected companies located in the state of Perak. Based on these 1000 questionnaires originally distributed, a total of 571 of them were found completed and usable, yielding a response rate of 57.1%. Majority of the participating companies were from the electrical, machinery and apparatus industries (31.2%) followed by the food products and beverage industries (24.5%). Social, economic and formal practices dimensions of sustainability positively affect competitive advantage, mediated by corporate reputation, customer satisfaction, and organizational commitment (Madsen & Ulhøi,, 2015). Research on 40 Romanian articles showed that strong commitment from managers will increase sustainability strategies and implementation (Zbuchea & Pinzaru, 2017). Ghandi et al. (2018) reveal that top management commitment, technology up-gradation, current legislation, green brand image and future legislation are the five most important drivers for the implementation of integrated lean and green manufacturing in Indian manufacturing SMEs. A competitive advantage acts as a second-stage mediator that positively contributes to financial performance (Cantele & Zardini, 2018). Cantele and Zardini (2018) surveyed Italian Manufacturing businesses; survey of 348 Italian manufacturing small and medium-sized enterprises. Whether it's a corporate social responsibility (CSR), economic advantage, or legal compliance, drivers serve as a motivation to achieve sustainable environmentally friendly practices in SMEs. Companies who have sustainable practices have an advantage over those who don't, not only because they are helping the environment and their own resources but they are also branding an image target customers will want to support. This competitive advantage ultimately helps a business financially.

Triguero et al. (2013) conducted a survey of 5,222 European SMEs and discovered that companies can more easily develop eco-innovation when they work closely with institutions and colleges/government. An example is the European Innovation Program which brought together private stakeholders. The driver of compliance with regulation took the highest rank in Niknamfar et al.'s (2018) study as well. Caldera et al.'s (2019) study found enablers consisting of organizational support, stakeholder collaboration, business direction, lean and green relationship; yet another research article with a similar pattern of drivers repeated in our research. Just like Caldera et al., Raar's (2015) study mailed out surveys and received 360 usable response rate, 319 were directors, managers/owners, general managers, or accountants. Surveys found the same drivers: collaboration, continuous innovation, clear narrative and vision, profitability, foundation for sustainability and lastly external events. In contrast, in Ashton et al.'s study (2017), a majority of firms appear to be internally motivated to implement green practices driven primarily by cost and competitiveness concerns, more than by social responsibility concerns. External coercive pressure from government or customers does not appear to be a significant motivation for these SMEs. However, informal pressure through government incentives and support programs, as well as mimetic pressure through peer learning via industry associations, appear to be more effective in helping these SMEs to further. This is one of the very few articles focusing in the U.S.

Barriers prohibit or create an obstacle for SMEs to implement sustainable practices. For example, in Ghadge et al.'s study (2017), poor market structure, lack of appropriate logistic structure and underdeveloped environmental legislation are all barriers to achieving such practices they had aimed for. Culture plays a role in situations also (Rekik & Bergeron, 2017). In Pinget et al.'s study (2015), they focused on French SMEs. Lack of financial sources revealed to be another main obstacle many businesses seem to have. Research has proven that smaller companies have more problems and barriers because of lack of funds and lack of educated workers (Pinget et al., 2015). It is even more difficult to start a business in developing countries because loans and support from the government are just starting to take hold (Silajdzic et al., 2015). Many of these companies started with support from family because of lack of funding. The barriers don't stop there, when questioning the academics underdeveloped countries were unfamiliar with the statement of green and are just starting to learn about green ideas. So as education goes, they are lacking many resources. Interviews with 24 SMEs, 24 literature review and 3 business analysis in Bosnia and Herzegovina revealed that majority of the SMEs are not planning to introduce green practices even after they were educated about sustainable practices because the weight of running a business keeps them busy enough (Silajdzic et al., 2015).

In Ghadge et al.'s study (2017), demanding warehousing, rough distribution process and unorganized return management all affected the hardship of obtaining greener practices. This study focused on fresh dairy products in Greece that are costly to store and even harder to distribute, both processes require refrigeration and have a great effect on the environment but are a necessity to the dairy market. Using descriptive research, sensitivity analysis, questionnaires, and analytical hierarchy processes, they found that the problem of unorganized return management in the dairy industry also creates waste generated from the return of products. If they overcome this hurdle, they can significantly reduce their waste (Ghadge et al., 2017). One of the main barriers we found during this research is the lack of awareness on sustainability, commonly, Singh et al.'s research (2018) supported those findings. This similarity is again seen in Mangla et al.'s (2017) study in which they examined dimensions of barriers. Organizational barriers ranked first when it came to environmental management. Among the sub categories were lack of appropriate tools and techniques. SMEs foundries lack the resources and technology needed to go green (Wadhwa, 2015; Halme & Korpela, 2014).

Lack of awareness, lack of education, lack of expertise, cost which consisted of high cost of implementing the technology, lack of funds, lack of financial resources, risk, policies and regulations were present in Caldera et al.'s study (2019). Lack of government regulation is another relatively high barrier to SMEs. Because of the lack of monitoring and enforcing strong regulations it does not motivate or encourage SMEs to practice green practices. Luthra et al.'s (2016) findings also showed a lack of rewards and promotions to be a setback to greener SMEs.

Ghazilla et al.'s (2015) study found 39 drivers and 64 barriers in their literature review. The main barriers found out of the 64 were weak organizational structure, lack of empowerment to support, delay of high internal policies, and management resistance; all of which are consistent with researches mentioned before. The most ranked drivers were, voluntary regulations and standards, and compulsory regulation mandated by local government (hazardous and toxic regulation).

METHODOLOGY

We conducted a meta-analysis which involves a carefully selected review of journal articles in relation to SMEs and their journey to adopting these environmentally friendly practices. We strictly used peer-reviewed journals for higher quality from the past 6 years (2013-2019) to investigate the most recent studies. We found our articles by searching online databases (ILLiad, Science Direct, Wiley, ResearchGate, Google Scholar, Etc.) by using keywords in relation to our research (Table 1). We have searched through a total of 845 research articles discovered from our keywords (Table 2). After carefully examining these articles only 122 reached the criteria and needs for our research. The review was carried out using a deductive thematic approach, by examining the findings and categorizing the types of SMEs and the drivers and barriers described by the authors.

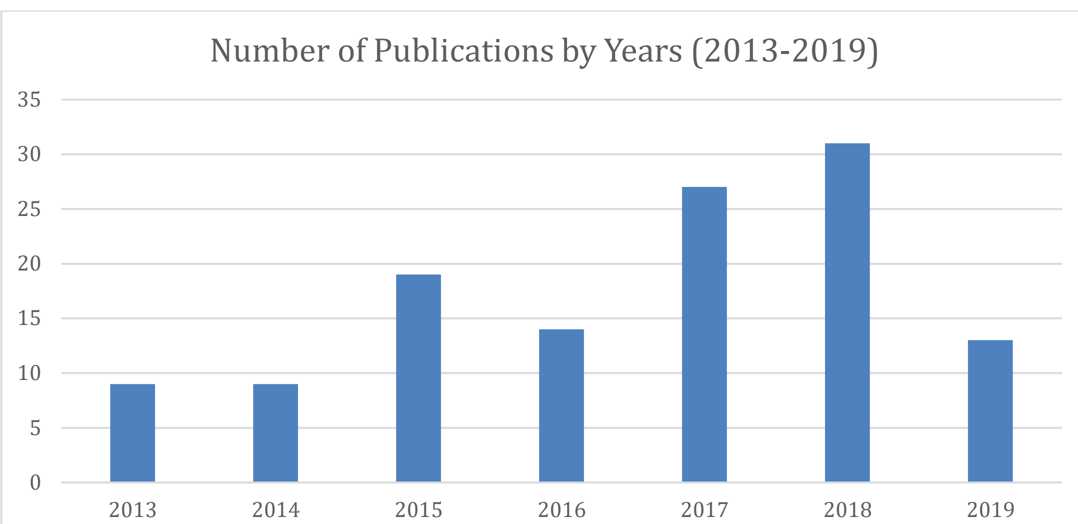
Figure 1 compiles the years in which the articles analyzed in this research were published.

Figure 1. Publication by Years



For each article, we analyzed the region in which it took place, the sector, method, sample size, theories and their conclusion. We examined each article closely and analyzed patterns, trends, similarities and differences of all aspects of each research to help draw our findings.

RESULTS AND DISCUSSIONS

The published meta-analysis studies are not as extensive as our study. Our meta-analysis investigates and analyzes 122 articles from 53 different journals and sources (Table 3).

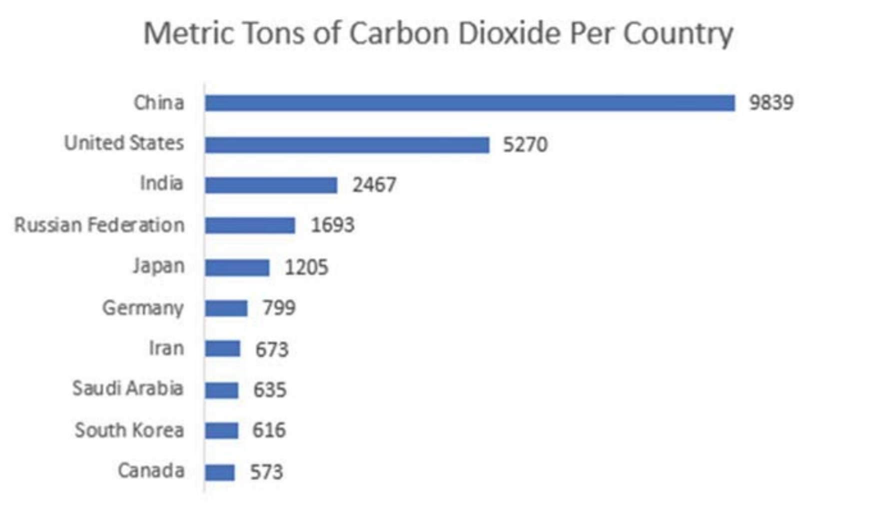
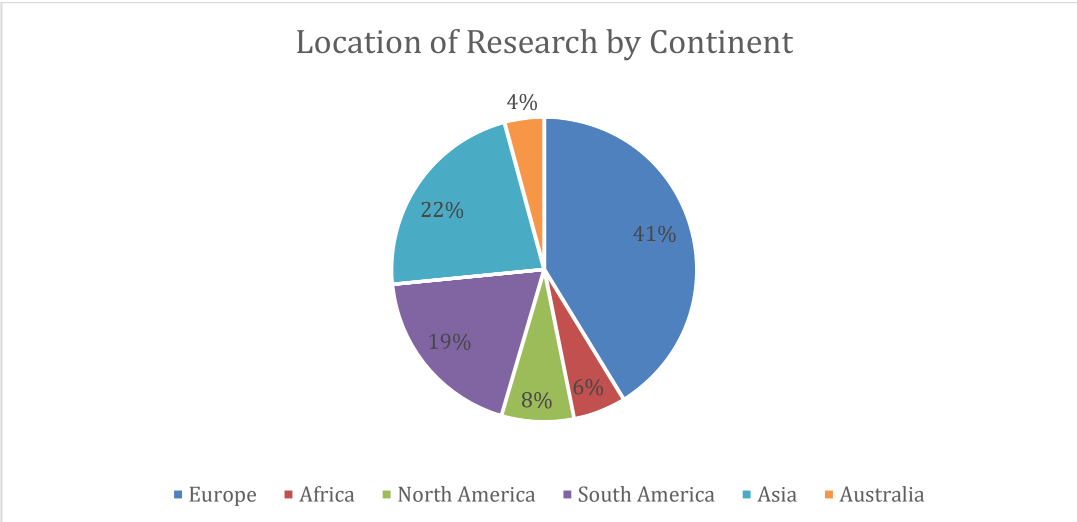
Most studies are not focused on SMEs in the United States. The pattern is disturbing because United States produces 30% of the earth's waste and is a consumer of 25% of the world's natural resources (Davis et al., 2010). The United States creates more pollution in the world and there is little research done on how to encourage SMEs to go green. China has overtaken the US as the world's largest producer of carbon dioxide but that does not downplay the United States involvement because the US receives a bulk of the imports from China (Rapier, 2018). Further research is needed to analyze the United States and regional specific drivers and barriers for environmental sustainability.

Figure 2. Metric Tons of Carbon Dioxide Per Country (Global Carbon Atlas, 2017)



China and the United States create a large amount of the greenhouse gases (Figure 2) and studies investigating how to improve emissions from SMEs fall behind in those countries. The next eight countries only add up to 57 % of the Carbon Dioxide of China and the United States. Figure 3 shows articles we reviewed broken into categories by continent.

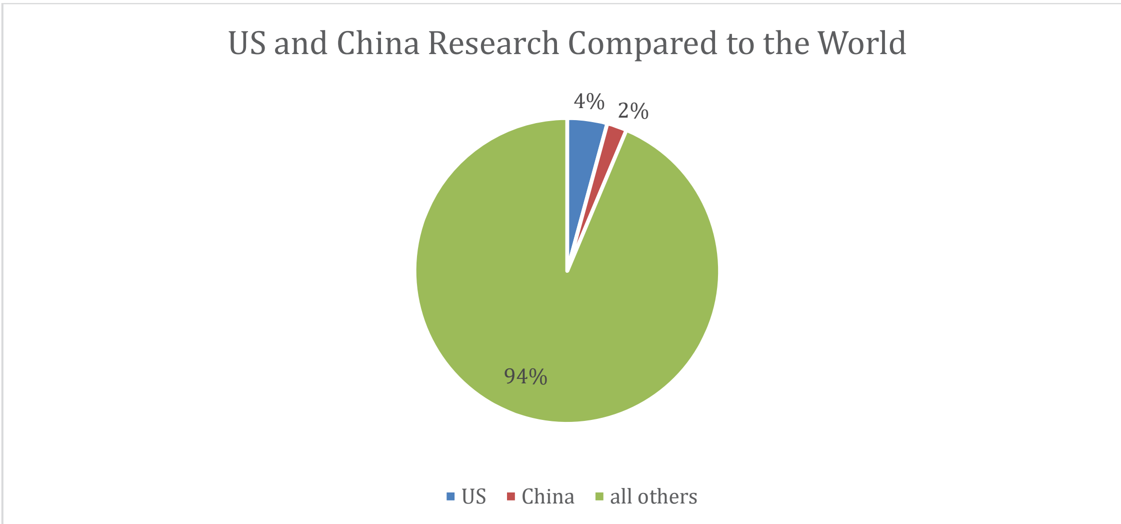
Figure 3. Location of research by continent



Most of the research studies we have found occur in Europe, which makes up 41% of the research we have analyzed, Asia accounts for 22% and South America at 19%. To compare, there was research done by Alvarez et al. (2018) which looked into barriers that were most frequent in SMEs. Alvarez et al. (2018) took 46 of the top cited articles to develop research and broke down what country the research oriented. Compared to our research, they investigated the 46 most cited articles and found 60% of the research oriented from Europe, which is well over half the researches done. Comparing to Parker's et al. (2009) study, it is still close to the same trend with Europe being the most concerned with environmental sustainability. There is more research coming from North America and Australia than what was observed in our latest research. Parker's et al. (2009) research was done on articles from 1999 to 2008 and the research we performed was from 2013 to 2019.

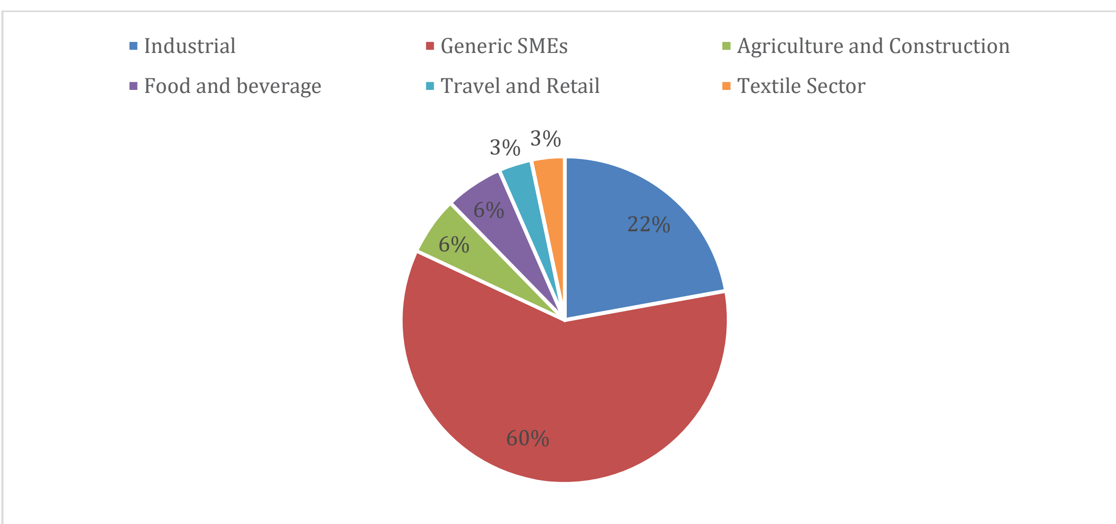
Figure 3 shows us the parts of the world that put an emphasis on environmental sustainability, but since the major contributors to pollution in the world are China and the United States, we broke it down further (Figure 4). China accounts for 2% of the research and the US accounts for 4% of the research. This leaves 94% of the research coming from countries that are not the major contributors to CO_2 gas in the world.

Figure 4. US and China Studies Compared to the World



Research shows that SMEs vary greatly between size, make-up, sector and location, all of which are factors influencing how an SME will develop an environmental sustainability business. Parker et al.'s (2009) recommended that researchers need to concentrate on industry-specific and other variables on which SMEs can be categorized. Based on our research we produced Figure 5 showing what sectors that have been researched from 2013-2019.

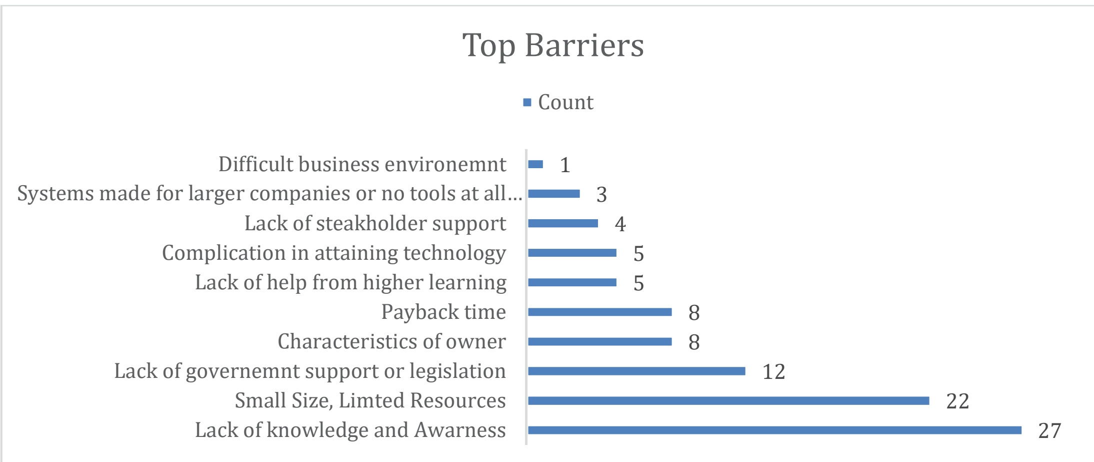
Figure 5. Research of SMEs by Sector



The research shows that 60% of articles focus on generic SMEs and is still not industry, sector or region specific. Further research should be done that is specific because SMEs vary greatly by sector.

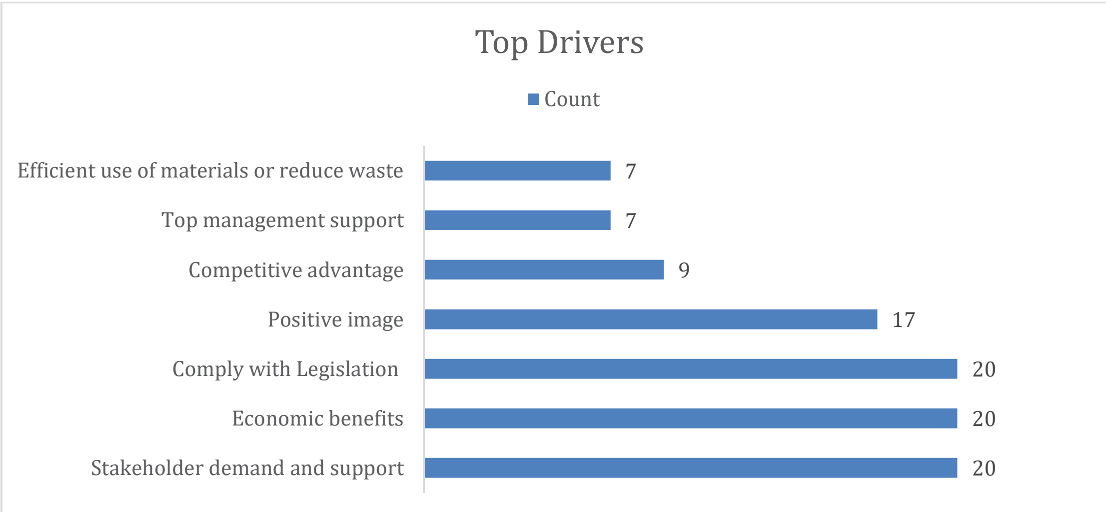
Drivers and barriers are another concern for companies going green. Barriers that seem to come up for SMEs are lack of resources, lack of knowledge, and lack of government support and legislation. These are all barriers faced by SMEs and not necessarily large corporations because they have the size, knowledge and resources. Figure 6 shows a breakdown of the number of studies in our research on barriers to environmentally sustainable SMEs. The major barriers are lack of knowledge and education, and limited resources in SMEs.

Figure 6. Top Barriers



Our analysis shows the drivers are concentrated in economic benefits, stakeholder demand and support and comply with legislation. Most of these were found in research based on SMEs. One unique driver we found was Eco-Islam and the 8 maxims. The authors use the idea of using the strength in the Muslim devotion to their religion to share the fact that the environment is a gift from Allah and should be protected (Abdelzaher, 2015). Figure 7 presents common drivers among the studies we analyzed.

Figure 7. Top Drivers



CONCLUSION

Our research shows that SMEs vary widely from sector, size and location and need to be addressed differently because of it. Papers we reviewed were focused on SMEs in 6 different sectors of Industrial, Generic SME's, Agriculture and Construction, Food and Beverage, Travel and Retail, and the Textile Sector. SMEs can also vary from 1 to 250 employees and are the majority of companies in the world. All SMEs are unique and so are their barriers and drivers. To help SMEs become the most environmentally sustainable they can be, future research needs to be addressed investigating the size, sector and location of the SMEs. One of the many barriers that was seen in almost all of the studies was lack of knowledge. We need future studies on training and support from the government to the public sectors. We need to use the vast knowledge at the colleges and universities around the world to do research and develop more specific tools and knowledge to help support green issues. SMEs don't have the time or the resources to educate themselves on environmental sustainability. Developing countries may not even have access to this information or anybody who was educated in the field. It is up to universities and governments of the world to help bridge this gap. ed in the field. It is up to universities and governments of the world to help bridge this gap. However, the United States is the second leading contributor to Carbon Dioxide output and has the knowledge and resources to lead this worldwide change. The US is leading when it comes to the standard of tertiary education and the top universities in the world are located in the United States. US universities need to focus on SME's in the United States and give them the knowledge and help they need to become green.

Email: christian.bautista01@utrgv.edu

ABSTRACT

Corporate Sustainability (CS) has been developed and deployed in established firms by implementing multiple sustainability business models. Lately, this business tendency has been extrapolated among young entrepreneurial firms, this investigation uses the tenets of Neo-Institutional Theory to explain how young entrepreneurial startup firms achieve legitimacy and external resource support. Factors such as sustainable business rhetoric and competitive advantage in entrepreneurial firms can help to achieve organizational legitimacy among startups towards achieving financial performance.

KEYWORDS: Sustainability, Sustainable embracement, Sustainable entrepreneurship, SMEs, Sustainability-oriented innovation, Sustainable supply chain management.

INTRODUCTION

Western industrial societies have experienced severe problems over the last three decades, and probably these problems will be transferred to future generations, as the scale of the environmental and natural resource or sustainability problems they face has become increasingly clear (Elkington, 1994). As a consequence, sustainability and multiple sustainable strategies & business models have been adopted and embraced by multiple firms worldwide in order to maintain profit and growth, including environmental performance or social equity (Bansal, 2002). This economic impact is around US$2.15 trillion, or 3.6% of global GDP, according to the United Nations Environment Program Finance Initiative in 2008, and includes leading public companies globally such as fresh water usage, pollution control, waste and land-use change (Sukhdev, 2012). Additionally, corporate sustainable responsibility extends more than just producing consciously and maybe collect waste created by those produced goods; corporate advertising plays a key role also, since it converts insecurities into a chain of desires and excessive demand of manufactured products or services that create a massive carbon footprint that exceed our planet ability to produce resources and absorb those emissions (Sukhdev, 2012; WWF, 2012).

Nowadays, corporations are considered the main players creating and developing environmental and social issues, as a consequence, they are pointed out as the generators of lack of sustainability in our society (Schaltegger & Wagner, 2011). Likewise, corporations at all levels believe that natural resources or externalities, clean air, fresh water, carbon storage, capacity of forest, among others, are a taken from granted capital and public goods; this is because those commodities are not being traded in any market and are mostly available for free (Sukhdev, 2009). Moreover, natural resources availability for the upcoming future has been a enormous concern for organizational and societal actors such as firm's executives, shareholders, policy-makers, academicians, environmentalists, among others (Bansal, 2002; Nandi & Kaynak, 2017), this fear affects big players such as corporations, however, small players such as small and medium sized enterprises (SME's) are concerned as well since the impact they might have is small, but cumulatively their impact is significant as institution (Hardy, 2011; Lawrence, Collins, Pavlovich,

& Arunachalam, 2006). Concurrently, the career related to reach economic, environmental and social sustainability is attracting more and more industry players, independently of their size, and becoming a focal objective for enterprises along different industries worldwide (Arevalo et al., 2011). Furthermore, corporations, established and young firms, are bodies that the main responsibility is create corporate profit, business growth, shareholder value, market share, economic performance, and innovation (Bansal, 2002; Goldratt & Cox, 2004); putting sustainability efforts not as priority until firms reach enough surplus to invest in (Berrone, Fosfuri, Gelabert, & Gomez-Mejia, 2013) due to higher operational expenditure and as a consequence lower margin profits at year end (Hart, 1995). Moreover, imbedding sustainability in firms is a difficult task since the internal and external system dynamics that surrounds those corporations is not well-defined in order to meet top notch sustainability standards (Arevalo et al., 2011). Additionally, firms' management is facing overwhelming challenges to meet regulations and requirements to meet new sustainability standards that are updating continuously, underestimating and distorting the role of companies in the society (Schaltegger & Wagner, 2011).

Lately, the sustainable development concept has been embraced more vividly by entrepreneurial firms, even developing a new set of streams of thought such as ecopreneurship; social entrepreneurship; sustainable entrepreneurship; and in an indirect way also, institutional entrepreneurship; each with different motivation, goals, and organization (Schaltegger & Wagner, 2011). Similarly, entrepreneurial firms have been recognized as a major contributor for innovative sustainable products and processes, among developing new ventures concerned for social and environmental issues that can resolve environmental problems of global socio-economic systems that current private and public institutions are not effectively attending (Dean & McMullen, 2007; Hall, Daneke, & Lenox, 2010; Tilley & Young, 2009). However, entrepreneurs might ask themselves what is needed to create a venture capable to meet the sustainable criteria nowadays. As a result, research has revealed five key principles of organizational design to have success for sustainability-driven entrepreneurial firms in a competitive market context are: purpose, efficiency, tradeoffs, criteria, and inducement (Parrish, 2010).

Furthermore, to create, and even maintain, sustainability legitimacy, reputation and image, firms need to open their operations for public scrutiny, emphasizing and focalizing transparency and openness, among design significant changes in order to reduce ecological impacts. (Hart, 1995; Sharma & Henriques, 2005). On the other hand, management literature supports that internal and competitive approach at the firm might not be sufficient to implement sustainability practices because issues of firm's external or social legitimacy and reputation are also extremely important (Hart, 1995). The purpose of this article is to focus on understanding the sustainable business rhetoric and competitive advantage in entrepreneurial firms and how they can achieve organizational legitimacy among startups towards achieving financial performance using the tenets of Neo-Institutional Theory.

LITERATURE REVIEW

Fundamentals

Table 1 illustrates the audience with fundamental concepts that will be used during the development of this research. It is important to review them before proceeding further with this document.

Table 1 - Fundamentals for this research

Term	Definition	Source
Sustainability or Sustainable development	This term has been accepted and developed by one of the previous United Nations entities in 1987, The World Commission on Economic Development, and its meaning is "development that meets the needs of the present without compromising the ability of future generations to meet their own needs".	(Development, 1987; Elkington, 1994; Kroll, Abebe, & Dadanlar, 2017; Shaker, 2015)
Rhetoric	The art of persuasion by words and has a long history in the humanities; it can overpass logic as a mode of assessing truth by reflecting message source's implicit intension and consequent actions.	(Aristotle, 1991; Burke, 1969; Kennedy, 1991; Richards, 1936; Searle, 1995; Suddaby & Greenwood, 2005; Zald, 2008)
Legitimacy	A generalized perception or assumption that the actions of an entity are desirable, proper, or appropriate within some socially constructed system of norms, values, beliefs, and definitions.	(Suchman, 1995)
Organizational Legitimacy	Organizational legitimacy refers to the extent to which the array of established cultural accounts explains organizational existence .	(Castelló & Lozano, 2011; R. W. Scott & Meyer, 1983)
Environmental Violation	Thus, environmental violations are disciplined largely through legal and regulatory penalties, not through reputational penalties.	(Karpoff, Lott, Jr., & Wehrly, 2005)
Business Model	Is a strategic management tool, a combination of material, existing structures and processes at a business organization to improve a company's value chain.	(Tikkanen, Lamberg, Parvinen, & Kallunki, 2005)
Sustainable Business Model	Are traditional business models with incorporated concepts, principles, and goals aiming sustainability, among integrating it in their value proposition, creation and mechanisms.	(Geissdoerfer, Vladimirova, & Evans, 2018)
Corporate Social Responsibility (CSR)	Contains some other constructs such as: corporate citizenship, issues management, and cause-related marketing, and goes beyond the compliance with the legal and basic moral rules of society.	(Montiel, 2008; Palazzo & Richter, 2005)
Entrepreneurship	Involving unique individuals who create value by engaging in the discovery and exploitation of profitable opportunities (Shane and Venkataraman, 2000: 217).	(Gartner, 1990; Ruebottom, 2013; Shane & Venkataraman, 2007)

THEORETICAL DEVELOPMENT/MODEL

Neo-Institutional Theory (NIT): a mean to reach sustainability in young firms

Institutions are embedded and influenced in an open system, exposed to external environment with resources exchanged with other entities, additionally, institutions can be bigger than organizations (W. R. Scott & Davis, 2007). Furthermore, institutions are the rules of the game and organizations are the players (North, 1990); even more important, the specific institutional constraints dictate the margins at which organizations to operate, shaped by broader social-political-cultural processes, and hence make intelligible the interplay between the rules of the game, institutional elements, and the behavior of the actors, institutional agents such as government and professions (North, 1990; W. R. Scott & Davis, 2007). Neo-Institutional Theory (NIT) present a guise with a bold argument: Organizations structures are far from reflecting the forces of task demands and competitive/efficiency requirements, Organizations are more responsive to a set of social-cultural pressures (Dimaggio & Powell, 1983; Meyer & Rowan, 1977; W. R. Scott & Davis, 2007) in this case to embrace sustainability. NIT main supporting pillars are legitimacy and isomorphism (Dimaggio & Powell, 1983; W. R. Scott & Davis, 2007; Suchman, 1995), and both become important at firm level since after implementing a norm or practice, the path that the norm's implementation path follows is: isomorphism, later to conform, this leads to legitimacy, and ultimately leads to resource acquisition (Meyer & Rowan, 1977; Suchman, 1995). Likewise, according to NIT, the resources provision depends on firm's legitimacy levels in an open system such as the institutional environment (Dimaggio & Powell, 1983; Suchman, 1995). As a result, in order to implement a corporate sustainable strategy, a firms need to review and assess the industry structure and norms initially, then the intended strategy to implement within the institution, and finally the expected performance (Dimaggio & Powell, 1983; Hart, 1995; Porter, 1981).

Moreover, NIT focus on how social influence toward conformity shapes organizations' actions, makes local firms to engage in environmental innovation given the regulatory pressures from governments, and normative pressures from non-governmental organizations such as activist (Berrone et al., 2013). Precisely, sustainability practices can develop systematic approaches at different levels that can be defined as sustainable business models (SBM) (Stubbs & Cocklin, 2008) in particular social enterprises, business models that aim at social impact by generating profits from economic activity or reinvesting them entirely (Defourny & Nyssens, 2010).

Young firms' resources acquisition to embrace sustainability challenges

Precisely, strategic and dynamic resources and its attainment is what a firm, particularly young entrepreneur firms, need to sustain a competitive advantage and subsequently have positive financial performance and success in a Schumpeterian economy (Barney, 1991; Dierickx & Cool, 1989; Eisenhardt & Jeffrey, 2000; Moore & Manring, 2009; Priem & Butler, 2001; Teece, Pisano, & Shuen, 1997). According to Bansal (2005), Resource-based rationales adopts corporate sustainable development (CSD) due to its firm influence (Hart & Ahuja, 2002; Waddock & Graves, 1997), substantial investment in capital and human resources (Sharma & Vredenburg, 2002), among changes in technology, legislation, market forces, and in a fast pace or Schumpeterian world with innovation-based competition and creative destruction of existing competences (Eisenhardt & Jeffrey, 2000; Porter & van del Linde, 1995; Teece et al., 1997). Among resources, some other factors are needed to impact venture subsequent growth such as goals, self-efficacy, and communicated vision, these mediated effect of passion, tenacity and new resource skills (J. R. Baum & Locke, 2004). Additionally, three firm motivations are required to take ecological responsive initiatives such as: competitiveness, legitimation, and ecological responsibility, these induced by field cohesion, issue salience, and individual concern (Bansal & Roth, 2000). Embed these efforts and practices, Bansal (2005) proposed three principles of sustainable development need to be included such as: *environmental integrity*, human activities do not erode the earth's land, air, and water resources through environmental management; *social equity*, all members of society have equal access to resources and opportunities by having social responsibility; and *economic prosperity*, a reasonable quality of life through the productive capacity of organizations and individuals in society and create value.

Nonetheless, multiple challenges need to be faced when adopting and embracing sustainability (Epstein & Buhovac, 2010) and the natural-resource-based view theory proposition offers a connection between the environmental challenge and firm resources operationalized through three interconnected strategic capabilities: pollution prevention, product stewardship, and sustainable development (Hart, 1995). This is supported by Sustainable, ethical, entrepreneurial (SEE) enterprises since they are seeking to regenerate the environment and drive positive societal changes rather than only minimizing harm (Markman, Russo, Lumpkin, Jennings, & Mair, 2016); and sustainability-oriented innovations (SOIs), that is, the integration of ecological and social aspects into products, processes, and organizational structures, are increasingly recognized as central contributors to sustainable development particularly in SMEs (Klewitz & Hansen, 2014).

Rhetoric and Sustainability

Rhetoric has been identified as a key tool in building legitimacy (Suchman, 1995). Likewise, a rhetoric perspective and perception can be gained by using legitimacy language, specifically using the conventional positive protagonist and the negative antagonist characters, having an impact on agents working for the firm, and the introduction of new ideas within it (Ruebottom, 2013). Furthermore, if the firm wants to implement as a strategy to implement new ideas to the corporation, a rhetorical strategy, persuasive language to build congruence, needs to be followed (Suddaby & Greenwood, 2005). Additionally, research indicates that rhetorical strategy and language per se has been underused and it can be developed as a core competency by entrepreneurs to pursue stakeholders (Ruebottom, 2013).

Three rhetoric types can be implemented: strategic, uses the scientific-economic paradigm; institutional, based on corporate social responsibility; and dialectic, improves the fuzzy communications channel between firms and stakeholders (Castelló & Lozano, 2011). And within those strategies, two main elements that needs to be present are institutional vocabulary, which means words that have a meaning and reference to the institutional logic, history and professionalism; as well as theorization of change by those characters who are proposing innovation changes and scenarios for firm's improvement, the five types of this kind of changes are: teleological, historical, cosmological, ontological, and value- based (Suddaby & Greenwood, 2005).

Moreover, by using rhetoric, entrepreneurs can use these strategies to create symbolism to connect new ideas to established cultural framework (R. W. Scott & Meyer, 1983), additionally, entrepreneurs can use rhetoric and their sensemaking ability to penetrate existing cultural schemas with cognitive legitimacy (Suddaby & Greenwood, 2005; Van de Ven & Garud, 1993). It would be appropriate to remember that entrepreneurs are looking to disrupt major institutions and create their own systemic change and vision (Ruebottom, 2013; Suddaby & Greenwood, 2005). These entrepreneurs' rhetoric and persuasion skills can be used to implement their vision and schema about sustainability in any realm they have penetration and governance. One example would be social enterprises, since they are the first mode of organization to respect natural system ecologies providing theoretical foundation for sustainable rhetoric in new small firms that has proliferated within the latest decades (Trexler, 2014). Moreover, social entrepreneurs who use rhetoric compel industry members to trend to adopt new practices, including sustainability (Markman et al., 2016; Waldron, Fisher, & Pfarrer, 2016). And precisely with sustainability, its corporate rhetoric needs to be maintained from journey from storytelling a metaphor to argument that sustainability has been achieved, contrary to common believe that this rhetoric is a one-time action (Ihlen, 2014; Ihlen & Roper, 2014; Milne, 2015),

Environmental violations leading to sustainability

In the corporate world a firm perceives that severe legal penalties and castigations are enforced against an environmental laws violator, other companies within the same industry truly learn and respond by themselves in order to be sustainable compliant, creating isomorphism inside their members (Deephouse, 1996; Thornton, Gunningham, & Kagan, 2005). This is because this general deterrence develops a perceived threat of legal punishment and reassurance that compliance is essential and reliable for those firms (Thornton et al., 2005). Furthermore, firms that violate environmental laws are hurt with substantial losses in the market value of firm's equity and profit (Karpoff et al., 2005); media attention can play an important role since it can expose enviromental efforts or issues that can lead to a institution-building process, shape the norms for acceptable and legitimate sustainable development practices (Bansal, 2005). However, pollution violation regulatory punishment by governments is the main pillar that sustains each developed economy country environmental policy, giving policy-makers a key role to develop effective pollution regulations, inspections and sanctions (Gray & Shimshack, 2011).

Likewise, complying with the society, not only with law regulations, becomes critical since negative publicity related to environmental harm potentionally can triggered corporate isolation with the firm's host community, leading to evil firm's visibility, market share loss, and future more closer and scrutinious inspections by regulators (Bansal, 2005; Thornton et al., 2005); creating a "good soldier" behavior within corporate stake and shareholders (Bolino, 1999; Thornton et al., 2005). This mimetic and normative isomorphism of sustainability image and behavior improvement, resulting in a enriched reputation, needs to be well-defined and inspected since it can be developed only as impression enhancement and self-serving (Bolino, 1999; Dimaggio & Powell, 1983); these practices can lead to a concept named: "greenwashing" and it is being used mainly to respond to negative media coverage and outsider stakeholders, such as organizations and government, that demand fundamental corporate conduct sustainable changes and business practices, but multiple times are only representative (Bansal, 2005; David, Bloom, & Hillman, 2007; Greer & Bruno, 1996; Kim & Lyon, 2015; Kroll et al., 2017; Meyer & Rowan, 1977; Thompson, 1967).

Young entrepreneurs' firm's performance by adopting sustainable rhetoric business model

Figure 1 below present and proposed a theoretical model that converges sustainable rhetoric among young entrepreneurial firms and its performance; as well as two factors that moderate positively such performance as low frequency of environmental violations, and high presence of activism; mediated by organizational legitimacy in order to reach firm's performance.

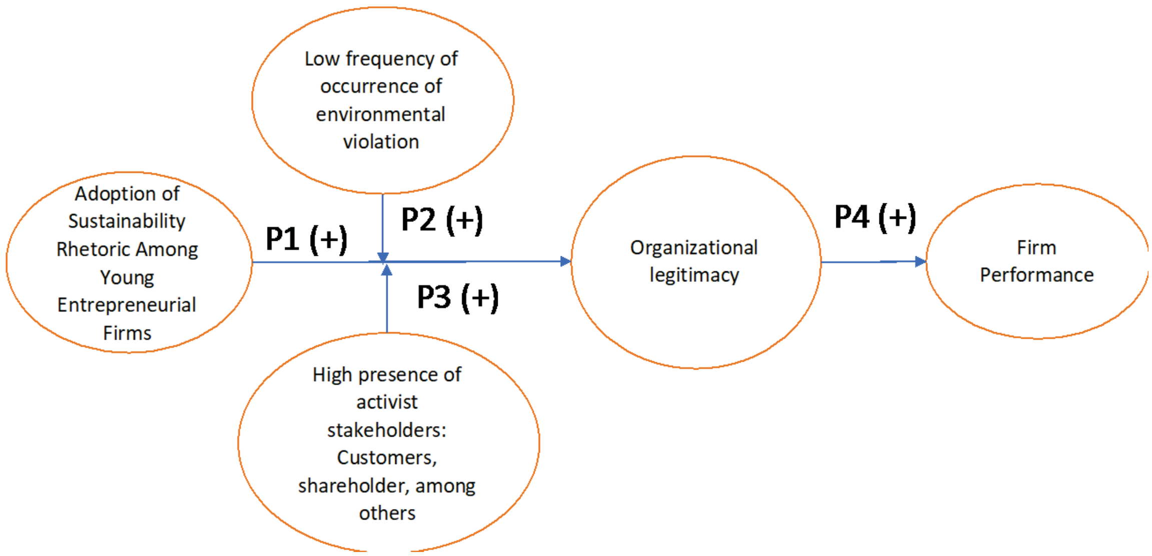

Figure 1 - Sustainable Rhetoric Adoption as Firm Performance Enhancer Model

Sustainability rhetoric adoption and its bond to organizational legitimacy

Rhetoric studies can be perceived as a superficial speech that can be given by a leader in order to persuade subordinates for their action; however, these studies are concerned with capturing the deep structure or the implicit categories of meaning (Berg, 2004; Castelló & Lozano, 2011). Furthermore, the rhetorical devices capable to create a positive narrative in order to produce a protagonist theme and finally organization legitimacy are: Contrastive typecasting, presenting a contrast between positive protagonist and a negative antagonist; Problematizing and theorizing, why the protagonist achieve those outcomes; Alignment, aligning supporters; and Evaluative Statements, must be positive and emphatic for the protagonist (Ruebottom, 2013).

Defining social enterprise is quite difficult since multiple authors, scholars, companies, among other have significant differences in its definition, however, one general conclusion is that it is an enterprise that its self-sustained and its profits benefit its members and their community (Trexler, 2014). This definition becomes important since the leaders of those enterprises, social entrepreneurs, facilitate the adoption of new industry practices including sustainability and ethics since the moment a company is conceived, and that leadership action is being pushed by using a rhetoric (Waldron et al., 2016). Furthermore, the psychological research to date has established that knowledge structures affect information processing in predictable ways and information environment can be interpreted and represented, or used as rhetoric, as knowledge structure that can be used to create consequences or impact at organizational level (Walsh, 1995). This reality interpretation or sensemaking, through leaders vision implemented by a rhetoric tactic, helps to extend and execute business practices (Markman et al., 2016; Waldron et al., 2016). The previous statement has been tested successfully by Thomas, Clark, & Gioia (1993) who investigated the strategic "sensemaking" processes of scanning, interpretation, and action and how those activities are linked to organizational performance; one of the main findings were that high information use strongly influences strategic interpretation, attention to a wide array of information tends to influence the interpretation of strategic issues positively. Even though, rhetoric techniques and persuasion are a great vehicle to move entrepreneurial firms to organizational legitimacy and finally to improve firm performance, those techniques depend on firm logics, norms, and differences between advocates and incumbents (Markman et al., 2016). Based on the above arguments, the following proposition has been conceived:

P1: Adoption of sustainability rhetoric drive firms to organizational legitimacy

Reduction in environmental violations improves legitimacy in a firm

Environmental violations becoming public affects firms reputation, as a consequence reputation repair following past noncompliance, can create organizational motivation to embrace sustainability, resulting in social legitimacy and reputation improvement and credibility at corporate level (Bansal, 2002; Hart, 1995). Furthermore, there is empirical evidence that propose that monitoring and enforcement are significant factors to prevent pollution, reduce emissions, and improve environmental compliance at firms, even those with high compliance levels, among generating substantial specific deterrence and reducing future violations (Gray & Shimshack, 2011).

Firms strategically respond to institutions such as government, professional associations, and particularly media, acknowledging that by complying with those institutions norms, it would provide access to resources (Bansal, 2005; Oliver, 1991; Suchman, 1995). Specifically, media coverage creates firm's visibility, resulting in more public attention and scrutiny, that in case of negative reviews, this coverage can be coercive pressure to implement sustainability and can erode firm's legitimacy (Bansal, 2005; Dimaggio & Powell, 1983). Thus, extrapolating the improving reputation by reducing environmental violation principle to SMEs, becomes an incentive for young entrepreneurial firms to optimize sustainability for the following reasons (Moore & Manring, 2009):

- Becoming valuable sustainable investment targets for larger firms;
- Creating highly competitive networks of sustainable SMEs in market spaces where large enterprises are less successful;
- Becoming highly efficient suppliers in global supply chains through sustainable practices.

One sustainable business model practice than can improve environmental reputation and obtain legitimacy is technological innovation (Boons & Lüdeke-Freund, 2013), this is helpful since is critical renewing competences to achieve good performance in a changing business environment (Teece et al., 1997). This model consist in offering current products in new selling and distribution ways, in order to reduce carbon footprint, for example the new internet based giant retailer: Amazon; the main challenge is convincing current customer about the innovative system that will make their products arrive to them (Boons & Lüdeke-Freund, 2013). Research shows eco-innovation is stronger than innovation from a dimentions economic, social and environmental on SMEs (Klewitz & Hansen, 2014). Based on the above arguments, the following proposition is stated:

P2: Frequency of occurrence of environmental violation moderates positively organizational legitimacy

Activist stakeholders push sustainable rhetoric in order to improve firm's legitimacy

Stakeholders theory is defined as an organizational management and business ethics that addresses morals and values in managing an organization (Hörisch et al., 2014). Furthermore, multiple parties around the firm are considered stakeholders such as employees, customers, suppliers, investors, communities, government, political groups, trade associations and unions, even competitors (Freeman & Reed, 1983); these organizational and societal actors, in addition to corporate governance and sustainability disclosure policies can function as legitimacy instruments for the firm (Michelon & Parbonetti, 2012). Particularly, stakeholder's activism may pull the firm in towards adopting sustainable practices, resulting in multiple times in stakeholders benefits such as return for invertors solutions as well as to preserve ecosystems and promote social equity (Sharma & Henriques, 2005); however, this relationship can create stakeholders dependency with activist stakeholders and even activist shareholders, the most appropriate strategy to handle dependency is: Direct-withholding influence strategy (Sharma & Henriques, 2005). Furthermore, stakeholder management proposed that by having transparent operations, representing stakeholders' interest in decision-making, and distributing the value created by firms equitably among all relevant stakeholders, relationship with stakeholders can be built strongly (Bansal, 2005). For instance, many sustainable entrepreneur firms increasingly engage with external stakeholders, especially, suppliers, buyers, NGO's and activist with the firm purpose to shape young entrepreneurial firm's policies (Markman et al., 2016; Waldron et al., 2016). Additionally, with no stakeholders legitimacy, a firm might have some issues to continue operating and its grow can be limited (Castelló & Lozano, 2011).

Sustainability strategies create many synergistic effects for SME's working collaboratively, as well as systemic benefits for the stakeholders in the value chain such as highly efficient suppliers, industrial ecology, enterprise resilience and global supply chain sustainability (Moore & Manring, 2009); additionally, this business social engagement looks for co-creating and co-engaging startups in create value by innovation and scalation (Crossan & Apaydin, 2010). Constant stakeholders inspection and audit along the value chain, particularly in developing economies countries producing low cost products for developed economies countries, need to be performed in order to be conscious about manufacturing socially undesirable products and not to involve with unethical partners, for example employing child labor (Bansal, 2005). Based on the above arguments, the following statement is being propositioned:

P3: Presence of activist stakeholders' moderates positively organizational legitimacy

Developing legitimacy at the firm enhance performance

The rise of institutional norms, either formal or informal, and social constructed practices is being supported by environments and environmental domains which have institutionalized a greater number of rational myths generate more formal organization (Meyer & Rowan, 1977). As a consequence, institutional rules function as myths which organizations incorporate, gaining legitimacy, resources, stability, and enhanced survival prospects (Meyer & Rowan, 1977) and organizations look similar overtime through Coercive, mimetic, or normative isomorphism (Tolbert et al., 1983). This explains how firms and organizations are being structured, and it is counterintuitive in the sense that decision at corporate level are not made rationally, multiple times decisions are made with the firm objective to imitate and copy what either competitors or some other similar firms are developing and deploying in the market with no logical or rational reason (Dimaggio & Powell, 1983; Meyer & Rowan, 1977; Suchman, 1995; Tolbert et al., 1983). This principle can be though that only applies to established firms, however, young organizations have a higher propensity to die than old organizations if they don't follow similar approach (Stinchcombe, 1965). Research shows support for the external legitimacy than for the internal coordination process and lack of institutional support are prominent underlie the liability of the newness (Singh, Tucker, & House, 1986).

Legitimacy becomes a critical resource because it can bring capital, human, among other important resources to young firm'x, as a consequence those resources can enhance firm's financial performance (Meyer & Rowan, 1977; Suchman, 1995). Moreover, firms of any size always try to be innovative when it comes to seek new forms of legitimacy (Castelló & Lozano, 2011; Palazzo & Scherer, 2006). That hypothetical limit expansion would be given by a bundle of resources that would remain until the enterprise reach its full potential (Lockett, Thompson, & Morgenstern, 2009), developing strong relationships along the supply chain all firm's stakeholders such as suppliers, distributors, wholesalers, retailers, even customers (Muratcan, Kaynak, & Montiel, 2015). Based on the above arguments, the following proposition is stated:

P4: Organizational legitimacy leads to firm performance.

DISCUSSION AND IMPLICATIONS

The combination of rhetoric adaptation framed by NIT for SME's can result on a proper channel of proliferation of sustainability in young entrepreneurial firms. Additionally, the power of narrative style is an potential powerful strategy when implementing changes within or around the corporation, particularly for entrepreneurial endeavors that need to be exposed (Ruebottom, 2013). Furthermore, during the last decades where NIT has accentuated the requirement or need to comply with external pressure, from either stakeholders or peer companies, to adapt industry rules and norms (Berrone et al., 2013; Dimaggio & Powell, 1983; Meyer & Rowan, 1977). Moreover, firms are ambitious of legitimacy with multiple stakeholders and this can be achieved through isomorphism that can be motivated by either intrinsic or extrinsic factors (M. Høgevold et al., 2014).Similarly, the role of rhetoric in successful implementation changes cases in corporations has its contribution, however, it needs to take in count that this rhetoric has its own interaction with some other dynamics around the firm (Suddaby & Greenwood, 2005). Dynamic capabilities are necessary, but not sufficient, conditions for competitive advantage (Eisenhardt and Martin, 2000).

However, rhetorical strategies often have some "missing parts", or enthymemes in a rhetorical syllogism context, and ideas or directions are only partially expressed; and the audience has to complete those enthymemes and its logic (Castelló & Lozano, 2011). This can lead to have a rhetoric ideational bricolage that can be manipulated to support controversial initial changes or modifications in a firm (Ruebottom, 2013), particularly in an start up with limited amount of employees. Within rhetorical tactics implementation and in order to make and give sense at startups, two cognitive structures need to be present such as identity and power, both affect how messages are framed to persuade social entrepreneurial firms to adopt new practices as well as how these firms customize messages related to the new practices (Markman et al., 2016; Waldron et al., 2016). These has been probed by Berrone, Cruz, Gomez-Mejia, & Larraza-Kintana, (2010) when they compared family and nonfamily corporations; these finding indicated that family-controlled firms have better environmental practices adoption predisposition to engage in substantive institutional compliance with environmental regulations depending on external stakeholders, such as government or customers, compared with those with nonfamily nature. For social entrepreneurs who seek to change existing community practices, the difficulties in building legitimacy may pose a challenge that compromises their ability to create sustainable institutional change by using rhetoric.

Additionally, greater environmental regulatory and normative policies can pull and influence corporations to embrace sustainability innovation; however, this needs to be systematically and gradually since these kind of organizational changes can overwhelm the current corporate structure creating a temporary increase in hazard organizational failure (Hannan & Freeman, 1984). For these implementation changes and introduction of new ideas, rhetoric perspective can help in order to keep a positive narrative within the firm (Ruebottom, 2013).

Implications for Research:

Stakeholders are entities that can enable resources and alternatives for learning about massive organizational changes such as implementing and integrating sustainability into firm's business model, this in order to obtain credibility and legitimacy (Arevalo et al., 2011). Furthermore, stakeholders need to have empirical foundations in order to implement any corporate sustainable responsible development model coming from research development stages (Arevalo et al., 2011; Harrison & Freeman, 1999; Palazzo & Richter, 2005). Likewise, stakeholder rhetoric represent a future research that would demonstrate the effectiveness of the protagonist/antagonist rhetorical strategy (Ruebottom, 2013), particularly those with multiple influence in a firm, and mainly in a young entrepreneurial firm. Probably, digging into the stakeholder's area, research as well needs to be done about stakeholders' heterogeneity since there is little known about principals' motivators, preferences, and values influencing the firm for institutional demands (Berrone et al., 2010; Birkin, Polesie, & Lewis, 2009). Firm's stakeholders need to recognize the value of the ecosystem, and understand that is an issue that has social, economic and policy dimensions (Sukhdev, 2011).

On the other hand, the role of culture has not been directed properly when reviewing rhetoric and corporations, finding only a few literature related (Conaway & Wardrope, 2010). This phenomenon is even more rare for that rhetoric including the constructs entrepreneurship and sustainability. An example of this are the high cultural complexity found in Latin-American rhetoric activity contained in CEO's annual reports compared with American corporations (Conaway & Wardrope, 2010). Likewise, finding empirical evidence related to forms and processes of legitimacy-building relations in CSR is a problem for researchers (Castelló & Lozano, 2011; Palazzo & Richter, 2005).

Implications for practice:

Firstly, corporations are using their annual report as a rhetoric strategy with narrative presentation and style, keeping accuracy, clarity and honesty, to convince stakeholders that they are improving in CSR activities (Castelló & Lozano, 2011; Conaway & Wardrope, 2010; Suddaby & Greenwood, 2005). This kind of reports is important in order to gain legitimacy has been confirmed by research in different cultural environments (Conaway & Wardrope, 2010). For that reason, if entrepreneurs are looking for legitimacy in order to obtain resources and firm performance, they need to add rhetoric to their main activities. Similarly, embracing and working with sustainability can provide revenue opportunities, cost savings and risk mitigation (Ihlen, 2014).

Secondly, rhetoric needs to include that natural resources are limited and they should not be taken for granted under any circumstance by any corporation independently of their size (Sukhdev, 2011). In addition, shared economy needs to be embraced in order reduce emissions and operational cost, among boost innovation, especially for production and consumption of goods and services firms (Heinrichs, 2013). These two propositions can be used to promote between startups young firms a rhetoric of low initial capital investment, and at the same time embrace sustainability with environmental management systems while they are growing up, besides commit those entrepreneurial firms to engage in an eco-efficiency model that can provide product stewardship to minimize environmental impacts on the product life cycle (Bansal, 2002). Moreover, this rhetoric to stakeholders needs to include in its vocabulary sets arguments such as: opportunities; risk; creativity and creation; passion, dedication, and importance of the people and multiple human resources; early stage products and spin-offs (Ruebottom, 2013).

Finally, an important, and strong, advice for corporations would be to use rhetoric to embrace sustainability in a short term; however, being accountable in social and environmental issues will help in the medium and long term (Ihlen, 2014).

CONCLUSION

Sustainable development is still under development, and trying to convince multiple audiences in order to being adopted as a daily basis task without leaving human needs fulfilment and most importantly respecting the environment is not an easy endeavor (Lorek & Spangenberg, 2014). This paper explored and analyzed if the adoption of sustainability rhetoric in entrepreneurial firms can help to obtain organizational legitimacy, thus, achieve high firm performance by having low frequency of environmental violations (Gray & Shimshack, 2011; Karpoff et al., 2005) and high present of stakeholders (Freeman & Reed, 1983; Harrison & Freeman, 1999) as moderators. As a result of this analysis, it can be seen that effectively, adopting a sustainability rhetoric, by using the tenets of neo-institutional theory (Castelló & Lozano, 2011; Dimaggio & Powell, 1983; Ihlen, 2014), can lead to obtain legitimacy, particularly critical in entrepreneurial firms (Ruebottom, 2013; Singh et al., 1986; Suddaby & Greenwood, 2005), and finally achieving firm performance. Furthermore, corporate rhetoric needs to formal and informal in order to convince firm's internal and external stakeholders about future plans, specifically, embracing sustainability.

ABSTRACT

Organizations are often unclear how to transform themselves from a traditional supply chain management to a green supply chain model. We interviewed several suppliers to design a transformation process. We illustrate a seven-step model ground in Stakeholder Theory on how those suppliers transformed themselves to be a green supplier.

KEYWORDS: Green supply chain, management, transformation, model

INTRODUCTION

Technological advances and intensified global competition in the market for products and services have contributed to numerous studies in examining the effectiveness and efficiency in supply chain management. Green supply chain management (GSCM), a concept that attempts to address these environmental concerns and efficiency improvements in supply chain processes, have been the subject of many recent studies. Due to environmental concerns, regulators, communities and employees, are demanding efficient actions from firms (Paulraj et al., 2017). Moreover, there is a consistent growth in the evaluation of green supply chain management practices and performance (Tseng, Islam, Karia, Fauzi, & Afrin. (2019).

Because of the growing awareness regarding environmental sustainability issues by consumers it is becoming important for manufacturers to adopt green supply chain management practices to remain competitive. The environmental awareness of customers has pushed manufacturers to adopt cleaner production techniques and implement GSCM practices. Mathiyazhagan, Govindan, Hag & Geng 2013). GSCM activities not only have to be adopted within the organization but in addition need to be coordinated with suppliers and customers (Green, Zelbst, Meacham & Bhadaurin, 21012).GSCM can result in improved organizational performance, Past studies have shown that the adoption of GSCM practices leads to better performance particularly economic performance. These improvements are across all size organizations and industries. The improved economic performance is because of better sales, profits, and market share. Other potential benefits of GSCM are better operational efficiency with reduced energy consumption lower scrap rates and inventory levels. (Geng, Mansoiuri & Aktas, 2017).

In 1989, Walmart launched one of the first major retail campaigns to sell environmentally safe products in recyclable or biodegradable packaging. The corporation promoted these eco-friendly products by labeling them with green-colored shelf tags. The idea was to improve the company's impact on the environment through a commitment to three ambitious goals including 100 percent renewable energy, zero waste, and sell products that sustain the resources and the environment (Scott, 2005). Walmart also cultivated deeper relationships with its suppliers in addressing the environmental concerns. In the past, retail textile buyers selected manufacturers based on the cost and quality of their products. Walmart, however, interacted with suppliers, more often, more directly, and for a greater duration than ever before. These closer relationships were necessary to sustain initiatives like the organic cotton project (Plambeck & Denend, 2008).

Walmart has forged ties further upstream to become more efficient and to reduce costs. The company used to buy cotton from Turkey, ship it to China for spinning and knitting, and then ship it again to Guatemala to be cut and sewn. Recently, they are finding opportunities to eliminate the shipment to China and have all processing done in Guatemala. Going directly to Guatemala not only saves time and money for Wal-Mart, but also further reduces the company's impact on the environment by lessening the amount of fuel and other resources used in shipping (Plambeck & Denend, 2008). According to Plambeck and Denend (2008), at the heart of Walmart's business sustainability strategy is a shift from generating value through price-based, transactional interactions toward generating value from longer-term, collaborative relationships with nonprofits, suppliers, and other external stakeholders. Through its sustainable value networks, Walmart gains a whole-system perspective that helps the retailer find profitable ways to address environmental issues such as fishery depletion, climate change, and pollution. Walmart set the goal of a 5 percent reduction in packaging by 2013. It has been widely reported that the retail giant expects the cut in packaging will save 667,000 metric tons of carbon dioxide from entering the atmosphere.

With increasing consumer awareness and regulatory compliances, organizations with GSCM practices will have a competitive advantage over others who are either lagging or reluctant to embrace GSCM. Many organizations are reluctant because they are not convinced how to deploy GSCM in ways that can benefit them from their desired cost savings and creation of value. An earlier study (Beamon, 1999) recognized five issues of environmental management in GSCM. The first issue is how to find out the environmental factors driving the green supply chain. The second is to understand the differences between the traditional supply chain and the green supply chain. The third is to understand the risks arise from practicing the green supply chain. The fourth is how to measure the performance for the green supply chain and the final problem is to develop a process that would create an effective green supply chain.

This paper illustrates how companies must collaborate and partner with their suppliers in order to produce a more effective green supply chain process. A seven-step model, grounded in the theoretical perspectives of the Stakeholder Theory, is developed to illustrate how suppliers can transform themselves from a traditional supplier to be a green supplier.

LITERATURE REVIEW

Since Carter and Rogers (2008) introduced the concept of sustainability —the integration of environmental, social, and economic criteria that allow an organization to achieve long-term economic viability —the environmental concerns in supply chain have received more attention in the literature and in business in recent years. Green supply chain has recently received much attention among researchers and practitioners of operations and supply chain management and has been the subject of numerous extensive studies in recent years due to environmental concerns and awareness. In a traditional supply chain process, the resources from suppliers are used by the manufactures to produce and sell products to retailers and consumers (Beamon, 1999). But the green supply chain would integrate the environmental elements into the supply chain process, and the goal is to address the influences and relationships between supply chain management and the natural environment. This would enlarge the consideration of whole manufacturing process to relate and include environment influences by products. For example, in April 2010, IBM announced that it will require its 28,000 suppliers in more than 90 countries to install management systems to gather data on their energy use, greenhouse gas emissions and waste and recycling. Those companies in turn must ask their subcontractors to do the same if their products or services end up as a significant part of IBM's $40 billion global supply chain. The suppliers must also set environmental goals and make public their progress in meeting those objectives (IBM. 2009).

Traditionally, environmental management in business has been limited to complying with the environmental laws and regulations, and their financial consequences. However, environmental awareness has been associated with competitive advantage in business, particularly when the companies taking a constructive approach to environmental issues, look beyond their current process to find and eliminate sources of waste. in this approach, the focus is on the value embodied in the product and process and maximization of the benefit attained from environmental initiatives (Walton, Handfield & Melnyk 1998). Still, there is another approach that integrate total quality environmental management (TQEM) into its planning and operations processes that includes not just executives and workers, but customers, suppliers, and neighbors (Makower, 1994).

Beamon (1999) explores Lamming and Hampson's definition of green supply chain as the environmental impact of the production process from the original resource to the end of the production including the disposal process. Zhu and Cote (2004) define the green supply chain as finding a 'win-win' strategy for both suppliers and distributors on marketing performance and environmental issues. In order to meet these requirements, the company needs to connect the suppliers to import environmental products.

Zhu and Sarkis (2004) notes various definitions of the green supply chain. Green, Morton, and New (1996) define it in the context of the environment in purchasing and innovations. Narasimhan and Carter (1998) define green supply chain as the activities that involve recycling, reduction, reuse, and substitution of materials. Godfrey (1998) defines the green supply chain as monitoring and improving environmental performance of the supply chain management. Messelbeck and Whaley (1999) assert that the green supply chain would be researching, developing, manufacturing, storing, transporting, and using a product, as well as disposing of the product's waste.

GREEN SUPPLY CHAIN BENEFITS

In the green world, every production process should meet the requirement of environmental protection policy. The public is aware that they need to protect the environment. In order to respond to the demands of the consumers and environmental groups, the manufacturers need to use any necessary means to improve the production flow process to reduce any pollution by any possible measure (Fiksel, 1996). On the other hand, the green supply chain needs to help the manufacturers to benefit from these changing processes. The companies could decrease the cost of the materials, maintenance, operation, and repairing by checking and investing the inventory operation. In addition, the companies could benefit from recycling materials and disposes products and decrease the risks to the workers' heaths by using environmental protection technologies during the production processes.

The benefits of green supply chain are much more than environmental protection. The green supply chain does not only provide the benefits by reducing hazardous wastes or purifying toxic water but also has the potential of sustainably social improvement, utilization of resources usage, and ethical perception development. Green supply chain provides both direct and indirect benefits. Direct benefits include reduction of air emission, waste water and solid wastes, decreasing of consumption for hazardous/harmful/toxic materials, decreasing of frequency for environmental accidents, improving an enterprise's environmental situation, decreasing of cost for materials purchasing, cost for energy consumption, fee for waste treatment, and fee for waste discharge, decreasing of fine for environmental accidents, reduction of cost of supply chain and cost of production, reducing cost of ownership of customer, and lowering resource consumption. On the other hand, GSCM gives indirect benefits on implanting the conscious of environmental protection, building up stronger connection among stakeholders, satisfying customer needs, and developing the relationship of society. Furthermore, a company should consider adopting of the green supply chain since the GSCM will give great benefits on customer relationship, resources management, cost reduction, product differentiation, competitive advantage, supply chain management, regulation and risk management, branding, return on investment, employee regulations, and ethics of business (Khiewnavawongsa and Schmidt, 2008).

THE GREEN SUPPLY CHAIN IMPROVEMENT PROCESS

The evolution to a greener supply chain is a continuous process with no final end point. Because it is an endless nature of becoming greener an appropriate method for developing a green supply chain is the continuous improvement methodology. Kazan or continuous improvement focusses on the reduction of waste and improving efficiency. The purpose of continuous improvement is to eliminate waste (muda) in all areas of an organization and the supply chain. Waste is considered anything that customers are not willing to pay for. (Bhuiyan and Bahel, 2005). Waste can take the form of pollution. With a continuous improvement process in mind, a seven-step model for greening the supply chain was developed.

The stakeholder Theory (ST) asserts that managers have a fiduciary duty not merely to the corporation's stockholders, but to the corporation's stakeholders— to those groups that are either vital to the survival and success of the corporation or whose interests are vitally affected by the firm (Smith & Hasnas, 1999). One of the four theories offered by Donaldson and Preston (1995) states that ST is managerial in that it recommends attitudes, structures, and practices and requires that simultaneous attention be given to the interests of all legitimate stakeholders. The seven-step model integrates the view of the stakeholders of a firm to develop a green supply chain strategy.
This seven-step approach was developed after interviews with business managers involved in the green supply chain process in companies located in Midwest US. The seven steps are listed below for transforming an organization's supply chain process to a greener or more sustainable supply chain:

- Calculate total cost of ownership and identify the green aspect of cost of ownership.
- Identify the touchpoints between product lifecycle and greening process;
- Evaluate all bases of touchpoints;

- Obtain “buy-in” from stakeholders;
- Develop green strategy for product lifecycle;
- Integrate (change management, process reengineering, and technology) and implement green strategy;
- Assess metrics and setup a continuous improvement process

Calculate Total Cost of Ownership and Identify the Green Aspect of Cost of Ownership
The first step in developing a greener organization is to document all the costs and causes of waste and pollution within the organization’s operations and supply chain. In conventional supply chains, the most visible costs are considered while ignoring less apparent costs, pollution, and waste. An example of this is when selecting a supplier only considering the purchase cost while not considering other less visible factors such as the environmental performance of the supplier. In a cost analysis, organizations would normally review all their purchases as a first step towards developing a strategic sourcing plan (Monczka, Handfield, Giunipero, & Patterson, 2014). In considering environmental aspects of purchases, all costs will be considered including not only purchase costs, but also the generation of waste and pollution. All steps and activities in the supply chain need to be considered and costs, waste, and sources of pollution identified. Once the costs and causes of pollution and waste are identified a plan can be developed to reduce the sources of waste and develop a greener supply chain in the following six steps.

Identify the Touchpoints Between Product Lifecycle and Greening Process
The second step in this process is to identify touchpoints or responsible parties in the supply chain. The product life cycle includes the introduction, growth, maturity, saturation, and decline stages. Touchpoints would include suppliers and logistics providers that could be sources of waste and pollution in those stages. This step identifies specific responsible parties where each source of cost and waste take place.

Evaluate All Bases of Touchpoints
Once the major touchpoints are identified each specific point is evaluated to see how it is responsible for costs, waste, and pollution. Possible changes that can be made to make the overall process greener are identified at each touch-point location. Touchpoint evaluations for example could identify alternative suppliers that are closer and require less energy costs for transportation.

Obtain “Buy-in” from Stakeholders
The next step is to identify and obtain buy-in from stakeholders that are impacted by the greening process. Stakeholders would include customers, suppliers, employees, stockholders, government agencies, and local communities. In this step the organization works with each of the stakeholders to make sure the stakeholder’s needs are met in the process of developing a greener supply chain.

Develop Green Strategy for Product Lifecycle
After working with each of the touch points and stakeholders the next step is to develop a holistic strategy for implementing a more greener supply chain and product lifecycle. Individual alternative changes to each of the touchpoints are evaluated for their impact on the performance of the whole supply chain. The basic principles of green strategy include repair, recycle, recover, repair, regeneration, remanufacture, reduction, and waste management (Glavic & Lukman, 2007).

Integrate and Implement Green Strategy
A detailed plan to transform the supply chain is developed based on information from all the previous steps. Change management, process reengineering, and technology strategies should be included in the integration. The transformation plan that includes those strategies should be implemented. Key metrics are developed and used to determine the effectiveness of the change. These metrics will serve as a yardstick to determine progress made in the supply chain transformation process.

Assess Metrics and Setup a Continuous Improvement Process
After changes have been implemented key measures are evaluated to determine the effectiveness of the transformation. Since this is a continuous process the organization returns to step 1 to develop further process improvements.

CONCLUSION AND FUTURE RESEARCH

We are planning to use qualitative research methods to analyze several consumer product manufacturing companies in Midwest. It focuses on five fields including materials used in product design for the environment, product design processes, supplier process improvement, supplier evaluation, and inbound logistics processes to find out the relationship between those processes.

A study by Cote, Lopez, Marche, Perron, and Wright (2008) examined three medium-sized companies in Burnside Industrial Park, Nova Scotia, and evaluated the challenges and opportunities for reducing greenhouse gas emissions and solid waste which are of significant concern to the Nova Scotia federal government. The study reviewed the procurement policies and practices of large corporations which serve as both suppliers and customers and the results show that time and financial resources are the greatest factors that limit many companies to employ environmental-based processes.

After analyzing the supply chain process for these companies, the paper shows that the design department and purchasing department should work together to make an environmental product from the resource directly because a lot of materials need to be concerned with the recycling issue and avoid any impact on the environment after producing the merchandise. We proposed that the company should use its purchasing power to influence the suppliers to let them evaluate their process into the green process. A qualitative study using the interview data is being planned.

LEVERAGING ONLINE SOCIAL RELATIONS TO IMPROVE THE DIVERSITY OF PERSONALIZED RECOMMENDATION LIST

(Full Paper Submission)

Xiaoyun He
Auburn University at Montgomery
xhe@aum.edu

ABSTRACT

Recommender systems typically focus on using accuracy as the key metric to evaluate the performance of the recommendations. However, recent studies suggest that recommending a diverse list of products enhances user satisfaction and is positively associated with customer retention rates. In this study, we propose to leverage the social relations of a user in an online environment to improve the diversity of personalized recommendation list. Our preliminary empirical results indicate that our proposed approach performs well in increasing the recommendation diversity while maintaining comparable level of accuracy.

KEYWORDS: social relations, the diversity, online recommendation, personalized list

INTRODUCTION

With the trend of consumers spending more time and money on online shopping than ever before, recommender systems have been widely used by online businesses to recommend products that are most likely to be of interest to users (Jannach et al. 2010). According to a Forrester Research report, one third of online customers that notice these recommendations wind up purchasing the recommended product (Mulpuru 2006). Given the increasingly intensive competition in online retailing, improving the quality of product recommendations becomes a critical factor for companies to gain sustainable advantage.

Traditional recommender systems have typically used the metrics such as accuracy and coverage to measure the performance of the recommendations (Adomavicius & Tuzhilin 2005). For example, the 1 million Netflix Prize (netflixprize.com) sought to substantially improve the accuracy of predictions about how much someone is going to enjoy a movie based on their movie preferences. However, recent studies have argued that the quality of recommendations should go beyond accuracy. As one of the goals of recommender systems is to provide a user with highly idiosyncratic or personalized items, more diverse recommendation list would result in more opportunities for users to be recommended such items (e.g., Adomavicius & Kwon 2009; Zhang & Hurley 2008; Zhang, et al. 2012; Ziegler et al. 2005). Park & Han (2013) find that recommending a diverse list of products enhances user satisfaction and is positively associated with customer retention rates. These, in turn, would lead to the boost of sales revenue and the bottom line.

In a nutshell, a basic recommendation method seeks to predict the 'preference' or 'rating' that a user would give to an item, such as music, books, movies, etc. that has not been seen by the user. A rating indicates how a particular user liked a particular item, e.g., Jane Betty gave the book ``Thinking, Fast and Slow'' the rating of 4 (out of 5). These ``particular'' recommendations are often referred as personalized recommendations (Kim et al. 2003). The task of personalized recommendation requires the ability to predict which items will be considered interesting by the user. The personalized recommendations have been viewed as an important source to assist and augment the natural social recommendation process - in our everyday life, we rely on recommendations from our social circles by word of mouth (Shardanand & Maes 1995).

The research on social relations and consumer decision making indicates that social influence is an important factor of affecting people's decision making and consumer decisions are best understood in the social contexts in which these decisions are made (e.g., Deutsch & Gerard 1955; Simpson et al. 2012). For instance, we tend to be influenced by our friends in terms of products purchase. Social influence not only occurs among the directly connected acquaintances, also propagates via the chain of online connections in a social network (Richardson & Domingos 2002). In addition, recent studies suggest that online social relations influence users' both product choices and ratings (e.g., He et al. 2017). Within an informal community of users and social context, it is therefore natural to incorporate the factor of social relations into recommendation model to enhance the diversity of the personalized recommendation list.

In this study, we utilize a data set collected from an online Web 2.0 site. The website integrates both online social networking and online product rating functions. In order to achieve recommendation diversity while keeping up with accuracy, we put more weight on the products rated by the focus user's social circle while limiting the degree of dissimilarity in user preferences. The preliminary empirical evaluation results show that our proposed approach performs in increasing the diversity while maintaining comparable level of accuracy in the recommendations.

LITERATURE REVIEW AND RELATED WORK

Collaborative Filtering based Recommendation Techniques

Over the past two decades, collaborative filtering techniques have been considered as the most commonly adopted in developing the recommender systems (Adomavicius & Tuzhilin 2005). These techniques rely on the past user behavior (e.g., their previous purchase transactions or product ratings) to predict what a user may like. The collaborative filtering methods can be generally classified into two categories: neighborhood-based methods and model-based methods.

The neighborhood-based approaches are centered on finding the relationship between users or, alternatively, between items. The initial form of neighborhood-based approaches is user-based (e.g., Herlocker et al. 1999). In the user-oriented case, the system predicts a user's rating based on the known ratings of similar users, i.e., the like-minded users. Later, an analogous item-based approach was proposed (e.g., Deshpande & Karypis 2004). In this case, a rating is computed based on past ratings made by the same user on similar items.

The model-based approaches typically involve two steps. First, training data consisting of past user-item ratings is used to train a predefined model. Then, the model is used to predict the unknown ratings. In this category, various models have been proposed, including clustering model (Merialdo 1999), latent semantic model (Hofmann 2004), ranking-based model (Liu & Yang 2008), to name a few.

Recommendation Based on Social Relations

Exploiting social networks to enhance recommendation performance has been studied by the researchers (e.g., Kautz et al. 1997; Guy et al. 2009; Liu & Lee 2010; Ma et al. 2011). Kautz et al. (1997) propose to build an interactive ReferralWeb system that uses social network to make recommendation / search more focused and effective. They argue that the referral chain arising from a social network enables the utilization of experts' expertise and the evaluation of trustworthiness of the expert. The explorative study in Guy et al. (2009) demonstrates a clear superiority of users' familiar network (e.g., being connected in a social network) over similarity network (e.g., having similar tastes as expressed in item ratings) as a basis for recommendation. Liu and Lee point out that their evaluation results on recommendations indicate that more accurate prediction algorithm can be developed by incorporating social network information into collaborative filtering (Liu & Lee 2010). Ma et al. (2011) propose a matrix factorization framework to include the social information as regularization terms into recommendation systems. The similarity between a pair of user in the social network is still based on the past ratings of the users. That is, the social information is based on users' similarity network.

The Diversity of the Recommendations and User Satisfaction

There has been considerable understanding that high recommendation accuracy alone does not necessarily provide users of recommender systems satisfying experience (Herlocker et al. 2004; Ziegler et al. 2005). As one of the goals of recommender systems is to provide a user with highly idiosyncratic or personalized items, more diverse recommendation list would result in more opportunities for users to be recommended such items (e.g., Adomavicius & Kwon 2009; Zhang & Hurley 2008; Zhang, et al. 2012; Ziegler et al. 2005). Diversification is defined as the process of maximizing the variety of items in a recommendation list. Diversity may refer to all kinds of features, e.g., genre, author, and other discerning characteristics (Ziegler et al. 2005). Park & Han (2013) find that recommending a diverse list of products enhances user satisfaction and is positively associated with customer retention rates.

Some recent studies have examined the principle of diversity to improve user satisfaction (Adamopoulos & Tuzhilin, 2015). For example, Ziegler et al. (2005) propose an approach that intends to balance and diversify personalized recommendation lists in order to reflect the user’s spectrum of interest. They show that the user’s overall liking of recommendation lists goes beyond accuracy and involves other factors, e.g., the user’s perceived diversity of the list. Hurley and Zhang (2011) argue that the motivation of diversity research is to increase the probability of retrieving unusual or novel items which are relevant to the user and introduce a methodology to evaluate their performance in terms of novel item retrieval. Adomavicius and Kwon (2009) define the concept of aggregated diversity as the ability of a system to recommend across all users as many different items as possible through a controlled promotion of less popular items toward the top of the recommendation lists while limiting the loss of accuracy.

RESEARCH CONTEXT AND METHODOLOGY

Research Context and Data

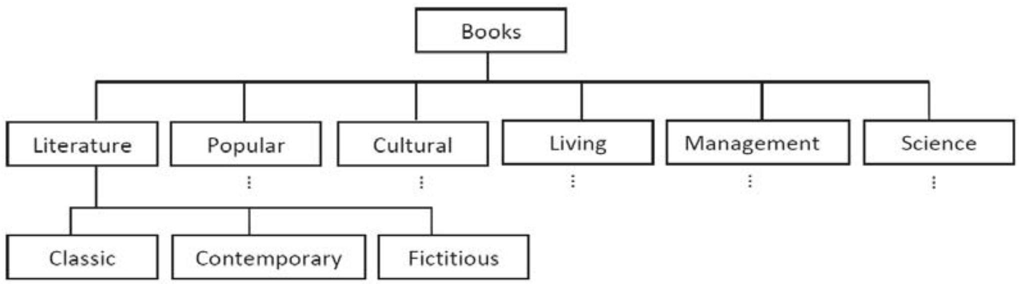
The data was obtained from a Web 2.0 site, which wishes to remain anonymous. The website offers the integrated social networking and online rating services to the users. It provides a unique platform for users to establish online social relations and to participate in rating and reviewing the products that they have consumed. The data of users' relationships establishment and rating participations generated from this platform enables us to empirically leverage the effects of online social relations so as to improve personalized product recommendation.

At the web site, a user may use a valid email address to register and create a screen name as the user identifier that is shown to the other registered users. The screen name does not have to be a user's real name, thus it offers certain level of anonymity. Over 95% of the registered users chose to use a screen name that is different from their real name. Registered users can rate and write reviews for specific product items. These ratings are available to be viewed by all other registered users. The products fall into one of three product categories - books, music, and movies. The rating scale is from 1 to 5 stars with 1 being the lowest and 5 being the highest level. In addition, the web site also supports online social network service that a registered user can choose to follow another registered user by simply clicking a "Follow" button. Unlike other well-known social networking sites such as Facebook or LinkedIn, the establishment of "following" relations does not need to be consented / invited by the followed user. Based on a survey of the registered users, about 87% of the respondents stated that they follow other users whom they do not know in person. In other words, the online "following" relations in this context are largely different from those in the physical offline world.

Consequently, different from the undirected social relations in a typical social network, the "following" relationships created at the website are directed, which forms a directed social network. Specifically, given a pair of users, namely user u_1 and user u_2, if user u_1 chooses to follow user u_2, then it represents that there is a directed link from u_1 to u_2. However, if user u_2 does not follow user u_1, then there is no directed link from u_2 to u_1. Then, user u_2 may have potential social influence on user u_1 in terms of product ratings and adoption. Such online social network can be modeled by a directed graph, where each node represents a user and directed links represent the established "following" relations between users. User at the tail follows the user at the head of arrow as a friend. The extracted data include the users' following relationships as well as review ratings.

The web site provides relatively simplified two-level hierarchical classification taxonomies for the product categories. For example, books are organized into 6 first-level categories - Literature, Popular, Cultural, Living, Management, and Science; each of these categories is further classified into second-level sub-categories. For instance, Literature is classified into Classic, Contemporary, Fictitious, and so on. See Figure 1 for a part of the taxonomy for books. Music is classified in terms of genre, country/region, artists, and year produced. Movies are classified in terms of genre, country/region, and artists.

Figure 1. A Sample Taxonomy for Books



The final sample data span the period from January 2008 to August 2011. The data that we used contain the following data sets: (1) Books: the rating data for books; (2) Music: the rating data for music; (3) Movies: the rating data for movies; (4) OnlineSN: the online social network that describes that “following” relationships among users including user identifiers and date when the relation was established. For each of the categories of items, the rating data include the following attributes: itemID (the specific item that was rated); userID (the user who rated the item); rating (an integer number between 1 and 5 assigned by the user to rate the item); date (when the rating was provided); (5) the taxonomies for books, music, and movies.

Proposed Approach

In this section, we first provide background knowledge and information model related to recommendation method that we use. Then, we discuss the detailed steps to generate the top-N recommendation list, including how social relations are leveraged to enhance diversity of the list while maintaining comparable level of accuracy.

Preliminaries and Collaborative Filtering Recommendation

For clarity and simplicity, we use the following notations to represent the various information. For the users, we use $U = \{u_1, u_2, \ldots, u_m\}$ to represent all the users. The list of product items are notated by $P = \{p_1, p_2, \ldots, p_n\}$. Each user u_i has a set of product ratings represented by R_i. Our approach utilizes the product taxonomy (see Figure 1. as a partial example) to create content-based user profiles. Such product taxonomy T is represented by $C = \{ c_1, c_2, \ldots, c_l\}$. Set T contains the categories of product classification. Graphically, the taxonomy has a tree structure. Each c_i represents the specific category that product p_i falls into. At the bottom of the product taxonomy, the category is the narrowest. From bottom up, the category becomes broader. For any pair of categories c_i and c_j $(i \neq j)$, $T(c_i) \cap T(c_j) = Ø$ holds.

In general, in order to discover like-minded users, we compute content-based user profiles that is consistent with the “collaboration via content” in recommendations (Ziegler et al. 2004). The similarity of the users are based on user profiles. Each user’s neighborhood with the most similar users is formed. The recommender focuses on products rated by those neighbors and generates top-N recommendation lists. The product ranking depends on the proximity of its classification categories with respect to a user profile. Specific details are provided in the next section.

The Steps to Generate Diverse Recommendation List

Below, we describe the detailed steps of our approach that leverages social relations to generate a diverse recommendation list while without losing much accuracy.

Step 1. Create user profiles. Traditional collaborative filtering techniques represent user profiles by the vectors of their product ratings. Then, the computation of the similarity between a pair of users is to apply Pearson correlation formula to their respective rating vectors. As our objective is to leverage the social relations to enhance the diversity of recommendations, we follow the work of Ziegler et al. (2004) to generate user profiles that are based on product taxonomy instead. Specifically, a user profile is represented by a vector of interest scores. Given a user u_i, the interest scores vector $sv_i = (sc_1, sc_2, \ldots, sc_l)$. Depending on the product categories in which the products rated by a user fall, each of the scores measures the degree of interest in a particular product category that the user has. Hence, the size of the vector sv_i equals to the number of distinct product categories in the product taxonomy, denoted by *l*. Score assigned to the upper-categories decays with increasing distance from leaf node in the taxonomy tree. To ensure a common scale, the user profile vectors are normalized to a fixed overall score *s*. In order to reflect the relationship between categories in the tree taxonomy, the interest score assigned to each of the product category along the tree path has to meet certain criteria. Given a category c_i, let $(p_0, p_1, \ldots, p_q)$ denote the path from its topmost super-category to its immediate super-category, then $\Sigma sc(p_m) = sc(c_i)$, where $0 \le m \le q$. In addition, the interest score $sc(p_m)$ depends on the score of its sub-category p_{m+1} and the number of its sub-categories, denoted by n_s. Specifically, $sc(p_m) = \lambda\ (sc(p_{m+1})/\ (n_s+1))$, where λ is a propagation factor to fine tune the process of profile generation.

Step 2. Form the neighborhood. First, for a given user u_i, a proximity measure is used to find the users that are most similar to u_i. Specifically, we use Pearson Correlation to compute the similarity between a pair of users, say u_i and u_j with the profile score vector sv_i and sv_j respectively. We use $SIM(u_i, u_j)$ to denote the similarity. Then, $SIM(u_i, u_j) = \Sigma(sv_k – M(sv_i))(sv_k – M(sv_j))\ /sqrt(\Sigma(sv_k – M(sv_i))^2(sv_k – M(sv_j))^2)$, where $0 \le k \le l$, and $M(sv_i)$ and $M(sv_j)$ are the mean value for vector sv_j and vector sv_j respectively. Because we normalize the user profile vectors, $M(sv_i) = M(sv_j) = s\ /\ l$. Values for $SIM(u_i, u_j)$ range from -1 to +1, where positive values indicate positive correlation, and negative values means negative correlation. For generic collaborative filtering, users who have rated many common products would have high similarity. In our case, as user profile generation is based on product taxonomy, a pair of users may have high similarity even though they have little or no common rated products. The more score values two profiles sv_i and sv_j have accumulated in the same paths of the taxonomy, the more similar they are. Then, the neighborhood of user u_i, denoted by $NB(u_i)$, is formed by including the top-M users based on the SIM values in descending order.

Step 3. Generate the diverse recommendation list. First, given a focus user u_i, if a product p_k is rated by one of u_i's neighborhood users derived from the previous step but not yet by the user u_i, then p_k is added to the candidate list. The relevance level of product p_k to user u_i is then computed. The relevance level may dependent on multiple factors such as the similarity between user u_i and the users that have rated p_k, how close the product p_k is considered to be close to the user u_i's interest profile. The latter is an important measure that is supplemental to the user similarity, as a user may be interested in something that is beyond what is specified in the focus user's profile. The computation of product similarity $SIM(u_i, p_k)$ follows that of user similarity through the creation of a dummy user u_d. That is, $SIM(u_i, p_k) = SIM(u_i, u_d)$. We use the same formula described in Ziegler et al. (2004) to compute the relevance level of product p_k for the focus user u_i. The relevance level is defined as $w_i(p_k)$ = q SIM(u_i, p_k) ΣSIM(u_i, u_j)/(|NB(u_i, p_k)| + Y_R), where u_j Є NB(u_i), |NB(u_i, p_k)| denotes the number of users that are in the set of NB(u_i) and have rated product p_k, q = (1.0 + $N_k T_\Delta$) (N_k is the number of categories in which product p_k falls), and T_Δ and Y_R are fine-tuning parameters that allow for customizing the recommendation process. T_Δ rewards those products that fall under relatively large number of categories in the taxonomy. Large Y_R makes popular products acquire higher relevance level, which makes it possible for users to be recommended those popular items, while low Y_R treats popular and new items in the same manner, thus helping to alleviate the cold start problem in recommendations.

Next, once all the relevance levels $w_i(p_k)$ are computed for the focus user u_i, they are ranked in descending order, and their corresponding products are considered as the baseline recommendation list, denoted by $L_{(w_i)}$. In order to diversify the baseline recommendation list, Ziegler et al. (2004) proposes a greedy re-ranking algorithm by iteratively re-ranking items based on the dissimilarity to the preceding items in the list. One issue with this approach is that the diversity is gained at the expense of recommendation accuracy. To measure the diversity of a given recommendation list $L_{(w_i)}$, intra-list similarity ILS($L_{(w_i)}$) is defined as follows: ILS($L_{(w_i)}$) = ($\Sigma p_k \Sigma p_e$ SIM(p_k, p_e))/2, where p_k, p_e Є $L_{(w_i)}$ and $p_k \neq p_e$. Higher value indicates lower diversity.

Instead, we propose to leverage the focus user's social circles to enhance the diversity of the baseline recommendation list. Specifically, we use CIR(u_i, FL) to denote user u_i's online circle of friends (e.g., either being followed or following) at the level FL. If FL = 1, then CIR(u_i, 1) indicates there is a direct following or being followed relationship between the focus user u_i and the friends in the set of CIR(u_i, 1); FL = 2 means that CIR(u_i, 2) is CIR(u_i, 1) plus the friend's friend. In other words, the relation is indirect with path length of 2; FL = 3 then denotes CIR(u_i, 2) plus friend's friends' friend, and so on. The procedure below describes the basic idea of our approach.

Input: Users' profiles, baseline recommendation list $L_{(w_i)}$, parameters: N, FL, Z, and ε.
Output: Diversified top-N recommendation list $DL_{(w_i)}$.

Identify the product list P_f = {p_1, p_2, … } that the users in CIR(u_i, FL) have rated but not
    being ranked as top-N in $L_{(w_i)}$;
Compute the similarity between each product p_f and the focus user u_i's profile;
Rank the above similarities in the descending order to create a list DSIM;
for each of the top-Z corresponding products in DSIM do
    Temporarily substitute it for the last ranking product in top-N list of $L_{(w_i)}$;
    Compute the new intra-list similarity ILS($L_{(w_i)}$)*;
    If (ILS($L_{(w_i)}$) - ILS($L_{(w_i)}$)*) > ε then
        Make the substitute permanent in the Top-N list of $DL_{(w_i)}$;
    end
end

We note that the parameters M and ε provide us certain degree of flexibility in balancing the trade-off between diversity and accuracy in the process of generating the top-N recommendation list.

EXPERIMENTAL EVALUATION AND PRELIMINARY RESULTS

In this section, we describe the metrics used for performance evaluation, present the evaluation results, and discuss the preliminary findings from our experimental evaluations. Evaluation metrics are essential in order to measure the quality and performance of recommendation approaches. We consider accuracy measurements such as precision and recall as well as non-accuracy evaluation metrics such as intra-list similarity.

As our approach does not actually predict the ratings, we cannot use the accuracy metrics that measure how close predicted ratings come to true user ratings. Such metrics include mean absolute error (MAE), the Root Mean Square Error (RMSE), etc. Instead, we use precision and recall. Recall indicates the percentage of relevant items that were included in the recommendation list, and precision gives the percentage of recommended products that are relevant. Suppose that the total number of products in test set is n_t, and out of these products, n_p of them appear in the top-N recommendation list, then recall is defined as: Recall = $100 \cdot (n_p / n_t)$. Accordingly, precision represents the percentage of test set products occurring in the recommendation list with respect to N (i.e., the size of the recommendation list): Precision = $100 \cdot (n_p / N)$. The diversity of a given recommendation list $L_{(w'i)}$ is measured by intra-list similarity $ILS(L_{(w'i)})$ defined in the previous section. In order to obtain "global" values, we average the respective metric values for all evaluated users.

We perform 5-fold cross validation in our experimental evaluations. In each fold, we use 80% of randomly selected data as training set and the remaining 20% as the test set. For the Books, Music, and Movies data, the observations for relative rankings are 1,052, 1,237, and 833 respectively. For our preliminary experiments, N is set to 20, FL is set to 3, Z = 30, and ε = 0.10.

In order to demonstrate the effectiveness of our proposed approach, we compare it with the baseline non-diversified collaborative filtering method. Table 1. Presents the preliminary results.

Table 1. Preliminary Experimental Results

Category	Methods	Recall	Precision	ILS
Books	Proposed	6.02	3.73	9.29
	Baseline	6.11	3.82	14.78
Music	Proposed	7.53	4.42	13.80
	Baseline	7.66	4.51	16.18
Movies	Proposed	5.84	3.46	21.32
	Baseline	6.02	3.77	30.65

At this point, we were only able to obtain the results from one set of parameters and the datasets are also relatively small. Thus, in terms of accuracy and intra-list similarity measures, we cannot draw definite conclusion yet on whether the differences between our proposed method and baseline approach are statistically significant. However, based on the closeness of the accuracies (i.e., measured by recall and precision) with lower inter-list similarity for our approach across all three product categories, it seems to be a good indication that our proposed approach might be able to perform well in enhancing the diversity of recommendation list while maintaining comparable level of accuracy. That is, our approach could be promising.

As we put more weight on the rated products from a user's online social circle, the above results suggest that leveraging the social relations data from online social circles may help to improve the diversity of personalized recommendation. In the context of online social networks, the ratings from a user's online social circle can be considered as a proxy for online social influence. Thus we believe that our findings might have practical implications for online retailers to take advantage of online social relations.

CONCLUSION AND FUTURE WORK

There has been considerable understanding that high recommendation accuracy alone does not necessarily provide users of recommender systems satisfying experience. Recent studies suggest that recommending a diverse list of products enhances user satisfaction and is positively associated with customer retention rates. In this study, we propose to leverage the social relations of a user in an online environment to improve the diversity of personalized recommendation list.

Our initial experiments show the promise of our proposed approach. However, the dataset that we have obtained so far are relatively small, and we have only tested our approach on one set of parameters. Obtaining and preprocessing the data is a time consuming process. We plan to expand our dataset to include more users, and also apply our approach to different levels of social circles. In the addition, we would like to experiment with different sets of parameters to find out how they might affect the accuracy and diversity of the recommendations. We also intend to compare our approach with the existing approaches to demonstrate whether our approach is computationally more efficient. It is worth noting that the quality of recommendations can be reflected in different dimensions, such as novelty, unexpectedness (e.g., Adamopoulos & Tuzhilin 2015; Hurley & Zhang 2011), etc. As this study only represents our initial effort in developing a novel approach, our primary focus is on the diversity. In this regard, future direction may include exploring the new dimensions of recommendation quality.

ACKNOWLEGEMENTS

We would like to express our gratitude to Auburn University at Montgomery for financial support. We also thank Qiyuan Peng for providing research assistance.

ABSTRACT"

Trends toward digital news media have driven readers away from most printed media causing many of them to reassess their products and processes. To spur growth in readership and revenue, media companies need to develop strong niche media products and companion digital components that are standardized and scalable for evaluating the potential success or failure of new product ideas to efficiently supplement their product portfolios. This paper describes a study conducted for a regional newspaper to achieve this objective.

KEYWORDS: printed media, digital media, market analysis, and new product development

INTRODUCTION

A California based media company (CBMC) was interested to explore and identify approaches to increase its revenue and readership as recent trends toward digital news media had driven readers away from printed media, causing this company to reassess its products and processes, which it had impacted its readership. This company had achieved a market share advantage within its region for printed news media and was a low-cost leader with extensive distribution reach. CBMC asked our university team to assist in market analysis and developing an easy, scalable method to evaluate new proposals for various products in its portfolio. Our team consisted of graduating MBA along with faculty who undertook to provide guidance. This paper describes our attempts in assisting this company to achieve its objective.

BACKGROUND

CBMC is a Pulitzer Prize winning daily newspaper published California. Its ownership has changed hands several times in the past two decades. It currently has about 250,000 daily and 400,000 Sunday readers. Its reach extends with its many locally distributed daily and weekly newspapers, entertainment guides, Spanish language editions, and website. It offers information on various topics such as sports, business, lifestyle, military, opinion, videos, obituaries, deals and classifieds, jobs, real estate, etc. With the exponential rise in digital media, the print medium has suffered a significant decline of 8-10% annually. Also, the majority of print media customers are the Baby Boomer generation (50 – 70-year-old). To drive growth in readership and revenues CBMC was looking to launch new products for its print media, as well as its digital medium that would be relevant to its targeted markets. In the past, when it had developed products, it tried to achieve a 100% market share, however, due to dwindling readership, the company is considering other print products to capitalize on its market position.

Historically, the news media industry tended to be very hierarchical in nature, resulting in inefficient and inconsistent decision making and not adept at managing change. CBMC's existing processes for new product development were not well defined or standardized. It did not offer an open platform or equal opportunity for everyone to pitch new ideas. Only staff members with most influence were able to push new product ideas with no requirements for data collection and analysis. Management was receiving about three to four new product proposals every month with varying degree of completeness, lacking clear understanding of the proposal requirements. To review these proposals, the management would rely on their own intuition as to the appeal of the proposal, the conviction of the presenter, and the perceived feasibility to decide on an ad hoc basis, and often without the underlying supporting data. This had resulted in failed product ideas. While intuition-based product decisions had worked in the past when CBMC enjoyed a dominant market share, its management decided to systematize its approach based on data-driven decision processes.

METHODOLOGY

To achieve the goals of the project, the following activities were pursued:

1. Formulated a functional and consistent new product development process to identify and prioritize key assessment criteria. The process was then used to evaluate the potential profitability of a new product's go-to-market plan.
2. Created a templated to input the data obtained in accordance with the new product process criteria and applies weights based on the priorities determined in step 1.
3. Demonstrated the functionality of the new product development process by empirically testing and calibrating the template using recent CBMC home improvement media product idea.

We first identified and researched the target market in which CBMC intended to serve and established standards for determining if a product would generate a sufficient primary and secondary audience. At this stage the basic data, such as demographic, ethnographic, and behavioral were researched and applied to the process. Then we considered plausible revenues that can be generated by analyzing CBMC's advertising revenue and product payback/profitability targets to establish a standardized methodology for projecting a new product's likely revenue generation. We also considered project startup and recurring costs, by reviewing CBMC's product portfolio to create cost projections for each of the Company's various product categories. Using these metrics, we established a template for projecting a new product's associated costs. Finally, we provided guidance for new product market release by examining CBMC's current portfolio success metrics to establish go-to-market guidance.

CBMC NEW PRODUCT DEVELOPMENT PROCESS

1. Application: CBMC Team Members who wish to propose a new product idea to the Vice President of Strategy and Operations.

2. Objective: To establish the key criteria and data inputs required to present a new product idea, in order to create a standardized, data driven evaluation environment.

3. Responsibilities:

   a. Idea Lead: The creator of the new product idea, who is responsible for collecting the standard data required to propose a new product.
   b. Research Lead: The research department member responsible for assisting the Idea Lead with any background research required to pitch a new product idea.
   c. Management Lead: The management representative responsible for verifying new product idea assumptions and using the excel model to make cost and revenue projections. Ultimately, the Management Lead will make the final go-to market determination based on the objective data.
   d. Marketing Lead: The marketing representative responsible for securing advertising sales prior to initial product release.

4. Outputs (Available upon request):

   a. New Product Idea Submission Form.
   b. New Product Evaluation Model: Excel

5. Process

   a. Idea Submission: The Idea Lead, who wishes to propose a new product idea, must first fill out the New Product Idea Submission Form. The proposer might already have that data on hand or may need to obtain it through relevant sources, with the assistance of the research lead. The required data is as follows:
      1. Develop a new product idea: The Idea Lead must identify the details of the proposed new product, including what the new product/service offers and what consumer needs it fulfills.
      2. Develop a consumer profile: The Idea Lead must create the optimal profile and characteristics of the anticipated new product user. This includes gender, age group, income group, education, geographical location, family/marital status etc. Surveys may be required to assist with profiling potential consumers. The parameters for any required surveys will be coordinated by the Idea Lead through the Research Lead.
      3. Define consumer target market: The Idea Lead must work with the Research Lead to funnel the population into a specialized target market in terms of households or page views.
      4. Define advertising market: The Idea Lead will gather data regarding the potential advertising market in the target category. Relevant data includes number of advertisers, spending by media product category, and any potential advertising leads for the new product. The Research Lead will assist with gathering any advertising spending surveys and/or data.
      5. Define the category competitive landscape: The idea lead will gather data regarding the competitive landscape within the proposed new product media category. This data includes the number of competitors, platform of each competitor's product, quality of

content (rated low, medium, high). Approximate revenue of competitors, if available. The Idea Lead should also score the overall competitive landscape on a scale from 1-10 (10 being most competitive) and attempt to determine whether the competitors are profitable or not.

6. Refine new product idea: Based on the acquired background research, the Idea Lead will provide a recommendation on product platform (i.e. tabloid, glossy, web), distribution frequency and mode, page count, and suggested content.
7. Submit the New Product Idea Submission form: Once all required data inputs are gathered, the Idea Lead must fill out the relevant form, and provide to the Management Lead.

b. Management Review: The Management Lead will then review the New Product Idea Submission form, including any assumptions made and evaluate for feasibility and profitability as follows:
   1. Review New Product Idea Submission Form: The Management Lead will review the submission to determine if all required data inputs are correctly identified, and accurate in nature.
   2. Input target market assumptions: The Management Lead will input the target market assumptions including households, distribution frequency and mode, and suggested page count into the New Product Evaluation Model Template (Excel).
   3. Set success metrics: Using the New Product Evaluation Model, the Management Lead will set profitability and market share targets for the new product.
   4. Go or no-go decision: Using the New Product Evaluation Model, the Management Lead will make a data-driven decision on whether the new product idea would be a profitable venture. The Management Lead will review the required revenue to become profitable and work with the Marketing Lead to determine if target advertising revenue can be achieved prior to initial product release.

c. Trial Phase: If a new product is released, the Management Lead will monitor actual revenue and readership data against defined success metrics to determine whether a new product's production should continue.
   1. Breakeven: The Management Lead will establish a breakeven point, at which point the new product must have recovered all costs associated with its initial release and production. If the product has not hit breakeven by the defined checkpoint, production should be suspended. The Management Lead will use the New Product Evaluation Model Template to graphically track the product's monthly progress.
   2. Profitability: The Management Lead will define a checkpoint at which the product must achieve its target profitability. The Management Lead will use the New Product Evaluation Model Template to graphically track the product's monthly profitability.
   3. Market share: The Management Lead will also track the new product's actual market share against its target. The Management Lead will use the New Product Evaluation Model Template to graphically track the product's monthly profitability.

NEW PRODUCT IDEA FORM TEMPLATE

We created a template form for pitching new product ideas. The form includes all the data and research requirements so that CBMC staff members know the exact expectations of a new product pitch. It guides the user through the data collection and research steps with specific questions to answer. We further integrated this form into an online application. This form serves to simplify the idea submission process and collect the necessary data. To create a New Product Evaluation Model, we researched CBMC’s reader base with regard to households in for a specific area. This data was included in a spreadsheet that can be easily sorted by household size, income, education, home value, etc.

Through several interviews with CBMC management, we defined key cost and revenue metrics and built them into an Excel Template; we included a control panel that would allow for customization the assumptions change. This allows the user to model and project costs across various product platforms based on key criteria such as product size, page count, distribution frequency and mode, content, and target households as shown in Figure 1.

Figure 1: New Product Development Model Excel, Tab 1

We also built in an assumption checker to ensure that the markup of the target matches market share target, and the category advertising revenue can support the new product based on our projected market share target. If the assumptions do not align, the user can adjust the inputs until they do. Per Example in Figure 2, if the markup-based revenue target was calculated much below the market share-based revenue target, the user would need to increase distribution type inputs (i.e. page count/distribution frequency) in order to create additional ad revenue space to match the market share target.

Along with CBMC management we established key success metrics that management found critical to a new product release. The first metric was to ensure that the product achieved a baseline advertising commitment prior to release, which was dependent on the cost of the product. The second was to achieve break-even at six months. We used a formula based approach to determine target revenue for the first six months to ensure break-even. The formula dynamically adjusts profit markup to display the required revenue for the initial release, and for each of the first six months to break-even, as depicted in Figure 4 and Figure 5.

Glossy			Inputs			
Month	Market Share Target	Revenue Target	Actual Revenue	Actual Market Share	Cum Profit Target	Cum Profit Actual
1	3%	$ 76,856	$ 85,000	19%	$ (34,530)	$ (26,386)

FIGURE 5: NEW PRODUCT DEVELOPMENT MODEL EXCEL, TAB 3A (MONTHLY REVENUE, TARGETS V. ACTUALS)

CONCLUSION

We developed a work-flow process to establish steps to generate a new product idea, from initial research to final management evaluation. We created an online Product Idea Submission form that can be used by employees and management along with an Excel evaluation template to assess the viability of proposed project. We validated our process by obtaining a set of real market data on the home improvement media market from CBMC. Overall, our process streamlined and standardize the idea generation and evaluation process, while ensuring resources are spent on ideas that meet CBMC's success targets.

ACKNOWLEDGEMENTS

We would like to recognize the dedicated work by Lindsay Boyd, Amruta Kulkarni, Sean Pierce, Taekyoo Shin, and Brett Thomason who participated in the data gathering, analysis and earlier drafts of the research for this case under the supervision of the authors.

ABSTRACT

The aim of this research is to evaluate the economic and financial viability of companies in the steel and metallurgy sector listed on the Brazilian stock exchange B3 in the period 2011 to 2018, using the perception of research accountants synthesized and measured using paraconsistent logic.

KEYWORDS: Paraconsistent Logic; Economic-financial indicators; Steel and Metallurgy.

INTRODUCTION

According to Falconi (2017), management tools in steelmaking need to be improved. One of the challenges that emerge in this subsector is the implementation of large investment plans, in which Falconi (2017) cites as some of the solutions: increase in Ebitda, productivity gains through standardization of operational processes, improvement of product quality, reduction of budget deviations and optimization of project development and implementation (deadlines, cost and quality).

However, the evaluation of a company's economic-financial information may suggest its potential to receive future investments (Aguiar, Corrar & Batistella, 2004). However, the success or failure of a particular project may differ between stakeholders, i.e. their views on performance may involve subjectivity. It is not always the decision-making about performance that consists of prioritizing the maximization of company value, due to personal impressions, feelings and opinions, that is, choices depend on subjectivity (Fernandes & Mazzioni, 2015).

Aiming at reliable scores of company performance, the integration of indicators is essential (Gasparetto, 2004). This synthesis can be done in several ways. However, the perception and interpretation of the accounting information by expert accountants depend on their training, vision and their theoretical-practical influences in which the use of Paraconsistent Logic allows to perform a form of integrated analysis between the indicators. The isolated interpretation of the quotients also has its importance (Souza, 2007). However, the generalization of a block of information in a single vector is far superior.

According to Bortoluzzi (2009), the use of only one indicator is not enough to explain performance, but the use of many indicators tends to confuse users. Therefore, it is vital that each sector of activity analyzes what the most relevant indicators to analyze the company's position (Soares, 2006; Fuenmayor & Angulo, 2008) are. Thus, one has as a research question: what is the degree of economic-financial viability attributed by research accountants of companies in the sector of Metallurgy and Siderurgy, synthesized and measured by the paraconsistent logic annotated?

The objective of the research is to evaluate the degree of the feasibility of companies in the Metallurgy and Metallurgy sector analyzed by accountants researchers from three university institutions of the South of Brazil, observing their economic-financial indicators.

The research is justified primarily due to the small number of investigations that use the economic-financial indicators in the evaluation of companies in the sector of Iron and Metallurgy. Also, it should be noted that there is a global crisis of overcapacity in the steel industry due to the growth of Chinese steel production, which has hit developed countries (The Economist, 2016), and a reduction in production in recent decades.

In addition to the market difficulties encountered in the steel and metallurgy sector, limitations are still perceivable in Brazil, such as: government economic policy based on a valued currency, lack of a specific industrial policy for the subsector, possibly tending to hamper performance improvement, reinforcing this research in the Metallurgy and Steel Industry (Poso, 2015).

THEORETICAL REFERENCE

Economic-financial indicators

Historically, the use of indicators is essential to companies and also to the scientific context (Antunes & Martins, 2007), which facilitate the understanding of complex phenomena as they are tools for synthesizing reality (Campos & Melo, 2008).

Primarily economic-financial indicators are used to measure aspects of companies through quantitative relationships, to indicate the economic and financial situation (Matos et al., 2003; Fuenmayor & Angulo, 2008; Rodríguez & Gutiérrez, 2011), which are related to activities, internal controls, organizations, and business management (Fuenmayor & Angulo, 2008, García Molina & Artola, 2010, Rodríguez & Gutiérrez, 2011).

The disclosure of economic-financial indicators occurs through the relationship between accounts or groups of financial statement accounts, where the indicators are generally divided into five categories: liquidity, activity, indebtedness, profitability (profitability) and stock analysis (García, Tabuenca, Martí, & Romero, 2007, Azeredo, Souza & Gomes Machado, 2009, Bortoluzzi, 2009, Gitman, 2010, Rodríguez & Gutiérrez, 2011).

Generally, debt, activity, and liquidity indicators are associated with data that may aid in knowledge about a company's operations (Ehrhardt & Brigham, 2012). According to Gitman (2010), indicators of indebtedness, activity, and liquidity contribute to risk measurement, while profitability indicators consist of measurement of return, while indicators of stock analysis can capture risk and return.

Despite the importance of economic-financial indicators, it is estimated that until the mid-1970s, business management used to rely only on one indicator of its decisions. However, since 1913, criticisms have emerged regarding the exclusive use of liquidity to understand the financial situation of the company. Alexander Wall was one of those responsible for the questioning of the restricted use of liquidity in business analysis. In this way, the use of indicators in isolation is not very useful to the company at present due to the changes in the productive systems, which are more complicated, but also a single financial indicator is not able to create value (Antunes & Martins, 2007).

In order to analyze the performance of companies, restricting themselves to liquidity measures alone may be inadequate, because according to Gitman (2010), current assets and current liabilities may not be able to make a real description of the company. However, Molina Y Artola (2010) argue that the comparison between indicators of liquidity, activity, indebtedness, and profitability are essential for analysis purposes, since according to the authors, the level of indebtedness is affected by the profitability of the company, as well as current liquidity is weakened by the rotation of inventories.

According to the specific objective of each indicator, Rodríguez, and Gutiérrez (2011) report that it is up to the company to select the indicators that best evidence its performance and its positions in the business, when considering its sectors of operations and operations.

Economic-financial positioning

Among the benefits in the literature regarding the company's position in the business, Prahalad & Hamel (1990) emphasize that a prominent position contributes to companies guaranteeing a superior economic performance. Other authors such as Notteboom & Winkelmans (2001) and Frémont (2009) argue that a favorable positioning in the business tends to provide higher profitability to the companies.

Winter (2002) argues that the industry environment in which firms operate is an influence on their economic performance. In order for a company to differentiate itself from the others in its industry, like Crook, Bratton, Street & Ketchen (2006) and Teece et al. (1997), it should possibly have a well-planned strategy. According to these arguments, Porter (1996) clarifies that the achievement of strategic positioning is related to the choice of activities that are different from the rivals so that there is a resistance to competition by the company.

Reed & DeFillippi (1990) argue that for firms to have an advantage over others, firms should develop internal competence. Specifically, Hofer and Schendel (1978) argue that competitive advantage can be achieved by deploying resources in these companies. Winter (2002) points out that as there is increased competition, increased turbulence, and reduced profits, among alternatives, managers may seek to compete with resources. According to the author, the use of internal resources can be used even to achieve impossible results (Winter, 2002).

On the other hand, Baron and Kenny (1986) argue that the accumulation of capabilities without a strategy can result in a resource extravaganza, that is, the resource effects on the performance of the business can be changed, which makes it necessary to mediate the resources that are in the organization. In this way, the strategic deployment of resources with the addition of new capabilities to the existing ones can provide the competitive advantage (Wernerfelt, 1984; Barney, 1986, 1991, Grant, 1991, Peteraf, 1993, Acar & Zehir, 2010).

Especially Tampoe & Macmillan (2000) argue that the best business strategies are the ability of the company to meet the needs of its customers. Storage, which integrates any logistics system, plays a crucial role in promoting a customer service at low cost (Stock & Lambert, 2001). Thus, according to Chopra & Meindl (2003), inventories can contribute to the adequacy and balance between supply needs and customer demand. However, Bowersox & Closs (2001) argue that the reduction of some resources committed in inventories may also be viable since it leads to cost reduction and increase profitability and profitability of a company.

Siderurgy and Metallurgy

Given the importance of the economic-financial positioning, for the steel and metallurgy subsector technology is increasingly advanced, as this segment requires highly efficient logistics, depending on the efficiency of the transport operations in the whole chain from the ore deposit to the end user of steel (Siderurgia Brasil, 2011, Libertá, 2015). According to Siderurgia Brasil (2011), material handling logistics has always been a fundamental factor in guaranteeing good results at Siderurgia. Specifically, transport in this sub-sector needs to be executed with maximum efficiency and at the lowest possible cost, which consequently leads to a greater need for modern equipment as well as more advanced management systems (Siderurgia Brasil, 2011).

Siderurgy and Metallurgy are subdivided into three segments: iron and steel artifacts, copper and steel artifacts, in which the last segment (Siderurgia) presents five companies, and iron and steel artifacts total four companies, and copper artifacts with a company (BM&FBovespa, 2016). Metallurgy is related to the processes of extraction, casting, manufacturing, and treatment of metals and alloys, such as: copper, aluminum, nickel, tin, zinc, and steel (MME, 2011).

The metallurgical sector has considerable importance for the Brazilian economic scenario since it has its relevance to other activities in the country such as civil construction, capital goods and the automobile industry (MME, 2011, 2013, 2016). As this sector is present in the value chain of several organizations, this segment can serve as a buffer against the impacts of the crisis, in order to reduce the adverse effects in large companies, and thus assuming importance to economic stability (Milk, 2014).

On the steel sector, this is known as the steel metallurgy sector (MME, 2011), or it can be said that it is the branch of metallurgy which is focused on the treatment of steel and cast iron (Silva, 2014). Among the steelmakers, CNM (2012) reports that the companies Gerdau, Usiminas, and Sid Nacional are ranked among the best positions in the world ranking.

In general, the steel industry is recognized as complicated, because it is necessary for the intensive use of energy, enormous capital contribution, and still the maturation of the investment is usually slow. However, in Brazil, the production of products and by-products is still simple, which in turn generates less value, even though there is an increase in the share of nobler products in national steel production (CNM, 2012).

According to information from the Brazilian Steel Industry (2015), the Brazilian steel industry's main objective is to participate in the world steel trade, aiming at the sustainable development of the country. Recently, China is the largest producer and consumer in the steel sector (World Steel Association, 2013), but it should be considered that Brazil currently has the largest steel industrial park in South America, and is also considered the largest producer in America Latina. Especially in 2014, Brazil ranked sixth as a net exporter of steel, and as the ninth largest producer of steel in the world, and in 2015 reached the eighth position in the world ranking as an exporter in the metallurgical sector (MME, 2016).

Paraconsistent logic

Western logical thinking was formed by the laws of Classical Logic, that is, by the law of non-contradiction. This classic logic has been created and sustained by rigid laws and is based on binary reasoning, in which its statements may be true or false, but cannot be partially true and partially false (Carvalho & Abe, 2011).

Often difficulties are encountered in establishing limits to be made affirmative or negative about the quality of things. The boundaries between "False" and "True" are uncertain, ambiguous, indefinite and contradictory, for many personal statements cannot only be classified as "true" or "false," or "yes" or "no." Thus, Non-Classical Logic seeks to give more satisfactory answers to problems related to situations in which the laws that are required by Classical Logic do not fit (Carvalho & Abe, 2011).

Paraconsistent Logic (LP), as Non-Classical Logic, is based on inconsistent and non-trivial theories, that is, it can manipulate systems that are both inconsistent and nontrivial (without the risk of trivialization). According to Carvalho & Abe (2011), Paraconsistent Logic invalidates the principle of Non-Contradiction and admits the treatment of different signals.

The Polish J. Lukasiewick and the Russian philosopher N. A. Vasilév are the forerunners of the Paraconsistent Logic around 1910. The publication of works of these authors consisted in the possibility of a logic that could consider the contradictions; their studies were independent of each other despite being performed at the same time. However, none of them had a broad view of non-classical logic, unlike today, because they were still restricted to traditional Aristotelian logic (Carvalho & Abe, 2011).

In 1948, Jäskowski formalized a paraconsistent propositional calculus which is termed as a discursive propositional calculus. At the same time (1954), however, the independent logician Newton Carneiro Affonso da Costa developed several paraconsistent systems (Carvalho & Abe, 2011).

There is a difference between the works of Jáskowski and Da Costa, while Jáskowski has elaborated a paraconsistent propositional calculation called Discursive (or Discursive) Propositional Calculus, Da Costa has deepened several paraconsistent logics that cover all the standard logical levels (Carvalho & Abe, 2011). According to the development of Paraconsistent Logic with Da Costa, studies related to this Logic were carried out. Among some of the researches that applied the Paraconsistent Logic, Torres (2004) developed an intelligent system for the control of autonomous mobile robots, and Falquete (2004) used in case-based reasoning systems for the treatment of inconsistencies. It is also possible to cite the work of Carvalho, Brunstein, & Abe (2004) in the decision making, for the evaluation of the project of implantation of a factory, through the use of Paraconsistent Logic.

Technological evolution has allowed a better application of the Paraconsistent Logic because instead of ignoring specific problems of inconsistencies in refuting such as false or confirming them as true, it allows the modeling of human behavior. Therefore, Paraconsistent Logic differs from quantitative reasoning methodologies by providing interpretations for different information (Carvalho, 2002).

The Peruvian philosopher Francisco Miró Quesada created the term Paraconsistent Logic in which he was first employed in a conference held at the University of Campinas in 1976 at the Third Latin American Symposium on Mathematical Logic (Carvalho, 2002).

According to Carvalho (2002), the calculation or logic underlies the theory T, that is,

$$T = \{A : T \vdash_c A\}$$

A represents the syntactic consequence of T, and in this condition A must belong to T, or it is also said that A is the "theorem" of T. According to Carvalho & Abe (2011), for a given theory T to be paraconsistent it needs to attend to two conditions: to be inconsistent and non-trivial.

A theory T is inconsistent when it has at least one "theorem" A of a set F of all sentences (formulas) whose negation ¬A is also "theorem" of T. For example, if a given sentence p "John is mortal "is considered in a theory T, it will also be considered its negation, that is, the -p meaning "John is not mortal. It makes theory T inconsistent. Otherwise, the theory is said to be consistent (Carvalho & Abe, 2011).

Some examples of situations of inconsistencies can be mentioned. According to Silva Filho (1999), in a condominium meeting, for the decision on a reform in the building, different opinions must be considered, since opinions are not always unanimous. If decisions were always unanimous, the trustee's decision would be facilitated, but some decision-makers wish to reform, and in contrast to others, not generating contradictions.

Another example cited by the authors is an administrator who is the head of a team that has the decision to promote one of its employees. To this end, various information is collected which come from various sources such as direct management, co-workers, personnel department, and others. The information coming from various sources can be simultaneously totally favorable and contrary. Usually, there are two paths to this situation, or the administrator considers that the information is insufficient, or that it is contradictory, and it is necessary to search for new information in his decision making about the employee.

According to Bishop & Cazarini (2006), specifically in the area of medicine, when there is a medical committee to decide which treatment is more feasible for a particular patient, there are often differences between opinions in which doctors end up proposing different treatments. In these particular cases, paraconsistency work can contribute favorably to making better decisions.

The presence of inconsistency can also be seen in the area of law during the trial of the defendant, according to Bishop & Cazarini (2006), in which there is evidence of contradictory evidence from lawyers, both defense and prosecution. About the decision that the jury must take on blame or innocence of the defendant, there is the presence of the paraconsistent, which, when considered, may facilitate the finding of the most appropriate final result.

Paraconsistency should also be considered as frequently present in companies. The authors, Bispo & Cazarini (2006), also cite especially the situation when a research is carried out in relation to a specific type of innovation, in which it is recurrent that such innovative product or technology can simultaneously present good receptivity by potential clients and also considerable aversion by other customers which are also considered potential. In this research, inconsistency can occur at the moment when the specialists answer the questionnaires, in which it can be visualized if the economic-financial position of the company is allocated in a region of inconsistency.

METHODS

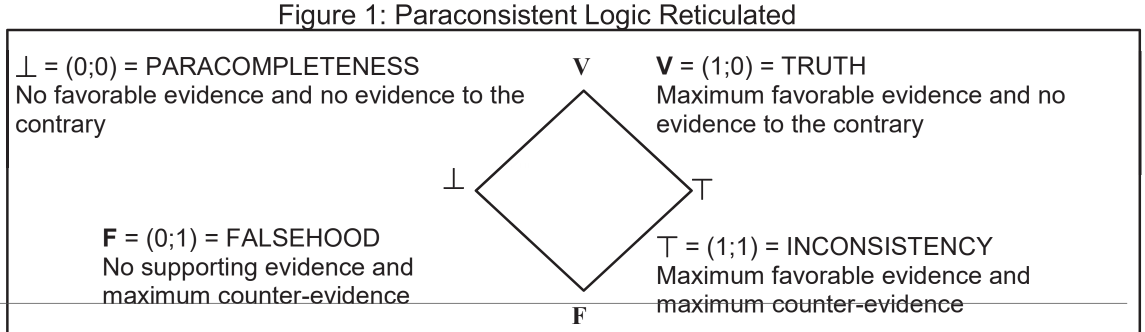
This study evaluated nine steel and metallurgy companies listed on BM&FBovespa using six specialists: two researchers and two finance assistants from three Brazilian universities.

In order to verify the influence of the indicators on the economic and financial positioning of the companies of Siderurgia and Metallurgy, the period from 2011 to 2018 was delimited for the study. For this purpose, the paraconsistent logic was used to determine the accounting position of the companies under analysis within the grid of annotations.

Technically, the Paraconsistent Logic consists of establishing propositions and then parameterizing them so that the factors of more significant influence in the decisions can be isolated, and, with the collaboration of specialists, notes are made for these factors. The objective of these procedures is to consider the concepts of uncertainty, inconsistency, and paracomplete so that the nuances of reality are better reflected and understood (Carvalho & Abe, 2011).

The annotations consist of the attribution of degrees of belief (μ_1) and degrees of disbelief (μ_2) for each elementary proposition p; these values range from 0 to 1 and are independent. According to Carvalho and Abe (2011), these notes are related to the concepts used in the LPA, in the case: inconsistency, paracomplete (indetermination), notions of truth and notions of falsity. The Hasse diagram represents the lattice in which the reticulate of the annotations can be called, where the pair (0; 0) represented by $\perp$ is the minimum of the lattice, and the maximum consists of the pair (1; 1) which is represented by $\top$. (Carvalho, 2002). Figure 1 illustrates this representation:

Figure 1: Paraconsistent Logic Reticulated

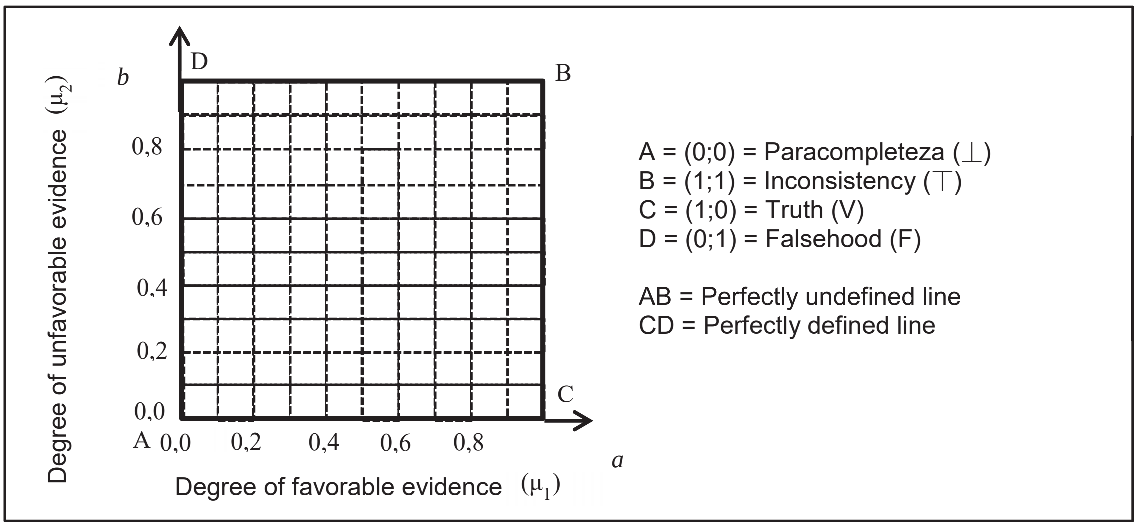


Thus, the pair (1; 0), which is associated with p, represents total belief and at the same time no disbelief in p; (Carvalho, 2002), or according to Carvalho & Abe (2011), this situation represents maximum favorable evidence and no contrary evidence. Even the pair (0,1) reveals the opposite: no belief and total disbelief in p, constituting a logical state of falsity (representation of no favorable evidence and together presents maximum contrary evidence).

The pair (1,1) means total belief and disbelief in p, translating a logical state called inconsistency (maximum favorable evidence and maximum contrary evidence). Finally, we have the pair (0,0), which indicates the total absence of belief and disbelief in p, that is, it consists of a logical state of indetermination or also called a state of paracompleteness (no favorable evidence and no evidence contrary) (Carvalho, 2002).

According to Carvalho (2002) and Carvalho & Abe (2011), the study of LPA can also occur in a Unitary Square in the Cartesian Plane (QUPC), because this QUPC is a way to represent the grid of annotations containing records of Degrees of Evidence Favorable (Belief) μ_1 moreover, Degrees of Unfavorable Evidence (Disbelief) μ_2. Figure 2 represents the Cartesian plane unit square (QUPC):

Figure 2: Unit chart of notes



Logic states in the reticulate associated with the four points are also called final states in which they belong to the sides AC, AD, CB, and DB of the QUPC. Through these sides, interpretations can be performed; for example, on the AC side, we have that the degree of belief varies between 0 and 1. However, the degree of disbelief is null (μ_2 = 0).

As a given point starts from A and advances to C, it passes from a situation of total indetermination (absence of all information), and in this way, one reaches a situation considered perfectly defined, that is, of total belief assuming a state of truth. Conversely, the AD side of the square has a zero belief degree (μ_1 = 0), and this time the degree of disbelief(μ_2) it varies from 0 (minimum) starting from A to C which represents 1 (maximum), and it is a perfectly defined situation (i.e., total disbelief or even the logical value is called falsehood) (Carvalho, 2002).

For the CB side, the degree of belief is equal to the maximum (μ_1 = 0) and is kept constant. However, there may be variation in the degree of disbelief (μ_2), which starts at minimum (zero) in C, up to the maximum value (1) in B. Thus it passes from a logical state of truth (situation perfectly defined) in C, to another logical value of inconsistency in which one has a belief and total disbelief at the same time (Carvalho, 2002). Finally, the DB side has the degree of disbelief kept to the maximum (μ_1 = 1), and the degree of belief varies from the minimum (zero) to the maximum (1). Therefore, there is a passage from a falsehood situation in D to another situation of inconsistency in B (Carvalho, 2002).

It should be noted that in the QUPC, there will never be a total belief or total disbelief, that is, a situation of absolute truth or absolute falsehood will never be seen, nor is there a situation of total inconsistency or complete misinformation. Thus, for the internal points we have 0< μ_1 < 1 e 0 < μ_2 < 1 (Carvalho, 2002).

The Variables

Because some companies do not present share information for each year and also negative equity, we opted for the exclusion of some economic-financial indicators. The economic-financial indicators are presented in Table 1.

Table 1: Construction of economic and financial		
VARIABLE	FORMULA	AUTHORS
LG	$\frac{\text{Current Assets + Long-Term Assets}}{\text{Current Liabilities + Long-Term Liabilities}}$	Souza (2007); Matarazzo (2010)

When we use tertiles, the standard indicators for the framing of each of the companies were determined in sections, in which the first, second and third tertiles were considered for the sections of the paraconsistent logic, respectively. The three sections used in the paraconsistent logic were: "S" _ "1", which translates the conditions in which the indicator is unfavorable to the researcher and/or auxiliaries; "S" _ "2", which translates the conditions in which the indicator is indifferent to the researcher and/or auxiliaries; and finally, "S" _ "3", which translates the conditions in which the indicator is favorable to the researcher and/or auxiliaries (Carvalho & Abe, 2011). Figure 1 depicts the paraconsistent logic tertiles, which were also represented in the questionnaires.

Figure 3: Representation of tertiles used as sections of Paraconsistent Logic for questionnaires

Panel A: Standard indicators for indicators that the higher, the better (general liquidity, current liquidity, dry liquidity, immediate liquidity, asset turnover, asset profitability, gross margin, earnings per share, dividends per share and price/earnings)

	Low	Medium	High	
Maximum	1º Tercil **(S_3)**	2º Tercil **(S_2)**	3º Tercil **(S_1)**	Minimum

Panel B: Standard indicators for indicators that the lower, the better (the composition of indebtedness, the average term of inventory renewal and an average term of receipt of sales)

	Low	Medium	High	
Minimum	1º Tercil **(S_1)**	2º Tercil **(S_2)**	3º Tercil **(S_3)**	Maximum

(S_1) Translates conditions where the factor is **unfavorable**

(***a***) Degree of Favorable Evidence	(***b***) Degree of Unfavorable Evidence

(**S_2**) Translates conditions into the factor is **indifferent**

(***a***) Degree of Favorable Evidence	(***b***) Degree of Unfavorable Evidence

(S_3) Condition translates into factor is **favorable**

(***a***) Degree of Favorable Evidence	(***b***) Degree of Unfavorable Evidence

For the determination of the standard value of the distribution, statistical measures such as arithmetic average, fashion, median, quartiles, decile, or even percentile are usually used (Silva, 2012). The choice specifically for tertiles is due to the necessity of the establishment of sections of the Paraconsistent Annotated Logic.

The business environment in the sections for each indicator performed by tertiles depends on whether the indicators are of the higher, the better, or the lower, the better. According to this logic, indicators belonging to Panel A located in the 1st tertile are characterized as unfavorable, and those that are allocated in the third tertile are considered favorable. About Panel B indicators that are in the 1st tertile, they are in favor of the companies, while the companies in the third tercile are unfavorable. The companies that are part of the 2 rd tercile, both in Panel A and in Panel B present such indicators as reasonable.

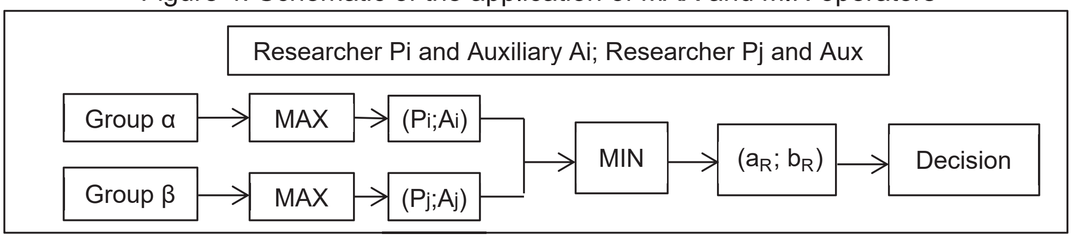
The business environment was made using three (3) teams of specialists. Each team was composed of two (2) professors/researchers belonging to the Postgraduate Programs in Accounting (PPGCCs) of the following higher education institutions (IES): Federal University of Paraná (UFPR), Federal University of Santa Catarina (UFSC)) and Regional Universities of Blumenau (FURB). Each researcher selected an assistant from among his masters and doctoral advisors. Thus, each of the 3 HEIs involved participated with a team of 4 members. It can symbolically establish the set {P1, P2, A1, A2}, where P1 and P2 are the professors/researchers and A1, and A2 are auxiliary.

The following set of ordered pairs performed the evaluations of each institution involved: {(P1, A1), (P1, A2), (P2, A2), (P2, A2)}. This type of composition intended to seek some underlying pattern in the evaluations.

The evaluators depended on the indication of degrees of indication of the factors in their three possibilities: favorable, indifferent and unfavorable (S1, S2, S3), associating in each of them a degree of favorable belief and another one of unfavorable belief, with values between 0 zero) and 1 (one).

The quartile of the pertinence of each company in each variable was previously determined, remaining the framework of the sections with the calculated indicators and measurement of the grades by the respondents. Then the MAX and MIN operators of the Annotated Paraconsistent Logic were applied, according to Figure 4, where Group α consists of Researcher Pi and auxiliary Ai and Group β adds the Researcher Pj and auxiliary Aj.

Figure 4: Schematic of the application of MAX and MIN operators



The maximization operator is applied from the degree of certainty within the set of annotations for each group separately, that is, it chooses both the highest degree of favorable evidence and the lowest degree of unfavorable evidence. Thus, the application of MÁX is made among the opinions of experts who are not all determinants, that is, it suffices the favorable opinion of only one expert so that the result is considered satisfactory (Carvalho & Abe, 2011). In contrast, the MIN operator consists of minimizing the degree of certainty within a set of annotations, with the choice of the least degree of favorable evidence and a higher degree of unfavorable evidence.

This minimization operator is applied among the maximum obtained from Groups A and B. Finally, the barycentre of each company was calculated, and this graph was calculated along with the other companies under study.

In particular, a proper evaluation, without the bias of inconsistency or for completeness, has an excellent adherence to the straight line segment that links the ordered pairs (0,1) to (1,0), that is, the values evaluated and framed in the lattice thus having almost no inconsistency (1,1) or paracompleteness (0,0). To generate the degree of viability (GV) of the companies from their position in the lattice, given by the ordered pair (x, y), will be projected on the line $x + y - 1 = 0$. To do so, we will initially calculate the distance from the point (x, y) to the line by equation $d(P,r) = \frac{|ax_0 + by_0 - c|}{\sqrt{a^2 + b^2}}$, which in this case will be given by $d(P,r) = \frac{|x-y-1|}{\sqrt{2}}$. To obtain the location of the projected point, we will calculate the Euclidean distance between (x, y) and the point (0,1) that will be called d +, since it will present the gross distance of the point (x, y) viability in V = (1.0). Similarly, the gross distance between (x, y) and the non-viability scenario (0,1) will be calculated. Using the Pythagorean Theorem, we will calculate the distance d and d, which will be the distances of the point projected on the line, to the point (0,1) and (1,0), that is, the feasibility and inviability. In mathematical terms, it will be: $d^{via} = \sqrt{(d^+)^2 + (d(P,r))^2}$ e $d^{inv} = \sqrt{(d^-)^2 + (d(P,r))^2}$. Finally, the degree of feasibility to be calculated: $GV_i = \frac{d_i^{inv}}{d_i^{via} + d_i^{inv}}$. Of course, each pair of evaluators will have a new scenario that will be synthesized by the average.

RESULTS ANALYSIS

The lattices for each year of the period from 2011 to 2018, obtained through the paraconsistent logic, are presented below. For esthetic reasons, only the results referring to the year 2018 will be presented, participating that the other years follow the same construction. Tables 01, 02 and 03 bring the results of the year 2015, from the framework made by the specialists of UFSC.

In Table 02 are the combinations made by the two groups of FURB expert reviewers, i.e., professors (P) and students (A) where P = {A1, A2} and A = {B1, B2}.

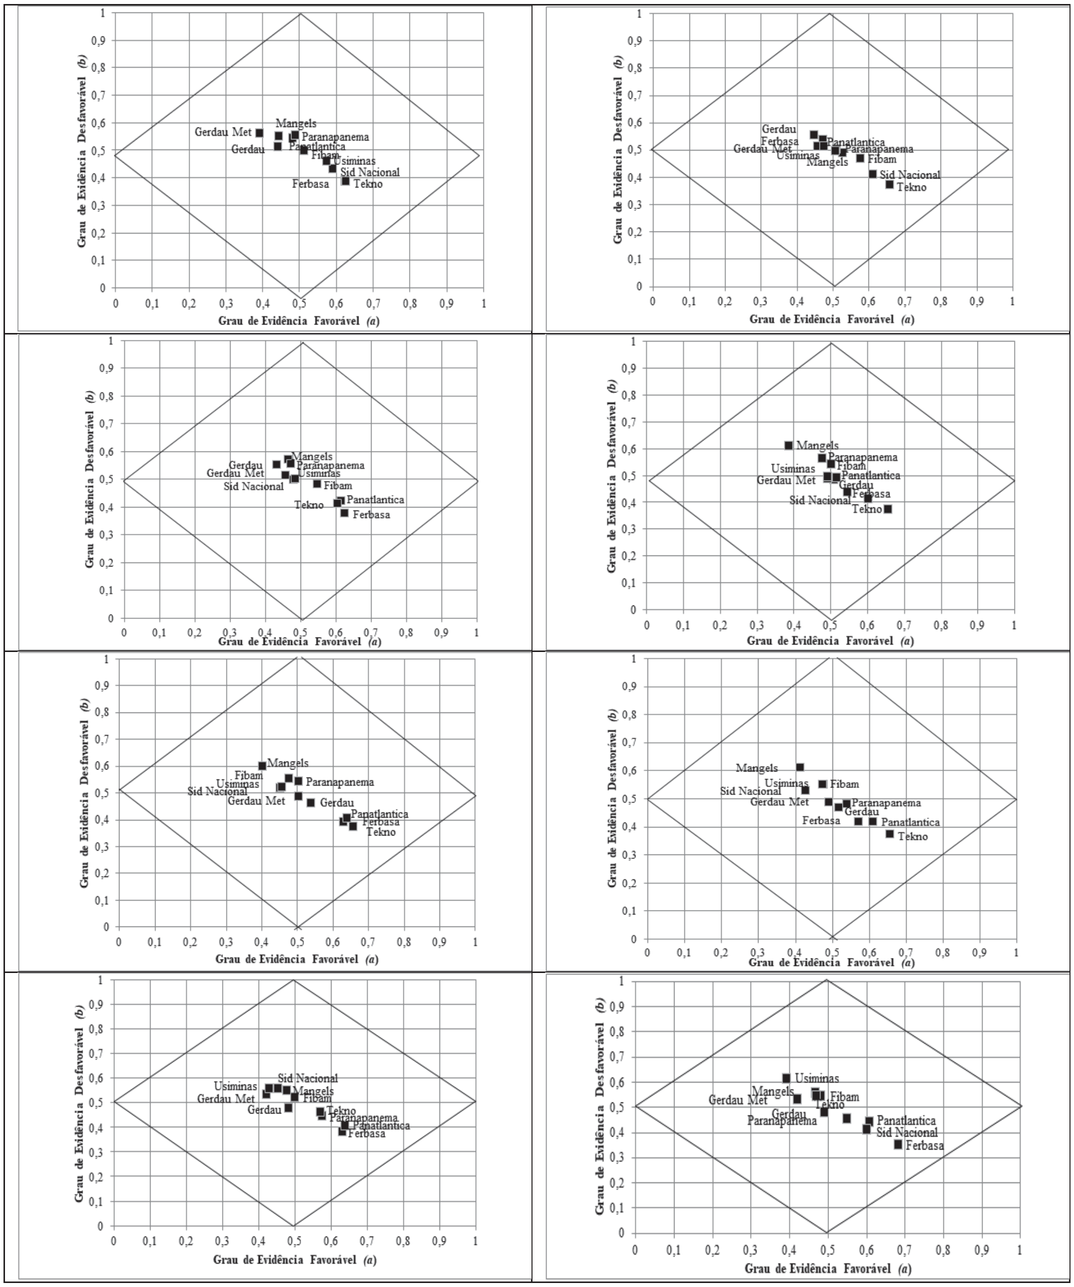
After 12 analyzes for each year, the position of each company was reduced to only one ordered pair (x, y), bringing the favorable degree of evidence (x) and its unfavorable degree of evidence (y). The values were synthesized using the mean of the ordinates and abscissa. The final result for the period 2011-2018 is in Figure 5.

Figure 5: Corporate positioning of the companies in the lattices - period 2011/18



In Figure 5, the accounting position of companies between the years 2011 to 2018 and should be understood by the matched charts: 2011/12, 2013/14, 2015/16, and 2017/18. In the first graph, the companies Tekno and Ferbasa presented the best positions. This result is consistent with the conclusions obtained in previous years, which were verified in the study of Kroenke (2009), for the period from 2004 to 2008, that the two companies also presented the first positions. The company Usiminas is in the third position, that is, it is ranked among the best. In contrast, the company Mangels is among the last place.

In the second chart, although the Ferbasa company is among the best positions in 2011, it loses much of its position when we compared to other companies in the subsector in 2012. The global crisis interfered with Ferbasa's performance, negatively affecting its costs and reducing the net income. These consequences may justify its change of position about Steel and Metallurgy. It should also be highlighted the loss of position of Usiminas, perhaps not as significant as Ferbasa, but it is noticeable since it had a distance from the viability region when compared to its position in 2011.

About Paranapanema, an improvement in its economic-financial position can be observed. According to the results of the fiscal year 2012, the company has higher gross revenue, sales volume, net income, net margin, and shareholders' equity when compared to 2008. It should be noted that Mangels also improved economic performance in 2012.

The third graph represents the positioning of the companies in the grid for the year 2013, in which Ferbasa resumes its position, as well as the company Panatlantica takes on new positions, being among the best along with Tekno and Ferbasa. On the other hand, the company Sid Nacional, which was ranked among the best in 2011 and 2012, loses an essential position in Siderurgia and Metallurgy. Mangels, which improved its positioning, returned to be among the worst positions, as happened in 2011.

It can be verified that the company Panatlantica, which was in unfavorable positions in the years 2011 and 2012, presents a significant advance in its position for the year of 2013.

In 2011, it can be noted that the company Sid Nacional, has a great improvement in its economic-financial positioning. However, it is noticed that Fibam has a considerable loss in its positioning when compared to the years of 2011 and 2012. Again it is recorded that Mangels is considerably in the last position, approaching more of the region of inviability than the other companies Steel and Metallurgy. The fifth graph shows the reticulation with the positioning of companies in the year 2015.

In 2015, Tekno, Ferbasa, and Panatlantica continued to present the best positions since 2013. However, as in 2013, it is noticeable that Sid Nacional again had an unfavorable position in Siderurgy and Metallurgy for the year 2015. In almost all previous years of the research, Mangels is in the last position. Specifically this year, Mangels was unable to continue its growth level due to the international crisis and also the European crisis, which was identified in 2014. It can also be seen that Fibam is in the last position. We can justify it by the worsening of the European crisis, in which in Fibam caused a decrease in sales, and consequently with a subsequent reduction in production in the year 2015.

In the sixth graph, specifically about Paranapanema, it is noticeable that this one has an improvement in its economic-financial positioning as of 2013. In contrast, except for 2014, the National Sid became among the worst positions of Siderurgia and Metallurgy. Mangels is again in the worst position. In the year 2016, due to its bank debts, Mangels decided to implement an asset sales process. The seventh graph represents the positioning of the companies in the network for the year 2017.

In the period from 2011 to 2016, Tekno was found to be in the top positions. However, in the year 2017, it can be observed that its positioning is reduced, losing four positions. This result of the company can be a consequence of the economic crisis of the country, which took place in the middle of 2017. This year, Tekno presented a considerable drop in supply to the domestic appliance and automotive sectors.

As already verified, Usiminas lost the position after the year of 2011, progressively lost positioning over the years, and in the year 2017 took the last position. This change of position in almost all the period is due to Usiminas being impacted by both the global crisis and the national economic crisis. Similarly, the National Sid also lost position again.

In the eighth and last graph, in general, it is noticeable that the company Mangels is in the last position in almost every year. Possibly, its positioning is due to the financial difficulties that already had in the global crisis, as well as to the steel crisis, which generated significant losses for the company in 2014 and 2015. In 2018, it was evidenced that Tekno has a significant loss in its economic and financial position due to the country's economic crisis. On the other hand, Sid Nacional achieved a favorable position, as it had also presented in the years 2011 and 2012.

Finally, the degree of general viability of the companies analyzed is analyzed. Table IV shows the GV of earned by each HEI in the period studied and its position in the viability ranking.

Table 5: Viability of the analyzed companies and their position in the ranking						
Empresa	**GV-UFSC**	**Posição**	**GV-UFPR**	**Posição**	**GV-FURB**	**Posição**
Ferbasa	0.541901	1ª	0.691138	1ª	0.586226	1ª
Fibam	0.327728	8ª	0.596294	6ª	0.415433	10ª
Gerdau	0.498995	5ª	0.552244	10ª	0.533942	3ª
Gerdau met	0.459769	6ª	0.562208	8ª	0.477668	6ª
Mangels Indl	0.445731	7ª	0.617089	5ª	0.455264	7ª
Panatlantica	0.510043	3ª	0.636549	4ª	0.546707	2ª
Paranapanema	0.311868	9ª	0.590777	7ª	0.434327	8ª
Sid Nacional	0.500048	4ª	0.658402	3ª	0.488654	5ª
Tekno	0.523108	2ª	0.667193	2ª	0.524567	4ª
Usiminas	0.299522	10ª	0.557875	9ª	0.417981	9ª

It should be noted that Kendall's correlation between GV attributed by UFSC and FURB is 90.3% (significant at the 1% level). Between the UFSC and UFPR, it is 59.9% without showing any significance. Similarly, the relationship between UFPR and FURB, the correlation is 57.7%, also without significance.

Between the UFSC and FURB evaluation, Kendall's ordinal correlation coefficient registered 77.8% among the positions in the ranking, being significant at the 1% level. The ordinal correlation between the UFPR and UFSC rankings registered 60.0%, significant at the 5% level.

FINAL CONSIDERATIONS

The objective of this article was to verify the influence of the economic and financial indicators on the economic and financial position of the Metallurgy and Metallurgy companies listed on the BM&FBovespa from 2011 to 2018. Through the application of the Paraconsistent Logic, it was possible to determine the economic, financial institutions. The methodology was characterized as descriptive, with documentary analysis as well as quantitative approach.

As a main result, current liquidity hurt the economic and financial position of Siderurgia and Metallurgy, as opposed to influences on other indicators such as dry liquidity, profitability on assets, asset turnover and average term for renewal of inventories, which had positive influences. In this way, the current liquidity of these companies is possibly weakened by the renewal of inventories, since the non-consideration of inventories through dry liquidity positively influenced the companies' positioning.

Therefore, it should be noted that steel and metallurgy may increasingly require more efficient logistics, which also depends on the efficiency of transportation operations throughout the chain. Thus, according to the importance of the improvement in the subsector, it is emphasized that there may be more significant needs for modern equipment, as well as the implementation of more advanced management systems.

These results reinforce the importance of new strategies for this subsector, to improve both the financial health and the economic and financial position of these companies. Moreover, given the consistency of the Paraconsistent Logic to the determination of the companies' positions, which are not allocated in regions neither for fullness nor for inconsistency, this evidence shows that Paraconsistent Logic may apply to the accounting area since few studies using this methodology in Accounting.

Among suggestions for future research, it is suggested that the same study be replicated in other sectors and different businesses, because according to literature, the consideration of the indicators to the study is different, depending on the sector in which it is being analyzed. Another suggestion is to increase the number of indicators used in the study wherever possible.

Email: hrweistr@vcu.edu

ABSTRACT

Overdose and misuse of over-the-counter (OTC) painkiller medicines and non-steroidal anti-inflammatory drugs (NSAIDs) is one issue in healthcare that has been addressed insufficiently. We propose a conceptual framework for a recommender system that enables users to self-evaluate the intensity of pain experienced, interprets the user inputs, and recommends relevant drugs.

KEYWORDS: Pain scale, pain management, pain perception, recommender system, OTC

INTRODUCTION

Pain is associated with actual or potential tissue damage, and is often subjective, as the tolerance level may vary from one individual to another. Pain is categorized as being acute or chronic. Acute pain results from an injury, disease, or inflammation and usually comes on suddenly and may result in anxiety or emotional distress. Chronic pain lasts beyond the normal healing time from an injury, surgical procedure, or disease. To alleviate pain, patients are prescribed medications. Unresolved pain can result in reduced mobility and function, increased depression, feeling of loneliness, sleep disturbance, heightened anxiety, and reduced life satisfaction (Hong, Cagle, Van Dussen, Carrion, & Culler, 2016). Acute pain can be treated using over-the-counter (OTC) medicines and non-steroidal anti-inflammatory drugs (NSAIDs).

This study proposes a conceptual framework for a recommender system that enables users to self-evaluate the intensity of pain experienced, interprets the intensity of pain together with other user inputs, and recommends appropriate drugs. We limit the scope of study to managing acute pain for end-users.

The paper is structured as follows: in the following section, we provide background about pain scales, pain management using OTC medicines and NSAIDs, and medical recommender systems. Next, the proposed conceptual framework is described with its modules explained. Lastly, evaluation of the framework, limitations of the study, and directions for future research are addressed.

LITERATURE REVIEW

The International Association for the Study of Pain defines pain as an unpleasant and emotional experience associated with actual or potential tissue damage or described in terms of damage. Pain is subjective as the tolerance level varies from one individual to another. Several factors define pain and its effects. Haefeli and Elfering (2006) in their article about pain assessment for patients with back issues introduced different aspects such as pain severity, chronicity, and pain experience that define pain and its effects. Pain severity encompasses pain-related interference with activities and the intensity of pain. Chronicity encapsulates various definitions for persistent back pain – lasting for several weeks to more than a year. Pain experience comprises pain amount (how much a patient is in pain) and pain affect (degree of emotional arousal or changes in action readiness due to pain sensation(s)).

Assessment of Pain Perception

Various instruments are in use for assessing the perception of pain from a patient's perspective. These provide effective and established approaches to assessing pain, which is a subjective measure. Healthcare practitioners then interpret the rating statements by patients as no pain, mild pain, moderate pain, or extreme pain. This section presents an overview of pain scales used by practitioners.

Table-1: Widely Used Scales to Assess Acute Pain

SCALE	DESCRIPTION
Visual Analog Scale (VAS) / Graphic Rating Scale (GRS)	Consists of a linear scale (a 100 mm long line) with end points *no pain* and *worst imaginable pain*. Respondents are asked to indicate on the line the point that best represents the intensity of pain experienced (Ferreira-Valente et al. 2011). The distance from the *no pain* point indicates the pain intensity.
Numeric Rating Scale (NRS)	Most commonly used scale, with an 11-point rating from *no pain* (=0) to *worst imaginable pain* (=10). Only whole numbers are used for assessing pain. NRS provides less-subtle distinctions between different pain levels than VAS/GRS.
Verbal Rating Scale	Uses a 5-point scale consisting of the expressions *no pain*, *mild pain*, *moderate pain*, *intense pain*, and *maximum pain* that describe increasing levels of pain intensity. Respondents select the phrase that best characterizes their pain (Ferreira-Valente, Pais-Ribeiro, & Jensen, 2011).
Facial Pain Scale (FPS)	Patients are asked to select a facial expression that best captures the level of pain experienced, choosing from 6 different faces that represent increasing levels of pain intensity, where the left-most face represents *no pain*, and the right-most face represents *very much pain* (Ferreira-Valente, Pais-Ribeiro, & Jensen, 2011).
Pain Drawing	Patients are asked to mark areas of pain on the outline of human figure. At times, patients are asked to indicate different types of pain experienced using different symbols.

Haefeli and Elfering (2006) identify three instruments for assessing the intensity of pain – visual analog scale (graph rating scale), numeric rating scale, verbal rating scale, and pain drawing. Breivik et al. (2008) identify and compare different pain scales in use for assessing intensity of pain. For assessing acute pain, they identify visual analog scale (VAS), numeric rating scale (NRS), and verbal categorical rating scale (VRS). These scales best capture the subjective feeling of patient about the intensity of pain. They recommend using these scales for worst, least, or average pain over the last 24 hours or during the week. After simultaneous recordings of pain intensity on VAS, NRS, and VRS scales in a large number of patients, they found the VAS and NRS scales to be superior over the VRS scale.

Ferreira-Valente, Pais-Ribeiro, & Jensen (2011) compared the relative validity of four scales – VAS, NRS, VRS, and FPS-R – so as to detect differences in pain stimulation as well as differences between men and women in response to experimentally induced pain within a sample of Portuguese subjects**.** Glowacki (2015) discussed the improved outcomes due to effective pain management in patients with acute pain, highlights the dimensions of pain management, and reports increase in patient satisfaction with respect to effective pain management. Baratloo et al. (2016), in their study of using caffeine for managing pain, determined that caffeine is frequently used as an adjuvant therapeutic agent for curing migrant headaches.

Table 1 summarizes the scales used to assess intensity of acute pain.

Over-the-Counter (OTC) Medicines and NSAIDs

In situations where patients choose to take medicines without seeing a physician, they can purchase OTC medications to help them alleviate pain. Furthermore, pain may also require specialized diagnostic procedures like central and peripheral neural blockage or monitored drug infusions. Pain relief medications, also termed as analgesics or painkillers, are regulated by the Food and Drug Administration (FDA). These medicines reduce the sensitivity to pain by acting on peripheral and central nervous system of the body. Based upon the sensitivity of pain and its cause, suitable medications are prescribed.

<u>Classification of pain relievers</u>

The FDA classifies analgesics as OTC medications and prescription medications. The former is useful to relieve minor aches associated with fever, cold, flu, toothache, cramps, etc. OTC medicines can be further classified into the following groups:

- Acetaminophen – used as pain relievers, cough suppressants and cold medications.
- Non-steroidal anti-inflammatory drugs (NSAIDs) – relieve fever, minor aches and pains. Common medicines available include aspirin, naproxen, ibuprofen as well as those to treat cold, sinus pressure, allergies. Pain is relieved by reducing the production of prostaglandins that cause pain.

Lessenger and Feinberg (2008) in their clinical review define OTC medicines as pharmaceuticals that do not require a prescription and are sold on shelves of markets, stores, and pharmacies. The article identifies commonly used prescription drugs that have potential to being abused as well as OTC medications that may be abused. They state that prolonged use of high levels of OTC analgesics such as aspirin and acetaminophen has been associated with dysphoric mood states.

Wilcox, Cryer, and Triadafilopoulos (2005) acknowledge the issue of overdosing and misuse of OTC and NSAID pain medicines. They conducted a comparative study with two surveys – Roper Starch survey and National Consumers League – to determine if users of medicines are ignorant of the potential side effects. The types of pain identified from both surveys are arthritis/joint pain, back pain, headache, sports/exercise related pain, and others. The frequency of using these medicines are categorized as daily, several times per week, several times per month, less than several times per month, and as needed. Joint pain or arthritis is factored as the most common cause for taking medicines. The attitudes towards side effects indicate that 46% of respondents from the Roper survey believed OTCs to be safer than prescription medicines, and 37% experienced side effects. The Analysis for National Consumers League survey indicated 49% of respondents were somewhat or very concerned about side effects, and 36% believe OTCs are safer than prescription medicines. The authors insist an educational intervention for patients as well as physicians is needed.

Blondell, Azadfard, and Wisniewski (2013) summarized the medications used for treating acute pain in adults. They state that acetaminophen is the first-line medicine for treating mild to moderate acute pain. Ibuprofen and naproxen are the preferred NSAIDs for treating mild to moderate acute pain, due to their effectiveness, side effects, cost, and over-the-counter availability. Cycloygenase-2 selective NSAIDs, which have similar effectiveness to non-selective NSAIDs, are second-line medications for treating mild to moderate pain because of their greater costs. The authors also identify the safety and effectiveness of acetaminophen, aspirin, and non-selective NSAIDs from Cochrane reviews with respect to amount needed to produce 50% pain reduction in 4-6 hours.

Pardutz and Schoenen (2010), in their review of clinical and experimental data for using NSAIDS to manage acute migraine pain, identify aspirin, acetaminophen and other NSAIDs as the most frequently used drugs. The randomized control trials reviewed show evidence that acetaminophens show less efficacy as compared to other NSAIDs. The authors also emphasize that there is no evidence that any particular NSAID is more or less effective than others, with notable exception of acetaminophen, and they recommend to select a drug with rapid GI absorption and the most favorable efficacy/side effect profile. Gelfand and Goadsby (2014) in their review summarize what is known about predicting the response related to medication withdrawal.

Pombo, Araújo, and Viana (2014), in their comprehensive literature review, focused on identifying computer technologies that facilitate knowledge discovery from clinical data produced by either patients or healthcare professionals. The strengths and weaknesses for rule-based algorithms, nonstandard set theory, artificial neural networks (ANNs), and statistical learning algorithms with examples are identified from the extant literature. The issues identified from the research include lack of integration with mobile devices, use of web-based interfaces, and scarcity of systems that allow for patients to enter data.

Westergaard, Munksgaard, Bendtsen, and Jensen (2016) present their perspective about headaches resulting from overuse of medications.

Medical Recommender Systems

Sodsee and Komkhao (2013) proposed a medical recommender system combined with evidence-based medicine. Their proposed *evidence-based medical recommender system* collects data related to medical history of patients, case reports and expert opinions, and experimental studies that are analyzed with intelligent algorithms. Some of the intelligent algorithms of relevance identified are neural networks, fuzzy theories, support vector machines, and data mining techniques. The emphasis of this approach is on telemedicine, i.e. allowing physicians to access the system anywhere with Internet connectivity, and recommendations from outcomes by intelligent algorithms delivered to physicians. Furthermore, the physicians can provide consultation to their patients.

Lalloo, Jibb, Rivera, Agarwal, and Stinson (2014) in their study reviewed the pain self-management applications that are available for download from application stores for smartphones. The criteria for identifying the applications for review included goal of app (treatment or mitigation of pain) and primary user (person in pain). The assessment of the applications was done based on the researcher-developed list of important self-management functionalities. The limitations identified include a lack of integrated features for personalization, lack of involvement of health care professionals in the development and evaluation of the app, lack of foundation in current research or established theories, and lack of feasibility or effectiveness testing. The authors also stress the need of research for developing comprehensive, evidence-based, and clinically informed self-management applications for smartphones that can be used by for people living with pain.

Heidarabadi et al. (2017) reviewed articles dealing with information systems for pain management of patients with spinal cord injuries. The 18 articles reviewed demonstrate the positive role of such systems in increasing accuracy and improving physician’s decision-making. Although the study is specific to chronic pain from spinal cord injury and identifies advantages for physicians in that context, some of its disadvantages are also applicable to the context of our study. The authors state that the greatest disadvantages of the systems reviewed are a lack of integration with mobile devices, a lack of web-based interfaces, and a lack of features that allow data entry by patients. Our proposed framework addresses this issue by allowing for the users to rate their pain and input the pain sensations experienced.

Ozsoy, Özyer, Polat, and Alhajj (2018) use a *Pareto dominance and collaborative filtering* method adapted from recommender systems to address the drug-repositioning problem. The selected method identifies drugs most similar to a target drug as well as neighbor drugs in order to predict new indication of the target drug.

We are not aware of any published studies dealing with recommender systems for selecting self-treatment with OTC pain relief medicine.

CONCEPTUAL FRAMEWORK

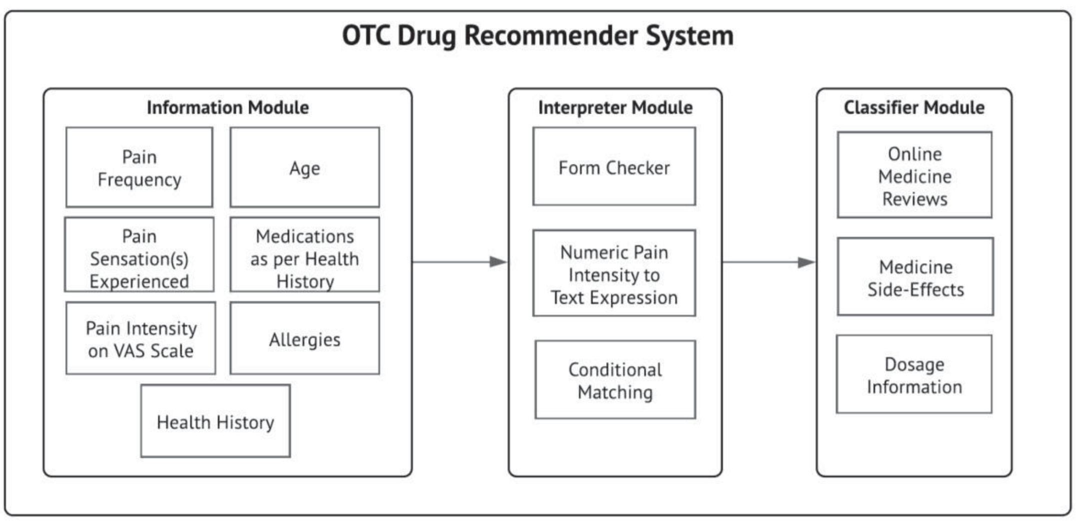
As shown in Figure 1, our proposed framework consists of three modules – *information module*, *interpreter module*, and *classifier module*.

The ***information module*** requires users to provide information related to their age, existing allergies, medical conditions (health history), other medications taken, the type of pain sensation, how often the pain occurs (pain frequency), as well as rate the intensity of pain experienced using VAS scale. We consider age, medications as per health history, allergies, pain intensity on VAS scale, and health history to be the mandatory fields.

Cues related to different types of pain sensation with explanation are presented to the users, so as to clarify the terminology related to pain sensation, and thus reducing errors in selecting incorrect options, which do not apply to their situations. Some examples of pain sensations include throbbing, palpitation, aching, shooting, pins and needles, pinching, crawling, itching, numbness, tightness, burning, radiating, nagging, phantom pain, etc. It is also important to have information about all medications taken by users for any allergies they may have. This information is required for recommending appropriate pain medicines given the interpretation of pain scale, and ensuring that the recommended medicine does not react with their ongoing treatment. Pain frequency requires for users to input how frequent they experience these pain sensations, and possibly provide description about the duration of the sensation. For example, a patient may experience a shooting sensation in a foot, the first thing every morning. If the users cannot find the specific pain sensation from the terms listed by the recommender system, they will be presented with an 'other' option. Selecting this option will then allow them to describe the sensation as experienced in their own words.

Pain intensity is entered on the VAS scale and users are provided instructions about using this scale to express the intensity of pain, to ensure that they do not assess the pain incorrectly.

Figure 1: Proposed Conceptual Framework



The ***interpreter module*** consists of a form checker, a convertor for numeric scale to text expression, and conditional matching. The form checker does a validation check to ensure that the required information (mandatory fields) is entered by the user. Age, medications as per health history, allergies, pain intensity on VAS scale, and health history are the mandatory fields. If any of these mandatory fields are incomplete, users are asked to provide the missing information and complete the form. The numeric level of pain is read and interpreted as a text expression. Collins, Moore, & Mcquay (1997) state “Our results indicate that if a patient records a baseline VAS score in excess of 30 mm they would probably have recorded at least moderate pain on a 4-point categorical scale; in excess of 54 mm and they would probably have recorded severe pain.” Using the interpretation of the 100-mm VAS scale as per the study by Jensen, Chen, & Brugger (2003), a rating of 0 to 4 mm can be considered no pain, 5 to 44 mm can be considered mild pain, 45 to 74 mm can be considered moderate pain, and 75 to 100 mm can be considered severe pain.

Conditional matching takes into consideration the data from the information module and the diagnosis of the user to determine the most effective medicine for the user. Conditional matching within the interpreter module is used to consider different scenarios based on allergies and medications taken by users, and the indicated pain sensation, frequency, and intensity, to identify which medicine is the most effective. A simple example for conditional matching is, say user1 who experiences pain due to cancer, versus user2 who experiences pain due to inflammation. Their respective subjective assessment of pain is likely to differ. That is, the severe pain experienced due to inflammation will be differentiated by conditional matching from the severe pain that is experienced by the cancer patient. Some users may accidentally provide information related to allergies, medicines as per health history within the health history field. This issue can also be considered as a conditional matching issue. In this context, conditional matching may distinguish between phrases used by users to explain their allergies from medicines taken as per health history.

The **classifier module** directs the users to online reviews of recommended medicines, their side-effects, and dosage information. It is important to note that the performance of the classifier module is dependent upon the information that is provided by users and the interpretation of pain by the interpreter module.

EVALUATION APPROACH

The proposed framework requires basic information related to users’ health history, allergies (if any), medicines taken, pain sensation, its frequency as well as their age. This information, in addition to the patient’s personal information is collected by healthcare practitioners before designing a treatment plan for the patient. In our framework, users are not required to provide personal information, but based upon the information they provide they will be informed about relevant over-the-counter (OTC) medicine(s) that can be taken by them, as well as reviews that describe possible side-effects and appropriate dosage information. This framework guides the development of recommender systems that can address the issue of overuse and abuse of OTC medicines.

The evaluation of information and interpreter modules is done simultaneously so as to ensure that the system can make correct interpretations about pain intensity, guide users to provide details in mandatory fields, and use conditional matching to recommend medicines to users.

To evaluate the performance of the classifier module, data is obtained from drug review websites (drugs.com, askapatient.com, and drugratingz.com); especially those websites with user reviews, information related to side effects, and dosages for the said medicine. Upon collecting reviews and cleaning data, text-mining software, such as QDA Miner and Enterprise Miner SAS can be used for analysis.

By synthesizing the data collected from these sources, the performance of the classifier module can be evaluated based upon its recall, precision, and accuracy.

Table 2 presents the conceptual definitions for the evaluation criteria.

Table-2 Evaluation Criteria

CRITERIA	DESCRIPTION
Recall	% of total relevant results correctly classified by the classifier
Precision	Proportion of outcomes correctly classified by the classifier
Accuracy	Proportion of negative outcomes classified correctly by the classifier

The performance of the overall framework with respect to information provided by users, the intensity of pain experienced, allergies, and age, and the interpretation of pain scale, and medicine recommendations must be evaluated with a healthcare practitioner. Furthermore, the authenticity of reviews provided by users on the websites, i.e. accuracy of side effects stated for the said medicine and appropriate dosages, can be validated only by healthcare practitioners. Hence, the recommendations presented by the classifier module should first be validated with healthcare practitioners. Also, the overall prediction as per our proposed framework for recommender system must be evaluated by healthcare practitioners.

LIMITATIONS AND FUTURE DIRECTIONS

The proposed framework needs to be evaluated in two ways. First, by simulation with QDA miner and Enterprise Miner SAS using data such as the required information in the information module and the classifier module. Second, the outcome must be validated by healthcare practitioners. The performance of the classifier module in terms of dosage information, side effects of medicine, and online medicine reviews should also be evaluated and validated by healthcare practitioners, to avoid providing users with incorrect dosage information and side effects for the medicines. In our proposed conceptual framework, we have not included healthcare practitioners, which is a limitation that should be addressed in future.

Our framework does not consider updating reviews of medicines and classifying comments for newly added comments. This is an issue that can be addressed in future research. Additionally, our framework does not incorporate a 'ask for help' feature where users can consult healthcare practitioners about the drug recommended by the system, or instances wherein they are unclear about side-effects of the recommended medicines.

Lastly, security and privacy concerns in extant healthcare systems are excluded from the scope of our framework. The users are not required to register with their email information for using our framework, and their medical information provided in the information module is not stored within our framework. Hence, future research can incorporate additional features that allow users to create their profile(s), update their information by offering enhanced security identification protocol. The security identification protocol can then be capable of addressing security and privacy concerns that are widely encountered in healthcare systems.

CONTRIBUTION AND CONCLUSIONS

Our conceptual framework presents a new perspective for recommender systems that may lead to the development of practical applications that allow users experiencing pain to self-manage that pain and find appropriate treatment in an efficient and effective manner. Furthermore, our framework may also lead to new ideas for more general research into medical recommender systems based on user needs and user provided input.

ABSTRACT

Proposed here is a new concept for a network of specialized continuous ambient air sampling systems, which employ a novel non-destructive ionization and separation method, coupled to a near real-time genomic sequencer. The network of preferably viral samplers would constitute a plurality of distributed nodes throughout the world, with viral concentration, identification, and mutation data uploaded to the cloud for epidemic/pandemic predictive modeling. The proposed model offers the ability to migrate from outbreak surveillance, to outbreak forecast. In addition, the capability for continuous pathogen data of predominately viral genomic sequencing offers an enhanced capability to help track antigenic drift and antigenic shift. While optimized for viral capture and analysis, any airborne pathogen or spore can be accepted using the technology. An effective monitoring system necessitates a predictive modeling system that is dynamic, which responds and adapts to similar epidemiological infection trends. Applications include world health monitoring, pandemic prediction, and detection of real-time bioterror pathogen deployment.

KEYWORDS: Epidemic, Pandemic, Air Sampling, Cloud, Electrospray, Genomic Sequencing

INTRODUCTION

Early efforts to predict the spread of disease have been traced back to the 14th century. Most notable in historical epidemics is the Black Death, which engulfed Europe from 1347 to 1351, killing an estimated 200 million people. Attempts to predict the spread of disease have, until recently, relied essentially on weather predictions coupled with the emergence of known vectors of a given pathogen. New software developments have allowed computer models to make use of predictive analysis of disease trends to help isolate the most likely path for disease expansion. Data from hospitals and clinics, combined with key word search of social media and air travel data add additional variables to the prediction process.

Mathematical models for epidemic spread were first employed in the early 20th century, which separated susceptible individuals into groups, which relate to various stages of the infectious disease. Such stages may include exposure to known vectors, infectious but not symptomatic, symptomatic, and death. Transition from one group or compartment to another are predicted using differential equations (Fuppa, 2017). These deterministic models necessitate prior history of the disease to yield useful prediction results (Brauer & Castillo-Chavez 2012). The most common predictive model is known as the SIR approach, which takes into consideration those individuals who are susceptible 'S' to a specific disease, such as infants or the elderly, the quantity of those already infectious represented as 'I', and the quantity of those in an exposed population that have recovered as ‘R’, who have now developed immunity. The model, however, is not applicable in cases where patients do not develop immunity, as in the case of influenza, and populations are continually at risk for redeveloping the disease, hence the need for continual vaccine development based on antigenic shift and antigenic drift. Antigenic shift is due to genetic mutation of a human flu virus after human exposure to an animal viral species that also can affect humans. Antigenic drift is caused by random events that alter the viral structure, which require new immune system adaptation for antibodies to recognize the new antigen sequence. Because of these changes in many airborne infectious diseases, defining who has been exposed and the time of exposure that defines the onset of the disease becomes ever more imperative if the transition rate to a given population is to be predicted with any accuracy. Clearly, a means by which additional near real-time genetic sequence information about airborne viral exposure to susceptible populations, and the exposure magnitude to a target population, would yield improved disease onset extrapolation, and help mitigate potential epidemic or pandemic events. Continuous airborne sampling and genetic sequencing of viral species coupled to a predictive model would offer a vast improvement in epidemiological prediction of evolving influenza or even potential bioterror agent exposure to large populations, mitigating the level of risk across those susceptible to a given pathogen threat.

LITERATURE REVIEW

The literature review pertaining to this study did not reveal any results on continuous air sampling of potential viral infectious agents where real time or near real time genetic sequencing has been proposed or attempted. Present methods of genetic sequencing rely on incubating samples in the lab in preparation for genetic amplification (PCR or Polymerase Chain Reaction) and subsequent sequencing, which can take upwards of a day or more to complete. A faster approach as proposed herein, could have a significant benefit in reducing the spread of a disease, and even help in narrowing the identification of patient zero, the source of a communicable disease. The review covering the decision process for both naturally occurring infectious diseases and for deliberate events relating to terrorist biowarfare pathogen release left the identification of a given pathogen in the hands of a clinic or hospital. The time constant by which patent admission, examination, sample collection, culturing, and genetic or other identification of the infectious agent, ranged from hours to days after exposure. In each instance, the exposure to susceptible populations cannot be ascertained with any degree of accuracy. Epidemiological data management systems (epiDMS) are increasingly being utilized to help predict the next epidemic spread. However, to be effective, real time data is necessary. In epiDMS, “the data, models, and underlying model parameters dynamically evolve over time. This necessitates continuous analyses and interpretations of the incoming data and adaptation of the networks and models. Therefore, simulation ensembles may need to be continuously revised and refined as the situation on the ground changes” (Liu et al, 2016). With epiDMS, healthcare providers provide the input data across the region of suspected infection. The modeling software does not by itself collect any pathogen data nor does it develop dynamic sequencing of a particular airborne pathogen. “Once the query is executed and the relevant simulations are identified, epiDMS then organizes the results in the form of a navigable hierarchy, based on the temporal dynamics of the disease: scenarios that result in similar patterns are grouped under the same branch, while simulations that show key differences in disease development are placed under different branches of the navigation hierarchy. The user can then navigate on this hierarchy using drill-down and roll-up operations and filter sets of simulations for further analysis” (Liu et al, 2016).

Many references refer to surveillance systems, but do not articulate exactly what those surveillance systems are, other than relying on hospitals and clinics to define what is and is not a verified outbreak of the target infectious agent. Because of the limited amount of available data in predictive models, some scholars have suggested the use of *Partially Observable Markov Decision Processes* (POMDPs) to anticipate a disease outbreak (Izadi & Buckeridge 2007).

The same situation of limited real time input data exists for bioterror predictive analysis. The assumption in this case is that disease will spread rapidly, in order to become as much a tool mass disruption as it would be a tool of mass destruction. Accordingly, inputs from medical care facilities, work absenteeism, and social media are currently the primary data sources for existing mathematical models. The goal of the Department of Homeland Security's *'BioWatch'* was to have an automated system that continuously samples the air in an effort to add a new near real time dimension to the aforementioned input variables, however all attempts at an automated BioWatch have met with failure. The equipment required for an airborne sample capture and subsequent processing were the key factors in DHS's BioWatch failure. At present, BioWatch consists of rooftop 'witness plate' air samples that are cultured and sequenced daily and brought to a laboratory for information on new and emerging disease. The process is cumbersome, hardly real time, and fraught with errors.

Other predictive models that look at animal farm infection, which could in some instances serve as vectors for human disease as in swine and bird flu, employ "an epidemic model to observed, spatially-explicit, infection data at weekly intervals throughout two historical outbreaks of foot-and-mouth disease, UK in 2001 and Miyazaki, Japan in 2010 (Probert, Jewell, et al, 2018).

Improved Epidemic Prediction With Live Agent Sequencing and Cloud Interface

Recent research by our group suggests that an improvement in epidemic prediction can be achieved using a novel means of distributed nodes capable of ambient live agent pathogen assessment, specifically genomic sequencing, with DNA/RNA data uploaded to the Cloud via the world-wide web.

In the following *Table 1*, some of the features of the proposed distributed pathogen air sampling nodes coupled to the cloud is summarized. The proposed system air sampling nodes in mass production are targeted to cost less than $5,000 U.S., while the DHS BioWatch program remains very costly because of the sheer number of highly trained personnel to prepare, distribute, and later collect and process the culture plates necessary. Distributed automated nodes also can be employed to sample air pathogens at animal farms which may be located great distances from urban centers and thus can add many hours or days to a BioWatch-like witness plate sampling approach to be conducted. One especially useful added advantage to an automated air pathogen system connected to 'the internet of things', is that selected nodes can be designed to automatically process mosquitos to look for the presence of such insect borne diseases such as Zika, Malaria, and EEE or Eastern Equine Encephalitis, to name a few. Early identification via near real-time genetic sequencing of insect borne disease jump starts the epidemic prediction process because no healthcare workers are required to identify the presence of a known disease in a given geographic area. Those at risk can be simply warned to taken appropriate precaution thus averting any epidemic.

HYPOTHESIS

We hypothesize that automated airborne live agent sampling nodes coupled to the cloud can be situated in multiple public spaces in greater numbers than a DHS BioWatch concept as presently employed by the U.S. government, because of low cost and small size of the approach. The epiDMS is a software package that relies exclusively on the data input of healthcare workers who have taken patient samples and identified a given airborne pathogen through laboratory testing. The proposed nodal analysis does not rely exclusively on healthcare worker input, but complements such data inputs to arrive at a more accurate prediction of potential disease to spread in a given geographical populace. Furthermore, a cloud-based nodal analysis of pathogens in public spaces such as airports, train and bus stations, allows predictions to be made regarding cities at risk based on travel destinations. Appearance of a disease in a new city after human-host incubation can provide data, which can be used to truncate the source via traveller bookings at an airport.

Table 1 –
Pros / Cons of Traditional Predictive Modeling vs. Pathogen Sampling & Cloud Interface

Comparison of Epidemic Prediction System				
TECHNOLOGY	Public Space Monitoring	Detection Under 1 Hour	Stand Alone	Cost per node
Sampling Cloud Nodes	YES	YES	YES	YES
DHS BioWatch	YES	NO	NO	NO
epiDMS	NO	NO	NO	NO

<u>The Importance of Detecting Viral Pathogens in Near Real Time in Public Areas</u>

Computational software promise to help stem the spread of disease that can decimate civilian populations, and incapacitate military forces. “Forecasts would be extremely helpful to public health officials in containing infectious diseases, but it is really difficult. The science of forecasting is a work in progress. It’s akin to trying to solve a jigsaw puzzle with some of the pieces missing and a vague sketch of what the finished image should look like” (Bushey, 2016). Because of the time constant between when an individual becomes exposed and infected to an airborne pathogen such as influenza, and when that individual becomes symptomatic may be many days (1-4 day incubation period), vector transmission to other persons will likely have occurred. Only a small fraction, generally the very young or the very old, in the early stages, will end up in a hospital or clinic where positive identification of the virus has been obtained and is available as a statistic. The ability to monitor the level of viral load in a local population outside of the hospital or clinic setting, coupled with an ability to know precisely what the virus genome sequence, would advance the state-of-the-art in epidemic predictive capability substantially. We believe we may be able to achieve this goal through the merging of several well-established technologies, and the combination of new developments in gene sequencing to be described.

Influenza, as well as many bacterial agents, can survive for hours as an airborne species. Because droplets from a cough or sneeze encapsulate many virons, the probability for disease transmission in congested public areas is very high. In general, particles that are extremely small (< 5 microns) can remain airborne for many hours and the smaller the particulate, the longer the residence time. As virons move through the air, evaporation of water (90% water, 0.5-5% mucous) causes the droplet to become smaller and thus more mobile. Residence time is further enhanced by humidity and the lack of direct sunlight. The research lab of Dr. Lydia Bourouiba at MIT has investigated the fluid dynamics of disease transmission, and has determined experimentally that cough ejecta and sneeze cloud duration of typically approximately 250 milliseconds, can literally shoot across a room in a matter of seconds, 200 times farther than previously thought (Bourouiba, 2019).

Given the high airborne viral load that exists in congested public spaces, it would seem natural to seek out such locations to place a viral air sampler that can provide real time indication of ambient viral species. The goal of such a sampler would be to capture trace species indicative of viral agents, concentrate such species to a level of at least 200 nanograms or better, and subject the viral species to continuous genomic sequencing. The viral concentration and sequence data ideally could then be uploaded to the cloud, for deterministic computer modeling (where successive operations are based on the previous state) that merges the data with other variables previously described, such as PAHO (Pan American Health Organization), weather, and social media input variables. The added advantage of the sequencing functionality is that emergent strains can be revealed in an almost near real-time fashion even before a patient-vector becomes symptomatic. An added benefit is that many patients who are symptomatic may never seek professional medical attention, and thus never end up as a PAHO data point. A distribution of automated viral air samplers worldwide, seeded in locations such as airports and train stations, could provide data never previously attainable in epidemiology.

METHODS

The proposed system is comprised of several key parts necessary to sample ambient air laden with target pathogens. The entrance to the air sampler utilizes a common aerosol impaction filtration method. High velocity air is channeled around a 90-degree bend, causing heavier fractions to impact and embed in the end channel. Soft media such as low vapor pressure grease allow heavy fraction to be permanently entrained. As lighter fractions negotiate the change in direction, subsequently smaller and smaller fractions can be derived through the stratification based on mass through the airflow. At a suitable point downstream, a cross current soft ionization source is employed to nondestructively capture bioaerosols from the airflow, and remove them from the air stream via electrostatic forces. To employ electrostatic separation, the bioaerosols are nondestructively ionized using a process known as ‘electrospray’. Electrospray is a process by which a conductive fluid, in this case an aqueous solution, is utilized to produce a nanospray of desorbing droplets which attract and capture polar or polarizable species from the air, of which virons are a part. The ability to non-destructively ionize a virus has been well reported in the literature (Bothner & Siuzdak, 2004), where electrospray air capture of polar and polarizable species was accidentally discovered by John Fenn et al at Yale in 1984. As a charged species, final filtration is accomplished using an electrostatic filter, similar to those found on magnetic sector mass spectrometers. In other words, once we have eliminated any dust or particulates using a prefilter (i.e., inertial aerosol separation), pathogens such as bacteria or viruses, can be grouped based on their difference in mass. A charged species passing through an insulated flight tube coupled to a sensitive electrometer circuit can detect the ‘image charge’ of the pathogen species passing through. The charge can provide information about the physical size and mass of the species, thus helping to sort viruses verses bacteria. This approach is known as CDMS or Charge Detection Mass Spectrometry (Pierson, et al., 2016).

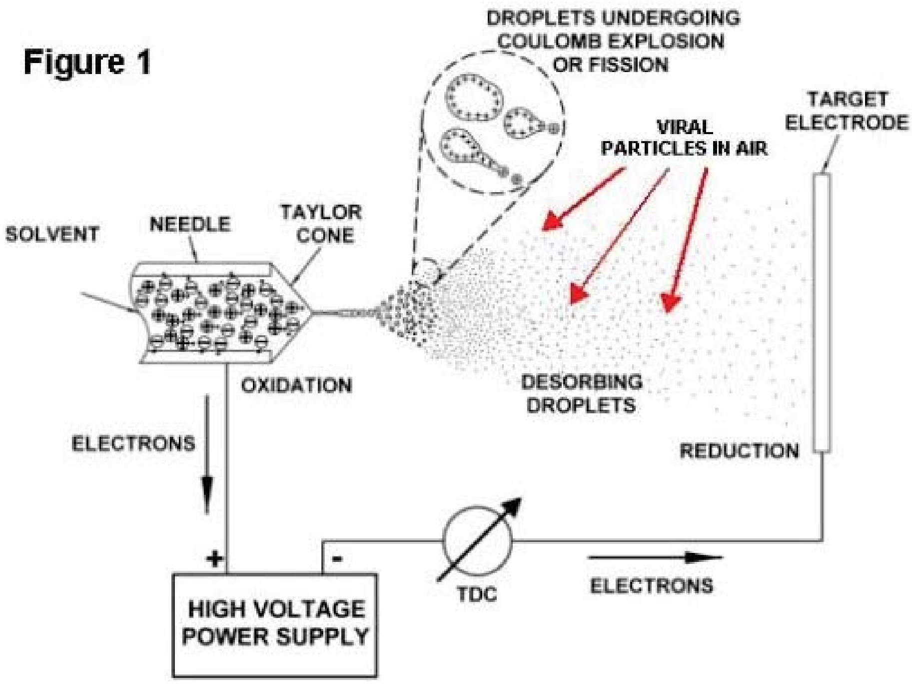
Once the virons have been selected, they are accumulated on a ‘witness plate’, in preparation for automated sequencing. The sequencer of choice is a ‘nano-pore- device, manufactured by Oxford Nanopore, and recently demonstrated aboard the International Space Station or ISS. The Nanopore system employs “bespoke, proprietary pore-forming proteins to create pores in membranes. Pore-forming proteins are common in nature. For example, the protein α-hemolysin and similar protein pores are found naturally in cell membranes, where they act as channels for ions or molecules to be transported in and out of cells. A protein nanopore α-hemolysin is a heptameric protein pore with an inner diameter of 1 nm, about 100,000 times smaller than that of a human hair. This diameter is the same scale as many single molecules, including DNA" (Oxford Nanopore, 2018). In the Nanopore DNA sequencing, the system may process the sample until a minimum of ten-fold read coverage over specified regions of interest has been seen, until a specific mutation has been observed in a sample or until enough sequence data has been collected to reliably assemble a sample against a reference (Oxford Nanopore, 2018). As DNA/RNA moves through the pore, changes in electric potential are translated into genetic sequence data. In discussion with James Brayer (Bango-Brayer email 2016) U.S. representative for Oxford Nanopore, it is feasible to adapt the sequencer to the proposed aerosol viral collector-concentrator. The process then is capture, concentrate, extract, genetic library prep, and continuous flow sequencing. The present system sensitivity is 200 nano grams of genetic material, but lower levels are anticipated. Importantly, no PCR or Polymerase Chain Reaction, an amplification step to duplicate genetic material in a concentration sufficient for identification, is required. Protein nanopores such as alpha-hemolysion or MspA have been demonstrated to work well. A longer-term solution with improved performance may be a graphene nanopore. Regardless of the genetic sequencer employed, the electrospray capture and pathogen selection concept is adaptable to any subsequent downstream analytical tool. The electrospray capture technology has been proven and applied to biowarfare agent capture under prior Navy, Marine Corps, and National Academy of Science support. In addition, the technology was featured in a NASA Tech Briefs edition in 2011-12 (Bango et al) after application on a spacecraft air filtration system contract that included Dr. John Fenn and former astronaut Dr. Buzz Aldrin (Bango & Dziekan 2013).

RESULTS

The lead author and his colleagues at Yale under the late John Fenn (2002 Nobel Prize Chemistry) discovered that electrospray ionization, now traditionally used for mass spectrometry, has the ability to "getter" or capture polar or polarizable trace species from the air, of which bio-species are a part. As is well known, since 9/11, there has been a flurry of development of many new methods and devices to identify potentially toxic agents of all kinds. But what seems to be missing is the fact that one needs to capture enough of the target species in order to achieve detection. Dr. Fenn once stated that the sensors should not be called detectors, but "identifiers", and that a "detector" is really composed of a collection device and an identifier. If we collect more analyte from the surrounding air-diluent, we need a less sensitive identifier and vice-versa. It is even better if the collection device captures and concentrates only the class of materials of interest while ignoring the background. Electrospray is unique in that it allows for non-destructive capture of all airborne pathogens, including spores, bacteria, and viruses out of the ambient air. For the purposes of tracking the spread of influenza, the present effort is directed at viral particles. Electrospray was shown to capture tobacco mosaic virus as far back as 2003 (Fuerstenau et al, 2003).

Subsequent experiments in our lab have revealed that ambient bacteria and viruses can be softly ionized by electrospray and carried into the partial pressure region of a vacuum system, detected using charge detection, and deposited on a 'witness plate' made 'sticky' using a thin layer of ionic liquid. Ionic liquids are room temperature salts, which have essentially zero vapor pressure. (Under present NASA support, contract 80NNSC19C0329, a system using this capture approach is being designed for possible microorganism life detection on the Saturn moon Enceladus).

Figure 1



Basic electrospray configuration illustrating an analyte dissolved in a solution and transformed into a jet of discrete charged droplets through the formation of a 'Taylor Cone'. The evaporation of the solvent species leaves behind just the analyte as a multiply charged ion or particle. This is a soft ionization process, which leaves fragile biospecies unharmed. (Source: Bango et al)

Viral Sequencing

The input to the pathogen sample pre-sorts the size of input media using well-known aerosol techniques. In the preferred embodiment of an ambient pathogen sensor, ionized viral species are introduced into a partial pressure region, and impacted onto a nanopore plate coated with a thin layer of ionic liquid previously described. The method of viral identification is to use the ionic liquid as a nanopore electrolyte that channels DNA and RNA to develop genetic sequence data, which is then uploaded to the cloud. As a result, viral sequence data can be collected and disseminated from multiple sources in near real time. Ideally, the sources of air sampling include all locations of human congestion, such as key travel points. These include airports, train and bus stations, shopping malls, public buildings, as well as hospitals and clinics. Livestock and avian breeding facilities can be included. The resulting influx of genetic data, combined with existing hospital and clinic data, plus travel and social media inputs, will enhance epidemiological predictive models for the spread of viral based disease.

<u>Decision Inputs</u>

The ability to share near real time viral genetic sequence data from multiple air samplers situated around the globe via the cloud, with comparisons to archived and other real time epidemiological data sources, would offer significant saving of life due to improved decisions based on deterministic computer modeling. The decision to curtail travel, impose quarantines, or to assist in precise vaccine fabrication and distribution all benefit from knowing precisely what pathogen is present where and when, and how presented to what population at risk.

Referring to Figure 3, additional information to supplement the decision algorithm is virtually unlimited. Ideally, verified infection attributable to a specific genetic sequence of an airborne pathogen from clinics and hospitals, coupled with current information about specific disease data from the Center for Disease Control, Homeland Security, the World Health Organization, and more serve to help track the spread of infection. Official healthcare and department of defense sites in the U.S. and with respective agencies in other participating countries, is provided for Cloud access as a genetic sequence. Information sourced from social media will be less precise, subject to word or phase identification of such general information such as individual reporting of personal or family illness. While social media is obviously not a reliable data input as is sequencing data in a laboratory, a critical mass of postings relating to disease may help improve epidemic model predictive results by affecting the sensitivity threshold of when certain predetermined interventional action should be taken in a suspect disease outbreak. Such intervention may be to concentrate specific regions to increased sample acquisition.

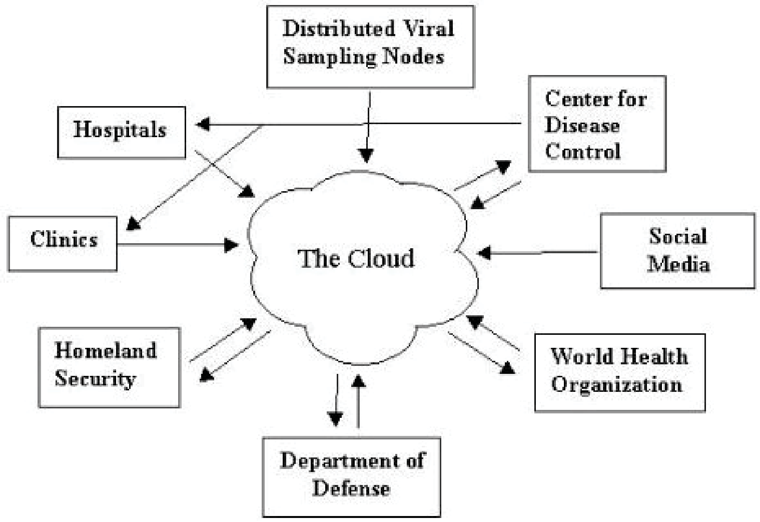

Figure 3

Sensitivity in Epidemic Decision Making & Risk Management

A significant problem in any epidemiological detection system concept or methodology, is ascertaining when to signal an alert regarding the possible beginnings of an epidemic. How many cases signify the start of an epidemic, and will a public alert make the situation worse are questions that come to mind? An airborne pathogen sampler situated in a public location which acquires and sequences a new strain of influenza for example, is not a condition sufficient to trigger an alert. Identical strains must be conclusively identified by healthcare professionals in a clinical setting where the infectious capability and debilitating results in humans has been clearly and definitively verified. While data input for identical strains may be derived from multiple distributed nodes, i.e., airborne samplers located in multiple airports for example, there will be a threshold at which public notification and/or travel restrictions need to be implemented. The combination of new strains, clinical cases, and defined spread of such strains radiating across a known geographic area, each serve as discrete decision inputs in a Boolean truth table. The results of the decision matrix in such a truth table determine when proactive action to stem the infection spread must transpire. However, if public notification of what is believed to be the onset of an epidemic occurs, there is a strong potential for psychosomatic responses which may have contracted the pathogen but are not yet symptomatic, either due to a delay in incubation or who may be affected but are only carriers. Such individuals seeking treatment believing they are sick but yet test positive to an immunoassay test could skew the trigger point in a decision tree to restrict travel or initiate inoculation protocols or other interventional activity. There could also be false positives or other variables where faulty inputs may skew the decision matrix.

A 30-year-old sensitivity conjecture involving how to measure the result in a given Boolean function, determines the result of an output bit based on the input string. Until recently, variable factors that determine whether a given input bit is asserted high or low, has not been quantified mathematically. Dr. Hao Huang of Emory University recently published an elegant proof, which solves this problem in computer science. “This "sensitivity" conjecture has stumped many of the most prominent computer scientists over the years, yet the new proof is so simple that one researcher summed it up in a single tweet: "This conjecture has stood as one of the most frustrating and embarrassing open problems in all of combinatorics and theoretical computer science," wrote Scott Aaronson of the University of Texas, Austin, in a blog post.

The conjecture concerns Boolean functions. Every computer circuit is some combination of Boolean functions, making them "the bricks and mortar of whatever you're doing in computer science" (Quanta Magazine, 2019; Clark, 2019). Furthermore, scientists at the French National Center for Scientific Research, described the sensitivity dilemma as “filling out a series of yes/no questions on a bank loan application.” that provides a score that determines qualifications. This process is a Boolean function where answers to questions are the input bits, and the decision is the output bit.

It is conceivable that an erroneous answer to a single question can change a decision outcome. If your application gets denied, you might wonder whether you could have changed the outcome by lying on a single question — perhaps, by claiming that you earn more than $50,000 when you really don’t. If that lie would have flipped the outcome, computer scientists say that the Boolean function is “sensitive” to the value of that particular bit. If, say, there are seven different lies you could have told that would have each separately flipped the outcome, then for your loan profile, the sensitivity of the Boolean function is seven.

Computer scientists define the overall sensitivity of the Boolean function as the biggest sensitivity value when looking at all the different possible profiles. In some sense, this measure calculates how many of the questions are truly important in the most borderline cases — the applications that could most easily have swung the other way if they’d been ever so slightly different” (Klarreich, 2019). Please refer to Figure 4.

Taking the sensitivity factor into consideration in epidemiological decision-making, should make the decision tree more accurate and thus effective in stemming the spread of disease. We must determine, similarly, what questions are essential in those borderline cases, such as defining at what point a patient becomes symptomatic and whether a carrier who is not symptomatic is assigned the same set bit value. After all, a symptomatic patient might be coughing and sneezing, and therefore expelling particulates that substantially increase the likelihood of airborne transmission to another uninfected individual, whereas a carrier may infect only by direct contact. The two carriers are not equal and thus should be assigned different sensitivity values in the decision logic network.

In developing new computer code for an improved epidemiological early warning system, the sensitivity factor must be taken into consideration as it would for a hardware Boolean switch subject to bit-flip errors. The addition of data concerning ambient pathogens sampled that have been positively identified coupled with objective patient infection rates by the same pathogen supplied by healthcare facilities treating such patients, will yield rapid assessment of infectious virulence and thus the ability to effect rapid countermeasures to stem the spread of the disease. Objective data may be added to subjective data from sources such as social media for possible input correlations if desired.

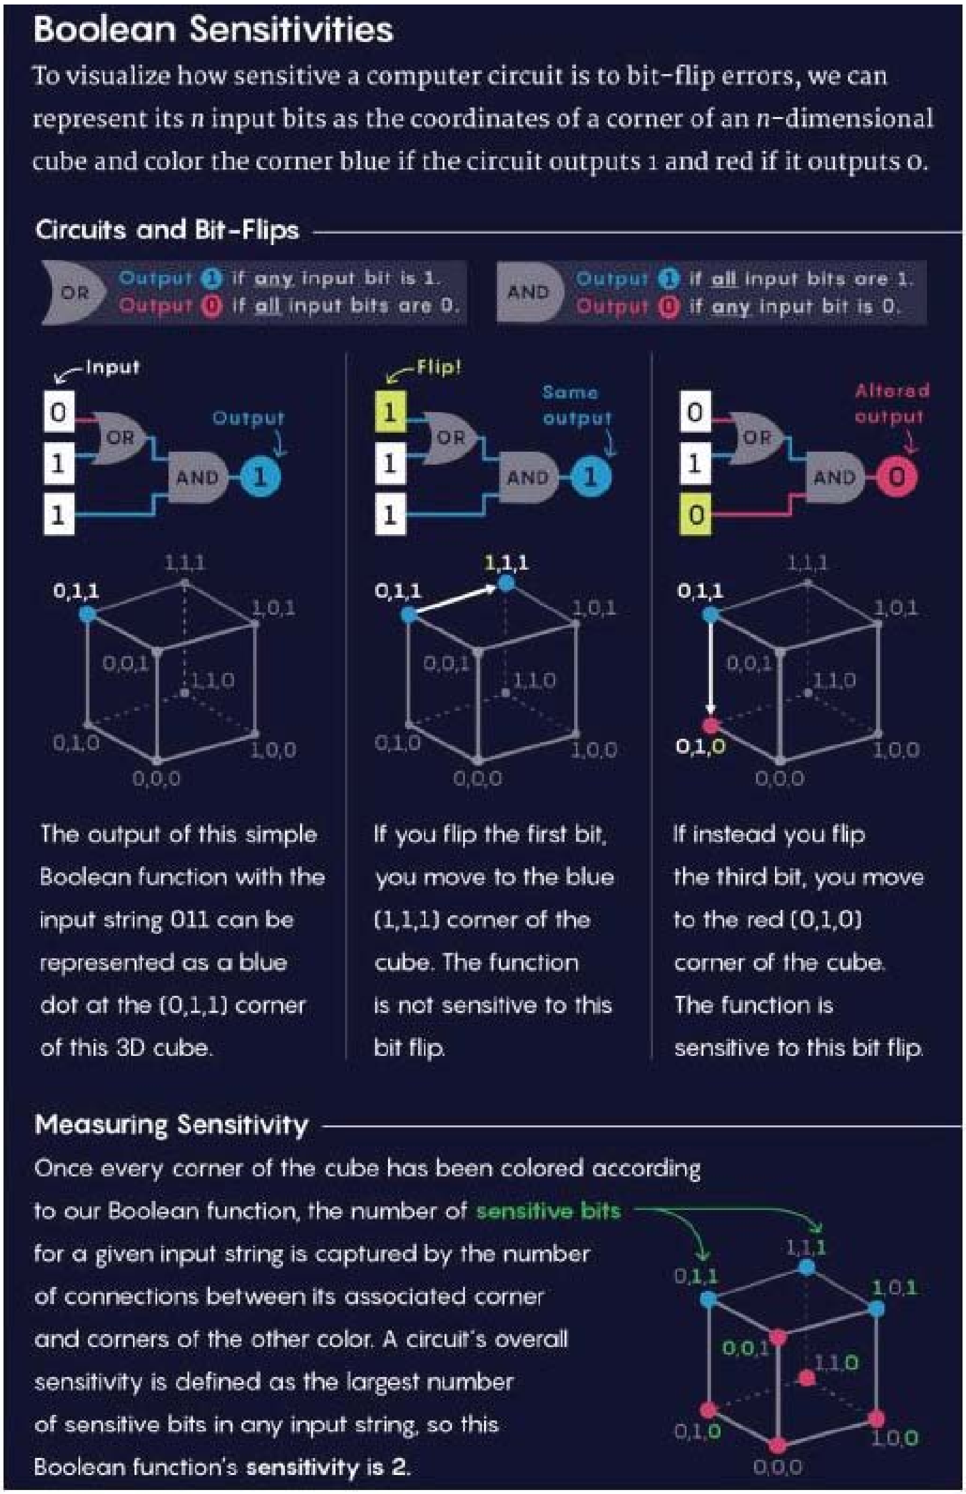

Figure 4

Concept of sensitivity in bit-flipping in a logic circuit influenced by sensitivity criteria

Live Agent Assessment

It has been indicated that in any airborne pathogen monitoring system, there needs to be provision for "live agent assessment". According to the CDC Ebola Response Team Incident Commander, there needs to be a means by which "to collect an aliquot which will NOT be inactivated or further processed – in order to have material readily at hand to assess for viable organism (whether bacterial or viral) in "real time" after a proteomic or nucleic acid assessment of material is completed – the absence of this capability would be a system deficit."

The proposed electrospray system would offer the capability to capture, concentrate, and retain live pathogen agents for subsequent collection and study in the laboratory. The essential system that will allow us to capture, charge, weigh, and collect viral species has already been constructed under NASA support for a future life finder mission (NASA Contract 80NSSC18C0056), shown in Figures 5 and 6. In this system, an electrospray source coupled to a vacuum system with charged species electrostatic acceleration and charge detection has been proven. A variant of the technology is being replicated in a separate system for capture and identification of nebulized viral particles introduced at the electrospray source. Note that the system shown is only an experimental research system. Production air samplers can be reduced to the size not much larger than a typical kitchen microwave oven.

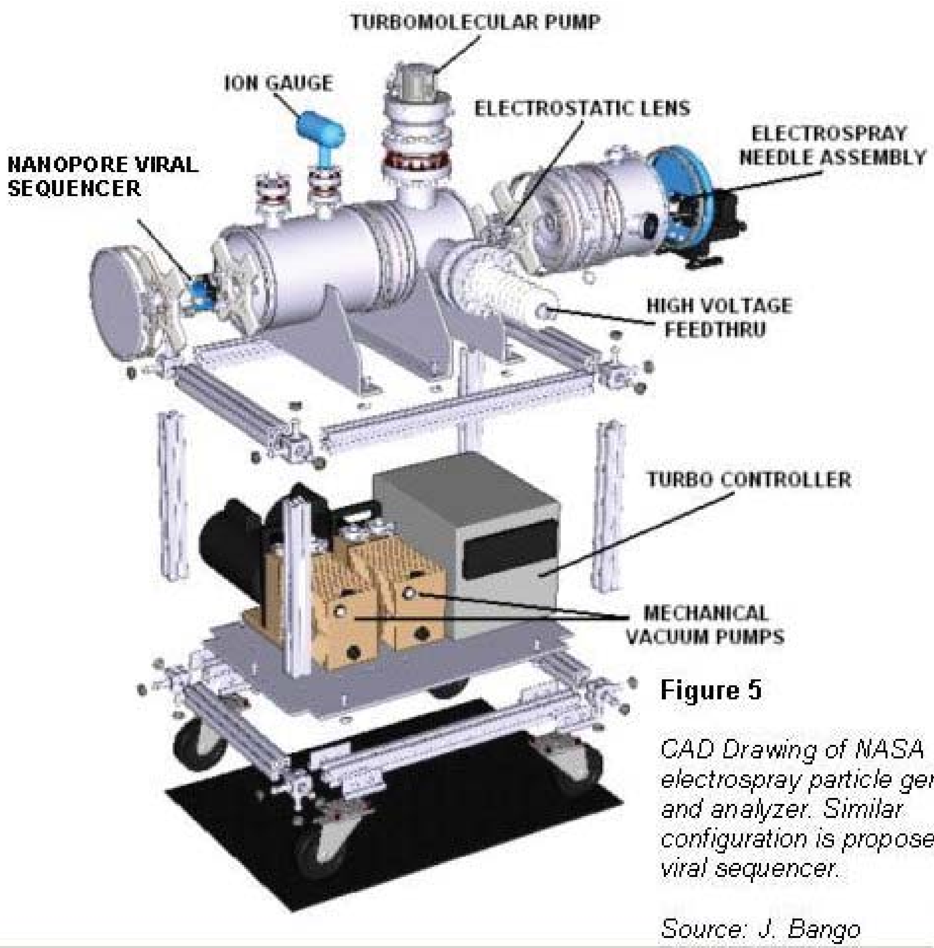

Figure 5

CAD Drawing of NASA electrospray particle generator and analyzer. Similar configuration is proposed for viral sequencer.

Source: J. Bango

Figure 6

Actual electrospray system as delivered to NASA. The viral sequencer will be similar in that the electrospray source at the right will be used to attract, capture, and ionize nebulized viral species. The viral 'ions' will be drawn into the partial pressure region of the system, and electrostatically channeled onto a solid-state nanopore plate upon which ionic liquid is used as the electrolyte. A patent has been applied for.

DISCUSSION AND CONCLUSIONS

The key lacking factor in all present decision processes in infectious disease prediction and intervention, has been a lack of real time and near real time information about the type of viral pathogen, its concentration, and its distribution among target populations.

The development of a decision matrix that takes into consideration the "sensitivity" conjecture will improve any response to the beginning of an epidemic. In the spread of any airborne transmissible disease, the decision of when to implement an interventional protocol cannot be absolute or binary based on inputs such as a finite threshold of reported cases. Supporting information derived from sources such as social media can influence when and where hard genetic sequence data derived from infected patients and airborne samples should be concentrated. The proposed electrospray-nanopore sequencing-cloud combination, deployed worldwide with participating international healthcare agencies, promises to help address the predictive model deficit to yield improved public health interventional management in precluding the next epidemic or pandemic.

5G MEC Offloading: Two QoE-based Strategies

Yang Lu
Old Dominion University
College of Charleston
Email: y1lu@odu.edu

ABSTRACT

5G MEC provides computing resources as services by 5G communication technologies. But, compared with conventional centralized cloud, MEC is a distributed resource with dynamic changes and conflicts between UEs (user equipment) and MEC servers. How to allocate MEC resources to meet users' requirements and to maintain QoE is an important issue in IT and across business disciplines. Offloading is an appropriate way to distribute MEC resources to achieve high levels of utilization and effectiveness. This study proposes two mechanisms that can work under complex conditions, such as multiple UEs' offloading requests, low latency, low energy consumption, and task consistency.

KEYWORDS: Mobile edge computing (MEC), Offloading, 5G MEC, MEC deployment scheme, Resource allocation, Quality of Experience (QoE)

INTRODUCTION

The development of mobile communication technologies and the adaptation of intelligent devices, various network services and applications are quickly emerging, and end-users are increasingly demanding high network performance, such as broad bandwidth, low latency, availability, reliability, and security. Although the processing power of the CPU (the central processing unit) of the new mobile device continue to strengthen, it still cannot process requests based on massive data in a limited time. In addition, the huge consumption of battery impedes the processing of applications by local servers. These issues affect the performance and the QoE (quality of experience) of the services on the UEs (user equipment). 5G MEC offloading has the potential to solve the problems and to provide high-performance services to end users (Mao, et al., 2017a; Guo, Liu & Zhang, 2018; Mach & Becvar, 2017).

MEC (Mobile edge computing) refers to the deployment of computing and storage resources at the edge of the mobile network, which provide IT services and cloud computing capabilities for mobile networks, and which provide end-users with low (no) latency and with high-performance service solutions. MEC is a critical factor improving the QoE of 5G network. As one of the key technologies in the MEC, task offloading refers to the transmission of part or all of the tasks of a UE with limited computing power to a cloud server through a network. Offloading allows a UE to extend functionality to the cloud and leverages the cloud's powerful computing power to expand its computing capacity, to decrease execution latency, to extend battery life, and to provide a high QoE for end users. The offloading technology consists of three aspects: a decision on computation offloading, the allocation of computing resources, and system implementation. In particular, a decision on computation offloading solves the problem of what resources the UE can offload, how to offload tasks, and how many resources need to be offloaded. Allocation of computing resources focuses on how to appropriately allocate resources that can be offloaded among entities (cloud, MEC, and UEs). System implementation deals with the implementation strategy for achieving offloading resources on the MEC platform (Abbas, et al., 2018; Mao, et al., 2017b; Pan & McElhannon, 2018).

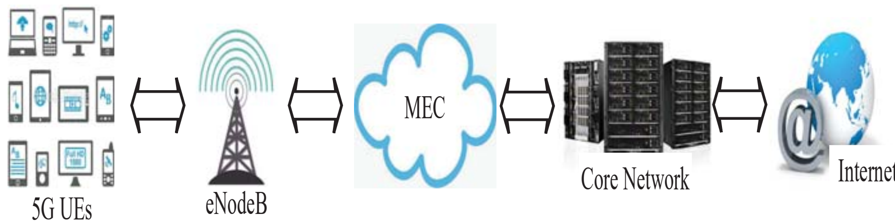
5G MEC offers the advantages of scalability, flexibility, mobility, virtualization, low cost and no terminal limitations, and is widely used in data sensing, medical and health industries, social networking, multimedia searches, and many other fields. It significantly improves the computing processing capability and the service quality in various fields, showing good development prospects and promising social benefits. The MEC offloading can transmit files to the MEC server that is closest to the UE. It not only reduces the network workload, but it solves the problems of energy consumption and transmission costs. Offloading also helps in the development of emerging technologies with zero latency. For example, autonomous vehicles need to sense road conditions, obstacles, and the driving information of surrounding vehicles in real time. Faster transmission and more accurate analysis of the related massive data and calculation can be realized through 5G MEC offloading (Wang, C. et al., 2017a; Liu, et al., 2016; Tao, et al., 2017).

The paper is outlined as follows. Section II depicts an overview of current research on MEC offloading. The two offloading mechanisms are described and explained in Section III. Section IV addresses research challenges and future trends toward 5G MEC offloading. The conclusion is in Section V.

CURRENT RESEARCH

The UE offloads partial of the computing task to the mobile edge cloud server deployed by the network operator near the base station by communicating with the nearby deployed base station (eNodeB). High-speed transmission of fiber enables rapid cross-response and low-latency connections. The MEC provides the UE with a wide range of caching, calculating and services. Upon the deployment of 5G MEC, it can provide session and business continuity, QoE and pricing, and support for MEC local networks. The MEC is also flexible in the specific deployment modes of the 5G network: centralization and distribution. Centralized deployment supports enhanced gateway capabilities with UE, and the distributed deployment allocates services in different locations. This hierarchical placement of resources in the network makes network management more flexible and dynamic (Muhammad, et al., 2018; Shi, et al., 2016; Li, J. et al., 2018; Zheng, et al., 2016). The following figure (Figure 1) illustrates a complete network of 5G MEC that includes 5G UEs (end users), eNodeB (the edge base station), the MEC server, the core network, and the Internet. eNodeB is the connection bridge between the UEs and the MEC servers. The edge computing server is deployed in the wireless access network, which greatly reduces the distance from the UE. Due to the reduced transmission distance, the task migration of the 5G MEC no longer needs to go through the long backhaul link and the core network, thereby reducing the delay overhead. On the other hand, since the computing capability of the edge server is greater than that of the mobile device, the task processing time is greatly shortened.

Figure 1. 5G MEC Typology



In an offloading process, the UE typically consists of a code parser, a system parser, and a decision engine. The execution of an offloading decision is divided into three steps. First, the code parser determines what can be offloaded, and the specific task offloading depends on the application type and the code and data partitioning. Then, the system parser is responsible for monitoring various parameters, such as the available bandwidth, the size of the offloading file, transmission costs, and energy consumption. Finally, the decision engine decides whether to offload, based on the evaluations. The offloading decision is mainly divided into three categories: the low latency offloading mechanism, the energy efficiency offloading mechanism, and the balancing latency and consumption offloading mechanism. For example, shortening the latency of offloading process, decreasing the energy consumption and costs, and mitigating the execution failure of offloading process. Game theory algorithms and the MDP (Markov Decision Process) are popular models used to estimate potential offloading mechanisms (Howard, 1971; Puterman, 2015; Zhou, et al., 2019; Chen, et al., 2013).

The decision to migrate tasks is the result of many factors, such as end-user, networks, mobile devices, servers and applications. End-user needs to consider offloading costs and QoE. Network mainly focuses on Wi-Fi and 5G. Processing capability, memory and storage are factors that affect mobile devices. Whether the edge server has enough resources to fulfill the offloading tasks and the environment in which the application is running appropriately directly affect the decision of offloading. For the application itself, the higher the computational complexity of the application and the smaller the amount of data transferred, the greater the likelihood of offloading of the tasks.

Among the extant offloading strategies, some are energy-oriented decision methods, some are corresponding time and energy decision methods, some are overall mobile terminals as migration targets, and some are converting mobile terminal applications into multiple partitions that are the smallest unit of offloading.

Low Latency Offloading Mechanism

If a task is executed locally, the elapsed time is the time during which the application performs the task. If the task is offloaded to the MEC, the time spent will include three parts: the time at which the file to be offloaded is transferred to the MEC, the time of the task required to receive file from the MEC, and the time of getting the file back from the MEC to the UE. Therefore, the delay caused by offloading the computing tasks to the MEC affects the QoE. Although a model of considering multiple UEs leads to NP-hardness, a low latency offloading strategy is still a practical approach to the allocation of resources in the MEC to multiple UEs. In order to ensure QoE, many studies, aimed at reducing delays, involve different optimization algorithms and application scenarios. Examples include constructing a model of NP-hardness to resolve offloading for multiple UEs, or the Lyapunov optimal dynamic offloading mechanism associated with energy harvesting technologies. Low latency is a key factor that affects offloading energy consumption and user's QoE. Service with low latency is more attractive to end-users, although they may pay extra for the energy consumption and other costs (Armbrust, et al., 2012; Kwak, et al., 2015; Mao, Zhang & Letaief, 2016; Kao, et al., 2017; Wang, C. et al., 2017b).

Energy Efficiency Offloading Mechanism

The energy consumed for offload tasks to the MEC server consists of two aspects. One is the transmission energy that transfers the offloading file to the MEC, and the other is the energy consumed by the data returned to the UEs. One study used the TDMA (time-division multiple access) system to divide time slots. In each time slot, the UE offloads its file to the MEC based on channel quality and local energy consumption. The optimal offloading strategy was proposed for each UE. If the UE has a priority above a given threshold, the UE completely offloads the computing task to the MEC. Conversely, if the UE has a lower priority than the threshold, only some of the tasks are offloaded to satisfy the delay constraint. For UEs that do not meet the application latency constraints, tasks will be implemented locally. Furthermore, the TDMA mechanism has been extended to the OFDMA-based offloading scheme (orthogonal frequency-division multiple access); this can reduce energy consumption by 90% (You & Huang, 2016; You, et al., 2016). Another study (Zhang, et al., 2016) attempted to minimize offloading transmission and radio energy consumption by optimization algorithm with latency constraints. Offloading in small-cell network is also worth of examining from task and transmission perspectives (Yang, et al., 2018; Munoz, P-Iserte & Vidal, 2015). Cloud computing is scalable and adaptable, it is potential to extend the mobile edge computing offloading mechanisms to other cloud-related systems, such as multi-access edge computing and cloud of things (El Haber, Nguyen & Assi, 2019; Nan, et al., 2017; Guo, et al., 2018).

Balancing Offloading Mechanism

When performing complex computing tasks, such as face recognition systems or real-time video systems, both energy consumption and delay can affect the QoE; a focusing only on one point cannot achieve UEs' requirements. So knowing how to achieve a leverage between energy consumption and latency when performing offloading tasks is crucial to build a balanced strategy to more efficiently allocate resources in a virtuous cycle.

The following parameters are considered in the offloading process as a trade-off analysis: the total amount of data to be processed, the computing power of the UE and the MEC, the channel state between the UE and the SCeNB (the intermediate base station connecting the UE and the MEC), the energy consumption of the UE, waiting time, and executing time, and other related costs (Kao, et al., 2017; You & Huang, 2016). Studies seek to construct the offloading algorithms through different combinations to optimize offloading processes. For example, You, et al. (2016) used Gurobi optimizer to analyze the offloading problem in the static environment and extend the condition to dynamic phenomenon.

5G MEC OFFLOADING MECHANISMS

Due to the diversity of offloading factors and metrics, it is not easy to design an appropriate offloading strategy and objective assessment of offloading performance. In this section, two offloading strategies will be introduced and generalized: the optimal offloading and the consistency offloading mechanisms. The optimal strategy analyzes various costs and consumption of the complete offloading process and seeks the optimal mechanism for each of the UEs to accomplish overall high utilization. The consistency strategy solves the issue of VM migration from one MEC to another, in order to maintain both task consistency and a high QoE with low latency. Both of the mechanisms are capable of handling malicious requests from multiple UEs (Ketykó, et al., 2016; Ndikumana, et al., 2017).

Optimal Offloading Mechanism

The first approach is an optimal offloading mechanism that adopts game theory to allocate limited edge resources to multiple UEs in order to benefit both end-users for maximum benefit and providers for the highest resource utilization. The route between the UEs and the edge servers is random. This leads to different transmission energy consumption, channel interference, and overall costs. If the edge center near the base station receives too many requests and uses the wireless channel to schedule resources, it can cause severe mutual interference. Hence, it is important to examine whether a request needs to be offloaded and how to appropriately allocate resources.

Model

Suppose there are *N* (= {1, 2, …, N}) UEs. Each one has a task that requires computing resources and can be selectively sent to close base stations (eNodeBs). eNodeB connected to the edge server can process the UE's request. The provider determines the communication speed between the UE and the eNodeB, such as file transmission channel, the uplink transmission rate, and the downlink transmission rate. There are *M* (= {1, 2, …, M}) wireless channels between the UEs and the eNodeBs.O_n is the offloading strategy of user *n*. $O_n = 0$ means that the UE will run the task locally, $O_n > 0$ means that the UE will offload the task to the edge. O_{1-N} (= $(O_1, O_2, \dots, O_N)$) represents the offloading strategies of all UEs.

If the total cost of MEC is less than or equal to the total cost of local computing, it is defined as effective edge cloud calculation, as in the following equation

$$C_n^E(O_{1-N}) \le C_n^L \tag{1-1}$$

C_n^L represents the total cost of local computing, and $C_n^E(O_{1-N})$ represents the total cost of MEC. For UEs, the optimal approach assists the UE in rationally selecting an offloading strategy with a high QoE. For providers, the optimal approach achieves higher resource utilization and revenues.

The above function can be described as an optimization problem. It is used to calculate the maximum number of UEs that can obtain MEC resources among all of the UEs. The mathematical expressions are shown in equation (1-2). R_O is 1 when A is true, and 0 otherwise.

$$\begin{gathered} max \sum_{n \in N} R_{\{O_n > 0\}} \\ C_n^E(O_{1-N}) \le C_n^L \\ R_O \in \{0, 1, \dots, \mathrm{M}\} \end{gathered} \tag{1-2}$$

This is an NP-Hardness issue, similar to the biggest packaging problem. Assuming another complete system cost is I_n, the target problem is transformed into a combinatorial optimization problem in a multidimensional discrete space environment, i.e., minimizing I_n. As shown in equation (1-3)

$$\min \sum_{n \in N} I_n$$
$$R_O \in \{0, 1, \ldots, M\} \quad (1\text{-}3)$$

The general expression is:

$$\Gamma_{MEC} = (N, \{O_n\}_{n\in N}, \{I_n\}_{n\in N}) \quad (1\text{-}4)$$

On the condition of

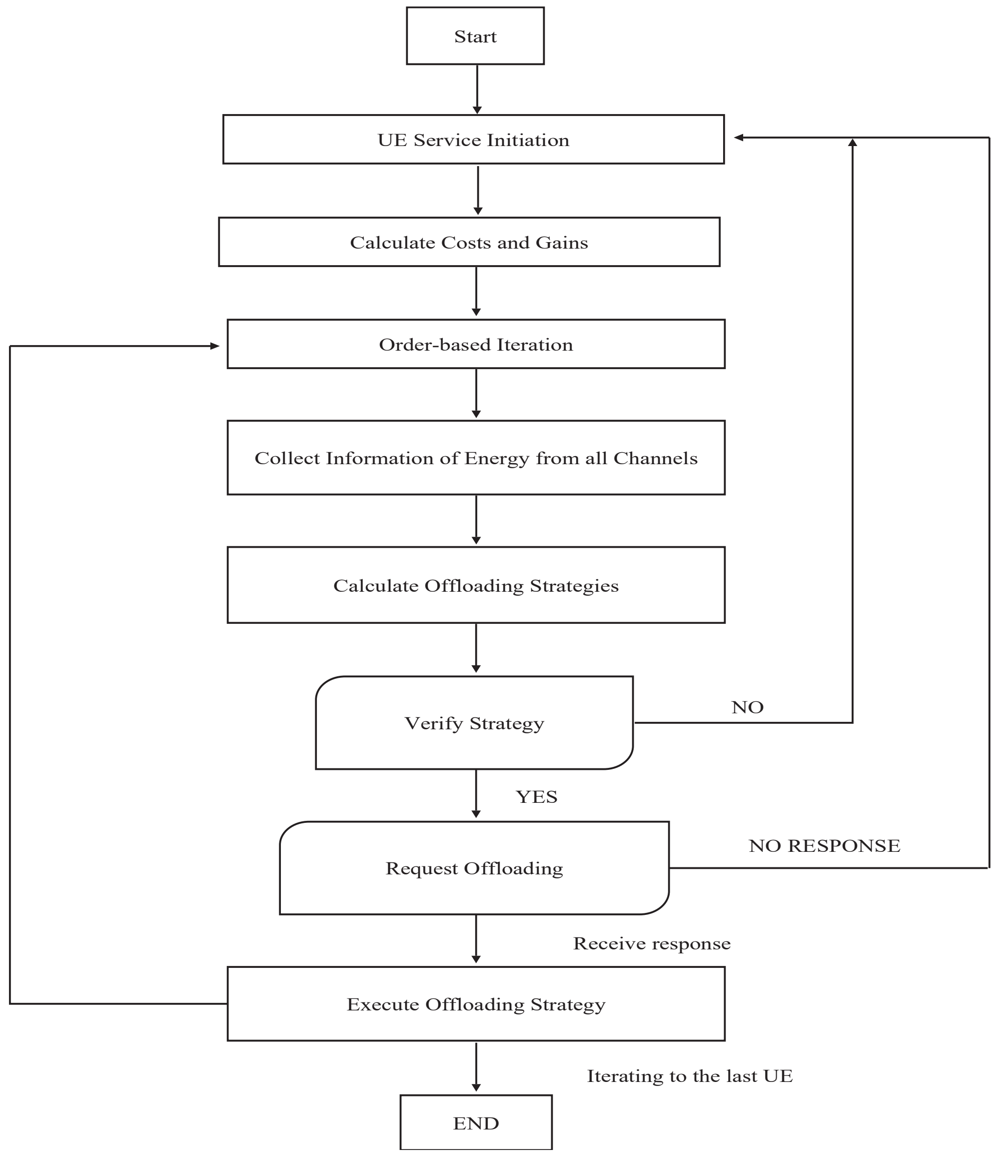
$$I_n(O_n^*, O_{N-n}^*) \leq I_n(O_n, O_{N-n}^*) \quad (1\text{-}5)$$

where O^* (= $(O_1^*, O_2^*, \ldots, O_N^*)$) is the set of all potential UEs' offloading strategies when MEC offloading is under the Nash Equilibrium.

Offloading Process

This section will depict the complete iterative processes in detail (Figure 2). In total, the process consists of ten steps, from beginning to end. The iteration will be terminated until all of the requested tasks are examined and assigned for potential optimal offloading strategies.

Figure 2. The Iteration Process



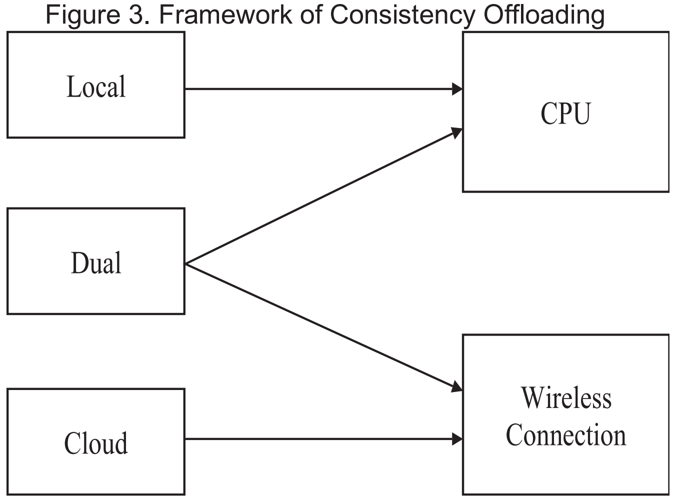
First is the initiation of every UE locally.
Second is the calculation of channel gain and the transmission of each UE based on the random distance between the UEs and the BS.
Third is the ranking of UE based on its power; the high channel power that the UE preferentially selects in the iteration process.
Fourth is the transferring of energy on selected channels and the collecting of energy information from all channels.
Fifth is the calculation of all of the potential offloading strategies and the examination of the related costs and consumption.
Sixth is verifying the strategy. If an offloading strategy is better than the local implementation, continue to the next step; otherwise, it will go back to the initiation for the next UE's decision making.
Seventh, the UE sends an offloading request to the related servers.

Eighth, if the UE receives a response from the servers, it will implement an offloading strategy.
Ninth, if the UE doesn't receive a response from servers, the local implementation will continue. The iteration will go back to the initiation for the next UE.
Tenth, the complete iteration will proceed from the first UE until the last, and then it will end. This approach is effective if all of the users are in a static environment; in that case, the UEs won't change the offloading decisions during the whole process. However, in practice, 5G users move frequently, and tasks relate to multiple MEC servers. In this circumstance, it is necessary to consider the VM migration, in order to maintain the continuity and the consistency of services.

Task Consistency Offloading Mechanism

By processing offloading technology, VM (virtual machine) migration can ensure the continuity and consistency of services. VM migration means that VMs running on the current node will migrate to another more suitable node(s) with higher utilization and lower costs (Wang, et al., 2015). Much research has focused on the offloading strategies from one node to another node. But, in practice, this phenomenon often occurs: VMs need to migrate to multiple nodes in order to achieve the optimal performance of QoE. Thus, the conditions of consistency offloading are complicated and dynamic. In this study, we present a generalized model, which can assist practitioners or scholars to implement offloading mechanisms through various perspectives (Kwak, et al., 2015).

Figure 3. Framework of Consistency Offloading



In 5G MEC offloading, tasks can be divided into three categories: 1) tasks that are executed locally in UE, 2) tasks that are executed in the cloud, and 3) tasks that can be executed either in local UE or in the cloud (Dual). Since it aims at optimizing resource utilization with the tolerated delay, this solution is designed to determine whether the VMs (virtual machine) need to migrate, and how to allocate limited resources after VM migration. It uses MDP (the Markov Decision Process) to evaluate which way is better to maintain task consistency and to guarantee QoE with potential low costs (Wang, et al., 2016; Ding, Fan & Poor, 2019; Jia, Cao & Yang, 2014). According to Figure 3, three factors that directly impact the final offloading strategy: processing costs, processing channel, and processing order.

<u>Processing Costs</u>

Low latency applications, such as IoT (Internet of Things) and the connected terminals, require high reliability and low end-to-end delay (millisecond) communications. To support low latency, virtual machines and data source are offloaded as users move from one MEC to another. The offloading process may have a negative impact on latency. Hence, it is possible to consider a high-speed path with a small delay in the backhaul link, meanwhile, the transmitted file needs to be compressed and the virtual machine recovery process needs to be simplified. In general, transmission, energy, waiting, and executing costs are the major factors that impact the overall utilization in 5G MEC offloading (Min, et al., 2019; Xu, He &Li, 2014; Lu & Xu, 2018; Lyu, et al., 2018; Kherraf, et al., 2019; Zhang, et al., 2017).

Processing Channel

In 5G MEC offloading, there exist two major channels. If tasks are implemented locally, the processing channel is the CPU. If tasks are implemented in the MEC, the wireless transmission channel is the cellular network or the WLAN (wireless local area network). In addition, some task may be allocated to a combined channel, such as CPU and WLAN, CPU and cellular, and cellular and WLAN. Based on the MDP, the particular channel with minimum costs and optimal utilization of the resources will be the offloading strategy (Mach & Becvar, 2017; Mao, et al., 2017b).

Processing Order

In the 5G MEC offloading process, there exist tasks with malicious requirements that come from different UEs. How to effectively fulfill tasks in the MEC, by certain orders, that impact the overall performance of services and resource utilization is the question under consideration. For sequential tasks, the optimal offloading strategy is suitable for processing tasks. For concurrent tasks, load balancing heuristics are used to offload tasks to the MEC. For the partial offloading model, the influence of inter-task dependencies is proposed, and the polynomial time algorithm is used to solve the optimal solution of offloading (Guo, Liu & Zhang, 2018; Kao, et al., 2017; Ding, Fan & Poor, 2019).

The following model is a general MDP that examines the minimum costs and optimal utilization. The goal is to minimize the total costs of a specific task:

$$min \sum \gamma^t C \tag{2-1}$$

where γ^t $(0 \leq \gamma < 1)$ is the discount, and C represents all possible costs during the offloading process. For example, transmission costs, energy consumption, waiting time, service time, etc. As MDP, we have two main algorithms: policy ($\pi(s)$) and value ($V(s)$).

$$\pi(s) = arg \min_a \{\sum_{s'} P(s' \mid s, a)[C(s' \mid s, a) + \gamma V(s')]\} \tag{2-2}$$

$$V(s) = \sum_{s'} P_{\pi(s)}(s, s')[C_{\pi(s)}(s, s') + \gamma V_{s'}] \tag{2-3}$$

There are the state transition *P*, cost function *C*, and the probability ($P_{\pi(s)}(s, s')$) that action $\pi(s)$ in state *s* will lead to state s' for an MDP. We seek the policy ($\pi(s)$) that minimize the discounted costs. Specifically, a represents an action, and *s* and s' represent certain states. The value $V(s)$ is the actual value of action *a* in state s. During the iterative process, these two steps are repeated until there is no change to calculate the strategy with the minimum cost.

CHALLENGES AND FUTURE TRENDS

In 5G networks, according to business needs, MEC can be flexibly layered to maximize resources utilization and to reduce the computational costs and energy consumption with low latency. However, the offloading of 5G MEC still faces problems, such as mobility management, security and interference control.

Mobility Management

In mobility management, in order to complete the offloading of the corresponding tasks, it is necessary to consider low latency and path prediction, in order to achieve high QoE communication.

Low Latency

Low latency applications, such as IoT (Internet of Things) and Vehicular Network, require high reliability and low end-to-end delay (millisecond) communications. To support low latency, virtual machines and data source are offloaded as users move from one MEC zone to another. The offloading process may have a negative impact on application latency. MEC systems require offloading with short time. Hence, it is possible to consider a high-speed path with a small delay in the backhaul link, meanwhile, the transmitted file needs to be compressed and the virtual machine recovery process needs to be simplified (Wang, S. et al., 2017a; Zheng, et al., 2016; Munoz, P-Iserte & Vidal, 2015).

Path Prediction

The key to mobility management is the offloading of virtual machines and file. Traditional MEC offloading only transfer computing tasks to another server when transfer is happening. Inappropriate data offloading will lead to high latency and will increase the MEC network load. The solution is to analyze user tracks when the MEC provides services to users, and to predict the next MEC that the user will arrive at, in order to transfer the data and resources to the new MEC, in advance. But this technology has two main challenges. The first is track prediction. An accurate prediction can achieve seamless switching between MEC servers and can reduce prefetch redundancy. It requires precise modeling and high-complexity machine learning techniques (Li, S. et al., 2018; Xu, Chen & Ren, 2017; Lu, 2019). The second challenge is how to access the data that needs to be delivered in advance. Inaccurate prediction will lead to unnecessary waste. Balancing the amount of data transmitted and the accuracy of the prediction is challenging. In addition, VM migration leads to a heavy burden on the backhaul link and to high latency. It is necessary to implement a technology that can quickly migrate VMs within a short time (e.g., milliseconds). Hence, if VMs can be migrated in advance, it will better solve both heavy load and high latency (Mao, et al., 2017a).

Security Management

Security is a technical challenge in cloud computing offloading. Since 5G MEC is a distributed system, single point is so weak that the attack of a single point may lead to a destruction of the entire system. Multi-tenant mode will cause malicious users to sneak into the network to exploit cloud platform vulnerabilities in order to attack the network. In addition, the open-source software is vulnerable to attacks as well. File that is offloaded to the cloud or to the edge can also be easily attacked or tampered with. Many of the security solutions originally used for cloud computing are no longer suitable for 5G MEC offloading. The security issues are distributed at various levels, including edge node security, network security, data application security, security situation awareness, security management and coordination, and identity management. Security issues in 5G MEC cannot be fully solved by conventional cloud resolution, due to its unique and complex distributed network. Therefore, it is important to design appropriate mechanism to deal with malicious safety issues (Shibin & Kathrine, 2017; Xiao, et al., 2018; Roman, Lopez & Mambo, 2016; Xu, et al., 2019; Chaudhary, Kumar & Zeadally, 2017).

Interference Management

Interference is also one of the key issues that need to be solved during the offloading process. If many applications of UEs are simultaneously offloaded to the MEC server, interference will occur. How to allocate resources with the guaranteed QoE while to mitigating interference is a critical question in 5G MEC offloading. Interference management has multiple implementation methods and is closely related to resource management. The nature of interference is the conflicting use of resources. Unreasonable allocation of network resources is the root of interference. In a distributed 5G MEC network, the large quantity of offloading requests of UEs and the complex network environment can reduce the overall resource utilization. Effective resource allocation is an important means for the management of interference. On the one hand, it can increase network capacity by reasonable use of network resources. On the other hand, it can correct resource allocation strategies and can increase network capacity through interference management (Bu, Yu & Yanikomeroglu, 2015; Li, et al., 2015; Wang, S. et al., 2017b; Huang & Li, 2016).

CONCLUSION

5G MEC is a cloud service platform that runs on the edge network. It can improve both service performance and user experience by deploying business processing and resource scheduling to the cloud service platform. 5G MEC offloads the services and capabilities originally in the cloud center to the edge network. By distributing computing, storage, communication resources at the edge, 5G MEC can effectively decrease network overload, can shorten service latency, can save energy consumption and other related costs, and can guarantee task consistency.
In this study, based on 5G MEC offloading, we present two potential robust and efficient offloading approaches to distribute services and to fulfill UE’s requests: an optimal offloading strategy and a task consistency offloading strategy. It is a good attempt to examine and to allocate cloud resources and offloading tasks from different aspects: low latency, energy efficiency, low costs and consumption, quick executing time, and waiting time.

ABSTRACT

Despite the rise of gamification nowadays, the role of achievement in a gamified information system on users' continuance intention is not well-understood. From the perspective of Self-determination theory, we predicted that gamification achievement affects continuance intention through the mediating roles of identity centrality and lost performance cost. Achievement motivation is considered a moderator to the relationship between gamification achievement and identity centrality. After analyzing 131 samples collected from Reddit.com users, we found that most of our hypotheses are supported. The findings have important implication for Self-determination theory as well as gamification research and practice.

KEYWORDS: Self-determination theory, Gamification, Online platforms, Gamification Achievement, Switching cost.

INTRODUCTION

Gamification is the idea of applying gaming elements in designing a non-gaming system (Koivisto & Hamari, 2019; Robson, Plangger, Kietzmann, McCarthy, & Pitt, 2015). The practice of gamification has been applied in various aspects of daily life such as education, government, and business (Koivisto & Hamari, 2019). In education, gamification has been found to increase students enjoyment and engagement, thus, improving learning outcome (Bonde et al., 2014; De-Marcos, Domínguez, Saenz-de-Navarrete, & Pagés, 2014). In business context, studies showed that gamification has a positive impact on customer engagement (Cechanowicz, Gutwin, Brownell, & Goodfellow, 2013). Furthermore, the application of gaming elements in working environment can also increase employee productivity (Landers, Bauer, & Callan, 2017; Morschheuser & Hamari, 2019). In general, the development of gamification is growing at a rapid pace. In fact, market value of gamification reached 5.5 billion USD in 2018 [https://www.mordorintelligence.com/industry-reports/gamification-market]. Furthermore, gamification is spreading online in recent years.

Literature of gamification has focused on dissecting the components and examining the consequences of gamification. However, there are some research gaps remain. Firstly, although previous studies indicated that reward is an important component of gamification (Hamari & Eranti, 2011; Khaleel, Sahari, Wook, & Ismail, 2016), few studies differentiate between various types of reward in a gamified system. Instead, previous studies tend to group many types of reward systems together under the same umbrella of Gamification. Secondly, to the extent of our knowledge, the role of individual differences in is not yet well-understood in gamification. Most studies conducted in this field assume that a gamified system has the same effect on every user. That is contestable because, from the observation of gaming industry, different people enjoy playing games on many different levels (Chou & Tsai, 2007; Jeng & Teng, 2008). Because of that, we argue that we have no reason to assume the replication of game element in a non-game environment would have the same effect on everyone.

By filling those research gaps in this study, we hope to improve our understanding of the effect of gamification on continuance intention, an important construct in information systems research. Firstly, we focus on only one type of reward, which is permanent reward. Unlike short-term rewards that only benefit users for a specific time period, permanent reward is always retained with users once given. These permanent rewards can be accumulated over time and become users' achievement. In this work, we are interested in how this accumulation of rewards affect continuance intention of users. Secondly, this study investigates the effect of gamification on continuance intention of system users while taking into consideration the uniqueness of each individual. Since this study focuses on the role of achievement, we would like to find out how achievement motivation, a personality trait representing the desire for achievement, could affect the aforementioned relationship. We hope to contribute to the understanding of the effect of gamification in information systems by answering the following research questions:

Q1: What is the effect of gamification achievement on system users' continuance intention?
Q2: What is the effect of achievement motivation on the role of gamification achievement in continuance intention?

To answer those questions, we started from the perspective of Self-determination theory. We then identified the key variables that play an important role in the process in which gamification achievement affects continuance intention. Those are identity centrality, lost performance cost, and achievement motivation. In the next section, we will review relevant literature and theories before constructing hypotheses.

LITERATURE REVIEW

Self-determination Theory

In the domain of human behavior in gaming, Self-determination theory is one of the most popular theoretical foundation (Koivisto & Hamari, 2019). That is because gaming behaviors express the influence of intrinsic motivations, which can be well explained by this theory. Indeed, empirical evidence suggests that people can play games for pleasure and enjoyment from the activity itself without an external reward (Rigby & Ryan, 2011). Due to the similarities between a gamified system and a normal game, we select Self-determination theory as our theoretical framework.

Self-determination theory explains behaviors from the perspective of intrinsic and extrinsic motivation. The theory posits that humans have universal needs for autonomy, competence, and relatedness (Deci & Ryan, 2000; Ryan & Deci, 2000, 2017). The need for autonomy refers to the fact that humans tend to value freedom of choice. Competence refers to the possession of skills or knowledge. Lastly, relatedness is the feeling of being respected, supported and acknowledged by other people (Deci & Ryan, 2000). The theory suggests that when a task can satisfy those needs, the individual is intrinsically motivated to perform the task (Deci & Ryan, 2000). That means even in the absence of external rewards, individuals can still perform the tasks themselves because it brings them pleasure.

In the context of a gamified system, we can expect that the gamification elements can intrinsically motivate individuals to increase the use of the system if they can satisfy one of the 3 needs mentioned above. However, motivation research showed that extrinsic rewards, in some situations, can cause a phenomenon called Motivation crowding out (Frey & Oberholzer-Gee, 1997; Georgellis, Iossa, & Tabvuma, 2010). That is when the introduction of external rewards undermines intrinsic motivation of the individual to carry out the task. In other words, the individual no longer feels enjoyment when engaging in that activity. This phenomenon is also reported in gamification literature (Zhao, Detlor, & Connelly, 2016).

Cognitive evaluation theory, as a subtheory of Self-determination theory, was developed to explain Motivation crowding out effect by focusing on autonomy and competence. According to Deci and Ryan (1985), an external reward can sometimes increase sometimes decrease intrinsic motivation, depending on the characteristics of the reward. If the reward seems to control the behaviors of the individual, lowering the sense of autonomy, then it can eliminate intrinsic motivation. On the other hand, if the reward, instead, signals the competence of the individual, it can raise intrinsic motivation.

Achievement in Gamified Systems

According to Simões, Redondo, and Vilas (2013), 2 categories of gaming elements are game mechanics and game dynamics. In game dynamics, Achievement is found to be an important factor (Khaleel et al., 2016) that can have a positive influence on the intrinsic motivation of players when performing tasks in games (Kumar, 2013).

In gamification literature, achievement can be defined as “goals in an achievement/reward system whose fulfillment is defined through activities and events in other systems” (Hamari & Eranti, 2011). However, we find that definition too broad for the purpose of this study, which is to focus on permanent and accumulative rewards. Therefore, in this study, we use the term “gamification achievement” to refer to the accumulative rewards displayed in a gamified system user’s profile. In reality, not all types of reward can be accumulated into achievements. There are one-time, short-term rewards that only take effect in a limited time window. After that time window ends, the reward is removed and the user can no longer benefit from it. For example, Reddit.com is operating a reward system, in which, premium users can reward other users they like by giving them a badge of honor. A badge can be of different levels (silver, gold, platinum, etc), which signifies different levels of a member’s status. With badges, users can let other people know that their contribution to the community is acknowledged and respected by the others. However, these badges only last for a short period. After that, the rewarded user’s account will turn into a normal account without any badge. This type of short-term reward cannot be accumulated over time, thus, cannot become a long term achievement in a user’s profile.

Identity Centrality

Contemporary literature in self and identity suggests that identity is a fluid, dynamic concept (Oyserman, Elmore, & Smith, 2012; Sussman, 2000). A person can adopt multiple identities within themselves, and at a specific moment, only one of those identities becomes salient to influence emotional and cognitive processes of that individual (Oyserman et al., 2012). However, among many identities an individual can have, there might be identities that are more important than others. These identities are given more weight and are easier to become salient than other identities. Identity centrality refers to the extent to which an identity is important to an individual (Stryker & Serpe, 1994). In this study, we use the term identity centrality to refer to the degree to which the platform member identity is important to a user.

According to Cognitive evaluation theory's viewpoint on competence, an extrinsic reward can make a task meaningful if that reward signifies to the individual about his competence, which is one of the three basic needs of humans, as discussed in the previous section. Because of that, rewards in gaming can raise intrinsic motivation of players. We argue that, in a gamified system, gamification achievement reflects the level of contribution to the community of a user. As is found in online community literature, individuals with high contribution to the online community are more likely to be perceived as high status, highly competent by the community (Alexander Hars, 2002; Stewart, 2005). Therefore, we expect the users with high gamification achievement to have more intrinsic motivation when participating in a gamified system. Self-determination theory also suggests that intrinsic motivation plays an important role in human character development (Deci & Vansteenkiste, 2004). If an activity is perceived as bringing meaningful, the individual will be more likely to incorporate that activity into her self-evaluation and personal needs (Deci, Eghrari, Patrick, & Leone, 1994). For individuals having rich gamification achievement in online platforms, we hypothesize that the importance of a platform member identity is higher than people with low gamification achievement.
H1a: Gamification achievement positively influences identity centrality.

However, the effect that gamification achievement has on identity centrality might not be unambiguous due to another possible mechanism. According to Cognitive evaluation theory, when an individual is a provided reward in a gamified system, it can create a feeling of losing control (Deci & Ryan, 1985). The presence of extrinsic rewards might cause the individual to think that the reason she participates in this platform is to gain those rewards, not because she enjoys doing it. As a result, the individual will perceive her activity to engage in the platform as a violation of her autonomy, thus, undermine her intrinsic motivation. This is consistent with findings in previous studies about gamification in Information Systems. Zhao et al. (2016) found that the introduction of virtual reward in a gamified system reduces individuals' intrinsic motivation to participate in that system. If the virtual rewards in a gamified system signify to the individual about their loss of autonomy, then it is possible that it will reduce the pleasure she has when participating. We can predict that the individual, in that case, will be less likely to internalize the value of membership in that platform, thus, identity centrality will diminish. This effect is the opposite of the aforementioned prediction, making the overall effect of gamification achievement on identity centrality ambiguous. Therefore, we propose a competing hypothesis in addition to H1a.
H1b: Gamification achievement negatively influences identity centrality.

Lost Performance Cost

By signifying their status in the community, highly accomplished community members can increase their influence toward others (Stewart, 2005). According to Self-determination theory, humans have a fundamental need to be recognized and understood by others (Relatedness); therefore, we expect that being able to influence other users and being recognized and respected by the community are important benefits to platform users. Literature in online communities also found that an important reason for people to participate in these platforms is to earn social status among the community members (Lampel & Bhalla, 2007; Y. Wang & Fesenmaier, 2004). In an online platform, giving rewards is a mechanism to give recognition for the contribution of users and signify their status (Alexander Hars, 2002). Therefore, gamification achievement can help increase the utility the platform can provide to its users.

Prior research defines Lost performance cost as the perceived lost of benefits and privileges from switching the use of a system into another (Jones, Mothersbaugh, & Beatty, 2002). Suppose that there is no connection between the 2 systems, all the gamified achievement in the old system will become valueless in the new one. Thus, the users have to restart the whole process to earn a status in the new community from scratch. If it is the case that achievement in a gamified system can provide perceived benefits to users, those perceived benefit will be lost when they switch to using a new system. Furthermore, the more achievement a user has in the old system, the more perceived benefits will be lost from the switch. From that reasoning, we can hypothesize:
H2: Gamification achievement positively influences lost performance cost.

Research in identity found that an identity, when made salient, can influence a person's values and beliefs (Oyserman et al., 2012). Individuals with a salient group identity tend to give a favorable assessment about their group (Turner & Reynolds, 2001). In addition, as explained in the previous sections, a certain identity can be important than others, which means it can influence an individual's values and beliefs stronger than other identities (Stryker & Serpe, 1994). Therefore, if an individual highly values her identity as a member of a group, that identity will become salient more frequently and influences her behaviors stronger than other identities. In the context of a gamified system, we could expect that people who highly value their identity as a member of the platform are more likely to appreciate the utility they receive from it. As a matter of fact, if they switch to use another system, they will have to give up a larger amount of perceived benefit compared to other people. Thus, we can hypothesize:
H3: Identity centrality positively influences lost performance cost.

Continuance Intention

Intention to continue using has been paid much attention in the field of Management Information System because an IS can only offer its full value when the users decide to continue using it (Bhattacherjee, 2001). Aside from the fact that platform providers' revenue is positively correlated with the amount if usage, encouraging users to continue their use of the system is important to platform provider because it increases users' familiarity with the system, thus, improve their quality of system use. That, in turn, helps users to contribute more to the platform and also receive more benefits from it. Literature of IS examined the antecedents of intention to continue using from different perspectives. A stream of research focus on satisfaction and perceived usefulness the system brings to users (Bhattacherjee, 2001; Hsieh, Rai, & Keil, 2008; T. S. H. Teo, S. C. Srivastava, & L. Jiang, 2008).

Another approach focus on the switching cost when a user faces the decision of switching to another system. Studies found that platform can derive users' continuance intention from their resistance to changes, caused by the costs that users perceive when switching the system (Jones et al., 2002; Kim & Perera, 2008). As a subconstruct of switching cost, lost performance cost was also found to positively influence continuance intention (Jones et al., 2002; Kim & Perera, 2008; Van Deventer, 2016). Consistent with the well-established literature, we also hypothesize that people who have high perceived lost benefits when switching the system will be more likely to use the old system.
H4: Lost performance cost positively affects continuance intention.

Moderating Role of Achievement Motivation

Need for Achievement is a personality trait which defines the desire of a person for accomplishment or high standards (Murray, 1938). Individuals with high Need for Achievement tend to be more competitive and more ready to overcome difficulty. Later, D. C. McClelland (1965) used the term achievement motivation to address that concept. Achievement motivation has been found to positively affect how individuals value achievement in working and learning environment (D. McClelland, 1985; D. C. McClelland, 1965; Schoen, 2015; Sikhwari, 2014; M.-T. Wang, Chow, Degol, & Eccles, 2017).

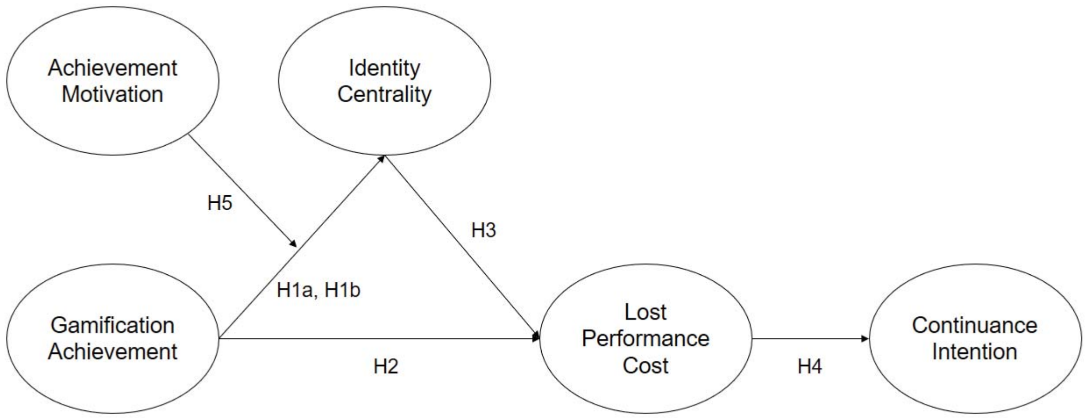
Despite being seemingly similar, the need for competence and achievement motivation are two different concepts. The need for competence refers to an innate basic need of humans meanwhile achievement motivation, coming from dispositional approach, refers to a situational motivation and can vary from people to people. According to previous studies, achievement motivation has been found to moderate the effect of feeling of competence, so that when achievement motivation is high, the effect of feeling of competence is stronger (Hofer & Busch, 2011; Schüler, Sheldon, & Fröhlich, 2010). In a gamified system, we expect the individuals that have high achievement motivation to value badges, scores, status more than people with low achievement motivation because achievements indicate how much they have accomplished compared to other people in the community. As a result, the feeling of competence that gamification achievement will bring to people with high achievement motivation will be greater than people with low achievement motivation.

As stated in the hypothesis development of H1a and H1b, the effect of gamification achievement on identity centrality is ambiguous. That is because we do not know which is stronger out of the two opposing effects, the loss of autonomy or the significance of competence. However, when achievement motivation is high, we can expect that the effect of competence will become stronger, changing the balance of the 2 opposing effects, which make the relationship between gamification achievement and identity centrality become positive. By contrast, when achievement motivation is low, we expect that the effect of competence will become insignificant, which is outweighed by the effect of loss of autonomy, making the relationship between gamification achievement and identity centrality becomes negative. Therefore, we have hypothesis 5:

H5: Achievement motivation moderates the relationship between gamification achievement and identity centrality, such that, when achievement motivation is high, gamification achievement will have a positive effect on identity centrality, but when achievement motivation is low, gamification achievement will have a negative effect on identity centrality.

CONCEPTUAL MODEL

Figure 1: Conceptual Model



METHODOLOGY

Reddit.com is one of the largest knowledge sharing platforms in the world at the moment. Also, this platform applies a gamified system in which users can collect achievement points, called Karma, for their contribution to the platform's discussion. Karma points are defined based on both the quality and quantity of their posts and comments on Reddit. When a user creates a new post or writes a new comment, Karma points will increase. If that post or comment is upvoted by other users, Karma points will also increase. By contrast, if it is downvoted, Karma points will decrease.

Regarding Reddit's immense popularity with diverse user demography and the fact that it applies a gamified system with accumulated achievement, we expect samples collected from this platform to have great generalizability and applicability. Therefore, to test the hypotheses in this study, we distributed a survey to users on Reddit.com. Only the users that own a Reddit account could participate in this study. By the end of the data collection process, we received 131 valid responses for the survey (51% male).

We adopted measurements from previous literature for identity centrality (Cohen et al., 2007), lost performance cost (Jones et al., 2002), continuance intention (T. S. Teo, S. C. Srivastava, & L. Jiang, 2008), and achievement motivation (Lang & Fries, 2006). All of these items are measured on 7-point Likert scale. The specific measurements for these constructs are presented in APPENDIX. For gamification achievement, we operationalized this variable as the number of Karma points a user has. As the number of Karma points has a highly skewed distribution, we had to transform this variable by calculating its logarithm with base 10. This log value is then used in further analyses.

This data set was then analyzed using SEM - Partial least square regression based with the software SmartPLS 3.0.

RESULTS

The data set consists of 131 samples with 51% male. Based on the results of confirmatory factor analysis, we dropped 3 items from the measurement model due to their low factor loadings (lower than 0.7). As can be seen from table 1, the remaining items all have good factor loadings. Reliability statistics indicate that our measurements have good consistency in measuring the research construct. For example, Cronbach's alpha values of all construct are higher than 0.8. Aside from factor loadings, we also take into account Average Variance Extracted (AVE) to assess convergent validity of the constructs. As is showed in the table, all AVE values are higher than 0.7, which suggests that the items can explain well the construct they are intended to measure.

Table 1: Constructs' convergent validity and reliability.

Construct	Item	Mean	Std. Deviation	Factor Loading	Cronbach's Alpha	rho_A	Composite Reliability	Average Variance Extracted (AVE)
Achievement Motivation	AM1	5.24	1.461	0.856	0.924	1.003	0.945	0.811
	AM3	5.08	1.69	0.922				
	AM4	5.75	1.576	0.908				
	AM5	5.19	1.66	0.914				
	AM2	5.13	1.629	Deleted				
Identity Centrality	IC1	2.48	1.68	0.936	0.856	0.856	0.933	0.874
	IC2	2.1	1.626	0.934				
	IC3	3.85	1.922	Deleted				
Lost Performance Cost	LP1	3.75	2.077	0.876	0.822	0.847	0.893	0.737
	LP2	3.98	1.941	0.909				
	LP3	3.98	1.933	0.785				
	LP4	2.18	1.538	Deleted				
Continuance Intention	CI1	6.05	1.49	0.912	0.896	0.925	0.934	0.825
	CI2	5.51	1.729	0.883				
	CI3	5.88	1.608	0.929				

In this study, we assess discriminant validity using the results of Heterotrait-Monotrait Ratio (HTMT) analysis (Table 2). Since HTMT values of all pairs of constructs in our model are lower than 0.9, we conclude that these constructs have good discriminant validity.

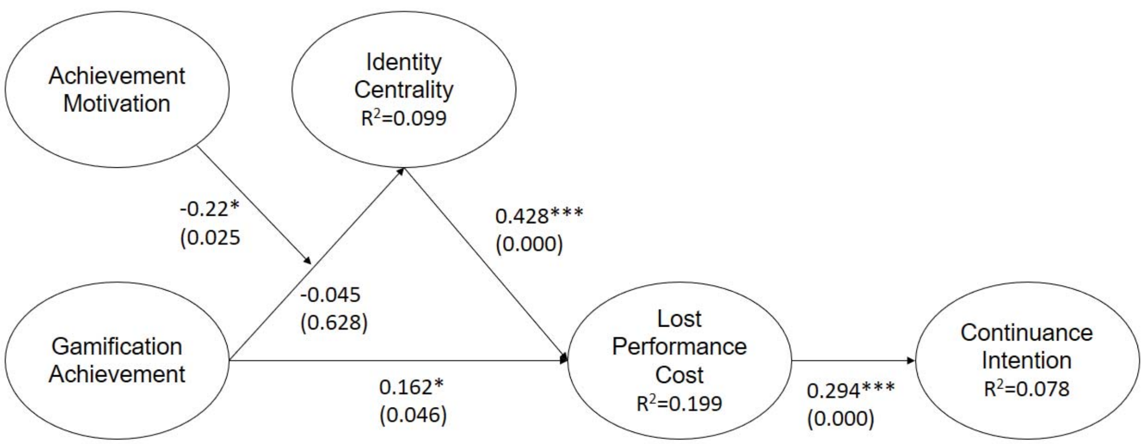
Table 2: The results of Heterotrait-Monotrait Ratio (HTMT) analysis

	Achievement Motivation	Continuance Intention	Identity Centrality	Gamification Achievement
Continuance Intention	0.257			
Identity Centrality	0.234	0.142		

Gamification Achievement	0.146	0.110	0.088	
Lost Performance Cost	0.233	0.319	0.477	0.154

Figure 2 illustrates the results of hypothesis testing. It can be seen from the result that the relationship between gamification achievement and identity centrality (H1a, H1b) is found insignificant (Beta = -0.045, p = 0.628). Next, we can observe significant relationships between gamification achievement and lost performance cost (H2, Beta = 0.162, p = 0.046), identity centrality and lost performance cost (H3, Beta = 0.428, p = 0.000), lost performance cost and continuance intention (H4, Beta = 0.294, p =0.000). In addition, we also found a significant moderating effect achievement motivation has on the relationship between gamification achievement and identity centrality (H5, Beta = -0.22, p = 0.025). This moderating effect will be examined further in the following section.

Figure 2: Results of hypotheses testing

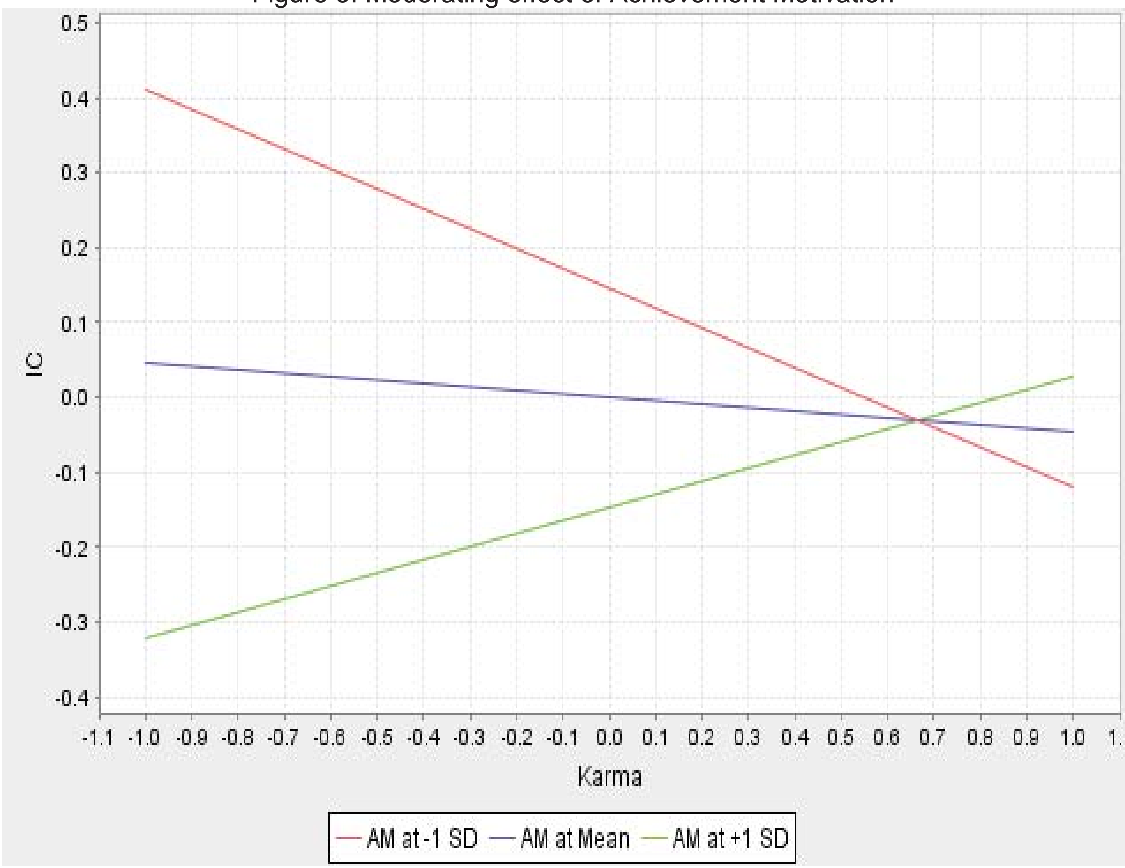


*** p < 0.001, ** p < 0.01, * p < 0.05

Figure 3 describes the direction of the moderating effect predicted in H5. In this graph, “Karma” is the abbreviation of “log of karma points”, which measures gamification achievement. IC is the abbreviation of identity centrality. From the graph, we can see that the relationship between this variable is positive when achievement motivation is high and negative when achievement motivation is low, which is consistent with hypothesis 5. However, we still do not know if these seemingly positive and negative relationships are statistically significant.

Therefore, we conducted another test using SPSS 18 software. Firstly, we used K-means cluster analysis to divide the variable Achievement Motivation into two groups. Then, we split our data set into two data sets based on these two groups. Lastly, a regression analysis is carried out for both groups with gamification achievement (Log karma points) as the independent variable and Identity Centrality as the dependent variable. From the results, when Achievement Motivation is low, Beta = - 0.477, p =0.019; when achievement motivation is high, Beta = 0.099, p =0.313. Therefore, we can conclude that achievement motivation moderates the relationship between gamification achievement and identity centrality, such that, when achievement motivation is low, this relationship is negative, when achievement motivation is high, this relationship is not significant. This result is partially consistent with hypothesis 5.

Figure 3: Moderating effect of Achievement Motivation



From the results of hypotheses testing, we conclude that H2, H3, H4 are supported. Even though the moderating effect of achievement motivation on the relationship between gamification achievement and identity centrality is not completely as predicted, the general direction of the moderating effect is still consistent with H5. Particularly, at low achievement motivation, the causal relationship is negative; at high achievement motivation, the causal relationship changes into a positive direction, even though this causal effect is not statistically significant. Therefore, H5 is partially supported. H1, however, is not supported.

DISCUSSION AND CONCLUSIONS

The results show that achievement in a gamified system increases lost performance cost for users. Even though there is no significant direct effect of gamification achievement on identity centrality, we observed a significant moderating effect of achievement motivation on this relationship. When a high achievement motivation is present, gamification achievement is found to have no impact on identity centrality. Meanwhile, gamification achievement has a negative effect on identity centrality if achievement motivation is low. This is interesting because it shows that self-determination theory can only reliably predict this causal relationship if we take into account individual differences. Next, as predicted, identity centrality has a positive effect on lost performance cost, which in turn, positively influences continuance intention.

In term of contribution to research, firstly, this study adds more to the literature of gamification on information systems. Our results show that gamification achievement influences intention to continue using the system through the mediating roles of identity centrality and lost performance cost. Interestingly, that relationship between gamification achievement and continuance intention is not straightforward. On the one hand, gamification achievement can increase lost performance cost, which, in turn, increases continuance intention. On the other hand, we found that achievement motivation, an individual trait, plays an important role in this relationship. High gamification achievement in the presence of low achievement motivation lessens identity centrality, which negatively affects lost performance cost and continuance intention. However, for individuals with high achievement motivation, the effect of gamification achievement on continuance intention is positive and straightforward. Secondly, this study also contributes to Self-determination theory by providing evidence that validates the theory and by adding individual differences when applying the theory to explain human behaviors. The results supported our prediction about the need for relatedness, which explains why gamification achievement directly increases lost performance cost. About the needs for competence and autonomy, we found that there is no significant direct effect from gamification achievement to identity centrality, probably due to the balance between two opposing effects of the loss of autonomy and the significance of competence. However, this balance changes depending on the level of achievement motivation, such that, at high achievement motivation, this causal effect is negative, at low achievement motivation, it is insignificant. The results of this study also provide evidence for Motivation crowding-out phenomenon. However, we found that the occurrence of this phenomenon varies depending on individual traits, in this case, achievement motivation. This is also a contribution to the literature of Motivation crowding-out. Last but not least, this result adds more to our understanding of Self-determination theory that only the individuals who have high achievement motivation manifest the effect of the need of competence.

For practice, this study provides important implications for gamified information systems. Firstly, platforms can encourage users to stay instead of switching to other platforms by offering permanent rewards for their contribution. In the context of a free internet nowadays, it is tempting for users to switch the use of a platform to another as they have many options at hand. Thus building relationships with users this way might be a low-cost but useful approach. Secondly, platform providers should invest more in users with much gamification achievement to encourage these people to contribute more to the platform. For example, platform providers may give these users physical gift, or extra system use privileges for these users. Compared to normal users, the investment in highly achieved users might be more worthwhile because, according to this study’s results, these users are likely to stick with the platform and contribute more in long-term. Next, the application of a permanent reward system has a more positive effect on people having high achievement motivation. Therefore, platform providers should consider the characteristics of their pool of users in terms of individual personality and culture. With the rise of big data analytics, online platform providers can have much information about their users, thus, a gamified system can be easily customized to match users’ characteristics.

This study has several limitations. Firstly, the data was collected in a single platform, raising the concern for the generalizability of our sample. However, since Reddit.com is one of the largest online forum in the world with diverse demography of users and a wide range of discussion topics, we believe this problem is not too severe. Secondly, we only investigated two direct consequences of gamification achievement, identity centrality and lost performance cost. In fact, the effect of gamification achievement might not be limited to those variables.
We have some suggestions for future research. Firstly, future studies should explore this phenomenon in different platforms with different types of reward. Secondly, scholars can explore more potential consequences of gamification achievement in terms of cognitive and emotional responses from users.

APPENDIX
Measurements

<u>Achievement Motivation</u>
AM1. I like situations, in which I can find out how capable I am.
AM2. When I am confronted with a problem, which I can possibly solve, I am enticed to start working on it immediately.
AM3. I enjoy situations, in which I can make use of my abilities.
AM4. I am appealed by situations allowing me to test my abilities.
AM5. I am attracted by tasks, in which I can test my abilities.

<u>Identity Centrality</u>
IC1. Being a redditor is an important part of who I am.
IC2. Being a redditor is important to my sense of self-esteem.
IC3. I embrace being a redditor.

<u>Lost Performance Cost</u>
LP1. Using Reddit provides me with particular privileges I would not receive elsewhere.
LP2. By continuing to use Reddit, I receive certain benefits that I would not receive if I switched to a new one.
LP3. There are certain benefits I would not retain if I were to switch to another system.
LP4. I would lose preferential treatment if stopped using Reddit.

<u>Continuance Intention</u>
CI1. I intend to use Reddit rather than discontinue it.
CI2. My intention is to use Reddit rather than use any alternative system.
CI3. I will not discontinue the use of Reddit.

ABSTRACT

This study evaluates factors that influence the perception of quality among customers of music streaming services. Multiple theoretical frameworks have been used to develop a conceptual model. This study analyzed survey data from 247 customers of different music streaming services using multiple regression analysis. Results of this analysis have been discussed to present new insight for different stakeholders in the digital music industry.

KEYWORDS: Music, Streaming, Quality, Technology Management, Decision Making

INTRODUCTION

Music streaming is disrupting music industry at an unprecedented rate (Datta et al., 2017). According to a recent report (RIAA, 2018) 75 percent of music industry revenue in the United States is accounted for by streaming services. As shown in figure 1, at the global level the revenue of music streaming services is greater than licencing, downloads, and physical CDs combined.

However, what seems to be missing from the literature, is the congestion of market. In other words, there is an evident gap in the literature when it comes to what defines quality in a highly competitive market. According to a recent report (Wilson, 2018) most streaming services are at par in terms of quality, subscription fee, availability of the free version, offering mobile app, and finally providing non-music content like podcasts. In this saturated and highly competitive market, the ultimate question is how consumers perceive quality.

This study, utilizing multiple theoretical perspectives, investigates the determinants of users' perception of quality with regards to music streaming services. Perception of quality in technology management literature has been proven to be an antecedent of perceived value which in turn affects the likelihood to adapt a technology (Venkatesh and Davis, 2000; Venkatesh and Bala, 2008; Venkatesh et al, 2003; Zeithaml, 1988; Lemon and Verhoef, 2016; Chiu et al., 2014). Drawing on this stream of literature, this study considers perceived quality as a significant proxy for adaptation of a specific streaming service.

LITERATURE REVIEW

This study synthesizes multiple theoretical frameworks to propose a conceptual model. These frameworks include theory of planned behavior (Ajzen, 1985, 1991), technology acceptance model (Davis et al, 1989), and objective studies of technology adaptation (Dodds et al, 1991; Cronin et al, 2000).

Theory of planned behavior (Ajzen, 1985, 1991) holds that behavioral intentions are the main driver of human behavior. This theory also states that intentions are driven by Attitude, subjective norms and behavioral control. Ajzen (1991, p.188) defines attitude as "the degree to which a person has a favorable or unfavorable evaluation or appraisal of the behavior in question". Ajzen (1991, p.183) defines perceived behavioral control as "people's perception of the ease or difficulty of performing the behavior of interest." Ajzen (1991, 188), continues to define subjective norm as "the perceived social pressure to perform or not to perform the behavior".

In a nutshell, the theory of planned behavior posits that attitude, subjective norms, and behavioral control, together shape user's intention, which in turn leads to a displayed behavior or act. In other words, if individuals believes that a certain action is advantageous, and if they believe that their immediate social network hold a favorable opinion towards that action, and finally if individuals conclude that they can properly perform that action, then they will form a positive behavioral intention towards that action.

The second theory that this study adapts is technology acceptance model (Davis, 1989). This theory has been widely employed and tested in technology management literature (Koufaris, 2002). Technology acceptance model states that the main reason behind individuals intention to use a computer system is their attitude towards that system. This theory also holds that attitude is formed by perceived usefulness and perceived ease of use. Davis et al. (1989, p.320) defines perceived ease of use as “the degree to which a person believes that using a particular system would be free from effort” and the perceived usefulness as “the degree to which a person believes that using a particular system would enhance his or her job performance”. Essentially, the technology acceptance model argues that what drives people to adapt a technology, is not the technology itself, but people’s perceptions towards technology, which obviously can change.

The third and last theoretical model that will be used in this study to develop a conceptual framework, is the performance-based approach that investigates specific characteristics of service as the main driver of behavioral intentions. According to these studies (Dodds et al, 1991; Cronin et al, 2000; Lemon and Verhoef, 2016) what actually leads to users’ intention to employ a system is not the subjective perception of users, but the objective characteristics of the system, i.e. quality of service. Lewis and Booms (1983) defined service quality as “a measure of how well the service level delivered matches customer expectations.”

According to this stream of literature, the main factor that leads to individuals’ intention to adapt a service is service value. Zeithaml (1988 p. 14) defines service value as “the consumers’ overall assessment of the utility of a product based on perceptions of what is received and what is given.” Service value itself is affected by perceived service quality. The relationship between quality, value, and intention, is the principal reason that this study chose perceived service quality as the dependent variable.

According to Cronin et al (2000), service value is also influenced by perceived sacrifice. Sacrifice in essence is what has to be given up (money, time, effort, etc.) to adapt a specific service. Multiple studies show that perceived sacrifice is directly or indirectly drive customers’ behavioral intention to act in a certain way, e.g. adapt a specific technology.

THEORETICAL DEVELOPMENT

Drawing on the technology acceptance model (Davis et al., 1989; Venkatesh and Davis, 2000; Venkatesh and Bala, 2008; Venkatesh et al, 2003), performance based approach towards intention for service adaptation (Cronin et al, 2000, Dodds et al, 1991), and theory of planned behavior (Ajzen, 1985, 1991), this study proposes a conceptual model that investigates what factors affect customers perceived quality in the context of music streaming services.

This study proposes the perceived quality as dependent variable (Y), and argues that it is affected by five main independent variables: subjective norm (X5), perceived usefulness (X6), perceived ease of use (X7), perceived sacrifice (X8), and perceived control (X9).

In the following section, this study defines each of these variables and provides reasoning for their relationship with perceived quality. Perceived quality in this study is conceptualized as the balance between service performance and customer expectations. In other words, based on the performance-based approach (Cronin et al, 2000, Dodds et al, 1991), this study defines perceived quality as the level and consistency of the characteristics of a specific music streaming service in its fit to subscriber’s expectation.

This study categories subscribers to music services in 5 different groups (X1, X2, X3, and X4) based on their previous usage of a service and decision of switching to a different service brand or staying with the same service brand. First group are “non-users subscribing to a brand” who are characterized as people who are not using any service but decide to subscribe to a brand. Second group are “free version users subscribing to the same brand”. This group are people who are using the free version of a brand and decided to subscribe to the paid version of the same brand. Third group are “free version users subscribing to a different brand”. This group are identified as people who are using the free version of a brand but decided to subscribe to the paid version of a different brand. Fourth group are “subscribed users subscribing to a different brand". These users are people who have subscribed to a paid service but decide to subscribe to a different paid service. Finally, fifth group are "users renewing their subscription". They are users who decide to renew their paid subscription to the same service they have been using.

This study conceptualizes subjective norm (X5) as the social pressures that individuals are under to subscribe to a specific music streaming service. This subjective norm could be exerted from peer or influencers (e.g., Venkatesh et al. 2003, Ajzen 1991, 2015). In other words, if an influencer or peer advocates for a specific music streaming service, individual would conclude that the streaming service bears high quality. Therefore a positive association between subjective norm and perceived quality is proposed.

Perceived usefulness (X6) in this study is construed as the extent to which a person believes that the music streaming service will enhance his or her music listening performance (i.e., accessibility to songs and frequency of listening) and enable him or her to enjoy music better (e.g., Venkatesh and Davis 2000). Similarly, perceived ease of use (X7) is defined as the extent to which a person believes that using the music streaming service will be effortless (e.g., Venkatesh and Davis 2000). Drawing on the technology acceptance model, a positive association between perceived usefulness and ease of use, and positive attitude towards the service is expected. This study defines quality as the balance between service characteristics and customer needs, among which are perceived usefulness and ease of use. Several studies (Landrum and Prybutok, 2004; Parasuraman et al., 1988) propose a positive association between perceived usefulness and ease of use, and perceived service quality. Therefore a positive association between these two variables and service quality is expected.

This study defines perceived sacrifice (X8) as monetary and non-monetary costs that subscribers of a specific music service should bear. This definition is developed based on the works of Lovelock and Patterson (2015), Lemon and Verhoef (2016), Cronin et al (2000), Dodds et al (1991), and Ponte et al. (2015). According to different studies, the relationship between sacrifice and value is an adverse relationship (Monroe, 2009, Dodds et al, 1991; Cronin et al., 2000; Woodruff, 1997; Sirakaya-Turk et al., 2015). Conversely, the relationship between value and quality is stipulated as a positive association (Hauser and Urban, 1986; Kumar and Reinartz, 2016). Therefore an adverse relationship between sacrifice and quality could be conferred. Moreover, this study argues that in a saturated and competitive market with low differentiation, users would be highly price conscious and price (i.e. sacrifice) is expected to negatively affect users' attitude towards quality of a specific music streaming service.

This study conceptualizes perceived control (X9) as the extent to which a person is confident in their ability to subscribe to, use, and unsubscribe from a service (Ajzen 1991). Literature (Parasuraman et al., 1988) holds a positive association between perceived control and perceived quality. This is in accordance with the definition of quality, i.e. balance between customers need and service performance. Customer would consider the quality of a service higher, if the service provider gives them confidence that they have full control over usage, subscription and opting out of the service. Therefore a positive association between perceived control and perceived quality is expected. Based on the above reasoning, this study proposes a multiple linear regression model. This multiple regression model, as shown in Equation 1, proposes that perceived quality is affected by subjective norm, perceived usefulness, perceived ease of use, perceived sacrifice, and perceived control. This model also suggests that different groups of users perceive quality of service in different ways. The relationship between Y and X1 to X9 is formulated as a multiple linear regression model as follow:

$$Y = \beta_0 + \beta 1(X_1) + \beta 2(X_2) + \beta 3(X_3) + \beta 4(X_4) + \beta 5(X_5) + \beta 6(X_6) + \beta 7(X_7) + \beta 8(X_8) + \beta 9(X_9) \quad (1)$$

Where:

Y:	Perceived Quality
X1 to X4:	Dummy variables showing 5 different groups of users
X5:	Subjective Norm
X6:	Perceived Usefulness
X7:	Perceived Ease of Use
X8:	Perceived Sacrifice
X9:	Perceived Control

DATA COLLECTION AND ANALYSIS

Amazon Mechanical Turk (MTurk) was used for data collection. Those who live in the United States and have 89% or higher incentive approval ratio were able to participate and fill out the survey questionnaire. In exchange for their participation, monetary compensation was provided. Respondents were instructed to review the given information of the three brands (i.e., Apple Music, Spotify, and Pandora), and make their service subscription decision. These three brands are chosen because the subscribers of these three brands account for more than half of total subscribers of music streaming services in the United States (Statista, 2018). Moreover, respondents could gain more detailed information by visiting the webpage of each brand by using URLs provided. The total sample size was 247. For the purpose of statistical analysis, along with theoretical constructs, five groups were recorded based on matching between each respondent's current usage of a service (free version user, subscribed user, or non-user; service brand in use) and his or her decision at the end of the survey questionnaire. These five groups are (1) non-user subscribing to a brand, (2) free version user subscribing to the same brand, (3) free version user subscribing to a different brand, (4) subscribed user subscribing to a different brand, and (5) users renewing their subscription. The fifth group is selected as the base case. Multiple Linear Regression was used to test the multiple regression model.

FINDINGS

Multiple linear regression analysis was used to describe the relationship between the dependent variable Y (perceived quality), four dummy variables (X1 to X4) which represent 5 different groups of users, and five explanatory variables (X5 to X9), Subjective Norm, Perceived Usefulness, Perceived Ease of Use, Perceived Sacrifice, and Perceived Control.
As shown in Table 1, in terms of their perception of quality, none of the customer groups showed a significant difference from the group who renewed the subscription (base group). Subjective norm and perceived control did not have a significant impact on perceived quality. Usefulness and ease of use, however, showed a positive and significant association with perceived quality. Finally, perceived sacrifice also showed a negative and significant influence on perceived quality.

Table 1: Summary of Multiple Linear Regression Analysis

Independent Variables	Coefficient	t-stat
β_0 (Intercept)	1.97**	4.39
X1	-0.02	-0.13
X2	-0.17	-1.82
X3	0.15	0.92
X4	0.4	1.83
X5 (Subjective Norm)	0.05	1.4
X6 (Perceived Usefulness)	0.3*	5.56
X7 (Perceived Ease of Use)	0.49*	7.3
X8 (Perceived Sacrifice)	-0.17*	-3.04
X9 (Perceived Control)	0.03	0.81
**: p-value less than .05*		
***: p-value less than .01*		

CONCLUSION

Findings of this study provide preliminary but interesting insights. First, it seems as if brand switching (i.e., free version users subscribing to a different brand and subscribed users subscribing to a different brand) does not occur solely because of the users' perceived quality of service. It may be caused by their variety seeking behavior. The insignificant influence of subjective norm and control shows that, in this saturated and highly competitive market of music streaming services differentiation is relatively low, information is abundantly available for users to evaluate alternatives, and it is easy to unsubscribe and switch to another service. In other words, users may have some amount of experiences with any music streaming service and also possess high levels of confidence in their ability to evaluate different services with respect to their usefulness and easiness to use.

Finally, the results of this study shows that music streaming service providers could no longer use higher prices as a quality signal. Monetary as well as non-monetary costs (perceived sacrifice) negatively influence users' perceived quality toward the service. Currently different music streaming service providers add more features to their service, and increase the price of their premium subscription services. However, the results of this study shows that users may not perceive these added features as a signal of high quality, but rather as unnecessary complexity added to the service. Therefore, this study suggests that the additional complexity, redundant features, or unrecognized benefits not only could not justify higher prices of premium music subscription services, but have a negative impact on users' perception of quality, and as the result, turn them away from the streaming service.

Visa Policies and Innovation: How Powerful Is Your Passport?

Marc S. Mentzer
University of Saskatchewan
Email: mentzer@edwards.usask.ca

ABSTRACT

The growth of isolationist ideologies in the United States and other countries has generated interest in the relationship between international mobility and innovation. This study focuses on visa policies as an indicator of a country's openness to cross-border flows of people, and examines the relationship between visa policies and innovation.

KEYWORDS: Expatriates, Innovation, International markets, Migration, Public policy

INTRODUCTION

The tightening of border controls by the United States has fueled dialogue asking to what extent cross-border mobility affects a country's prosperity, with such discussions often centering on the role of those from other countries in contributing to innovation and creativity. Would the Silicon Valley and Hollywood – or their counterparts in other parts of the world – be the same without the influx of people across borders? These issues have been discussed long before Donald Trump became president; for example see Travern's concerns in 2006 about how the border policies of the George W. Bush administration would hamper innovation. However, the actions of the current administration have renewed concern about this issue.

Regarding the openness of the US to those who might contribute to innovation, the topic of H-1B visas was a contentious issue in the 2016 US presidential election. H-1B visas allow a foreign person to work in the US for a particular, specified employer, for a maximum of three years, although in practice the time period can be much longer. On one hand, Kerr and Lincoln (2010) have demonstrated that H-1B visa holders lead to a net increase in inventions. Others argue that H1-B visa holders are depressing wages and taking jobs that would otherwise go to US residents.

The question is not limited to the United States. The United Kingdom's decision to leave the European Union has sparked similar discussion of how the transborder flow of people helps or hinders the British economy. Several European countries are witnessing the rise of political parties who campaign for tighter border controls. Every country weighs the pros and cons of tight border restrictions to protect jobs and safeguard national security versus the free transborder movement of people, which it might be argued, enhances economic competitiveness through innovation.

Wagner and Jonkers' (2017) essay in *Nature* has sparked an interest in how national "openness" (their term) affects a country's scientific influence. Wagner and Jonkers' analysis used countries as their unit of analysis, and found that national openness correlated strongly with scientific impact, measured though a system of weighting citations in scholarly articles. Their measure of national openness was comprised of variables measuring immigration and emigration of scientists coupled with international co-authorships. They succeeded in documenting that openness correlates with scientific impact. Of particular interest are the outliers to the regression line. In the low-openness high-impact quadrant, the largest outlier was the United States, with extraordinary influence in science despite relatively closed borders. The other quadrant that is an outlier to the regression line, the high-openness low-impact quadrant, was empty except for Hungary. With that exception, Wagner and Jonkers found that high openness, implying a free flow of researchers across borders, always resulted in an above-average impact on scientific research.

The recent findings of Sugimoto, Robinson-Garcia, Murray, Yegros-Yegros, Costas, and Larivière (2017) are parallel to the research of Wagner and Jonkers (2017). Sugimoto *et al.* looked at this issue using individual researchers as their unit of analysis, and asked how Trump's border-tightening might affect US scientific productivity. Their analysis, based on data from 16 million authors from the Web of Science, showed that tighter US borders would cause non-US researchers to move to countries other than the US. In examining patterns of co-authorship, Sugimoto *et al.* found that when a researcher moves to another country, that person constructs a research network connecting both the old country and the new country, thus boosting that person's influence. In other words, the flow of researchers out of a country into another country actually helps develop innovation in both countries, as those in the first country become able to join multinational networks of researchers. Instead of the phrase "brain drain," it would be more useful to think of this as "brain circulation" (Gaillard & Gaillard, 1997; Sugimoto *et al*., 2017). Sugimoto *et al*. conclude that Trump's border policies will damage US influence in the sciences, and that other countries will fill the void by welcoming researchers who seek to advance their careers.

Wagner and Jonkers (2017) point out that their study did not include a potentially important variable, that being ease or difficulty of obtaining a visa. The current study uses measures of visa policies as indicators of a country's openness, and it is anticipated that openness will be associated with measures of innovation.

MEASURES

Independent Variables: Visa Policies

A nation's practices regarding mobility across borders comprise a broad construct that does not easily lend itself to quantitative measurement. One approach to this construct is to examine, for citizens of a given country, how many other countries they can visit without obtaining a visa in advance, a concept sometimes referred to as "Passport Power." For example, a German citizen can visit 161 countries without obtaining a visa in advance, while at the opposite end of the spectrum, an Afghan citizen can visit only 25 counties without obtaining a visa in advance (Arton, 2018b).

The mirror image of Passport Power is whether a country is welcoming to foreigners who do not have visas (Arton, 2018c). In other words, for a given country, how many countries' citizens can visit without obtaining a visa in advance? There are many countries that never require a visa in advance for any visitor. Some of these are small developing countries that cannot maintain a global network of consulates to issue visas; Djibouti, Micronesia, and Samoa are examples. At the other extreme, four countries are “least welcoming” because they require visas in advance of all visitors (Afghanistan, North Korea, Syria, and Turkmenistan).

The country scores for Passport Power and Welcoming Countries have been developed by Arton Capital, a Montreal-based consulting firm that specializes in advising clients about investor visas and second passports. Arton maintains a website, passportindex.org, which displays the scores they have assigned to each country (Arton, 2018a, 2018b, 2018c). Their list includes every jurisdiction that issues passports, including non-sovereign jurisdictions such as Hong Kong and the Palestinian Territories, as well as microstates such as Andorra and Kiribati, although these were dropped from the current analysis due to lack of data for the corresponding dependent variables. Where a country allows a visa to be issued on arrival, Arton treats the situation as one in which a visa is not required; however, as described below, whether a country issues visas on arrival is more ambiguous than one might guess at first glance. For example, the United States has created an on-line procedure known as ESTA (Electronic System for Travel Authorization), which technically is not a visa although it has many of the characteristics of a visa. Where a country allows a traveler to use an on-line procedure such as ESTA, Arton categorizes the situation as one in which a visa is not required.

The scores of Passport Power and Welcoming Countries are statistically unrelated to each other, with an insignificant correlation of -.11. Visa policies are not determined by symmetry or reciprocity. A United States citizen can visit 158 countries without an advance visa, but that does not mean that the US is easy for other citizens to enter. On the other hand, there are small, developing countries who are unselective about who they will admit because their economies depend on tourism, such as the Maldives, Seychelles, and some independent Caribbean islands, yet their own citizens find it difficult to travel abroad without visas. Supply and demand does not seem to determine a country’s visa policies. Some of the most restrictive countries are unlikely to be inundated with foreign visitors, such as Bhutan, Equatorial Guinea, Eritrea, or South Sudan, yet they have remarkably stringent polices on admitting citizens of other countries.

One relatively straightforward approach would be to distinguish between situations where a person could enter a specific country without a visa, versus those situations where a person needs a visa to enter. As experienced international travelers know, the reality of countries’ admissions standards is more nuanced than the dichotomy of visa versus non-visa. For example, one country might be casual about questioning incoming visitors at the border, while another country might subject visitors to a regimen of interrogation, searches, and official harassment. Any variable based on a numerical measure of formal rules will be imperfect in its failure to capture these qualitative shades of gray.

Further complicating the question of measurement is that some countries require a visa in advance, while others issue visas upon arrival, at least to citizens of certain countries. In some instances, this is a pro forma process that is a routine part of the bureaucracy of airport arrivals; in other instances, getting a visa at the border or airport is a roll of the dice. For example, one well-travelled business executive had harshly criticized Mauritania for its bureaucratic hurdles in issuing visas, pointing out that a country is unlikely to get foreign investment if it refuses to issue visas to foreign investors like himself (Biddlecombe, 2004). Mauritania now offers visas on arrival at their capital’s airport for visitors of all nations, although those entering at land borders must still obtain their visa through a consulate. The visa-at-airport procedure yields the highest possible score for Mauritania on Arton’s scale of Welcoming Countries (Arton, 2018c).

Travel guidebooks sometimes bluntly reveal the quirkiness and "vague bureaucracy" surrounding visa procedures, as in this statement about Cameroon:

> "Obtaining a visa is an example of how haggling and vague bureaucracy can affect all areas of African life. Strictly speaking, visitors without a visa may be required to leave Cameroon on the next available flight... Unofficially, visas are usually available at the airports at Doula and Yaoundé [West, 2011: 50]."

In a situation like the above, Arton's scores are based on a country's official visa rules, not practices that are occurring on an informal level.

An additional variation is the introduction of on-line pre-screening procedures in lieu of visas, such as the Electronic System for Travel Authorization (ESTA) procedure, described above, which the US commenced in 2008. ESTA is for those visiting the US from visa-waiver countries, but it would be justifiable to regard ESTA as a sort of "visa-light." ESTA is for short-term visitors and is not available to those who intend to work or study in the US. Other countries are beginning to introduce similar forms of advance, on-line screening that resemble the ESTA process, such as Canada's Electronic Travel Authorization, Australia's Electronic Travel Authority, and the European Travel Information and Authorization System (ETIAS). Inevitably, more pre-screening systems will be developed around the world on the ESTA model, sometimes replacing traditional visas procedures and in other instances creating a visa-like process for travelers who previously did not need a visa.

Despite these shortcomings, the current study is predicated on the assumption that the country scores for Passport Power and Welcoming are indicative of a country's overall policy toward transborder movements of people. Whether a country requires a visa for casual visitors might or might not be related to that country's openness to migrants, short-term residencies of workers, and other border movements. Nevertheless, the current study uses visa policies for casual visitors as a proxy for openness toward transborder movements of people.

A final caveat concerns the measure of Passport Power, in which it is assumed that any citizen of a country can get a passport. In practice, citizens' access to passports varies across countries, even if one sets aside the question of whether people can afford fees for issuing a passport. In some countries, all citizens have an absolute right to a passport; for example, in Canada, it is a right that is embedded in the constitution. Meanwhile, there are places where issuance of a passport to a country's citizens is sometimes denied due to ethic discrimination, sexual discrimination, a criminal record, or the political purity of the applicant.

Dependent Variables: Innovation Outputs

Measuring a construct as broad as innovation is obviously a challenge; however, the World Intellectual Property Organization (WIPO) has released a publication titled *The Global Innovation Index* with various measures of innovation for 127 of the countries of the world. For each country, over 100 highly specific measures are aggregated into seven indices labeled "Institutions," "Human capital and research," "Infrastructure," "Market sophistication," "Business sophistication," "Knowledge and technology outputs," and "Creative outputs" (WIPO, 2017). These seven indices are, in turn, aggregated into a single Global Innovation Index. As WIPO acknowledges, some variables are measures of input and others are measures of outputs. For example, the quality of government institutions, human capital, and infrastructure are the ingredients for innovation rather than measures of innovation (outputs) themselves.

The two measures of output, "Knowledge and Technology Outputs" and "Creative Outputs," are the principal dependent variables in the current study, and both measures are remarkably inclusive in how they capture a country's innovation output. Knowledge and Technology Output includes such items as patents, scientific articles, software spending, and intellectual property receipts, among other times. Creative Output includes trademarks, industrial designs, feature films, publishing, Wikipedia edits, and YouTube uploads, among other items. The composition of these variables is listed in Appendix A, and greater detail regarding how they these measures have been developed is available in Appendix III of The Global Innovation Index (WIPO, 2017). The variables have been scaled in a way to allow an equitable comparison across countries, in many instances expressed in relation to purchasing power parity of gross domestic product (GDP). Variables such as "Wikipedia edits" or "YouTube uploads" have been expressed on a per capita basis, ages 15-69. The approach of WIPO to data means it is unnecessary to adjust their data for differences in population size, purchasing power parity, or size of the economy.

RESULTS AND DISCUSSION

As shown in Table 1, there were strong correlations between one of the independent variables (Passport Power) and the principal dependent variables (Knowledge and Technology Outputs, and Creative Outputs). These results are parallel to the findings of earlier researchers who established a connection between international mobility and innovation.

Table 1: Bivariate Correlation Matrix

		1.	2.	3.	4.	5.	6.
Independent Variables	1. Passport power	1.00					
	2. Welcoming countries	-.11	1.00				
Principal Dependent Variables	3. Knowledge & technology outputs	.66**	-.06	1.00			
	4. Creative outputs	.78**	-.07	.81**	1.00		
Other Dependent Variables	5. Scientific & tech publications	.64**	-.05	.68**	.70**	1.00	
	6. H-Index	.60**	-.12	.76**	.65***	.57**	1.00
	Notes: N = 126 ** *p* < .01						

On the other hand, the ease of entering a country (the variable Welcoming Countries) was not significantly related with any measure of innovation. This is contrary to expectations.

These findings point to the conclusion that open borders are associated with innovation when we are talking about the ease of a country's citizens travelling elsewhere, but openness to other countries' citizens is *not* associated with innovation.

The explanation for such anomalous findings might rest with the phenomenon where extraneous variables lead to two variables being correlated, creating the illusion that a causes b. In other words, a plausible argument is that visa policies are mere proxies for basic, underlying national characteristics that the WIPO scores did not directly measure. Countries like the United States, low on the scale of Welcoming Countries, is likely to maintain high levels of innovation regardless of its visa policies. Countries that are high on the Welcoming scale, like the Maldives and the independent Caribbean islands, as well as troubled countries such as South Sudan, Syria, and Afghanistan, would probably rank low on measures of innovation even if they changed their visa policies. In short, the variable of Passport Power appears to capture the extent to which a country has a wealthy, highly advanced economy. Such countries are innovative for reasons that are unrelated to openness to international travelers.

Admittedly, the measures of innovation outputs used here are extremely broad. In contrast to the broad measures of innovation in the current study, Wagner and Jonkers (2017) and Sugimoto *et al*. (2017) focused specifically on published research articles, using patterns of authorship and citation patterns as their measures of innovation. One of the components of Knowledge and Technology Outputs is the number of scientific and technical articles, expressed in relation to purchasing power parity of GDP to enable easy cross-national comparisons of the data. Only articles in science and engineering journals were included (WIPO, 2017: 412-413). As shown in Table 1, Passport Power has a correlation of .64 with Number of Articles; however, contrary to expectations, Welcoming Countries has a correlation of -.05 with Number of Articles. Another measure of research publication activity is the H-Index, which WIPO operationalized in an unconventional manner as the average number of citations per article (WIPO, 2017: 413). As shown in Table 1, Passport Power has a correlation of .60 with H-Index, while Welcoming Countries has a correlation of -.12 with Number of Articles.

Even among highly educated people, most stay in their country of origin. Sugimoto *et al.* (2017) were able to measure this precisely, finding that of authors of academic articles, 96% maintain the same "country of affiliation" throughout their career. In any case, the openness-innovation relationship is more complicated than it initially appears. The ease with which a country's citizens can travel is associated with innovation, but lowering visa barriers to entry by other countries' citizens has no relationship to innovation. A country's overall state of development probably provides the best explanation of why some countries are more innovative than others.

APPENDIX

Components of Dependent Variables

1. The variable “Knowledge and technology outputs” is an index comprised of:

    a) Patents by origin/bn PPP$ GDP
    b) PCT patent applications/bn PPP$ GDP
    c) Utility models by origin/bn PPP$ GDP
    d) Scientific & technical articles/bn PPP$ GDP
    e) Citable documents H index
    f) Growth rate of PPP$ GDP/worker
    g) New businesses/th pop. 15–64
    h) Computer software spending, % GDP
    i) ISO 9001 quality certificates/bn PPP$ GDP
    j) High- & medium-high-tech manufactures, %
    k) Intellectual property receipts, % total trade
    l) High-tech exports less re-exports, % total trade
    m) ICT services exports, % total trade
    n) FDI net outflows, % GDP

2. The variable “Creative outputs” is an index comprised of:

    a) Trademarks by origin/bn PPP$ GDP
    b) Industrial designs by origin/bn PPP$ GDP
    c) ICTs & business model creation
    d) ICTs & organizational model creation†
    e) Cultural & creative services exports, % of total trade
    f) National feature films/mn pop. 15–69
    g) Global ent. & media market/th pop. 15–69
    h) Printing & publishing manufactures, %
    i) Creative goods exports, % total trade
    j) Generic top-level domains (TLDs)/th pop. 15–69
    k) Country-code TLDs/th pop. 15–69
    l) Wikipedia edits/mn pop. 15–69
    m) Video uploads on YouTube/pop. 15–69

Notes:

The variable labels above are directly quoted from WIPO, 2017, Appendix I.
More detailed explanations of variables are in WIPO, 2017, Appendix III.

Abbreviations used in this appendix:

FDI = Foreign direct investment
GDP = Gross domestic product
H index = Hirsch index (impact of research)
ICT = Information and communication technologies
ISO = International Organization for Standardization
PCT = Patent Cooperation Treaty
PPP = Purchasing power parity
TLD = Top level domain (internet)

Examination Customization: A Simple Procedure to Enhance Academic Honesty

David M. Bowen
California State University, East Bay
Email: david.bowen@csueastbay.edu

ABSTRACT

Analytical courses are susceptible to academic dishonesty as complex analyses are assessed via numerical answers. Such answers are easy to grade and easy to copy from classmates. To combat the copying of answers, we introduce the concept of 'examination customization;' exams that require unique answers for each student and minimal extra time to construct and grade. Anecdotal evidence suggests that students faced with such an exam realize that copying is pointless (and in fact leads to getting caught). The majority of students appreciate test problems that force honesty and minimize peer pressure to participate in answer sharing.

KEYWORDS: Academic honesty, cheating, examination problems, student assessment

INTRODUCTION

Academic honesty is fundamental to the integrity of academic institutions, from research that accurately reports and interprets scientific data, to researchers and students generating their own results and taking credit only for their own work.

According to the International Center for Academic Integrity (ICAI), academic dishonesty has reached epidemic proportions with 39% of undergraduates admitting on surveys that they have cheated on tests and 68% that they have cheated on tests and/or written assignments (ICAI, 2019).

There are a multitude of causes contributing to this epidemic, including deterioration of negative social connotations of cheating, technological advances, and availability of internet based businesses designed to provide papers and homework or test answers for a fee (McCabe, 2012).

In Engineering Education there has been a large emphasis on fostering collaboration skills in graduates (Bowen, 2013), and so mixed messages of 'You must be able to collaborate well with others,' alongside, 'You must do this particular work completely on your own,' are received by students. For international students from cultures less individualistic in nature, the stigma of the transgression of not helping a colleague in need may be considered worse than a transgression against academic honesty.

Analytical course exams in particular can be susceptible to academic dishonesty by virtue of the fact that complex concepts and analyses are often assessed via student generation of correct numerical answers. Such exam questions are typically easy to construct, easy to grade, and easy for students to copy answers from classmates.

FACILITATING ACADEMIC HONESTY

In order to foster academic honesty, I use a three pronged approach that includes an emphasis on behaving ethically, examinations that are always ‘Open Book, Open Note and Closed Neighbor’, and constructing exams that have unique answers for each student. The latter is the focus of this paper, but the former deserve brief explanations.

In emphasizing academic integrity, I take pains to describe the implications of cheating. Of course there is the getting caught and failing or receiving zero credit, though research indicates that most cheating students do not get caught [], so such consequences are not likely to deter many. Rather, I attempt to influence students’ sense of the size, scope and implications that such dishonest conduct leads to. It is not just about fooling the professor and getting a better grade in a class. It is about the integrity of the institution, it is about the value of the degree they receive and it is about the graduates before and after, and how willing employers and others are to respect the knowledge represented by a degree. I let them know that they are relying on the integrity of those that came before them, and they are indebted to prior graduates. It is that existing integrity which gets them the interview or the job offer when an employer that does not know them is willing to take a chance on them due in large part to the stamp of approval bestowed by our institution. If they then do not have the expected professional competencies because they were more concerned with cheating to get a better grade than learning the material, they will fail professionally as well as shut doors for future graduates. At least some students nod their heads in agreement, and it seems, surprisingly, that many of the students have not made those connections before.

One common form of cheating is using prohibited notes or violating ‘closed book’ examination instructions, especially for multiple choice or fill-in-the-blank type examinations. An easy way to avoid this is to not construct exams which are closed book/notes. This does mean that a bit more time and effort is typically spent constructing and grading the examinations. This extra effort is warranted if we consider what skills will be most valued in the future. Based on those future skill considerations, it becomes apparent that closed book/note exams should be a relic of the past.

Memorization, especially of formulas or techniques in the decision sciences, is not the critical skill we need to impart. Rather, valued graduates are those who can encounter an unstructured situation and are able to identify which analytical tools can be used and then to accurately do so, including understanding any underlying assumptions. When they engage in this process professionally in today’s world, they will have virtually infinite resources available to them in real time to assist any application. Therefore it is much more important that they know where/how to find such resources and filter and utilize them correctly than it is to memorize a formula. Furthermore, if we teach them the skills and provide opportunities to practice those skills associated with utilizing available resources, then they are more likely to establish a habit of life-long learning and less likely to experience obsolescence of the facts they memorized in school.

Another easy form of cheating on examinations is looking at the answers of another student and copying that answer. This practice can be stifled if each student by design has a unique correct answer, and all the students know that their answers are *supposed* to be different than their neighbors. This practice can be thought of as ‘Examination Customization.’

Such customization is relatively easy to accomplish with little if any extra burden on faculty or students.

Constructing Custom Examination Questions

Students at all universities should have a unique identifier, usually called a registration number. At CSU East Bay, each student is assigned a 'NetID' which is two letters of the alphabet followed by 4 numbers. Other ways to generate unique input numbers could be to use 'How old you are in months,' 'Last four digits of your Driver's license/Tax Identification Number, etc..

To customize exams, simply specify the input data used in problem solving in terms of the unique identifier. For example in the following decision analysis problem (Figure 1), the ticket price is defined for each student by their unique NetID, resulting in unique correct answers:

Figure 1. Customized Final Examination 'Ticket Purchase' Problem Decision Analysis

Final Exam

Fall 2010

NAME______________________________________NetID_____________

Points

1) You have been looking forward to travelling during the holidays (New Orleans?), but it has become so expensive! Right now, you have the choice to buy a cheap (non refundable) ticket, buy a more expensive ticket that is refundable, or wait and buy a ticket next month. You estimate that the chances that the ticket price next month will increase/remain the same/decrease are 35% / 25% / 40%. Ticket prices are:

	Now	Next month
	Cheap = your NetID	Increase of 15% (= NetID*1.15)
	Refundable = your NetID + $250	Same = Your NetID
		Decrease of -20% (= NetID*0.8)

Note: If you buy the refundable ticket, next month you will see if prices increase / remain the same / decrease, then have the option to pay a $75 dollar fee to get a full refund then buy a ticket at the new rate.

20 a) What should you do and why?

10 b) A travel consultant charges a fee and then can tell you now for certain what prices will be next month. What should you be willing to pay for such a service?

Constructing the problem in this way ensures that each student that correctly solves this decision analysis problem will have a unique answer. For grading, it is convenient to construct an Excel spreadsheet to calculate solutions to test problems. Inputting the student's NetID into the appropriately constructed spreadsheet supplies all the correct answers for that student's examination. Figure 2 shows screen shots of the solution spreadsheet for the Ticket Purchase decision analysis problem for students with NetIDs of 1234 and 6789.

Figure 2a. Solution Set Screenshots: Decision Analysis Ticket Purchase Problem, NetID=1234

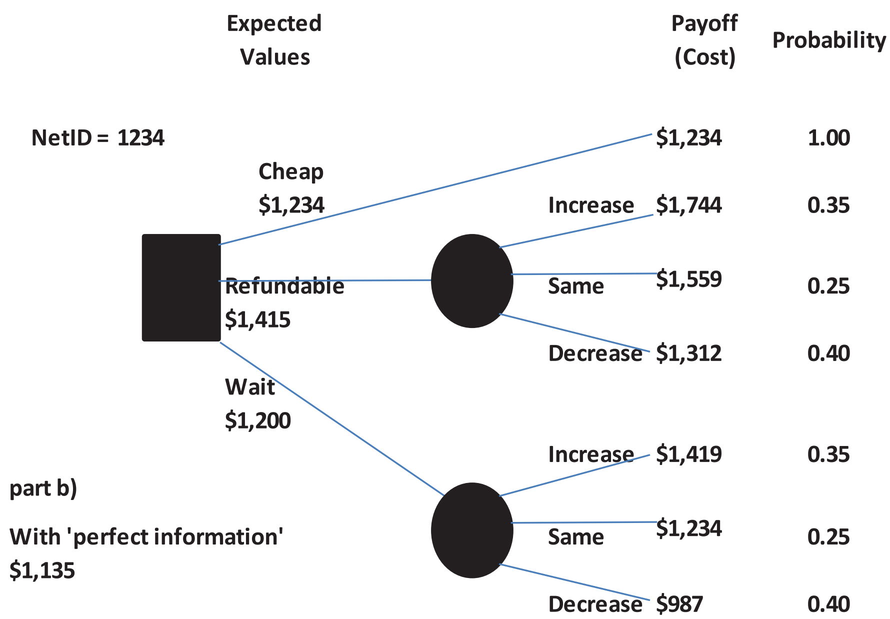

Figure 2b. Solution Set Screenshots: Decision Analysis Ticket Purchase Problem NetID=6789

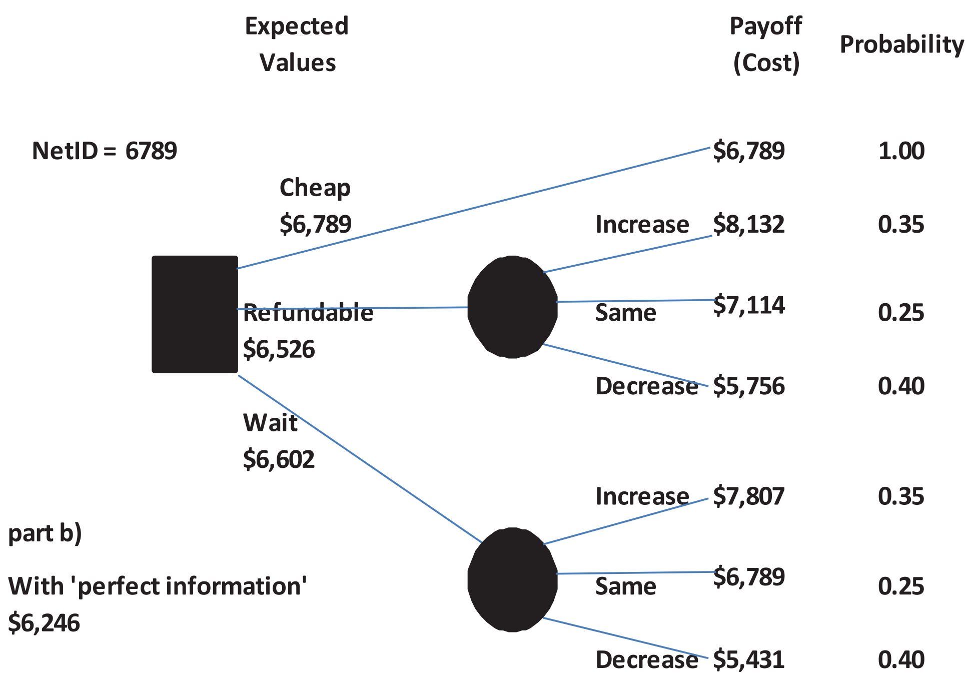


The solution spreadsheet shows that the best decision, from an expected value perspective, is different depending on the NetID value, with the NetID=1234 best (lowest expected cost) decision is to 'wait' and buy ticket next month, (expected cost of $1,200), while for the student with NetID =6789, the best decision is to purchase a refundable ticket and then either keep it (60% chance) or pay $75 to get a refund and then buy the ticket at a decreased price (40% chance) for an expected value (cost) of $6,526. Similarly, the value of perfect information (part b) of the problem) is different for each case, with EVPI= $65 (=$1,200 - $1,135) for the lower NetID and EVPI = $280 (=$6,526 - $6246) for the higher NetID value.

Resource Consumption Implications for Solution Set Construction

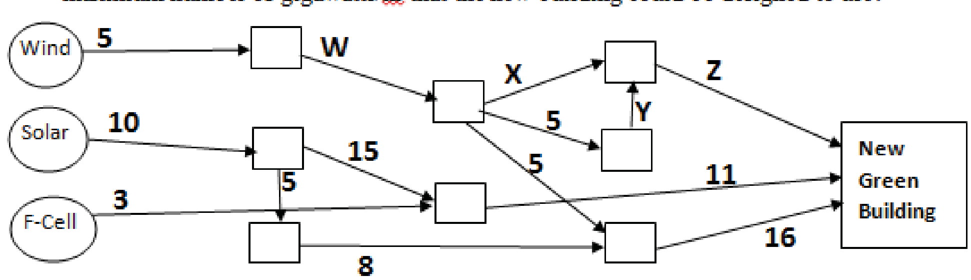
Construction of the Excel Spreadsheet to calculate answers takes approximately 10 minutes, and something similar is typically needed to calculate the answers even if the exam is not customized. Using paper and pencil might require approximately 5 minutes. The added burden on instructors to customize and grade customized exams is minimal. Inputting the NetID information requires 1 to 2 seconds to decipher and enter for each student exam paper. Likewise, the added burden on students ranges from nothing to performing a simple mathematical operation on the NetID to determine input data.

Another benefit to constructing such an Excel Solution Spreadsheet is utilizing it as a tool and visual when reviewing the examination. It can also be used to demonstrate 'sensitivity analysis' to students if there is, for example, a problem that utilized a customized interest rate. Demonstrating to students how solutions/decisions might change based on the specific value of an input such as interest rate (or tax rate or cost) can be enlightening, and is all the more memorable if it is a problem that they have considered in some depth and tried to solve.

Figure 3 shows a network flow problem, which is again based on the student's NetID digits and can result in different answers between students. In this case the students need not perform any calculations on their NetID digits prior to using them to solve the problem. They only need to transfer the W, X, Y & Z values on to the diagram and then determine their answer by identifying the 'min cut set' for their individualized network. In this case the min cut set will be 18 if W>4, or will be 13+W if W<5.

Figure 3. Customized Network Flow Exam Problem.

30 2) The University wants to build a new green building, supplied with power from renewable plants and utilizing the transmission capacities as shown. If the values are in gigawatts/hr, what is the maximum number of gigawatts/hr that the new building could be designed to use?



Linear Programming Example Examination Problem

Figure 4 shows a relatively complex linear programming formulation problem, but the customization itself is simple, straight forward, and results in unique answers. In this case only two digits from the NetID are utilized and will serve as 'right hand sides' in two constraint inequations.

Figure 4. Customized Linear Programming Formulation Exam Problem

Open Book, Open Notes & Closed Neighbor—Good Luck!

Engineering 3841

Midterm #2

Points NAME________________________ NetID____________

W X Y Z

1) A regional University is doing some energy planning to determine the best course of action over the next 2 years. Options are to purchase energy from the local utility, and/or to invest in one or more alternative energy sources, where money is paid initially for the plant, but then energy is produced at no additional cost. For each technology at most one plant can be built, but 'partial' plants can be built with proportional costs and capacities, up to the max capacities shown below. Below, **all $ figures are in millions of dollars**, and capacity/demand figures are in **thousands of gigawatt hours**:

		Max Annual Capacity	
	Cost	**Peak**	**Nonpeak**
Wind	**$3**	**5**	**1**
Solar	**$5**	**10**	**1**
Fuel cell	**$2**	**3**	**3**

Expected Annual Demand		
	Peak	**Nonpeak**
Yr1	**12**	**W**
Yr2	**14**	**X**

Additionally, 'grid' energy costs $0.25 million per thousand Gigawatt hours (non peak) and $1.0 million per thousand Gigawatt hours (peak) both with unlimited capacity.

10 a) Define appropriate decision variables. (HINT: What are you deciding to do or not do?)

10 b) Show the objective function, including units.

15 c) Show the constraints, including units.

10 d) Identify a feasible solution including values of variables and objective function (HINT-No Simplex required for this!)

15 e) Set up the initial tableau and perform the first pivot.

20 f) After the pivot, what are the values of each of the variables and of the objective function? Is the current solution optimal after the first iteration? Explain.

20 g) The University administration has just decided that, independent of the cost, the University will get a fuel cell for demonstration purposes. How does this change your **formulation**? How would it affect your **answer to part d)**?

DISCUSSION

The method for examination customization is simple and straight-forward, but there are a few pitfalls to be avoided. One pitfall can occur when constructing a problem with probabilities. For example you do not want the possibility that related probabilities do not sum to one. Using customization in the face of probabilities is still possible, it just needs some extra thought and attention. Figure 5 displays an information processing problem with state events whose probabilities should sum to one. This is accomplished by specifying some probabilities in terms of the others. Since a digit of the NetID is 9 or less, dividing that number by 10 provides a positive probability less than 1 for Py (probability of 'yellow' result). Subtracting that number from 1 and then dividing the result by 2 will give the probabilities for the probabilities of blue and green (Pb & Pg).

Figure 5. Customized Information Processing Exam Problem Involving Probabilities.

2) The A/H1N1 virus outbreak (Swine Flu) has over-run the testing capacity used to determine if blood samples contain genomic evidence of A/H1N1. The CDC needs to hire more people to interpret the test results. A sample card has been developed that, when a drop of suspect blood is applied, turns either green (no A/H1N1), blue (A/H1N1 present) or yellow (inconclusive, requires re-test). The probability of each of the colors appearing is as follows:
Py=(last digit of NetID)/10 and Pb=Pg. And, Pg+Pb+Py=1
   a) What is the average information in bits of this test?
   b) The CDC wants to hire enough workers to interpret 4 million of these initial tests every day. Accounting for meetings, breaks, lunch, scrubbing in and gowning, workers will be left with 4.5 hours a day of actual processing. If reaction time (in seconds) is equal to (1st digit of NetID) + (2nd digit of NetID)x(average information in bits), how many workers will need to be hired?

Another pitfall to avoid is constructing a problem that has extremely unrealistic values. For example you do not want to construct a problem where the speed of an airplane is 10,000 miles per second or 5 miles per hour. A good rule of thumb is to calculate your NetID-based values using the highest and lowest numbers in the NetID range and see if they give reasonable values. If not, some minor manipulation can probably fix it so that the results are reasonable. For example, if the range of values is too broad, then divide the input data by a number that makes the range reasonable. Let's say you want an input value to be a person's weight in pounds. Using two digits of the NetID gives a range of 11 lbs to 99 lbs, too light unless the people are infants and young children. Using three digits gives a range of 111 lbs to 999 lbs which most likely includes values that are too heavy. Depending on the target population, more realistic ranges could be constructed by specifying "100 plus the last two digits of your NetID," which would give a range of 111 lbs to 199 lbs, or "100 plus 2*(last two digits of NetID)" which would give a range of 122 lbs to 289 lbs. It should also be kept in mind that the customization can be introduced in any numerical value, so it might make more sense to just specify a weight and introduce the customization values elsewhere in the problem. The goal is merely to get unique answers and deter answer copying.

Student Experience and Reactions

I utilize this customization technique in many courses. The first time students are exposed to this sort of customization there are always a few students who are confused by it. To clear up any potential confusion, during the first exam I will introduce the customization by directing students' attention to the problem at the beginning of the exam period. I will ask a student for their NetID and demonstrate how that translates into input data for the problem. I will also note that the input data will be different for each student based on their NetID, and also point out that this means everyone should get a different correct answer for the problem so copying from another student is futile.

Students seem to readily accept these customizations. They understand that customization reduces opportunities for academic dishonesty and realize that it does not really make the problems any harder to solve.

Every once in a while, a student will interpret the question differently from what was intended. For example if the NetID is 1234 and I write that the datum is "YZ, the last two digits of your NetID," some students correctly interpret this as '34' while others multiply 3 times 4 to get '12'. The only real issue here is to be able to understand that it was interpreted in this way so that the student can be given credit for their answer even though the number does not match that generated by the Solution Spreadsheet.

In discussion with alumni, many years after their school days, I have been told that, "Everyone knew it was pointless to try and cheat on your exams." Many students, frustrated by prior cheating by other students, expressed appreciation for the effort that made it much more difficult to copy answers. Of course this is anecdotal, but then again measuring how many students actually cheat (or are willing to self-report cheating to the instructor) is also problematic.

ABSTRACT

Safe transportation for employees is a perk many organizations are offering to mitigate women abuse in public transportation. This research extends the home-to-work employee transportation problem by adding two constraints: (a) an escort must be present if a female passenger is alone in the vehicle; (b) a ride-time threshold for all passengers. Route generation heuristics for inbound (home to work) and outbound (work to home) scenarios are developed. Even distribution of passengers across routes and minimal use of escorts are the hallmarks of the proposed solution. Results from representative datasets provide valuable insights to employee transportation providers.

KEYWORDS: Home-to-work employee transportation, Route optimization, Minimal spanning tree, Route improvement heuristics, Escorts for female employee safety

INTRODUCTION

Empowering women's mobility is a primary concern for many societies around the world. Numerous studies show the rampant nature of this abuse in public and private transportation. A report by the World Health Organization states that 35 percent of women globally undergo some form of abuse or physical violence while commuting (https://www.who.int/news-room/fact-sheets/detail/violence-against-women). Women often face misbehavior, abuse, and harassment from male drivers in public transportation vehicles. For example, in Mumbai, 95% of women reported abuse in public transportation; 23% of them at a bus stop and 46% inside a bus (http://www.aksharacentre.org/ht2/). Unfortunately, the abuse creates a much deeper psychological impact beyond a woman's physical and emotional health – it impacts their ability to enter the workforce. A study conducted by International Labor Organization, states that in Delhi alone, 27% employed and 13% of non-working women see safe mobility as a hindrance to joining the workforce (http://www.aksharacentre.org/wp-content/uploads/2017/01/Akshara-Transport-Report.pdf). Many organizations are realizing the fact that female employee productivity is directly related to their well-being, sense of security and happiness. Several companies are already providing ride sharing services as benefits to employees to ensure their commute to work is safe, especially at night (https://quickride.in/, https://www.onpoint-us.com/services/workforce-transportation/, https://www.gosafr.com/about-safr/), while others are reorganizing company bus routes so that women are never left alone on the bus. Potential safety risks for a female while travelling in a ride-share vehicle are (a) abuse by the male-driver (b) abuse by the fellow male-riders. Escort services are offered by transportation provides to protect female employees from physical abuse and provide a safe environment during the journey. Trained drivers can also act as escorts, but it is usually preferred for drivers to focus on driving and leave the escort duties to someone else. Escorts are usually trained and, in some cases, armed. Many transportation providers are now ensuring at no point women employees are alone in the vehicle either with other male co-passengers or the driver (https://www.routematic.com/safety-measures-for-female-employee-transportation/).

The problem addressed in this work is concerning an Employee Transportation Provider (ETP) who intends to generate efficient vehicle routes to transport employees, from their home to work and vice versa. The ETP provides female employee safety by ensuring that they are always accompanied by an escort if they are the only passenger aboard the vehicle (with the driver). Currently many ETPs are facing challenges and deterrents to operate successfully and profitably. The key challenges are highlighted below:

a) *Dynamic nature of employee shifts*: Employee shift changes, which means different work hours and work start times, happen frequently and mandate rerouting on a short notice.
b) *Limited vehicle capacity*: Capacity constrained vehicle route planning where several constraints must be satisfied. For example, determining the number of vehicles needed to pick-up (or drop-off) employees at the same location such that their capacity is fully utilized.
c) *Forecast driver availability*: Forecasting the number of drivers needed ahead of time such that efficient driver staffing can be performed based on their availability.
d) *Forecast escort availability*: Forecasting the number of escorts needed to accompany female employees and matching that to their availability.
e) *Escort pickup and drop-off locations*: When and where to pick-up or drop-off escorts along a route.
f) *Ensuring on-time arrival to work*: Satisfying the time constraints for pickup and drop-off along with vehicle capacity constraints is challenging.
g) *Last minute requests*: Ability to alter routes to accommodate last minute cancellations and additions on short notice.
h) *Lack of good route planning tools*: Efficient route generation is very hard problem to solve for a route planner. Awareness of the road patterns in the area and its traffic patterns is needed to plan a route. Also, route generation software solutions are costly and may not satisfy all the constraints the ETP has to honor.
i) *Large volume of pickups and drop-offs*: The sheer volume of employees increases route planning time.
j) *Traffic conditions*: Unpredictable traffic conditions can disrupt existing route plans and may require real-time rerouting to a different vehicle or adding an extra vehicle.
k) *Inbound and outbound trips*: Difficulty in routing early morning trips and late-night trips back to home because of limited escort availability and unsafe conditions for female riders.

Plagued by the above problems many new ETPs are hesitant to enter the market. ETP profit margins are affected due to: (i) over-staffing escorts and drivers because of the inherent uncertainty around how many employees are transported per shift; (ii) high fuel costs because of poorly designed routes; (iii) revenue loss from paltry employee service rate. Another important aspect in routing ETPs that is usually considered is whether to originate routes from a central depot or the last known location of the vehicle. In the inbound scenario where employees are picked up from their home, many ETPs usually allow drivers to start from their last know location such as their home. Whereas in the outbound scenario, where employees are transported back to their home, many ETPs have vehicles starting from a centralized depot location. Also, many ETPs have poor data collection such as taking requests over telephone and text messages, and poor data storage methods like use of spreadsheets and handwritten notes. Such methods only add to the woes of ETPs. Moreover, route optimization is a NP-hard problem which means designing truly optimal routes is not possible in finite time. Hence, heuristic and meta-heuristic approaches are employed to solve the route optimization problem.

The main objective of this research is to design efficient inbound and outbound vehicle routes for an ETP. The goal is to find routes with the least total route distance under these constraints (a) employee pickup and drop-off is with a certain time window; (b) number of employees in a vehicle must not exceed capacity; (c) an escort must be present if a female employee is the only passenger in the vehicle; (d) ride-time of employees cannot exceed a certain threshold. Furthermore, the number of escorts needed is reduced by ensuring female passengers are not alone in the vehicle.

RELATED WORK

Perugia et al. (2011) studied the HWTP at ENEA Casaccia Research Center in Rome with fair route generation for all employees, acceptable to the company management and worker unions. Their objective was to determine routes such that total costs are minimized and quality of service, as perceived by the employee, is maximized. Route fairness was imposed by adhering to time windows on the arrival time of a bus at a stop. The problem was modeled as a multi-objective generalized vehicle routing problem with time windows (GVTPTW) which was solved using a novel incremental Tabu search algorithm. The next closest work related to HWTP is by Leksakul et al. (2017) who addressed the employee transportation for a large industrial facility in Thailand framing it as a SBRP. Their problem was to design efficient bus routes to pick-up workers who live far away from a large-scale factory. They solved the problem in two stages: (1) bus stops are allocated based on employee home location and proximity to the bus stop using cluster-based methods; (2) an ant-colony-optimization approach was used to find the optimal route between all proposed bus stop locations. Apart from the work of the above two authors there is hardly any research work related to HTWP. Hence, problems that have some commonality with HTWP are discussed below.

HWTP is related to the school bus routing problem (SBRP) which aims to design optimal routes to transport students, who board the bus near the vicinity of their home to get transported to their school. Constraints of the problem are (a) number of students in the bus cannot exceed its capacity, (b) upper threshold on the maximum ride time of a student in a bus, (c) students must reach school before school start time, (d) upper limit on the number of student at stops. Desrosiers et al (1981) decomposed SBRP into five steps: data preparation, bus stop selection (student assignment to stops), bus route generation, school bell time adjustment, and route scheduling. Data preparation loads all the necessary input data such as the locations of student homes, school, bus depot, and the origin-destination matrix. In the bus stop selection step, students are assigned to bus stops using techniques such as location-allocation-routing and allocation-routing-location which use the maximum distance from home to bus stop as the constraint (Laporte, 1988; Bowerman et al., 1995; Bodin and Berman, 1979; Dulac et al., 1980; Chapleau et al., 1985). In bus route generation, mainly two techniques are used to generate routes – “route-first, cluster-second” and “cluster-first, route-second” (Laporte and Semet, 2002). In school bell time adjustment, the objective is to determine the school starting and ending time such that the number of students served is maximized by the same bus and number of buses is minimized (Desrosiers et al., 1981, 1986; Bodin et al., 1983; Fügenschuh, 2009). In route scheduling, a sequence of successive routes is determined with the exact starting and ending time of each route (Graham and Nuttle, 1986; Braca et al., 1997; Li and Fu, 2002; Spada et al. 2005).

The current work introduces two constraints to the HTWP – escorts to accompany female employees; and a ride-time constraint. The current has some commonalities with the dial-a-ride problem. Dial-a-ride-problem (DARP) is the transportation of people between an origin and destination with the following constraints (a) pickup at the origin stop and drop-off at the destination must occur within a certain time window, (b) there is an upper limit on the maximum ride time of a person in the vehicle, (c) satisfy level-of-service requirements such as door-to-door service, wheelchair assistance, etc. (Cordeau and Laporte, 2003, 2007; Parragh et al., 2008; Ho, 2018; Molenbruch et.al., 2017a, 2017b, 2017c, 2017d). Unlike in DARP where the driver assists passengers, in the present work escorts can be considered as service providers of safety for female passengers. Presence of a ride-time constraint is another common feature with DARP.

This research is unique in three aspects:

1. It solves both inbound and outbound scenarios unlike many SBRP studies that are only focused on solving the inbound scenario (Braca et al., 1997; Li and Fu, 2002). The outbound or the afternoon problem, where students are dropped to their bus stops, received very little attention in the SBRP literature.
2. It extends the HWTP to include two constraints – escort for women employees and a ride-time limit.
3. It extends HWTP, by considering different starting locations for vehicles in the inbound scenario.

PROBLEM DESCRIPTION

A corporate company is providing safe transportation services as a benefit to its employees to ensure their wellbeing. It outsources this job to a third-party ETP, who must transport employees from their home to the office and vice versa in a metropolitan area. The ETP aims to design optimal routes to maximize the number of employees transported, reduce operational costs, improve employee satisfaction and increase profit margins. ETP executes two types of trips – inbound and outbound. In the *inbound trip*, employees are transported from their home to work; in the *outbound trip* they are transported from work to home. Inbound and outbound scenarios are depicted in Figure 1 and 2 respectively.

The following assumptions are made to limit the scope of this work:

- ETP has fixed number of vehicles.
- Drivers report their location to the ETP prior to inbound trip planning. Vehicles are assumed to be with the driver in this case.
- Drivers and vehicles are stationed at the office before the outbound trip starts.
- Seat capacity of each vehicle can be different.
- Vehicles do not return to their starting location at the end of a route.
- Work location is same for all employees.
- Employees live in a city where there are road and traffic restrictions.
- Employees living in the same residential premises are transported together if possible.
- Single load i.e., male or female employees; and mixed load i.e., a mix of female and male employees is possible.
- Special need employees are not considered, only general employees are assumed.
- Finite number of shifts are serviced in a day. For example, an organization can operate, 3 shifts of 8-hour durations.
- Starting and ending time of an employee shift is provided.

- The shifts do not overlap with each other (i.e., the starting and ending time of a shift does not overlap with another shift).
- Employees are contacted by email or text message about their pickup time for the inbound trip and the drop-off time for the outbound trip.
- Escort pickup location is known before route planning.
- Escort pickup location can either be their home or anywhere between the office and employees' home.
- Escort scheduling and optimizing the number of escorts across all routes is not considered.
- Escorts are either male or female security personnel who are trained and skilled to protect the female employee during the ride.
- Escort drop-offs is not considered in route planning, i.e., their drop-off is not part of the route sequence.

Inbound Model

Given a fixed number of vehicles, what is the optimal routing sequence to pick up employees and drop them all at the same work location such that the total route distance and number of escorts are minimized?

Figure 1: Inbound scenario

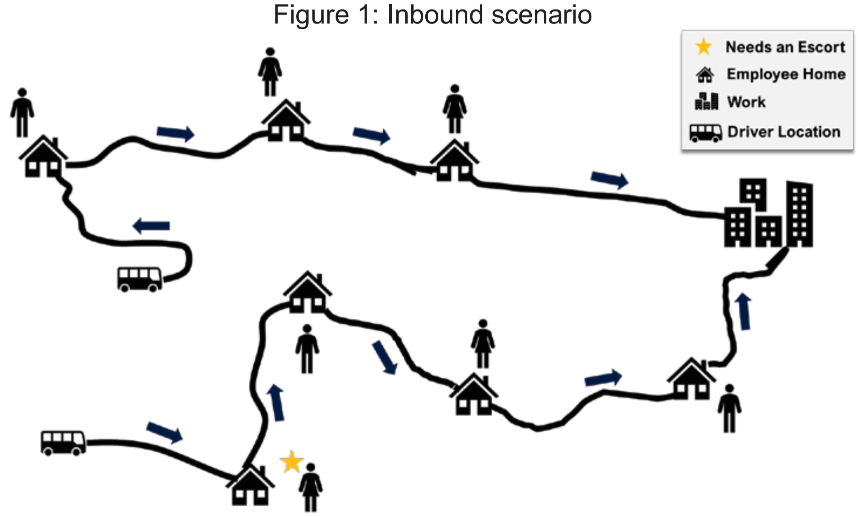

Figure 2: Outbound scenario

The constraints of this problem are:

a. employees must be picked up in a certain time window and dropped off at the office by the start of the employee shift time
b. vehicle capacity is not exceeded
c. an escort must be in the vehicle if a female passenger is the first employee to be picked up in the route
d. each pickup location is only visited once, i.e., only one vehicle services a pickup stop
e. upper limit on the number of employees transported in a vehicle (usually set by the ETP)
f. threshold limit on the ride-time of each employee in a vehicle

Escorts are provided when the female passenger is the first person in the route sequence. This service is used by many ETPs in practice. In a situation where the first person in the route is a male and the next employee in the route is a female, it is assumed to be a safe practice by the ETP because the employer has strict disciplinary rules to prevent employee harassment.

Outbound Model

Given a fixed number of vehicles, what is the optimal routing sequence to drop off employees after being picked up from the same work location such that the total route distance and number of escorts are minimized? The constraints of this problem are:

a. employees must be picked up at the end of their shift and dropped off at their home in a certain time window
b. vehicle capacity is not exceeded
c. an escort must be in the vehicle if a female employee is the last passenger to be dropped-off in the route
d. each drop-off location is only visited once
e. upper limit on the number of employees transported in a vehicle (usually set by the ETP)
f. threshold limit on the ride-time of each employee in a vehicle

Escorts are provided if the employee is the last person in the route sequence. Again, similar to the inbound case, ETP considers it safe if the penultimate passenger is a female followed by a male employee.

SOLUTION METHODOLOGY

A heuristic solution is proposed to solve the above two problem scenarios since they both are NP hard problems.

Inbound Model

The inbound problem is modeled as a VRP (Vehicle Routing Problem). Since employee actual pickup time is provided only after route planning is finished, it is safe to assume that there is a reasonably large time window for their pickup. Unlike the actual VRP problem, here vehicles are distributed across an area. The route planning algorithm is described below.

1. Get input data – employee home locations, driver locations, escort locations, vehicle-seating limit threshold, shift start time, employee ride time threshold.
2. Group employees at the same location so that they are picked up at the same time.
3. Calculate the midpoint of all employee pickup locations.
4. Calculate the distance from each vehicle's current location to the midpoint of all pickup locations. Sort the vehicles in the ascending order of this distance.
5. Calculate the distance of each employee's home location to office. Sort the employees in the ascending order of this distance.
6. If the employee pickup consists of both male and female passengers or only male passengers, then:
    a. Determine the least number of vehicles required to transport all employees while maintaining an even distribution of employees in a route. This is formulated as integer linear optimization problem where the objective function is the sum of distances between each vehicle's location and all employee pickup locations subject to vehicle available capacity constraint. The decision variable is binary, if a vehicle is assigned to an employee then the decision variable is 1 otherwise it is 0. The optimal solution is a set of vehicles that are assigned a set of employee pickups. The main purpose of calculating the number of vehicles upfront is to reduce the number of drivers and escorts required.

    If the employee pickups are only females, then:
    b. Assign an escort to a vehicle and reduce the available capacity by 1.
    c. Selection of vehicles is identical to 6 (a)
7. Create an initial route sequence for each vehicle from its corresponding assigned stops in 6 (a).
8. For each pickup stop in the sorted list of employee pickups from step 5, assign it to a vehicle such that the incremental change in route distance is at minimum. This is achieved by inserting the stop in the best possible position within a vehicle's route and recording the incremental change in route distance of the vehicle.
9. Apply the Relocate Operator on each pair of vehicle routes (Braysy and Gendreau., 2005)
10. Apply the 2-opt operator on every vehicle's route (Braysy and Gendreau., 2005)
11. Identify routes where the first pickup is a female employee and an escort is not provided.
    a. If there is available capacity in vehicle, insert the escort pickup stop that is closest to the vehicle's starting location or the first female pickup stop
    b. If the vehicle capacity is reached, rearrange the route sequence such that incremental change in route distance is least and the first pickup stop is a male employee.

Outbound Model

The outbound problem is also modeled as a VRP. Since employee actual drop-off time is provided only after route planning is finished, it is safe to assume that there is a reasonably large time window for their drop-off. Route planning algorithm when employee pickups are both male and female is described below.

1. Get input data – in all employee home locations, driver locations, escort locations, vehicle-seating limit threshold, shift end time, employee ride time threshold.
2. Group employees at the same drop-off location so that they are dropped at the same time.
3. Calculate the distance of each employee's home location to office. Sort the employees in the ascending order of this distance.
4. If the employee drop-off consists of both male and female passengers or only male passengers, then:
    a. Estimate the number of vehicles needed, ensuring an even distribution of employees in a vehicle's route using a cluster-based approach:
        i. Construct a minimal spanning tree with the drop-off stops as the nodes of the tree and the work location as the root of the tree.
        ii. Traverse the tree from the deepest node to the root node.
        iii. Assign each node traversed to a vehicle and terminate when the vehicle's capacity is reached.
        iv. The output is a set of employee pickups assigned to a vehicle.

    If only female passengers have to be dropped, then:
    b. Assign an escort to a vehicle and reduce the available capacity by 1.
    c. Estimation of vehicles needed is identical to 4(a)
5. Create an initial route sequence for each cluster in 4(a).
6. Apply the Relocate Operator on each pair of vehicle routes.
7. Apply the 2-opt operator on every vehicle route.
8. Identify routes where the last drop-off is a female employee and an escort is not provided.
    a. If there is available capacity in the vehicle, insert the escort pickup stop at the right spot in the route sequence that is before the last female drop-off stop
    b. If the vehicle capacity is reached, rearrange the route sequence such that incremental change in route distance is least and the last drop-off stop is a male employee.

COMPUTATIONAL EXPERIMENTS

An example dataset is constructed to illustrate the solution methodology because no benchmark datasets are available for the HTWP with female employee safety constraint. The dataset is adopted from a real-world situation faced by an ETP, however due to data sovereignty some data elements are masked. The results and insights from this dataset are significant for an ETP.

Inbound Scenario

4 test instances are considered here. In the first 2 test instances, the employee home locations are uniformly distributed and in the remaining 2 test instances, employee home locations form distinct clusters, see Figures 3-6. The office location is assumed to be located between employee home locations or far away from it. Driver locations and escort locations are uniformly distributed; vehicles reside at driver home locations. All vehicles have the same capacity of 10 seats. Employee gender at each stop is randomly generated for all test instances. All employees must in office by their shift start time of 7 am. They are picked up after 5 am and before 7 am. The ride-time threshold is 30 minutes. A constant vehicle velocity of 40 miles per hour is assumed and all distances are assumed to be Euclidian.

Outbound Scenario

4 test instances are considered here. The employee home and office locations are identical to the inbound scenario. Vehicles, drivers, and escorts are all present at the office location before the route start. Vehicle capacity and employee gender for all test instances is identical to the inbound scenario. The employee shift end time is 2 pm. They should be dropped before 4 pm at their home and their ride-time threshold is 30 minutes. A constant vehicle velocity of 40 miles per hour is assumed and all distances are assumed to be Euclidian and in miles.

Table 1: Input parameters inbound and outbound for test instances

Scenario	Test Instance	Number of Vehicles/ Drivers	Number of Escorts	Number of Male Employees	Number of Female Employees	Vehicle capacity
Inbound	5501	20	20	49	51	10
Inbound	5502	20	20	45	55	10
Inbound	5503	20	20	51	49	10
Inbound	5504	20	20	49	51	10
Outbound	4401	20	20	49	51	10
Outbound	4402	20	20	45	55	10
Outbound	4403	20	20	51	49	10
Outbound	4404	20	20	49	51	10

Results of the test instances are summarized in Table 2. It can be observed that

a) vehicle capacity is utilized completely in test instances 5502, 4401, 4402, and 4404.
b) maximum ride-time in a route across all test instances is below the ride-time threshold.
c) escorts were not needed in all inbound test instances because either the capacity was reached, or the route distance was at minimum by having a male employee as the first pickup passenger (see Figure 7). Two routes in outbound test instance needed escorts (see Figure 8).
d) even load of employees across all routes, which means there is a fairness among all drivers on their workload.

Table 2: Summary of optimization results for test instances

Scenario	Test Instance	Number of Routes	Avg. Stops Per Route	Total Distance (miles)	Max Ride Time (mins)	Escorts Used
Inbound	5501	10	9	922.9	20	0
Inbound	5502	10	10	687.0	20	0
Inbound	5503	10	9	1132.0	20	0
Inbound	5504	10	9	870.9	20	0
Outbound	4401	10	10	1050.0	21	0
Outbound	4402	10	10	972.9	21	0
Outbound	4403	11	9	1078.3	21	2
Outbound	4404	10	10	829.5	21	0

The rearrangement of a route to that the female is not alone in the vehicle certainly reduced the need for more escorts however it did increase the route time. In such instances the ETP should evaluate the fuel cost and escort wages and decide if having more escorts is beneficial.

CONCLUSIONS AND FUTURE WORK

This work presented a HWTP by adding a ride-time constraint and providing escorts for female passengers if they are alone in the vehicle. In the inbound and outbound scenario, a cluster-first route second approach is applied to attain an even distribution of stops across vehicle routes. A linear optimization is used to perform clustering in the inbound scenario. A minimal spanning tree is used to perform clustering in the outbound scenario. A feasible initial solution is obtained and 2-opt and relocate route improvement heuristics are applied.

As part of future work, several extensions to the current work are planned:

a) Exploring the use of variable neighborhood search, adaptive variable neighborhood search, Tabu search, and other meta-heuristics to attain better solutions
b) Including a constraint where escorts must be on a vehicle if male passengers are also traveling with female passengers.
c) Relaxing the criteria for escort drop-off – they can be dropped off when no female passengers are present on the vehicle.
d) Including a constraint where the ETP operates exclusive vehicles for female passengers on certain routes.

ABSTRACT

This paper is an extension of a detailed research which is primarily conducted to make an overall improvement of a steel pipe manufacturing system. In order to achieve that goal, four distinct problems namely, buffer capacity, tool magazine size and reload timing, pipe sizing, and inspection and rework problems, in the system are solved optimally. To validate that the overall effectiveness of the system significantly improves while the optimum solutions are implemented in the production floor, the whole system is simulated with existing and optimum configurations. The comparison is presented in terms of overall equipment effectiveness.

KEYWORDS: Overall Effectiveness, Simulation, Continuous Production.

INTRODUCTION

This paper presents the numerical application of some locally optimized operational solutions in a continuous steel pipe manufacturing system. The optimum solutions for four different operational problems are compared with existing non-optimal situations. The optimum solutions to those four problems are generated based on some data imitating a practical industrial environment. The first problem was focused in obtaining an optimum buffer capacity for the steel coil accumulator (Hossain and Sarker 2018a). The second problem focused in finding the optimum tool order quantity in addition to the tool magazine size and magazine reload timing (Hossain and Sarker 2018b, 2018c). The cutting length (size—standard/substandard) of the pipes and the rework policy are optimized in the third problem (Hossain and Sarker 2017). Wherein, the fourth problem of this research dealt with off-line inspection-rework facility to find the optimum number of servers and space for the inspection and rework stations (Hossain and Sarker 2018d). Subsequently an additional evaluation system called weighted *overall equipment effectiveness* (OEE) is developed, based on the monetary loss based regression method (Hossain and Sarker 2016, 2019), to measure the economic performance of the individual or composite performance of the system. It is expected that, OEE of the system is improved when the optimum solutions for these four problems are fully implemented in the production floor. In order to check this expectation, the whole system is simulated for two cases: (1) with the existing configuration as well as (2) with the improved or optimum configuration.

Non-disclosure of data proprietorship: This paper presents a detailed information of the simulation results that mimics a steel pipe manufacturing system. The system parameters used in this paper do not represent the original data of any industrial setup, but the data chosen here capture a close picture of the aforementioned industrial sector. The name of the industry is not disclosed to preserve the confidentiality of its proprietorship.

Literature Survey

The recent available literatures on buffer capacity optimization are either evolved from approximation of discrete systems [Alvarezvargas et al. (1994), Rajaram and Tian (2009), Bierbooms et al. (2013), Ozdogru and Altiok (2015)], or focused in modeling the system as a fluid flow. None of the available researches is specifically oriented with the situation of a coil accumulator in continuous steel pipe manufacturing systems. Hence, the first optimization problem was oriented in determining the optimum buffer capacity.

In the second operational problem a multiple-tool magazine system is proposed for the steel pipe manufacturing system. Some research works are reported in the literature, that deals with tool life prediction [Karandikar et al. (2012), Yao and Chien (2014), Wang and Gao (2015)], or tool replacement scheduling [Lamond and Sodhi (2006), Sodhi and Sarker (2003), Hippalgaonkar and Shin (2011)]. However, a generalized model for multiple-tool magazine system in terms of magazine reload timing, magazine size, tool order quantity, and generalized tool-life distribution, still absent in the available literatures. In this paper, an optimization model is evaluated that deals with the impact of tool magazine system on the cost savings.

Some research works are found, which deal with the one-dimensional slitting problems [Sarker (1988), Hsieh (1997)], knapsack problems [Yan (2003), Lee et al. (2013), Della Croce et al. (2017), Feng et al. (2017), Furini et al. (2017)], or discrete rework optimization [Selim and Al-Zu'bi (2011), Hossain and Sarker (2016a, 2016b)]. However, the on-line defect detection and rework policy in a continuous process, as well as the sizing policy for the pipes cut are not precisely addressed in the available research works. The third operational problem here, is concerned about determining the optimum pipe cutting length and pipe rework policy.

The inspection and rework queues, in the fourth problem of pipe manufacturing, depend several system parameters and constraints. Though several literatures on the production line queues are reported [Laghaie et al. (2012), Ravid et al. (2013)], the appropriate model for the intertwined inspection-rework queuing network in the pipe manufacturing system, is not specifically exemplified in the available researches. A specific model for determining the number of inspection/rework server(s), with the appropriate system parameters for a steel pipe manufacturing line, is presented in this research paper with a practical field data.

Finally, a suitable method for evaluating the effectiveness of the pipe manufacturing system is implemented in this paper. The old measures [Raouf (1994), Wudhikarn (2010), Yuniawan et al. (2013)] of weighted overall equipment effectiveness (OEE) do not provide a concrete method for determining the weights in the expression. Moreover, the old performance measures do not consider the weights in terms of cost parameters. Hence, this research is followed with a new approach of measuring the weighted OEE that suits with the continuous pipe manufacturing system. The overall effectiveness's (OEE) of the pipe manufacturing system, for both existing and improved configurations, are evaluated by comparing the WOEE (weighted overall equipment effectiveness) and PEE (production equipment effectiveness) methods. The newly developed MLBR (monetary loss based regression) method presented in by Hossain (2019), is used for finding the WOEE and PEE. The numerical example taken here, is solved for obtaining optimum solutions, following the approaches described by Hossain and Sarker (2017-2018).

Notations

Some notations listed below are used in this paper to explain the system.

T_{br}	Buffer runout duration in a cycle (hours)
T_c'	Coil feed cycle time (hours)
$T_{cr,i}$	Remaining cycle time in Day-i , for next day use (hours)
$T_{r,i}$	Remaining tool life in Day-i , for next day use (hours)
n_t	Number of magazine reloads in a day
l_1^s	Scrapped pipe length from the online rework-scrap decision (feet)
n^{st}	Number of standard size pipes
n^i	Number of inspected pipes in the off-line inspection-rework facility
n^{ex}	Number of pipe external failures that customer identifies
n^r	Number of reworked pipes in the inspection-rework facility
n^s	Number of scrapped pipes in the inspection-rework facility
l^s	Total length of the scrapped pipe in a day (feet)

The parametric values of the system for the four optimization problems, the existing configuration of the line and the corresponding optimum solutions are presented in the next section.

SYSTEM PARAMETERS

Two different scenarios are evaluated for comparison purposes. In one scenario the line is configured with the traditional non-optimum parameters; this situation is termed as *existing* configuration. In another scenario, the line is configured with the optimum solutions from the four optimization problems. The system described with the optimum solutions is termed as *improved* configuration. The numerical values of the parameters, corresponding to the (1) buffer capacity, (2) tool life, (3) pipe sizing and rework polity, and (4) inspection-rework facility configuration problems are listed in Table 1, 2, 3 and 4, respectively.

System Parameters Relevant to Buffer Capacity

The coil feeding system in the pipe manufacturing line consists of a coil joining station and a coil accumulator. The joining time (T_J) follows normal distribution with mean $\overline{T}_J$ = 0.85 hours and standard deviation σ_T = 0.35 hours. All other parameters which are involved in the feeding stage, are listed in Table 1. Here, c_B indicates the operational cost for the coil accumulator, α denotes the acceleration of strip input to the coil accumulator, c_{td} indicates the line stoppage or downtime cost, h_B defines buffer strip holding cost at the coil accumulator, D_c expresses the demand of coils in a year, and L_c is the average length of the steel strip coil. The strip output rate from the coil accumulator is the same as the actual rate of material flow in the line or the rate of pipe production λ .

Table 1. System parameters involved in the coil feeding system.

c_B \$/feet/year	$\bar{T}_J$ hours	σ_T hours	α feet/hour^2	λ feet/hour	c_{td} \$/hour	h_B \$/feet/year	D_c coils/year	L_c Feet
100	0.85	0.35	3600	300	600	250	700	800

System Parameters Relevant to Tool Life

In the pipe manufacturing industries several cutting tools are used. Flash trimming tool is one of them which is used for removing extra weld metals from the welding zone. The manager plans to purchase an automated tool magazine for handling the flash trimming tools. In the market, several tool magazines are available with variable sizes. The tool magazine capacity ranging from n = 2 to 15 are considered here, among which the optimum size for the tool magazine has to be selected. The distribution of the life (T) of a flash trimming tool is given as $T \sim N$(6, 1.5^2) hours. Other relevant information about this tool magazine system are listed in Table 2 which includes the operating cost for an *n*-tool magazine (c_o), service rate of the tool (μ), tool storage cost at tool crib (h), scheduled tool replacement cost (c_s), unscheduled tool replacement cost (c_u), price of a tool (c_p) and the tool ordering cost (A_o).

Table 2. System parameters involved in the flash trimming tool magazine system.

c_o \$/tool/year	μ feet/hour	h \$/tool/year	c_s \$/magazine	c_u \$/magazine	c_p \$/tool	A_o \$/order
$10n$	500	30	10	900	20	60

System Parameters Relevant to Pipe Sizing and Rework Polity

At the end of the manufacturing line the pipes are cut into standard and/or substandard lengths. During production some welding defects occur randomly. The linear distance between two consecutive defects (L) follows exponential distribution with a mean rate of defects δ. Here, L can also be defined as the defect free length. All other relevant information about the on-line inspection facility and the pipe sizing system are listed in Table 3. In this table, L_s and L_b represents the desired length of a standard and substandard pipe, respectively. On the other hand, P_o and P' are denoted for the standard size and substandard size pipes, respectively.

The cost parameters in this problem are pipe cutting cost (c_t), fixed cost (C) and variable cost (c) of the pipe manufacturing line, online (c^{on}) and offline (c^{off}) repair costs for a defect, and the scrapping cost (c_s). Here, $L_b^{\max}$ is the maximum demand of substandard pipes, which limits the amount of total substandard pipes.

Table 3. Relevant numerical information about the pipe sizing and online inspection.

L_s feet	L_b feet	P_o \$/feet	P' \$/feet	c_t \$/cut	C \$/hour	c \$/feet	c^{on} \$/defect	c^{off} \$/defect	c_s \$/feet	$L_b^{\max}$ feet/hour	δ defects /hour

System Parameters Relevant to Inspection-Rework Facility Configuration

Now, after partitioning the pipes into standard and/or substandard lengths, some pipes are randomly selected for ultrasonic inspection. Any defective pipe that is repairable by grinding or polishing operation is sent to the rework station, and the unrepairable pipes are scrapped. The important parameters which influence the optimal decision on the number of inspection/rework servers are noted in Table 4. The parameters listed in this table are defined for the pipes holding costs h^r and h^{os} at the regular and overstock holding area; the required floor spaces a_p , a_1 and a_R for a pipe, an inspection server and a rework server; the variable costs c_1 and c_R for inspection and rework of a pipe; the fixed costs C_1 and C_R for maintaining an inspection and a rework servers; service rates μ_1 and μ_R at the inspection and rework servers, all respectively. The other parameters are available floor space A_T , pipe arrival rate at the inspection-rework facility λ' , and repairable and unrepairable defect proportion p_1' and p_1 , respectively.

Table 4. Important parameters involved in the inspection-rework facility.

Parametric description	h^r \$/pipe/hour	h^{os} \$/pipe/hour	a_p (feet²)	a_1 (feet²)	c_1 \$/pipe	C_1 \$/hour	μ_1 pipes/hour
	3.50	5.50	200	2000	100.00	120.00	2.55
A_T (feet²)	λ' pipes/hour	p_1'	p_1	a_R (feet²)	c_R \$/pipe	C_R \$/hour	μ_R pipes/hour
17,000	5	0.0820	0.050	4000	120	200	0.5

EXISTING CONFIGURATION OF THE SYSTEM

The existing state of the steel pipe manufacturing system is discussed here from the perspective of the four optimization problems. The system is currently equipped with a coil accumulator. The coil feeding system is designed considering the average coil joining time ($\bar{T}_J$). A minimum buffer capacity level, $B_{\min} = \lambda^2/\alpha + \bar{T}_J\lambda$ = 280 feet, is used in the system. On the other hand, the current system is equipped with single-tool magazine for all kind of cutting tools. Thus, for the flash trimming operation, a single-tool holder is used and the tool is replaced once it fails. For a single-tool magazine system the optimum tool reload timing is found as τ_1^* = 10.97 hours. Reloading a new tool takes T^R = 0.5 hours. In other words, if a tool fails or about to exceed 10.97 hours of active operation, it should be replaced, and the replacement process takes on an average 0.5 hours. In place of a single-tool holder for the flash trimming tool, a multiple-tool magazine is proposed to be used.

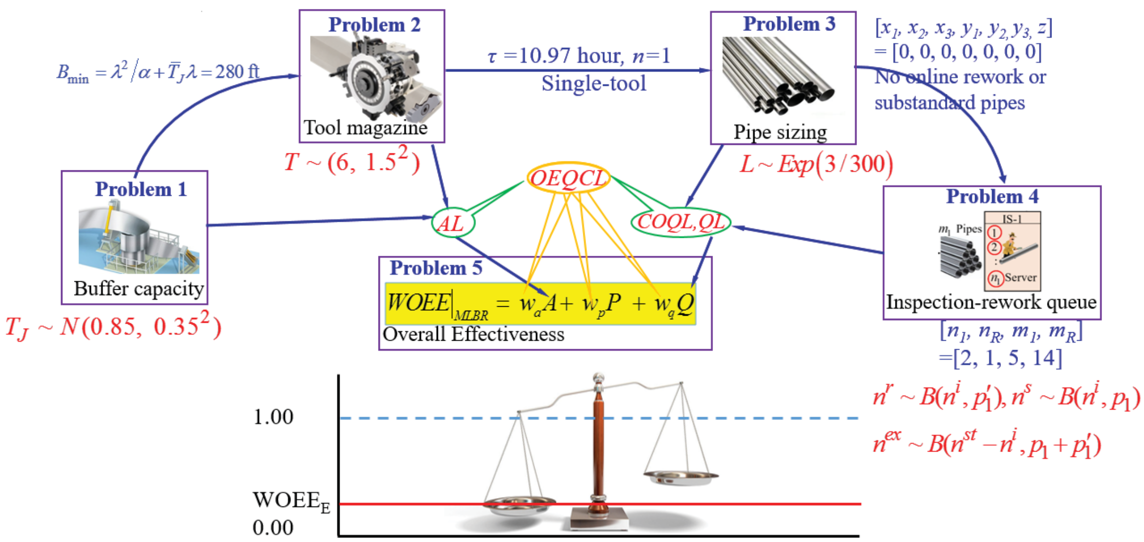

Figure 1. Simulation model for the existing system.

In the existing condition the pipe manufacturing line is not facilitated with an online inspection device. In addition to that, no online rework facility is available in the system. As a result, any defect can only be detected after the pipes are cut into standard pieces. In other words, no rework decision can be taken online, and no substandard size pipe can be cut directly from the continuous line. After cutting the pipes into standard lengths it goes to the inspection-rework facility and that facility is equipped with 2 ultrasonic testing machines (n_1 = 2) that detects hidden welding defects, and a rework station (n_R =1). Rework operations includes cutting off the defective portion of the pipe if the defect falls within 5 feet from any end of that pipe. Some surface defects are removed by grinding or polishing the pipe. Both of these rework operations are currently done in a single off-line rework station. The existing system configuration is graphically shown in Figure 1.

PROPOSED IMPROVED CONFIGURATION OF THE SYSTEM

The pipe manufacturing line is proposed to be improved with some local optimum solutions. The corresponding optimum solutions for (1) buffer storage, (2) flash trimming tool magazine size and reload timing, (3) pipe sizing and rework policy, and (4) the inspection-rework servers are calculated from the information provided in Tables 1 to 4.

The optimum buffer size is obtained from Eq. (1) as [Hossain, 2018]

$$B^* = \lambda\left[\frac{\lambda}{\alpha} + \bar{T}_J + \sigma_T F_{T_J}^{-1}\left(1 - \lambda\frac{c_B + h_B}{c_{td} D_c}\right)\right] = 350.82 \text{ feet.} \quad (1)$$

On the other hand, the optimum magazine size for the flash trimming tool, is found as n^* = 12, and the magazine reload timing is found as τ_{12}^* = 121.29 hours. These solutions are obtained with help of *Tool Heuristic* presented in by Hossain (2018). In the proposed configuration an online inspection facility is planned, which creates an opportunity to decide whether a defective portion should be scrapped or reworked, or a substandard pipe should be made from the defective portion. Making of substandard pipes depend on the sales price of the pipes. With the online inspection facility, only one type of defect (surface scars) is detectable. From the information provided in Table 3, the optimum policies for dealing the defects are found as (x_1, x_2, x_3, y_1, y_2, y_3, z) = (1, 0, 1, 1, 0, 1, 1). This solution indicates that, the defective spots should be reworked at the off-line rework station if the defect free length L falls in the range $L < L_b$ or $L \geq L_s$. However, the defect-free portion should be cut at substandard lengths if $L_b \leq L < L_s$.

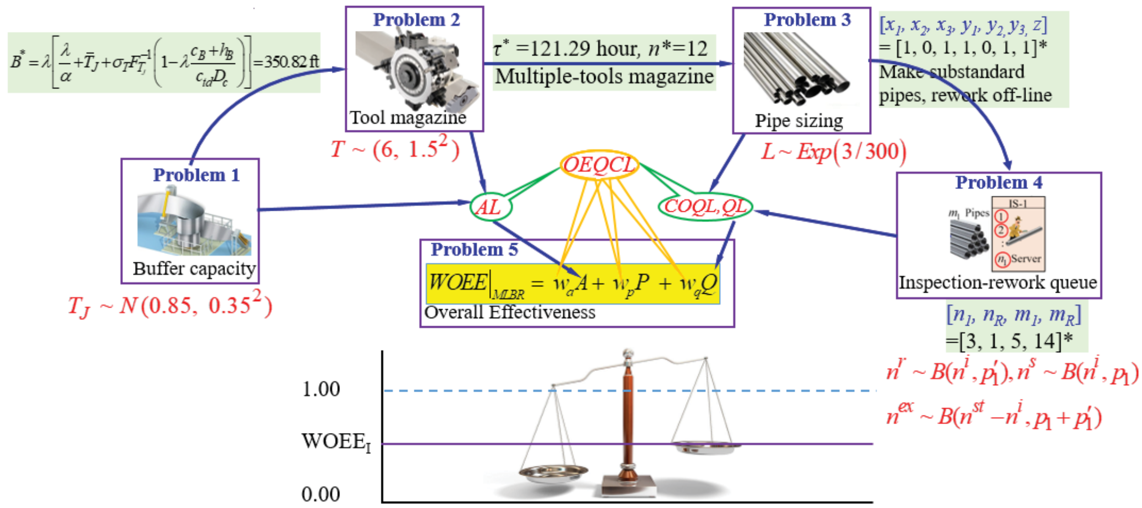

Figure 2. Simulation model for the improved system.

From the information listed in Table 4 the optimum number of servers can be found as n_1 = 3 and n_R =1 for the inspection and rework stations, respectively. These solutions are obtained using the IR-Algorithm presented by Hossain and Sarker (2018). From these algorithm, the optimum space allocations for the inspection and rework stations are found as m_1 = 5 and m_R = 14 pipes, respectively. The improved system configuration based on the local optimum solutions, is presented in Figure 2.

SIMULATION RESULTS

In the pipe manufacturing system several parameters are probabilistic, including coil joining time $T_J \sim N\,(0.85, 0.35^2)$ hours, tool life $T \sim N\,(6, 1.5^2)$ hours and defect free length $L \sim$ Exp (3/300). The arrival of discrete pipes at the inspection-rework facility is also probabilistic, follows approximately Poisson distribution with mean λ' = 5 pipes/hour. Again, the detection of defective pipes in the inspection-rework facility follows binomial distribution with probabilities p_1' and p_1 for the repairable and unrepairable defects, respectively. These uncertainties are captured by simulating the system for several days. The whole pipe manufacturing system is simulated over a month (effectively 22 working days). It is to be noted that the factory is kept running for $T_p = 8$ hours in a day (single shift).

Simulation of the Line with Current Configuration

The system is first simulated with the existing configuration. The coil joining time T_J , and tool life T are randomly generated for each day. All other columns in Appendix 1 are obtained from these two random variables. The coil joining times for the first day are obtained as 0.9776, 0.8679 and 0.7952 hours, respectively. With the buffer capacity $B_{\min}$ = 280 feet, a maximum joining time of $B_{\min}/\lambda - \lambda/\alpha$ = 0.85 hours can be supported. The buffer runout duration in a cycle (T_{br}) is defined as $T_{br} = \max\{0, (T_J - B_{\min}/\lambda + \lambda/\alpha)\}$. As, no joining time should exceed 0.85 hours, buffer runouts will occur for the first two coil joining in the first day. Hence T_{br} = 0.1276, 0.0179 and 0 hours for three coil joining, respectively. Now, the coil feed cycle time will be $T_c' = t_5 + T_J - T_{br} = L_c/\lambda - \bar{T}_J + T_J - T_{br}$ = 800/300 - 0.85 + $T_J - T_{br}$ = 1.8167 $+ T_J - T_{br}$ hours. Hence, the cycle time will be 2.6667, 2.6667 and 2.6119 hours, respectively [Day 1, Column 4 in Appendix 1]. Thus, the available time of production using these three coils is found as 2.6667+2.6667+ 2.6119 = 7.9452 hours, for Day 1.

On the other hand, the first flash trimming tool can run for 5.5423 hours; hence, the second tool needs to be loaded. The life of the second tool is found as 6.0015 hours. These two tool loadings require T^R + T^R = 0.5 + 0.5 = 1 hour, where T^R is the time required for a tool reloading. Thus, the actual production time for Day 1, is found as $T_a = T_p - \sum T_{br} - 2T^R$ = 6.8545 hours, where the potential production time is T_p = 8 hours. From this result, the remaining tool life in Day 1 ($T_{r,1}$) can be found as $T_{r,i}$ = 5.5423 + 6.0015 - 6.8545 = 4.6893 hours [see Day 1, Column 7, in Appendix 1]. Similarly, the remaining coils in the line can be used for $T_{cr,i} = \sum T_c' - T_a$ = 2.6667+ 2.6667+ 2.6119 - 6.8545 = 1.0907 hours in the next day (Day 2). Now, the availability rate (A) for Day 1 can be found as $\mathrm{A} = T_a/T_p$ = 6.86/8 = 0.8568.

Again, if the production line does not produce anything, the industry still has to bear an overhead cost of $600 per hour. Hence, the monetary value for the availability loss becomes AL^c = \$($T_p - T_a$)600 = $687.29 for Day 1. Similarly, the actual production is found as $P_a = T_a\lambda$ = 2056.36 feet. The system is designed with a theoretical capacity of production, λ_{th} = 325 feet/hour. In a real environment this designed capacity is not achieved. So, in general, the theoretical production in Day 1 should be $P_t = T_a\lambda_{th}$ = 2227.72 feet. Hence, the performance rate of the line can be found as $\mathrm{P} = P_a/P_t$ =2056.36/2227.72 = 0.9231.

Now, it is estimated that if the theoretical production rate λ_{th} could be achieved, the manufacturer could make additional profit of $30 from the additional production. So, the monetary value of the availability loss should be $PL^c = \$30(P_t - P_a)$ =$5,140.89. All values in Appendix 1 are evaluated in a similar way.

Appendix 2 is presented to calculate the scrapped pipe lengths, due to the defects that can be detected with the online inspection device. The random defects are simulated and the distance between two consecutive defects (L) are listed in Appendix 2. In the existing situation the defects detected online, are marked on the pipe. Then the pipes are cut into standard lengths ($L_s = 40$ feet). Some defective pipes can be shortened not less than 35 feet by cutting off the defective portion from one end. However, when the defect on the pipe does not fall within 5 feet from any end, the whole pipe is scrapped. This scenario is replicated for all of the defect free lengths in Appendix 2 and the summation of the lengths of all scrapped pipes are noted in that table. The cost of quality loss (QL_1^c) at this stage includes the sales price of the pipe $(P_p = \$180$ /feet) which is scrapped and the scrapping cost of the pipe ($c_s = \$10$ /feet). The cost for the online inspection is considered with a flat rate of $1/feet.

The quality loss and the cost of quality are listed in Appendix 3. The number of pipes produced (n^{st}) in each day are obtained from the simulation of defect free length (L). The number of inspected pipes (n^i) depends on the random arrival process of pipes at the inspection-rework facility. This arrival process follows approximate Poisson distribution with mean λ' = 40 pipes/day, from where n^i is simulated. The number of reworked pipes (n^r), the number of scrapped pipes (n^s) and the number of external failures (n^{ex}) are also simulated, from their corresponding binomial distribution parameters, n^r ~B(n^i , p_1'), n^s ~B(n^i , p_1), n^{ex} ~B(n^{st} - n^i , $p_1 + p_1'$). The external failure cost includes customer dissatisfaction, loss of business goodwill and warranty, which is approximately estimated as $10,000/pipe. From these simulated and estimated information, the monetary equivalent of *QL* (QL_2^c) at the inspection-rework server, is evaluated.

Finally the total quality loss ($QL^c = QL_1^c + QL_2^c$) in monetary unit, is found as the sum of quality losses from the defects detected at the on-line inspection (QL_1^c) and the quality losses in the inspection-rework facility. The cost of quality (COQ) is different from the quality losses. This cost includes all inspection costs (on-line and off-line) as well as external failure costs.

Simulation of the Line with Improved Configuration

The steel pipe manufacturing system is simulated with the optimum solutions and proposed improved conditions. The optimum solution suggests that the buffer capacity should B^* = 350.82 feet, and there should be multiple-tool magazine facility with magazine size n^* = 12 tools and magazine reload timing τ^* = 121.29 hours. For the improved configuration the substandard pipes should be made when $9 \le L < 40$ feet. On the other hand, if the $L < 9$ feet and $L > 40$ feet, the repairable defects, detected with the on-line inspection device, should be marked on the pipes and then repaired at the off-line rework station. The improvement for the system also includes n_1 = 3.

Now, with these locally optimized parameters listed above the simulation model is modified and the system is simulated again. The similar tables are generated for this improved configuration, and corresponding A , P , Q , AL^c , PL^c , QL^c , COQL are evaluated. The values of availability rate A , performance P , the monetary equivalents of availability loss AL^c , and performance loss PL^c are listed in Appendix 4. On the other hand, Appendix 6 summarizes the quality rate Q , the monetary equivalent of quality loss QL^c and the cost of quality loss (COQL). Appendix 5 is presented here to list the random numbers for the defect free length *L* (feet). These results are finally used to evaluate the WOEE, and PEE values.

Comparing Overall Effectiveness of the Existing and Improved Systems

The overall effectiveness of the system, with both existing and improved conditions, is evaluated for 22 days in terms of WOEE and PEE. For this WOEE and PEE calculations, the monetary loss based regression (MLBR) method is used to obtain the weights. Detailed calculations are reported in Table 5. In this table, the overall equipment and quality cost losses (OEQCL) are calculated by summing up all cost losses, as OEQCL= AL^c + PL^c + QL^c +COQL.

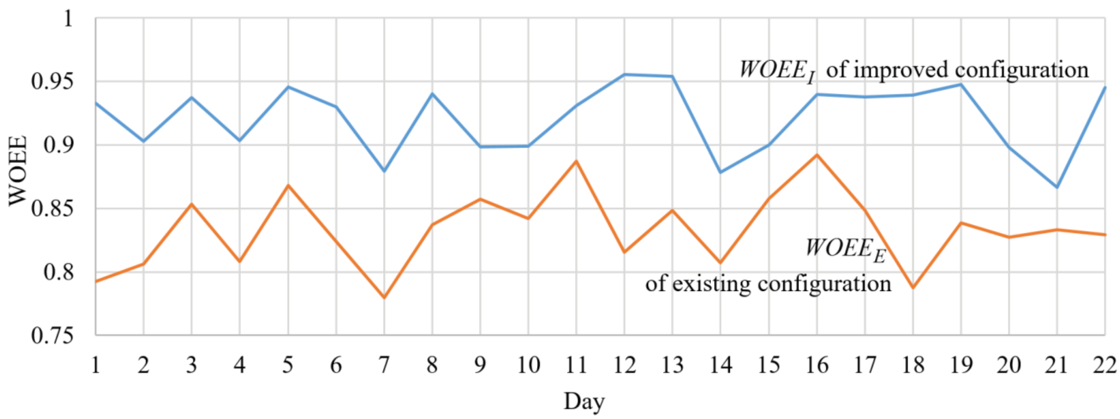

Figure 3. WOEE values of the system with existing and improved configuration.

From the WOEE as well as PEE values it is observed that, the overall effectiveness of the system improves almost 10% when the suggested optimum solutions are incorporated in the system. Figure 3 presents a graphical presentation of WOEE of the system for 22 days. It shows that the WOEE is better for each of the 22 days, when the system is configured with the optimum solution. A paired comparison is done to check the difference with statistical evidence [see Table 5]. Calculating the mean and standard deviation of the differences gives, $E|WOEE_I\text{-}WOEE_E|$= 0.0873 ≈ 8.73% and $SD_{WOEE_I - WOEE_E}$ = 0.0341 ≈ 3.41%.

The *t*-statistic for the difference in WOEE become *t* = 11.9952. On 21 degree of freedom the *p*-value is found as *p*-value = 5.84×10^{-08}. Therefore, there is a strong evidence that, on average, the proposed solution does lead to significant improvements in the overall system. Similarly, in the last column of Table 5, the differences between PEE values for existing and improved system, are listed. The mean and standard deviation of the differences in PEE are found as, $E|PEE_I\text{-} PEE_E|$= 0.0890 and $SD_{PEE_I - PEE_E}$ = 0.0352. The *t*-statistic for the difference in PEE become *t* = 11. 8475 with *p*-value = 6.63×10^{-08}. Hence, the same conclusion can be drawn when the comparison is made in terms of PEE.

Table 5. OEE and PEE of the line in existing and improved configuration.

CONCLUSION

This paper numerically shows the overall improvement of the system when proposed local-optimum solutions are implemented. An impression of a pipe manufacturing system is simulated for 22 working days, for the existing and the proposed optimum conditions. It is statistically proven that the overall effectiveness of the system improves with the optimum solution. On an average, the WOEE and PEE improve more than 10%. The proposed local optimum solutions can lead to the improvement in availability rate (A) and quality rate (Q) only. The first and second optimization problems were concerned about buffer capacity and cutting tool magazine, jointly improve the availability rate by reducing the productive time losses. While, the third and fourth problems were dealing with pipe sizing and inspection-rework facility, collectively improve the quality rate by optimally suggesting some rework processes. Another element of OEE is performance (P), which is an internal technical issue of the machine, and hence, it can be improved by technical modification of the machine. Besides these important observations, this simulation result presents a clear insight of the system and explains the implementation phase in a virtual environment.

ABSTRACT

In order to build relationships, personalize products, and enhance customer loyalty, it is important for organizations to utilize data to generate meaningful, fact-based insights. This study focuses on identifying the organization's marketing analytics orientation and the adopted analytical tools used to generate insights. Using the statistical techniques of text-mining and cluster analysis, the marketing analytics orientations of the organization were uncovered. Also, the relationships among organizational characteristics, marketing analytics orientation, and adopted analytical tools were assessed. The results provide insights into organizations utilizing marketing analytics capability and analytical tools.

KEYWORDS: Marketing Analytics Orientation, Analytical Tools, Organizational Characteristics, Text-Mining, Cluster Analysis

INTRODUCTION

The top reason cited for organizations implementing marketing analytics processes was to improve customer relationships. This was followed by two additional reasons: gaining the ability to translate real-time insights into marketing and competitive advantage (Ertemel, 2015) and gaining the ability to process and evaluate the ever increasing, massive amounts of unfiltered and unstructured data (Ghasemaghaei et al, 2018). Further, since organizations gain competitive advantage through improved problem-solving and decision-making performance, advantage goes to organizations that can effectively using the wide-ranging talents of analysts performing varied insight generation tasks (Ghasemaghaei et al, 2018). So, exploiting the vast quantity of available structured and unstructured data simultaneously is both a monumental challenge and a tremendous opportunity as organizations strive to achieve action-oriented, data-driven, decision-making (Doumpos & Zopounidis, 2016).

When organizations operate in a rapidly changing and highly competitive market, studies have reported the positive impact based upon the various insights generated from marketing analytics (Popovič et al, 2012). Yet, which particular marketing analytics orientations are utilized by organizations to produce the insights are not well understood and continues to be an ongoing area of investigation. Further, limited information exists in the literature regarding what and how organizations utilize analytics (Doumpos & Zopounidis, 2016; Kakatkar & Spann, 2019). Therefore, the focus of this research is to provide an awareness of how organizations use analytics and which specific marketing analytics orientations are demanded by organizations. This research contributes to the literature as it seeks to identify which decision areas organizations require marketing analytics for by exploring various marketing analytics orientations. This study also evaluates the various analytical tools managers are provided to perform their insight generation activities. Further, this study intends to investigate whether the marketing analytic orientations utilized by organizations vary by industry classification. The results of this study can provide insights into the determinants and nature of marketing analytics orientations adopted as well as providing insights on the types of selected marketing analytical tools.

LITERATURE REVIEW

Marketing Analytics Orientation

The use of marketing analytics by the organization is of vital importance as marketing analytics are increasingly being used to create knowledge and generate meaningful insights thus leading to more informed, fact-based decisions (Doumpos & Zopounidis, 2016). The marketing analytical tools used by the organization are viewed as well-designed data stores containing volumes of high-quality information connected with user-friendly software tools that can provide managers timely access and intuitive presentation of sought-after information enabling the managers to develop marketing strategic actions or provide the managers with insights to better grasp marketing problems or make better marketing decisions (Popovič et al, 2012).

When defining marketing analytics, it is important to recognize the integration of the concepts of business intelligence and big data along with a strong focus on data collection, model creation, and data analysis all fostered within an evidenced-based organizational culture (Davenport & Kim, 2013). As such, an organization’s marketing analytics orientation can be viewed as a decision area focus utilizing marketing analytics with the practice of first collecting, then measuring, managing, and finally analyzing market performance with the goal to obtain useful insights and maximizing the effectiveness of a particular marketing objective (Cao et al, 2019). The concept of big data adds massive volumes of structured and unstructured data from numerous sources which can then be used to support multiple types of strategic marketing decisions over specified time-frames. Organizations also need to ensure that marketing analytics using these data for fact-based decision-making and problem-solving should be actionable (Davenport & Kim, 2013; Vidgen et al, 2017). To become actionable, the generated insights need to be connected to all aspects of the processes used to enhance problem-solving and marketing decision-making in the organization (Baesens et al, 2016).

Conceptual Framework

This study investigates marketing analytics orientations that organizations may adopt. While organizations can utilize any permutation of these orientations separately or in combination, it is expected that the organization will primarily focus on one orientation when completing marketing analytics tasks. It is also thought that the chosen marketing analytics orientation is influenced by organizational characteristics such as industry classification type. In addition, it has been suggested that the primary marketing analytics orientation utilized by the organization will have an impact on the specific marketing analytics tools utilized.

<u>Marketing Analytics Orientation</u>

An organization can select from a variety of marketing analytic orientations. Several common action-oriented marketing orientations include campaign analytics, digital presence, and product research as well as general marketing and model creation analytics. The general premise for selecting a marketing orientation is that the use of marketing analytics by the organization should lead to improved marketing decision-making and organizational competitiveness, hence, the use of marketing analytics should provide the organization with valuable insights. Thus, an organization's use of marketing analytics can be expected to permit it to achieve sustained competitive advantage from its sensing, seizing, and reconfiguring capabilities as it creates its knowledge base to better sense threats and opportunities in the marketplace (Cho et al, 2019).

Monitoring the competitors' products and gauging the marketplace's reaction to them is an important marketing analytic task. Managers can monitor the competitors' sites, relevant blogs, potential suppliers, and distribution channels to gather product and user information (Vreeman, 2014). This information provides the organization with insight into product features, pricing strategies, and customer feedback thus focusing the organization on discovering competitive advantage (Cho et al, 2019). These insights can also be useful in determining new product strategies (Comm & Mathaisel, 2018) and information for developing product launches. Other important marketing analytic tasks include developing marketing campaigns and sales promotions with key tasks involving determining which campaigns are the most convincing and which analytic measures should be used for the marketing campaigns (Liu & Burns, 2018).

General modeling and insight generation is viewed as a marketing task when data mining is a central part of analyst's knowledge discovery and seeks patterns and knowledge from large amounts of data. The goal of this marketing task is to enhance customer relationships with more accurate response models. While using the explanatory response model is something most marketing managers are accustomed to, additional care should be taken when using predictive analytic models as they are different from explanatory modeling in many aspects.

The organization also seeks to optimize their digital presence to improve their rankings with search engines as it has been shown that positive optimization increases both search rankings and visitor satisfaction. Therefore, understanding the various elements contributing to search engine rankings and optimizing those elements can help the organization promote its products and improve its brand visibility, hopefully leading to an increase of sales and profits (Liu & Burns, 2018; Rosenkrans & Myers, 2018). This study suggests that organizations have specific marketing analytics orientations as the managers generate marketing insights, solves problems, and focuses on decision making. The particular marketing analytics orientation employed, focuses the organization on various marketing analytics tasks in terms of what is to be accomplished by the specific marketing program.

Organizational Characteristics

It has been argued that an organization's size, number of skilled personnel, and organizational culture contribute to the successful adoption and usage of marketing analytics (Trieu, 2017). Further, Gupta & George (2016) highlight that an organization needs to possess a unique blend of cultural, financial, and human resources to create a marketing analytic capability so that their competitors will find it difficult to replicate. To accomplish creating this capability, however, requires that an organization either needs to improve the managers' analytic skills via training or search for individuals who can fulfill the organization's marketing analytics demands. Ideally, marketing managers with improved competencies will provide improved insight generation capabilities for the organization (Ayyagari et al, 2011; Davenport & Patel, 2012). To accomplish this goal of creating a marketing analytics capability for the organization requires that the organization has a clear understanding of both the marketing analytics objectives and the connection between the expected outcome and the skills required to achieve it (Ghasemaghaei et al, 2018). In various studies, an increase in investments related to the budget for education and training have been reported by successful organizations (Trieu, 2017).

Yet, not everyone embraces this data-driven culture. Certain industries are characterized as more data-driven and have adopted advanced marketing analytics tools and approaches. For example, although many healthcare organizations have adopted marketing analytics to support their processes, few of these organizations had significant experience using marketing analytics (Wang et al, 2018). Thus, various industries have adopted different levels of fact-based decision-making and problem-solving which ultimately leads to the use of diverse marketing analytics orientations. Yet, for many organizations, the marketing analytics use is still in its initial stages (Lismont et al, 2017).

Marketing Analytics Tools

Organizations acquire or develop appropriate marketing analytics tool capabilities considering their specific marketing analytics orientation. Ghasemaghaei et al. (2018) argue that there is a strong connection between the marketing analytic tool sophistication and the quality of insights capable of being achieved by the organization. This suggests that these analytical tools can help the organization improve its performance. Wang and Byrd (2017) report that the effective use of marketing analytics tools indirectly influences problem-solving and decision-making efficiency and effectiveness. Thus, it is important that the tools have the right capabilities that can facilitate the marketing insight generation.

Marketing analytics capabilities encompass a portfolio of various analysis methods, tools, and data transformations. Three specific types of analytic capabilities employed by organizations include descriptive, predictive, and prescriptive methods (Bayrak, 2015). Additional analytic capability examples include content analytics, speech analytics, text analytics, dashboards, and visualizations. The decision capabilities of analytic tools include applications to help analysts learn, share, and understand data. Decision capabilities examples include scenario modeling and simulation thus allowing the analysts to communicate the results that could optimally balance required trade-offs. The information capabilities focus on the technology infrastructure that ensures proper interfaces with other parts of the organization permitting the exchange of data, documents and other content. The level of capabilities achieved by organizations must support the goals established for the marketing analytics orientation. Organizations may also combine these tool capabilities by establishing proactive use in which insight generation is based on rationality as it is believed that managers will adopt and use the organization's analytics tools to a greater extent if the right analytics culture is in place (Popovič et al, 2012).

METHODS

Data Collection

Marketing analytics orientation descriptions were created through the extraction of analytics job postings. During 2017, 286 marketing analytics job postings were collected by using various online job search sites. The job postings showing a high relevance or containing marketing analytics job titles were then selected. The organization's name from the job postings were used to identify industry type. The identified organizations were classified into one of the four industry classification types (consumer products, industrial products, financial and health services, and retail) by finding their SIC code as well as exploring their primary markets served.

Text Mining Process

A four-step text mining process (Inzalkar & Sharma, 2015) was used in this study. The first step in this process was to collect marketing analytics descriptions from the job postings. Over a two-month period, marketing analytics job postings that were highly relevant for marketing analytics work were collected. The second step in the process was to prepare the collected text using text refining and pre-processing. Text refining and pre-processing was accomplished by clearing the unnecessary formatting as well as implementing tokenization and stemming for text reduction. The third step in the process was to perform text-mining analysis using the refined and pre-processed texts. The text mining analysis generated document-based intermediate output that contains the relevant term concepts related to the marketing analytics components. The final step was to perform clustering analysis. The clustering analysis provided the marketing analytics orientation clusters to be used for insight generation.

RESULTS

Cluster Analysis Results

The k-means clustering procedure was chosen to perform this analysis. Five unique clusters from the clustering procedure were generated. 19 relevant word concept terms were used in generating the five clusters. These word concept terms are related to five marketing analytics orientations. To characterize the resulting clusters, the cluster centroids were examined thus allowing interpretation of what each cluster grouping represented.

The product research analytics orientation cluster with 44 organizations became cluster 1. The word concept terms showing the highest values for this cluster were product and research. This cluster shows large centroid values greater than .500 for word concepts which are relevant for product development research analytics. The second cluster contained 142 organizations and represented a general marketing analytics orientation. The word concept term list showing the highest values greater than .240 for this cluster were the following three term concepts: market, data, and insight respectively. This cluster does not have the highest centroid values indicating no specific analytics focus and this cluster was characterized by relatively small centroid values for most of the word concept terms. The third cluster contained 37 organizations and is referred to as the campaign and sales analytics orientation cluster. The word concept term list showing the highest values greater than .500 include test, campaign, report, insight, and lead respectively. These concepts are primarily related to promotional campaigns as well as sales lead analytics. The fourth cluster represents data modeling analytics orientation and contains 39 organizations. The word concept term list showing the highest values greater than .500 include the following terms: model, data, and insight. These concepts are related to developing insightful models and generating forecasts using data. The fifth cluster contains 24 organizations and was referred to as the search engine and web analytics orientation cluster. The word concept term list showing the highest values greater than .500 include SEO, SEM, campaign, web, and traffic respectively. These concepts were primarily related to online and web search related analytics. These results highlight that approximately half of organizations are classified into the general marketing analytics orientation cluster whereas the other half are classified into clusters related to the four specific analytics orientation clusters.

Cross-tabulation Results

This study evaluates the relationship between the marketing analytics orientations and organizational characteristics as well as between marketing analytics orientations and marketing analytic tools. Chi-square statistics for cross-tabulations were used to test these relationships. The chi-square test also indicates a significant relationship between marketing analytics orientations and industry type (chi-square = 21.54, $p < .05$).

Insights can be ascertained by first examining each cluster to determine the key industry, then examining each industry to understand the desired marketing analytic orientation pattern. Thus, examining each cluster, the results show that for the first cluster, industrial product and retail organizations belong to this group and utilize product-related analytic orientations. Examining the second cluster highlights that approximately 55% of organizations in all four industry types are in this group suggesting the universal utilization of general marketing analytics orientation. More service organization belong to the third cluster which highlights the utilization of promotional campaign and sales lead analytics orientation. Consumer product and retail organizations tend to dominate the fourth cluster as those organizations utilize data and forecasting model analytic orientation. The fifth cluster primarily includes industrial product organizations as they utilize search and web related analytic orientation.

All organization utilize general marketing analytic orientation. In addition, consumer product organizations primarily focus on data modeling analytic orientation indicating required insight generation through data modeling. Industrial product organizations focus on product research analytics as well as search engine and web analytics as they focus on product research and competitive intelligence and then on ensuring they have a digital presence to get found on the internet. Service industry organizations are focused on campaign and sales analytic orientations to gain insights utilizing A/B testing and lead generation in a relationship-oriented industry, whereas retail organizations primarily focus on product analytic and modeling/forecasting orientations to capture consumer trends and manage inventories. The chi-square test for the relationship between marketing analytics orientations and marketing analytics tools used by organizations indicates a significant relationship between marketing analytics orientations and the marketing analytics tools used (chi-square = 247.01, $p < .01$). The selected organizations reported a total of 21 different analytics tools in their job postings. The results show that organizations are using a diverse set of marketing analytics tools. These tools include generic business analytics tools such as Python and SQL as well as more commonly used marketing analysis software such a SAS or SPSS.

DISCUSSION AND CONCLUSIONS

This study developed and tested a conceptual model capturing the relationships among marketing analytics orientations, organizational characteristics, and marketing analytics tool adoption. Text mining analysis of analytics job postings together with cluster analysis results provide interesting insights into the nature of marketing analytics orientations and tools being adopted by organizations. Evaluating job postings provides a leading indicator view of where organizations desire to be on their marketing analytics adoption and usage journey. These are the marketing analytics orientations that organizations view as important to possess to meet their strategic goals. Each word concept term the organizations uses in their job postings belongs to a specific cluster. The cluster analysis results identified five marketing analytics orientations that organizations are utilizing for their insight generation. These results provide important theoretical implication.

This study empirically identifies five marketing analytics orientations. Text mining analysis was performed to identify the relevant concepts used by organizations to describe marketing analytics orientations required for marketing analytics professionals. Text mining output was further analyzed using clustering analysis to identify marketing analytics orientations of the organizations. The cluster analysis results show that the largest cluster containing about half of the organizations focused on the general marketing analytics orientation. The next largest clusters, in order, were the product research analytics, data modeling analytics, and campaign and sales analytics orientation clusters with 15.4%, 13.6%, and 12.9%. The smallest cluster with 8.4% of organizations was the search engine and web analytics orientation cluster. These results suggest that organizations are utilizing various marketing analytics orientations for marketing decision-making. This is important because as Wedel and Kannan (2016) discuss, “one-size-fits-all analytic solutions are neither desirable or likely to be effective”. For organizations, the movement toward marketing analytics is impacting organizational processes, rebalancing the power of relationships in decision-making, and altering the scope and scale of optimization challenges (Baesens et al, 2016). Drawing out decision-ready inferences from marketing analytics influences and enhances the organization’s marketing decision-making (Baesens et al, 2016).

This study also evaluates antecedents and consequence of an organization’s marketing analytics orientations. The antecedent industry classification type is evaluated to assess whether they are related to marketing analytics orientations. The results show that marketing analytics orientations are related to the industry classification type. There exist significant differences in utilizing various marketing analytics orientations by the type of industry the organization resides. As certain industries utilize different marketing analytics orientations, organizations need to develop unique marketing analytics competencies to remain competitive in the market. The results show a significant relationship between marketing analytics orientations and marketing analytics tools used by organizations. Interestingly, the results show that there are no dominant marketing analytics tools used by organizations. These findings are consistent to the reported statistics suggesting that the marketing analytics tool market is highly fragmented (Columbus, 2016). Turck (2016) highlights that the analytic tool landscape focused on various areas such as artificial intelligence, log analytics, machine learning, mobile analytics, social analytics, statistical computing, visualization, and web analytics. Yet, as Wheatley (2016) reports, the software market that drives these marketing analytics tools is expected to surge by a 23% compounded annual growth rate by 2026 with analytics tools brought about by the emergence of cloud-native business analytic startup firms.

The findings from this study provide important managerial implication regarding marketing analytics training and education. The results can be used in developing the appropriate approach in marketing analytics training and education as multidisciplinary skill set are required for effective marketing analysts (Wedel & Kannan, 2016). As no specific marketing analytics tools are dominantly used by organizations, tool independent training may be needed for marketing analytics competence. This means that marketing analytics training should focus on the basic mechanisms and processes of marketing analytics rather than tool specific marketing analytics knowledge (Turel & Kapoor, 2016). The cluster analysis results suggest that various marketing analytics orientations are utilized by organizations in different industries. These findings shed light on the nature and content of marketing analytics knowledge and training required. While this study provides valuable insights, the results are based on the marketing analytics job posts of 286 organizations. The findings may not be generalizable given the limited nature of this sample. Future research should further validate the findings of this study and extend the study by evaluating marketing analytics orientations utilized for specific marketing problem-solving and marketing decision-making tasks.

ABSTRACT

Innovation rejection is one of the biggest issues of marketing research and active innovation resistance has been identified as one of the main driver behind conscious innovation rejection. The current research that is focused on understanding active innovation resistance, has produced significant findings. A typology of functional and psychological barriers has been developed to comprehensively explain active innovation resistance. However, no effort has been made to apply these findings to the real world. Simulation is a great tool that can be used to apply theory to real world scenarios. A simulation model that uses the aforementioned typology to explain innovation rejection remains unexplored. We propose a model that uses agent-based simulation to predict the rejection of innovation by a group of consumers. This model provides insights into the reasoning behind these rejections and how they relate to the proposed typology. The model uses statistical data about the typology to predict the active innovation resistance values of its population of agents. The model also uses agent networks to inform the values of the barriers that depend on the social groups of the consumer. The proposed model can be beneficial to companies aiming to reduce the uncertainty associated with launching innovation. This study opens the gate to further study into active innovation resistance working in tandem with simulation.

KEYWORDS: Agent-based Simulation, Active innovation resistance, Simulation modeling, Structural equation modeling, marketing research

INTRODUCTION

For companies with an established consumer base, introducing an innovation can be a risky and uncertain process. This innovation can be a new product or a new service but the reaction of consumers remains largely unpredictable (Castellion & Markham, 2013). For companies that want to remain to be on the cutting edge and retain their competitiveness, this uncertainty is troublesome (Hansen, McDonald, & Mitchell, 2013). A failed innovation can cause a company to hurt their brand's image and lose the trust of investors (Liao, Chou, & Lin, 2015). Product failure rates are on the rise, and big companies are becoming more and more reluctant to innovate (Castellion & Markham, 2013). Therefore, reducing innovation failure rate is one of the biggest challenges of marketing research (Henard & Szymanski, 2001; Joachim, Spieth, & Heidenreich, 2018). This study will attempt to tackle the aforementioned problem of innovation failure. Our objective is to reduce the unpredictability of consumer behavior and provide insights into the potential causes behind consumer rejection.

Using the literature, we can conclude that the majority of innovation failures are caused by consumer rejection (Kleijnen, Lee, & Wetzels, 2009; Laukkanen, Sinkkonen, & Laukkanen, 2009). Consumer rejection occurs after the consumer has evaluated the proposed innovation. Talke and Heidenreich (2014) talk about how rejection is a direct result of conscious decision-making by the consumer. According to their research, this conscious decision is a vital step in the evaluation phase of the adoption process of the consumer, they call it active innovation resistance (AIR). AIR is the dependent variable that we will be studying in this research. The independent variables will be the typology of barriers, introduced by Talke and Heidenreich (2014), that directly affect AIR.

The purpose of this study is to propose an agent-based simulation (ABS) model that can determine the probability of rejection of an innovation by predicting the active innovation resistance of a group of consumers. It will also highlight the reasons behind the rejection and provide valuable insights into innovation rejection. ABS is a paradigm of simulation that focuses on the dynamic behavior of agents in an environment. The individual decision-making model of agents determines the behavior of the overarching system (Gilbert, 2008). The focus on micro-behavior makes ABS a great tool for marketing research (Meyer, Lorscheid, & Troitzsch, 2009). This is because these micro-behaviors can be used to simulate observed market phenomena. Marketing research has made significant strides by using simulation to better understand the adoption process of the consumer (Meyer et al., 2009; Schubring, Lorscheid, Meyer, & Ringle, 2016). However, the same cannot be said for consumer rejection and there is still a lot of room for improvement (Talke & Heidenreich, 2014).

The hyper-competitive world of business makes innovation a necessity for companies to in order to be competitive. Even big companies face uncertainty in terms of innovation success, and with failure rates standing at 40%, the risk factor seems to be uncomfortably high (Castellion & Markham, 2013). A simulation model that can map consumer behavior could be a very useful tool in marketing research (Meyer et al., 2009). It can help companies reduce the level of uncertainty, associated with innovation, and quantify their performance expectations for said innovation. To accomplish the aforementioned objectives of this study, a set of research questions have been proposed. These research questions are listed in Table 1.

Simulation modeling is a great tool for marketing research. A simulation is only as good as the data that is used to build it. The data used in this study will be taken from a previously published research study done by Joachim, Spieth, and Heidenreich (2018). The data sample is a cross-sectional data sample and represents a population of 1000 individuals. Additionally, the model assumes that consumer behavior is limited to the prescribed variables. This is a big assumption because in the real world there are many other factors that affect consumer behavior. However, this assumption is necessary because one of the goals of this study is to determine which of the independent variables has the most significant effect on AIR. This study chooses to limit agent behavior in this way because of the findings of Joachim et al. (2018). They provide evidence for the comprehensiveness of the AIR barrier typology that we will use in this model. Based on this evidence, we believe that the limitation of agent behavior is valid. To conclude, the limitations of the proposed model are as follows. The model is a meager representation of the real world due to the limited behavior of its agents. The model is not too generalizable because of the limited nature of the data available. The model does not take other factors that affect innovation resistance into account. However, the proposed model will still offer insight into innovation rejection and is a worthwhile effort.

The structure of the paper is as follows. First, we elaborate on the concept of ABS and its application in the field of marketing research. Second, through the use of literature, we discuss the context of consumer behavior that is relevant to this study. Additionally, we operationalize our definition of active innovation rejection and define the relationship between our dependent and independent variables. Third, we describe the methodology and the tools that will be used to make the ABS model. Finally, we discuss the outcomes and benefits of the proposed model.

Table 1
The proposed research questions.

- **Research question 1.** What is the likelihood that the proposed innovation will fail?
- **Research question 2.** What portion of the consumer base will reject the innovation?
- **Research question 3.** What are the reasons behind the rejection of the proposed innovation?

LITERATURE REVIEW

Agent-based simulation

Agent-based simulation modeling uses simulation experiments to investigate the dynamic behavior of real world situations. This dynamism has led to its firm establishment in social sciences, as a useful simulation paradigm in the field (Meyer et al., 2009). The rudimentary idea behind ABS modeling is to specify micro behavior of agents and use them to model a developing phenomenon, such as the behavior of a consumer market base or social group (Gilbert, 2008). ABS is a great tool for studying Innovation diffusion and other marketing phenomena (Garcia & Jager, 2011). This paper intends to use ABS to simulate consumer rejection to the innovation. In this scenario consumer networks hold particular relevance to the study; they are ideal for simulating social groups of consumers. ABS is the perfect tool to explore the interactions and behavior of consumers at a micro-level (Gilbert, 2008). Despite the availability of data and theory, the failure of innovations is still largely unpredictable (Hansen et al., 2013; Hui, Goldberg, Magdon-Ismail, & Wallace, 2010; Repenning, 2002). ABS can provide verifiable insights that can help assess the causes and effects of rejection. Therefore, this study will use data and theory to create an ABS model that explores the reasoning behind consumer behavior, with respect to innovation.

Consumer Behavior in the context of innovation

The study of consumer behavior, with regards to innovation, has evaluated many causes and effects. These range from acceptance to rejection, delay, and even opposition (Davidson & Walley, 1985; Eric A. Greenleaf & Donald R. Lehmann, 1995; Nabih, Bloem, & Poiesz, 1997; Rogers, 2003). These are behavioral outcomes that classify a consumer’s response to innovation. Therefore, it can be said that the success or failure of a new product or service depends on the consumer’s perception of it (Heidenrich & Spieth, 2013). During the evaluation phase of the adoption process (Talke & Heidenreich, 2014) the consumer forms attitudes towards the innovation. A positive attitude can lead to innovation acceptance, whereas a negative attitude can lead to innovation resistance (Nabih et al., 1997). Thus, the consumer’s mindset in the decision stage of the adoption process (Kuisma, Laukkanen, & Hiltunen, 2007) is a direct consequence of these attitudes (Rogers, 2003). These negative attitudes lead to active innovation resistance by the consumer (Talke & Heidenreich, 2014).

The barriers of active innovation resistance

The term “active innovation resistance” refers to the conscious decision of rejecting the innovation, that the consumer makes, after evaluating a new product or innovation (Kleijnen et al., 2009). Ram and Sheth (1989) first proposed a framework of five barriers and discussed its relationship with innovation resistance. Later, Talke and Heidenreich (2014) provided a much more comprehensive framework of seventeen barriers that contribute to active innovation resistance. The framework of barriers introduced by Talke and Heidenreich (2014) is a thorough and complete typology of barriers that directly affect active innovation resistance (Joachim et al., 2018). There are eight psychological barriers, that “arise as soon as the innovation conflicts with a consumer's social norms, values, or individual usage patterns, or if its usage is perceived as being too risky” (Talke & Heidenreich, 2014, p. 899). Research by Joachim, Spieth, & Heidenreich (2018) provides an excellent collection of definitions for the aforementioned typology. The following is an elaboration of the definitions compiled by Joachim et al. (2018). The psychological barriers are a conceptual take on the consumer’s reaction to the innovation and how it relates to their social environment. The *personal risk barrier* is a psychological response to the perception, that the innovation could cause personal harm to the consumer of their property. Similarly, the *usage barriers* arise if the consumer perceives that the innovation will cause a disruption in their regularly established usage patterns and routines. Both of these barriers arise from the natural fear of change or the unknown that humans feel. The *social risk barrier* arises from a fear of rejection, from the consumer’s social group, as a result of adoption to the innovation. Similarly, the *norm barrier* results from the perception that the innovation conflicts with social norms or established traditions within the consumer’s social environment. If the innovation is associated with a brand or country that is perceived negatively by the consumer and their social group, this culminates in the rise of the *image barrier*. These three barriers are strongly dependent on the reaction of the consumer’s social group to the adoption of the innovation (Kleijnen et al., 2009). If adoption of the innovation means hurting their social standing, the consumer will be more likely to reject the innovation. The *economic risk barrier* stems from the fear that the innovation is not worth the financial investment that it demands. Finally, rejection can also be attributed to the fear of the innovation being dysfunctional. This is known as the *functional risk barrier*. All of these psychological barriers affect the customer’s decision to adopt an innovation or to reject it (Ram & Sheth, 1989). Additionally, there are nine functional barriers, that come into play “as soon as a consumer perceives any product attribute as dysfunctional or inadequate for their individual requirements and usage expectations (Talke & Heidenreich, 2014, p. 899). Functional barriers are all about how the consumer perceives the traits of the innovation. The *value barrier* depends on how the consumer compares the value of the innovation to its competitors and its precursor. If an innovation is complex and difficult to understand it will face the *complexity barrier*. Furthermore, if the consumer feels that the innovation doesn’t work well with the other products that they use this will result in the *compatibility barrier*. Additionally, if the consumer finds that the innovation is incomplete or needs to be supplemented, to realize its full benefits, then this will lead to the *Co-dependence barrier*. If it takes too long for the innovation to provide the consumer with noticeable benefits, then it makes it more likely that the consumer will reject it, this is the essence of the *realization barrier*. If the innovation is difficult to observe it will face the *visibility barrier*, and if the consumer finds it hard to share the benefits of the innovation with others, it will face the *communicability barrier.* If the consumer perceives that they have missed the chance, or have not gotten the chance, to try the innovation before adopting it, this will result in the *trialability barrier.* Finally, if the innovation cannot be modified to fit the requirements of the consumer than the *amenability barrier* applies, consumers want to use products and services that fit their needs well (Kleijnen et al., 2009).

How the barriers relate to active innovation resistance

According to the findings of the empirical study done by Joachim et al. (2018), all seventeen barriers have shown positive effects on AIR. Hence, we can definitively say that they have a positive association with the AIR. Furthermore, Joachim et al. (2018) also found that some barriers are more significant to AIR than others. The norm barrier, the value barrier, and the communicability barrier rank the highest, with respect to importance, among all seventeen barriers. Additionally, even the barrier with the least negative effect, such as the co-dependence barrier, show substantial influence on AIR. The results published by Joachim et al. (2018) can be seen in Table 2. To address the aforementioned problems this study proposes a simulation model that will use the AIR barrier proposed by Talke and Heidenreich (2014) to predict the AIR of its agents in response to an innovation.

Table 2. Structural model results of functional and psychological barriers

Barrier Type	Barrier Name	Path C ($\beta_{Prod.}$)
Psychological Barriers	Norm barriers	−0.676
	Economic risk barriers	−0.456
	Image barriers	−0.439
	Social risk barriers	−0.374
	Functional risk barriers	−0.348
	Personal risk barriers	−0.271
	Usage barriers	−0.225
	Information barriers	−0.186
Functional Barriers	Value barriers	−0.601
	Communicability barriers	−0.475
	Trialability barriers	−0.470
	Amenability barriers	−0.450
	Compatibility barriers	−0.349
	Complexity barriers	−0.283
	Visibility barriers	−0.276
	Realization barriers	−0.229
	Co-dependence barriers	−0.142

Note. Adapted from “Active innovation resistance: An empirical study on functional and psychological barriers to innovation adoption in different contexts”, by Joachim, V., Spieth, P., & Heidenreich, S., 2018, *Industrial Marketing Management, 71*, p. 104

SIMULATION FRAMEWORK

In this study, we plan on using the work of Joachim et al. (2018) as the basis of our simulation model. They provided empirical evidence for each barrier in the typology and its relational significance to AIR. The results published by Joachim et al. (2018) is produced by applying partial least squares structural equation modeling (PLS-SEM) to data they gathered through surveys. PLS-SEM is a statistical tool that can be used to model the relationship between variables. The results produced by Joachim et al. (2018) will provide a solid and practical basis for the simulation model. The use of this data will provide validity to the model. Validity is one of the most important aspects of simulation modeling. If a model is not validated by literature and real data, it is essentially useless. By using the published work of Joachim et al. (2018) as a basis for the simulation model, we have affirmed its validity. The innovations that were used by Joachim et al. (2018), for their survey of innovation rejection, were as follows: “the dual tablet Toshiba Libretto, the 3-D camera Fujifilm Finepix 3D and the holographic laser projector Blueoptics Light Touch" (Joachim et al., 2018, p. 103). However, we believe that using a fixed set of innovations would limit the generalizability and usefulness of the model. Therefore, instead of testing these innovations on the model, we will conduct simulation experiments by testing a combination of the attributes of innovations. Each test will have a combination of high, medium, and low values for innovation attributes, by doing this we can test the effect of these attributes on the AIR of the consumer. Functional barriers will be influenced by the functional attributes of the innovation. The most important aspect of the proposed model will be the behavior of the consumer (agent). The data provides us with a strong base for our model, but we also need a robust structure. The core logic of the agent behavior will act as our model's skeletal structure. "The PLS path model is the modeling anchor for the specification of agent behavior" (Schubring et al., 2016, p. 4607). Schubring et al. (2016) provide formulae for using the PLS-SEM path model to dictate agent behavior, they are as follows.

$$Active\ Innovation\ Resistance = \frac{\sum_{i=1}^{n} attribute\ score_i \times effect_i}{\sum_{i=1}^{n} \max(attribute\ score_i) \times effect_i} \quad (1)$$

The agent's actions are determined by the value of "*Probability (action)*". *Probability (action)* describes the activity of an agent. For example, based on the value of "*Probability (action)*" the agent will decide to either buy or not buy. In our study, this can be used to evaluate AIR, our dependent variable. Therefore, we will be able to use the PLS-SEM data published by Joachim et al. (2018) to define agent reasoning.

We provide an example to convey a better understanding of the aforementioned formulae and how we can measure our data. Each agent in the model will have a perception of the proposed innovation. We know, from the work of Talke and Heidenreich (2014), that this perception can be boiled down to seventeen barriers, when considering AIR. These barriers will act as our independent variables. Each of them will have an "*attribute value*" which will vary for each agent and be determined by the perception of the said agent in the simulation. The attribute value can range from 1 to 10. A high "*attribute value*" will mean that the agent perceives that barrier to be highly influential and vice versa. "*total effect*" will be the individual significance of each attribute, with respect to AIR. This will be determined from the data presented in Table 2. For AIR, let's take the example of *value barrier* and *norm barrier*, their attribute values can be 8 and 2 respectively. From table 2 we can see that their total effect is 0.601 for the value barrier and 0.676 for the norm barrier. We ignore the negative sign because we are calculating rejection rather than adoption. We also want to define that we are considering rejection by the consumer to be a result of the initial contact with the product. We are not considering any future contact that the customer will have with the product in question and how that might affect their decision. The latent variable score for value barrier and norm barrier will be 6.16, this value requires normalization, as a standard, we use the maximum value ($max\left(latent\ variable\ score_j\right)$). The maximum value in this example is 12.77 and thus, the value for AIR will be 48% (6.16/12.77). An AIR value of less than 50% will mean that the consumer will not reject the innovation.

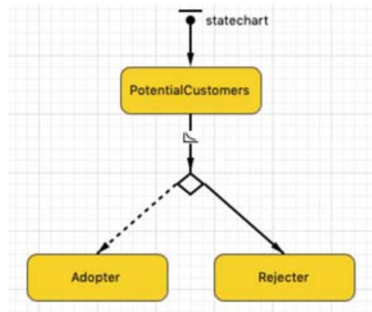

Figure 1. Decision model of agents

The decision model of an agent will have three distinct states. Based on the AIR value of each agent, the agents will move from the *PotentialCustomer* state to either the *Adopter* state or the *Rejecter* state. This decision model is represented in Figure 1. The number of agents that reject the innovation is the evaluation measure for the proposed innovation. In addition to the decision model, there is also a network that connects agents and dictates their interaction with each other. Like many ABS models we use a stylized random network (Trusov, Rand, & Joshi, 2013). This network will be used to simulate the social network of consumers. Some AIR barriers depend on the behavior of the consumer's social group, using the aforementioned networks we can simulate these social groups and get values for these barriers. These psychological barriers will be influenced by the properties of the agent and the abovementioned social network. We have provided sequence diagrams that provide a better understanding of the interaction and behavior of agents. Figure 2. shows the decision logic of the consumer in the model and the sequence of events that result in innovation rejection or adoption. We can see that the consumer makes a conscious decision to either reject or adopt the innovation after they have gained information about the functional traits of the innovation and evaluated it.

In figure 2, we can also see the sequence of events that lead to a *PotentialConsumer* rejecting the innovation due to advice from rejecters in their social group. If a rejecter feels that an innovation is too expensive, they will relay this message to people in their social group. Based on the established contact rate this message will result in other *PotentialConsumers* rejecting the innovation as well. We can see in figure 2, a rejecter will think that the innovation is too expensive if the perceived value of that innovation is less than 2 out of a possible 10.

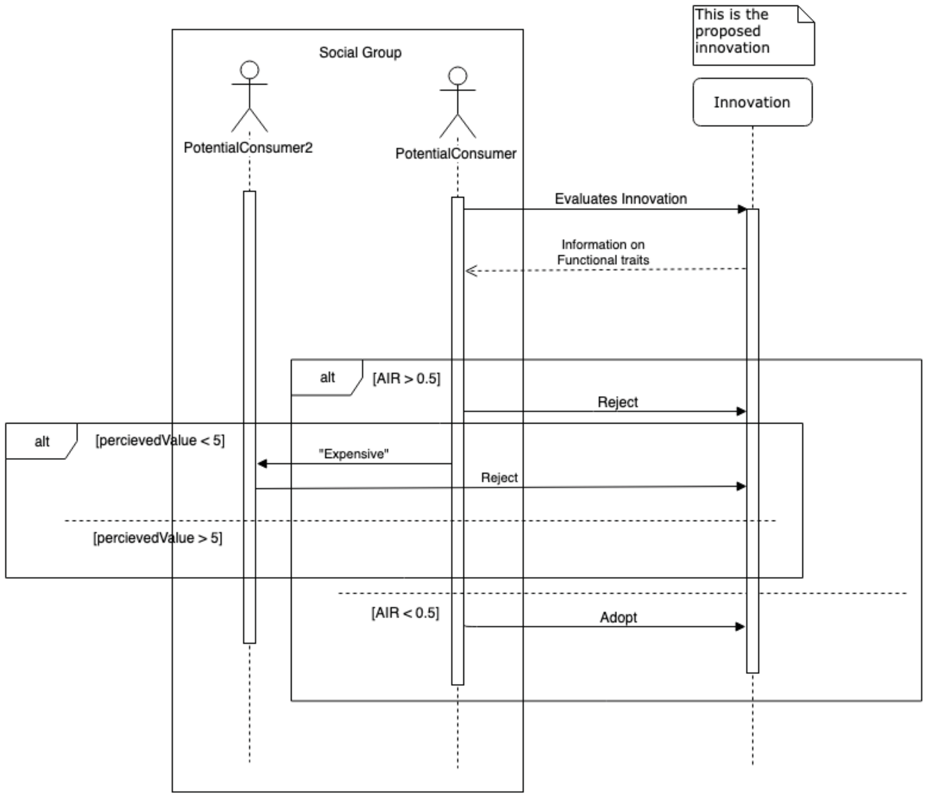

Figure 2. A sequence model that the decision and interaction model of agents (showing the sequence of actions that leads to rejection by agents and the interaction between agents)

Additionally, to provide a graphical visualization of the population of agents a rectangular space is used. Inside this rectangular space, we have our population of agents, rejecters are represented by red and adopters are represented by green. Furthermore, the lines between the agents represent the network they are connected with. We can see this visualization in Figure 3.

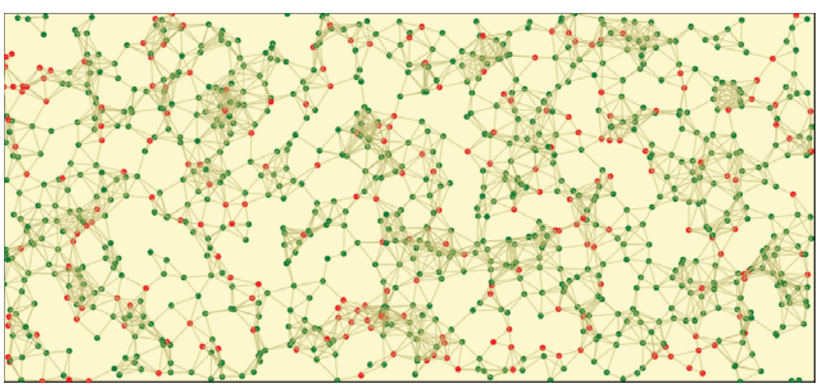

Figure 3. Visual representation of the population of agents and their network

We have decided to use Anylogic 8 to build the proposed model. Anylogic 8 is an industry standard tool for simulation modeling. It provides the depth and computation support necessary for this project. Anylogic 8 also provides integrated analysis tools to track the behavior of the simulated consumer base. Each agent will have behavior in accordance with the reasoning described in the previous section. Anylogic 8 will keep track of the most significant barriers that resulted in rejection. This will give us an insight on what aspect of the innovation causes influences the decision of the consumer. These insights can be used to improve future innovations and help mitigate the risk associated with launching innovations.

SIMULATION EXPERIMENTS AND RESULTS

The simulation experiments explore the consumer reaction towards multiple proposed innovations. The experiments will focus on the relationship between the innovation characteristics and the corresponding AIR of the consumer population. The results will help us better understand the model. The independent variable will be the functional traits of the innovation, derived from the functional barriers in the typology proposed by Talke and Heidenreich (2014). The notion is that an innovation can be represented by these attributes that affect the perception of the barriers in the mind of the consumer and it is this perception that leads to adoption or rejection. This experiment will vary the attributes of the innovation to high, medium and low values. Each innovation attribute can have a value ranging between 1 to 10, where a value of 10 has the maximum effect on AIR. We will use the values 2, 5, and 8 as the test values. This range of values is a conceptual definition. Varying these values will allow us to represent a number of different prospective innovations in the context of the model.

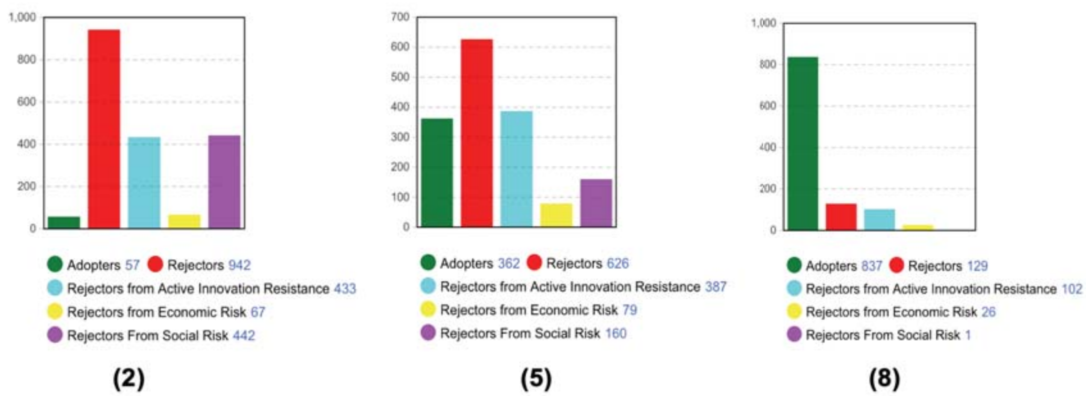

Figure 4. The bar charts show the comparison in the number of rejecters and adopters, in the agent population, for the innovation traits 2,5, and 8

In figure 4 we can see the change in the number of adopters and rejecters as we vary our independent variables. It can be concluded that, an innovation with higher values for its functional traits will result in lower values for the perceived barriers that are derived from those traits. Furthermore, these perceived barriers will result in less active innovation resistance and the proposed innovation will be largely adopted. Additionally, we can also see that our independent variables, not only affect rejection from active innovation resistance, but also have an effect on the number of rejecters from other sources. We believe that this effect is due to the initially higher number of rejecters from active innovation resistance caused by low functional traits. It seems that the initial rejecters spread their influence throughout the population. This seems to have a sort of domino effect on the entire population of agents. Which is apparent in the small number of adopter in the left most graph in figure 4. Figure 5. reaffirms these findings;

we can see that the rate of diffusion of rejecters increases as we increase our independent variables.

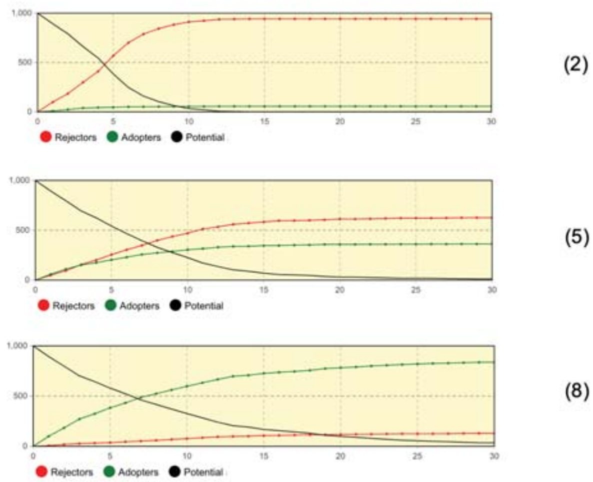

Figure 5. The diffusion of innovation with respect to time
(The x-axis shows the progression of days the model simulates and the y-axis shows the number of consumers, either adopted (green), rejected(red) or are potential consumers (black))

These results show how the change in the attribute of the innovation effects the behavior of the consumer base. Hence, by using the barriers of resistance we have defined attributes for an innovation that can directly affect the rejection it faces by consumers.

Figure 6. The attributes of innovation that are derived from the typology of active innovation resistance barriers

DISCUSSION AND CONCLUSIONS

This paper uses the predictive qualities of the data provided by Joachim et al. (2018) to construct a simulation model. This model has helped us reduce the unpredictability of innovation by providing a set of attributes that directly affect consumer behavior. We used simulation experiments to study the change in consumer behavior with respect to the change in the attributes of the innovation. We can conclude that the nine functional attributes in Figure 6 provide a good measure of success for prospective innovations that hope to succeed in the market. By using an agent network to represent a social group, this model can also successfully simulate the effect that a social group can have on a consumer’s rejection to an innovation.

Joachim et al. (2018) proposes a two-step procedure for companies to address the relevant barriers of innovation rejection. First, they propose a study that asses the influence of these barriers on intention to adopt of the targeted consumers. The model that has been proposed in this study can assist in this step of the procedure. By providing relevant insights on the significance of each barrier, this model can form the basis of the first step in the proposed two-step procedure. The second step in the procedure is to conduct a further study to reduce the identified barriers. The model that we have proposed can also be used to assess the effectiveness of the second step. By revealing the number of rejecters an innovation has the model can provide a base line for further improvements to the innovation to be measured against. Any effort made to reduce the identified barriers will have a quantifiable effect on the rejection of the innovation, this effect can be measured by using the model proposed in this study.

The study has successfully answered the research questions that were posed. Firstly, by providing a fair estimate of the rate of rejection, the model has successfully accomplished one of its goals. Secondly, the model also records the portion of the rejecters and adopters in response to a certain innovation. This is a vital statistic for managers that want to evaluate the performance of innovations with regards to their rejection ratio. Out of a target population of 1000 consumers the number of rejecters is a good indicator of the prospect of innovation rejection. Thirdly, the model records the reason for rejection of each consumer. It is not enough to know that a consumer has rejected the innovation, we must also be able to determine the reasons of rejection. Therefore, by providing the reasons of rejection to managers, we give them aspects of the innovation that they can improve upon to effectively reduce innovation resistance. By answering the posed research questions, the study has successfully produced a simulation model that managers and companies can use to effectively manage innovation resistance; thus, the study has managed to accomplish its research goals.

Further research can be done to improve the model. We recommend that any future research be aimed at introducing different types of consumers to the model. This will help grow the generalizability of the model and help it better represent a target market. Another possible extension would be to introduce multi-group analyses of SEM results so that the model can compare and contrast the results between groups of consumers and how the barriers vary with each group. Finally, improvements can be made to better represent innovations in the model. Currently, an innovation is only represented by nine functional attributes, this is an area which can improve the model. Utilizing more aspects of the innovation in the model will help the model better represent the innovation in the simulation.

ABSTRACT

In order to examine the decisions rationally and intuitively processed, this paper reports the results of a research developed with 115 professionals working in managerial positions in Brazil. The data analysis used the structural equation modeling. The results revealed the extent to which the antecedent variables along with the decision process generate performance impacts.

KEYWORDS: Decision-making approaches, Situational antecedent, Personal antecedents, Information processing, Decision-making performance

INTRODUCTION

The rapid technological change that society has been experiencing in the last decades, known as the BigData era (Barbosa, Vicente, Ladeira, & Oliveira, 2017; Ghasemaghaei, Ebrahimi, & Hassanein, 2018; H. Wang, Xu, Fujita, & Liu, 2016), creates a problem of information processing, culminating in the increase of the load to be processed by the decision maker (Ensley, Pearce, & Hmieleski, 2006; McCormack & Trkman, 2014; Tushman, 1979). Weiss and Heide (1993) have shown that individuals respond to this increased information processing burden by intensifying cognitive effort in data search and analysis.

Besides the emerging context of high data and information production, world economies face greater dynamism and complexity (Luo, 2003), as well as environmental uncertainty (Duncan, 1972). In this scenario, decision-makers also tend to perceive more uncertainty at different levels and directions, thus requiring the use of decision strategies that are effective in dynamic and complex environments, affected by a multiplicity of organizational, situational, and personal variables (Carter, Kaufmann, & Wagner, 2017; Riedl, Kaufmann, Zimmermann, & Perols, 2013).

Given the large amount of data and information present in organizations and the advancement of technologies that support managerial activities, it is increasingly expected that today's managers make decisions based on rationality and analytical models (Appelbaum, Kogan, Vasarhelyi, & Yan, 2017; Vidgen, Shaw, & Grant, 2017).

It is believed that the use of formal logic results in the best available solution (Neumann, John Von Morgenstern, 1944). In fact, rational decision-making theory presupposes that the decision-maker possesses - and invariably uses - a logical strategy to produce valid inferences, on which an appropriate response option is made.

It is important to consider that a full set of tool-technology, as well as all information concerning a scenario or a problem situation, will not always be available to the decision maker. Some information available may be accurate, however, others may be incomplete or even confusing. In addition, the decision can be developed in contexts of multiple actors with organizational and environmental constraints that bring consequences that are often difficult to evaluate (Sincorá, Poubel, Souza, & Oliveira, 2018; Sincorá, Oliveira, Zanquetto-Filho, & Ladeira, 2018).

By considering such elements, which form a complex backdrop for the development of decision-making, it is difficult to articulate decision-making purely based on rationality and analytical models (Sayegh, Anthony, & Perrewe, 2004; Simon, 1987), as advocated by traditional Decison Making theorists. Thus, it is important to look at other elements that guide the decision-making process, besides the rational, for a more subjective and intuitive perspective. The relevance is to understand how they influence, complement and participate in managerial decision-making, and its results, which can bring relevant contributions to the advancement of both traditional and emerging approaches to Decision Making.

In addition to the discussion inherent to rational and intuitive decision-making processes, based on the literature review, it has been observed that it still embryonic the empirical research showing the effects and values generated by analytical capabilities to decisions (whether strategic, tactical or operational) and how these combined concepts are applied in practice (Bon & Broersen, 2017; Sharma, Mithas, & Kankanhalli, 2014; Shuradze & Wagner, 2016; Sincorá, Oliveira, Zanquetto-Filho, & Ladeira, 2018).

It was found that despite the existence of literature on time pressure in an experimental perspective (Gazdag, Haude, Hoegl, & Muethel, 2018; Lohse, Simon, & Konrad, 2018; Skerlavaj, Connelly, Cerne, & Dysvik, 2018; Szollos, 2009), the investigation of time pressure over decision-making in a quantitative survey-type approach is still relatively unexplored. The need for scales to measure this phenomenon is important to advance the understanding of how the decision-making process is configured and generates results in terms of performance in the presence of situational variables, specially those strongly present in our post-industrial society.

Another aspect is that there are few management studies bringing empirical evidences of the extent to which the individual's professional experience level may influence their decision-making process when intuitively configured (Dane & Pratt, 2007; Fisher, Chengalur-Smith, &

Ballou, 2003; Phillips, Fletcher, Marks, & Hine, 2016). However, there is also the question of how decision makers process information under uncertainty, which has received increasing interest in management literature, especially in behavioral operations. In addition, few studies investigate the information processing and decision-making strategies (rational and intuitive) that are used to minimize uncertainty in decisions (Kaufmann, Michel, & Carter, 2009).

Therefore, this article aims to fill these gaps through a quantitative approach, by analyzing what extent the manager's rational and intuitive load influence his decision results. Therefore, it proposes to answer the respective research problems: *To which extent do different situational and personal variables impact the use of rational and intuitive approaches to decision-making? And how do rational and intuitive approaches impact decision-making?*

DEVELOPMENT OF HYPOTHESES AND RESEARCH MODEL

The theoretical relationships that provide the basis for the proposition of the theoretical hypotheses of the research will be presented below. In addition, a brief conceptual argument is presented for the Total Decision-Making Cost (TDMC) construct, considered as a proxy of performance, representing an effort of this research to offer an alternative to understand the decision-making results.

Situational Antecedent

Tabatabaei (2002) highlights the important antecedent role of time pressure in the selection of decision strategies. Due to its relevance as a determinant of decision-making behavior (Szollos, 2009), time pressure is examined here as a situational antecedent of the decision-making process.

It is observed that, in certain contexts, the decision-making process may undergo the influence of the situational variable time pressure (Gazdag et al., 2018; Lohse et al., 2018; Skerlavaj et al., 2018). When the decision maker needs to articulate decisions under time pressure, which means being pressured to quickly make decisions, this situational characteristic can make rational/analytical decision strategies less attractive or even unfeasible (Ordonez & Benson III, 1997), influencing the selection of other decision methods. In particular, decision makers facing time pressure tend to rely more on intuitive decision strategies and less on analytical decision strategies (Vanharanta & Easton, 2010). Following this line of thinking Riedl et al. (2013) argue that the time pressure also restricts the search for appropriate alternatives and induces the individual to adopt more intuitive decision-making. Consequently, the time pressure is shown to be negatively related to the rational decision-making process. It is assumed that it will probably prevent the decision maker from collecting, processing and properly applying information in the delineation of its decision-making, indirectly and negatively impacting the results in terms of the total decision-making cost.

Still considering the emerging scenario marked by the high production and dissemination of data and information, and by the technological revolution, authors such as Dholakia et al. (1993) already pointed out at the end of the last century that time pressure in high technology environments - as experienced in today's society - would certainly lead people to adopt inadequate mechanisms of information collection and non-systematic and insufficient evaluation of alternatives. Following this line of thought, it is conjectured that time pressure not only restricts the search for appropriate alternatives and leads to intuitive decision strategies but increases the probability of the individual to generate choices based on biases and misperceptions (Kahneman, 2011). When the deadlines are tight, people are encouraged to speed up their deliberations since 'there isn’t much time', leading to a lower performance. In addition, when time becomes restricted and conservative, the decision-maker tends to "cut" his thinking, leading to a "cognitive closure" situation (Wright, 1974).

Therefore, it is worth considering that under high time pressure both individuals, the one that decides more rationally and other that decides more intuitively, will drastically reduce the amount of information processing, culminating in poor performance in both behavioral scenarios. According to this, the first two research proposals are raised:

H1a. Time pressure negatively impacts rational decision-making process performance;

H1b. Time pressure negatively impacts the intuitive decision-making process performance.

Personal Antecedents

In addition to situational antecedents, decisions are also influenced by personal variables (Ackerman & Thompson, 2017, Carter et al., 2017, Frederick, 2005, Jackson, Kleitman, Stankov, & Howie, 2017, Kirchler et al., 2017, Moritz , Hill, & L.Donohue, 2013, Narayanan & Moritz, 2015, Toplak, West, & Stanovich, 2014. Weinhardt, Hendijani, Harman, Steel, & Gonzalez, 2015). Previous research has argued that professional experience and analytical capabilities are important factors that affect decision-making behavior (Dane & Pratt, 2007; Sincorá, Oliveira, Zanquetto-Filho, & Ladeira, 2018). In this sense, it is pertinent to examine these factors as antecedents of both rational decision-making process and intuitive decision-making process.

It is recognized that professional or work experience interferes the decision strategy employed by the individual (Tsiros & Heilman, 2005). Beach and Mitchell (1978) have shown that past experience can help the decision maker regain specific decision strategies that have been successfully used previously and discard unsuccessful ones. In addition, Browne et al. (2007) argued that the level of experience determines whether a person uses a more rational or more intuitive decision-making approach. Therefore, studies suggest that experience is an important factor in trying to understand which decision strategy individuals’ use.

As far as the relationship between experience and rational decision-making is concerned, previous literature has shown that more experienced decision-makers consider more sources of information (Perkins & Rao, 1990), are more sensitive to information relevance, and process data in more complete form (Sanbonmatsu, Kardes, & Herr, 1992). This suggests that more experienced decision makers are more likely to use more sophisticated decision-making approaches, such as procedural rationality and decomposition (Riedl et al., 2013) - basic constituents of rational decision-making.

In this way, it is assumed that the decision-maker, by having significant professional experience, can complement his rational decision-making process by using intuitive judgments based on the recognition of situations-problems that have already been experienced and need to be resolved. Thus, the third hypothesis of the research is formulated:

H2a. Professional experience has a positive impact on rational decision-making process.

Consequently, it can be seen that the intuitive capacity and the expert judgment of the decision maker can be refined by the experience acquired by her over time in the exercise of his professional activity. According to Simon (1987), the intuition of the individual is formed by the storage of a large amount of knowledge in memory, which in turn, is obtained from formal trainings and experiences lived by the managers throughout their professional trajectory. Shanteau (1992), for example, when conducting a study analyzing the performance of intuition in different professions, found out, among other factors, that the amount of experience of the studied professionals was determinant for one group to perform well in relation to another that demonstrated low intuitive ability.

Therefore, the level of professional experience may act as an antecedent element, allowing decisions based on intuition to achieve less negative results, that is, minimizing possible negative influences coming from the decision-making strategy itself, allowing the use of a more intuitive and accurate ability to the detriment of biased impressions (Kahneman & Klein, 2009). Through the logical sequence, the fourth hypothesis of the research is presented:

H2b. Professional experience has a positive impact on the intuitive decision-making process.

In addition to professional experience, the analyst's level of analytical capabilities also impacts decision-making strategies. According to Sincorá et al. (2018), analytical capabilities can be subdivided into statistical capabilities, business capabilities, and information technology capabilities - perspectives related to human cognition - that are necessary for an individual to be able to take the advantage of analytics to support decision-making, thus enhancing the information processing.

The literature argues that analytical capabilities increase (i) the robustness of decision-making processes, since they are based on fact and data (Davenport & Harris, 2007; Sharma et al., 2014); (Bon & Broersen, 2017; Davenport & Harris, 2010; Y. Wang & Byrd, 2017), (ii) the amount of attention and effort that individuals invest in their decisions and (iii) the use of cognitively more demanding decision strategies (Delen & Demirkan, 2013, Gorman & Klimberg, 2014, Kahneman, 2011). However, empirical research that investigates the role of analytical capabilities in decision-making processes is still underdeveloped. Recent studies suggest that such capabilities can change strategies and entire decision-making philosophies, leading not only to increased cognitive effort and reflection, but also to the use of more analytical methods and tools in decision-making (Vale, Sincorá, & Milhomem, 2018).

Nonetheless, the use of analytical capabilities to transform data and information into decision-relevant knowledge makes decision-making tasks more robust and less uncertain. In addition, it facilitates the distinction between relevant and irrelevant information as well as the identification of attributes against which the available alternatives can be discriminated. Likewise, it is supposed that decision makers with an ability to understand the needs of the business, interpret analyzes carried out in large databases, and provide meaning to them in order to make decisions regarding problems and opportunities that emerge in the organization (Acito & Khatri, 2014, Delen & Demirkan, 2013, Wilder & Ozgur, 2015), can be more easily involved in more complex and structured decision-making such as procedural rationality (Riedl et al., 2013). Moreover, the ability to discriminate relevant data from irrelevant data is a key influencing factor in rational decision-making. Therefore, it is understood the appropriateness for the construction of the respective theoretical hypothesis:

H3a. Analytical capabilities positively impact rational decision-making process.

Consistently within this logic, but analyzing through the lens of intuitive decision-making processes, it is assumed that analytical capabilities also exert a positive influence on intuitive approaches. Such capabilities corroborate to make the decision maker more analytically oriented, allowing her to more easily identify the misperceptions generated by her cognition in information processing.

This supposition is justified by the assumptions of the Dual Process Theory (Evans, 2003; Kahneman, 2011) in recognizing that the individual, in facing a decision-making task, will activate 'System 1' (referring to the set of cognitive processes that are automatic, effortless, associative and fast) and will automatically generate intuitive proposals on how to solve the problem. 'System 2' (inherent in cognitive processes that are controlled, hard-working, deductive and slow) can be triggered to analyze intuitive proposals and decide whether to reject, approve or modify them. Final judgments are generally highly anchored in the initial impressions generated by System 1, which may in turn be 'contaminated' by heuristics and biases, culminating in unsatisfactory performance results.

Based on discussions about analytical capabilities, it is suspected that they are closely related to 'System 2', popularly known as 'reflexive reasoning' (Holyoak & Morrison, 2005; Kahneman, 2011). Such a relationship leads to the assumption that the more developed these capabilities are in the individual, the more analytically oriented their decisions will be. Thus, by accrediting it in intuitive decision-making, 'blocking' with more frequency and accuracy inconsistent impressions and judgments, commonly produced by 'System 1', thus increasing the probabilities of correctness and the overall quality of the decision. In this way, it is postulated:

H3b. Analytical capabilities positively impact the intuitive decision-making process.

Total Decision-Making Cost (TDMC): a performance proxy

The decision when analogously compared to a 'transaction' (Williamson, 1981) is subject to incurring costs before and after its occurrence. The way the decision-making process is constructed reflects on the results that are obtained. In this way, it is possible to measure the performance of the decision by mapping the costs incurred before and after the decision. These costs refer to tangible and intangible attributes that the decision maker can add to the decision-making scope.

Every decision has an inherent risk of something unexpected to happen (Knight, 1964), above all, it depends on the rationality limits of the decision maker (Simon, 1955), on the situational variables that influence the configuration of the decision process - , Goodie, Hall, & Wu, 2012) - as well as personal variables - such as professional experience and capabilities of the decision maker (Dane & Pratt, 2007; Sinanca, Oliveira, Zanquetto-Filho, & Ladeira, 2018), and of course, the probabilities of gain and loss with the choice of an alternative (Kahneman & Tversky, 1979). These factors, in turn, shape different behaviors in decision makers, who are likely to assume or minimize the harmful effects of risk and decision uncertainty, depending on the impact that such choices tend to produce on performance outcomes (Kahneman & Tversky, 1979).

Thus, individuals incur different types of "costs" to obtain positive decision outcomes, especially those related to information processing (Galbraith, 1974; McCormack & Trkman, 2014), since the knowledge acquired by the information processed contributes to reduce the uncertainty of decision making, increase the robustness of the probabilities and correct answers, identify needs for changes in resource allocation, timelines and criteria to be prioritized in decision making, thus favoring the results.

The theoretical concept of the decision making total cost is defined as the total cost of a decision considering the sum of the resources consumed prior to decision making (denominated costs ex-ante) and resources consumed after the decision (denominated costs ex-post). The main idea is that the more resources are spent before the decision, by reflecting, processing and reconsidering alternatives, the greater the chance of the decision being successful and contributing to the needs of individuals and companies. Whereas, the higher the ex-post cost incurred in a decision-making configuration, the greater the resource consumption to correct/adjust what went wrong, pointing to an unsatisfactory decision.

Rational Decision Making (RDM) and Total Decision-Making Cost (TDMC)

Commonly, people are highly vigilant and meticulous information processors when they need to justify their decisions to others (Wouters et al., 2009), especially when they hold management positions. They are also concerned with intensifying the search and overall acquisition of data and information (Doney & Armstrong, 1996; Siegel-Jacobs & Yates, 1996). In addition, they feel more responsible for the results produced by their choices, tending to use more analytical and to use complex decision-making strategies (Kaufmann et al., 2009), such as procedural rationality and decomposition in the execution of their tasks (Beach & Mitchell, 1978).

Considering that the rational decision-making process is that characteristically deliberative, structured and quantitative, supported by a wide range of statistical tools and expert system technology (Simon, 1987), it is assumed that this rational processing has a positive impact on the total decision-making cost, enabling the manager to generate satisfactory results. The positive relationship between rational decision-making processes and different performance dimensions has been found in several Decision Making studies (Carter, Kaufmann, & Michel, 2007; Miller, 2008; Mueller, Mone, & Barker, 2007; Phillips et al., Riedl et al., 2013; YI Wang, Highhouse, Lake, Petersen, & Rada, 2017).

This assumption is raised because it is precisely in the rational decision-making process that the manager is more likely to prioritize her decision, to consume more time and cognitive effort by collecting and analyzing information, managing complex tasks, determining a set of relevant criteria, and identifying priorities in the context of the decision (ex-ante costs) (Elbanna, 2006). These actions and activities corroborate that the result of the decision has greater feasibility to be satisfactory, reducing the need for adjustments and punctual corrections after decision making (ex-post costs). Thus, the theoretical hypothesis is postulated:

H4. Rational decision-making has a positive impact on the performance of the decision.

Intuitive Decision Making (IDM) and Total Decision-Making Cost (TDMC)

Although it is recognized in the literature a negative relationship between the intuitive processing and the decision performance result (Frederick, 2005; Kahneman & Frederick, 2002;

Lakeh & Ghaffarzadegan, 2015, 2016, Phillips et al. 2016; Weinhardt et al., 2015) there is no real decision-making option to make only rational and analytical decisions. This is because, due to increasing uncertainty and complexity that managers face in their work environments, it becomes almost impossible to rely solely on a rational decision-making process (Carter et al., 2017; Dane & Pratt, 2007), thus opening space for intuition.

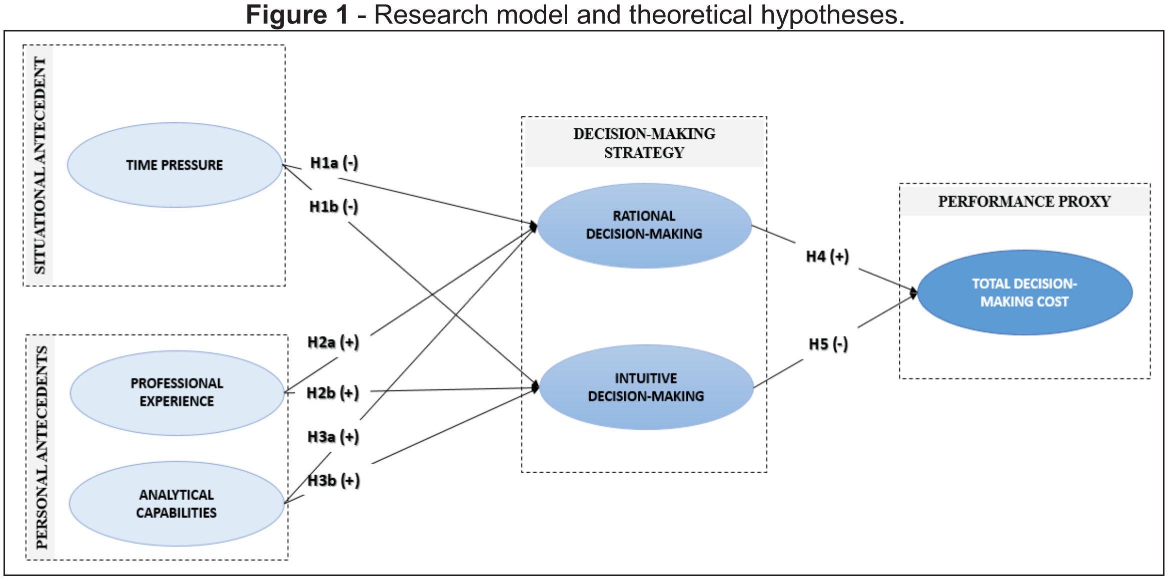
Taking into account that the intuitive decision-making process is characteristically qualitative and loosely structured (Simon, 1987), it is verified that the decision maker probably does not consume significant time for the construction of his decision, culminating in the use of little cognitive effort, low processing and analysis of information, inadequate evaluation of possible risks, insufficient identification of alternatives and development of decision steps (ex-ante costs). Undoubtedly, in this context, the probabilities of unsatisfactory results are high. Therefore, the following research hypothesis is formulated:

H5. Intuitive decision-making has a negative impact on the performance of the decision.

Research Model

The reflections obtained from the evaluation of the theoretical contents of rational decision-making (RDM), intuitive decision-making (IDM), analytical capabilities (AC), time pressure (TP), professional experience (PE) and total decision-making cost (TDMC), provided a fertile ground for the establishment of hypothetical relations amongst them. In this way, it is understood that the articulated literature confers conceptual justification for the proposition of the theoretical model (Figure 1).

Figure 1 - Research model and theoretical hypotheses.



Source: Prepared by the authors.

Figure 1 presents the nomological model of research, linking the rational decision-making (RDM) and the intuitive decision-making (IDM) to its antecedents and to the total decision-making cost (TDMC), considered as a consequent variable. The Appendix section of this manuscript presents in details the operationalization of each of the model's constructs.

METHODOLOGY

Scale Validadion and Construction of the Data Collection Instrument

The research questionnaire was elaborated based on a vast literature, which served as a theoretical basis for the formulation of 54 assertions - being 9 on the profile of the respondent/company and 45 on the constructs studied. In addition, the Likert scale was used from 1 (one) to 7 (seven) points, anchored at 1= Strongly Disagree up to 7 = Strongly Agree.

For the construction of the TP (time pressure), PE (professional experience) and TDMC (total decision-making cost) scales, a literature was mapped to identify a set of manifest variables - of higher incidence - that could measure the constructs studied, since no scales were found that were aligned with the research objectives. While the measurement of the RDM (rational decision-making), IDM (intuitive decision-making) and AC (analytical capabilities) constructs were inspired by previously developed scales, which have undergone occasional modifications due to linguistic adaptation and cultural validation. RDM, for example, was obtained from the work of Reidl et al. (2013), who investigated the procedural rationality of managers. IDM, was derived from the study by Carter et al. (2017), who proposed a unifying concept of intuition for the supply chain. Finally, the scales for AC emerged from the work of Sincorá et al. (2018) and validated with data from 288 companies in the industry, commerce and service sectors.

After the structuring of the questionnaire, the 30 assertions that had their scales constructed from the research effort (TP, PE and TDMC), received face validation (Mosier, 1947), in which 29 items obtained a correspondence of 80% for one same construct, based on the evaluation of 12 experts. After this step, all the items of the scale - 65 to the total - were evaluated by this same group of experts (teachers-doctors, academics and managers from different areas of the market) experienced in the conduction and application of surveys. Their validation contributed to the objectivity, clarity and coherence of the instrument, eliminating redundancies, ambiguities and content overlaps and allowing the common variance bias of the research instrument to be reduced.

The data used in the survey were collected from online questionnaires – through Google Docs technology - applied to managers affiliated with FINDES (Federation of Industries of the State of Espírito Santo), CRAES (Regional Council of State Administration of Espírito Santo), and those who had accounts on LinkedIn's social network (from all over Brazil). The data collection was performed between the last two months of 2017 and the second two months of 2018.

The respondents selected to participate in the research were those who held management positions in different areas (human resources, financial, accounting, production, logistics, marketing, sales, quality, research and development, supplies and others). In order to allow the use of the analysis technique of Structural Equation Modeling (SEM) in software Smart PLS-SEM 3.8.2 (Ringle, Wende, & Becker, 2014), which in turn is based on the Partial Least Squares (PLS) algorithm, it was identified the need to collect a minimum sample value of 60 respondents (Hair, Hult, Ringle, & Sarstedt, 2017). After performing a preliminary analysis to identify and treat possible problems with the data collected, the final sample consisted of 115 valid cases.

In order to evaluate the validity and reliability of the measurements, the PLS-SEM Smart software was started to perform tests for validation of the reflexive measurement models (composite reliability test, cronbach alpha, convergent validity, AVE and fornell-larcker test), formative measurement models (test of multicollinearity and significance and relevance), and structural model (test of multicollinearity, significance and relevance, determination of the coefficient of determination - R2 size of effect f2, predictive relevance Q2 and size of relative predictive relevance q2). All tests were performed according to the validation stages recommended by Hair et al. (2017).

RESULTS OF THE STRUCTURAL EQUATION MODELING

Validity and Reliability of the Measurement Model

When developing the validation tests of the reflective measurement models, from the PLS Algorithm method, it was observed that the values of Cronbach's Alpha and Composite Reliability attested that all the manifest indicators of the reflexive constructs were not measuring the same phenomenon and, thus, showing a high probability of being constituted in valid measures for the constructions. In relation to the Convergent Validity test, the values indicated that the reflective indicators have strong factorial loads, denoting that they really belong to their referred construct in the model, since they reveal to have much in common with each other. And as for the reflexive constructs, it turns out that they are responsible for explaining more than half the variation of their indicators. The exception lies only in the construct of ex-post costs which presented values of convergent validity and average variance extracted a little below the reference parameters, signaling the need for its measures to be reevaluated theoretically.

Finally, with regard to the Discriminant Validity test, the need to remove the 'EAC4' indicator belonging to the ex-ante costs construct was identified, in order to reduce the correlation between this construct and the Analytical Capabilities, and thus, minimize the likelihood that the indicators measure the same phenomenon in a similar way. After the withdrawal of the indicator that presented problems, all reflexive constructs were found to have a greater correlation with themselves than with any other construct of the model (Fornell-Larcker test).

Therefore, it is inferred from the results obtained in Table 1 that all existing relationships amongst reflexive constructs and their respective indicators are considered valid and reliable, within the quality criteria explained by Hair et al. (2017).

As for the formative measurement models, it has been identified through the Multicollinearity test (Table 2) that all the indicators of the constructs Statistical Capabilities, Business Capabilities, Information Technology Capabilities and Professional Experience are not convergent (equal) nor measured same part of the model. This indicates a good quality criterion to reveal the theoretical consistency of such indicators for the formation of the constructs to which they are related.

Therefore, from *Bootstrapping* it was possible to determine the significance and relevance of each set of formative indicators for its corresponding construct. The relevance test, then, was evidenced by the result of the statistic *t* that the indicators: SC1, ITC3, PE1, PE2, PE3, PE4 and EP5 presented values above the level of significance (0.05). However, such formative indicators were not removed from the model, since Hair et al. (2017) recommend that if the previous research and the theory consulted provide support to highlight the importance of the indicators to form the constructs to which they relate, then they must remain in the model. As for the other indicators, they all remained within the level of significance and statistical relevance.

All the tests developed for the reflexive and formative models had the objective to identify if the quality of the model would be adequate and adjusted. Therefore, the results obtained, after adjustments, showed that the relations amongst indicators and constructs were considered valid. This demonstrates that the indicators selected for the study have robustness, reliability and validity to measure the first-order constructs to which they are related, demonstrating that they are good quality measures.

Structural Model Analysis

From the Multicollinearity test for the structural model it was not possible to verify any problem of high correlation between the constructs. This procedure is necessary to indicate that there is no conceptual shadowing between the investigated constructs, that is, that two or more latent variables are not equally measuring the same phenomenon.

The Significance and Relevance test of *t* distribution, with 114 degrees of freedom and 5% of significance level, was carried out by means of data extracted from *Bootstrapping* - Table 3 -, in which it was possible to identify that the hypotheses **H1a:** Time pressure negatively impacts the rational decision-making process; **H2a:** Professional experience has a positive impact on rational decision-making process; **H2b:** Professional experience positively impacts the intuitive decision-making process; and **H5:** The intuitive decision-making process has a negative impact on the performance of the decision, do not have statistical significance for the test. So, with 95% confidence, it is not possible to state that the antecedent variables of Time Pressure and Professional Experience have a relationship with rational and intuitive decision-making approaches for the sample researched. In addition, it was found that the Intuitive Decision Making (IDM) does not generate impacts on Total Decision-Making Cost (TDMC).

On the other hand, the other hypotheses **H1b:** The time pressure negatively impacts the intuitive decision-making process; **H3a:** Analytical capabilities positively impact rational decision-making process; **H3b:** Analytical capabilities positively impact the intuitive decision-making process; and **H4:** The rational decision-making process has a positive impact on the performance of the decision, were considered are significant to the theoretical model.

Source: Elaborated by the authors based on the research data.

One of the main questions of this research was to know to what extent the antecedent variables selected for the study impact on the rational and intuitive decision approaches. In this way, when analyzing the value of the Variance Determination Coefficient (R^2) for the Rational Decision Making ($R^2 = 0.575$), it can be stated that 57.5% of the variation occurring in this endogenous construct can be explained by the variation in behavior of the antecedent variables of the structural model (Time Pressure, Professional Experience and Capabilities Analytical) that influence it. On the other hand, it is worth noting that about 32.5% of the variation that happens in the RDM is not explained by the model. Considering that this is a value of moderate magnitude, it opens the possibility of a conceptual and empirical reflection on the need to identify other variables that are not contained in the model and that would help to clarify the behavior of the rational approach within the decision-making process. This gap should be incorporated into the model in future research.

Nevertheless, it was verified that the same antecedent variables are responsible for explaining the variation that happens in the behavior of the Intuitive Decision Making in approximately 27% (R^2). This reveals to be a 'weak' impact, since most of the variation (73%) cannot be justified by the model. Thus, it is reflected that there are other variables that are not articulated in the scope of work that could increase the explanatory power of the variation that happens in essentially intuitive decision-making. New investigations are then needed to uncover variables that contribute to a more holistic understanding of this decision strategy.

Also, concerning to the analysis of the value of R^2, it was verified that the endogenous Total Decision-Making Cost construct could have its variation explained in the order of 50% by means of the impact that it receives from the constructs RDM and IDM.

Now, in order to evaluate the size of the change in R^2 value, when a given exogenous construct is excluded from the structural model, it has been identified from the size of the f^2 - which evaluates how much each construct is 'useful' for the general adjustment of the model - that only the exogenous constructs Analytical Capabilities and Time Pressure, respectively, have large (1,17) and medium effect (0,16) in the endogenous RDM construct. With respect to the IDM endogenous construct, it is noted that only the Analytical Capabilities variable exerts an average effect (0.20) on the change in its coefficient of variance. Finally, when analyzing the TDMC, it is perceived that the RDM construct exerts great effect (0.79) and the IDM construct exerts a small effect (0,03) on its behavior. This assumes that all the constructs responsible for generating large and medium effect sizes functions as an important support to explain the behavior of the variables which are theoretically related.

Finally, in investigating the predictive relevance (Q^2) of the path model, referring to endogenous constructs of a reflexive nature (RDM, IDM and TDMC), we used *Blindfolding.* According to Hair et al. (2017) for predictive relevance (1-SSE / SSO) the values resulting from such a procedure must be > 0, and as shown in Table 4, it can be observed that the values of the tests for determination of Q^2 are different and larger that "0", thus demonstrating that the endogenous constructs have predictive relevance.

Table 4 - Values of the tests to determine the predictive relevance (Q2).

TOTAL	SSO	SSE	Q^2 (=1-SSE/SSO)
RDM	230,000	141,510	0,385
PRI	345,000	313,168	0,092
TDMC	805,000	696,381	0,135

Source: Elaborated by the authors based on the research data.

Within this same logic, from another dimension of analysis obtained through the *Blindfolding* procedure, it was possible to determine the size of the effect of the relative predictive relevance (q^2) of each exogenous variable in relation to its corresponding endogenous variable.

The results indicated that the omission of the Analytical Capabilities construct made the structural model practically incapable of predicting the variation that occurs in the RDM. Subsequently, the elimination of the RDM construct represented a medium effect of changing the R^2 value of the endogenous TDMC construct to which it relates. While the other constructs showed almost no change.

Thus, from the evaluation of the relative predictive relevance (q^2) and the size of the effect (f^2), it can be deduced that the analytical capability and the rational decision-making strategy are the variables responsible for verifying and contributing to the general adjustment of the structural model.

DISCUSSION AND MANAGERIAL IMPLICATIONS

The relationship between time pressure and rational decision-making was not shown to be significant (H1a). Research suggests that the choice of a decision maker under time pressure depends on the amount of pressure it receives (Ordonez & Benson III, 1997). More specifically, the low time pressure does not cause changes in decision strategies (Payne, Bettman, & Johnson, 1988), while the moderate time pressure leads to a more focused collection of relevant information, which is a component of rational decision-making, based on procedural rationality and decomposition of decision making (Riedl et al., 2013). Severe time pressure causes subjects to shift from more rational strategies to more intuitive strategies (Dane & Pratt, 2007). In view of the findings of previous studies, it is suspected that the interviewed managers may in their decision-making reality, not generally experience decision-making under moderate-time pressure, which would encourage the adoption of more rational and analytical strategies in the choice of alternatives, and explain the relationship between them. Thus, it is assumed that respondents are likely to 'suffer' relatively high pressure and, in these conditions, culminate in adopting other decision-making strategies.

On the other hand, a significant relationship between time pressure and intuitive decision-making (H1b) was identified. One explanation may be that survey respondents often deal with the physiological, cognitive, and emotional "stress" caused by the high time pressure in their work context, resulting in stress (Selye, 1983). The conceptual links with stress emphasize that time pressure is always an interaction between the person and the environment, and that variations of individual contexts always need to be taken into account (Szollos, 2009). Thus, in practical terms, it is suspected that the urgency to finish a given task or achieve a certain goal, culminates in decisions taken intuitively, above all, based on experience, emotion and automatic processing, generating many consequences in the processes of judgment of individuals. Thus, time pressure induces changes in the affective states of decision makers and their cognitive strategies (Ben Zur & Breznitz, 1981; Maule, Hockey, & Bdzola, 2000), imposing a series of limitations on them and, therefore, results in unsatisfactory performance.

According to H2a and H2b, it was not possible to find, respectively, a significant and positive relationship between professional experience and both rational and intuitive decision-making processes. The literature states that greater professional experience is likely to allow individuals to make more effective decisions with less cognitive effort, based on the recognition of situations and problems that have been experienced in the past, as a basis for approving choices in the present (Carter et al., 2017, Riedl et al., 2013, Simon, 1987). Under these conditions, the individual turns out to base her decision on tacit knowledge and expert judgment, characteristics of intuitive approaches. The adoption of more rational approaches, receives a divergent understanding in the scientific community. There are authors who believe that more experienced decision-makers tend to rely more on the principles of rationality, yet others understand that individuals with low to moderate work experience tend to adopt more rational decision-making strategies (Riedl et al., 2013). However, it was found that, although the managers who participated in the study had an average of 19 years of professional experience and 10 years of management occupation, this antecedent variable did not demonstrate any relationship with the principles of rationality or intuition in the decision-making process, which requires future research to understand the motivations.

Regarding the hypotheses H3a and H3b, it is understood that the benefit of using analytical capabilities in both rational and intuitive decision-making processes is significantly positive. It is argued that decision-makers having a certain level of analytical *expertise*, can exploit this potential as an additional benefit in their decision-making strategies, and can be indirectly rewarded with lower decision-making costs, which in turn act as indicators of positive performance outcomes. An explanation for the positive influence of analytical capabilities on decision-making processes may be that they are closely related to System 2, that is, to mental cognitive processes known to act in a controlled, laborious, deductive, and slow (serial) in situations of choice (Kahneman, 2011). Such a relationship leads to the assumption that the more robust such capacities are in the individual, the more developed will be his "System 2" and, therefore, the more analytically oriented his decisions will be. The decision maker will have the ability to transform data and information into knowledge useful and applied to the needs of rational decision-making; and on the other hand, she will have the ability, in intuitive decision-making, to 'block' more often incoherent impressions and judgments, commonly produced by its 'System 1', increasing the probabilities of correctness and improvement in the overall quality of the decision.

Previously, it has been argued that decision makers who use rational decision-making strategies, mainly based on procedural rationality, concentrate their search for relevant information (Browne et al., 2007) and thus gain a better understanding of their decision-making process (Ketchen , Snow, & Street, 2004), reducing decision uncertainty. By targeting their cognitive resources to more relevant information and having a better understanding of the decision process, decision makers are able to evaluate and project future performance more accurately and assertively. In this sense, it is possible to find explanations that justify the confirmation of the theoretical hypothesis H4, that rational decision processes generate positive impacts on performance. On the other hand, we identified the absence of statistical significance for the negative relationship between the intuitive decision-making process and the performance dimension, measured from the total decision-making cost. This may have occurred because of the managers who participated in the study, since they recognize that their decisions are predominantly taken analytically (from the constant use of results from data analysis) and not intuitively (based in their experience, tacit knowledge, instinct and emotions).

A curiosity observed in the study is that despite the average age of those who participated in the study being 42 years old, with μ=19 years of professional experience and μ=10 occupations in managerial positions, the respondents stated that they were more confident in strategies decisions that privilege the analysis of data and information, based on analytical capabilities, than involved in more intuitive decision strategies, which in turn privilege the professional experience acquired over the years. This counterintuitive result can be clarified by the combination of the current context in which organizations are overwhelmed with data and information produced daily by their ongoing operations. Furthermore, there is a growing popularization on analysis software and decision support systems that facilitate access to interpretation of information, motivating people to engage in more rational decision-making processes (Mortenson, Doherty, & Robinson, 2015).

Another explanation may lie in the fact that these managers simultaneously combine elements of rational and intuitive decision-making processes. The disciplines of psychology and management suggest that intuition can complement rationality as an effective approach to decision making (Carter et al., 2017; Dane & Pratt, 2007). Researchers who advocate a dual-process approach - which differentiates a rational system from an intuitive system - assume that these two systems work together in decision-making. Nonetheless, researchers of the subject present a variety of recommendations on how to use intuitions in combination with more rational decision-making. Simon (1987), for example, states that effective managers do not have the luxury of choosing between analysis and intuition - actual experience involves the use of both types of decision making. Hodgkinson and Sadler-Smith (2003) argue that the ability to switch between "mental habits" and "active thinking" is the ultimate skill of today's organizations.

Obviously, such clarifications are based on assumptions that merit more consistent exploration in order to identify characteristics and mechanisms that explain how decisions are being modeled in the current context.

CONCLUSIONS AND LIMITATIONS

This research provided several important *insights* to understand decision behavior when processed rationally and intuitively. By integrating the literature of the antecedent variables (TP, PE and CA) with the behavioral decision-making research, this study contributed to the *Decision Making* theory (i) developing a relatively comprehensive model of decision-making approaches; (ii) analyzing empirically what situational and personal characteristics influence the use of rational and intuitive decision-making processes; (iii) revealing the effectiveness of analytical capabilities as an additional resource for improved decision-making; and (iv) examining the idiosyncrasies of hypothetical model relationships from a sample of professionals working in managerial positions for at least 10 years. Moreover, research results point out to the need to deeply investigate the role of process rationality and decomposition as robust strategies for reducing uncertainty, and indirectly improving overall decision performance;

The empirical validation of the antecedent variables proved to be pertinent, since it provided a more complete understanding of the situational and personal characteristics that drive the rational and intuitive approaches of decision. In addition, revealing the extent to which rational and intuitive decision-making processes impact the performance. Although it lacks theoretical and operational adjustments, this study shows an effort in offering an alternative to the understanding of the behavior and results coming from management decisions. Therefore, these findings contribute to the important literature on antecedents and decision-making strategies that impact decision performance (Krause, Scannell, & Calantone, 2007; Modi & Mabert, 2007).

In summary, the purpose of the research served to answer the central problems of this study on the *extent to which different situational and personal variables impact the use of rational and intuitive decision-making approaches? And how do rational and intuitive approaches impact decision making?* The response obtained, then, was that PT negatively impacts the IDM, whereas the AC's positively influence the RDM and the IDM. Another relevant finding of the research lies in the RDM acting as a precedent of the TDMC generating positive impacts, as evidenced empirically. Therefore, half of the theoretical propositions of the work were confirmed (H1b, H3a, H3b and H4), and the other part was rejected (H1a, H2a, H2b and H5).

As a limitation of the study, among other points, it is important to emphasize that the research did not deal with a specific decision-making, but rather with a general evaluation of the decisions that are performed by the managers. Thus, it is understood that the use of unique respondents, and perceptions about general and non-specific decisions, probably added 'noise' to the study. However, it is believed that the methodological design of a single informant and the absence of a specific decision of the organizational context, do not violate the results obtained. In this way, future research is encouraged to collect responses from several respondents from the same company, who participate in specific decisions, such as in the area of operations management that involve supplier selection; deciding what, when and how much to buy; closing contracts; allocation of industrial plants; development of new products; production scheduling; project management; outsourcing; *etc.*, in order to validate the findings of this article.

Another possible extension of the research is to use longitudinal data, aiming to evidence stronger and more significant causal relationships. Future investigations should also consider participants from other countries and map moderating and mediating factors that provide more definite explanations as to why the theoretical relationships among variables exist. In addition, it is envisaged to discuss the interrelationship between rational and intuitive decision-making in normal working contexts and under the influence of situational variables - such as risks and uncertainties, from an experimental design approach.

Finally, it is important to highlight that articulating the analytical capabilities in the managerial decision-making process represents significant contours for the field. Considering that a few years ago the topic was effectively discussed within the organizational studies and the science of management, taking root and becoming rooted as a possibility of generation of teaching and research, since the publications are increasingly growing and popularizing, contributing for the evolution of the analytics movement.

APPENDIX

Figure 2 – Research constructs and indicators.

FORMATIVE CONSTRUCTS: SECOND-ORDER	FORMATIVE CONSTRUCTS: FIRST-ORDER	ITEM	INDICATORS
INTUITIVE DECISION-MAKING	**Experience-Based Processing**	EX1	Usually when I make decisions, I try to relate to similar situations in the past to decide what to do
		EX2	Usually when I make decisions, I look in other contexts for a reference to support my decision
		EX3	Usually when I make decisions, I rely on lessons learned by me considering my experience
	Emotional Processing	EM1	I always trust my feeling (feeling)
		EM2	When I'm not completely sure how to decide, I follow my feeling
		EM3	When I come across a problem for the first time, then I decide based on my feeling
		EM4	When my feeling says "something is wrong," then I reevaluate my decision
	Automatic Processing	AUT1	Usually when I make decisions, I know almost instantly what is the best course of action to follow
		AUT2	Usually when I make decisions, I know the right decision for the needs of the company without having to think too much
		AUT3	Usually when I make decisions, I always know exactly what to do
RATIONAL DECISION-MAKING	**Procedural Rationality**	PR1	Usually when I make decisions, I am rational
		PR2	Usually when I make decisions, I try to base my decisions on information
		PR3	Usually when making decisions, I use quantitative analyzes to identify what to do
		PR4	Usually when I make decisions, I analyze the relevant information extensively before reaching a conclusion

Figure 2 – Research constructs and indicators.

FORMATIVE CONSTRUCTS: SECOND-ORDER	FORMATIVE CONSTRUCTS: FIRST-ORDER	ITEM	INDICATORS
	Decomposing	DE1	Generally when I make decisions, I manage complex tasks, dividing them into subtasks, and dealing with each one at a time
		DE2	Usually when making decisions, we determine in advance a set of relevant criteria
		DE3	Usually when I make decisions, I identify what is priority in the context of the problem before requesting additional information that I need
ANALYTICAL CAPABILITIES	**Statistical Capabilities**	SC1	Data always inspires me with questions that I had never thought of before.
		SC2	I always use data to answer questions like "what happened and / or what is happening?"
		SC3	I always use data to answer questions like "what will happen and/or why will this happen?"
		SC4	I always use data to identify the best course of action to act on a particular situation.
	Business Capabilities	BC1	I know my work processes in an intensive way.
		BC2	I use logical reasoning when dealing with situations inherent in my context of work.
		BC3	I know the needs of the business in which I am inserted.
		BC4	I interpret the data to guide them in support of decision-making.
	Information Technology Capabilities	ITC1	I have the ability to organize data from different sources and formats in a logical way.
		ITC2	Work effectively with data (databases, reports, documents, sensors, maps, *click-streams,* etc.).
		ITC3	I have the ability to work with information technologies (computers, machines, systems, *software, hardware,* applications, computer modeling, etc.).
TOTAL DECISION-MAKING COST	**Ex-Ante Costs**	EAC1	Before making a decision, I usually collect and process information
		EAC2	Before making a decision, I usually review the information available carefully.
		EAC3	Before making a decision, I usually evaluate the possible consequences of the alternatives I have.
		EAC4	I usually spend a lot of time to make a decision.
	Ex-Post Costs	EPC1	After making a decision, I usually find myself rethinking if it was actually the most satisfactory.
		EPC2	After making a decision, I usually interrupt my activities to monitor the consequences of it.
		EPC3	After making a decision, I usually need to make corrections to what went wrong.
		EPC4	After making a decision, I often regret any thing.
	Time Pressure	TP1	The pressure of time causes me to decide as a matter of urgency.

Figure 2 – Research constructs and indicators.

FORMATIVE CONSTRUCTS: SECOND-ORDER	FORMATIVE CONSTRUCTS: FIRST-ORDER	ITEM	INDICATORS
		TP2	The pressure of time causes me to make decisions quickly, almost automatically.
		TP3	I usually have little time to decide.
		TP4	I usually have insufficient time to make a safe decision.
		TP5	The pressure to make an immediate decision is always very high.
	Professional Experience	PE1	What is your age?
		PE2	What is your time of professional experience?
		PE3	How many companies have you worked for?
		PE4	How many different departments / departments have you worked for in the companies you have worked with?
		PE5	How long have you held the management position?
		PE6	How many years of formal training do you have in the management area?

ABSTRACT

Organizational sustainability is heavily influenced by companies' ability to recognize the importance of green movement, and their ability to execute greener strategies. We examine the annual revenue levels of organizations and their connections to organizational green orientation and employee perceptions of impact, quality management maturity, cultural practices, and organizational performance.

Keywords: Green Movement; Quality Management; Organizational Culture.

INTRODUCTION

While most green movement research focus on green manufacturing, sustainability, green marketing, and green consumers, few studies discuss internalized characteristics of which may influence the success of companies' green initiatives. This study focus on organizations' revenue levels and explore the connections between revenue and the green movement within companies.

LITERATURE REVIEW

There have been significant interests in green movement research, such as studies focusing on sustainability based on green practices (Ahn, 2014; Lagas, 2016; Paul, Bhole, & Chaudhari, 2014) and green marketing (Maheshwari, 2014; Sujith, 2017; Yeow, Yazdanifard, 2014).

Some of the world's biggest companies – Walmart, GE, DuPont, among others – have incorporated green initiatives into their core strategies (Unruh & Ettenson, 2010).

Raluca and Cuza (2014) posited three stages to green marketing: finding solutions, cleaner technology, and quality outputs. They specifically differentiated the difference between green products and organic products. Yeow and Yazdanifard (2014) examined potential problems when failed to implement green marketing. They explained when customers are aware of production process contributing negatively to the environment; they can refuse to purchase those items. The authors also pointed out another advantage of green marketing are in the form of government assistance (i.e., grants or loans).

Total Quality Management (TQM), Sustainability, and Green Initiatives

Research examined employee involvement (Rapp & Eklund, 2002), human resource management and leadership (Daily & Huang, 2001), commitment (Matta, Davis, Mayer, & Conlon, 1996), and personality traits (Ahmad & Schroeder, 2002) all expressed possible connections between perceptions and attitudes. How employees perceive the effectiveness of TQM tools used in the workplace should have significant influences on employees' attitudes about going green.

Sustainable development is based on the perceived need to address environmental deterioration and to maintain vital functions for the well-being of all generations. It has been perceived as a new tool in company planning (Beatley & Manning, 1998) and a fundamentally important concept which should influence all policy developments within a firm (Loffler, 1998). Zairi and Liburd (2001) defined sustainability development as the ability of an organization to adapt to change in the business environment in order to deploy best contemporary methods to achieve and further maintain superior performance. Total Quality Management (TQM) represents the integrative approach in the pursuit of customer satisfaction (Chin, Pun, & Hua, 2001) and overall success. Facing intense pressure from global competition, organizations realize the need to incorporate sustainable development and TQM in order to reach higher level of improvement and ultimate profitability (Hitchcock & Willard, 2002; Jonker, 2000; McAdam & Leonard, 2003). The idea of expansion of TQM to include sustainability, and the expansion being fueled by pressure to ensure long-term survival or growth surrounded by the emphasis of globalization is thus born (Dervitsiotis, 2001; Wilkinson, Hill, & Gollan, 2001; Zairi, 2002).

Organizational Culture

Organizations incorporating green initiatives as part of their corporate culture could become the leaders in the green movement and reach higher level of sustainability and profitability (Acharya, Vadher, & Acharya, 2014). Organizational culture may impact employee perceptions of the green movement and its importance to the organization, and overall performance outcomes. We theorize that as organizations become greener, organizational culture will become more employee- and customer-centered. Employees may become more empowered and thus perform better.

Organization Size

Size is highly relevant to organizational strategy and structure, as mentioned in the literature of "Differences between Strategic Planning at Small Versus Large Firms" (Boundless, 2016). In an early research, Child (1972) highlighted the importance of *strategic choice* by organizational decision makers and its impact upon factors including organizational size and market focus. Other research has previously examined whether organizations of different size and market focus may differ on several variables related to the green movement and Quality Management in Jamaica and in the United States (Zee, Fok & Hartman, 2011). In other research, company size impacts its focus points, challenges and approaches in quality management strategies (Ahire & Golhar, 1996; Roberts, 2013). Studies can be found looking specifically into firm size versus implementation successes of quality management programs. For example, studies by Kober, Subraamanniam, and Watson , (2012), Assarlind and Gremyr (2014), as well as Melao and Guia (2015) all reinforced the differences in ability to successfully implement quality management programs between large firms and small firms. Finally, Cho (1994) and Isa, Zaroog, and Raju (2016) investigated the factors affecting successful implementation of TQM in large versus small organizations in the United States and in Malaysia, respectively. In turn, these choices ultimately impact organizational effectiveness (see especially Beckman, 2006; Kreitner & Kinicki, 2007).

RESEARCH QUESTION

In this study, we examine issues regarding the impact of size in terms of revenue to consider organizational culture, employee perceptions of organizational commitment to the green movement and QM maturity of the organization. Specifically, small revenue and large revenue organizations will have different levels of organizational green orientation, QM maturity, organizational culture, and report differing impacts of the green movement.

> Research Question: Small and large organizations in terms of annual revenue will have different levels of organizational green orientation, organizational culture, QM maturity, organizational performance, and report differing impacts of the green movement.

METHODOLOGY

Subjects of the Study

Subjects in the sample were approximately 331 full-time employees from a wide variety of industries in the South. The subjects were roughly 51.7 % male and 48% female with an average age of 41.49. The results are shown in Table 1.

Approximately 31.1% of the subjects are employed in a company which has over $1,000 million annual revenue, 4.2% of the subjects are employed in a company which has $501 to $1,000 million annual revenue, 3.9% of the subjects are employed in a company which has $251 to $500 million annual revenue, 4.2% of the subjects are employed in a company which has $101 to $250 million annual revenue, 4.5% of the subjects are employed in a company which has $51 to $100 million, 6.3% of the subjects are employed in a company which has $25 to 50 million annual revenue, and 34.1% of the subjects are employed in a company which has less than $25 million annual revenue. Subjects responded to a survey which asked about their perceptions and experiences about the green movement, quality management, and organizational culture in their own firms.

Table 1 Types of Industry and Annual Revenue of the Organizations

Industry		Frequency	Percent	Valid Percent	Cumulative Percent
	Manufacturing	42	12.7	12.7	12.7
	Financial Services	15	4.5	4.5	17.3
	Retail	73	22.1	22.1	39.4
	Utilities	9	2.7	2.7	42.1
	High Technology	7	2.1	2.1	44.2
	Education	18	5.4	5.5	49.7
	Health Care	69	20.8	20.9	70.6
	Government	5	1.5	1.5	72.1
	Other	92	27.8	27.9	100.0
	Total	330	99.7	100.0	
Missing	System	1	.3		
Total		331	100.0		

Annual revenue		Frequency	Percent	Valid Percent	Cumulative Percent
	Over $1,000 Million	103	31.1	35.2	35.2
	$501-$1,000 Million	14	4.2	4.8	39.9
	$251-$500 Million	13	3.9	4.4	44.4
	$101-$250 Million	14	4.2	4.8	49.1
	$51-$100 Million	15	4.5	5.1	54.3
	$25-$50 Million	21	6.3	7.2	61.4
	Less than $25 Million	113	34.1	38.6	100.0
	Total	293	88.5	100.0	
Missing	Unkmown	37	11.2		
	System	1	.3		
	Total	38	11.5		
Total		331	100.0		

Instrument

Organizational Green Orientation

Based on the previous research (Li, Hartman, and Zee, 2009), we measured the Organizational Green Movement by using the survey which provides twenty-one organizational green initiatives question items. The factor “Green Orientation” is a count of the total numbers of green initiatives implemented in an organization.

Quality Management (QM) Maturity

QM Maturity refers to the *degree* of QM implementation in an organization. We suggest, and previous research has shown (Ahire & Golhar, 1996; Flynn, Schroeder, & Sakakibara, 1994; Fok et al., 2000, 2001; Patti, Hartman, & Fok, 2001; Saraph, Benson, & Schroeder, 1989) that it can be measured by examining the perceived use of QM programs. In earlier research (Fok et al., 2000, 2001; Patti et al., 2001), we began the process of developing a measure of QM maturity. The instrument we developed dealt with perceived program *use* and asked respondents whether certain programs were in use in the organization, with a range from “not used” to “high usage.”

In this study, the QM maturity instrument was used to gauge QM maturity. We conducted a factor analysis to identify the underlying dimensionality. Two factors emerged from the “Usage” items. The first factor appeared to include all the traditional quality management programs and was termed “Basic Quality Improvement Tools.” The second factor was termed “Advanced Quality Improvement Tools” which includes programs like Six Sigma programs and Black Belt training. 67.39% of the variance was explained by these two factors. Table 2 below provides the items and shows the results of our factor analysis.

Table 2 Factor Analysis on Quality Programs Usage Items

Total Variance Explained

	Rotation Sums of Squared Loadings		
Component	Total	% of Variance	Cumulative %
1	2.275	37.915	37.915
2	1.768	29.475	67.390

Extraction Method: Principal Component Analysis.

Rotated Component Matrix

	Component	
	1	2
Quality management (QM) program	.646	.186
Employee suggestion channels	.714	.135
Employee quality training programs	.828	.051
Quality improvement seminars	.771	.181
Six sigma programs	.231	.903
Black belt training	.111	.930

Organizational Culture

Based on previous research (Fok et al., 2000, 2001; Harman, Fok, & Zee, 2009), we measure the Organizational Culture by constructing a series of paired opposite items which asked whether the organization's climate should be described as open vs. closed, soft vs. tough, competitive vs. collaborative, and the like. Table 3 below provides the items and shows the results of our factor analysis. We obtained a two-factor solution in case of the Organizational Culture items and have labeled Factor 1 as "Continuous Improvement Culture" and Factor 2 as "People Friendly Culture." 44.529% of the variance was explained by these two factors.

Table 3 Factor Analysis on Organizational Culture

Total Variance Explained

Component	Rotation Sums of Squared Loadings		
	Total	% of Variance	Cumulative %
1	2.128	26.596	26.596
2	1.435	17.933	44.529

Extraction Method: Principal Component Analysis.

Rotated Component Matrix[a]

	Component	
	1	2
Open	.759	.161
Tough	.300	.639
Formal	-.230	.656
Team-Oriented	.657	-.288
Impersonal	.376	.100
Centralized	-.097	.627
Participative	.666	-.114
Proactive	.618	-.268

Organizational Performance

The Organizational Performance items were primarily adapted from the Malcolm Baldridge National Quality Award outcome assessment measures. The Baldridge Awards are designed to identify organizations which are performing in an exceptional manner and include criteria for identifying excellence. We used the Baldridge criteria in the form of a scale which asks respondents to provide perceptions about their organizations along Baldridge lines. The resulting scale has been used and reported in previous work (Fok et al., 2000, 2001; Hartman, Fok, & Zee, 2009). Factor analysis in this study indicated that one factor was present. The results showed that 56.205% of the variance was explained by the factor and we named the factor as "Organizational Success."

Impact of Green Movement

The instruments included are items such as “Provide better products,” “Have better relationship with suppliers,” “Have better reputation,” “Increase profits,” “Reduce costs,” and “Improve productivity.” Factor analysis produced a single-factor solution and we named it “Impact of Green Movement.” 70.987% of the variance was explained by this factor.

Revenue Size

In this research, we extend the respondents to report the approximate annual revenue in their organizations. Those who reported with less than $25 million annual revenue are grouped into the small revenue group and those who reported with over $1,000 million annual revenue are grouped into the large revenue group. While those with between $25 million and $1,000 million annual revenues are dropped from the analysis.

RESULTS

Our research question suggested that small revenue (less than $25 million annual revenue) and large revenue (over $1,000 million annual revenue) organizations would have different levels of organizational green orientation, organizational culture, QM maturity, organizational performance, and impact of the green movement. As shown in Table 4, the MANOVA results are significant with p-value of .000, which implies that small revenue organizations were significantly different from large revenue organizations, and that respondents reported different levels of organizational culture, QM maturity, and impact of the green movement. Among the seven factors, we found that both “Use of Basic Quality Improvement Tools” and “Use of Advanced Quality Improvement Tools” are statistically significant at the levels of .000 and .000, respectively. For “Use of Basic Quality Improvement Tools”, the mean factor score of large revenue companies (0.255) is greater than that of small revenue companies (-0.309). For “Use of Advanced Quality Improvement Tools”, the mean factor score of large revenue companies (0.326) is greater than that of small revenue companies (-0.216). The results imply that large revenue organizations have higher levels of usage of both traditional TQM tools and advanced TQM tools than small revenue organizations. “People Friendly Culture” is significant at the level of .000. The mean factor score of small revenue organizations (0.298) is greater than that of large revenue organizations (-0.231). The results suggest that small revenue companies are more informal, more decentralized, and more personal than large revenue companies. The factor “Organizational Performance” is significant at the level of .000. The mean factor score of large revenue organizations (0.286) is greater than that of small revenue organizations (-0.221) which implies that large revenue organizations have higher levels of organizational success than that of small revenue organizations.

Table 4 Summary of MANOVA results – Revenue Size

Multivariate Tests[a]

Effect		Value	F	Hypothesis df	Error df	Sig.
Intercept	Pillai's Trace	.944	486.196[b]	7.000	200.000	.000

People-Friendly Culture	.000**
Basic TQM Tools	.000**
Advanced TQM Tools	.000**
Organizational Performance	.000**

** F test is significant at the 0.05 level.

DISCUSSIONS AND CONCLUSIONS

In this research, we investigated whether companies with large annual revenue report differing perceptions of the company's impact on the environment compared to companies with small annual revenue. Results showed that smaller revenue companies are more likely to be informal employees are more likely to feel their work environment is a more people-oriented and friendlier. They also showed that participants from larger revenue organizations report higher usage of traditional TQM tools and advanced TQM tools compared to smaller revenue organizations. This can be explained by the availability of resources. Implementing TQM tools can be rather costly, and affordability may be a factor for smaller revenue companies. This study acknowledges the effort and movement to reduce environmentally harmful processes and the factors which influence the movement. Understanding the components related to the green movement should enable us to improve operations and skillsets, which could lead to bettered health and safety procedures and also employee morale.

ABSTRACT

Manufacturing firms consume electrical energy in large quantities. Reducing energy consumption is a concern not only for governments, but also for firms. By reducing consumption of resources needed to produce electricity, firms' can significantly increase their productivity and conserve environment. In green manufacturing literature, the topic of energy conservation in manufacturing context has received less research attention when compared to other green practices such as eco-friendly product development and pollution reduction. In this study, we address this gap by investigating on what are the predominant green strategies for energy conservation implemented by US manufacturing firms in *Industrial Machinery and Equipment* sector. In addition, the study identifies the economic and organizational factors that influence firms' greening efforts of energy management. To achieve these two research objectives, energy assessment data comprising of 119 manufacturing firms is analyzed using descriptive statistics and Poisson regression technique. Findings of the study are expected provide insights to relevant stakeholders, such as manufacturing firms, governmental bodies, energy supplying companies, and universities, in collaborating for designing and emphasizing on appropriate greening interventions needed to promote green manufacturing practices pertaining to energy conservation.

KEYWORDS: Green manufacturing, Energy management, Green strategies, Energy conservation, Energy sustainability

INTRODUCTION

In recent past, manufacturing firms are forced to adopt an environmental perspective in planning and executing their operations due to several factors including concerns on deterioration of natural resources, customer preferences for green products/services, and regulatory pressure from government. Subsequently, 'green manufacturing' emerged as a topic of interest for global community including governments, firms, consumers and researchers. Green manufacturing refers to green strategies and techniques that firms employ in their production systems to become more eco-efficient (Deif, 2011). It reflects a manufacturing approach of the firms, that is aware of the impact of their production and product on environment. Some examples of green manufacturing practices include creating products with less material and energy consumption, using more eco-friendly materials, and renewable energy for production, reducing unwanted outputs and recycling the used products (Helu & Dornfeld, 2013).

Existing academic research on green manufacturing mainly comprises of studies that focus on developing frameworks and indices to assess, measure and monitor the greening efforts (Deif, 2011; Salem & Deif, 2013), impact of green manufacturing on firms' performance (Rusinko, 2007), green manufacturing practices pertaining to raw material usage and recycling in specific industries (Rusinko, 2007) and green energy recommendations (Anderson & Newell, 2004). Studying upon influencing factors, such as level of disruption, environment norms and local adopters, on implementation of a government recommendation is yet another underdeveloped area in green practices research (Muthulingam et al., 2013; Dowell & Muthulingam, 2017). In this vein, the present study focuses on green manufacturing practices pertaining to reducing energy consumption, which is a relatively under-researched area in comparison to other green manufacturing practices (Oh & Sun, 2016). According to a recent report on greenhouse gas (GHG) emissions by the United States Environmental Protection Agency (USEPA), electricity generation contributes the most to the total GHG emissions, accounting for 28% of the total GHG emissions (USEPA, 2016). Further, manufacturing sector is the third largest contributor to the total GHG emissions, accounting for 22% of the total GHG emissions. GHG emissions in manufacturing sector are produced directly from burning fuel for energy, chemical reactions, and from leakages of industrial processes or equipment. Manufacturing sector also contributes indirectly to the GHG emissions by the use of electricity that is produced by burning fossil fuels and other natural resources. In its attempt to reduce the amount of GHG emissions resulting from energy generation and consumption, the US government is emphasizing on energy conservation through various initiatives for manufacturing firms such as providing free energy assessment consultancy services, providing tax incentives for using renewable energy, and penalizing excessive energy consumption. As such, when manufacturing firms implement energy recommendations by the government, they compare costs of implementing a government recommendation with their energy savings (Anderson & Newell, 2004). In this background, the present study aims to extend the stretch of existing literature by providing an overall understanding of predominant green strategies implemented by firms in *Industrial Machinery and Equipment* sector.

The specific research questions addressed in this research study are as follows:

RQ1: What are the green strategies in energy management that manufacturing firms in *Industrial Machinery and Equipment* sector predominantly apply?

RQ2: What are the economic and organizational factors that influence manufacturing firms' greening efforts of energy management in *Industrial Machinery and Equipment* sector?

The findings are expected to provide deeper insights to scholars about the factors influencing the energy conservation efforts of firms in *Industrial Machinery and Equipment* sector. From a practitioner perspective, managers shall benefit from this study in designing appropriate greening interventions and in approaching energy conservation efforts more proficiently at least in *Industrial Machinery and Equipment* sector. Relevant stakeholders, including governmental bodies, energy companies and supply chain partners related with *Industrial Machinery and Equipment* sector., will additionally benefit from these findings in formulating useful collaborations to endorse for green manufacturing practices. The subsequent sections discuss the possible green strategies in energy management and methodology, followed by conclusion.

GREEN STRATEGIES IN ENERGY MANAGEMENT

Oh & Soh (2016) suggest that manufacturing firms can potentially deploy combinations of four different strategies in their energy management for achieving green manufacturing systems, which are peak demand management of electric power, production energy management, utility energy management, and use of renewable energy. Each of these green strategies in energy management are discussed in detail in the following sections.

Peak Demand Management

Peak demand management of electric power refers to a firm's efforts to reduce and manage load spikes in their manufacturing operations, thereby, reducing load on the power grid system. Achieving a perfect real-time balance between supply and demand is a critical factor for reliable operation of power grid systems (Albadi & El-Saadany, 2008). Industrial consumers such as manufacturing firms play a key role in achieving this supply-demand balance of power grid (Zhang & Grossman, 2016). Load spikes in manufacturing firms result when firms employ high short-term energy consumption processes within the same time-periods. Load spikes subsequently translate to high demand charges, which typically constitute major portion of the electricity costs for manufacturing firms. Peak demand management of electric power by manufacturing firms not only reduces the overall electricity costs of the firm, but also contributes to overall greening efforts at national level through reduction of social costs associated with generation of electricity and consistent operational performance of the power grid system (Oh & Sun, 2016). Firms manage peak demands using a different combination of methods such as use of alternate sources of energy supply such as power generators and solar energy to cater to peak demands, storing electric energy for later use to offset the load spikes, and make relevant changes in processes that can augment peak load reduction. The former two solutions for peak demand management of electric power involve high capital cost investments by the firms, while the latter solution involves significant implementation effort in terms of coordination among the different departments and adjustment to the changed processes and routines.

Production Energy Management

Production energy management refers to a firm's efforts to reduce the energy consumption in its production processes by upgrading the machinery, improving the utilization rate of production equipment, and exploring ways to reduce task time. Traditionally, manufacturing firms handled production and energy management separately, by determining production schedule first following by planning for electricity procurement (Zhang & Grossman, 2016). Such an approach typically led to suboptimal solutions by blindsiding firms on possible improvements that could be achieved on the production side (Zhang & Grossman, 2016). In the recent past, with mounting pressure to optimize production costs and adopt environment-friendly production systems, manufacturing firms are gradually shifting to an integrated approach for production and energy management (May et al., 2016). This approach however, is associated with significant capital costs and implementation effort in terms of identifying optimal schedule for operations, implementing process improvement programs, researching for better materials and method alternatives, integrating information flows, laying out preventive maintenance schedules, and investing on better machinery and equipment (May et al., 2017).

Utility Energy Management

Utility energy management refers to management of energy consumption by the utilities that essentially support core production processes such as heating, cooling, humidity control and lighting. Utility energy management is an easy target to improve energy efficiency, without affecting the core processes. Typically, utilities in a production system account for 30% of the energy consumption and therefore, is a hotspot for energy efficiency innovations and improvements (May et al., 2016). Continuous product innovations by utility equipment suppliers in bringing more eco-friendly products into market and development of smart devices further complement the potential for greening effort of firms in this area. These improvements typically do not entail large capital costs or implementation costs to companies.

Use of Renewable Energy

The strategy of using renewable energy refers to a firm's efforts to either generate or procure renewable energy for its consumption. Manufacturing firms are increasingly exploring the possibility of generating renewable energy, especially, solar energy to offset their energy requirements and support their objective of achieving green manufacturing systems, relatively lower levels of thermal efficiency, lack of reliability, and lack of sufficient market base to stimulate related technological innovations and standardization (Eleftheriadis & Anagnostopoulou, 2015; Luthra et al., 2015).

RESEARCH METHODOLOGY

Sampling and Analysis

A section of data of the Industrial Assessment Centers (IAC) program, an energy management initiative of the United States Department of Energy, is coded and analyzed. The IAC program partners with several reputed universities to establish IAC centers across the U.S. The IAC centers provide free consultancy services to medium and large sized manufacturing firms for energy and natural resource management and provide recommendations for improvement. Thereafter, the IAC centers follow-up with the consulted manufacturing firms on implementation of the recommendations and resulting savings from their implementations. In this study, we limit the scope to energy related assessments and recommendations of firms in one sector, namely, *Industrial Machinery and Equipment* sector. Accordingly, a random sample of 119 firms from the IAC database is extracted and carefully coded for analysis purpose. The details of the variables considered for the data analysis are presented in Appendix A.

In our first analysis (Analysis 1), we identified predominant green strategies of energy management that the sample firms' have implemented based upon IAC recommendations. The predominant strategies are identified by analyzing the total number of recommendations given to the firms in the data sample and total number of recommendations implemented by the firms for each green energy management strategies. In our second analysis (Analysis 2), we identified the economic and organizational factors that influence the sample firms' greening efforts of energy management using Poisson regression technique. The greening effort is represented by the total number of recommendations in energy management that have been implemented by the firms. Organizational and economic factors that are considered for the analysis include level of demand management recommendations, level of production management recommendations, level of utility management recommendations, annual sales of the firm, total employees of the firm, plant area, annual production hours, potential savings expected from the recommendations, annual electrical costs, and total costs associated with the recommendation implementation. Poisson regression technique is apt for the present research model since the dependent variable is a count variable and approximates a Poisson distribution (Nussbaum et al., 2011; Dunteman & Ho, 2011). A variable can be approximated to follow a Poisson distribution if it has similar values of mean and variance. In the present case, the dependent variable has a mean of 5.5 and the variance of 5.79 as shown in Table 1. Also, some of the independent variables in the research model are categorical, while others are continuous. Poisson regression model accommodates both types of independent variables (Nussbaum et al., 2011; Dunteman & Ho, 2011). Poisson regression is conducted using IBM-SPSS software package for this study.

Table 1: Mean and Variance of the Dependent Variable

Dependent Variable	Mean	Standard Deviation	Variance
TotRecImp	5.55	2.407	5.794

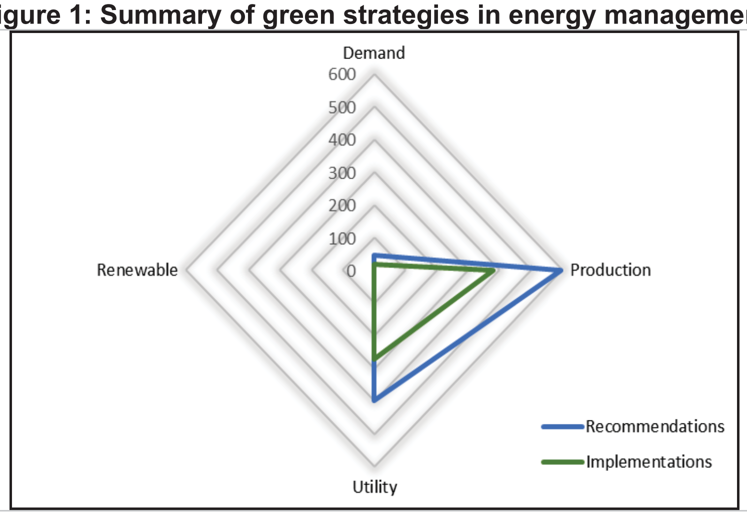
RESULTS

The results for Analysis 1 are presented in Table 2 and Figure 1. The results revealed that the production energy management and utility energy management predominantly implemented by the firms. These two strategies accounted for 96% of the recommendations indicating a greater potential for bringing in energy efficiencies and subsequently, contribute to the greenness of the production system. Demand management recommendations accounted for 4% of the recommendations, indicating that the firms in this sector are doing well with management of electricity loads in their operation. There were no recommendations offered to the manufacturing firms by the IAC centers related to use of renewable energy. One of the possible reasons for the lack of recommendations in this area could be that the recommendations related to use of renewable energy are not viable for the huge and critical power requirements on the firms in this sector. Also, the large capital costs associated with laying out the infrastructure for generating renewable energy do not necessarily justify the expected benefits from these recommendations.

Table 2: Results of Analysis 1

Strategy	Recommendations	Implementations
Demand	45	17
Production	595	377
Utility	399	271
Renewable	0	0
Total	1039	665

Figure 1: Summary of green strategies in energy management



The results of Analysis 2 are presented in Table 3, Table 4 and Table 5. The independent variable representing recommendations related to use of renewable, RenRecLevel, is dropped from the analysis, since there are no recommendations given in this category. Table 3 presents the results of goodness-of-fit test that assesses how well the regression model fits the data. The parameter "Value/df" for Pearson Chi-Square needs to close to 1 confirming the assumption of equi-dispersion (Bruin, 2016; Laerd Statistics, 2018). For the study's model the value for this parameter is 0.737 indicating slight but acceptable level of under-dispersion. Overall, the regression model can be assumed to fit the study data. The results for Omnibus Test, which is a likelihood ratio test that compares the full regression model with all the independent variables with the intercept-only model (Bruin, 2016; Laerd Statistics, 2018). The p-value of .000 in the present analysis indicates a statistically significant overall model. The results for the "Tests of Model Effects" indicating the statistical significance of each independent variable is presented in Table 5. The results indicate that the variables ProdRecLevel, UtilRecLevel, Sales, Employees and TotSav have statistically significant influence on the dependent variable TotRecImp. The parameter estimates of the independent variables are presented in Table 6. The regression model for the study is presented in the equation below.

$$\begin{gathered} logTotRecImp = 1.875 + exp(-0.583)*ProdRecLevel1 \\ + exp(-0.393)*ProdRecLevel2 \\ + exp\ (-0.391)UtilRecLevel1 \\ + exp(-0.002)Sales \\ + exp(-0.001)Employees \\ + exp(3.47*10^{-6})TotSav \\ + exp(-2.465*10^{-7})ElecCost \end{gathered}$$

CONCLUSION

The present study seeks to investigate the predominant green strategies for energy conservation adopted by the US firms in Industrial Machinery and Equipment sector and identify the economic and organizational factors influencing the greening effort in energy management of these firms. The study results indicate that manufacturing firms in the focus sector predominantly implemented production energy management and utility energy management strategies in their greening efforts. The economic and organizational factors that influence the greening effort include level of production recommendations, level of utility management recommendations, annual sales of the firm, number of employees, potential savings resulting from implementation of the recommendations. Surprisingly, annual cost of electricity has a positive but somewhat weak influence on total recommendations implemented by the firm. The findings of the study point out that the costs associated with recommendation implementations do not seem to affect the firms' greening effort, which indicates firms' positivity in committing to green manufacturing practices in Industrial Machinery and Equipment sector.

The study adds new perspectives to the existing literature on implementation of environment focused energy-saving initiatives in at least two ways. First, our study replicates earlier studies on energy-saving initiatives. When we compared our study findings based on recent IAC energy data for the period 2000 – 2017 with that of an earlier study by Anderson & Newell (2004) based on IAC energy data for the period 1981 – 2000, both studies appeared consistent about adopting production and utility energy-saving recommendations. Similar to Anderson & Newell (2004), we find that firms are likely to adopt production and utility energy savings recommendations when such adoptions can lead firms to save of energy costs. Counterintuitively, this finding suggests that firms may be less likely to commit to invest in environment focused energy savings measures when there is lesser scope for immediate returns. However, this is not the case in our data sample of randomly selected 150 firms representing Industrial Machinery and Equipment sector. Our results show that the effect of implementation costs is not significant on the number of energy related recommendations that a firm has implemented. As such, this finding contradicts with earlier studies, such as Dowell & Muthulingam (2017), that suggested implementation costs as a major factor. We argue that this inconsistent finding is an outcome of the industry effect (i.e., specific to Industrial Machinery and Equipment sector), or the effect of type of recommendations (i.e., energy related). Second, our study finds that firm characteristics, such as annual sales of the firms, number of employees, annual electricity costs, act as significant proxies to indicate for firms' likelihood of adopting energy-saving recommendations. Our finding is based on our independent treatment of each attribute of firm characteristics as an orthogonal statistical approach to prior studies, e.g., Dowell & Muthulingam (2017), that controlled for firm characteristics.

The study is expected to provide deeper insights to researchers and managers about factors influencing the energy conservation efforts in Industrial Machinery and Equipment sector. As such, researchers at national level energy guiding agencies, such as IAC, can outrightly use several of the study findings to support their ongoing consulting efforts to manufacturing firms. The study offers a model that can help managers in predicting the number of energy management recommendations that are likely to be implemented by the firms in this sector based on the significant factors found in the analysis. Future research studies can test this model can for manufacturing firms in other sectors to gain sector-specific insights. The study has some limitations as well. One main limitation relates to the under-dispersion of the dependent variable. Even though the under-dispersion of the dependent variable is expected to not hinder the robustness of the study results, further in-depth examination can offer rich insights on effect of under-dispersion of the dependent variable in a Poisson regression model.

APPENDIX A

Variable Name	Variable Description
TotRecImp	Total energy management recommendations implemented
DemRecLevel	Level of demand management recommendations Categorical variable: 1: 0 recommendations 2: 1 to 3 recommendations 3: 4 and above recommendations
ProdRecLevel	Level of production management recommendations Categorical variable: 1: 0 recommendations 2: 1 to 3 recommendations 3: 4 and above recommendations
UtilRecLevel	Level of utility management recommendations Categorical variable: 1: 0 recommendations 2: 1 to 3 recommendations 3: 4 and above recommendations
RenRecLevel	Level of renewable energy use recommendations Categorical variable: 1: 0 recommendations 2: 1 to 3 recommendations 3: 4 and above recommendations
TotCost	Expected cost of energy management recommendation implementation
TotSav	Potential savings resulting from implementation of energy management recommendations
ElecCost	Annual electricity consumption cost
Sales	Annual sales of the firm
Employees	Number of employees working in the firm
Plant Area	Built-up area of the production system
ProdHours	Annual hours of production operations

ABSTRACT

Big Data Analytics (BDA) supports industries by providing insights from data. A significant amount of previous research documented that the construction industry, embraced BDA poorly. This study explores the dispersion of BDA in various sectors of construction using a systematic literature search. The study identifies that BDA penetrated well into transportation sectors such as highways and railways compared to building construction. The reasons for uneven absorption are deficiency in data science education in civil engineering curriculum, lack of simple BDA tools, resistance to embrace BDA, etc. The study also presents recommendations for effective diffusion of BDA in construction.

ABSTRACT

Healthcare data used in predictive analytics are typically highly imbalanced with high dimensionality, which affects classification performance negatively. This study focuses on improving model performance in healthcare analytics under these constraints. It uses data sampling to reduce imbalance and feature selection to reduce high dimensionality, thereby improving overall model performance.

KEYWORDS: Hospital Readmission, High Imbalance, High dimensionality, Data Sampling, Feature Selection

INTRODUCTION

Electronic health record (HER) systems produce high volumes of healthcare data which can be used to develop machine learning and classification algorithms to analyze and predict various healthcare challenges. Healthcare data including patient discharge summaries are of high predictive value (Isaac et al., 2015; Joseph et al., 2015). But the discharge summary datasets used in prior studies are highly imbalanced and have high dimensionality, which is a common characteristic of all healthcare datasets because the minority (positive) class is often the class of interest. In addition, the feature set extracted from discharge summaries generally has high cardinality (Shanab et al., 2011).

High imbalance in healthcare datasets is caused due to uneven distribution between a minority of positive cases and a majority of negative cases. Classification algorithms tend to assign the predicted label to the majority class in order to reduce the overall misclassification rate (Shanab et al., 2011), resulting in poor classification performance, higher false negatives, and higher false positives. These usually result in overfitting the data (Soltani et al., 2011; Sandhan et al., 2014).

In addition, a wide variety of data including data from various hospitals, various health practitioners, and their varied methods of writing discharge summaries in the case of text data, also result in high dimensionality datasets. In this study, we used a bag-of-words model to extract features from all discharge summaries which resulted in a large number of features. The high dimensional dataset shows problems such as overfitting, more space and memory needs, and requires high processing power for data analysis. The solution is to filter the features and use these filtered datasets to measure the classification performance. The basic assumption behind selecting optimal feature sets is that they would provide higher classification accuracy, since the subset captures all basic information about the dataset and excludes features which are noisy or irrelevant (Lusa and Blagus, 2012; Taşkın et al., 2017).

The dataset used in this study shows high imbalance and high dimensionality with a total number of 191,205 patient discharge summaries with 8,204 records for positive (minority) cases and 183,001 negative (majority) cases. This study used a data sampling technique to reduce the imbalance and achieve better classification performance. A total of 391 features were extracted by using bag-of-words model with a minimum document frequency of 0.05. The high dimensionality of the resulting dataset is then reduced by using a feature selection technique.

The Naive Bayes classification algorithm was used in this study. A Naive Bayes implementation allows the system to be highly scalable and non-sensitive to irrelevant data. In addition, newly acquired patient data can be incrementally utilized to train the model which will allows the model to be relevant over time. The model was designed on the High Performance Computing Cluster (HPCC), a big data platform. This allows the model to be used in real life scenarios where new discharge summaries can be continuously added and utilized to improve the current model.

This study addresses the hospital readmission problem for patients with Chronic Obstructive Pulmonary Disease (COPD) because it is a major challenge, with almost 20% of Medicare beneficiaries hospitalized for COPD getting readmitted within a 30-day period (Surya et al., 2017). Further, a significant percentage of these readmissions are avoidable. Hence there are many ongoing efforts to develop effective predictive models to reduce this.

LITERATURE REVIEW

The growth of healthcare related information has led to an increase in implementation of various healthcare related machine learning tools and platforms to support decision making, such as identifying high-cost patients, analyzing and predicting hospital readmissions (Carolyn, 2012) and improving patient triage where the risk of complications is estimated (Xiaoqian et al., 2012).

The focus of this study is to predict and analyze hospital readmissions for COPD within a 30-day period of initial discharge. This study uses discharge summaries as opposed to claims data (Danning et al., 2014) because discharge summaries are available in a timely fashion when the patient is being discharged. They also summarize all the information about patient's condition at the time of discharge. In contrast, claims data takes significant time to get generated and processed. Since hospital readmissions must be predicted within 30-days of initial discharge from hospital, discharge summaries provide a better option to generate true predictions in a timely fashion. This would support timely and effective preventative interventions to help mitigate the risk of avoidable patient readmissions.

As indicated earlier, since the discharge summary dataset is produced by various hospitals and healthcare practitioners, the data has many features and is highly imbalanced. According to the study performed by (Van Hulse et al., 2011), sampling techniques improve the performance of various classification algorithms where the dataset is highly imbalanced. Their study generated a total of 1,232,000 classifiers using 35 different benchmark datasets, 11 learning algorithms and 7 different sampling techniques. It further showed that Random Under-Sampling (RUS) performed better than other intelligent sampling techniques across different learners. In another study (Seiffert et al., 2009), RUS was also shown to perform better than other sampling techniques, for software quality prediction dataset. Joffrey et al. (2018) also show that the Random Under-Sampling technique improves the overall classification performance for a range of learners, datasets and environments. Khoshgoftaar et al. (2014), shows that RUS in conjunction with other performance improvement techniques achieve good results for six different highly imbalanced bioinformatics datasets.

To reduce high dimensionality in the data, feature selection techniques work best as compared to other dimensionality reduction techniques. This improves overall performance, and reduces the memory and processing power requirements. According to Gao et al. (2011), feature selection plays a very important role in reducing dimensionality. Kira and Rendell (1992) developed the first Relief algorithm as a feature selection method based on evaluating individual features (Figure 1). The algorithm calculates a feature weight (also referred to as feature score) for each feature that can be used to estimate its relevance to the predicting value. It ranges from -1 (worst) to +1 (best). The original algorithm was limited to binary classification problems with many limitations including the lack of ability to handle missing data. So a variety of methods have since been developed to extend the Relief algorithm. Urbanowicz et al. (2018) review relief-based feature selection research in further detail.

Require: for each training instance a vector of feature values and the class value
$n \leftarrow$ number of training instances
$a \leftarrow$ number of features (i.e. attributes)
Parameter: $m \leftarrow$ number of random training instances out of n used to update W

initialize all feature weights $W[A] := 0.0$
for i:=1 **to** m **do**
randomly select a 'target' instance R_i
find a nearest hit 'H' and nearest miss 'M' (instances)
for A:= 1 **to** a **do**
$W[A] := W[A] - diff(A, R_i, H)/m + diff(A, R_i, M)/m$
end for
end for
return the vector W of feature scores that estimate the quality of features

Figure 1: Pseudo-code for the original Relief algorithm (source: Urbanowicz, R.J et al., 2018)

Their study evaluated various feature selection techniques and measured the stability. ReliefF was shown to be most stable and achieves the best classification performance. It is the most used Relief-based algorithm, and the 'F' in ReliefF refers to the sixth algorithm variation (from A to F) proposed by Kononenko (1994). Visalakshi and Radha (2014), evaluates different feature selection techniques and their performance measures in various datasets and shows that feature selection improves the performance. According to Khoshgoftaar et al. (2011) ReliefF performs best when compared with other techniques. The algorithm continues to be improved in some recent applications (Wang et al., 2016). So we find that prior studies performed in various application areas on high imbalance and high dimensionality show that sampling and feature selection techniques work best in varying scenarios and provide better classification performance. However our literature review indicates that these techniques have not been used for the COPD hospital readmission problem.

Shanab et al. (2011) evaluated various sampling and feature selection techniques. The best approach takes the original data and applies data sampling techniques. The sampled data set is then used for feature ranking, and the features with high ranks are then selected. These selected feature values from the sampled dataset are used for analysis. This approach was adopted in the current study.

The Naive Bayes implementation in this study allows the framework to be highly scalable and non-sensitive to irrelevant data. According to Bingwei et al. (2013), Naive Bayes tend to perform better when the dataset increases and suggests that Naive Bayes provides simple data fusion architecture which allows the algorithm to be flexible and elastic. In a real-world setting, newly acquired and sampled patient data can be incrementally utilized to train the model which will allows the model to be relevant over time. The model in this study was designed on a High Performance Computing Cluster (HPCC) big data platform which allows the model to be used in real-world scenarios where large number of new discharge summaries exist.

DATA AND METHODS

COPD Data

Discharge summaries and clinical notes were extracted from 191,205 hospital admissions and readmissions between 2009 and 2015 from various hospitals across the region in which the authors work. The data was gathered from a variety of care centers including but not limited to Skilled nursing facility, rehabilitation centers, independent hospitals, hospital associations, nursing homes and long-term care facilities. A variety of datasets were utilized in order to capture different styles and forms of written discharge summaries. The data was labelled with a Boolean variable (readmit) showing readmission status for all the COPD related readmissions. This study was conducted using de-identified patient health records including discharge summaries and readmit status, taken from multiple hospital EHR systems. This study and the dataset used in this study were approved by the authors’ Institutional Review Board.

Data preprocessing was used to remove special characteristics and stop words. The extracted discharge summaries were used to generate a bag-of-words from all the discharge summaries, and then a count vector was created by applying minimum document frequency (Min-df) of 0.05 and Maximum document frequency (Max-df) of 1.0. This allowed removing of corpus specific stop words and removing words that appeared too infrequently. A total of 391 distinct features were extracted from the dataset. Table 1 below shows a sample of categories of different extracted features.

Category	Count	Sample Features
Encounter Reason	58	Headache, Infection, lymphadenopathy
Location	44	Abdomen, kidney, chest
Medications	27	Creatinine, Lasix, Albuterol
Vitals	22	Vitamin, Weight, Glucose
Health History	8	Alcohol, Allergy, Smoking
Demographics	2	Female, male

Table 1: Sample Categories and Extracted Features

Model Improvement Methods

The Data Preprocessing component included two main subcomponents, Python Engine and Sampling and Feature Selection using WEKA. The Python Engine was used to create the bag-of-words for all the words in the entire discharge summary dataset. On the extracted bag-of-words, scikit-learn Python package was used to create a count vector for all words with the count of number of times a word appears in a specific instance of the discharge summary. The dataset was further filtered to reduce dimensionality and remove words that appear too infrequently and increase false positives. The filtering was done by limiting and removing the words with document frequency lower than 0.05 and resulted in a total of 391 features with a total of 191,205 instances as shown in Table 2. The dataset is also highly imbalanced with only 4.4% instances of positive class in the original dataset.

The filtered dataset was still highly imbalanced and with high dimensionality. This was resolved by implementing the Random Under sampling technique and ReliefF Feature Selection technique based on the discussions in Literature Review section. The Random Under-sampling was implemented using WEKA and three different under sampled datasets were created by changing the distribution spread between majority (negative) and minority (positive) cases or classes. Table 2 shows how the distribution spread was used to Randomly Under-sample the majority class and reduce imbalance in the dataset.

Dataset	# of Instances	# Positive Class	# Negative Class	%Positive	# Features
No Sampling	191,205	8204	183,001	4.4%	391
RUS (50:50)	16,408	8,204	8,204	50%	391
RUS (65:35)	23,438	8,204	15,234	35%	391
RUS (80:20)	41,020	8,204	32,816	20%	391

Table 2 Dataset description showing High Imbalance improvement with Random Under-Sampling (RUS)

For reducing the dimensionality of the data, ReliefF feature selection technique was implemented in WEKA on the four datasets (sampled and non-sampled). This technique calculates a feature score for all features based on the determination of feature value differences between nearest neighbor instance pairs. If the observed difference is between feature pairs of same class, the score decreases, but if feature pairs are from different classes, the score increases. The feature score can then be applied to rank and select top scoring features for feature selection. In this experiment, we extracted three different feature set sizes from original dataset and three datasets were extracted for each sample. For each dataset, we extracted 300 features and also used all the features, and generated multiple datasets including one dataset with no sampling and no Feature selection as shown in Table 3 in the next section.

DISCUSSION AND CONCLUSIONS

The experiments performed in this study used area under ROC (Receiver Operating Characteristic) curve, recall, and precision as performance metrics. The AUC denotes a trade-off between sensitivity and fall-out rate. The higher the value of AUC, better the classification performance. AUC is an important classification performance indicator in healthcare as it denotes higher TP (true positive) recall and lower FP (false positive) recall. This experiment also uses recall which denotes what proportion of actual positives was identified correctly [TP/(TP+FN)], where FN is false negative. This determines the positively identified actual readmission. Precision denotes what proportion of positive identifications was actually correct. This determines the correct rate of positively predicted values [TP/(TP+FP)].

Table 3 below shows mean values of all performance metrics across various distribution sizes. Based on this, it shows that the sampled datasets performed better than the base imbalanced dataset on which RUS was not implemented. Among the three sampled datasets, the dataset with distribution spread of 65:35, which is also the median distribution spread selected under this study, performed the best.

Distribution Spread using RUS	Mean AUC	Mean Precision	Mean Recall
ALL	0.54	0.90	0.50
50:50	0.56	0.71	0.49
65:35	0.56	0.88	0.60
80:20	0.54	0.85	0.60

Table 3: Mean Performance Metrics across various Distribution Spreads

Table 4 below shows the implementation of feature selection has evidently improved classification performance. The dataset with maximum number of features selected has shown highest mean performance.

Feature Selection	Mean AUC	Mean Precision	Mean Recall
No	0.54	0.90	0.50
ReliefF-300	0.57	0.91	0.59

Table 4: Mean Performance Metrics for Feature set size of 300

Distribution Spread using RUS	Feature Selection	Number of Features	AUC	Precision	Recall
ALL	No	ALL	0.54	0.9	0.5
50:50	No	ALL	0.56	0.89	0.46
50:50	ReliefF	300	0.6	0.91	0.64
65:35	No	ALL	0.54	0.89	0.48
65:35	ReliefF	300	0.58	0.95	0.6
80:20	No	ALL	0.55	0.89	0.45
80:20	ReliefF	300	0.54	0.88	0.53

Table 5: Performance metrics for different Distribution samples and feature sets

Table 5 above shows the results for each sampled dataset in terms of AUC, precision, and recall. Recall and precision are the most important measure as recall shows the ability of this model to identify all the relevant cases within a dataset and precision, since it identifies the proportion of data points which are flagged as relevant, as actually being relevant. The dataset with even distribution and 300 extracted features shows best precision value of 0.91 and the recall value 0.64 which is higher than the other datasets. This is a positive indicator showing that data with even distribution and feature selection implemented shows the best performance for our COPD data.

The results show that data sampling and feature selection have positively impacted the classification performance. This paper presents an empirical study of supervised classification of COPD-related hospital readmission prediction models when the dataset is highly imbalanced and has high dimensionality. We address the issues of negative impact of imbalanced and high dimensional data on classification performance. This study, to best of our knowledge, is the first to use sampling and feature selection technique, and achieve positive classification performance for COPD readmission data. Future work will include implementing the improved model in a high performing computing cluster, and develop a real time clinical decision support system.

ABSTRACT

In this paper, a service-learning integration is introduced to a newly developed Data Analytics and an existing Statistics courses. Both courses were taught in graduate levels in three terms (Spring, 2016, 2017 and 2018). The service-learning integration was made possible with local collaborations with 3 non-profit organizations. A total of 19 projects were completed by 60 graduate students (study sample). The impacts of SLPs on students learning, educational growth, civic engagement, community awareness, personal and professional growth were surveyed with a response rate of approximately 75%. Majority of the survey categories were found to be positively impacted by the SLPs, which was also supported with instructor assessment and course evaluations.

KEYWORDS: Service learning, Learning effectiveness, Statistics, Data Analytics, and Curriculum development

INTRODUCTION

Service learning (SL) is a pedagogical approach used in higher education and K12 levels which focuses on providing students a practical exposure to preferably local or global community issues where they could utilize the knowledge that they acquired in the course towards community contexts (Bringle & Hatcher, 1996). SL has long time been used and implemented in various higher education settings in various majors including social work (Lalayants, 2012), anthropology (Fletcher & Cambre, 2016), mechanical engineering (Tsang, Haneghan, Johnson, Newman, & Eck, 2001), supply chain management (Tsang et al., 2001) (Schoenherr, 2015), humanitarian logistics (Tsang et al., 2001), statistics (Anderson & Sungur, 1999; Lalayants, 2012), and at the institutional levels (Bennett, Sunderland, Bartleet, & Power, 2016).

SL aims to establish a mutually beneficial environment among the student, instructor and the non-profit. The students are expected to have practical exposure to the local community issues which fosters civic engagement as well as utilization of the theoretical knowledge in non-structured problem settings (Schoenherr, 2015). Therefore, it is a demanding educational development and growth process both from instructors' and students' perspective. The instructor needs to identify a SL partner from the local community and establish a framework which enables the local non-profit to receive technical and professional domain-specific support (e.g. statistics, procurement, staff planning, project management, etc.) from the higher education institution. In the majority of regions, local nonprofits lack the technical resources in terms of personnel (engineers, statisticians, managers, business and marketing people, etc.), budget, hardware, logistics, software, etc. to be able to carry out such projects, and in an ideal situation, the instructor and students team up with the nonprofit to fill this gap. SL can be implemented in a course in numerous ways depending on the context and scope of SL activity. For instance, students could be assigned a week-long HW or mini project with reflection after an pre-arranged visit to SL facility where they could provide assistance and then are asked for reflection on their learning. Furthermore, SL could be implemented as a semester long project which requires more intense collaboration among the students, instructor, and SL partner. This could also be termed as Project-based Service Learning (PBSL) since SL is integrated in a project-based learning structure. The students are expected to put more efforts in an organized way as a team, and are expected to be more pro-active in terms of defining the problem and working on a potential analytical solution unless the problem and data are given to them in advance by the instructor and/or the SL partner (Schoenherr, 2015).

LITERATURE REVIEW

Statistics and business analytics are among the most convenient courses where SL could be applied effectively since many community organizations have data in need of summary and analysis (Anderson & Sungur, 1999). As a matter of fact, both of the courses include learning outcomes that generally include the gaining practical knowledge of collecting, preparing, cleaning, and analyzing data from various perspectives and for various objectives. The state of art indicates that SL is beneficial to the students in many ways including students' engagement, willingness to explore nuances, and understanding of the material, enjoyment, social responsibility, and personal growth (Root & Thorme, 2002; Nordmoe, 2007; Schoenherr, 2015; Hiedemann & Jones, 2010). In contrast to many benefits, Hiedemann and Jones found that there was no statistical difference between integrating SL vs. using case study in statistics courses in terms of "mastery of course content" and " appreciation of the relevance of statistics" (Hiedemann & Jones, 2010). Even though there are many advantages of integrating SL in statistics course, these aforementioned benefits purely relies on successful integration of SL in a project-based environment where instructor, students, and the non-profit partner receives the utmost benefit from their sides (Schoenherr, 2015). Compared to statistics course, business analytics gained less attention in terms of SL in the literature. Even though previous works addressed the advantages and challenges, and effectiveness of SL in undergraduate course settings, it is important to address graduate level courses. In addition, it is also beneficial to compare statistics and business analytics courses from SL effectiveness perspective. In this study, a PBSL framework is introduced and students' perceptions of reaching learning outcomes, and other impacts of SL from civic engagement and professional growth perspectives are studied. The in investigation was focused on application of PBSL in statistics and business analytics courses that were taught at the graduate level at a mid-size higher education institution is conducted. The investigation covered both quantitative (empirical surveys, tertial data, instructor's assessment) and qualitative feedback, and results are analyzed graphically and statistically.

METHODS

At the authors' institution, service learning (SL) implementation requires an institutional process where the faculty who are interested in implementing SL are required to place an application fo SL implementation. If approved, the letter S is added to the end of the corresponding course code ID, which is also termed as S-designation. However, prior to the SL application, the instructor needs to attend the service-learning partners' speed dating event, which takes place every semester and the instructor needs to attend either the prior year or the prior semester to the term the course is to be taught. The speed dating event gathers over 50 local non-profit organizations (potential SL partners) and faculty who are interested in integrating SL into an undergraduate and/or graduate level courses. Following step-by-step procedure is employed during the deployment of PBSL in statistics and business analytics courses at the authors' institution. The courses are taught in Spring 2016, Spring 2017, and Spring, 2018 semesters to a total of 60 students, and a total of 19 Service-learning projects (SLPs) were completed.

Service-learning course development process

1. Identification of a Service-learning (SL) Partner: SL partner was identified during the interviews conducted at the Community Partner Speed Dating event hosted by the University's Service-Learning Center in the previous semesters.
2. S-designation application: S-Designation application does not require an assigned SL partner but encourages during the application phase, which takes place in the end of the 2nd month of the semester prior to the scheduled semester of the course. The S-designation application requires approval of the department chair and the program coordinator as well as the Institution's Service-Learning Center Director.
3. Service-learning integration into the Course Syllabus: The integration of SL into the courses was made as a project-based learning framework. The instructor arranged multiple online and in-person meetings with the SL partner to frame the scope and objectives of the Service-Learning Projects (SLPs).
4. Introducing SL partner to the students: The introduction of the SL partner was made in the first week and at least one representative from the SL partner was present and gave an overview about the partnering organization.
5. SL project team up: Students were asked to team up to groups whose size ranges from 2 to 4 students depending on the enrollment size (e.g. 12 students were enrolled in Spring 2018 course, which required 2 students per team, whereas 24 students were enrolled in Spring 2017, which required 3-4 students per team). The group size decision was also affected by the number of SLPs arranged with the SL partner.
6. SLP meetings and visits
7. SLP presentations and reports
8. Assessment and wrap-up

Descriptions of the Deployed SLPs

Following section introduces the descriptions of SLP deployed in Spring 2016, 2017, and 2018 semesters in 3 distinct service-learning partners.

<u>SLPs of the Data Analytics taught in Spring 2016 and Spring 2017</u>

The term project will function as the service (project-based) learning activity which will require students' participation in meetings, individual and collective work with team mates and the organization officer on a predefined problem related to organization's mission.

Definition: Service learning is defined as "Service learning is a credit-bearing, educational, experience in which students participate in an organized service activity that meets identified community needs and reflects on the service activity in such a way as to gain further understanding of course content, a broader appreciation of the discipline, and an enhanced sense of civic responsibility (Bringle & Hatcher,1995).

Justification: The service-learning experience is highly related to the course because of the following reasons: 1) Students will be collecting data about a previously defined research question that is important for the regional, national, and/or global socio-economic and environmental sustainability-related development. 2) Various data analytics methods and model validation techniques will be heavily employed in the project. 3) All in all, students will be using the acquired knowledge in the class systematically for the project and the project tasks and meetings with mentors will enable them to develop a variety of professional skill sets and disseminate the findings of the projects with the specific community through online and onsite presentations.

Reflection: Reflection is critical part of service learning. Therefore, specific attention will be paid in this course towards making sure that students are reflecting the abovementioned knowledge and skills gained this course at the end and they will utilize from now on in their personal and professional life. To do so, there will be frequent meetings between project groups and mentors where students will be asked about how they can utilize the knowledge and skills gained for the projects. So, the interactive meetings will be playing a critical role for initiating the reflection. Discussions, presentations, Q&A sessions, the project report, and the online published content will be predominantly used as the strategies for reflection.

Length of Service: The students will spend about 4 weeks and 5 hours per week on the service-learning project. Typical project steps and timeline are also included in the syllabus.

SLP Summary: In the service-learning project, students will work on cleaning, preparing the previously funded projects by Service-Learning Partner 1& 2. Service-Learning Partner 1&2 expects the project groups to figure out ways to assess their impacts on the community. They will be providing their project information and report files, which will be used by students to carry out the SLP. SLP will take about 6 weeks, in the beginning phase of the semester. A total of 25 hours will be required to conduct the literature survey about the United Nation's Climate Change and Environmental Sustainability goals and local community guides. Then, students will start creating a database of projects, and developing a method to assess the impact of the agency on the community by using data analytics methods.

SLP of the Applied Statistics, Quality, and Engineering Management taught in Spring 2018:

Assessing Community Well-being in the State of Connecticut:

Community well-being is a vital phenomenon that needs to be studied and assessed frequently to inform the policy makers and politicians about the area of improvements within local communities. In this context, Service-Learning Partner 3, a local nonprofit organization has conducted a community wellbeing survey for the last decade and recently developed a visual assessment tool. The 2016 dataset consists of 12 main variables 189 rows, which are aggregated based on state house district and chamber. The dataset can be accessed with the link given on BB. Following are main category variables given in a tabular format:

There were 12 students in class, which made up 6 groups of 2. Each group was asked to pick 1 of the main variable categories including: Community Vitality, Economic Security, Community Health: Adults, Households, Education, Income

Assessment

The total sample size of the study was 60 students (Spring 2018: 12, Spring 2017 and Spring 2016: 24 students each). The assessment focused on instructors' assessment, student evaluations of the courses, and an empirical survey that focuses on assessing the students learning effectiveness in SLP.

Empirical survey

Since the course evaluations conduct a general assessment of the course, which indirectly assesses SL, it is important to survey students to have them provide quantitative and qualitative feedback about their learning experience specific to the service-learning project. To do so, an empirical survey is developed and deployed to the students. The survey consisted of 5 sections:

1) Demographics (Self-identification, Race/ethnic heritage, Job status, and Major)
2) Community needs addressed with the SLP
3) Impact of SL on Learning and Professional Growth
4) Impact of SL on Community Awareness and Civic Engagement
5) Impact of SL on Personal and Professional Growth
6) Qualitative feedback

A Likert Scale was used to organize and standardize students' responses, which consisted of the following levels: 5: Strongly agree (SA), 4: Agree (A), 3: Neutral (N), 2: Disagree (D), 1: Strongly Disagree (SD).

Instructor assessment

The instructor assessment consisted of Service-learning Project Report, Service-learning Project Presentation, pre and post-surveys (Deployed in Data Analytics course since it was a newly developed special-topics course).

Course evaluations

Student evaluations are also used as part of assessment. Following questions are surveyed to the students enrolled in the course at the end of the enrollment term. Students were asked to provide answer over the same Likert scale used in empirical survey.

1. The objectives of the course were clear
2. The course materials (as listed on the syllabus) contributed to my learning.
3. Assignments and other graded activities gave me an opportunity to demonstrate what I learned.
4. The grading system for the course was clear.
5. The instructor was prepared for each class.
6. The instructor's presentations were understandable.
7. The instructor provided helpful feedback.
8. The instructor used class time effectively.
9. My interest in the subject matter was enhanced by the instructor's enthusiasm.
10. The instructor raised questions or problems that encouraged me to think critically.
11. The instructor explained the relevance of the subject matter.
12. The instructor established a positive learning environment.
13. The instructor was accessible outside of class (for example: held office hours, communicated via email, or offered to meet via video conferencing).
14. Overall, I was satisfied with the educational experience provided by the instructor.

RESULTS

Results are organized in parallel with the methods section. Firstly, the results of empirical survey are provided. Secondly, results of instructor's assessment are provided. Thirdly, course evaluations are shared.

Results of empirical survey

Results of the survey is explained in twofold: quantitative and qualitative feedback. In the quantitative part of the survey, demographics (self-identification, race/ethnic heritage), job status and major are given in figures 1,2, 3, and 4, respectively. Majority of the students were male and from Caucasian or Asian backgrounds. These are quite typical of engineering schools in terms of self-identification and major since majority of the graduate students are recruited from Asian countries at the Institution (see fig. 1,2). About half of the students were not actively working during the time of the assessments and a quarter of them was found to be full time employee (fig. 3). Furthermore, table 1 shows the community needs addressed with the SLPs. In this category, students could pick multiple sections as some SLPs address more than one community need. It was found that education was found to be the most frequently addressed community need with a quarter of response frequency.

<u>Quantitative assessment</u>

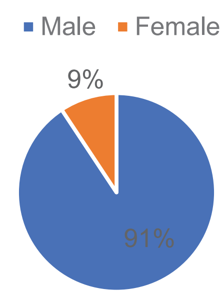

Figure 1. Self-identification (Total response: 43, Missing: 17)

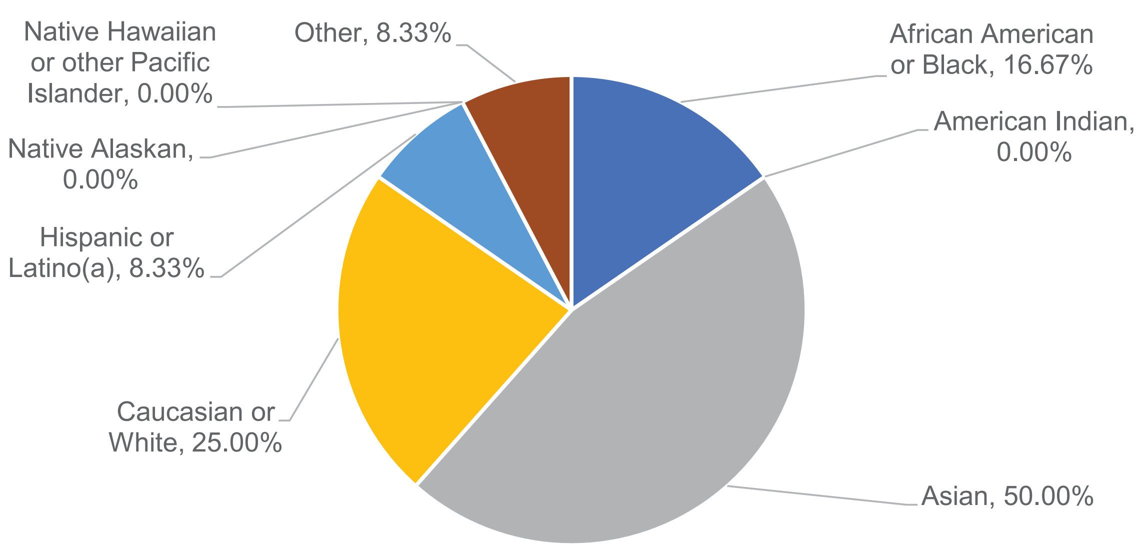

Figure 2. Race/ethnic heritage (Total response: 45, Missing: 15)

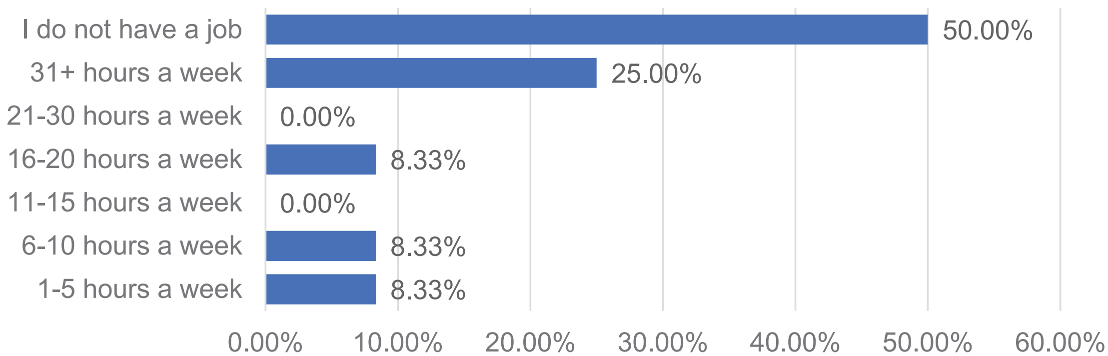

Figure 3. I have a paying job that requires me to work___ (Total response: 42, Missing: 18)

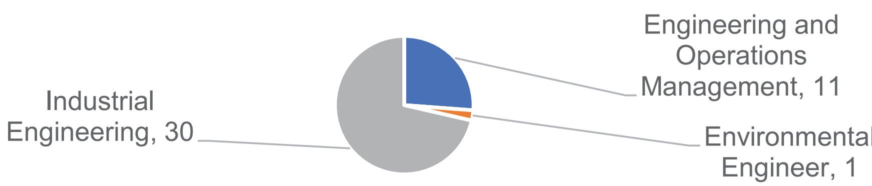

Figure 4. Major (Total response: 42, Missing: 18)

Table 1. Community Needs Addressed with the SL Experience

Community Needs Category	Responses	
Education	23.2%	23
Other	12.1%	12
Employment	9.1%	9
Youth issues	9.1%	9
Communication/Educational Outreach	8.1%	8
Financial Literacy	6.1%	6
Housing	5.1%	5
Infrastructure	5.1%	5
Environment	4.0%	4
Community Well-being	3.0%	3
Income & Economic Security	3.0%	3
Immigration	2.0%	2
Info Systems	2.0%	2
Victim Rights/ Services	2.0%	2
Community Health	2.0%	2
Disability Issues	1.0%	1
Elderly Care	1.0%	1
Mental Health	1.0%	1
Self-Image	1.0%	1
Total	100%	99

The latter section of the survey was focused on students' perception of the SL experience on a variety of categories including learning and educational growth (Table 2), community awareness and civic engagement (Table 3), personal and professional growth (Table 4). In each of the tables (2,3, and 4), the share of responses on Likert scale categories (5: Strongly agree (SA), 4: Agree (A), 3: Neutral (N), 2: Disagree (D), 1: Strongly Disagree (SD)) as well as the mean response over 5 (μ). It was found that the learning and educational growth was positively impacted by the SLPs as all of the category means were found to be over 4 in Table 2. And, the highest mean score was obtained from the question, entitled "Service-learning should be implemented into more classes at the Institution", which indicates that students were in favor of SL integration in other courses after the experience.

Table 2. Impact of SL on Learning and Educational Growth

Question	SA	A	N	D	SD	μ
The community work helped me see how course material can be used in everyday life.	39.5%	53.5%	4.7%	2.3%	0.0%	4.3
The community work helped me to better understand the material from my lectures and readings.	48.8%	37.2%	7.0%	7.0%	0.0%	4.3
My community experience was directly linked to what I learned in the classroom.	37.2%	46.5%	9.3%	7.0%	0.0%	4.1
Participation in service-learning made me take more responsibility for my own learning.	53.5%	34.9%	4.7%	4.7%	2.3%	4.3
Service-learning should be implemented into more classes at the Institution	52.4%	33.3%	11.9%	4.8%	0.0%	4.4
I would like to enroll in additional service-learning courses offered through my degree program.	35.7%	40.5%	16.7%	2.4%	4.8%	4.0

Results of community awareness and civic engagement questions were provided in Table 3. Except the initial question about students' previous service-learning experience, all categories results indicate a positive impact due to the mean scores that are greater than 4. The students strongly indicate that they do have a responsibility to serve the community with a mean score of 4.5, which is a remarkable finding since about half of them did not indicate a service-learning experience previously in question 1. In general, SL experience positively impacted and contributed to the civic engagement development of the students and their awareness about community issues, which are quite essential growths expected from especially international graduate students in terms of their adaptation and sustained success at the Institution.

Table 3. Impact of SL on Community Awareness and Civic Engagement

Question	SA	A	N	D	SD	μ
I was already volunteering before this service-learning experience.	23.3%	32.6%	20.9%	16.3%	7.0%	3.5
The community work showed me how I can become more involved in my community.	41.5%	46.3%	4.9%	4.9%	2.4%	4.2
The community work I did benefit the community.	30.2%	37.2%	32.6%	0.0%	0.0%	4.0
Service-learning helped me to become more aware of community needs.	46.3%	39.0%	9.8%	2.4%	2.4%	4.2
I will continue to be involved in the community as a result of this experience.	38.1%	45.2%	11.9%	4.8%	0.0%	4.2
I have a responsibility to serve the community.	58.5%	31.7%	7.3%	2.4%	0.0%	4.5

Table 4 depicts the survey results related to personal and professional growth. Except two categories ("The community work helped me clarify and/or confirm which major I will pursue" and "The community work helped me in defining my career choice/specialization"), all categories' results positively favor the SL experience on personal and professional growth. The highest response mean was obtained from enhancing leadership skills, which is a very critical skill that graduate students are expected to develop and continuously add on during the graduate study.

Table 4. Impact of SL on Personal and Professional Growth

	SA	A	N	D	SD	μ
The community work helped me to define my personal strengths and weaknesses.	47.6%	38.1%	7.1%	2.4%	4.8%	4.2
The community work helped me clarify and/or confirm which major I will pursue.	21.4%	28.6%	40.5%	4.8%	4.8%	3.6
The community work helped me to develop my problem-solving skills.	34.1%	46.3%	12.2%	4.9%	2.4%	4.0
The community work helped me to enhance my leadership skills.	47.6%	40.5%	7.1%	2.4%	2.4%	4.3
The community work helped me in defining my career choice/specialization.	26.2%	40.5%	28.6%	2.4%	4.8%	3.9
The community work helped me to enhance my ability to communicate my ideas in a real-world context.	42.9%	42.9%	7.1%	4.8%	2.4%	4.2
The community work I accomplished in this course has made me more marketable in my chosen profession.	35.7%	45.2%	14.3%	2.4%	4.8%	4.1

Qualitative assessment

At the end of the empirical survey, students were asked to share any other comments that they have about their service-learning experience. Total of 9 comments were received. Six of the comments were positive and indicating that the student was appreciative of SL experience. One student indicated a motivation to carry out similar project in her/his home country. Another student indicated that SLP having a social aspect made it a great experience as engineer. Two of the students indicated that the SLP experience make them more aware about environmental sustainability and sustainable development. The three students who provided negative feedback about the SLP experience. One stressed that the topic was not directly related to engineering field even though the experience was rewarding. Another student stressed that having 10+ years work experience in statistics, the SLP did not enhance his/her knowledge in statistics. Another student stated the he/she did not get to use the knowledge acquired in course towards the SLP.

Instructor Assessment

The instructor assessment was focused on SLP report, SLP presentation, and the weighted total grade. The assessment results are provided in figure 5. Figure 5a indicates the SLP report for the 3 terms the SL was integrated. The first year that SLP was integrated, the course was also a special topics course (Data Analytics, in Spring 2016) and it was offered for the first time. As shown in the SLP description, the report structure asked from students was quite demanding and the project topics were not given with sufficient level of detail, since the instructor and SL partner purposely pushed students to define the problem, collect data, identify an appropriate analytics method and answer a few pre-determined research questions. This somewhat affected the students produce not very good quality reports and projects even though the experience was found to be rewarding by majority as shown in the previous section. The second year, all student teams were given the same problem with more detailed directions and raw data in agreement with the SL partner's interest, which yielded better reports and better-quality projects. However, this had the drawback of lack of diversity in project focus areas. The third year, a well-being survey data was provided from the SL partner and students worked on the same data with specific focus areas, which provided them room for creativity as well as medium-level of directions and guidelines. This yielded highest project report grades. In terms of SLP presentations, the grades were somewhat in similar range as shown in figure 5b. In terms of weighed total grades, similar trend was observed compared to the SLP reports. Over the 3 years of implementation of SLP, student grades tend to increase in terms of both mean and the range from 2016 to 2018.

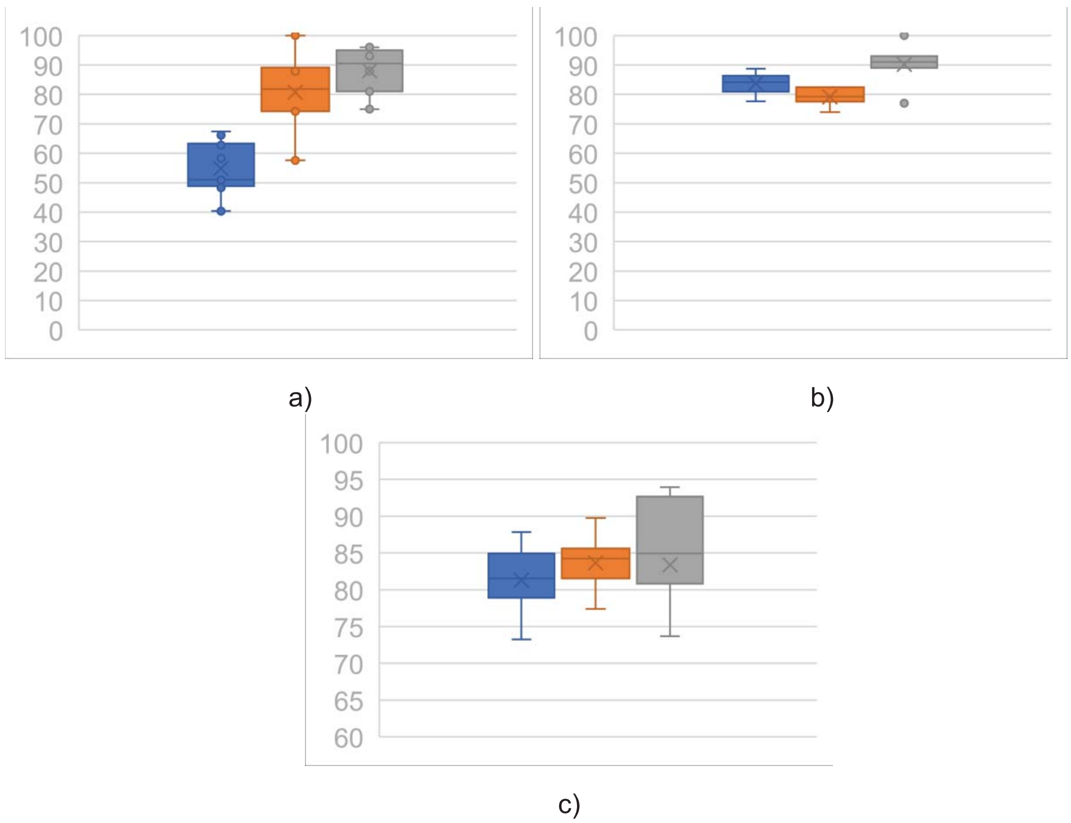

Figure 5. a) SLP Report, b) SLP Presentation (Peer-evaluation), c) Weighted Total – Course Grade (**Blue: Spring 2016**, **Orange: Spring 2017**, **Gray: Spring 2018**).

Course evaluations

In terms of the course evaluations (See figure 6), the least that could be said that the SLP did not negatively impact the course evaluations. This is important because integrating SLP into a course automatically brings challenges and complexities from both the instructor and the students' perspectives. Both stakeholders need to go out of their comfort zones to make this experience real and rewarding for each other. In all of the evaluation categories, the course was found to be positively impacting the students' learning as the mean scores were greater than 4 out of 5.

	Spring 2016		Spring 2017		Spring 2018	
Question	Mean	Std. Dev.	Mean	Std. Dev.	Mean	Std. Dev.
The objectives of the course were clear.	4.54	0.78	4.2	0.8	4.3	0.7
The course materials (as listed on the syllabus) contributed to my learning.	4.71	0.55	4.4	0.7	4.2	1.2
Assignments and other graded activities gave me an opportunity to demonstrate what I learned.	4.75	0.53	4.4	0.7	4	0.9
The grading system for the course was clear.	4.63	0.65	4.4	0.7	4.3	0.7
The instructor was prepared for each class.	4.67	0.56	4.3	0.7	4.4	0.5
The instructor's presentations were understandable.	4.62	0.72	4.3	0.7	4.3	0.5
The instructor provided helpful feedback.	4.67	0.56	4.4	0.7	4.4	0.7
The instructor used class time effectively.	4.79	0.51	4.3	0.8	4.6	0.7
My interest in the subject matter was enhanced by the instructor's enthusiasm.	4.46	0.72	4.3	0.8	4.2	0.6
The instructor raised questions or problems that encouraged me to think critically.	4.5	0.59	4.2	0.9	4.2	0.9
The instructor explained the relevance of the subject matter.	4.5	0.78	4.3	0.8	4.1	1
The instructor established a positive learning environment.	4.71	0.46	4.5	0.7	4.5	0.5
The instructor was accessible outside of class.	4.79	0.41	4.5	0.7	4.2	1
Overall, I was satisfied with the educational experience provided by the instructor.	4.71	0.69	4.4	0.7	4.2	0.8
Overall	4.63	0.62	4.4	0.7	4.3	0.8

Figure 6. Course Evaluations

DISCUSSION

Integrating service learning into a course could be very enjoyable or very frustrating experience from both the instructor's and the students' perspectives. The main reason is that there is always a degree of uncertainty since both stakeholders get to work with a 3rd stakeholder (the SL partner organization), which expects them to produce a project that will somewhat be beneficial for their operational or strategic decision-making processes. The experience is primarily dependent on the instructor's continuous enthusiasm to make the SLPs carried out throughout the semester. It generally demands a continuous and rigorous Project Management effort to organize all of the stakeholders to work for a common set of goals. This also becomes more challenging if student teams get to work on diverse set of projects.
One of the most impactful benefits of the SL experience is that students are exposed to community issues. This is specifically important for international students because such experience improves and fastens their adaptation to the country through being involved in the local community. This was also substaintially supported by the student survey responses. Their civic engagement and awareness about local community problems are heightened at the first minute of meeting with the SL partner organization. And, in SL course, this could go beyond the expectations of the SLP description in the course depending on the SL partner's mission and vision. Some student teams presentations went beyond the expectations and it was very rewarding to see them advocating and promoting solutions for community problems. This was also seconded by the 2nd SL partner representative as she was quite impressed with the presentations.

The lessons learned from this experience indicate that it is very crucial to find a SL partner who will support the students and instructor towards to SLP goals throughout the semester. If the SL partner did not take some of the heavy lifting in the Project Management, the instructor ends up being the solo go-to person, which cause the students' experience a limited exposure to the SL partner organization, through the instructor. This could be alleviated by producing a well-structured and detailed project charter with the SL partner prior to the semester. Furthermore, not all students will be willing to go out of their comfort zone and they would like to continue just doing the coursework and attending the lectures. In this regard, it is very important responsibility of instructor to enthusiastically promote the SLPs and invite the SL partner representative to the first lecture of the semester to have an effective kick off. In person meetings with the SL partners significantly improves the students' engagement with SLPs and with the course too.

CONCLUSIONS, LIMITATIONS, AND FUTURE WORK

In this paper, SLP integration into Statistics and Data Analytics courses at the graduate level is introduced. Three distinct SL organizations were partnered with in Spring 2016, Spring 2017, and Spring 2018 semesters. The study sample included 60 students and 19 SLPs were completed in three terms. The SL integration process was explained as a roadmap with the DSI community. The impacts of SLPs on students learning, educational growth, civic engagement, community awareness, personal and professional growth were surveyed with a response rate of approximately 75%. Majority of the survey categories were found to be positively impacted by the SLPs, which was also supported with instructor assessment and course evaluations. This study has the following limitations. First of all, the newly proposed Data Analytics course was elective even though the Statistics course was a mandatory course for the students. Elective courses tend to create selection bias (Anderson & Sungur, 1999). The impact of selection bias could be minimized by relying on a sample who took mandatory courses, in this case Statistics course. The author(s) plan to continue integrating SL into Fall 2019 and Fall 2020 Statistics courses, which will yield an increased sample size with no selection bias, and this is left as future work. Moreover, a comparative analysis was left as future work with the other sections of the statistics course since a recent work did not find a statistically significant difference between SLPs and Case-study based approaches in terms of "mastery of course content" and " appreciation of the relevance of statistics" (Hiedemann & Jones, 2010). However, this study did not address the main benefits of SL, which are civic engagement and community awareness which are as much essential as the course learning outcomes. Therefore, the author(s) will collect more data in Fall 2019 and 2020 to conduct a comparative analysis, which is also left as a future work.

ABSTRACT

Due to the low rate of mobile financial services (MFS) adoption, this research accesses the trust and risk factors at multidimensional level regarding MFS, using the integrated structural equation modeling-TOPSIS based on the survey data collected in Togo to offer new insights.
The results show particularly strong support for the dispositional trust and perceived privacy risk. Trust has a negative relationship with perceived risk, which finding was limited partly. For the MFS perspective, mobile money transfer (MMT) remains the core application used, followed by mobile payment (MP) and mobile banking (MB). The implications, limitations, and future research are provided.

KEYWORDS: Mobile financial services (MFS); Trust; Perceived risk; Structural equation modeling (SEM); Technique for order preference by similarity to ideal solution (TOPSIS)

1. INTRODUCTION

Innovations and technological expansion have emerged with significant advantages to the recent commercial market. Over the last few years, businesses have been redirecting their goals to making information system technology an essential part of their processes (Oliveira, Faria, Thomas, & Popovič, 2014). Therefore, more and more literature is diverted to the IS-related field (Agarwal & Prasad, 1999). The investigation of some existing studies which recommend integrating various theoretical models to understand the IT adoption has stressed that a comprehensive analysis in the context is required (Afshan, Sharif, Waseem, & Frooghi, 2018; Oliveira et al., 2014). From these perspectives, an increasing number of researchers are focused on the mobile financial services (MFS) considered as the development of IS domain (Abrahão, Moriguchi, & Andrade, 2016; Al-Jabri & Sohail, 2012; Gbongli, Dumor, & Kissi Mireku, 2016; Muñoz-Leiva, Climent-Climent, & Liébana-Cabanillas, 2017).

MFS refers to any financial transaction remotely conducted by the application of a mobile phone (e.g., smartphone or tablet) and mobile software (e.g., apps programs) either through banking service or network provider service (Gbongli, 2017; Yen & Wu, 2016). MFS providers allow their consumers the flexibility to access their financial services (access information inquiry, bill payment, and money transfers) anywhere and anytime via a mobile phone, to support and improve service relationships by investing lots of resources using wireless internet technology (Gartner, 2004; H. F. Lin, 2011; Scornavacca & Hoehle, 2007).

The studies of MFS that focused on e-money transfer fall into three major mobile technologies-related fields of study, primarily mobile banking (MB), mobile payment (MP), and mobile money transfer (MMT) (Gbongli, 2017). MB is among the latest in a sequence of new mobile technological wonders (Mohammadi, 2015). Therefore, it is expected to have a significant impact on the market (Safeena,Rahmath; Date,Hema;Kammani, Abdullaj; Hundewale, 2012). Payment today has now progressed to mobile devices (m-devices) identified as mobile financial services, particularly mobile payment (Ooi & Tan, 2016). M-payment denotes any payment in which a mobile device is used to initiate, authorize, and confirm a commercial transaction (Srivastava, Chandra, & Theng, 2010). Furthermore, mobile money has appeared as a significant innovation with a potential expansion to financial inclusion in developing countries in various ways (Gbongli, Xu, & Amedjonekou, 2019). It is, therefore, growing access to financial services for a large number of people, who are completely ignored by banks because of longer travel distances or lacking funds to meet the minimum deposit recommended to open a bank account (Jack, Ray, & Suri, 2013; Kikulwe, Fischer, & Qaim, 2014), low income population in developing countries (J. Anderson, 2010), insofar, as it has several advantages (Assadi，D. & Cudi，A, 2011; Chaix，Laetitia & Torre，Dominique, 2015; Gbongli et al., 2019). In addition to the advantages granted to certain persons and companies, there are also advantages at the national economy level, primarily in emerging economies such as Hungary. The use of increasingly more accommodating tools may incentivize the suppressed use of cash, parallel to which, the countability of economic performance with statistical instruments continues to improve; meanwhile tax payment discipline also improves and the total social cost of payments decreases, etc., that is, overall the economy begins to whiten, leading to improved competitiveness (MNB, 2019).

While tremendous benefits are associated with adopting MFS as opposed to traditional payment methods, such as physical exchanges notes, cheques, coins (J. Anderson, 2010), the adoption rate is far from full utilization in many developing countries. This is characteristically the situation of West African Countries and particularly Togo. Rendering to the Statista Portal (2016), the number of smartphone users worldwide is predicted to be over five billion marks in 2019. Approximately 67% of the Togolese population subscribed to the handphone in 2015, and the number of mobile internet users doubled between 2014 and 2015. However, the banking rate in Togo is less than 15% (Couchoro, 2016) and, the rate of consumer’s acceptance of mobile banking remains lower than expected, i.e., 1% (Financial Afrik, 2015). It is therefore coherent to merely guess that mobile money should offer a significant input to grow the rate of MFS usages. In reality, this is far from being the case. The experiences of more developed countries also suggest the same, not technological limitations were the primary obstacle of the extension of the innovative payment solutions (Divéki, Keszy-Harmath, & Helmeczi, 2010). Therefore, the motives for the success or failure together with the causes and reasons for mobile money acceptance, are still not understood sufficiently, which infers that the technology has not been extensively adopted. These trends recommend that significant growth opportunities remain, leading to predictions of potentially massive rises in the number of m-banking users. Furthermore, it enables a partial knowledge regarding the motivators and inhibitors that impact the acceptance of this mobile service, which supports the limited studies that have been conducted in this field (Hassan Hosseini, Fatemifar, & Rahimzadeh, 2015).

Understanding why it is worth it to select to use MFS can help in strategy development and allow businesses to effectively communicate benefits to their customers (Johnson, Kiser, Washington, & Torres, 2018; Liébana-Cabanillas, Sánchez-Fernández, & Muñoz-Leiva, 2014). Mobile financial service operators could increase their competitiveness if they were able to enhance their performance in meeting consumer demand. Therefore, they need to understand the requirements of MFS users and the relative weight of each factor that affects consumers' needs. One possible motive for the existence of a gap between these could be the perception of risk that limits consumers’ ability to make informed decisions to partake the advantage of MFS technology in Togo (Gbongli, Csordas, & Kissi Mireku, 2017). This is particularly true for emerging nations, mainly in an unstable country where the consideration of risk and loss of privacy in the security system played a crucial part in adopting IT (Gbongli, Peng, & Ackah, 2016). Users are concerned about whether service providers correctly gather, store, and use their financial and private information. Moreover, the studies in the past revealed that once there are risk issue concerns, the demand for trust becomes a necessity, since trust and risk are interrelated facets (Gbongli et al., 2017; Mayer, Davis, & Schoorman, 1995). Not only the developing countries facing the issue of e-business but also the reflection of the online risk has called for a considerable attention amongst developed countries like Hungary, particularly in 2014 when the case of fraud risk in electronic payment transactions ascended in Hungary (the case was discussed in the work of Kovács & David (2016) in detail).

Driven by studies towards the multiple dimensionalities for risk and trust and the central research on trust in contrast to risk in new IT perspective (David Gefen, Benbasat, & Pavlou, 2008), we suppose that initiating research into novel IT artifacts like this study could enlighten how trust and perceived risk might affect the ultimate adoption of innovative technologies in developing countries.

The goal of this study is to disclose mechanisms related to behavior associated with MFS adoption and sustainable development when decision making involves multiple criteria issues. One main research question is to understand how multi-dimensional trust and multi-faceted perceived risk perceptions affect a new emerging information technology such as MFS adoption at the individual level in an unstable country. Our approach differs from most prior studies that assess trust and risk perception of individual behavior. Indeed, most of the research that investigated the adoption and use of communicative technology has been done within highly-developed, stable, capitalist societies. Moreover, the majority of research assumes that individuals have freedom of speech, basic protection, and safety of their lives and business offered by the government. However, little has been known regarding the adoption of IT in emerging, and dynamic societies (Goodman, 2011; Marett, Pearson, Pearson, & Bergiel, 2015; Wells, Campbell, Valacich, & Featherman, 2010). The Fund for Peace identifies 31 countries around the globe that fall into a high-warning context based on different pressures they face that impact their fragilities, such as security apparatus, group grievance, human rights and the rule of law, deteriorating government, poverty, and social indicators. Therefore, we explore the fundamental trust and risk allied with MFS technology usage in high poverty.

The majority of prior research typically tests trust as a single construct (Alsaad, Mohamad, & Ismail, 2017; Gao & Waechter, 2017; K. C. Lee & Chung, 2009) or investigates trust constructs and risk dimensions disjointedly (Johnson et al., 2018; Lowry, 2008). In other words, how to effectively assess trust and risk concerns concurrently remains a black box. Drawing on research in Information Technology (Luo, Li, Zhang, & Shim, 2010; Park & Tussyadiah, 2017), we stress that multi-dimensional trust and perceived risk concepts may jointly play an integral part in individual behavior with regard to adopting a novel MFS, and it is of paramount importance for this to be investigated, particularly in developing countries such as Togo.

Furthermore, a plethora of research has been done in order to fully understand the factors that affect MFS adoption and their significance. However, most earlier research in this area has emphasized the general factors regarding the adoption of MFS, using explanatory statistical analysis as the research method (Aktepe, Ersöz, & Toklu, 2015; Alzahrani, Al-Karaghouli, & Weerakkody, 2018; Leida Chen, Meservy, & Gillenson, 2012; Chong, Chan, & Ooi, 2012). Although the beta coefficients gained in multiple regression analysis can be considered as the relative weights of the factors, their values are obtained indirectly through testing. Additionally, a negative value of beta can be found, making it complex to judge the importance of the resultant value (Shieh, Chang, Fu, Lin, & Chen, 2014). Making decisions has continually been an essential activity in day to day life. Therefore, using services such as MFS necessitates a careful decision from an individual so that he/she would not regret his/her decision, ever since decision-making has emerged as a mathematical science today (Figueira, Greco, & Ehrgott, 2005). From there, multiple criteria decision-making (MCDM) techniques constitute a critical framework through which companies focus on which strategy to implement to meet the needs of consumers, to acquire the appropriate income and to prosper in the competitive milieu (Valaskova, Kramarova, & Bartosova, 2015). A growing number of recent studies link MCDM to financial decision making (Gupta, Bhaskar, & Singh, 2017). In order to advance current IS researches, Esearch & Koppius (2011) stressed that there is a necessity to integrate decision modeling methods in IS research to generate data estimates as well as methods for assessing the analytical power of the result. Therefore, adopting a multi-analytic approach revealed how merging two diverse data analysis techniques in either methodology or analysis can enhance the validity and confidence in the output (Gbongli et al., 2019; Scott & Walczak, 2009).

Moreover, most managers make strategic decisions grounded in a single goal or dimension, but strategic planning is impacted by many different factors and regarded from several perspectives (Hung, Chou, & Tzeng, 2009). As the traditional notion of strategic planning lacks a multidimensional prominence, this paper integrates the structural equation modeling and technique for order preference by similarity to ideal solution (SEM-TOPSIS) method to construct the relationships between decision factors for MFS adoption strategic planning, while classifying the alternative of MFS. It is a unique decision support technique grounded in structural modeling.

The primary objectives of this research are: To explore the influential antecedent of trust and risk perception at the multidimensional level regarding MFS adoption. To propose and validate model MFS acceptance using SEM technique by employing data collected through experts of MFS and MFS experienced users. To develop an SEM-TOPSIS-based model for multi-criteria decision making by selecting the appropriate MFS type for MFS, based on experts' viewpoint and by ranking the effective trust-risk factors while uncovering the hidden relationship amongst factors that influence customers in the MFS.

As the main contribution, this study incorporates a complex multi-criteria decision-making problem by assessing types of multidimensional trust and risk in MFS that have rarely been investigated and touched in past studies. Furthermore, a literature review is conducted, and then SEM analysis is used to construct a hierarchical structure for trust and risk factors, which includes a total of ten sub-factors. According to the identified criteria and sub-criteria and by considering relationships among them, TOPSIS is adopted for selecting the appropriate types of MFS, based on the critical factors that influence customers' trust and risk. Therefore, the study proposes a solution that could effectively enhance trust and mitigation-perceived risk measures through a multi-level approach to planning strategy by using MFS.

2. LITERATURE AND THEORY REVIEW

2.1 Understanding Mobile Financial Services (MFS)

The rapid adoption of mobile devices in developing countries (Abu-Shanab & Abu-Baker, 2014), together with widespread mobile financial services, have recently drawn practitioners and academics' attention (Laukkanen, 2017). Since consumers are spending gradually more and more time online and are "going mobile", financial digitalization is now driving banks and network companies' providers to undertake the most extensive shift in their history. Mobile financial services (MFS) refers to financial services and transactions delivered through mobile devices (Donovan, 2012). Hence MFS has been described as a generic term, which entails the application of the devices in the conduct of various financial services, including mobile money, mobile credits, mobile insurance, mobile savings, mobile payments, and mobile banking (Adjei & Odei-Appiah, 2018).

MFS characterizes an area of innovation and strategic importance for global initiatives to counter poverty and mobile telecommunication providers (Nesse, Risnes, & Hallingby, 2018). It has been said to have carried about a positive shift in customers' perceptions in many countries. Mobile operators grasp MFS as an opportunity to engender revenue via an adjacent business (both basic payment and services) and recovery of cost and investments through enlarged data usage by consumers (Dennehy & Sammon, 2015). The goals of MFS are accompanied by various advantages for banks, such as the decreased use of cash, while cost-effectively serving the unbanked population, protecting current accounts and products. The major benefit of MFS regarding trade are higher Point-of-Sale (PoS) throughput, less cost for cash handling, and real-time messaging to users. Accessing transaction data and ownership of the user interface are further viewed as an important perceived valued of MFS. For the customer, MFS makes payments possible anytime, anywhere, and with the alleviated risk of theft (cash—especially in underdeveloped countries) (Nesse et al., 2018).

These advantages could be equally valid for Togo. Not much attention has been given to the empirical research on the adoption of MFS in Togo. Furthermore, in less affluent nations stricken with socio-political instability and vulnerability, MFS technologies may have different implications toward usage and are likely to impact the initial decisions to adopt (J. K. Lee & Rao, 2007; Li, Sarathy, & Xu, 2011). The country of Togo sometimes encounters a kind of socio-political crisis. Given a negative socio-political and external influence such as the physical atmosphere of development and growth, policies, regulations, and social environment unsupportive of adoption are suggested to hinder innovation adoption (Wisdom, Chor, Hoagwood, & Horwitz, 2014). MFS unavoidability might confront such challenges due to consumers' lack of trust in the novel wireless technology, and their risk perceptions associated with the open airwaves of a wireless medium. We thus stress that consumers' trust and risk perception may impact their espousal of MFS services.

2.2 Theory and past research

As an emerging service, mobile financial services (MFS) has not been widely adopted by users. Therefore, researchers have paid attention to assess the factors impacting its user adoption. Furthermore, technology adoption is one main area of focus for information systems (IS) researchers. A diversity of theoretical perspectives has been developed to study MFS adoption. More assertively towards another direction, the current literature on consumer behavior related to acceptance of IT, such as MFS, tends to elaborate on a theoretical model of technology adoption theories (Safeena, Date, Hundewale, & Kammani, 2013). They often employ the traditional information system models like theory of reasoned action (TRA), theory of planned behavior (TPB), technology acceptance model (TAM), diffusion of innovation (DOI), innovation diffusion theory (IDT) and unified theory of acceptance and use of technology (UTAUT) as the foundation of their research. They examine whether the models' theoretical constructs are likely to affect the consumer acceptance of an MFS (Gbongli et al., 2019; E. L. Slade, Williams, & Dwivedi, 2013; Tam & Oliveira, 2017; Yan & Yang, 2015) or assess whether consumers are ready to adopt m-payments grounded in the supposed factors (E. Slade, Williams, Dwivedi, & Piercy, 2015).

The TRA model stipulates that a particular behavior is directed by the individual's intention to conduct that action, which itself hinges on the attitude to behavior and subjective norms (Fishbein & Ajzen, 1975). For TPB model, the perceived behavior was added to the attitude towards behavior and subjective norms that affect both the intentions of people's perceived behavior and actual behavior (Ajzen, 1985). Past studies elucidated behavioral perception control as the degree to which one has control over launching a particular behavior as well as facing the circumstances, while the full volitional control over the behavior of interest is found limited (Barua, 2013; Yzer, 2012; Zolait, 2014). Although their finding pinpointed the internal and external factor of perceived control, as an example self-efficacy and facilitating condition, technology, and government sustenance, the utmost impact on the behavior is somehow associated with the type of the innovation. The TAM model, as the extension to the TRA and TPB models, bears a significance of perceived usefulness and perceived ease of use factor to affect actual behavior geared toward innovation (F. D. Davis, Bagozzi, & Warshaw, 1989). Based on the review of TAM literature, Marangunić & Granić (2015) revealed seven past TAM-related studies. However, the goal of these works and the various analysis techniques adopted differ. For instance, Legris, Ingham, & Collerette (2003) examine the question of whether the TAM explains actual use while Mortenson & Vidgen (2016) conducted the review of TAM studies employing the computational literature review (CLR). Moreover, TAM (F. Davis, 1989) and its extended version has been used in various online milieu to assess the adoption of consumer's online-system (Gbongli et al., 2019; David Gefen, Straub, Mack, & Distinguished, 2000; Paul A. Pavlou, 2001; Waite & Harrison, 2015).

The TRA model, however, has some drawbacks, comprising a major threat misleading between attitudes and norms because attitudes can commonly be viewed as norms and conversely. Similarly, further explanatory variables are required for TRA (Thompson, Higgins, & Howell, 1991; Webster & Martocchio, 1992). As such, TAM has then been successfully combined with TRA and TPB in parsimonious capability (Suh & Han, 2003). The theory of adoption, such as DOI theory (Rogers, 1962), is a handy systemic background to define either adoption or non-adoption of new technology. The theory put forward is that people will be more likely to accept innovation grounded in the innovation facets and appearance of comparative benefit, compatibility, intricacy, trialability, and observability (Plouffe, Vandenbosch, & Hulland, 2001). Regardless of the enlightened strength of this model, the weaknesses go a long way in decreasing its power. For instance, the relationship between attitude and espousal or rejection of innovation was restricted (Lei da Chen, Gillenson, & Sherrell, 2002; Karahanna, Straub, Chervany, & Karahanna, 1999); the innovation-decision process and the features of innovation remain unclear as well. The theory posits technology to pass via a linear stage; however, an intricate technology (Lyytinen & Damsgaard, 2001) has been perceived not on linear stages. Rendering to the critical review and meta-analysis of TAM (Legris et al., 2003), it was suggested as a useful model; although, it suffers from the trade-off of dropping information richness resulted from the investigation (Napaporn, 2007).

Despite the various advantages that might be incorporated into every theory or model, their competency in predicting and elucidating is due to the degree to which the predictor could get a sound proportion of variance explained in intention and usage behavior (Singleton, Straits, & Straits, 1993; Taylor & Todd, 1995). Even though the prevailing models, are indicative of e-service or MFS acceptance behavior, many researchers believe that they are not sufficiently robust with regard to assessing all the aspects clients intend obviously throughout the various phases of their decision-making process and thus require further integration (El-Kasheir, Ashour, & Yacout, 2009). George's findings (2004), after reviewing previous information acceptance models, revealed that trust consideration could be a major laudatory and backup for an online vendor.

It is important to recall that trust and risk are interrelated facets (Mayer et al., 1995), where the degree of importance of the situation depends on the impending outcome of risk. Given that the adoption of MFS becomes an important decision that consumers are required to make for a long-term impact, the function of risk is more likely to be vital. The extensive review of the literature revealed diverse antecedents to the adoption of mobile banking (Aboelmaged & Gebba, 2013; Alalwan, Dwivedi, & Rana, 2017; Johnson et al., 2018; Narteh, Mahmoud, & Amoh, 2017; Shaikh & Karjaluoto, 2014). Studies were carried out in both developing and developed countries; however, a limited number have been conducted in Togo (Afawubo, Agbagla, Couchoro, & Gbandi, 2017; Gbongli, Dumor, et al., 2016). These outcomes are therefore insufficient to offer meaningful insights into predicting which multi-dimensional trust and risk influence customers' use of MFS in Togo while providing a strategy decision analysis framework for understanding the multiple factors that entail to the decision of the acceptance. Moreover, many of these theories and models were used in developed countries, and their direct application in developing countries such as Togo might not be sufficiently robust for the economic situation of the country. Given that MFS belongs to information technology to which some adoption model might exist, it requires a distinctive conceptualization that might better pronounce the fact in emerging's countries situation.

Regarding these ends, this study uses components from both trust and risk dimensionality literature and proposes conceptual research to envisage consumer appraisal of MFS (mobile banking, mobile payment, and mobile money transfer) adoption in Togo while ranking their perspective.

3. THEORETICAL FRAMEWORK AND HYPOTHESES

3.1 Antecedent of Trust

The concept of trust remains an intricate, multi-dimensional, and context-dependent paradigm (David Gefen & Straub, 2003). Past researchers emphasize the diverse aspects of trust, a fact which frequently leads to discrepancies between numerous studies outcomes. After the appeal from Gefen et al. (2008) for additional new IT-related research on trust, there is a need to collectively assess the most crucial trust's dimension such as a disposition to trust, technology trust, and vendor trust that seems to impact MFS.

Some scholars have proposed trust dispositional, trust belief, structural assurance (Mcknight & Chervany, 2001). From others' point of view, the interpersonal trust, the dispositional trust, and institutional trust are also essential constituents of the trust dimension (F. B. Tan & Sutherland, 2004). Others found the dimension of trust to be trusting behavior, dispositional to trust, and institution-based trust (Vidotto, Massidda, Noventa, & Vicentini, 2012). Disposition to trust denotes the general susceptibility for a person to trust others (Nor & Pearson, 2008). It is grounded in the personality, which explains the reason why some of us have a tendency to either trust or mistrust and doubt others (Hallikainen & Laukkanen, 2018; Schoorman, Mayer, & Davis, 2007). Disposition to trust is, therefore, crucial for the establishment of initial trust and subsequently accommodating to less importance in the presence of pre-existed trust belief (David Gefen, Karahanna, & Straub, 2003).

Technology Trust is considered as an antecedent of trust and connotes the readiness of an individual, or individual's technological dependency, to achieve a designated task by the positive feature incorporated in the technology (Mcknight, Carter, & Thatcher, 2011) and the benefit arises from the particular technology (Muir & Moray, 1996). With this view, Technology Trust refers to the role of technology in building a trusting relationship with the user (Misiolek, Zakaria, & Zhang, 2002). From the above perspective, when an MFS user considers the technologies that are being applied to be reliable and consistent, then the probability to assess the aggregate service seems more promising, and trust will increase. Although admitting that the threefold technology aspect affects the environment of MFS (i.e., website, network, and mobile technology), the present study intends to treat them as a whole without separating them. As such, the user or potential user is called upon the strong level of comprehensive understanding purposively for MFS optimum usage. Past research has revealed much importance and many benefits of the technological trust to the behavioral field of application (Lankton, Harrison McKnight, Wright, & Thatcher, 2016; Mcknight et al., 2011; Meng, Min, & Li, 2008; Min, Meng, & Zhong, 2008).

Vendor Trust denotes the extent to which the consumer sees and believes that the vendor will accomplish the designated transactional requirements in risky or ambiguous conditions (Bailey, Gurak, & Konstan, 2002). Many situations can raise consumer's trust toward the vendor. An online consumer who perceives the vendor in presenting an opportunistic behavior can create a kind of reluctance within that particular consumer. Earlier studies have revealed a negative relationship between the online vendor's opportunism and online consumer's trust (Paul A Pavlou, Liang, & Xue, 2007). Trust, and in specific the confidence in the mobile vendor, plays an exceptionally important role in the digital environment (Liu, Min, & Ji, 2009; Nilashi, Ibrahim, Reza Mirabi, Ebrahimi, & Zare, 2015; S. Yang, 2016; S. Yang, Chen, & Wei, 2015). For Roger C. Mayer et al. (1995), vendor ability, integrity, and benevolence are crucial vendor trust features, although ability can also be regarded as vendor competence (Bhattacherjee, 2002). By relating that logic to the MFS environment, vendors with a good reputation/integrity will be less expected to bear unscrupulous behaviors and threaten their status. As a result, we posit the succeeding three assumptions to inspect the causal effect relationships between trust's antecedents and trust in the MFS perspective.

H1. Dispositional trust would significantly influence users' trust in using MFS.
H2. Technological trust would significantly influence users' trust in using MFS
H3. Vendor trust would significantly influence users' trust in using MFS.

3.2 Antecedent of Perceived Risk

Perceived risk can denote a combination of uncertainty added to the severity of consequence involved (Bauer, 1960). It is similarly taught as a kind of uncertainty and outcomes (S. M. Cunningham, 1967). In the psychological field, perceived risk is the emotional sensitivity and subjective thoughts of various objective risks. Although it is the derivative of the objectives risk, nevertheless they are different from each. From the perceptive of trust-risk relationship, prior researchers understood that the readiness to take risks is a general characteristic of all trust circumstances (Costigan, Ilter, & Berman, 1998; Gbongli et al., 2017; Johnson-George & Swap, 1982). From this point, consumer trust could be noticed and subjected to the degree of the intricate risk presented in the situations (Koller, 1988). Awkwardly perhaps, due to the complex nature of trust and risk variable, countless scholars have disregarded the function of risk perceptions (D. Gefen, Srinivasan Rao, & Tractinsky, 2003). E-commerce trust investigators have shown that, when trust increases, the trustee's perception of risk reduces and impacts their attitudes to the trustor, which successively, influences the readiness to procurement (Jarvenpaa, Tractinsky, & Vitale, 2000). In the view of risk management field, the risk is the construct associated with the cost of outcomes, empowering trust and risk as mirror images while both incorporate differing relationships (Grandison & Sloman, 2000). The study focuses on the rapport amongst trust and risk (D. Gefen et al., 2003), and the trust-related works and empirical confirmation predominantly emphasis on industrial relationships, nonetheless theoretical and empirical support encountered in MFS is limited. When people trust others, they believe that those they trust will act as anticipated, which diminishes the intricacy of the interaction. Understanding the high convolution of the relationship between trust and risk concept, and considering likewise the absence of scholarly unanimity that lack on how to account their relationship via model (Johnston, Allen C. Warkentin, 2004), this study takes the view of a mediating relationship (D. Gefen et al., 2003) instead. On the mediating standpoint, if trust exists, then the risk perceived is reduced, which successively will impact the degree of decision-making to use MFS. Consequently, trust mitigates the perceived risk effect (Lewis & Weigert, 1985; Luhmann, 1979; Mayer et al., 1995).

These ideas of risk and others will endure a detrimental dominance on the acceptance of MFS. For instance, Swaminathan et al. (1999) revealed consumers' opposition to providing their credit card information through the Internet. With MFS, the consumers are required to entrust not only their credit card information but a whole account of information in most cases. Wide-ranging, trust ameliorates the consumer's conception towards online service and the related component, diminishing the level of the risk perception allied with the transaction process.

From the attribute of risk opinion, a plethora of researchers brought that studies on consumer's risk perception are a kind of a multi-facet concept (Featherman & Pavlou, 2003; Gbongli et al., 2017; Luo et al., 2010), which becomes the root of the aggregate perceived risk.

To date, perceived risk has been employed to elucidate both offline and online risk shopping behavior. The finding derived from the work of Featherman and Pavlou (2003) on the consumer's adoption of e-services has been widely accepted which classified perceived risk dimension as an economic risk, social risk, time risk, functional risk, psychological risk, and privacy risk. Bellman et al. (1999) informed regarding the prominence of time concerns and argued that it is a substantial predictor of online buying behavior. According to the finding, consumers in a hurry who have less time are more plausible to buy on the internet. The perception of time risk can refer to the integration of time lost and determination expended in acquiring any item and service (Murray & Schlacter, 1990). Grounded in this similar logic, the current study proposes that consumers are time-oriented, time-conscious, and therefore value the potential time they might spend in implementing, searching and learning the application process of the new MFS.

Security/privacy risk is categorized as an inherent loss undeviatingly to fraud or hacktivist haggling the security of the user of an online service (M. C. Lee, 2008). Security or privacy issues mostly arise when a customer is transferring money from his/her account or dealing with his/her secluded economic information, and where others view this information without his/her consent (Littler & Melanthiou, 2006). The perception of costs applied to the MFS application reveals fear amongst consumers. Empirical evidence stressed that mobile banking adoption is highly sustained by economic aspects such as beneficial transaction service fees (A. S. Yang, 2009). Alternatively, it is impeded by economic considerations (issues centered on basic fees for assessing mobile banking), like cost burden (Cruz, Neto, Muñoz-Gallego, & Laukkanen, 2010) or high payment incorporated in using mobile banking (Yao & Zhong, 2011). Therefore, the perception of cost risk tends to negate the adoption of mobile banking (Luarn & Lin, 2005).

Centered on the work of Featherman and Pavlou (2003) predominantly, and throughout the previous studies towards risk components so far; the present study deduces four important dimensions of risk perceived, which are expected to influence the consumer's overall risk concerning the MFS adoption. They are the perceived privacy risk, time, security, and financial risk in the form cost perceived. Hence, we can posit the following assumption based on the discussion being done under this section.

H4. Consumer's trust would negatively associate with the perceived risk in MFS.
H5. Perceived privacy risk would significantly influence users' perceived risk of using MFS
H6. Perceived time risk would significantly influence users' perceived risk of using MFS
H7. Perceived security risk would significantly influence users' perceived risk of using MFS
H8. The cost perceived would significantly influence users' perceived risk of using MFS

3. 3 Antecedents of MFS Adoption

Under this section, three antecedents (dispositional trust, trust, perceived risk) of MFS adoption will be taken into consideration. Being part of a personality trait, a disposition to trust can denote an individual's predilection to show reliance on humanity and to support a trusting standpoint concerning others (McKnight, Choudhury, & Kacmar, 2002; McKnight, Cummings, & Chervany, 1998). Many researchers hypothesize the disposition to trust as partaking a positive impact on trust towards online shopping websites (McKnight et al., 2002). This relationship was also supported in various IS research, particularly in e-commerce (David Gefen, 2000; David Gefen & Straub, 2003; K. K. Kim & Prabhakar, 2004) and moreover in mobile banking (Guangming & Yuzhong, 2011). Accordingly, David Gefen et al. (2003) pointed out that disposition to trust is crucial, particularly for the development of early trust and befits less significant for established trust or pre-existing relationships trust beliefs. Once encountering people with trifling or no experience using the wireless internet as a platform for financial transactions, a disposition to trust is predictable to affect their trusting perception on the internet. People partaking high disposition to trust are more favorable to feel relaxed or secured when using wireless internet for financial transactions (Luo et al., 2010). Inferring from this lucidity to the MFS, we expect that consumers having a higher disposition to trust are more probable to espouse MFS than those with a lower disposition to trust.

Taking the antecedent of MFS from a different angle, the importance of trust has been revealed to be an extensive subject matter. Trust, combined with the previous definitions so far, denotes the readiness of one party to be exposed to the actions of another party deal with the hope that the other will accomplish the designated task needed to the trustor (Mayer et al., 1995). The empirical findings of Jarvenpaa and Tractinsky (1999) revealed the trust element to influence the decision to purchase in various manifold cultures. The prominence of trust is so decisive that it may be extended to be viewed as the “wild wild west” of the 21st century (McKnight et al., 2002). The more MFS users or potential users believe and trust the services, the more they can develop an affirmative goal for its usage. User trust, which has been revealed to be an important adoption facilitator in many IS environments, lacks adequate inspection in the context of MFS as a whole.

The next antecedent of MFS adoption resides in risk perception. Since its application amongst consumer behavior literature (Bauer, 1960), the conception of perceived risk has been reviewed from a multiplicity of viewpoints. The classical decision concept considers risk perception as a function of the distribution of probable outcomes of conduct, its likelihoods, and subjective values (Pratt, 1964). Accordingly, risk encompasses two dimensions: uncertainty and outcome where there is the possibility of experiencing a loss as a consequence of a behavior and the significance accredited to the loss (Cox, 1967; Kogan & Wallach, 1964). While various researchers have criticized this approach due to its strictness to apprehend a perceived risk variable equally to be ambiguous and indistinct (Sjoberg, 1980), some others were heightened to this concept definition as expected utility theory (Bonoma & Johnston, 1979; Currim & Sarin, 1983). Explicitly risk, therefore, carries on the subjectively driven expectancy of loss by the customer when denoting the perceived risk (L. F. Cunningham, Gerlach, Harper, & Young, 2005). Internet banking and MFS, predominantly mobile banking, rely on a similar type of risk (M. S. Y. Lee, McGoldrick, Keeling, & Doherty, 2003), only, the information media channels differ. Prior IS studies showed that the imperative attitudinal of perceived risks impact adoption behavior where much is based on the privacy risk and transaction security risk (Abrahão et al., 2016; K. K. Kim & Prabhakar, 2000; Laforet & Li, 2005; E. Lee, Kwon, & Schumann, 2005; M. Tan & Teo, 2000). Preceding studies have equally supported the negative effect of the perceived risk of online usage and purchasing behavior (D. J. Kim, Ferrin, & Rao, 2008; Liang & Huang, 1998; Liao & Cheung, 2001; P.A. Pavlou, 2003). Likewise, earlier researchers agreed that the more risk is perceived by someone in purchasing context, the less probable he/she will be resolved to buy (Dowling & Staelin, 1994).

Furthermore, the level of personal participation in the decision-making process exposes the degree of risk perceived combined with the significance attributed to the choice of the object while allowing for the desires, interest and personal values of the individuals (Assael, 1998; Coulter, Price, & Feick, 2003). Based on the perception of risk assigned in past works as the main inhibitor elements of various IS arena; similarly, it is expected to affect the acceptance of MFS negatively. In line with the literature allied with the antecedent of adoption of MFS in this study, we can, therefore, posit as follows:

H9. Disposition to trust would have a positive effect on individual’ espousal of MFS.

H10. User trust will positively influence an individual’s acceptance to use MFS.

H 11. User risk perception in MFS would have a negative impact on the adoption of MFS.

3. 4 Conceptual Framework

To assess how trust and risk perceptions at the multidimensional level affect mobile financial services (MFS) acceptance in Togo, we propose a research model, as shown in Figure 1. The proposed model is used to identify several attributes as predictors of MFS. Based on the above discussion related to the suggested hypotheses, we considered three antecedents for the general trust (dispositional trust, technology trust, and vendor trust), four antecedents for the aggregate perceived risk (privacy risk, time risk, security risk, and cost).

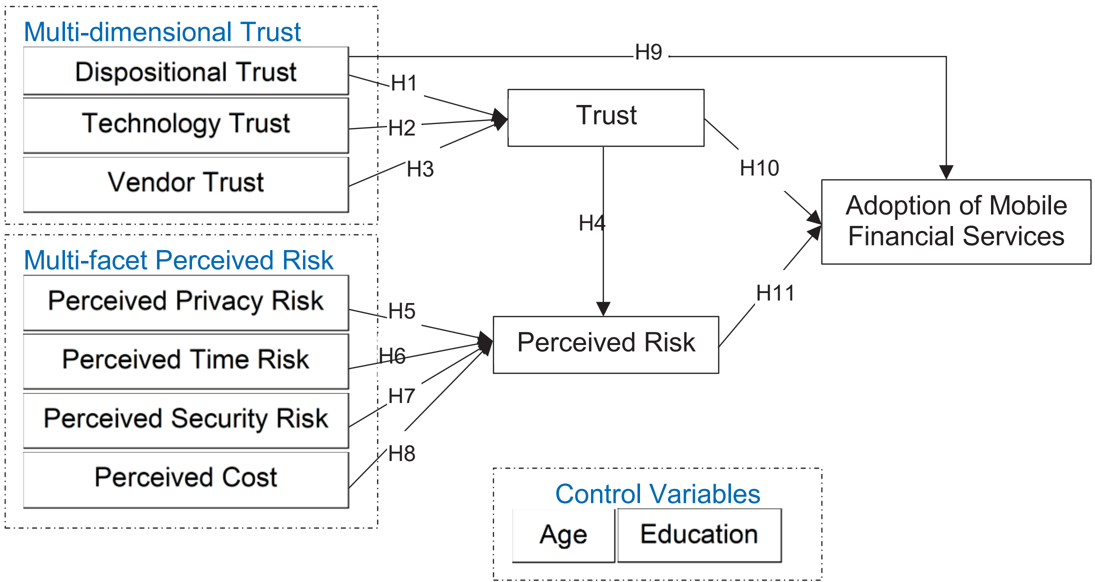

Figure 1. Proposed research model.

4 RESEARCH METHODOLOGY

4.1 Design and Data Collection

Various schools of thought questioned how data collected would be executed as well as the content of the studies. Amongst them, Cooper & Schindler (2003) have suggested two approaches of scrutinizing issues: One technique called observational approach is to gather data on people, event, situations, and behavior; while the next one, the so-called communication approach, has considered the attitudes, expectations intentions, and motivator aspect.

This research, as a result, used data collection via communication approach taking a form of the survey since the motive of the study turns to capture the influential factor of MFS adoption once testing the research model. A survey instrument was then established for indicators and criteria development, which primarily got ratified after revising the suitability of the constructs by the chosen experts of MFS. The preliminary draft of the questionnaire was prepared in English then translated into French (the official language of Togo) for its assessment as well. Both questionnaires in English and French have been retained as to avoid any confusion related to the scope, purpose, and content; so far, allowing the comparison of the versions for discrepancies concerns, steadfastness to be easily acknowledged and established. Following the advice and the opinion from the experts, redundant and confusing items were either improved or removed. As a result, new items were included in the questionnaire lastly, permitting the validity of the survey instrument employed. The research model embodies ten factors; each factor remains evaluated with multiple items. Also, all item were accommodated from existent literature to increase content validity (Straub, DetmarBoudreau & Gefen, 2004). There were two types of questionnaire. The first type (SEM questionnaire) was divided into two parts. The first part was distributed with bio-data of the sample, and the second part answered the MFS questions using the five-point Likert scale bounded from strongly disagree (1) to strongly agree (5).

For the second type of questionnaire (TOPSIS questionnaire), we arbitrarily contacted users and potential users and questioned them whether they had mobile MFS usage experience to ensure their familiarity to some extent as recommended (Gbongli, 2016, 2017). Thus, those with two or more MFS experience years were further invited to fill the TOPSIS questionnaire format.

The empirical study took almost three months of the span for data collection due to the delay in obtaining some participants' responses and an awkward time-period indicated by some of them. Data were collected at some of the busiest and most crowded places of the capital town Lomé (i.e., Assivito, Dekon, Be, and Université de Lomé) where potential users and currents users of mobile financial services (MFS) can relatively be found and inspected better than in other sectors. Literate people filled in their survey questionnaires themselves, whereas for illiterates, help was given. The questionnaire took almost 10–15 minutes to complete by a given participant.

Once the data collection procedure was completed, we examined all questionnaires and discarded cases with too many missing and or rushed responses.

As such, 538 questionnaires were both ready and yielded usable samples. Amongst them, 294(54.6%) were male and 244(45.4%) female. Seventy-five (13.9 %) respondents were aged below 18 years, 145(27%) aged between 19-24 years, 199 (37%) aged between 25-30 years, and 119(22.1%) aged above 31 years. Regarding educational qualifications, the majority of respondents (two hundred and sixty-seven) had a high school certificate or below, i.e., Baccalaureate (49.6%), 203(37.7%) had a graduate degree, while 57(10.6%) had a master degree. The remaining (2%) had a doctorate. Concerning MFS years of experiences, 187(34.8%) of respondents claimed to have no experience with MFS, 194(36.1%) used it for less than one year, 125(23.2%) MFS usage ranged from the 1-2 years, 26(4.8%) were found between 3-4 years of MFS experience. Only 6(1.1%) had MFS experience for more than five years. Hence, very few respondents had MFS experience above three years from the deduction. Moreover, they are those respondents engaged in MFS application at the early stage of its implementation (Most MFS companies in Togo started launching their activities in the year 2013) and dwell on it.

4.2 Proposed Technique of Data Analysis: SEM-TOPSIS Methods

The SEM-TOPSIS technique was employed to construct the MFS evaluation decision support system. Therefore, SEM was utilized to generate critical criteria and weights, whereas TOPSIS was used to engender the rank and score of alternatives as well permitted the fullness of the data, improved the data accuracy via group decision making.

SEM is suitable to estimate and test casual relationships by employing a combination of statistical data and qualitative assumptions (Gbongli et al., 2019; Kumar Mittal & Singh Sangwan, 2014). It remains a second-generation multivariate technique that tolerates the simultaneous assessment of multiple equations, embraces multiple regression analysis, factor analysis, and path model analysis (Hair, Black, Babin, Anderson, & Tatham, 2010). SEM incorporates the whole analysis of construct concurrently rather than separately (Chin, 1998), with this application being emergent in the social sciences (J. C. Anderson & Gerbing, 1988). Accordingly, it is the handiest method adapted for checking causative relations between predictors and adoption behavior (Hair, Black, Babin, Anderson, & Tatham, 2006; Schumacher & Lomax, 1996). It offers greater flexibility in matching a theoretical model with a data sample when compared with techniques like PCA and factor analysis (Aloini, Martini, & Pellegrini, 2011).

TOPSIS: Technique for Order Preference by Similarity to Ideal Solution. The various process of TOPSIS will concurrently be explained along with the finding under the analysis section.

5. DATA ANALYSIS

5.1 Measurement and Hypotheses Testing with SEM Analysis

We performed exploratory factor analysis (EFA) employing maximum likelihood estimation with Promax because of the large sample of data set (n=538) and its intricacy related to the outcomes elucidation which is trivial in resolving the correlated. The EFA reveals the output of KMO as 0.809 and Bartlet's test of sphericity to be significant at α=0.000 with a Chi-square of 11598.920, indicating the relevance for performing exploratory factor analysis (Kaiser, 1974). Besides, the communalities for each variable were sufficiently high (lowest was 0.343, the majority were beyond 0.597, and the greatest was 0.975) showing the evidence that these variables were effectively correlated for factor analysis. The ten-factor model obtained a total variance explained with more than 60% along with all extracted factors partaking eigenvalue beyond 1.0.

To continue assessing our quantitative model, we settled the subsequent analysis in two phases (J. C. Anderson & Gerbing, 1988): first, via confirmatory factor analysis (CFA), we appraised both reliability and discriminant validity of the ten constructs (Campbell & Fiske, 1959). The outcomes will achieve validity unless the researchers employ constructs that diverge from another construct in a similar model (Campbell & Fiske, 1959). From the second step, we valued the structural model then SEM for hypotheses testing. These last two steps are adopted from previous studies (Gbongli et al., 2017; Zhou, 2012). Hence, we estimated the reliability of each construct based on three indices, such as composite reliability (CR), average variance extracted (AVE), and Cronbach's alpha (CA). The suggested values for good measures were at least 0.70, 0.50, and 0.70, respectively (Fornell & Larcker, 1981), (see Table 1). In patronage of convergent validity, the AVE found to be higher than 0.5 for all constructs, and all item factor loadings remain beyond the minimum threshold of 0.4 (Hair, Anderson, Tatham, & Black, 2010).

Moreover, all loadings of items arose in the corresponding construct, and no item loaded with the high value in another construct. This technique was espoused in past research (Gbongli et al., 2019; Y. Hwang, 2014; Zhou, Lu, & Wang, 2010). As such, we established that our ten constructs displayed convergent validity (see Table 1 below).

Table 1. Reliability and validity in CFA

	CR	**AVE**	**MSV**	**MaxR (H)**	**(1)**	**(2)**	**(3)**	**(4)**	**(5)**	**(6)**	**(7)**	**(8)**	**(9)**	**(10)**

We designed Table 2 to portray the goodness of fit of CFA and SEM. Apart from the goodness-of-fit index (GFI) for CFA slightly below the recommended, as this index is sensible to sample size, and in this study, we use large sample size (n = 538); for all indexes, our measurement model and structural model indicated sufficient goodness of fit.

Table 2. The goodness of fit (CFA and SEM)

Indices	Abbreviation	CFA Value	SEM Value	Thresholds	References
Chi square	x^2	1068.904	30.445	Pval>0.05	(Wheaton, Muthen, Alwin, & Summers, 1977)
Normed chi square	$x^2_{/DF}$	2.104	1.903	1< x2/df< 3	(Bm M. Byrne, 2010)
Root mean square residual	RMS or RMR	0.066	0.015	<0.08	(Browne & Cudeck, 1993)
Goodness-of-fit index	GFI	0.889	0.991	>0.90	(Jöreskog & Sörbom, 1984)
Adjusted GFI	AGFI	0.862	0.955	>0.80	(David Gefen, Straub, & Boudreau, 2000)
Normed fit index	NFI	0.900	0.941	>0.90	(Bollen, 1989)
Comparative fit index	CFI	0.944	0.968	>0.93	(B. M Byrne, 1994)
Tucker-Lewis index	TLI	0.935	0.869	0<TLI<1 TLI > 0.9	(Bentler & Bonett, 1980)
Root mean square error of approximation	RMSEA	0.045	0.041	<0.05 excellent fit <0.08 good fit	(Browne & Cudeck, 1993)

Before the structural model, we conducted a common method bias. Since the data for the variable was led through a single method (survey), we performed a test to check if a common factor might have been impacted our outcomes. Hence, the test adopted was unmeasured latent factor suggested by Podsakoff, MacKenzie, Lee, & Podsakoff (2003) and Siemsen, Roth, & Oliveira (2009) towards studies that do not obviously measure a common factor, mentioned as a common latent factor (CLF) method. The most prevailing and best method in checking the CMB is the zero-constrained test where the CLF is involved along with Marker if accessible (Podsakoff et al., 2003). This approach checks whether the shared variance across all variable differs significantly from zero. In a case it is, then there are bias issues. To proceed, we computed the chi-square difference test among the unconstrained model and the model per all paths regarding the CLF constrained to be zero. Since the result is markedly different from zero, we can conclude that method bias does occur in our measures. Thus, moving to the causal model based on the result, CLF was retained for our structural model (by imputing composites in AMOS in the presence of CLF) which provided CMB-adjusted values.

We also check for invariance (configurable and metric) due to the presence of two groups, such as gender included in our data to see whether the factor and loading are adequately equivalent across groups. Davidov (2008) has claimed that the assessment of path coefficients could only be useful if the invariance test has been done beforehand. The result signpost that the model fit of the unconstrained measurement models (per groups loaded distinctly) presented a sufficient fit ($\chi 2$ /DF = 1.623, TLI=0.928, CFI=0.938, RMSEA=0.034) when assessing a freely estimated model across genders. Grounded on the result, the model is configurally invariant. Once the model was constrained to be equal, the result of the chi-square difference test reveals p-value (0.226) to be nonsignificant. So, the measurement model satisfies the benchmarks criteria for metric invariance across gender as well. Then and there, we move on making the composite from this measurement model, to build SEM for verification of hypotheses testing. The results of the structured model, together with parameters, was obtained while controlling for age and education. The standardized path coefficients, path significances, and explained variance R^2 of the structural model (See fig 2).

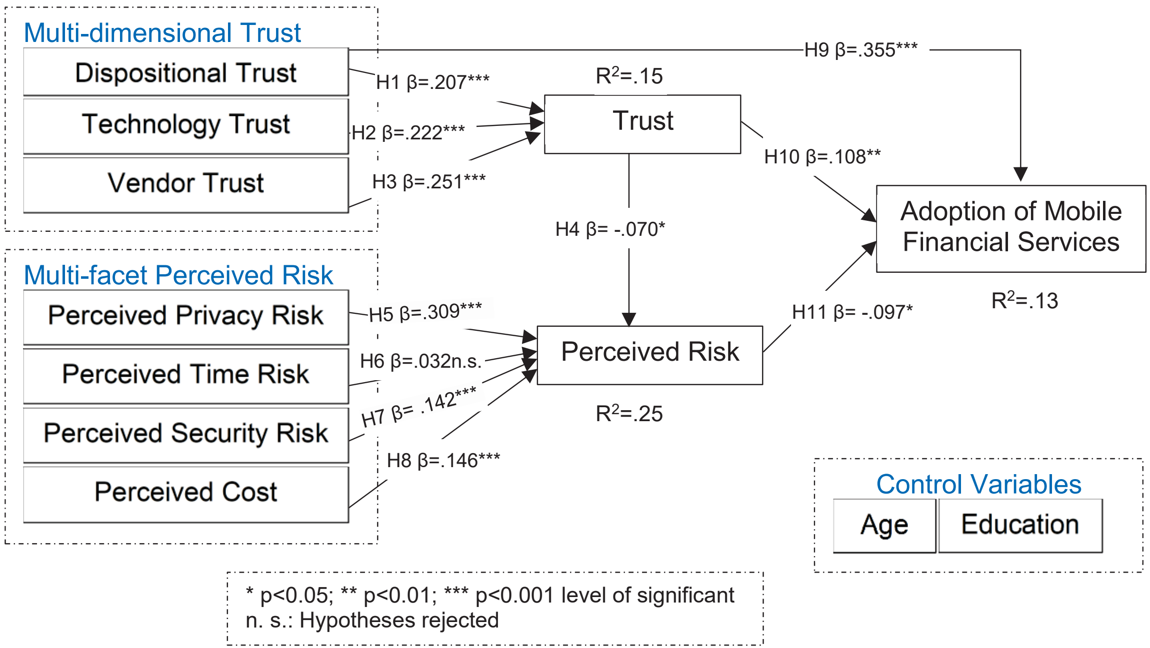

Figure 2. Final model after validation

5.2 TOPSIS Analysis

The Technique for order preference by similarity to ideal solution (TOPSIS) is a multiple criteria decision-making (MCDM) technique developed by Hwang & Yoon (1981). It is grounded in the criteria that the alternative should have the shortest distance from the positive ideal solution and the farthest from the negative ideal solution (Patil & Kant, 2014). It has been extensively employed by researchers for the ranking of alternatives centered on different criteria (Dhull & Narwal, 2018; Gbongli, 2016; Gbongli, Dumor, et al., 2016; Kumar Mittal & Singh Sangwan, 2014; Mahdevari, Shahriar, & Esfahanipour, 2014). When compared to other MCDM methods, TOPSIS:

• Necessitates limited subjective inputs from decision-makers (Vinodh, Prasanna, & Hari Prakash, 2014), it is a deterministic technique; • provides solution on both positive and negative way, which is beneficial for applications where there are considerations such as cost and benefits; and • is a rational method and works agreeably across various application areas (Behzadian, Khanmohammadi Otaghsara, Yazdani, & Ignatius, 2012). Recall that the process of the SEM-TOPSIS can be characterized as follows. Primarily, SEM was applied to compute the hierarchical criteria and their relatives to ensure their significance. This is the reason why having the relative weightage obtained from SEM is reflected more valid than via any other method. The antecedent of trust and perceived risk given by the SEM model were deliberated for the relative weightage of the sub-criteria. The relative weightage is computed from the standardized total effect, normalized (Gbongli, 2017; Punniyamoorty, Mathiyalagan, & Lakshmi, 2012) and presented in Table 3. The weightings showed the importance of each sub-criteria for the MFS companies.

Table 3. Relative weightage of sub-criteria

DTrust	TTrust	VTrust	PPrivR	PTimeR	PSecurR	PCost
0.265	0.128	0.177	0.200	0.021	0.109	0.101

To compute the relative weightage of MFS alternatives to each sub-criteria towards the criteria (Trust and Risk), the decision matrix of alternative performance evaluation (Eq.1 step 1) was created. Participants (74 MFS experienced users and experts) were asked to provide a set of values within the range of one to nine for the sub-criteria, as shown in Table 4.

Table 4. Transformation of linguistic scale into quantitative values		
Linguistic Scale	Quantitative Values	
	Benefit-Max	Cost-Min
Very High	9	1
High	7	3
Average	5	5
Low	3	7
Very Low	1	9
Intermediate values between the two-adjacent judgment: (2,4,6,8)		

The computation of TOPSIS methods grounded on Hwang & Yoon (1981), Lin & Tsai, (2010), and predominantly the one required for grouping decision Shih et al. (2007) were adopted and presented as followed:

Step 1: construction of decision matrix $\mathrm{D}^{\mathrm{k}}, k = 1, \ldots, K$ for each DM. The matrix structure can be viewed as follows:

$$\mathrm{D}^{\mathrm{k}} = \begin{array}{c} \\ \\ A_1 \\ A_2 \\ \vdots \\ A_{\mathrm{i}} \\ \vdots \\ A_{\mathrm{m}} \end{array} \begin{array}{c} n\ Criteria \\ \begin{array}{cccccc} X_1 & X_2 & \cdots & X_{\mathrm{J}} & \cdots & X_{\mathrm{n}} \end{array} \\ \begin{bmatrix} \mathrm{x}_{11}^{\mathrm{k}} & \mathrm{x}_{12}^{\mathrm{k}} & \ldots & \mathrm{x}_{1\mathrm{j}}^{\mathrm{k}} & \ldots & \mathrm{x}_{1\mathrm{n}}^{\mathrm{k}} \\ \mathrm{x}_{21}^{\mathrm{k}} & \mathrm{x}_{22}^{\mathrm{k}} & \ldots & \mathrm{x}_{2\mathrm{j}}^{\mathrm{k}} & \ldots & \mathrm{x}_{2\mathrm{n}}^{\mathrm{k}} \\ \vdots & \vdots & \ldots & \vdots & \ldots & \vdots \\ \mathrm{x}_{\mathrm{i}1}^{\mathrm{k}} & \mathrm{x}_{\mathrm{i}2}^{\mathrm{k}} & \ldots & \mathrm{x}_{\mathrm{ij}}^{\mathrm{k}} & \ldots & \mathrm{x}_{\mathrm{in}}^{\mathrm{k}} \\ \vdots & \vdots & \ldots & \vdots & \ldots & \vdots \\ \mathrm{x}_{\mathrm{m}1}^{\mathrm{k}} & \mathrm{x}_{\mathrm{m}2}^{\mathrm{k}} & \ldots & \mathrm{x}_{\mathrm{mj}}^{\mathrm{k}} & \ldots & \mathrm{x}_{\mathrm{mn}}^{\mathrm{k}} \end{bmatrix} \end{array} \qquad (1)$$

Where A_i refers to the likely alternatives of the decision process i with $i = 1, \ldots, m$; X_j denoting the attribute or criterion $j, j = 1, \ldots, n$; with both quantitative and qualitative data. The value $\mathrm{x}_{\mathrm{ij}}^{\mathrm{k}}$ remains, therefore, the performance score of alternative A_i in relation to attribute X_j by decision-maker $k, k = 1, \ldots, K$, while x_{ij}^k is the element of D^{k}. It is important to mention that there should be K decision-maker matrices designed for K participants of the group. Moreover, the output of the qualitative attribute from each alternative can also be set as discrete value or linguistic values (referring to Table 4) intentionally that the quantitative values could be set in the decision matrix above (C.-L. Hwang & Yoon, 1981).

Step 2: the normalized decision matrix $\mathrm{R}^k, k = 1, \ldots, K$ is generated for each DM. Vis-à-vis to any $DM\ k$, the normalized value r_{ij}^k from the decision matrix R^{k} can take any linear-scale transformation to preserve $0 \leq r_{ij}^k \leq 1$ inequality. Since we consider the vector normalization operation, then r_{ij}^k can be computed as follow:

$$r_{ij}^k = \frac{x_{ij}^k}{\sqrt{\sum_{\mathrm{j}=1}^{\mathrm{n}} \left(\mathrm{x}_{\mathrm{ij}}^{\mathrm{k}}\right)^2}}, \qquad (2)$$

Where $i = 1,2, \ldots, m$; $j = 1,2, \ldots, n$; and $k = 1,2, \ldots, K$. It is also necessary to clue that vector normalization method makes provision as to which one represents a cost criterion for additional management. Moreover, there is no need to directly assess the weighted normalized as per the case of the original TOPSIS (Shipley, de Korvin, & Obid, 1991).

Step 3. Computation of the positive ideal solution V^{k+} (PIS), and negative ideal solution V^{k-} (NIS) for each DM $k = 1, \dots, K$.
For any given $DM\ k$, his/her PIS and NIS can be characterized in the form of

$$\mathrm{PIS} = \mathrm{V}^{\mathrm{k+}} = \{\mathrm{r}_1^{\mathrm{k+}}, \dots\dots, \mathrm{r}_\mathrm{n}^{\mathrm{k+}}\} = \left\{\left(\max_i \begin{matrix} k \\ r \\ ij \end{matrix}\middle| \mathrm{j} \in \mathrm{J}\right), \left(\min_i \begin{matrix} k \\ r \\ ij \end{matrix}\middle| \mathrm{j} \in \mathrm{J}'\right)\right\} \tag{3}$$

$$\mathrm{NIS} = \mathrm{V}^{\mathrm{k-}} = \{\mathrm{r}_1^{\mathrm{k-}}, \dots\dots, \mathrm{r}_\mathrm{n}^{\mathrm{k-}}\} = \left\{\left(\min_i \begin{matrix} k \\ r \\ ij \end{matrix}\middle| \mathrm{j} \in \mathrm{J}\right), \left(\max_i \begin{matrix} k \\ r \\ ij \end{matrix}\middle| \mathrm{j} \in \mathrm{J}'\right)\right\} \tag{4}$$

Where J is related to the benefit criteria and J' allied with the cost criteria, $i = 1, \dots, m$; $j = 1, \dots, n$; and $k = 1, \dots, K$

Step 4. A weigh vector W is allocated to the attribute set for the group. Each DM will produce weights for attributes as w_j^k where $j = 1, \dots, n$ and $\sum_{\mathrm{j=1}}^{\mathrm{n}} w_j^k = 1$; and for each DM $k = 1, \dots, K$. Each element of the weigh vector W will result from the operation of the corresponding components of the attributes' weights for every DM.

Step 5. Evaluate the separation measure through the positive ideal and the negative ideal solutions, $\overline{S_I^+}$ and $\overline{S_I^-}$, relatively to the group. Due to the group decision with respect to this research, this step requires two sub-steps, where the initial one considers the distance measure for individuals while the next one aggregates the measure for the group.

- **Step 5a**. Assessment of the measure from PIS and NIS individually.
  Assuming a given DM k, his or her separation measures from PIS and NIS via Euclidean distance are

$$\mathrm{S}_\mathrm{i}^{\mathrm{k+}} = \sqrt{\sum_{\mathrm{j=1}}^{\mathrm{n}} w_j^k \left(v_{ij}^k - v_j^{k+}\right)^2} \text{, for alternative } i, i = 1, \dots, m \tag{5}$$

$$\mathrm{S}_\mathrm{i}^{\mathrm{k-}} = \sqrt{\sum_{\mathrm{j=1}}^{\mathrm{n}} w_j^k \left(v_{ij}^k - v_j^{k-}\right)^2} \text{, for alternative } i, i = 1, \dots, m. \tag{6}$$

- **Step 5b.** Assessment of the measure from PIS and NIS for the group. In this part, the individual group measure of each alternative is to be integrated via an operation ⊗ for all DMs, $k = 1, \dots, K$. As such, the twofold measure of the PIS and NIS are presented below

$$\overline{S_i^+} = \overline{S_i^{1+}} \otimes \cdots \otimes \overline{S_i^{K+}} \text{, for alternative } i, \tag{7}$$

$$\overline{S_i^-} = \overline{S_i^{1-}} \otimes \cdots \otimes \overline{S_i^{K-}} \text{, for alternative } i. \tag{8}$$

Though this operation can provide various choices like geometric mean, arithmetic means with their related extended; this study pondered only on the geometric one for the group computation. Its calculation's formulae are below shown for PIS and NIS (Eq. 9); (Eq. 10)

$$\overline{S_i^+} = \left(\prod_{k=1}^{K} S_i^{k+}\right)^{\frac{1}{K}} \text{, for alternative } i, \tag{9}$$

$$\overline{S_i^-} = \left(\prod_{k=1}^{K} S_i^{k-}\right)^{\frac{1}{K}} \text{, for alternative } i. \tag{10}$$

Where $i = 1, \dots, m; k = 1, \dots, K$

Step 6: Measure the relative closeness $\overline{C_i^*}$ to the ideal solution for the group while ranking the alternative in descending order. The following formulae (Eq.11) reflect the relative closeness of the i^{th} alternative A_i regarding PIS.

$$\overline{C_I^*} = \frac{\overline{S_i^-}}{S_i^+ + S_i^-}, i = 1, \dots, m \tag{11}$$

With $0 \leq \overline{C_I^*} \leq 1$. The larger the index values, the higher the rank order and so, the better the alternative' performance.
Step 7: Ranking the preference order which remains to define the rank a set of alternatives by comparing their $\overline{C_I^*}$ values in descending order are starting from values closest to 1.

Following the procedure of the TOPSIS method, through a TOPSIS algorithm built-in MATLAB technical computing tool, the relative weightage of MFS allied with each sub-criterion is calculated and shown in Table 5. After aggregating the individual PIS and NIS via geometric mean from the Step 5b eq. (7) and eq. (8), then the final score $\overline{C_I^*}$ is computed using Eq. (11) of Step 6, followed by the ranking of MFS perspective from step 7 as being portrayed in Table 6 and Fig. 3.

Table 5. Summary of the relative weightage of MFS to each sub-criterion

Sub-criteria weightage	0.265	0.128	0.177	0.200	0.021	0.109	0.101
Sub-criteria	DTrust	TTrust	VTrust	PPrivR	PTimeR	PSecurR	PCost
MB	5.40	4.78	6.23	-3.56	-7.53	-4.20	-6.50
MP	8.50	5.40	4.43	-2.34	-8.20	-5.00	-7.00
MMT	7.30	4.70	5.11	-1.42	-8.00	-4.48	-7.20

Table 6. MFS perspectives ranking

MFS	$\overline{C_I^*}$	Rank	% distribution of coefficient
MMT	0.7454	1	46.68%
MP	0.6106	2	38.24%
MB	0.2407	3	15.07%

6. DISCUSSION

New technology adoptions are impacted mainly by many factors, which may vary from technology concerns to the trust dimension, the perception of risk facets, and the behavior of users, to mention a few. The intricacy and significance related to the effort in elucidating the motives or reasons for users' adoption or rejection of new IT have led to the development of various concepts. Furthermore, there are a plethora of studies on the influence of trust and perceived risk with their determinant towards the adoption decision in an online environment.

Conversely to prior research works, this study scrutinizes the influence of critical variables such as multi-dimensional trust and perceived risk facets on the consumers' adoption behavior of MFS and incorporates each of them into the MFS alternatives decision-making scenario. Some postulations were made towards the possible relationship amongst the factors. The findings are yet to be probed purposively to draw an important conclusion and implication. The result of the MFS structural model analysis regarded as a final model after validation is summarized and portrayed in Figure 2. To be specific, the discussion section is scheduled to be under two sections. The first section will be made with SEM methodology grounded on hypotheses results, which are comprised of three sets. First set: hypotheses associated with trust; second set: hypotheses associated with perceived risk; and third set: hypotheses associated with MFS adoption constructs. The last section of the discussion is booked for a succinct analysis of TOPSIS output obtained via SEM-TOPSIS hybrid technique.

It should be mentioned that all hypotheses were tested when controlling for age and education. The reason for controlling variables is to support mitigating the unrelated effect.

Moreover, its use contributes to improving the robustness and validity of the outcome. In terms of relationships, the study account for the p-value column allied with each variable where the related p-value of less than 0.05 indicates a significant relation associated. The results of the entire tested eleven hypotheses were statistically significant except for the relationship between perceived time risk (PTimeR) and perceived risk (PRisk, i.e., H6 as displayed from Figure 2.

The first set is hypotheses related to trust, which was scrutinized by H1-H3. Empirical evidence is found to accept hypothesis H1 ($\beta = 0.207$, $p < 0.001$), which refers to the positive effect the disposition to trust has on trust in MFS**.** Payne and Clark (2003) showed that the general disposition to trust exerts a substantial control on the trust amongst senior managers in an industrial context. Moreover, Consumers' disposition to trust has been revealed to maintain a strong influence on their trust in an e-vendor (McCord & Ratnasingam, 2004). Although most of the previous studies did not plainly define the direction of the impact, the present study ratifies that disposition to trust and trust are positively related in MFS. Such information comes to back the knowledge that consumers who unveil a greater disposition to trust will more willingly trust the e-vendor (David Gefen, 2000) compared to those who will require more info (Salam, Iyer, Palvia, & Singh, 2005). However, our results are contradicted by earlier e-services (Liu et al., 2009), particularly in mobile banking. The reason might be that when consumers are to encounter a choice within MFS perspectives (mobile banking, mobile payment, mobile money), their trust disposition significantly affects the general trust more or less that of the single type of MFS. As a result, companies dealing with MFS should be aware of this critical effect and prepare for any competitive advantage strategies in the marketplace.

H2 ($\beta = 0.222$, $p < 0.001$) tested the effect of trust in technology on trust in general, and the findings stressed that technology trust has a strong positive impact on trust. Given technological trust as a sole antecedent of trust whereby the object upon which the trust remained imparted when referring to the inert technology (Lippert & Forman, 2006), then, our empirical results are in line with previous findings in the context of mobile banking (Liu et al., 2009). Furthermore, previous works (P. Pavlou & Ratnasingam, 2001) implicitly incorporated the concept of trust technology to trust with its importance being emphasized as a facilitator of e-commerce adoption.

Trust in the vendor was also found to have a positive influence on general trust, which supports H3 ($\beta = 0.251$, $p < 0.001$). The results of this research are reliable with the previous finding in which vendor trust has been defined as multi-dimensional and influential levers that the vendors could employ to build consumer trust (Harrison McKnight, Choudhury, & Kacmar, 2002; Nilashi et al., 2015). Vendor trust remains so vital to promoting trust in changing a potential consumer from curious viewer to one that will be ready to perform MFS. Thoughtful discerning of the essence and antecedents of consumer trust in MFS can support e-vendors with a set of controllable, strategic levers to develop such trust, which will encourage greater MFS acceptance and usage.

As a result, lack of consumer trust (Trust Disposition, Technology Trust and Vendor Trust) in the overall online environment has been, and persists in being, a hamper to IS adoption (Aldridge, White, & Forcht, 1997; Hoffman, Novak, & Peralta, 1999) and thus to MFS. All these could serve as a clue to the concept that the consumers' espousal of MFS may be shaped accordingly.

The second set is hypotheses associated with perceived risk. From this part, perceived risk has five antecedents such as H4 and H5-H8. The investigation of the relationship between trust and perceived risk has been one of the main issues in the development of IS (A. P. Pavlou, 2003). Our result shows that trust has a negative influence on perceived risk, which supports H4 ($\beta = -0.070$, $p < 0.05$). The literature offers supportive studies on the import of this relationship (Muñoz-Leiva et al., 2017; A. P. Pavlou, 2003). Various researchers have also contributed to the belief that trust mitigates consumers' perceived risk (Cheung & Lee, 2000; Fukuyama, 1995; Kesharwani & Bisht, 2012) as well as affecting perceived benefit in e-commerce (Ratnasingham & Kumar, 2000). Lots of incentives that increase trust are similar incentives that reduce perceived risk. This result clarifies to some extent, the doubt related to the direction of the causality between trust and risk, which were found deficient from the past literature (D. Gefen et al., 2003; Mayer et al., 1995; Rousseau, Sitkin, Burt, & Camerer, 1998). From H5-H8, the empirical study found to patronize all the hypotheses at a different level of p-value mention that each dimension of perceived risk has a positive influence on the overall perceived risk except H6 (see Figure 2). At that point, the moderate to weak positive relationships between the perceived risk (aggregate) and the risk component offers further reinforcement that risk can be researched as a multidimensional phenomenon (Zikmund & Scott, 1974). These results are also consistent with the work of Featherman and Pavlou (2003), which validated a majority of these antecedents as a risk dimension; therefore, being the influential element of the aggregated risk. Again, the outcomes reveal the multidimensional nature of perceived risk in information technology, mainly MFS. Boksberger et al. (2007) are supporters of these findings in the area of air travel. Again, the results show that perceived privacy risk H5 ($\beta = 0.309$, $p < 0.001$) is indeed the predominant perceived risk dimension for the partakers of MFS, shadowed by the perceived cost H8 ($\beta = 0.146$, $p < 0.001$) and perceived security risk H7 ($\beta = 0.142$, $p < 0.001$). Moreover, this study confirms the positive effect of the perceived cost on the consumers' perceived risk, such as that the lower the cost, the more minor the perception of risk and the more the likelihood of MFS adoption. As such, the involvement aspect of the risk (Choffee & McLeod, 1973) is importantly observed when the price or cost is high, and the consumers risk losing money.

This research reveals no statistical evidence to support the hypothesis H6 ($\beta = 0.032$, $p < 0.342$) that perceived time risk has a positive influence on the aggregate perceived. Although H6 is rejected; the expected direction of the relationship is kept just so that the p-value is not statistically significant at 0.05. However, our findings are controverted by prior online payment research that has indicated a positive relationship between time risk and perceived risk (Zhang, Tan, Xu, & Tan, 2012). It has stressed that consumers lack patience in waiting a long time because they always delight in pursuing new things (Zhang et al., 2012). Then, a longer waiting time for service delivery would deter the desire, impact their buying disposition or decision to adopt as well. In the view of this current study, the perceived risk dimension, such as perceived time risk, does not appear to impact specific information technology acceptance, at least for the Togolese MFS investigated in this research. The reason may be related to the participants (user and potential user) MFS experience. Since quite many of them lack experience in MFS, they might not be conscious regarding the real time needed for a service done. This implies that the effect of time risk perceived is worthy of further development in future researches and MFS companies are encouraged to continue easing the transaction process of MFS in terms of time spent.

The third set is hypotheses associated with the adoption of MFS. Among them, the hypothesis associated with the positive relationship that the dispositional trust has with MFS adoption was supported by the test result, hence, H 9 ($\beta = 0.355$, $p < 0.001$) is accepted (Figure 2). This infers that when increasing the level of trust disposition, individuals tend to adopt MFS technologies without necessarily cogitating on the general trust. The finding is consistent with e-commerce adoption for SMEs (Chakuthip, Brunetto, Rod, & Sheryl, 2007). Moreover, the scholars reported that indicators for the dispositional trust should be incorporated into empirical studies either as a moderating variable or as a precursor of trusting beliefs, intentions, and behaviors (Grabner-Kräuter & Kaluscha, 2003). Being an antecedent of trust, a disposition to trust remains one of the most operative elements required during the launch phases of a relationship when parties are generally unacquainted with each other (Rotter, 1971). Given that MFS is still in the early stage of adoption in Togo, services providers are recommended to promote the variable that could increase the consumer's dispositional trust.

The study entails and accepts the hypothesis H10 ($\beta = 0.108$, $p < 0.008$) in which general trust has a positive influence in MFS adoption. Generally, trust remains a vital factor in various economic and social relations involving uncertainty and reliance (Hosmer, 1995; Rousseau et al., 1998), particularly those regarding important decisions (Luhmann, 1979) and new technology

(Fukuyama, 1995) as an MFS perspective. Accordingly, our findings are sustained via the idea that trust in business rests on the pertinent and the crucial stimulus of behavior in general (Konovsky & Pugh, 1994; Rossiter & Barnett, 1975; Schurr & Ozanne, 1985), and the facilitator factors for MFS adoption and usage in particular.

Last but not least, from Figure 3, perceived risk significantly negates the adoption and usage of MFS, rendering the support of H11 (β= -0.097, $p < 0.022$). It is so crucial to signpost the feasibility of this outcome to be enlightened by the theory of consumer behavior (Bauer, 1960) allied with risk perception. The importance of perceived risk in the study also confirms previous studies that demonstrate that consumers' perceived risk is more efficacious at clarifying purchasing or adoption behavior inasmuch as consumers are more recurrently driven to avert mistakes than to capitalize on utility in purchasing (Mitchell, 1999). This output is also coherent with a recent report on mobile payment adoption, which underlines rapid technology innovation while stressing the importance of perceived risk in the form of security (De Fouchier & Larduinat, 2016; Manchiraju, Vudayagiri, & Garg, 2016).

Under this set, it can then be deduced that both improving trust and decreasing risk continue to raise the likelihood level of consumers' engagement in MFS transaction. Companies are required to take the necessary precaution to balance the trade-off.

SEM-TOPSIS: It is noteworthy to recall that the second section of discussion concern the output of MFS alternatives computation. The overall result from the TOPSIS technique shows the preference of each alternative regarding the various sub-criteria. The relative closeness $\overline{C_I^*}$ results obtained satisfies the sine qua non-condition, i.e. $0 \leq \overline{C_I^*} \leq 1$. Furthermore, TOPSIS technique is grounded on the principle that the higher the value of $\overline{C_I^*}$, the high the rank order, and consequently, the more the chosen alternatives are favored over others. The final result reveals that mobile money transfer (MMT) is the most preferable MFS to adopt and use with $\overline{C_I^*}$ tantamount to 0.7454 signifying 46.68% compared to the last two remaining. Mobile payment (MP) with 0.6106 (38.24%) was found to be the second MFS alternative used, whereas mobile banking (MB) adoption with 0.2407 (15.07%) is considered minor. This finding is relatively supported from the prior study on mobile banking and mobile payment, where 82% of participants under 35 years old have made mobile payment as compared to 79% who used mobile banking (Fox, Causey, & Cencula, 2016). The similar past study has further shown that mobile payment usage amongst USA millennials was higher than that of mobile banking generally. The likely motive of the MFS preference acknowledged in this study can be explained based on the significant issues of concern towards perceived privacy risk. Using mobile money transfer or mobile payment service do not necessarily involve consumers' personal information or an account that needs to be connected to a bank account. By that, lots of end-users would rather opt for mobile money transfer and mobile payment than for mobile banking accordingly.

7. CONCLUSIONS

The objective of this study was to examine the influence of both multidimensional trust and perceived risk facets at the individual level concurrently on the acceptance of mobile financial services (MFS) when prioritizing MFS perspective. This paper's goal is to illuminate, to some extent, the MFS accessibility in Togo allied with the potential facilitators or inhibitor factors. Also, to evaluate them based on the consumer's experience and experts through a benchmark robust SEM-TOPSIS methodology. A qualitative study in the context of the Togolese was performed together with a literature review to derive the most probable factors that might influence end-users' perception of MFS since there was a scarcity of research investigating trust and perceived risk antecedents. A quantitative study was then propelled to test the hypotheses formulated through the collected information obtained.

Our research model efficaciously integrates these dimensions, such as trust (dispositional trust, technological trust, and vendor trust), perceived risk (privacy, time, security, and cost) viewed as complex multidimensional factors. The data support the underlying assumption of the study except for H6 (see Figure 2). Mainly, our study is partially similar to the recent study done in Ghana (neighboring country of Togo) in which the perceived risk found to be related to the customer's trust in service providers regarding the adoption of mobile money (Abdul-Hamid, Shaikh, Boateng, & Hinson, 2019). In this line, our study provides more information to the various role-players of MFS about the necessity to emphasize on the trust and risk at the multidimensional level while making strategic and multicriteria decision-making.

Amongst the MFS alternative, the ranking result revealed mobile money to be the preferable MFS type used, followed by mobile payment and mobile banking with a minor percentage.

7.1 Implication for Practice

The outcomes of this study expose and validate the factors that impact consumers' adoption of MFS. Firstly, the relative level of the path coefficients in our analysis model recommended that disposition to trust (an antecedent of trust) be the most salient factor that facilitates either directly or indirectly the adoption of MFS. The perceived privacy risk (an antecedent of perceived risk) as the next influential factor, however, hinders MFS adoption. Given this trusting disposition is developed throughout a lifetime (Rotter, 1971) and reveals social impact over broad periods (Fukuyama, 1995), it implies that there might be a presence of a cross-cultural difference in trust. If so, MFS companies' providers must expect various levels of trust, and thus, different proportions of MFS adoption as well. As a deduction, companies are recommended to be acquainted in building trust-based tools and for instance, increasing awareness and firms' reputations by keeping their promises while treating the customer as individuals, mainly in societies which acknowledge exhibiting a lower level of trust. MFS service providers could meritoriously upsurge adoption behavior by publicizing the advantages of MFS to potential consumers, seeing that the findings supported trust with all of its antecedents.

Moreover, by modeling perceived risk with various facets, this study's finding imparts numerous risk effect concern. From this perspective, when companies propagandize their MFS services to ease the adoption issues, they should realistically underline a neutralizer or counter step for those risks' perceptions. The prominence of privacy risk and financial risk in the form of perceived cost as confirmed by this study and others prior research (José Liébana-Cabanillas, Sánchez-Fernández, & Muñoz-Leiva, 2014) signposts that customers still have doubts about the security of virtual transactions. For instance, these companies may stimulate a privacy risk protection strategy and grant technological support and anti-fraud to guarantee potential end-users minimal security risk. It is typical in the practice of emerging and developed countries (and it should be considered in developing countries as well) for payment service providers to try and promote trust in mobile financial services, in payments in general, as well as in other banking services by improving the general financial literacy of the population and small and medium enterprises. This is important, as those individuals who are familiar with financial processes and concepts demonstrate more trust towards financial services and can assess their risks better (Kovács & Terták, 2016). An increasingly popular practice is for certain governments to aid this process through an appropriate strategy and programs that serve the execution of that strategy. Because perceived time risk did not hold statistical significance in Togo, this phenomenon pinpoints that using MFS has little to do with time spent. As such, service providers should preserve those features that ease MFS application in time-frame.

Lastly, the outcome of TOPSIS through an SEM-TOPSIS integrated study specifies that mobile money transfer (MMT) is indeed the predominant mobile financial service (MFS) alternative used in Togo followed by mobile payment (MP), while mobile banking (MB) is reflected as trifling. In general, MFS companies should concede that consumer trust and risk with their antecedent create a tremendous barrier to MFS transactions. This study still demonstrates that amongst MFS companies, mobile money transfer companies are not powerless. It provides a practical guideline towards mobile financial service companies compared to the prevailing competitors within the related field such as online banking and ATM, for constructing more trust-based strategies to manipulate favorable consumer attitudes certainly, actions and eventual transaction behavior whereas mitigating the perceived risk factors. Regarding MFS, companies offering mobile money transfer are suggested to sustain the adoption growth, while those performing mobile payment, mobile banking predominantly, are to bear their target consumers at the core of the business model by diversifying market strategy.

With regard to the above, we cannot ignore the network nature of the payments market, an essential characteristic of which is that the market's dynamics (all the services provided and their prices) depend on the cooperation between many actors. Therefore the optimizing and maximizing effect of the traditional, individual competition on efficiency does not necessarily prevail by itself (Divéki et al., 2010). This may account for why collaboration between actors plays a positive and decisive role in improvements in the fields of trust and encountered risks.

7.2 Implication for Methodology and Theory

This research remains the first to assess the multi-dimensional trust and perceived risk facet concurrently towards consumers' adoption decision in mobile financial services while ranking their perspective.

The result obtained will open doors for scholars to explore further trust and perceived risk antecedents. It will support the theory of trust and risk literature in general, and IT in particular, since many prior studies lacked conclusive outcomes about the directivity of the causative relationship between trust and perceived risk (D. Gefen et al., 2003; Mayer et al., 1995; Rousseau et al., 1998). Our finding acknowledges the trust to be the potential predictor of risk in technology adoption. The scale items employed were greatly adopted from the prevailing studies in developed countries that are allied with technology acceptance adoption behavior, trust, and perceived risk. This section provides a crucial methodological implication for the marketing scholar, who might require a hint to cross-cultural appraisal concerning the application of scales, like those established in the USA and their relevance or relatedness in Togo. Our study outcomes not only enhance the clarification of mobile financial services adoption via the effect of trust and perceived risk but also hold some strategic implications for the global expansion of managerial implementation decision tools. This study provides a benchmark integrated methodology based on an SEM-MCDM application which found lacking in the adoption decision in general. The theoreticians and practitioners should comprehend that the prominence of the integrated SEM-TOPSIS is rooted in its robustness to test multifarious postulations made, combined with the high level in ranking the countless alternatives when multiple criteria issues arise in decision making.

7.3 Limitation and Future Research

Notwithstanding some contributions to the literature, practical, theoretical and methodological applications, all research unavoidably entails drawbacks that should be addressed. Our study outcomes are unique to Togo, although they are similar to IT in general and mobile financial transactions studies, predominantly. Preferably, a longitudinal study on our framework might need to gain a better understanding of how the variables relay over time. We expect future research will address these concerns. This research displays that time risk concerns are not significant antecedents of perceived risk. We hope that future research will further elucidate the relationship between time risk issues and adoption behavior in other populaces and circumstances.

Emphasizing multi-dimensional trust and perceived risk influences, this research projected to offer a wide-ranging still parsimonious decision-making model for MFS acceptance. However, the present model expounds only 13.1% of the variance in behavior to adopt. Future studies can incorporate additional variables, such as usefulness, perceived ease of use, and familiarity in an attempt to enhance the explanatory power. Based on the respondent's educational background, our distributed questionnaire appears to be limited to the more educated and technically competent elements of society, who would be more inclined to accept MFS applications. Therefore, researchers interested in MFS for adoption and sustainability should focus more on the underbanked population where illiterate people might be found in the majority.

ABSTRACT

We investigate the impacts of board's corruption culture on the financing costs of firms. Evidence shows that lending banks attach higher loan spreads, higher total costs of borrowing, and stricter covenants to firms with a strong corruption culture in their boards. The results are robust to controlling for the endogenous matching between firms and boards using a variety of econometric techniques. We further document that the effect of the board's corruption becomes stronger when firms have weak governance mechanisms. Our paper suggests that banks recognize board's culture of corruption as a sort of agency problem when they make lending decisions.

KEYWORDS: Corruption culture, Bank loan spread, Corporate governance, Financial cost, Agency problem

INTRODUCTION

Boards have an important role in a firm's corporate governance. Conventionally, boards perform monitoring and advisory roles (Schwartz-Ziv & Weisbach, 2013). The empirical evidence usually focuses on the structure of the board's composition, such as inside and outside directors, in which the directors are assumed to maximize shareholders' wealth. In contrast, a few recent studies have found several cases of inefficiency in the board structure. For example, the powerful CEOs are more likely to influence the selection of board members and invite related directors on to the board, which leads to weak monitoring by board directors (Fracassi & Tate, 2012; Coles et al, 2014). However, studies have not examined whether the board's culture of corruption influences the functions of board governance. Specifically, this paper investigates the effects of this corruption on the loan costs of firms.

The board of directors can be a critical function of board governance (Core et al, 1999; Fich & Shivdasani, 2006; Adams & Ferreira, 2009; Adams et al, 2010; Li & Srinivasan, 2011; Masulis et al, 2012; Baldenius et al, 2014; Coles et al, 2014; Kim et al, 2014). Boards with a strong level of corruption tend to be more tolerant of corrupt behavior, and thus the function of board governance is more likely to be invalid. This invalidity indicates that the culture of corruption will exacerbate the agency problem. The findings confirm this conjecture that boards' corruption culture is associated with firms' misbehavior (DeBacker et al, 2015; Liu, 2016).

In practical cases, some corporate scandals are related to the board's corruption. WorldCom disclosed US$3.8 billion in expenses, US$11 billion in inflated assets, and US$180 billion in losses for investors. This scandal was one of the biggest accounting frauds in the US and involved the CEO and outside directors. Accused of manipulating earnings and profits, the CEO was sentenced to 25 years in prison and outside directors were fined US$54 million that included US$18 million from their own pockets. Furthermore, the total fine was US$500 million and in 2002 WorldCom filed for Chapter 11 bankruptcy (The New York Times, 2002; Washington Post, 2005).

The Rigas family was a major stockholder of Adelphia Communications and held several top executive positions. The Rigas family hid US$2.3 billion in bank debt in accounting reports that they used for personal expenses. Once the case was uncovered, the CEO and the executives were charged 15 and 20 years in prison respectively, and the internal corruption forced Adelphia into bankruptcy in 2002 (Newton, 2010).

The banking literature finds that agency risk is the foremost consideration in the design of loan contracts (Rajan & Winton, 1995; Hart & Moore, 1998; Hart, 2001; DeMarzo & Fishman, 2007). The agency risk that lenders face results from the potential misbehavior of management, such as shirking, expropriation, entrenchment, myopia, and empire building, all of which not only reduce shareholders' wealth but also increase the probability of default (Sufi, 2007; Bharath et al, 2008; Graham et al, 2008). Accordingly, we hypothesize that lending banks charge higher loan spreads, have higher total borrowing fees, and attach stricter covenants to contracts if the borrowing firms have a board that displays a strong corruption culture.

To test our hypothesis, we measure the corruption culture of the firms' boards by using the average level of director corruption. For each director, we use his or her surname to identify the country of ancestry. Then, we match the country of ancestry with the Corruption Perception Index (CPI) to measure the level of their corruption.

We use a sample of 7,517 loans for US firms between 1996 and 2015. We find that the loan spread is positively associated with the level of corruption in the borrowing firm's board, which means that banks charge higher rates for firms with boards that have stronger corruption. The results are robust to various sets of control variables (firm characteristics, loan characteristics, macroeconomic variables, industry fixed effects, loan purposes, and loan types). Our main result is also economically important. For example, the average natural logarithm of the loan spread in our sample is 4.8143 (123.26 basis points). A one-standard-deviation increase in corruption results in an increase of 0.1176 that is about 15.38 basis points, which is around 12.48% of the average loan spread.

To address endogeneity concerns, we use four strategies. First, we construct a two-stage least square (2SLS) with an instrumental variable of political rights (Brunetti & Weder, 2003; Jong-sung & Khagram, 2005; Arezki & Bruckner, 2011). The 2SLS results show a positive relation between the corruption culture and the loan spread, which is consistent with our findings in the baseline regressions. Second, our results hold even if we use a firm fixed effect to control for the influence of unobservable omitted variables. Third, we use propensity score matching (PSM) to control for a self-selection bias (Rosenbaum & Rubin, 1983; Heckman et al, 1997; 1998). We sort firms into quartiles and take the top quartile as the treated firms and the bottom quartile as the control firms. Our evidence shows that the treated firms are charged a higher loan spread than the control firms.

Last, we use a quasi-natural experiment, the enactment of the Sarbanes-Oxley Act (SOX) of 2002, to generate a plausibly exogenous shock to board composition during our sample period (Coles et al, 2014; Balsmeier et al, 2017). Based on a difference-in-differences (hereafter, DiD) approach, we use the change ratio of the board's corruption culture to differentiate treated firms (top 50%) and control firms (bottom 50%) before SOX. We find that banks charged treated firms a higher loan spread after SOX that indicates that the boards' corruption culture is viewed as an agency concern for firms. Overall, our four identification tests confirm that the board's corruption culture has a positive causal impact on the bank's loan spread to the firm.

Furthermore, we investigate the cross-sectional variation in the effect of the board's corruption culture on loan contracting. We expect that the corruption culture is particularly crucial for firms with poor governance mechanisms. This is because the board's corruption culture should have a substitution effect with other governance mechanisms. In the literature, several studies have confirmed that the substitution effect exists among various governance mechanisms, such as the board of directors and severance pay (Almazan & Suarez, 2003), independent boards and board incentive pay (Adams et al, 2010), CEO ownership and external governance (Kim & Lu, 2011), external governance and weak internal governance (Fracassi & Tate, 2012), and independent boards and external governance mechanisms (Guo et al, 2015).

We then provide evidence from a conditional test based on strong and weak governance subsamples. The corruption culture leads to a firm's weak corporate governance that raises an agency problem between banks and firms. Based on the agency argument, the agency problems induced by the board's corruption culture should be deteriorated if the firm has weak governance mechanisms. This is because if the corruption culture is viewed as an agency problem, then the effect of the corruption culture on loan prices should be more significant when firms are associated with weak corporate governance.

We use several dummy variables to measure the corporate governance, such as institutional ownership, entrenchment index (Bebchuk et al, 2009), financial experts, and busy boards. Our evidence indicates that weak corporate governance increases the effect of the corruption culture, and hence banks punish these firms with higher loan spreads. This evidence supports our conjecture that banks consider stronger corruption as one type of agency cost when they make lending decisions.

We conduct several additional tests to corroborate our main results. First, banks also charge unfavorable non-price terms in loan contracts when the borrowing firms have boards with a strong corruption culture. Second, these firms are given low ratings. Third, we test the effect of the board's corruption culture with a combination of sin and politically sensitive industries (Hong & Kacperczyk, 2009; 2012). Because these industries are more likely to allow corrupt behaviors, the effect of the corruption culture should lessen. Fourth, we find similar results even if we define the corruption culture as coming from independent directors. Finally, we use alternative measures of the board's corruption culture (Mauro, 1998; Kaufmann et al, 2007). All results are consistent with our main finding.

Our paper contributes to the literature in several ways. First, it is related to the studies on failed governance mechanisms. For example, friendly boards monitor the CEO less and are not too independent (Adams & Ferreira, 2007). CEO's network connections with the board engage in more frequent value-destroying acquisitions and that connected independent directors provide less monitoring (Fracassi & Tate, 2012). Co-opted boards are more sympathetic to the CEO and not all independent directors are monitoring the effectiveness of the board (Coles et al, 2014). Directors with multiple directorships are less willing to relinquish their prestigious directorships (Masulis & Mobbs, 2014). Newly independent boards with newly appointed CEOs need to better assess their CEOs than CEOs from parent firms (Denis et al, 2015). Independent directors will depart before a bad event to protect their own reputation or to avoid work overload (Fahlenbrach et al, 2017). However, studies have ignored the role of the board's corruption culture in corporate governance. Our paper shows that weak governance mechanisms and an agency problem influence the firm's financing costs for private debt.

Second, we contribute to the literature on corporate culture. Previous studies have focused on cultural beliefs and societal organizations (Greif, 1994), culture and economic outcomes (Guiso et al, 2006), culture distance (Giannetti & Yafeh, 2012), culture of integrity and a firm's performance (Guiso et al, 2015), national culture and M&A (Ahern et al, 2015), domestic culture and stock price movements (Eun et al, 2015), unethical culture and corporate misbehavior (Biggerstaff et al, 2015), and corporate risk culture and investments (Pan et al, 2017). Our paper complements these studies by exploring how the board's corruption culture influences a firm's financing costs.

Third, our study contributes to the recent studies on the determinants of bank loan contracting, including shareholder rights (Chava et al, 2008), corporate misreporting (Graham et al, 2008), political connections (Houston et al, 2014), tax evasion (Hasan et al, 2014), private information (Carrizosa & Ryan, 2017), and social capital (Hasan et al, 2017). We complement this line of research by showing that the board's corruption culture has a significant impact on loan contracting.

LITERATURE REVIEW

Corruption Culture

Empirical studies have examined the impacts of corruption on corporate behaviors. Private monitoring and regulations force banks to disclose more information and this information can reveal the private gains of bank officials that improve the integrity of lending (Beck et al, 2006). Unpaid parking violations are based from diplomats from strong corruption countries and this evidence shows that social norms or cultural is strongly correlated with home country (Fisman & Miguel, 2007). Information sharing and bank competition reduces the corruption in lending (Barth et al, 2009). Beyond these findings, the structure of ownership and the legal environment play important roles in the level of corruption in bank lending. Strong corruption state is associated with higher default risks of credit and bond yield (Butler et al, 2009). However, firms with propensity to corrupt are significantly perform better than those without a propensity to corrupt firms (Mironov, 2015).

Outside of corruption, a couple of studies investigate bribes also harmful to corporate value. One of the reasons that firms spend on lobbying is to increase stimulus funds (Adelino & Dinc, 2014). The effect of spending on lobbying is to decrease market value because investors perceive lobbying as an unethical practice that increases the potential of conspiracy between firms and government officials (Borisov et al, 2016). Bribery activities reflect lower abnormal returns (Zeume, 2017). Fraudulent firms that lobby delay the detection of corporate fraud because they can allocate resources and sell their shares in the meantime (Yu & Yu, 2011). Firms typically pay bribes when they need something from government officials, for example, export-import services or public infrastructure services and innovative firms are more likely to pay bribes to public officials than non-innovative firms (Svensson, 2003; Ayyagari et al, 2014).

Corruption Culture and Agency Problem

Over the past decade, the conflicts of interest between managers and shareholders have persisted as corporate finance issues. In the banking industry, the loan officer may enjoy private benefits from corruption at the cost of borrowers and depositors because he or she approves the loans (Akins et al, 2017). Firm with a stronger culture of corruption displays an increasing opportunistic behavior and that the corrupt firm attracts a similar behavior in employees (Liu, 2016). State corruption is a part of political misbehavior that interacts with governments and financial institutions (Butler et al, 2009).

In our study, we are interested in whether the board's culture of corruption affects the firm's loan spread. We argue that this culture creates an agency problem. Moreover, the link between this culture and the loan spread provides evidence on the pricing of a bank's risk. Thus, we propose the following hypothesis:

Hypothesis 1. Firms with a stronger corruption culture in their boards are charged higher loan spreads*.*

Boards' Corruption Culture and Corporate Governance Roles

Most studies show that corporate governance bridges the gap between managers and stakeholders. Therefore, the agency problem is related to corporate governance mechanisms. Firms with a higher ownership concentration mitigate the agency conflicts (Jensen & Meckling, 1976; Mitton, 2002; Baek et al, 2004). The outside directors should increase the firm's reputation through better monitoring (Beasley, 1996; Beneish et al, 2017). A number of good corporate governance mechanisms can reduce the agency problem and increase the monitoring of firms (Lin et al, 2018).

From a different perspective, a weak corporate governance is associated with the value destruction that arises from the agency problem (Hoechle et al, 2012). A poor internal monitoring raises the loan spread (Kim et al, 2011).Thus, we propose our second hypothesis:

Hypothesis 2. The effect of the board's corruption culture on the loan spread is stronger for firms with weaker corporate governance.

METHODS

Data and Variables

We compute the corruption culture with the corruption perception index (CPI) as the main explanatory variable (DeBacker et al, 2015; Liu, 2016). Following previous studies, we measure the corruption culture of a firm with the average corruption culture of all directors (excluding the CEO) that we determine from the ancestral country of their surname. The corruption perception index (CPI) ranges from 0 (Denmark) to 9.6 (Bangladesh), where the United States index is 2.6.

We use surnames to capture the corruption culture for more than 187,000 boards of US public firms from Risk-Metrics. These data are from Origins Info Ltd. We hand-check their country of ancestry by using sources from ancestry.com if the surnames are unmatched. We are able to match 98.43% of the surname-ancestry countries and board names.

Loan data are collected from the DealScan database such as the loan spread and other non-price terms. The dependent variable is *Spread* (the natural logarithm of the amount of pay scaled by the London inter-bank offered rate). The other loan characteristics are *TCB* (the natural logarithm of loan spread plus other fees), *Maturity* (the natural logarithm of maturity in a month), *Loan Size* (the natural logarithm of the loan amount), *GenCov* (the natural logarithm of the general covenants), *FinCov* (the natural logarithm of the financial covenants), *Performance* (a dummy variable equal to one if the loan uses performance pricing and zero otherwise), and *Collateral* (dummy variable equal to one if the loan has collateral and zero otherwise).

We obtain the firm characteristics and macroeconomic control variables from Compustat, The Center for Research in Security Prices (CRSP), and Datastream. The firm characteristics are *Assets* (the natural logarithm of the total assets), *Market-to-Book* (total assets – book value of equity + price x common shares outstanding / total assets), *Leverage* (current liabilities plus long term debt scaled by the total assets), *Tangibility* (the sum of net property, plant, and equipment scaled by the total assets), *Profitability* (the earnings before interest, taxes, depreciation, and amortization scaled by the total assets), *Z-Score* (modified Altman's Z-score 1.2 x working capital + 1.4 x retained earnings + 3.3 x earnings before interest and taxes + 0.999 x sales scaled by the total assets), *Cash Flow Volatility* (standard deviation of quarterly cash flow from operation scaled by the total assets), and *Rating* (the Standard & Poor's debt rating that is converted into 0= no rating to 22=AAA (Klock et al, 2005; Jiraporn et al, 2014).

The macroeconomics variables are *Credit Spread* (the difference between the AAA corporate bond yield and the BAA corporate bond yield) and *Term Spread* (the difference between 10-year and 2-year Treasury yields).

Descriptive Statistics

Table 1 presents the descriptive statistics of the corruption culture, the loan spread, the total cost of borrowing (*TCB*), and the other control variables. The value of the corruption culture from 1996 to 2015 is positive, which is reasonable and consistent with the previous studies on the corruption culture. The mean value is 2.4702 with a standard deviation of 0.6083.

For firm characteristics, the mean value of *Assets* is US$4.416 million (8.3931 in natural logarithm). For loan characteristics, the mean value of *Spread* is 123.3 Bps or 1.233% (4.8143 in natural logarithm) and a mean of *TCB* is US$68.993 (4.2340 in natural logarithm). A loan contract in the sample has an average *Loan Size* of US$329 million (5.7957 in natural logarithm) with a mean *Maturity* of 41 months (3.6954 in natural logarithm). The average of the general covenants (*GenCov*) is 3.1918 (maximum of 11 covenants), and for the financial covenants (*FinCov*), it is 1.8784 (maximum of 7 covenants).

Table 1: Descriptive statistics

This table reports the descriptive statistics for the main variables used in the study. The main sample consists of firm-year observations in the US from 1996 to 2015. All the data are winsorized at 1% and 99%. See the appendix for the variable definitions.

Table 2 presents the mean differences between firms with strong or weak corruption cultures. For firms with a stronger corruption culture, banks charge a higher loan spread, higher total cost of borrowing (*TCB*), require more *Collateral*, and attach a higher number of covenants (*GenCov*). Lower *Profitability* and *Tangibility* and higher *Market-to-Book* and *Cash Flow Volatility* are also observed in firms with a stronger corruption culture.

Table 2: Mean difference between strong and weak corruption culture

This table reports the mean and mean difference between firms with strong or weak corruption cultures. Superscripts *, **, and *** denote significance of the *t*-test for the difference in the means between the two subsamples at the 10%, 5%, and 1% levels, respectively.

Table 3 reports the Pearson's correlation coefficient matrix. We find a positive and significant coefficient for the correlation between *Spread* and the corruption culture at the 1% level. The coefficients for the correlation between the board's corruption culture and loan terms (*Loan Size*, *Maturity*, *Collateral*, *GenCov*, and *FinCov*) are also positive and significant at the 1% level. The coefficients for the correlations between the spread and firm characteristics (*Assets*, *Profitability*, *Leverage*, and *Tangibility*) are also negative and significant.

RESULTS AND DISCUSSION

Boards' Corruption Culture and Their Loan Spread

To examine the effect of the board's corruption culture on the loan spread, we follow the regression setting of previous studies (Hasan et al, 2014; 2017).

$$Spread_{i,t} = \alpha_0 + \alpha_1 BCC_{i,t-1} + SOX_t + \boldsymbol{\beta}'\boldsymbol{Firm}_{i,t-1} + \boldsymbol{\theta}' Z_{i,t} + v_k + \varepsilon_{i,t}, \quad (1)$$

where the dependent variable $Spread_{i,t}$ is the natural logarithm of the loan spread for firm *i* in year *t*. The main independent variable is an average board's corruption culture (hereafter, *BCC*) in year *t-1*, which is calculated based on previous studies (DeBacker et al, 2015; Liu, 2016). SOX_t is a dummy variable equal to one if the year is 2002 or later and zero otherwise. $Firm_{i,t-1}$ is the characteristics of *Assets*, *Market-to-Book*, *Leverage*, *Tangibility*, *Profitability*, *Z-Score*, and *Cash Flow Volatility*. $Z_{i,t}$ is the characteristics of *Loan Size*, *Maturity*, *Performance*, *Collateral*, *GenCov*, and *FinCov* that are all measured in year *t*. The v_k and $\varepsilon_{i,t}$ represent the 2-digit SIC industry fixed effect and the error of the regression.

Table 4 shows the regression results. The coefficients are significantly positive in all models that indicate that firms with a stronger corruption culture are charged higher loan spreads (H1). The results are robust to several models when using the corruption culture as the sole explanatory variable or with various sets of control variables. The average natural logarithm of the loan spread in our sample is 4.8143 (=123.26 basis points). Thus, a one-standard-deviation increase in the board's corruption culture results in an increase of 0.1176 that is about 15.38 basis points ($e^{(4.8143+0.1176)} - e^{4.8143}$), which is around 12.48% (15.38 ÷ $e^{4.8143}$) of the average loan spread. Furthermore, 0.1176 is similar to the estimated coefficient for the dummy variable for repeat borrowers in Bharath, Dahiya, Saunders, and Srinivasan (2011) and for those for the politically connected firms in Houston et al. (2014). This result indicates that the board's corruption culture has not only statistically significant but also economically meaningful effects on banks' loan spreads.

In addition, firms with larger *Assets*, higher *Profitability*, higher *Tangibility*, and a better *Z-Score* tend to obtain a lower loan spread. However, firms with higher *Leverage* and higher *Cash Flow Volatility* are charged higher loan spreads.

Endogeneity Problems

The endogeneity problems can influence the effect of the corruption culture on the loan spread. The problems are reverse causality, measurement error, and omitted variables. First, reverse causality is the situation in which firm can improve the board's corruption culture to pursue a lower loan spread. To address the reverse causality, we estimating a two-stage least squares (2SLS) procedure (Griliches & Hausman, 1986; Berger & Hannan, 1998). Second, the coefficient becomes inconsistent if the corruption culture has a measurement error (Biddle & Hilary, 2006; Rajgopal & Shevlin, 2002; Chen et al, 2011). Third, if the board's corruption culture correlates with an omitted variable, then the estimator is inconsistent and biased and a regression with a firm fixed effect can eliminate this bias (Roberts & Whited, 2013).

<u>Two-Stage Regressions</u>

We eliminate endogeneity with the 2SLS with an instrumental variable.

$$BCC_{i,t} = \pi_0 + \pi_1 Political\ Rights_{i,t-1} + SOX_t + \boldsymbol{\beta}'\boldsymbol{Firm}_{i,t-1} + \boldsymbol{\theta}'\boldsymbol{Z}_{i,t} + u_k + \varepsilon_{i,t}, \quad (2)$$

$$Spread_{i,t} = \alpha_0 + \alpha_1 \widehat{BCC} + SOX_t + \boldsymbol{\beta}'\boldsymbol{Firm}_{i,t-1} + \boldsymbol{\theta}'\boldsymbol{Z}_{i,t} + v_k + \varepsilon_{i,t}, \quad (3)$$

where *BCC* (Board Corruption Culture) is the average corruption values for all boards, and *Spread* is the natural logarithm of the amount of pay scaled by London inter-bank offered rate. *Political Rights* is the rights to political participation. Firm characteristics are measured in year *t-1*. *SOX* is a dummy variable equal to one if the year is 2002 or later and zero otherwise. Loan and macroeconomic characteristics are measured in year *t*.. In all models, the *t*-values are computed for the heteroskedasticity-robust standard errors. Coefficients: ***, **, and * denote significance at the 1%, 5%, and 10% levels, respectively.

The first-stage regression, we use political rights (defined as the rights of political participation) as the instrumental variable by following previous studies (Brunetti & Weder, 2003; Jong-sung & Khagram, 2005; Arezki & Bruckner, 2011). They find that higher political rights are likely to have high agency problems. The data for political rights is obtained from Freedom House. The measurement of the political rights score is equal to an average of the boards' countries of ancestry. The political rights range from 1 to 7, where the lower score means more freedom. In the second-stage regression, we use the fitted value of the corruption culture from the first-stage regression to estimate the effect on the loan spread.

In column 1 of Table 5 presents the results of the first-stage regression of political rights on *BCC* and all other control variables. The coefficient for political rights is positive and significant. The Cragg-Donald Wald *F*-statistic is 1,936.187, which rejects the null hypothesis that the political rights are a weak instrumental variable. In the second-stage regression (in column 2), we replace the fitted value ($\widehat{BCC}$) from the first-stage regression. The coefficient for $\widehat{BCC}$ is still positive and significant for the loan spread. These results show that a stronger corruption culture leads a higher loan spread.

Regression with Firm Fixed Effect

We use a regression with a firm fixed effect to control for the influence of unobservable omitted variables.

$$Spread_{i,t} = \alpha_0 + \alpha_1 BCC_{i,t-1} + SOX_t + \boldsymbol{\beta}'\boldsymbol{Firm}_{i,t-1} + \boldsymbol{\theta}'\boldsymbol{Z}_{i,t} + \mu_i + \varepsilon_{i,t}, \qquad (4)$$

In column 3 of Table 5, the coefficient for the corruption culture is positive and significant at the 1% level. After controlling for the firm fixed effect, the result still supports H1.

Propensity Score Matching

The hire of corrupt directors as board members could be self-selection. Even if we control for the firm fixed effect, there still is a concern for the self-selection bias. To solve the self-selection bias, we use propensity score matching (PSM) by following previous studies (Rosenbaum & Rubin, 1983).

We sort firms into quartiles and take the top quartile as the stronger corruption culture (treated firms) and the bottom quartile as the weakest corruption culture (control firms). We use a Probit regression on the top and bottom quartiles and include all control variables. For the robustness results, we use five different matching methods: (1) Nearest neighbor (n=1), (2) Mahalanobis, (3) Nearest neighbor (n=2), (4) Gaussian Kernel, and (5) Radius (1.0).

In Table 6, we show the differences between the treatment and control firms. In all models, the *t*-statistic's value is positive and significant at the 1% level, which confirms that firms with a stronger corruption culture in their boards are charged higher loan spreads. The results show that banks consider the stronger corruption culture as an agency problem and thus charge high loan spreads.

Table 6: Propensity score matching (PSM)

Matching method	Treatment	Control	Difference	*t*-Statistic
(1) Near neighbor (n=1)	5.0559	4.8390	0.2169***	2.79
(2) Mahalanobis	5.0591	4.5680	0.4911***	8.54
(3) Near neighbor (n=2)	5.0559	4.8223	0.2336***	3.29
(4) Kernel Gaussian	5.0559	4.7664	0.2895***	5.14
(5) Radius (0.1)	5.0559	4.7669	0.2890***	5.10

The dependent variable is *Spread* (the natural logarithm of the amount of pay scaled by London inter-bank offered rate). In all models, the *t*-values are computed for the heteroskedasticity-robust standard errors. Coefficients: ***, **, and * denote significance at the 1%, 5%, and 10% levels, respectively.

Difference-in-Differences Analysis

We use the Sarbanes-Oxley Act of 2002 (SOX) as an exogenous shock in a DiD analysis Coles et al, 2014; Balsmeier et al, 2017). We focus on the sample period 2001 – 2003 and calculate the change in the board's corruption culture. We use the change ratio to differentiate treated firms (top 50%) from the control firms (bottom 50%) before SOX. The sample size is 537 observations with 118 firms (55 treated firms and 58 control firms) after we use the PSM for selecting control firms. We use the same setting as in Equation (1) and run the OLS as follows:

$$Spread = D_{Tr}\times Y_{2002} + D_{Tr}\times Y_{2003} + D_{Tr} + Y_{2002} + Y_{2003} + \varepsilon, \quad (5)$$

Table 7: Difference-in-differences (DiD)

Panel A: Difference-in-differences matching analysis			
	Pre	Post	Difference (Post - Pre)
Control	4.429	4.445	0.016 (0.10)
Treated	4.106	4.572	0.466*** (3.68)
Difference			0.450**
			(2.31)

		(2.34)	
D^{Tr}		-0.324**	
		(-2.51)	
Y_{2002}		-0.191	
		(-1.33)	

Y_{2003}		0.015	
		(0.11)	
Obs.		537	
Adj. R^2		0.021	

where the dependent variable is *Spread*. Y_{2002} and Y_{2003} are time dummy variables. D_{Tr} is a treated group dummy that equals to one if the change ratio of the corruption culture is larger than the median and zero otherwise. $D_{Tr}{\times}Y_{2003}$ is a DiD estimator. In all models, the *t*-values are computed for the heteroskedasticity-robust standard errors. Coefficients: ***, **, and * denote significance at the 1%, 5%, and 10% levels, respectively.

In Table 7, the interaction of $D_{Tr}{\times}Y_{2003}$ is positive and significant for banks charging firms a higher loan spread if the firm's corruption culture on the board increases after SOX. Therefore, banks consider a stronger corruption culture is an agency problem.

The Moderating Effect of Corporate Governance

The empirical studies show that corporate governance mechanisms can reduce agency problems and increase monitoring roles. Firms with stronger institutional ownership are associated with lower loan spreads (Lin et al, 2018). In other ways, weak corporate governance destroys rather than creates value because of fewer financial experts and entrenchment index (Farber, 2005; Bebchuk et al, 2009). Following the previous studies, we use busier boards as a proxy for weak corporate governance (Hoechle et al, 2012). We then do a conditional test based on strong and weak governance subsamples. If the corruption culture is an agency problem, then its effect on loan prices should be more significant when firms are associated with weak corporate governance. We use several corporate governance measures such as institutional ownership (*IO_Low*), financial expertise (*Expert_Low*), entrenchment index (*E_Index_High*), and busy boards (*BB_High*). All of the corporate governance measures are defined in the appendix.

We set the dummy variables for corporate governance as follows: (1) firms with institutional ownership lower than the median; (2) firms with no financial expertise on the boards; (3) firms with an entrenchment index higher than the median; and (4) firms with board directors who serve on at least three boards. We set a dummy with these criteria equal to one and zero otherwise. We use the following regression to test the moderating effect of corporate governance:

$$Spread_{i,t} = \alpha_0 + \alpha_1 BCC_{i,t-1} + \alpha_2 BCC_{i,t-1} \times CG_{i,t-1} + \alpha_3 CG_{i,t-1} + SOX_t + \boldsymbol{\beta}'\boldsymbol{Firm}_{i,t-1} + \boldsymbol{\theta}'\boldsymbol{Z}_{i,t} + v_k + \varepsilon_{i,t}, \quad (6)$$

Table 8 presents the interaction effect of corporate governance on the corruption culture. The coefficients in all models remain significant and support our expectations. In all models, the coefficients for the interaction terms between the corruption culture with institutional ownership (*IO_Low*), financial expertise (*Expert_Low*), entrenchment index (*E_Index_High*), and busy boards (*BB_High*) are positive and significant. These interaction terms confirm H2.

where the dependent variable is *Spread* (the natural logarithm of the amount of pay scaled by London inter-bank offered rate). *BCC* (Board Corruption Culture) is the average corruption values for all boards. $CG_{i,t-1}$ is the corporate governance with institutional ownership (*IO_Low*) that equals one if no percentage of shares is held by institutional ownership and zero otherwise, e-index (*E-Index_High*) equals one if the Entrenchment Index is higher than the median and zero otherwise, financial experts (*Expert_Low*) equal one if no financial expertise exists on the boards and zero otherwise, and busy boards (*BB_High*) equal one if the a board director serves on at least three boards and zero otherwise. *SOX* is a dummy variable equal to one if the year is 2002 or later and zero otherwise. Firm characteristics are measured in year *t-1*. Loan and macroeconomic characteristics are measured in year *t*. In all models, the *t*-values are computed for the heteroskedasticity-robust standard errors. Coefficients: ***, **, and * denote significance at the 1%, 5%, and 10% levels, respectively.

Additional Supporting Evidence

Boards' Corruption Culture, Non-Price Terms, and Firms' Rating

Following the previous studies, we use non-price terms (covenants) to test the effect of the board's corruption culture (Graham et al, 2008; Hasan et al, 2014; 2017). We use an ordinary least square (OLS) to construct the effect of *BCC* on non-price loan terms and the firm's rating as follows:

$$Y_{i,t} = \alpha_0 + \alpha_1 BCC_{i,t-1} + SOX_t + \boldsymbol{\beta}'\boldsymbol{Firm}_{i,t-1} + \boldsymbol{\theta}'\boldsymbol{Z}_{i,t} + v_k + \varepsilon_{i,t}, \tag{7}$$

Table 9 shows the results. In columns 1 and 3, the coefficients for the corruption culture are positive and significant at the 1% level. These results show that firms with a stronger corruption culture are given more general and total covenants.

where the dependent variables of non-price terms and rating include general covenants (*GenCov*), financial covenants (*FinCov*), total covenants (*TotalCov*), and *Rating* is Standard & Poor's debt rating. *BCC* (Board Corruption Culture) is the average corruption values for all boards. *SOX* is a dummy variable equal to one if the year is 2002 or later and zero otherwise. Firm characteristics are measured in year *t-1*. Loan and macroeconomic characteristics are measured in year *t*. In all models, the *t*-values are computed for the heteroskedasticity-robust standard errors. Coefficients: ***, **, and * denote significance at the 1%, 5%, and 10% levels, respectively.

In addition, the credit rating is one good measure for firms' credit risk (Jiraporn et al, 2014). To test whether the corruption culture causes a lower credit rating, we use credit rating as the dependent variable in column 4 of Table 9. The coefficient for the corruption culture is negative and significant at the 1% level, which confirms that firms with a stronger corruption culture have a lower credit rating.

Specific Industries: Combination of Sin and Politically Sensitive Industries

We classify alcohol and gaming industries sin industries and tobacco, guns and defense, and natural resources industries as "politically sensitive industries" (Hong & Kacperczyk, 2009; 2012). We expect that the effect of the corruption culture should be weak in these industries. This weakness is because these industries are more likely to allow corrupt behaviors. Consistent with our expectation, we find insignificant and significant results for the corruption culture in specific industries and other industries (Panels A and B of Table 10).

Table 10: Boards' corruption culture in specific industries

This table presents the regression results for the effect of the board's corruption culture on loan spreads. *BCC* (Board Corruption Culture) is the average corruption value for all boards. Firm characteristics are measured in year *t-1*. Loan and macroeconomic characteristics are measured in year *t*. In panel A, following the study of Hong & Kostovetsky (2009, 2012), the specific industries are alcohol, gaming, tobacco, guns and defense, and natural resources. In Panel B, the other industries are all others except finance and the specific industries. In all models, the *t*-values are computed for the heteroskedasticity-robust standard errors. Coefficients: ***, **, and * denote significance at the 1%, 5%, and 10% levels, respectively.

Robustness Checks

Alternative Measures of Corruption Culture

In this subsection, we use other corruption measures such as *CEO Corruption*, *Independent Corruption*, and *Insider Corruption* to examine the effect of the corruption culture. In columns 1 and 2 of Table 11, the results show that the corruption culture of board and CEO are significant for the loan spread. In columns 3, 4, 5, and 6, the corruption culture of board, independent boards, and insider boards are positive and significant for the loan after controlling for the *CEO Corruption*. Thus, our findings confirm that the firm's corruption culture comes from independent boards and insider boards but not from the CEO.

We also use two alternative measures of the corruption culture from the International Country Risk Guide (Mauro, 1998) and the Worldwide Governance Indicators (Kaufmann et al, 2007). In columns 7 and 8 of Table 11, the evidence shows that the board's corruption culture is positively and significantly related to the loan spread, which supports H1 again.

This table presents the regression results for the robustness checks. In Models (1)–(8), the dependent variable is *Spread* (the natural logarithm of the amount of pay scaled by London inter-bank offered rate). *BCC* (Board Corruption Culture) is the average corruption values for all boards. *Independent Corruption* is the average corruption values for all independent directors. *Insider Corruption* is the average corruption values for the executives. *CEO Corruption* is the average corruption values for CEOs. *BCC_WGI* (The Worldwide Governance Indicators) follows Kaufmann et al, (2007), and *BCC_ICRG* (International Country Risk Guide) follows Mauro (1998). Firm characteristics are measured in year *t-1*. Loan and macroeconomic characteristics are measured in year *t*. In all models, the *t*-values are computed for the heteroskedasticity-robust standard errors. Coefficients: ***, **, and * denote significance at the 1%, 5%, and 10% levels, respectively.

Total Cost of Borrowing (*TCB*)

Throughout the study, we use loan spread as the measure of the loan price. However, Berg et al., (2016) recently recommended that over 80% of US syndicated loans contained at least one of type fee, and contracts often specify a whole menu of spreads and types of fees. Therefore, we use their measure as another dependent variable in the robustness check: total cost of borrowing (*TCB*) as the dependent variable as follows:

$$TCB_{i,t} = \alpha_0 + \alpha_1 BCC_{i,t-1} + SOX_t + \boldsymbol{\beta}'\boldsymbol{Firm}_{i,t-1} + \boldsymbol{\theta}'\boldsymbol{Z}_{i,t} + v_k + \varepsilon_{i,t}, \quad (8)$$

Obs.	3,749	3,749	3,514	3,514	3,514
Adj. R^2	0.580	0.581	0.708	0.774	0.807

where the dependent variable is *TCB* (the natural logarithm of loan spread plus other fees). *BCC* (Board Corruption Culture) is the average corruption values for all boards. *SOX* is a dummy variable equal to one if the year is 2002 or later and zero otherwise. Firm characteristics are measured in year *t-1*. Loan and macroeconomic characteristics are measured in year *t*. In all models, the *t*-values are computed for the heteroskedasticity-robust standard errors. Coefficients: ***, **, and * denote significance at the 1%, 5%, and 10% levels, respectively.

Table 12 presents the regression results. The coefficients of *BBC* for *TCB* are positive and significant at the 1% level. The results thus support our hypothesis that firms with a stronger corruption culture have higher loan costs.

CONCLUSIONS

An increasing number of studies discuss the influences of corporate culture or corruption culture on corporate decisions. However, whether the board's corruption culture affects the firm's financing cost has not been investigated yet. Thus, this study examines whether this corruption culture influences the bank's loan terms by using 7,517 loans of US firms between 1996 and 2015. We use the average corruption culture of boards (excluding the CEO) by determining their ancestral country from their surname to measure the corruption culture of firms.

Our empirical results show that a stronger corruption culture increases the loan spread and total cost of borrowing. In addition, we use several methods to address endogeneity concerns. All the results support the main hypotheses. In further testing, our evidence indicates that the effect of the corruption culture on the costs of bank loans increases when firms have weak corporate governance. Such evidence indicates that (1) a stronger corruption culture is one kind of weak corporate governance for firms and (2) banks consider a stronger corruption culture as a type of agency problem when they make lending decisions.

We also conduct several tests and robustness checks to corroborate our main hypotheses. First, we find that the bank requires more covenants (especially general covenants) for firms with a stronger corruption culture. Second, our evidence shows that the stronger corruption culture of firms also reduces their ratings. Third, we find the effect of the corruption culture is less in specific industries that encourage more corrupt behaviors. Fourth, we find similar results even if we use alternative measures of the corruption culture (Mauro, 1998; Kaufmann et al, 2007).

Overall, our findings support the banks' view that the firms' with a strong corruption culture are an agency risk, which provides a reference for scholars, policy makers, and market investors for assessing the role of the corruption culture in regulating corporate governance.

ABSTRACT

The paper conducts a DCF valuation for Syracuse University and Indiana University. We find that the conversion of social benefit to net earnings and free cash flows adds value to equityholders. In the best scenario, the net worth is about 2 times the book equity.

KEYWORDS: DCF valuation, Nonprofit universities, Net worth, Social benefit

INTRODUCTION

Nonprofit universities in the U.S. distribute most earnings as scholarship and financial aid to students, pay zero tax, and incur zero cost for financing with donated equity capital. This poses two challenges to financial analyses of such institutions. First, it is difficult to estimate their net worth (market value of equity) due to their low levels of net earnings and free cash flows as well as zero cost of equity. Second, it is difficult to directly compare nonprofits with for-profits in terms of financial performance and net worth.

Recent literature has explored several corporate finance aspects of nonprofit institutions. Adelino, Lewellen, and Sundaram (2015) examine the investment-cash flow sensitivity for nonprofit hospitals and point out that it is similar to the sensitivity for shareholder-owned corporations. Jegers (2011a) shows the existence of financing constraints when nonprofits have no substantial opportunities to increase revenues from fundraising and their managers are unwilling to exert high fundraising efforts. Jegers (2011b) detects that tighter equity constraints are associated with more debts relative to total assets for Belgian nonprofits. Jegers and Verschueren (2006) argue that equity is cheaper than debt for nonprofits, and report that almost half of Californian nonprofits use no debts at all. Bøhren and Josefsen (2013) study the profitability of Norwegian banks and report that stockholder-owned banks do not outperform nonprofit ones. Kalodimos (2017) documents that stronger internal governance of nonprofit hospitals results in better performance as measured by the heart attack survival probability. Gertler and Kuan (2009) investigate the takeover market for hospitals and find that a nonprofit hospital tends to be sold at a lower price to a “like-minded” nonprofit buyer than to a for-profit buyer, based on the measure of Tobin’s *q*.

This paper conducts the Discounted Cash Flow (DCF) valuation of nonprofit universities, a process revealing the relationship between institutional fundamentals and value. Given their problems of low earnings and zero equity cost, we adjust nonprofit net earnings, free cash flows to equityholders, cost of equity, and tax rate to fit into the for-profit model. Hence, the nonprofit net worth can be estimated with the DCF approach. Two organizations, Syracuse University (SU) and Indiana University (IU), are studied in the paper. SU at Syracuse, New York is a nonprofit private organization that does not receive any government appropriations. IU at Bloomington, Indiana, with a few other branches located in the state, is a nonprofit public organization that receives state appropriations. For both, the current time refers to June 2017, and the 10-year historical period ranges from June 2007 to June 2017. The potential investors or acquirers are assumed to be for-profit publicly traded companies in the education industry. We collect the financial reports and other information of SU and IU from their public sources, and obtain the data of the education industry from the website of Professor Damodaran. Two DCF methods, Economic Profit to Equityholders (EP to Equityholders) and Free Cash Flow to Equityholders (FCFE), are applied in the valuation process. The forecasting of future earnings, cash flows, and discount rate is based on the subjective view of the for-profit acquirers. Such analysis does not apply to the situation in which the potential acquirers are governments or nonprofit organizations, since different types of investors hold different perspectives on the value of an acquisition target.

Our study yields several findings. First, we transform nonprofits to for-profits by adjusting a few relevant variables. The transformation generates a considerable market value added to nonprofit equityholders. In the best scenario, the net worth is about 2 times the book equity for both SU and IU. Second, with the net worth breaking even at the book equity, we find that about half of the existing social benefit needs to be converted to net earnings and free cash flows, while the rest is distributed to students. Third, when changing from a nonprofit to a for-profit status, the university would lose some public-and-government-supported fund revenues, and this potential loss would be offset by a potential increase in tuition revenues. A nonprofit private university seems more likely to achieve such a task than a nonprofit public university because the former relies much less on the supported fund revenues than the latter.

This paper attempts to make a few impacts on practitioners. First, it would be easier for government agencies to recognize the value-creating nonprofits in order to allocate funds. Second, it would be easier for public investors to identify the value-enhancing nonprofits in order to make donations. Third, it would be easier for corporations to understand the intrinsic value of nonprofits in order to conduct mergers and acquisitions. Fourth, it would be easier for nonprofits to compare themselves with for-profits.

DCF VALUATION PROCESS

We use two DCF methods to estimate the net worth, by following Pinto, Henry, Robinson, and Stowe (2015), Koller, Goedhart, and Wessels (2015), and Damodaran (2012). Based on the first method, the net worth is calculated as the current book equity plus the present value of expected future EPs to Equityholders. Based on the second method, the net worth is calculated as the present value of expected future FCFEs.

Nonprofit universities provide substantial social benefit, such as granting scholarship and financial aid to students each year. In theory, these organizations are tax free and they distribute all their profits to students as social benefit, leading to zero net earnings as well as zero return on equity. In addition, their equity financing comes from donations, incurring zero cost of equity. With zero return on equity and zero cost of equity, the annual economic profit to equityholders becomes zero, and the market value added to equityholders also becomes zero. Therefore, the net worth is equal to the book value of equity.

When a nonprofit university is purchased by a for-profit company, the tax payment becomes required, the social benefit distribution becomes non-required, and the cost of equity becomes larger than zero. In this transformation, the amount of social benefit distribution is converted to net earnings and free cash flows, generating a market value added to equityholders. The discount rate is defined as the cost of equity of the potential acquirer. The tax calculation is based on the tax rate of the acquirer.

Meanwhile, as it changes itself from a nonprofit to a for-profit organization, a university would lose some public-and-government-supported fund revenues, such as gifts (or contributions), grants and contracts, and state appropriations. We assume that the potential loss in these fund revenues would be offset by the potential increase in tuition revenues. That is, the total revenues would not be affected by this change.

Table 1. DCF valuation process

Panel A. All methods

Current time	June 2017
Past 10 years	June 2007 to June 2017
Future growth pattern	One-stage constant growth rate for the university
Future growth rate (g) First proxy	The first proxy is the geometric average growth rate of the university's adjusted net earnings in the past 10 years.
Future growth rate (g) Second proxy	The second proxy is the geometric average growth rate of the university's revenues in the past 10 years.
Future cost of equity (k)	Proxied by the average cost of equity of the education industry in the past 10 years
BE_0	Book equity of the university at the current time

Panel B. EP to Equityholders method

Adjusted net earnings	(Reported net earnings + Reported scholarship and financial aid*Social benefit converted in %) *(1-tax rate)
Adjusted ROE	Adjusted return on equity Calculated as the adjusted net earnings divided by prior book equity.
Future ROE	Proxied by the average adjusted ROE in the past 10 years.
EP_1	Economic profit to equityholders in future year 1 $EP_1 = BE_0$*(Future ROE – k)
NW_0	Net worth of the university at the current time $NW_0 = BE_0$ + Market value added, where Market value added = $EP_1/(k–g)$

Panel C. FCFE method

FCFE	FCFE = Cash flow from operations – Investment in fixed capital + Net borrowing
Adjusted FCFE	Adjusted FCFE = FCFE – Reported net earnings + Adjusted net earnings
Adjusted FOE	Adjusted FCFE on equity Calculated as the adjusted FCFE divided by prior book equity.
Future FOE	Proxied by the average adjusted FOE in the past 10 years.
$FCFE_1$	Free cash flows to equityholders in future year 1 $FCFE_1 = BE_0$*Future FOE
NW_0	Net worth of the university at the current time $NW_0 = FCFE_1 / (k–g)$

Table 1 presents the DCF valuation process. Panel A provides illustrations for all the methods used, Panel B for the EP to Equityholders method, and Panel C for the FCFE method.

In Panel A of Table 1, the future growth pattern is set up as one-stage constant growth because both the student enrollment and the total revenues of the two universities have climbed slowly in the past. It seems unnecessary to use a two-stage or three-stage pattern. The future growth rate (g) has two proxies: one is based on the average growth rate of the university's adjusted net earnings in the past 10 years, and the other, the average growth rate of the university's revenues in the past 10 years. The future cost of equity (k) is proxied by the average cost of equity of the education industry in the past 10 years.

In Panel B of Table 1, the future return on equity (ROE) is proxied by the average adjusted ROE in the past 10 years, and the adjusted ROE is estimated as the adjusted net earnings divided by the prior book equity. The adjustment of net earnings is made by adding the converted amount of social benefit to the reported net earnings, and by paying taxes. See Equation (1) below for the definition of the adjusted net earnings.

$$\begin{aligned}&\text{Adjusted net earnings}\\&= (\text{Reported net earnings}\\&\quad + \text{Reported scholarship and financial aid*Social benefit converted in \%})\\&\quad * (1\text{-tax rate}).\end{aligned} \tag{1}$$

Specifically, the reported net earnings refer to the increase in net assets, i.e., the bottom line of the income statement. The tax rate means the newly updated marginal tax rate (21%) instead of the old rate (35%), because the purpose of this calculation is to estimate the future ROE. Finally, the net worth at the current time (NW_0) is equal to the current book equity (BE_0) plus the market value added, where the market value added is equal to the projected economic profit to equityholders in future year1 (EP_1) divided by the difference between cost of equity and growth rate, and the economic profit (EP_1) is equal to the current book equity multiplied by the difference between the future ROE and the future cost of equity. See Equation (2) below for the net worth calculation.

$$NW_0 = BE_0 + \text{Market value added,} \tag{2}$$

where Market value added = $EP_1/(k–g)$, and $EP_1 = BE_0*(\text{Future ROE} – k)$.

In Panel C of Table 1, the future FCFE on equity (FOE) is proxied by the average adjusted FOE in the past 10 years, and the adjusted FOE is estimated as the adjusted FCFE divided by the prior book equity. The adjustment of free cash flows is made by subtracting the reported net earnings and adding the adjusted net earnings, as presented in Equation (3) below.

$$\text{Adjusted FCFE} = \text{FCFE} – \text{Reported net earnings} + \text{Adjusted net earnings,} \tag{3}$$

where FCFE = Cash flow from operations – Investment in fixed capital + Net borrowing. Lastly, the net worth at the current time (NW_0) is equal to the projected FCFE in future year1 ($FCFE_1$) divided by the difference between cost of equity and growth rate, as displayed in Equation (4) below.

$$NW_0 = FCFE_1 / (k–g), \tag{4}$$

where $FCFE_1 = BE_0*\text{Future FOE}$.

SUMMARY DATA OF ACQUIRERS AND TARGETS

For-profit publicly traded companies in educational services are regarded as potential acquirers. Table 2 provides summary data of education companies. The average cost of equity is 8.24%, which will be used as the future discount rate in valuing SU and IU. The average percentage of equity out of capital (based on market measures) is as high as 83.73%, implying a financing structure of light debt and heavy equity. We presume that both the cost of equity and the equity to capital ratio will remain constant in the future for the acquirers. Since the tax rate was reduced in January 2018, the new rate (21%) will be used to estimate the future ROE and the future FOE for SU and IU. The average growth in net income (7.51%), the average growth in revenues (7.68%), the average ROE (12.95%), and the average price/book ratio (3.59) are much higher than the current growth in net income (-10.92%), the current growth in revenues (-

3.90%), the current ROE (3.10%), and the current price/book ratio (1.95), respectively. The results suggest better performance historically than currently for education companies. The current price/book ratio (1.95) denotes that the net worth of education companies is nearly 2 times the book equity in 2017.

Table 2. Summary data of education companies

	Current year	10-year average	Future years
Cost of equity	9.42%	8.24%	8.24%
Equity/Capital	74.97%	83.73%	
Marginal tax rate	35%	35%	21%
Historical 5-year average growth in net income	-10.92%	7.51%	
Historical 5-year average growth in revenues	-3.90%	7.68%	
ROE	3.10%	12.95%	
Price/Book ratio	1.95	3.59	

SU and IU are treated as acquisition targets. Table 3 provides summary data of the targets. Panel A reports the current-year data, and Panel B, the 10-year-average data. In Panel A of Table 3, we note that the two universities are large and comprehensive in general. Specifically, SU is smaller than IU in terms of student enrollment (21,970 vs. 94,698), total revenues ($1.0 billion vs. $3.2 billion), total assets ($2.9 billion vs. $5.5 billion), and book equity ($2.0 billion vs. $3.9 billion). The per-student tuition and fees are much higher for SU as a private university than for IU as a public university ($39,907 vs. $15,337).

In Panel B of Table 3, first, we find that both the student enrollment and the total revenues of the two universities grow slowly in the past 10 years. The growth rate of student enrollment is 1.42% for SU and 0.24% for IU. The growth rate of revenues is 2.43% for SU and 2.81% for IU.

Second, pertaining to the income statement, the student tuition and fee revenues out of total revenues are 84.62% for SU vs. 41.86% for IU. The public-and-government-supported fund revenues out of total revenues, including gifts (or contributions), grants and contracts, and state appropriations, are 17.59% for SU vs. 41.82% for IU. Additionally, these fund revenues out of student tuition and fees are 20.89% for SU vs. 100.86% for IU. Therefore, SU relies much less on supported fund revenues than IU. It is noted that SU as a private university receives zero state appropriations. IU as a public university receives considerable amount of state appropriations, which are 19% out of total revenues and 45.99% out of student tuition and fees. The scholarship and financial aid costs out of total revenues are 31.21% for SU vs. 11.99% for IU; and these costs out of student tuition and fees are 36.87% for SU vs. 28.59% for IU. That is to say, SU distributes more social benefit to students than IU, since the former charges much higher per-student tuition and fees than the latter. The instructional costs out of total revenues are similar for the two universities (38.47% vs. 34.34%).

Third, with regard to the balance sheet, the asset turnover (total revenues divided by total assets) is 34.39% for SU vs. 61.43% for IU, suggesting that IU is more efficient in asset usage. The non-current assets contain two major items: the investments which are financial securities such as stocks and bonds, and the fixed assets which are long-term physical assets such as land, land improvements, buildings, and equipment. The investments out of total assets are 45.30% for SU vs. 26.45% for IU, and the fixed assets out of total assets are 39.77% for SU vs. 55.05% for IU. Thus, SU endures more risk exposure to financial markets. The capital structure measures are similar to those of the education companies, including the long-term debts to total assets ratio (15.75% for SU vs. 19.04% for IU), the book equity to total assets ratio

(69.05% for SU vs. 67.14% for IU), and the book equity to capital ratio (81.46% for SU vs. 76.67% for IU). Thus, SU and IU have a capital structure of light debt and heavy equity.

Table 3. Summary data of universities

Panel A. Current-year data (2017)

	Syracuse University	Indiana University
Enrollment of students	21,970	94,698
Total revenues ($million)	995	3,193
Net earnings ($million) (unadjusted)	198	154
Total assets ($million)	2,852	5,474
Book equity ($million)	2,018	3,866
Student tuition and fees per student ($)	39,907	15,337
Panel B. 10-year-average data (2007-2017)		
Annual enrollment growth	1.42%	0.24%
Annual revenue growth	2.43%	2.81%
Student tuition and fees/Total revenues	84.62%	41.86%
Gifts (or contributions)/Total revenues	7.65%	3.49%
Grants and contracts/Total revenues	9.94%	19.33%
State appropriations/Total revenues	0.00%	19.00%
Scholarship & financial aid/Total revenues	31.21%	11.99%
Instructional costs/Total revenues	38.47%	34.34%
Net earnings/Total revenues (unadjusted)	1.88%	6.45%
Gifts (or contributions)/Student tuition and fees	9.16%	8.33%
Grants and contracts/Student tuition and fees	11.73%	46.54%
State appropriations/Student tuition and fees	0.00%	45.99%
Scholarship & financial aid/Student tuition and fees	36.87%	28.59%
Total revenues/Total assets	34.39%	61.43%
Investments/Total assets	45.30%	26.45%
Fixed assets/Total assets	39.77%	55.05%
Long-term debts/Total assets	15.75%	19.04%
Book equity/Total assets	69.05%	67.14%
Book equity/Capital	81.46%	76.67%
ROE (unadjusted)	1.99%	6.42%
FOE (unadjusted)	-1.50%	1.84%

Finally, the net earnings, the net margin (net earnings divided by total revenues), the ROE, and the FOE are unadjusted for social benefit conversion. It is noted that the unadjusted 10-year average ROE is 1.99% for SU and 6.42% for IU, which are much lower than the average ROE of education companies (12.95%). The unadjusted 10-year average FOE is -1.50% for SU and 1.84% for IU, which are also quite low. Since SU and IU dispense some profits as social benefit each year, they end up with low levels of net earnings and free cash flows to equityholders as well as low ROE and FOE ratios. If the unadjusted average ROE and FOE are used to forecast future net earnings and free cash flows, and if the for-profit cost of equity (8.24%) is used as the discount rate, the estimated net worth would be much lower than the book equity.

VALUATION RESULTS: FULL CONVERSION OF SOCIAL BENEFIT

The analysis in this section is based on the best-scenario assumptions summarized as follows. First, the existing social benefit is fully converted to net earnings and free cash flows, i.e., 100% of scholarship and financial aid are not distributed to students any longer; instead, they are converted to profits. Second, the potential loss of the public-and-government-supported fund revenues is offset by the potential increase in tuition revenues. That is to say, the total revenues remain the same.

Table 4. Valuation results: full conversion of social benefit

Panel A. Inputs and assumptions

	Syracuse University		Indiana University	
	Earnings growth	Revenues growth	Earnings growth	Revenues growth
Future growth rate (g)	3.74%	2.43%	4.38%	2.81%
Future cost of equity (k)	8.24%	8.24%	8.24%	8.24%
BE_0 ($million)	2,017.59	2,017.59	3,865.54	3,865.54
% of social benefit converted	100.00%	100.00%	100.00%	100.00%
Panel B. EP to Equityholders method				
Future ROE	14.12%	14.12%	14.22%	14.22%
EP_1 ($million)	118.78	118.78	231.25	231.25
NW_0 ($million)	4,658.39	4,065.13	9,868.44	8,130.68
NW_0/BE_0	2.31	2.01	2.55	2.10
Panel C. FCFE method				
Future FOE	10.62%	10.62%	9.63%	9.63%
$FCFE_1$ ($million)	214.36	214.36	372.33	372.33
NW_0 ($million)	4,765.74	3,695.10	9,665.19	6,867.24
NW_0/BE_0	2.36	1.83	2.50	1.78

Table 4 reports the net worth valuation results for SU and IU, assuming social benefit fully converted to earnings and cash flows. Panel A provides the inputs and assumptions for all methods used. Panel B provides the results for the EP to Equityholders method, and Panel C for the FCFE method. In Panel A of Table 4, the growth rate based on historical adjusted net earnings is 3.74% for SU and 4.38% for IU, and the growth rate based on historical revenues is 2.43% for SU and 2.81% for IU. They are much lower than the average growth rates of education companies (7.51% and 7.68%). Thus, it seems proper to employ a one-stage constant growth pattern in the valuation of SU and IU. In addition, we assume that 100% of social benefit is converted to net earnings and free cash flows.

In Panel B of Table 4, the future ROE (based on adjusted net earnings) is 14.12% for SU and 14.22% for IU, roughly in line with the average ROE of education companies (12.95%). For both universities, since the future ROE is larger than the cost of equity (8.24%), the annual economic profit and the market value added to equityholders are positive, and the net worth exceeds the book equity. As shown, the net worth of SU is estimated to be $4.1 to $4.7 billion, which is 2.01 to 2.31 times the book equity. The net worth of IU is estimated to be $8.1 to $9.9 billion, which is 2.10 to 2.55 times the book equity.

In Panel C of Table 4, the future FOE (based on adjusted free cash flows) is 10.62% for SU and 9.63% for IU. As displayed, the net worth of SU is estimated to be \$3.7 to \$4.8 billion, which is 1.83 to 2.36 times the book equity. The net worth of IU is estimated to be \$6.9 to \$9.7 billion, which is 1.78 to 2.50 times the book equity.

BREAKEVEN: PARTIAL CONVERSION OF SOCIAL BENEFIT

In the previous section, we report that the estimated net worth is higher than the book equity based on the best-scenario assumptions. In this section, we assume that less than 100% of social benefit is converted to profits. That is, one part of existing social benefit is converted to net earnings and free cash flows, and the other part is distributed to students as scholarship and financial aid. With lower adjusted net earnings and lower free cash flows, the net worth would become lower. If the net worth is reduced to the level of book equity (i.e., the breakeven situation), the required percentage of social benefit conversion can be estimated.

Table 5. Breakeven: partial conversion of social benefit

	Syracuse University		Indiana University	
	Earnings growth	Revenues growth	Earnings growth	Revenues growth
Panel A. Inputs and assumptions				
Future growth rate (g)	3.74%	2.43%	4.38%	2.81%
Future cost of equity (k)	8.24%	8.24%	8.24%	8.24%
BE_0 (\$million)	2,017.59	2,017.59	3,865.54	3,865.54
NW_0 (\$million)	2,017.59	2,017.59	3,865.54	3,865.54
NW_0/BE_0	1.00	1.00	1.00	1.00
Panel B. EP to Equityholders method				
Future ROE	8.24%	8.24%	8.24%	8.24%
EP_1 (\$million)	0.00	0.00	0.00	0.00
% of social benefit converted	53.08%	53.08%	34.56%	34.56%
Panel C. FCFE method				
Future FOE	4.50%	5.80%	3.85%	5.42%
$FCFE_1$ (\$million)	90.75	117.04	148.91	209.58
% of social benefit converted	51.17%	61.56%	36.78%	53.95%

Table 5 reports the breakeven results for SU and IU, assuming net worth equal to book equity. In Pane A of Table 5, the growth rates, the cost of equity, and the book equity are the same as those in Panel A of Table 4. For the breakeven assumption, we set the net worth equal to the book equity. Thus, the net worth to book equity ratio is 1.00 accordingly.

In Panel B of Table 5, the future ROE is equal to the cost of equity, and the annual economic profit is zero, implying zero market value added to equityholders. Both the future ROE and EP_1 are lower than those in Panel B of Table 4. In this situation, SU needs to convert 53.08% of existing social benefit to net earnings and free cash flows, and IU, 34.56%.

In Panel C of Table 5, the future FOE is 4.50% to 5.80% for SU and 3.85% to 5.42% for IU. Both the future FOE and $FCFE_1$ are lower than those in Panel C of Table 4. In this situation, SU needs to convert 51.17% to 61.56% of existing social benefit to net earnings and free cash flows, and IU, 36.78% to 53.95%.

CONCLUSIONS

We use the DCF approach to estimate the net worth for two nonprofit universities: SU and IU. Our study transforms nonprofits to for-profits by converting nonprofit social benefit distributions to net earnings and free cash flows and by adopting for-profit cost of equity and tax rate. These adjustments add considerable value to nonprofit equityholders. The following provides a summary of our main results.

First, by using different valuation methods (EP to Equityholders and FCFE) and different growth rates (earnings and revenues), we demonstrate that the net worth to book equity ratio is 1.83 to 2.36 for SU and 1.78 to 2.55 for IU in June 2017. These ratios of SU and IU are by and large consistent with the price/book ratio (1.95) of the for-profit education companies at the same time. Our results are established based on the best-scenario assumptions. That is, the existing social benefit could be fully converted to net earnings and free cash flows, and the potential loss of the public-and-government-supported fund revenues could be offset by the potential increase in tuition revenues.

Second, when the net worth breaks even at the book equity, we find that SU needs to convert 51.17% to 61.62% of existing social benefit to net earnings and free cash flows, and IU, 34.56% to 53.95%, while the rest is distributed to students as scholarship and financial aid.

Third, once acquired by for-profit companies, SU and IU in the worst situation would lose all the fund revenues (gifts or contributions, grants and contracts, and state appropriations). To make up for these losses and to maintain the same levels of total revenues, SU would have to increase tuition revenues by 20.89%, and IU, 100.86%. Therefore, SU relies much less on the public-and-government-supported fund revenues than IU. This is in line with the fact that the former charges much higher per-student tuition and fees than the latter.

Please note that the discussions in this paper do not represent opinions of any universities, nor those of any potential investors. They are only the academic inquiries of the authors, and they may contain errors and biases.

ABSTRACT

This research investigates whether CEO using twitter, proxied by CEO_twitter influences CEO compensation. First, we find that CEO_twitter is significantly positive related to total compensation (TDC1), confirming CEO_twitter has a real effect on compensation. We also examine whether posting more tweet can curtail the market responses to the earning announcements. In addition, the effect is more salient in the sample of higher information asymmetry. Besides, the effect of CEO Twitter becomes stronger when firms have a high product market competition. Overall, our findings support that CEO with twitter account receive more total CEO compensation.

KEYWORDS: CEO Twitter, Compensation, Abnormal return, Information asymmetry

INTRODUCTION

Information intermediaries, besides traditional ones (Miller 2006; Miller and Skinner 2015, Bushee and Miller 2012), recently explode in new sources of information like Twitter, is of crucial importance for a firm. It can improve the firm's information environment (Chen, Hwang, and Liu, 2017,2018; Bartov, Faurel and Mohanram, 2018; Elliott, Grant and Hodge 2018) so that investors can take some advantages, acquire timely and value-relevant information. Corporate executives are becoming increasingly active on twitter owing to direct-access information technologies (DAITs), which allow users to directly access investors. In the research of Blankespoor, Miller and White, 2014, to examine the effect of

DAIT dissemination on information asymmetry, they focus on sample of information technology firms with active Twitter accounts and find that dissemination via Twitter is associated with lower bid-ask spreads, greater depths, and a higher liquidity ratio after controlling for the information content of the news and other firm as well as market characteristics. It supports that firms use Twitter to spread out news, and this dissemination helps reduce information asymmetry. Firms can use twitter to reduce investors' information acquisition costs and allow more potential investors to process the information.
Further, the results from the study of Chen et al, 2018 suggest that tweets coming out of top executives' personal Twitter accounts are significantly more impactful than those coming out of firm-managed accounts (Chen, Hwang and Liu, 2018). Using Twitter gives CEO any benefit in compensation is an intriguing question which has not been addressed. In this paper, we fill this gap in the literature by examining whether using twitter is associated with higher compensation. Specifically, we explore the following three research questions: (1) Do CEOs with twitter account get higher total compensation? (2) whether posting more tweet can curtail the market responses to the earning announcements (3) the effect is more salient in the sample of higher information asymmetry and high market competition product? (4) Do twitter effects still hold after adjusting for other CEO compensation schemes.

To study our three research questions, we construct our sample of top executives' personal Twitter accounts, we download a list of all CEOs in the Execucomp database between 2006 and 2015. Execucomp covers the S&P 1500 as well as companies that were once part of the S&P 1500 index and that are still trading. We start with the complete list of all CEOs in Execucomp and locate users with active Twitter accounts that have the same first and last names as the CEO in question. We then cross-check the executives' middle names, gender, and company information with user characteristics; we also read tweets to determine whether any account that we find does indeed belong to the executive in question. Through this labor-intensive process, we determine that 336 S&P 1500 CEOs have active personal Twitter accounts and work for firms that have the data necessary to conduct our tests. We obtain all accounting variables and stock prices from the Compustat database and the Center for Research in Security Prices (CRSP). Corporate-governance and CEO-compensation-related variables come from RiskMetrics and ExecuComp.
We document three sets of findings. First, in our main finding we find that CEOs using twitter had higher total compensation (TDC1). That is, with CEOs own at least one personal twitter account, their compensation is higher after controlling for CEO characteristics, firm characteristics and corporate governance factors. The evidence remains strong when we control for industry and year fixed effects.
In further testing, we examine in greater detail whether the effect of using twitter derives from the information asymmetry channel. We use several variables to measure the information asymmetry, including firm age, number of analyst coverage and rating. We argue that, if

CEO with twitter account is viewed as a representation of information asymmetry, then its effect would be outweighed in the sample of higher information asymmetry. Our results provide supportive evidence for this channel, confirming that our main findings of twitter effect are driven primarily by firms with high information asymmetry. Hence, our results suggest that the influence of twitter derives from information asymmetry problem between executives and shareholders. We find supportive evidence that the effect tends to be stronger if the firm is younger, less coverage, and low credit rating.

Next, we analyze the market response of the earning announcements. The dependent variable is the cumulative abnormal return (CAR hereafter), which is the sum of abnormal returns over the windows. The independent variable is standardized unexpected earning (SUE), which is defined as the standardized of the difference between actual earning and the mean of analyst earnings forecasts. To incorporate the role of using twitter, we interact SUE with CEO_twitter in the right-hand side of the regression. Intuitively, we want to explore whether using twitter can affect the market responses to the earning announcements. We run the regression for its subsamples: (1) no twitter; (2) tweet with low frequency; (3) tweet with high frequency.

The regression results show a positive relation between SUE and the CAR, which is plausible. Our key coefficient is the interaction between SUE and CEO_twitter is positive but not significant in the low frequency sample. On average, the market reacts similarly to the news, regardless of whether CEO using twitter or not. However, we find that investors react differently to group with CEOs tweet frequently. Specifically, the interaction between SUE and CEO_twitter is negative and statistically significant in the subsample of high frequency.

Another possible channel is market competition. We further investigate whether the twitter effect would react differently to firms with high market threat. We conduct a subsample analysis by partitioning firms by several proxies for market competition such as CP oriented, product similarity, and product market fluidity (Hoberg and Phillips (2016), Hoberg et al. (2014), and Hoberg and Phillips (2010)) into high and low groups. The results show that the positive association between TDC1 and CEO_twitter occurs more strongly in high market competition group.

As a robustness check of our findings, we consider alternative measures of compensation (delta, vega, firm related wealth; nonequitybase) and test the effect of using twitter on them and find that the results remain supportive of our hypothesis.

Our paper contributes to several ways. First, our paper is related to the studies of social media. Overall, our findings highlight the benefit of using Twitter as a direct-access information - communication channel. These findings make two important contributions. First, they have important implications for the role Twitter plays in executives’ compensation. Most of the literature that addresses issues related to CEO compensation is based on agency theory, our results suggest that individuals use Twitter as an important social network to share information for CEOs's mutual benefit.

Second, our paper contributes to a burgeoning group of literature that focuses on the importance of the managers on a firm's policy such as investment policy and financing policy (Malmendier and Tate, 2005; Malmendier and Tate, 2008; Malmendier, Tate and Yan, 2011; Hirshleifer, Low and Teoh, 2012). The information on CEO Twitter account can help investors in their investment decisions. Thus, Twitter can play a role in making the market more efficient by uncovering additional value-relevant information, especially for firms in weak information environments, and regulatory intervention does not seem warranted.

Third, we contribute to the literature on information asymmetry. The existing studies have examined the information asymmetry issues on disclosure (Brown and Hillegeist, 2007; Shroff et al., 2013), media coverage (Fang and Peress, 2009), cost of capital (Armstrong et al., 2011), and financial reporting frequency and cost of equity (Fu, Kraft, and Zhang, 2012). Our paper also adds to growing literature linking information asymmetry and CEO compensation.

The rest of the paper is organized as follows: Section 2 discusses hypothesis development; Section 3 presents data sources, main variables, and methodology; Section 4 offers empirical results and provides several robustness checks; and Section 5 concludes the paper.

LITERATURE REVIEW AND HYPOTHESIS DEVELOPMENT

Before the mass adoption of social media applications, to disseminate financial information for the demand of investors, it can't help referring to the role of some internet tools such as: Google search (Da, Engelberg, and Gao (2011), Drake, Roulstone, and Thornock (2012)), Internet bulletin boards (Hirschey, Richardson, and Scholz (2000), Tumarkin and Whitelaw (2001)), message boards, such as Yahoo! or Raging Bull, (Antweiler and Frank (2004), Das and Chen (2007). However, these platforms are limited in term of online interaction in financial market and personal finance (Gallaugher and Ransbotham 2010). To adjust this drawback in recent years, social media appears and explodes in popularity with different forms (eg., Facebook, StockTwits, Twitters) and can have important economic consequence for the using firm and financial market (e.g., Tetlock 2007; Bollen, Mao and Zeng 2011; Laroche, Habibi and Richard, 2012; Chen et al 2014; Lee, Hutton, and Shu 2015; Jung, Naughton, Tahoun, and Wang 2018). Nowadays the power of social media in organizations is significant for not only short-term performance but also long-term productivity benefits inherently connected to firm equity value (Luo, Zhang and Duan 2013). Curtis, Richardson, and Schmardebeck (2016), who focus on the overall social media activity over 30-day rolling windows, find that high levels of activity are associated with greater sensitivity of earnings announcement returns to earnings surprises, while low levels of social media activity are associated with significant post-earnings-announcement drift. Firms increasingly make use of these channels so that the information environment is improved or information asymmetry is reduced, then increase the liquidity of the market for a firm's securities, lower bid-ask spreads and increased trading activity (Diamond and Verrecchia 1991; Leuz and Verrecchia 2000; Verrecchia 2001, Bushee and Leuz 2005; Xu and Zhang 2013, Blankespoor, Miller and White 2014).

Twitter was created in 2006 and undoubtedly is one of the most popular social media disclosure platforms in USA with short format (140-character limitation) and ease of information search. Jung, Naughton, Tahoun, and Wang (2018) collected data from all firms included in the S&P 1500 index and show that Twitter has become the preferred social media platform for companies. Using twitter gives account users opportunity to communicate, share opinions and facilitate open sharing of information in a timely fashion. The text content of Twitter may be day-to-day activities, current interests, and personal mood (Naaman, Boase, and Lai (2010)). Bollen, Mao, and Zheng (2011) find that by text processing techniques, the collective mood states posted on Twitter can help predict changes in the value of the Dow Jones Industrial Average over time. Consistently, using Twitter data, Mao, Wei, Wang, and Liu (2012) show that the daily number of tweets that mention S&P 500 stocks is significantly associated with S&P 500 daily closing price, S&P 500 daily price change and S&P 500 daily absolute price change.

The results in the research of Blankespoor, Miller, and White (2014) indicate that additional dissemination of firm-initiated news via Twitter is associated with lower bid-ask spreads and greater depths, and a higher liquidity ratio after controlling necessary factors such as the information content of the news, the presence of information intermediaries, market conditions, and firm-specific characteristics. Unlike traditional approach of relying on users to access content that is disseminated through media outlets, Twitter allows companies to “push” disclosures directly to users and so directly disseminate news, hereafter helps reduce information asymmetry.

Beside the benefits of company’s own social media pages, a CEO who is an influencer in his or her space can be a big advantage. Users can cultivate their own followings, effectively reduce cost of digital distribution. Making use of Twitter, CEO can write their own stories which influence media narratives rather than press. For example, to become a superstar, the media play a causal role in fostering a celebrity culture and enable the observed changes in CEO behavior, as a consequence, CEO compensation increase following CEO awards (Malmendier and Tate 2009). So why don’t CEOs make use of this free channel to increase CEO status and power within the organization. What left unexplored by these literatures is the question of whether in a company CEO use Twitter account is correlated with CEO compensation, the very question we examine in our paper. Because CEO pay is a topic that has received significant attention both in the popular press and academic journals. Despite a wealth of research, largely grounded in agency or managerialist perspectives (Hartzell and Starks 2003; Chhaochharia and Grinstein 2009; John, Mehran, and Quian 2010, Bugeja, Matolcsy and Spiropoulos 2012; Banker et al 2013). It is significant to have new approaches in the study of CEO rewards. We argue that inasmuch as CEO external directorate networks are strategically valuable to firms, they should be reflected in CEO compensation levels, particularly when the benefits of those ties are of greatest value. Further, the results from study of Chen, 2018 suggest that tweets coming out of top executives' personal Twitter accounts are significantly more impactful than those coming out of firm-managed accounts (Chen, Hwang and Liu 2018). Karadunam 2013, in his preliminary study on the effect social media on personal branding efforts of top level executives of the company, he also emphasizes that making use of social media, CEOs not only can create value for themselves but company also. Based on this considerations, it is hypothesized that:

Hypothesis 1: firms with CEO using twitter are more likely to pay higher compensation

In our paper, we refer to earnings announcements information because information fully reflects the abnormal returns on market efficiency that captures the economic hypothesis (Fama (1998) and large abnormal returns around earnings announcement dates (Kaniel et al. (2012)). Furthermore, the previous studies confirm that earnings announcement influence price changes and abnormal returns (May, 1971; Kane et al., 1984; and La Porta et al., 1997). For example, La Porta et al. (1997) mention that 20% stock returns around the earnings announcement dates. In addition, Lee, Hutton, and Shu (2015) document that the impact of Twitter can weaken the negative price reaction to recall announcements by direct broadcasting firm's intended message to investors without distorting the content. The authors find if properly managed, firms can engage users and customers through social media to mitigate the adverse effect of bad reputation associated with product recalls, a result that potentially extends to other types of corporate events. Also Bartov, Faurel, and Mohanram (2018) argue that twitter can be useful in predicting abnormal return around earnings announcements. They classified two notable roles of Twitter in providing new sources of information as well as disseminating existing information. Especially the opinion from Twitter posts is more prominent in predicting announcement return for high information assymetry environment. Thus, we examining whether CEO twitter effect as information react on earnings announcement dates that reflect the market efficiency and expect our next hypothesis as follow:

Hypothesis 2: the CEO twitter effect are more likely to curtail the market responses to the earning announcements.

The investors may obtain a different level of information with several characteristics, thus, we distinguish original sample into two groups for each characteristic to discuss the information asymmetry. One group of investor has superior information before being spread to the public and another group received after the information is spread to the public

(Tetlock, 2010). Armstrong et al. (2011) argue that information asymmetry impact on the cost of capital when the market competition is low. Tang (2009) find that credit rating information reduces the information asymmetry and allows the lender to access the borrowers' risk profile. Baik, Kang, and Kim (2010) analyze the role of geographic proximity and find that the significant positive correlation of local institutional investors and stock returns is stronger in firms with high information asymmetry. Also, Boone and White (2015) find that institutional investors are associated with analyst following reduces the information asymmetry, trading costs, and enhances monitoring. Blankespoor, Miller, and White (2014) show evidence that Twitter using help reduce information asymmetry by directly spreading out information to investor. Thus, we expect our next hypothesis as follow:

Hypothesis 3: The effect of CEO using twitter on CEO compensation is stronger for firms with high information asymmetry.

According to Akins, Ng, and Verdi (2012), Easley and O'Hara (2004), and Kyle (1985), a degree of private information for investors is lower when firms have a strong competition because competition leads information more quickly that reduce investors to price protect being reflected in the equilibrium price and competition reduces the information asymmetry to uninformed investors. They also mention that pricing is decreases with quality of information. Furthermore, Armstrong et al. (2011) find that firms with lower market competition tend few to no analyst following increases information asymmetry and implied the slope of cost of capital. They also find that information asymmetry with strong market competition degree has no effect on cost of capital.

Hoberg et al. (2014) argue that competitive threats firms to repurchase fewer shares and paying lower dividends and holding more cash and liquid assets. Furthermore, Hoberg and Phillips (2010) also argue that firms face nearer rivals' threats that may need to change their product frequently to maintain firm's profit. In other way, the product similarity is associated with lower profitability. Thus, we expect our next hypothesis as follow:

Hypothesis 4: The effect of CEO using twitter on CEO compensation is stronger for firms with high market competition.

DATA AND SUMMARY STATISTICS

Data and Other Variables

Our main explanatory variable is an executive's Twitter account. It takes the value of one if the executive of firm *i* adopted Twitter as of year *t*, and zero otherwise. To construct our sample of chief executives' personal Twitter accounts, we download a list of all CEOs in the Execucomp database between 2006 and 2015. Execucomp covers the S&P 1500 as well as companies that were once part of the S&P 1500 index and that are still trading. We start with the complete list of all CEOs in Execucomp and locate users with active Twitter accounts that have the same first and last names as the CEO in question. We then cross-check the executives' middle names, gender, and company information with user characteristics; we also read tweets to determine whether any account that we find does indeed belong to the executive in question. Through this labor-intensive process, we determine that 336 S&P 1500 CEOs have active personal Twitter accounts and work for firms that have the data necessary to conduct our tests. We exert great effort in separating out Twitter accounts managed by firms.

The main dependent variable is the level of annual CEO compensation collected from Execucomp databases. CEO compensation is measured using three alternative measures: total annual compensation, annual salary, and annual bonus. The natural logarithm of Execucomp's TDC1 is used to measure total annual compensation. Total compensation (*Total_comp*) includes the CEO's salary, bonus, other annual compensation, total value of restricted stock granted, total value of stock options granted (valued using Black–Scholes), long-term incentive payouts, and all other compensation (in thousands of dollars).

The remaining independent variables are identified from Bugeja, Matolcsy and Spiropoulos 2012; Chhaochharia and Grinstein 2009. They provide controls for governance, CEO, and economic characteristics that are associated with CEO compensation. CEO characteristics include the natural logarithm of the number of years of service of the current CEO (*Log(CEO_tenure)*), dummy variable equal to 1 if the CEO is also the board chairperson (*CEO_chair*) and otherwise is zero, dummy variable equal to 1 if it is the CEO's first year of service at a firm (*CEO_firstyear*) and otherwise is zero, dummy variable equal to 1 if the CEO owns 5% or more of the company's stock (*CEO5pct*) and otherwise is zero.

Firm characteristics are from Compustat and included a firms' book-to-market ratio (*BMV*), company's annual common stock return (*RET*), accounting measure is return on assets (*ROA*), the standard deviation of common stock returns (*Log(Std5RET)*), the standard deviation of return on assets measured over the previous five years (*Log(Std5ROA)*), average total liabilities divided by average total equity (DE).

Corporate governance controls from Risk Metrics included number of board directors (*Bdsize*), dummy variable equal to 1 if the compensation committee is comprised wholly of independent directors(*Indcompcom*) otherwise is zero. Finally, we also control for industry and year-fixed effects. We adjust the standard errors by within-firm clustering (White, 1980).

Summary Statistics

Table 1 presents the summary statistics of *total compensation(TDC1)*, CEOs with twitter account (*CEO_twitter*), and other control variables. The mean value of *CEO_twitter* is 0.0576 with a standard deviation of 0.2331. For CEO characteristics, the mean of *TDC1* is US$ 3003 thousand (natural logarithm of 8.0074) with a standard deviation of 1.0350. The average number of years the CEO held his/her position in a company before he/she signed the bank loan contract is 6 years (natural logarithm of 1.7985) in the sample.

Table 1: Descriptive Statistics

This table presents the descriptive statistics of all the main variables used in this research. The sample period is from 2006 to 2015.

Variables	Mean	p25	p50	p75	Sd
TDC1	8.0074	7.3147	8.0651	8.7572	1.0350
CEO_twitter	0.0576	0.0000	0.0000	0.0000	0.2331
CEO5pct	0.1155	0.0000	0.0000	0.0000	0.3196
CEO_firstyear	0.0683	0.0000	0.0000	0.0000	0.2522
CEO_tenure	1.7985	1.0986	1.9459	2.3979	0.8666
CEO_chair	0.1240	0.0000	0.0000	0.0000	0.3296
Bdsize	9.4386	8.0000	9.0000	11.0000	2.4191
Indcompcom	0.9550	1.0000	1.0000	1.0000	0.2074
BMV	0.5503	0.2827	0.4672	0.7234	0.4044
DE	0.8705	0.1125	0.4645	1.0310	1.7270
ROA	0.0419	0.0125	0.0435	0.0829	0.0896
RET	0.1711	-0.1008	0.1179	0.3481	0.5018
Std5RET	0.1080	0.0687	0.0959	0.1323	0.0560
Std5ROA	0.0509	0.0115	0.0253	0.0576	0.0721

As a univariate test, we split the sample into two groups based on whether CEO using twitter or not Then, we compare our main variables of two groups and conduct a *t*-test of mean equality. Table 2 presents the comparison between two groups. In the group with twitter account, the mean of *TDC1* is 8.2070, which is higher than that in the group of not using twitter by 0.2119. The mean difference between the two groups are statistically significant at 1 percent level.

Turning our firm characteristics, the group with CEOs twitter account tend to have greater return RET and firm risk Std5ROA. However, these firms have less leverage and investment opportunity BMV.

Table 2: CEO, governance, and firm characteristics for CEOs with and without Twitter account.

This table presents the mean comparison of CEO, governance, and firm characteristics for CEOs with and without Twitter account. *t*-test deployed to compare the mean. *, ** and*** denote significance at 10%, 5% and 1% levels, respectively.

Variables	With twitter	Without twitter	Differences	*t*-statistics
