We also report the Pearson's correlation coefficient matrix in Table 3. As expected, we find a positive and significant correlation between *TDC1* and *CEO_twitter*. The correlation coefficients between total compensation and other control variables such as return on assets and annual common stock return are also positive and significant at the one-percent level.

Table 3: Correlation matrix

This table presents the Pearson correlation matrix between all the variables. The sample period is from 2006 to 2016. * and ** denote significance level at 5% and 1%, respectively

EMPIRICAL RESULTS

Main Result: Twitter and CEO Compensation

We use the following regression setting to test our main hypothesis following Vidhi Chhaochharia and Yaniv Grinstein, (2009).

$$TDC1_{i,t} = \alpha_0 + \alpha_1 CEO\_twitter_{i,t} + \beta' F_{i,t-1} + \theta' Z_{i,t} + \gamma_i + \mu_t + \varepsilon_{i,t} \quad (1)$$

where the dependent variable is *TDC1(total compensation)* and the main explanatory variable is *CEO_twitter*. Specifically, $tdc1_{i,t}$ is the natural logarithm of compensation for chief executives officer *i* in year *t*; $CEO\_twitter_{i,t}$ represents CEO with twitter account, takes the value of one if the executive of firm *i* adopted Twitter as of year *t*, and zero otherwise. $F_{i,t-1}$ is a vector of control variables (firm characteristics) for firm *i* in year *t-1*. $Z_{i,t}$ is the vector of the control variables for corporate governance and CEO characteristics *i* in year *t*. γ_i and μ_t represent the fixed effects of industry and year, respectively, and $\varepsilon_{i,t}$ represents the error term of the regression. In all specifications, the *t-statistics* reported are based on heteroscedasticity at firm-level robust standard errors (White, 1980).

Table 4 presents the effects of using twitter and CEO compensation. Our focus is the coefficient of *CEO_twitter* on *TDC1*. For the robustness of our results, we conduct four specifications in the regression setting. The first one do not control for industry and year fixed effects; the second adds controls for year fixed effect, the third for governance characteristics, CEO characteristics, industry and year fix effects and the fourth for all governance characteristics, CEO characteristics, firm characteristics, industry and year fix effects.

Consistent with our expectation, positive and significant coefficients are observed in all specifications, even though we have controlled for all potential factors, indicating that CEO with twitter account will get higher compensation. Thus, the results support our Hypothesis 1 that *firms with CEO using twitter are more likely to pay higher compensation*. Specifically, the coefficients of *Vega* are positive and significant at the one-percent level from a 0.1430 to 0.3070, indicating that using twitter is associated with higher compensation in a firm.

Table 4: Bank's CEO risk-taking incentives and Bank loan spread

These tables present the ordinary least squares (OLS) regression results of CEO twitter effect on CEO compensation.

$$TDC1_{i,t} = \alpha_0 + \alpha_1 CEO\_twitter_{i,t} + \beta' F_{i,t-1} + \theta' Z_{i,t} + \gamma_i + \mu_t + \varepsilon_{i,t} \quad (1)$$

where the dependent variable is TDC1(total compensation) and the main explanatory variable is CEO_twitter. Specifically, $tdc1_{i,t}$ is the natural logarithm of compensation for chief executives officer i in year t; $CEO\_twitter_{i,t}$ represents CEO with twitter account, takes the value of one if the executive of firm i adopted Twitter as of year t, and zero otherwise. $F_{i,t-1}$ is a vector of control variables (firm characteristics) for firm i in year t-1. $Z_{i,t}$ is the vector of the control variables for corporate governance and CEO characteristics i in year t. γ_i and μ_t represent the fixed effects of industry and year, respectively, and $\varepsilon_{i,t}$ represents the error term of the regression. In all specifications, the *t-statistics* reported are based on heteroscedasticity at firm-level-robust standard errors (White, 1980). The sample period is 2006-2015. All the variables are defined in Appendix A *, ** and *** denote the significance level of 10%, 5% and 1%, respectively.

Concerning control variables, the results are generally consistent with previous studies (Chalmers et al., 2006; Core et al., 1999, Bugeja, Matolcsy and Spiropoulos, 2012). Compensation is significantly negatively associated with *CEO5pct* and *CEO_firstyear* which consistent with the notion that in the first year of employment CEOs receive significantly lower total compensation and CEOs who own more than 5% of stock are paid significantly less. This finding can be explained by agency costs: CEOs with lower ownership are more likely to extract higher pay inconsistent with maximizing shareholder wealth. Conversely, compensation is significantly positively associated with *CEO_chair.* This may be interpreted as CEOs using their power to extract greater pay, or it may reflect additional talent or effort so CEOs who are also chairpersons receive significantly more pay.

The significant results on the corporate governance measures are generally positive and indicate that total compensation increases with board size and total compensation increases with independent compensation committee. An independent compensation committee is unrelated to CEO remuneration. Overall, the results for the corporate governance measures are similar to those in prior literature (Core et al., 1999; Wade et al., 1990, Bugeja, Matolcsy and

Spiropoulos, 2012). The relationship between firm stock performance and remuneration is positive for total pay. but surprisingly the impact of firm risk on total compensation is significant negative which is shown by the relationship between salary and the standard deviation of returns. Overall, the effects of the control variables exhibit a similar pattern as reported in the existing literature.

Twitter Effect and Cumulative Abnormal Return (*CAR*)

Information fully reflects the abnormal returns on market efficiency that captures the economic hypothesis (Fama (1998) and large abnormal returns around earnings announcement dates (Kaniel et al. (2012)). Furthermore, the previous studies confirms that earnings announcement influence price changes and abnormal returns (May, 1971; Kane et al., 1984; and La Porta et al., 1997). For example, La Porta et al. (1997) mention that 20% stock returns around the earnings announcement dates. In addition, Lee, Hutton, and Shu (2015) document that the impact of Twitter can weaken the negative price reaction to recall announcements by direct broadcasting firm's intended message to investors without distorting the content. The authors find if properly managed, firms can engage users and customers through social media to mitigate the adverse effect of bad reputation associated with product recalls, a result that potentially extends to other types of corporate events. Also Bartov, Faurel, and Mohanram (2018) argue that twitter can be useful in predicting abnormal return around earnings announcements. They classified two notable roles of Twitter in providing new sources of information as well as disseminating existing information. Especially the opinion from Twitter posts is more prominent in predicting announcement return for high information assymetry environment.

To examine the effects of using twitter in cumulative abnormal return (*CAR*), we use the sensitivity of earnings announcement. We run a regression model as follows:

$$CAR[-1;1]_{it} = \beta_1 SUE\_mean_{it} + \beta_2 CEO\_twitter_{it} + \beta_3 SUE\_mean\_Twit_{it} + \gamma' Z_{it-1} + u_j + v_t + \varepsilon_{it} \quad (2)$$

where $CAR[-1;1]_{it}$ is the cumulative abnormal return (from the Fama-French three factor model) in the window [-1;1]; SUE_mean_{it} is the difference between actual and the mean of earning per share (EPS) forecasts of the analysts, divided by the standard deviation of EPS forecast; $SUE\_mean\_Twit_{it}$ is the interaction between SUE_mean and *CEO_twitter;* Z_{it-1} is the vector of control variables; u_j and v_t are industry and year fixed effect, respectively. Control variables include *Asset* (natural logarithm of total assets), *Q* (Tobin's Q), *Leverage* (ratio of long-term debt plus debt in current liabilities to total assets), *BHAR* (the corresponding buy-and-hold abnormal return), *Tangibility* (ratio of net property, plant, and equipment to total assets), *Profitability* (ratio of earnings before interest, taxes, depreciation, and amortization to total assets), *Z-score* (a modified Altman's Z-score), and *CF volatility* (ratio of standard deviation of quarterly cash flows from operations over the four fiscal years prior to loan initiation year to total debt).

Our key independent variable is the interaction between SUE_mean and *CEO_twitter*, which shows how the market reacts to the CEO using twitter of the reporting firm. According to our predictions, this interaction term's coefficient should be negative and significant.

Table 5 presents the regression results. Our key coefficient is the interaction between SUE and CEO_twitter is positive but not significant in the low frequency sample (Model 2). On average, the market reacts similarly to the news, regardless of whether CEO using twitter or not. However, we find that investors react differently to group with CEOs tweet frequently. Specifically, the results support the hypothesis 2 that the interaction between SUE and CEO_twitter is negative and statistically significant in the subsample of high frequency.

Table 5: Earning Announcement Responses: Mean SUE

This table presents regression results for the effects of using twitter in cumulative abnormal return (*CAR*), we use the sensitivity of earnings announcement. We run a regression model as follows:

$$CAR[-1;1]_{it} = \beta_1 SUE\_mean_{it} + \beta_2 CEO\_twitter_{it} + \beta_3 SUE\_mean\_Twit_{it} + \gamma' Z_{it-1} + u_j + v_t + \varepsilon_{it} \quad (2)$$

where $CAR[-1;1]_{it}$ is the cumulative abnormal return (from the Fama-French three factor model) in the window [-1;1]; SUE_mean_{it} is the difference between actual and the mean of earning per share (EPS) forecasts of the analysts, divided by the standard deviation of EPS forecast; $SUE_mean_Twit_{it}$is the interaction between SUE_mean and *CEO_twitter;* Z_{it-1} is the vector of control variables; u_j and v_t are industry and year fixed effect, respectively. Control variables include *Asset* (natural logarithm of total assets), *Q* (Tobin's Q), *Leverage* (ratio of long-term debt plus debt in current liabilities to total assets), *BHAR* (the corresponding buy-and-hold abnormal return), *Tangibility* (ratio of net property, plant, and equipment to total assets), *Profitability* (ratio of earnings before interest, taxes, depreciation, and amortization to total assets), *Z-score* (a modified Altman's Z-score), and *CF volatility* (ratio of standard deviation of quarterly cash flows from operations over the four fiscal years prior to loan initiation year to total debt).Appendix A provides the definitions of variables. In all equations, we report *t*-values based on the robust standard errors adjusted for the clustering at the firm level (White,1980). Appendix provides the definitions of variables. Superscripts *, **, and *** denote significance at the 10%, 5%, and 1% levels, respectively.

As a robustness check, we replace the SUE_mean by SUE_median in Table 6. Specifically, SUE_median is the difference between actual and the median of analyst forecasts on EPS. We repeat our analysis in the Table 5 by SUE_median. Similar to Table 5, we find that the interaction between SUE_median and CEO_twitter is negative and significant only in the subsample of high frequency of tweet, also support hypothesis 2 (Model 3).

Table 6: Earning Announcement Responses: Median SUE

This table presents regression results for the effects of using twitter in cumulative abnormal return (*CAR*), we use the sensitivity of earnings announcement. We run a regression model as follows:

$$CAR[-1;1]_{it} = \beta_1 SUE\_median_{it} + \beta_2 CEO\_twitter_{it} + \beta_3 SUE\_median\_Twit_{it} + \gamma' Z_{it-1} + u_j + v_t + \varepsilon_{it} \quad (3)$$

where $CAR[-1;1]_{it}$ is the cumulative abnormal return (from the Fama-French three factor model) in the window [-1;1]; SUE_median_{it} is the difference between actual and the mean of earning per share (EPS) forecasts of the analysts, divided by the standard deviation of EPS forecast; $SUE_median_Twit_{it}$is the interaction between SUE_median and *CEO_twitter;* Z_{it-1} is the vector of control variables; u_j and v_t are industry and year fixed effect, respectively. Twitter Effect and Information Asymmetry

The empirical studies have indicated that information asymmetry cause a gap of information between managers and shareholders. Following the study of (Chae, 2005), (Autore and Kovacs, 2010), and (Leary and Roberts, 2010), we use several proxies to measure the information asymmetry such as, firm age(*Age*), analyst coverage(*Coverage*) and credit rating (*Rating*). They mention that proxies can capture the time-variation and cross-sectional levels in information asymmetry. We separate information asymmetry variables into high and low. The criteria for high information asymmetry as follows: (1) firm age (*Age*) are smaller than median; (2) analyst coverage(*Coverage)* are smaller than median; and (3) firms with low credit rating (*Rating low*); and the low information asymmetry is vice versa. The equation form of model is:

$$TDC1_{i,t} = \alpha_0 + \alpha_1 CEO\_twitter_{i,t} + \beta' F_{i,t-1} + \theta' Z_{i,t} + \gamma_i + \mu_t + \varepsilon_{i,t} \quad (1)$$

where the dependent variable is *TDC1(total compensation)* and the main explanatory variable is *CEO_twitter*. Specifically, $Tdc1_{i,t}$ is the natural logarithm of compensation for chief executives officer *i* in year *t*; $CEO\_twitter_{i,t}$ represents CEO with twitter account, takes the value of one if the executive of firm *i* adopted Twitter as of year *t*, and zero otherwise. $F_{i,t-1}$ is a vector of control variables (firm characteristics) for firm *i* in year *t-1*. $Z_{i,t}$ is the vector of the control variables for corporate governance and CEO characteristics *i* in year *t*. γ_i and μ_t represent the fixed effects of industry and year, respectively, and $\varepsilon_{i,t}$ represents the error term of the regression. In all specifications, the *t-statistics* reported are based on heteroscedasticity at firm-level robust standard errors (White, 1980).

In Table 7 we hypothesize that the effect should be more significant in cases of high information asymmetry. In particular, CEOs using twitter account in young, low credit rating, or low analyst coverage firm tend to be positively related to compensation. Those results support Hypothesis 3 to confirm that t*he effect of CEO using twitter on CEO compensation is stronger for firms with high information asymmetry*.

Table 7: Market-based information asymmetry

This table presents the results of OLS regression that estimates the influence of twitter effect on CEO compensation by considering the subsample of information asymmetry. We separate information asymmetry variables into high and low. The criteria for high information asymmetry as follows: (1) firm age (*Age*) are smaller than median; (2) analyst coverage(*Coverage)* are smaller than median; and (3) firms with low credit rating (*Rating low*); and the low information asymmetry is vice versa. The equation form of model is:

$$TDC1_{i,t} = \alpha_0 + \alpha_1 CEO\_twitter_{i,t} + \beta' F_{i,t-1} + \theta' Z_{i,t} + \gamma_i + \mu_t + \varepsilon_{i,t} \quad (1)$$

where the dependent variable is TDC1(total compensation) and the main explanatory variable is CEO_twitter. Specifically, $tdc1_{i,t}$ is the natural logarithm of compensation for chief executives officer i in year t; $CEO\_twitter_{i,t}$ represents CEO with twitter account, takes the value of one if the executive of firm i adopted Twitter as of year t, and zero otherwise. $F_{i,t-1}$ is a vector of control variables (firm characteristics) for firm i in year t-1. $Z_{i,t}$ is the vector of the control variables for corporate governance and CEO characteristics i in year t. γ_i and μ_t represent the fixed effects of industry and year, respectively, and $\varepsilon_{i,t}$ represents the error term of the regression. In all specifications, the *t-statistics* reported are based on heteroscedasticity at firm-level-robust standard errors (White, 1980). The sample period is 2006-2015. All the variables are defined in Appendix A *, ** and *** denote the significance level of 10%, 5% and 1%, respectively.

Twitter Effect and Market Competition

Next, we extend another channel though how the twitter can affect compensation by examining the possibility of market competition. We use several proxies for market competition such as consumer product-oriented (CP oriented), product similarity, and product market fluidity (Hoberg and Phillips (2016), Hoberg et al. (2014), and Hoberg and Phillips (2010).

We separate market competition proxies into strong and weak. The criteria for strong market competition if product similarity, and product market fluidity are larger than median, CP oriented is smaller than median and the weak market competition is vice versa.

In Table 8 shows the regression results of twitter effect on total compensation with strong and weak market competition. The proxies of CP oriented, product similarity, and product market fluidity show that the effect of CEO using twitter is stronger with firm with high market competition. The results support the hypothesis 4 that the significant positive association between TDC1 and CEO_twitter occurs more strongly in high market competition group.

Table 8: Product market competition

This table presents the results of OLS regression that estimates the influence of twitter effect on CEO compensation by considering the subsample of market competition. We use several proxies for market competition such as consumer product-oriented (CP oriented), product similarity, and product market fluidity (Hoberg and Phillips (2016), Hoberg et al. (2014), and Hoberg and Phillips (2010)). The equation form of model is:

$$TDC1_{i,t} = \alpha_0 + \alpha_1 CEO\_twitter_{i,t} + \beta' F_{i,t-1} + \theta' Z_{i,t} + \gamma_i + \mu_t + \varepsilon_{i,t} \quad (1)$$

where the dependent variable is TDC1(total compensation) and the main explanatory variable is CEO_twitter. Specifically, $tdc1_{i,t}$ is the natural logarithm of compensation for chief executives officer i in year t; $CEO\_twitter_{i,t}$ represents CEO with twitter account, takes the value of one if the executive of firm i adopted Twitter as of year t, and zero otherwise. $F_{i,t-1}$ is a vector of control variables (firm characteristics) for firm i in year t-1. $Z_{i,t}$ is the vector of the control variables for corporate governance and CEO characteristics i in year t. γ_i and μ_t represent the fixed effects of industry and year, respectively, and $\varepsilon_{i,t}$ represents the error term of the regression. In all specifications, the t-statistics reported are based on heteroscedasticity at firm-level-robust standard errors (White, 1980). The sample period is 2006-2015. All the variables are defined in Appendix A *, ** and *** denote the significance level of 10%, 5% and 1%, respectively.

Robustness Checks

This subsection provides additional evidence on how CEO twitter account affects other measures of compensation. We replace *TDC1* by different dependent variables: *delta, vega, firm related wealth* and *non-equity base compensation*. Specifically, *delta* stand for manager's change in wealth (expressed in thousands of dollars) for a 1% increase in the firm's stock price. Calculated from managers' complete portfolio of stock and options from Execucomp or Yermack (1995) using the methodology from Core and Guay (2002). The value of the option portfolio is the sum of the Black–Scholes values of the newly granted options and previously granted unexercisable and exercisable options. The Yermack sample contains information on a manager's previously granted stock but not options, so we use information only on options granted in the last year to calculate the managers' options' delta. *Vega* stands for manager's change in wealth (expressed in thousands of dollars) for a 0.01 increase in the annualized standard deviation of firm's stock returns. *Firm-related wealth* is the sum of the value of the stock and option portfolio held by the executive (Daniel, Li and Naveen 2013), *non_equity-based* compensation is total compensation (*TDC1*) minus equity-based compensation (Chhaochharia and Grinstein, 2009).

Table 9 shows the regression results in terms of other measure for compensation. Across all specifications, the coefficients of *CEO_twitter* are significantly positively related to the delta, vega, firm_ related_ wealth and non_equity base. Thus, the evidence still supports our hypothesis 1.

Table 9. Robustness Checks: Alternative Measures of compensation

This table presents regression results for the effect of twitter on alternative measures of compensation. The equation form of model is:

$$Compensation_{i,t} = \alpha_0 + \alpha_1 CEO\_twitter_{i,t} + \beta' F_{i,t-1} + \theta' Z_{i,t} + \gamma_i + \mu_t + \varepsilon_{i,t} \quad (4)$$

where the dependent variable is Compensation (delta, vega, firm related wealth, non_equity base) and the main explanatory variable is CEO_twitter. Specifically, $Comp_{i,t}$ is the natural logarithm of delta,vega, firm related wealth, non_equity base alternatively for chief executives officer i in year t; $CEO\_twitter_{i,t}$ represents CEO with twitter account, takes the value of one if the executive of firm i adopted Twitter as of year t, and zero otherwise. $F_{i,t-1}$ is a vector of control variables (firm characteristics) for firm i in year t-1. $Z_{i,t}$ is the vector of the control variables for corporate governance and CEO characteristics i in year t. γ_i and μ_t represent the fixed effects of industry and year, respectively, and $\varepsilon_{i,t}$ represents the error term of the regression. In all specifications, the *t-statistics* reported are based on heteroscedasticity at firm-level-robust standard errors (White, 1980). The sample period is 2006-2016. All the variables are defined in Appendix A *, ** and *** denote the significance level of 10%, 5% and 1%, respectively.

CONCLUSION

Our study is the first to document and describe how the effect of chief executive officer using Twitter on their compensation. We examine the potential consequences of such behavior for the underlying firm. Twitter was created in 2006 and undoubtedly is one of the most popular social media disclosure platforms in USA with short format (140-character limitation). With the complete list of all CEOs in Execucomp, we locate users with active Twitter accounts that have the same first and last names as the CEO in question. We then cross-check the executives' middle names, gender, and company information with user characteristics; we also read tweets to determine whether any account that we find does indeed belong to the executive in question. Through this labor-intensive process, we determine that 336 S&P 1500 CEOs have active personal Twitter accounts and work for firms that have the data necessary to conduct our tests. Using a sample from 2006 to 2015 of a total 10,093 observations in the U.S., we find an evidence that CEO_twitter is significantly positive related to total compensation (*TDC1*), confirming *CEO_twitter* has a real effect on compensation. In addition, the effect is more salient in the sample of higher information asymmetry. Third, the effect of CEO Twitter becomes stronger when firms have a high product market competition. Besides, we also examine whether posting more tweet can curtail the market responses to the earning announcements Overall, our findings support that CEO with twitter account receive more total CEO compensation. Together, our results point to the growing significance of social media in financial markets and show that social media activity can have important consequences for CEOs that engage in it.

APPENDIX 1: VARIABLES DEFINITION

Variables	Definition	Data source
Dependent variable		
Total annual compensation (TDC1)	Total compensation consists of salary, bonus, value of restricted stock granted, value of options granted (using Black–Scholes), long-term incentive payouts, and other compensation	Execucomp
Main independent variable		
CEO_twitter	CEO with twitter account, takes the value of one if the executive of firm i adopted Twitter as of year t, and zero otherwise	Hand collect
Firm characteristics		
BMV	Book to market ratio	Compustat
DE	Firm leverage, average total liabilities divided by average total equity	Compustat
ROA	Return on assets	Compustat
RET	Company's annual common stock return	Compustat
Std5RET	Standard deviation of common stock returns over the previous five years	Compustat
Std5ROA	Standard deviation of return on assets measured over the previous five years	Compustat
Assets	Natural logarithm of total assets in millions USD.	Compustat
Q	Tobin's Q	Compustat and CRSP
Leverage	Long term debt and debt in current liabilities divided by total assets.	Compustat
Tangibility	Net property, plant and equipment divided by total assets.	Compustat
Profitability	Earnings before interest, taxes, depreciation, and amortization (EBITDA) divided by total assets. This measure is adjusted by industry median of Profitability.	Compustat
Zscore	Modified Altman's Z-score (1.2 × working capital + 1.4 × retained earnings + 3.3×EBIT + 0.999×sales)/Total assets.	Compustat
CF-volatility	Standard deviation of Quarterly cash-flows from operations over the four fiscal years prior to the loan initiation year scaled by total assets.	Compustat
BHAR	Buy and hold abnormal return, $BHAR_{iT} = \prod_{t=1}^{T}(1+R_{it}) - \prod_{t=1}^{T}(1+R_{mt})$, where R_{it} is monthly stock return of firm *i* and R_{mt} is the monthly value-weighted CRSP market return. Similarly, BHAR3y and BHAR5y are defined for periods of three and five years.	CRSP
CEO characteristics and corporate governance		
CEO5pct	An indicator variable equal to 1 if the CEO owns 5% or more of the company's stock	Execucomp
CEO_firstyear	An indicator variable equal to 1 if it is the CEO's first year of service at a firm	Execucomp
CEO_tenure	The natural logarithm of the number of years of service of the current CEO	Execucomp
CEO_chair	An indicator variable equal to 1 which identifies if the CEO is also the board chairperson	Execucomp
Bdsize	Number of board directors	Execucomp

Indcompcom	An indicator variable (Indcompcom) equal to 1 if the compensation committee is comprised wholly of independent directors.	Execucomp
Market competition variables		
CP _oriented	The ratio of advertising expenses to sales revenue	Compustat
Similarity	A degree that firm's product is nearer to rivals	Hoberg and Phillips (2010, 2014)
Fluidity	A degree of rival firm's products change relative to firm's products	Hoberg et al. (2016)
Earning announcement, crash risk, and information asymmetry		
SUE_mean (SUE_median)	Difference between actual and forecast EPS, scaled by standard deviation of forecast EPS by analysts. Forecast EPS is mean or median of analysts' forecasts.	I/B/E/S
CAR[a;b]	Cumulative abnormal returns in event windows [a;b] of the earnings announcements. The estimation windows are [-230; -31] and are required at least 100 observations in the estimation window. Returns in event windows are adjusted by Fama-French three-factor model.	Compustat
Firm age	Firm age is calculated since the first year with non-missing price in CRSP database (CHECK THE REFERENCE THAT WE FOLLOW)	CRSP
Coverage	Number of estimates that constitute EPS Forecast from I/B/E/S Unadjusted Summary Data (WRDS file name is *ibes.statsumu*).	I/B/E/S
Has Rating	Dummy variable, equals to one if the firm has S&P rating in a year	Compustat

* CRSP: Center for Research in Security Prices

ABSTRACT

The emphasis is on Blue Ocean markets and businesses are struggling to create more products with greater value and lower cost. Innovation delivers value in a frugal product and process. Achieving competitive advantage involves efficient management of all aspects of the operation consistent with the applying principles of Operations Management.

KEYWORDS: Operations Management, Blue Ocean, Product Design, Value Added, Low Cost

INTRODUCTION

A current issue that has been addressed by many business leaders is that the business environment is changing as a result of increasing globalization, economic changes, changes in personal preferences, and digitization. The uncertainty that this has caused has made the global market more volatile, complex, and ambiguous. The one constant factor is that there will be a growing demand for products that are of higher quality and of lower cost. This is the essence of the Blue Ocean strategy that aims for products that are of greater value to the customer and are a combination of more for less. The more for less syndrome has transformed from a short-term response to market needs to a long-term strategy. Businesses that realize this reality stand to prosper and those that continue to live in denial will suffer.

It appears that enterprises are in the race to create more blue ocean markets for the future, with far greater speed compared to the past. Firms, whether well-established or in the small-to-medium range, with their varied advantages and disadvantages, are left with few options other than innovating new products and services, Even business models to be focused increasingly on sustainability, have to be customer-centric, and have to have value-innovation goals. The management of the processes of converting input resources into outputs as goods or services, that is known as Operations Management (OM) plays an ever-important role for firms to establish competitive advantages in a business environment that has sharply changed due to penetrating globalization and digitization. Operations hold a vital position in any business unit, in pursuing increasing productivity and putting the organization in a more competitive position in the market, to increase revenues and market share, with greater profitability, and higher levels of quality and customer satisfaction.

Whether with consumers beginning to actively participate in product creation in areas such as product/ service innovation, supply chain management in an expanding international business platform, or managing human resources with a rising percentage of knowledge workers, firms need to utilize Operations Management to improve an R&D approach tailored to customer needs for mass customization, creating sustainable solutions and co-creating values with prosumers, group of consumers participating in the producer process (Prabhu & Radjou, 2015).

All of these efforts have the goal of establishing distinctive competitive advantages. This paper will discuss how competitive barriers removed by the speeding up of changes in the global business and social environment impact the way businesses are run, and the role of Operations Management principles and techniques in aiding firms to stay relevant and ahead of the competition. The business landscape is giving rise to competition from emerging markets, and is attuned to frugal innovation, which forces developed economies to rethink and innovate products and systems and compete in the global market. The process of competition even has an impact on the core business model, forcing innovation in areas that no one had thought to look before.

THE RISE OF FRUGAL ECONOMIES AND DIGITAL PENETRATION IN BUSINESSES

Widespread economic changes, advancements in technology, the rising growth of emerging markets and deep penetration of digital are reasons that give rise to frugal innovation in the developed world. It is of special note that this trend of producing more and better with less resources started from resource-constrained economies, then gradually spread to the more developed countries and has become the new norm in innovation as well as operation management across many industries.

Advanced economies have entered an age of relative austerity in which the idea of frugal living and consuming is becoming popular. In the recent decade, the middle classes in the US, Canada, Europe, Japan, Australia and elsewhere have witnessed their incomes deteriorate and their purchasing power shrink. “Adjusted for inflation, the real median household income in the US increased by merely 19% between 1967 and 2013. According to a 2014 Pew Research survey, only 44% of Americans now define themselves as middle class, a nine-percentage point drop since 2008. Over the same period, the number of Americans who believe that they have fallen into a lower income class has shot up from 25% to 40%. Moreover, since 2009, 95% of all income gains in the US have gone to the top 1% of earners. The richest 20% of Americans now account for over 60% of the country’s consumer spending” (Prabhu & Radjou, 2015, p. 5). With rising inflation and shrinking income, consumers have become more sensitive for pricing when considering purchases. In parts of Europe where recession persists, intensifying poverty is further destroying middle-income purchasing power. Spain and Greece have suffered the most, but more affluent states such as France and Germany are no exception. “For instance, only 58% of Germans now identify themselves as middle class compared with 65% in 1997. In France, between 2008 and 2012, average salaries fell by 24%, while the cost of living rose by 30%” (Prabhu & Radjou, 2015, p. 5-6). As a result of these economic pressures, North American and European consumers are becoming increasingly aware of getting value when they spend and are selecting less expensive products. For example, nearly 30% of European consumers, especially young people who have only experienced recession in their adult lives, are now more attracted in buying a low-cost rather than a premium car. Car purchases by Americans aged 18-34 fell 30% between 2007 and 2012 (Prabhu, Radjou, 2015). Japan sets disposable income below $14,424 as the poverty level. In 2013, in Japan there was 12 percent of the national population under the poverty level (Lu, 2018), consumers are shifting from premium brands to low-priced private-label products in retail stores. Rather than eating out, more Japanese workers now pack their own lunch.

These changes are not temporary but look likely to be persistent. Thomas Piketty, a French economist, forecasts that income inequality in established economies will broaden in the forthcoming decades, as long-term annual growth rates remain stuck below 2%. With inflation overtaking their incomes since 2007, 76% of US adults now believe that in the future their children will be financially worse off than them. And well over half of consumers, surveyed by Booz & Company (now Strategy&), a global management consultancy, reported in late 2012 that they would not revert back to their previous spendthrift behavior even when times improve. Booz calls these frugal buyers “permanently value-sensitive consumers” (Prabhu & Radjou, 2015, p. 6).
It is not only consumers who have become more cost-conscious. Governments throughout the developed world are also tightening budgets. Ageing populations, escalating health-care expenses,

the pensions burden, huge debts and deficits since 2008 have combined to introduce a new spirit of austerity in the US, Europe and Japan. However, within this landscape, the frugal innovation revolution is about more than austerity. Consumers in the developed world are becoming not only more value conscious but also more *values* conscious. They increasingly care about social harmony, worry about ecological degradation and the depletion of natural resources, and want businesses to play their part in making the world better. 81% of consumers say they will make personal sacrifices to address social and environmental issues (Anonymous, 2016). According to the 2014 Edelman Trust Barometer, an annual global study of consumer attitudes, 84% of respondents believe that business can pursue self-interest while doing good work for society. As Carol Cone, who heads Edelman's social business practice argues, that "to increase trust levels among consumers – and earn the 'license to lead' – businesses must learn to simultaneously create more operational and societal value while also impacting less the environment. "Citizen consumers" will vote with their wallets for brands that are socially inclusive and environmentally active." (Prabhu & Radjou, 2015).

A slightly earlier Report, the *2013 Cone Communications Green Gap Trend Tracker,* suggests that 71% of Americans consider the environment when they shop. This is up from 66% in 2008 (Anonymous, 2014). The survey concluded that 7% of individuals consider the environment every time they shop, while 20% consider it regularly and 44% sometimes consider it. Over 80% of Europeans believe that a product's environmental impact is a critical element in their purchasing decisions. 84% of consumers globally report they prioritize socially and environmentally responsible products whenever possible (Anonymous, 2016).

More troublingly for businesses, 90% of millennials (the 70 million or so Americans in their 20s and early 30s), who contribute $180 billion annually to spending, are inclining to shift to more socially and environmentally responsible brands. Despite their tight budgets, millennial consumers also seek for high quality and sustainable products. To gain the trust of these values-conscious consumers, Cone believes that companies must "move beyond transactional thinking towards a better understanding of tangible actions needed to solve critical societal issues necessary to mutual benefit" (Prabhu & Radjou, 2015). As best practices, Cone cites Gap raising its employees' minimum wage; and Starbucks offering employees who work at least 20 hours a week tuition settlement. (Prabhu & Radjou, 2015).

Governments across the developed world are also playing a role in this process. New regulations require businesses to be resource efficient. The US under the leadership of President Obama passed a new law requiring US carmakers to improve fuel efficiency from the current average of 27.5 miles per gallon to 54.5 miles per gallon by 2025. Similarly, in 2012, the European Parliament passed a stricter recycling law that requires by 2020 electronic and electrical goods suppliers and retailers to collect, and potentially recycle, 85% of the electric and electronic scrap they generate. In early 2014 the European Parliament voted in favor of requiring member states to meet stricter binding national targets for 2030 to deal with climate change. The directive includes a 40% reduction in greenhouse gases (compared with 1990 levels) and at least 30% of energy to come from renewable sources. As noted by the European commissioner for the environment, a combination of utilizing environmental benefits and innovative growth opportunities is needed to counter the economic turmoil and rising prices for raw materials of the present time.

Perhaps politicians are aware that consumers' standards are shifting, valuing quality over quantity. Studies show that between 15% and 28% of Americans have willingly reduced their material belongings in favor of greater self-sufficiency, with the goal of leading a humbler and more meaningful life. In Japan, a country famous for intensive working hours, almost 50% of consumers across generations now spend more time at home. Across the developed world – from New York to Paris to Tokyo – consumers now view frugality as a means to *increase,* rather than decrease, their quality of life. It is evident that consumers are looking for a substantive improvement in the quality of life and are not to be satisfied with the appearances of it. The positive side of the post-crisis gloom is that citizens' search for a more balanced lifestyle is helping to create a new economic system – a frugal economy. It represents an improvement of the more excessive trends of 20th century overconsumption and waste.

In addition to the changes in consumers' perception and behavior already noted for the Western world, there are similar growing influences among the largest emerging consumer economies of China and India. While they have to innovate, and grow with huge consumer populations, constraints on resources that have forced developed economies to rethink how to design products/ services have created an awareness of untapped potentials from the market at the bottom of the pyramid. Markets in the developing economies can nurture global business through their sheer size, rate of growth and consumer demands. Everyone knows that the world's poor are distressingly plentiful. Fully 65% of the world's population earns less than $2,000 each per year—that's 4 billion people (Hammond, & Prahalad, 2002). The market for goods and services serving the world's poor – families with an annual household income of less than $6,000 – is massive. The 18 largest emerging and transition countries include 680 million such households, with a total annual income of $1.7 trillion – roughly equal to Germany's annual gross domestic product. Brazil's poorest citizens comprise nearly 25 million households with a total annual income of $73 billion. India has 171 million poor households with a combined $378 billion in income. China's poor residents account for 286 million households with a combined annual income of $691 billion. Surveys show that poor households spend most of their income on housing, food, healthcare, education, finance charges, communications and consumer goods. Multinational corporations have largely failed to explore this global market, even though the rewards for doing so could be significant (Hammond, & Prahalad, 2004).

What these figures indicate is that while assuming that the poor have no money sounds obvious on the surface, it's not entirely true. While individual incomes may be limited, the cumulative buying power of poor populations is quite significantly large. The average per capita income of villagers in rural Bangladesh, for instance, is less than $200 per year, but as a group they are devoted consumers of telecommunications services. Grameen Telecom's village phones, which are owned by a single entrepreneur but used by the entire community, generate an average revenue of roughly $90 a month—and as much as $1,000 a month in some large villages. Customers of these village phones, who pay cash per usage, spend an average of 7% of their income on phone services—a far higher percentage than consumers in existing markets do (Hammond & Prahalad, 2002).

It's also incorrect to assume that the poor are too concerned with fulfilling their basic needs to squander money on luxury goods. In fact, the poor often do buy luxury items besides daily essential goods. For example, in the Mumbai shantytown of Dharavi, 85% of households possess a television set, 75% own a pressure cooker and a mixer, 56% own a gas stove, and 21% have telephones. One of the explanations for this phenomenon is that buying a house in Mumbai, for most people at the bottom of the pyramid, is not a realistic consideration. Neither is getting access to running water. They accept that condition, and rather than saving for tough periods, they spend their income on things that can immediately improve the quality of their lives (Hammond & Prahalad, 2002). These unexpectedly hidden potential markets present an opportunity for any firms that can understand the provision of appropriate solutions.

For instance, as markets become increasingly global, improvements through effective OM could be made in areas such as cost reductions in supply chain and market expansion, with revenue boost and increasing effectiveness as well as the speed of doing business being credited to the development of Internet and other digital technologies. But the expansion of opportunities on an international scale requires firms to adopt relevant global strategies. Three primary strategies that . Nag (2011) introduced in his book, based on Michael Porter's devised set of strategies for businesses to use are (1) Differentiation Strategy, (2) Cost-Leadership Strategy and (3) Response Strategy. A more recently developed strategy mentioned followed the three primary ones is Mass Customization Strategy. A firm can adopt one or a combination of these strategies to achieve its mission. There is no mandatory or set of structures firms must follow, because creating a strategy is an innovation process itself (Nag, 2011). Operations Management activities are based on and guided by organizational strategies. As enterprises drive to establish and maintain competitive advantage and to gain more market share of their target segments, one of the goals organizational strategy tries to achieve is to lay out a process designed with a view to realize the objectives. In this way Operations Management is becoming increasingly vital for firms to compete in the global digital era.

OPERATIONS MANAGEMENT ADJUSTMENTS TO ACHIEVE EFFICIENT MASS CUSTOMIZATION AND SUCCESSFUL PRODUCT AND PROCESS DESIGN

During the 20th century, established corporations such as General Motors (GM) and General Electric (GE) invested lavishly in R&D labs intending to industrialize and centralize the innovation process. These labs consisted of thousands of engineers and scientists charged with pushing technological boundaries in order to invent the next big innovation. These firms' industry dominance enabled them to drive their new products and services out to fairly passive customers. They employed large sales forces and spent weightily on mass marketing, especially TV and print media, to encourage demand. Successful as this model was for decades, its useful cycle is ending. The industrial R&D model, based on science and technology pursuit, is increasingly unfit to the 21st century's fast paced digital economy. In a world of growing financial constraints, resource scarcity and increased competition, including highly empowered, cost-conscious and eco-aware customers, there are several reasons why the industrial R&D model is losing its effectiveness. Some of the disadvantages that can be listed are: 1) High Investment for low value; 2) Time-consuming and inflexible R&D; 3) Rewarding innovation quantity over quality; 4) Complex, expensive and environmentally unfriendly products; 5) Alienating customers through treating them as passive users (Prabhu & Radjou, 2015).

The 20th century witnessed the birth of three significant organizational innovations: the corporate R&D lab (pioneered by Thomas Edison, who founded GE); mass production (developed and refined by Henry Ford); and "big-box" retail and mass distribution (developed by Sam Walton, the founder of Walmart). All three centralized company functions – from R&D and purchasing to manufacturing, sales and marketing – with the goal of generating economies of scale. Although this centralized approach helps mass production, thus reducing per unit costs, it also expends a lot of energy and has become costly to sustain. Even worse, this approach reduced not only consumers, but many employees also to being passive users of products and services, excluding them from involvement in a production process that, typically, would occur distantly from where they live. However, developed world consumers are rapidly and dramatically evolving into creative producers of personalized products and services. Much of this is thanks to 3D printing and do-it-yourself (DIY) platforms such as TechSchop and FabLab, which cut production costs. This new group of consumers participating in the producer process is termed *prosumer.* A new era of distributed manufacturing will be less resource intensive and will yield higher-quality, mass-customized products and services that are also affordable and sustainable (Prabhu & Radjou, 2015).
Due to the fact that many prosumers felt restricted in the real world by physical boundaries, they choose the online environment where they can create applications and communities with an unprecedented level of freedom of speech. These virtual prosumers develop their own features, becoming "knowledgeable consumers, digital users who employ technologies (software applications) for collaboration, have the ability to participate in a product or service conception, design, execution and/or testing and have a certain impact on their social network" (Izvercianu & Seran, 2011).

Companies need to differentiate their products or services to gain market share. Because innovation is considered to be indispensable to competitive advantage (Belardo, & Belardo, 2002) with customer relationships creating the condition for market acceptance, firms need to focus on ways to involve prosumers into co-creating innovation alongside companies. The results of such an activity present a mutual favorable situation, with benefits for both market stakeholders. The traditional focus of a company has always been on prioritizing its own objectives and resources, with relative relationship marketing results like commitment, trust and loyalty. Another new priority for the company to consider focusing on is prosumer orientation. In addition to this, by integrating consumers and especially prosumers in new product or service processes, firms can achieve a wide range of benefits like: new product development (Enkel, 2005) or service design and improvement (Sigala, 2012), which ultimately determine innovation.

Some approaches managers should consider in integrating prosumers into the product or services innovation and creation are:
1) Engage target consumers throughout product and customer life cycles via direct interaction instead of trusting secondary market research. R&D teams would be most efficient in identifying realistic and unmet needs if they are exposed to customers in their natural settings. This continuous observation throughout the product development cycles will expose R&D engineers to relevant customer insights, which might save the whole product design process time and finance as well as other resources in developing products that meet real market demands.
2) Seek affordable, good-enough solutions to the immediate unmet needs faced by customers instead of trying to impress them with technical complexity or widgets, complicating the best simple solution to meet their requirements.
3) Involve customers from the outset, share prototypes with end-users. Firms should actively seek ways to engage consumers in the early stages of product development to ensure that the result is a market-desirable offering. By designing just good-enough, usable products R&D teams could already be sharing their prototypes with early adopters in the market, via some online platform such as Affinova's tools for greater exposure, hence resulting in more relevant feedback to the process.
4) Utilize big data analytics. As discussed earlier, with increasingly connected consumers to the internet and digital channels, mobile phones and digital networking allow researchers to tap into huge amounts of detailed and specific data sets to detect customer needs and trends, so that firms could respond with appropriate solutions (Prabhu, & Radjou, 2015).
In order to support the innovation process, there are considerations for firms to take when it comes to execution agility to improve efficiency and effectiveness as well as keeping the cost down during each innovative stage. With resource scarcity, R&D teams could enjoy the advantages of using dynamic portfolio management tools to identify priorities and focused projects. The portfolio management will reduce the risk of unfocused and wasteful scattering allocated resources to develop products that might not match with real market demands. Another activity to prevent firms from developing over-engineered products is using just-in-time design method, where good enough prototypes are presented to consumers and more functions/ features are only added based on feedback of early users (Prabhu, & Radjou, 2015).

OPERATIONS MANAGEMENT SHIFT FROM ECONOMY OF SCALE IN INDUSTRIAL ERA TO FRUGAL SUPPLY CHAIN MANAGEMENT AND MANUFACTURING

The future role of supply chain strategies will rely on a thorough understanding of today business environment's challenges. Supply Chain Management issues are no longer considered simply a tactical, manufacturing, or logistics issue, but a strategic capability that is critical to the success of the company. This section will discuss some observation of the shifting trends in supply chain management and manufacturing to adapt to today's business.

Local sourcing:

The business world is now witnessing a shift from low cost to local sourcing. Western multinationals are already sourcing from local suppliers in emerging markets as part of localization strategies. Apart from meeting local sourcing requirements, this also allows firms to create more affordable products. This trend is becoming more apparent in mature economies too, where sourcing smaller quantities from smaller firms located near factories and R&D facilities reduces costs and risks.

Motorola, a multinational telecoms company, decided to manufacture all its Moto X smartphones in Texas so that its manufacturing engineers in Texas and its R&D team in Illinois and California could collaborate more closely with local suppliers and respond more quickly to demanding US consumers (Prabhu, & Radjou, 2015).

These large manufacturers are taking their lead from big retailers. In 2010, for instance, Walmart, the US's biggest importer, devoted to doubling the sales of locally sourced products in the US by 2015. Waitrose, a UK supermarket chain, sources nearly 70% of its food from suppliers situated within a 30-mile radius of a location. This is an interesting return to much earlier market places, where the countryside around a large town supplied that town with food through local markets. In modern markets the risks of variations in supply and quality are offset by reduction in transportation and storage costs, the changes being managed by logistics and operations management.

Sharing resources

Rather than letting their production and distribution assets idle, some manufacturers now allow other firms, including rivals, to use their facilities. It has long been common in areas like Africa and India for competing telecoms providers to share mobile-phone towers, and Western telecoms companies are now doing the same. Western firms are also learning from health-care firms in Africa which imitated Coca-Cola's "cold chain" (a temperature-controlled supply chain) as a cost-effective way to preserve life-saving medicine and have it delivered rapidly to remote villages. In many respects, the developments listed are the business-to-business equivalent of the sharing economy, in which companies trade and share supply-chain assets (Prabhu, & Radjou, 2015).

Distributing to the last mile

Fulfilling orders for customers in far-flung locations is a particular challenge. The so-called last-mile challenge exists because it is costly for companies to implement physical distribution (such as bank branches or retail stores) in locations with few users. Innovative distribution models, which make use of dependable locals and networks, are often used in emerging markets. The development of drones is likely to be the next major impactor on this problem (Prabhu, & Radjou, 2015).

Decentralize supply chains with smaller, nimbler factories

Decentralized supply chains, whereby production happens as close as possible to the point of consumption, will help bridge the supply-demand gap. One way to do this is by shifting production from big factories with inflexible manufacturing processes to smaller, nimbler plants that are flexible and versatile. Danone, a French multinational food products company, was capable to build in Bangladesh a yogurt-making micro-factory only 10% the size of Danone's existing factories and much lower cost to build. Impressed, Danone's chairman Franck Riboud asked his R&D and supply chain leaders to find out how Danone could build such low-cost micro-factories in other markets, including in Europe (Prabhu, & Radjou, 2015).

MANAGING HUMAN RESOURCES, JOBS, AND WORK IN A BUSINESS LANDSCAPE OF KNOWLEDGE WORKERS AND AN ENLARGED SERVICE SECTOR

Since the introduction and growth of digital channels and the internet, information is penetrating to whichever customer base that has access to the network. Consumers have become more informed than at any period in the past. In 2015, the International Telecommunication Union (ITU), a United Nations body, predicted that 3.2 billion people would be online, edging towards a half of the world population that is currently standing at 7.2 billion. About 2 billion of those will be in the developing world, the report added (Anonymous, 2015). This number rose from just 400 million internet users worldwide in 2008, an eighth of the 2015 figure. A growing and better-informed consumer base, deep penetration of digital channels and increasing advancement of technology all contribute their share in giving rise to knowledge workers. The management of this rising labor force is a central focus for any firms seeking to establish sustainable competitive advantages.

The change in access to information and knowledge poses significant challenges to the creation of business value. In an industrial economy business value, measured in terms of high rates of productivity and the associated costs, came first from machines and then from labor efforts. According to Drucker (1993), information-based and knowledge-based production had not resulted in higher productivity rates in service and knowledge work. Drucker explains this by, first of all, the immaterial and complex nature of information and knowledge as economic resources: that they cannot be treated and processed in the exact same way as material economic resources. Knowledge and information, Drucker argues, is not productive in and by itself; putting more information into a service does not make a person perform that service more effectively as such. The same is true in the case of the knowledge worker; his specialized knowledge is not productive in and of itself. Knowledge only becomes productive by fusing different kinds of specialized knowledge into something that makes a difference (Drucker, 1993). Also, and according to Drucker perhaps even more problematic, knowledge and information is intimately related to the knowledge worker, who now "collectively own the means of production" (Drucker, 1993).

Drucker believed that managerial success in a new economy rests on the aptitude to build a new organizational and managerial system that is able to differentiate productive activity from the busy-ness of people (Bang, Cleemann, & Bramming, 2010). Drucker proposes that a central premise must be to return to the fundamental strength of a business, meaning: "Accountability and measurability. It is the discipline of test, productivity measurements, and profitability requirement. Where these are lacking, businesses are essentially out of their depth" (Drucker, 1973). In the later part of the twentieth century, building on this agenda, accountability and measurability become the premises for business value, with work organized around the factory or firm as having a one task-purpose. However, due to the immaterial nature of information and knowledge, the "traditional factory" - the one task-purpose organization - cannot depend on traditional economic factors such as consumption and investment as indicators of business value.

Therefore, Drucker suggests that the focus of the modern factory must be at the level of costs: minimization of costs becomes the visible aspect of how to measure economic results, as costs are the only known factor in the organization's economy. A tight focus on costs, implying a continuous strive to lower costs, is key for the assessment of "performance" and "results". Consequently, Drucker suggests that all work is reorganized around the *task* and its flow, and to measure the costs of the organization by "time". It "has to be time" Drucker (1992) says, as the only thing that is "variable and controllable is how much time a given process takes. And benefit is whatever reduces that time" (Drucker, 1992). In effect, the production, the organizational structure, its management and employees all become factors that are organized around the task's time flows.

Due to growing automation in all business areas, the more it is likely to do a certain task the same way twice, the harder it is for companies to differentiate their offerings from the bloody competition. Innovation becomes the answer to this stringent problem, and it is highly reliant on intellectual capital. Thus, human capital and customer capital become primary sources of innovation. An extension of the concept that human capital refers to employee capabilities is that customer capital represents the relationship with important stakeholders (Potra, Izvercian, 2017).

Half a century ago, Peter Drucker presented the term “knowledge worker” to describe a new class of employee whose fundamental production was no longer capital, land or labor but, rather, the constructive use of knowledge. Today, these knowledge workers, a group that might be referred to as professionals, represent a large and growing percentage of the employees of the world biggest corporations. As stated by Bryan and Joyce (2005), in industries such as financial services, health care, high tech, pharmaceuticals, and media and entertainment, professionals now account for over 25 percent of the workforce, and in some cases undertake some of the key line activities. New business ideas are continuously generated among these groups of employees. They make it feasible for companies to deal with today's speedily-changing and ambiguous business environment, and they generate and administer the intangible assets that are the main way many companies across industries now create value. Dynamic professionals make big enterprises competitive. A few startups which have grown into giants in knowledge-based industries that attract global best talents are GAFAs (Google, Amazon, Facebook, Apple) (Galloway, 2017), Airbnb, Uber (Stone, 2018) and many more if somewhat smaller organizations.

Besides Drucker, another notable representative of this approach is Jack Vinson, who sees a knowledge worker as someone who depends on his knowledge and ability to learn, and who works with his brain (Vinson 2009). Lowe's (2002) definition of knowledge worker is limited to those with a university degree. Thomas Davenport (2005) sees knowledge workers as people with great levels of expertise, education, or intensive experience. Davenport states that the fundamental purpose of a knowledge worker's job involves the creation, distribution, or application of knowledge. Knowledge workers utilize their knowledge and think for a living (Davenport, 2005).

There is intangibility in the specifics of a knowledge workers' major tool and resource - knowledge. Knowledge consists of two dimensions, explicit and tacit. The explicit dimension is easy to solidify and share, by language, pictures and notes. The tacit dimension is associated to practical activity; it is greatly personal, partly or fully subconscious. It cannot be detached from its human owner. Due to tacit knowledge, upon which judgement is based, knowledge as a whole is intangible. The intangibility of knowledge makes knowledge workers special and difficult to manage. The most important part of the work of knowledge workers occurs in their heads even though the final result may be materialized. It cannot be observed, supervised or measured.

Many knowledge workers state that their finest ideas and solutions were conceived outside their professional working environment when they were relaxing, not officially at work. Even more, the results of the work of knowledge workers may differ from the short and long-term perspectives, which causes problems with standards, measurement and evaluation.

Literature offers some but not many concepts on how to manage knowledge workers. A literature review suggests that there is lot of room for future research on this topic. As a new rising and increasingly popular percentage group in the labor force, managing knowledge workers requires different approaches, tools and methods than managing traditional non-knowledge workers. As Peter Drucker conveyed, knowledge workers are employees who would oppose the command-and-control model that business took from the military 100 years ago (Brinkley, Fauth, Mahdon, Theodoropoulou, 2009). Managers cannot monitor the progression of the work of knowledge workers, which makes control or supervision challenging. Knowledge workers understand their work better than their managers and they are capable of and generally willing to be accountable for autonomous decision-making.

At the turn of the century Newell (2000) proposed six key requirements that are necessary to manage knowledge worker group productively: autonomy, achievement, keeping up to date, professional identification, participation in missions and goals, support and sharing. At much the same time Harman and Brelade (2000) advise managers to focus on six other factors important for knowledge workers: networking and broad contacts externally and internally, respect for individuals, creativity and innovation, trust, knowledge sharing and sound underlying systems and development. Suff and Reilly (2005) observe that knowledge workers are likely to thrive in some cultures, but also there are situations that inhibit their performance. Organizations should seek to develop the right climate. For example; is information sharing encouraged in practice or discouraged? Is direct involvement favored over indirect representative involvement? Is risk taking supported, tolerated or frowned upon. Knowledge workers will be sensitive to these organizational signals and will respond accordingly. They will not take risks if they think they will be penalized. They will not share information if they think it pointless. Knowledge workers will look after their careers and exhibit behaviors that help them further their ambitions in the context of what the organization appears to value" (Mládková, 2012).

A special task of the management of knowledge workers is the management of their performance. The CIPD (2004) emphasizes the need for a performance management system that knowledge workers feel comfortable with. The study says that knowledge workers are quite sensitive to performance management schemes because of the high degree of ownership they have over their skills and knowledge, which means they incline to take great pride in realizing progressive standards of performance. It recommends that knowledge workers be involved in the development of such performance evaluation structures, as knowledge-intensive outcomes tend to be vague and are often problematic to measure (Suff & Reilly, 2005).

Probably the most complex approach to the management of knowledge workers and their productivity is offered by the research of the Gallup Organization on motivation and management of so-called *talented employees* (Mládková, 2013). Research for over 25 years focused on employees' performance and loyalty to their organizations. The term 'talented people' is close to our term 'knowledge workers' and the results of the research are entirely relevant to this group of employees (Buckingham, & Coffman, 2005).

Analysis of the hugely extensive volume of data determined twelve key factors, summarized through twelve questions, that affect the behavior of an employee in an organization. These factors are needed to attract, develop and keep knowledge workers in the company because they are considered as crucial for their labor productivity. Factors are presented as questions knowledge workers ask and answer continuously. These twelve questions are:

- Do I know what is expected of me at work?
- Do I have the materials and equipment I need to do my work correctly?
- At work, do I have the opportunity to do what I do best every day?
- In the last seven days, have I received recognition or praise for good work?
- Does my supervisor, or someone at work, seem to care about me as a person?
- Is there someone at work who encourages my development?
- At work, do my opinions seem to count?
- Does the mission and purpose of my company make me feel like my work is important?
- Are my co-workers committed to doing quality work?
- Do I have a best friend at work?
- In the last six months, have I talked with someone about my progress?
- At work, have I had opportunities to learn and grow? (Buckingham & Coffman 2005).

The research also displayed great impact by direct managers on the performance of knowledge workers. (Buckingham, & Coffman, 2005; Mládková, 2012). The research on knowledge workers and their management shows that knowledge workers are proud experts whose performance is influenced more by good co-workers, the availability of contacts and knowledge than by HR policies and the material benefits that their organization offers them. They highly value it if their manager continuously communicates with them, if s/he creates an appropriate environment for their work and aligns their objectives with the objectives of the organization. They do not wish managers to interfere in their work but do not dislike being appropriately controlled.

CONCLUSION

Economic changes are happening, and happening globally, with greater speed than ever before. Firms from small to medium to large corporations are under severe pressure to keep up not only with innovation to stay relevant in their competitive environment but also being agile enough in operations to adapt to a fluctuating business landscape. Widening inequalities in income gaps in both developed and emerging markets present both opportunities as well as pressure for incumbent businesses to cope with. Increasing globalization, growth and penetration of a digital infrastructure, a growing percentage of knowledge workers and changing trends in consumers' behaviors all require managers of Operations Management to prepare not only for short-term competitive pressures but, more importantly, creating companies capable of innovating for long-term strategic competition with resource scarcity. Though there has been much research and suggested concepts for firms to utilize their operations management to adapt to changes, there are still a lot of space for creativity and future exploration. Operations Management must always be necessarily evolving if it is to respond effectively to the changing business landscape. It is not as it was in past decades. With today's sharply volatile business landscape, organizations and their executives need to be prepared with the most agile and lean structure, tangible as well as intangible resources to cope with changes and secure competitive advantages. Operations Management has the capacity to do that if it has the will to embrace frugal innovation.

ABSTRACT

We investigate holistically the questions: How can producer-side synergies be created by employing the strategy of economies of scope? And how can demand-side synergies be developed by making use of simultaneous consumer utilities and multi-sided markets? We describe how resources interact with each other and how simultaneous consumer utilities, two-sided markets and consumers' willingness to pay react to each other. By modeling business firm, resource, innovation, diversification, synergy, segment of consumers, etc., as interacting systems, we establish 8 propositions through examining how relevant systems exert forces on each other. This work provides practical managerial guidance for creating and capturing values.

KEYWORDS: competitive advantage, economy of scope, resource, simultaneous consumer utility, two-sided market

INTRODUCTION

Recent researches in strategic management suggest and demonstrate the need for firms to develop the necessary organizational culture and capability to effectively ride waves of transient competitive advantages (e.g., McGrath, 2013). For a firm to do so successfully it can look either inwardly at its nascent, heterogeneous resources and dynamic capabilities to see what values it can create for consumers (e.g., Barney, 1991; Eisenhardt & Martin 2000), or outwardly at product markets and consumer demands to find out where consumer synergies are located and what can be potentially developed (Drucker, 1954). No matter whether to look inwardly or outwardly, one way for a firm to possibly find potentials of different competitive advantages is to create economies of scope by diversification at either the producer side (Porter 1985; Santalo & Becerra 2008) or the demand side (Ye et al, 2012) or both. If a firm adopts this approach, then the firm has to address the following natural questions: (1) how can producer-side synergies be created when using the strategy of economies of scope? (2) How can demand-side synergies be developed by making use of simultaneous consumer utilities and multi-sided markets, after all consumers determine the success of companies (Penrose, 1959)?

Aiming at addressing these two questions, this paper develops a cohesive theory on how to potentially develop synergistically innovative ideas at either the producer side or the demand side. In this theoretical development, we rely one-hundred percent on logic reasoning, systems thinking and the intuitive yoyo model (Lin, 2009) without analyzing any set of data or anecdotes. Considering the fact that data mining and anecdotal analysis can only help uncover potential facts because of their constraints inherently existing in the available data/anecdotes and limitations existing in the analysis tools, results and conclusions established in this paper are more reliable and practically useful than those based on data and anecdotes.

In terms of the structure of our cohesive theory, we first spell out the basic assumptions and meanings of particular terms. Then by using the reasoning of logic and the methodology of systems science we develop formal propositions, which address various issues related to the two questions given above.

The rest of this paper is organized as follows. The next section reviews the relevant literature and demonstrates the contributions of this work. The following section provides the basics of systems science and methodology in order to make this presentation self-contained and the necessary assumptions and terminology in order to make the following logic reasoning rigorous. Then developed are a few insights on synergistic innovation on the producer side, and similar issues on the demand side. And this paper is concluded in the last section with managerial recommendations and problems for future research.

LITERATURE REVIEW

Because this paper contributes simultaneously to the literatures of innovation and strategy, in this section, we will look at the relevant literatures individually and show where our contributions lie in each case.

For the literature of innovation, over two hundred years ago Adam Smith (1776) acknowledges the importance of innovation. The topic of innovation of the producer side has been well investigated through the years by many scholars (Aas et al, 2015; Adner & Levinthal, 2001; Damanpour, 1991; Visnjic et al, 2016). In the business world, innovation is characterized as the introduction of original products and processes (Becheikh et al, 2006) that enable firms to competitively enter or create new markets (Smith & Tushman 2005). And it has been treated by many as one major factor of long-term performance (Kanter 2001). Veugelers and Cassiman (1999) find that high perceived risks and costs and low appropriation do not discourage innovation, but determines how the innovation sourcing strategy is chosen. They find that small firms are more likely to restrict their innovation strategy to an exclusive make or buy strategy, while large firms are more likely to combine both internal and external knowledge acquisition in their innovation strategy. With economic globalization and the advent of internet-based technologies, firms experience increasing pressures to become more competitive and innovative than ever before (Caputo et al, 2016; Buffington 2016; Zollo et al, 2016).

Contributing to this activity area of research, this paper establishes the following general result: by adding to a successful set X of resources or replacing some resources in X by other resources, a firm can potentially create to positive synergies.

For the literature of strategies, resource-based approaches tend to look inwardly at how heterogeneous resources and dynamic capabilities of firms can create value for consumers (e.g., Barney, 1991; Eisenhardt & Martin, 2000; Nason & Wiklund, 2018) through bundling internal resources in different ways (e.g., Sirmon et al, 2008). Because the concept of resources offers a framework for integrating multiple, dissimilar resources to explain their synergistic, differential effects on firms' performance and the contingencies associated with each effect (Fang et al, 2011), these approaches greatly contribute to knowledge of strategies (e.g., Lockett et al. 2009). At the same time, Barney (2001) and Priem and Butler (2001a, b) recognize that when looking instead outwardly, demand issues need to be addressed equally seriously, because after all consumers determine the success of firms (Drucker, 1954; Penrose, 1959).

Along this suggestion of outward looking at the demand side, scholars examine various strategic issues, such as how technological innovations and competitive advantages are affected by market demand (e.g., Adner & Zemsky 2006; Tripsas, 2008), how value can be created and captured by employing consumer-focused strategies (e.g., Priem 2007, Gans et al. 2008, Adner & Snow 2010), and how entrepreneurial innovation can be influenced by consumers (Sawhney et al. 2005, Shah & Tripsas 2007). More specifically, Ye et al. (2012) study how bundled preferences of consumers can be employed as a basis for developing firms' strategies in an effort that is parallel to the recent producer-focused synergy studies on economies of scope (e.g., Crossland & Smith 2002; Gary, 2005; Tanriverdi & Venkatraman, 2005).

By attending to both the demand side and the producer side of the literature of strategies, this paper establishes the following main results, among others, that are generally true: (1) if a firm makes its resources available to all business units in its attempt to produce an economy of scope, the firm will then be able to innovate synergistically. (2) Mobilizing inconsistent resources generally produce negative synergies. And (3) If a set of core resources is behind a firm's portfolio of offers, it is likely for the firm to focus on exploiting its existing competitive advantages instead of developing new advantages.

Other than contributions in the previously listed individual literatures, what is more important is that this paper holistically incorporates the demand side simultaneously into the studies of strategic management and innovation. At the same time, by using logic reasoning, as a well-tested method in science and mathematics, this work integrates different streams of research into an organic whole. On top of that a theoretical foundation is developed so that strategic relatedness in providing simultaneous consumer utilities of the demand side (Sakhartov & Folta, 2014; Ye et al, 2012) and resource-based relatedness in diversification of the supply side (Farjoun, 1998; Kim & Finkelstein, 2009; Villasalero, 2017) can be identified. Additionally, we generally theorize some of the fundamental properties of two-sided markets uncovered previously by Rochet and Tirole (2006), Sun and Tse (2009), Ye et al (2012), and others, either empirically or anecdotally. (For a similar but different approach, see Azevedo and Leshno, 2016).

Another important contribution this work makes is the introduction of systems science (especially, the systemic yoyo model) into the study of synergistic innovations. Although written statements, data analysis, and systemic expressions are essentially different forms of articulations, there are major differences. In particular, written statements, no matter how logically and precisely they are transcribed, are often inconclusive due to their nature of linearity and inability of simultaneously controlling the effect of several arguments. Although methods of data analysis overcome these weaknesses of written statements, the essence of these methods is to extrapolate the known past into the unknown future. That explains why methods of data analysis cannot be successfully employed to predict drastically different future (Lin & OuYang, 2010). In comparison, systems science is fundamentally different from written statements and data analysis. It looks into the internal structure of the organization of concern, where the structure and the organization come into being simultaneously. Hence, conclusions of investigations based on systems methodology are much closer to the real situation under investigation than those produced otherwise.

PREPARATION

To make this paper self-contained, this section introduces the relevant concepts and the yoyo model of systems science, the basic assumptions and terminology.

Relevant Elements of Systems Science and Methodology

To make this presentation self-contained, this subsection briefly introduces the relevant basics and facts of systems science and methodology, in order to help keep scholars in works related to this paper updated with many technical details of systems science.

Systems can be seen everywhere in real life, especially in investigations of issues related to economies and business decision making. For example, each individual is a biological system that is made up of many smaller systems. He/she is a part of many social and economic systems, such as families, neighborhoods, communities, etc., and he/she interacts with various kinds of systems, such as an automobile, a smart device, retail businesses, the company he/she works for, etc. Through the wide-range existence of such individuals, these large-scale social and economic systems constantly interact with one another. Hence, when we study social phenomena and economic problems involving organizations, other than using numbers and variables, which is mostly reflected in the literature of social sciences, there is a real need to employ the concept of systems and relevant methods to study how organizations evolve and how they interact with each other in order to produce insightful understandings and conclusions that can practically lead to tangible conclusions in addressing real-life challenges.

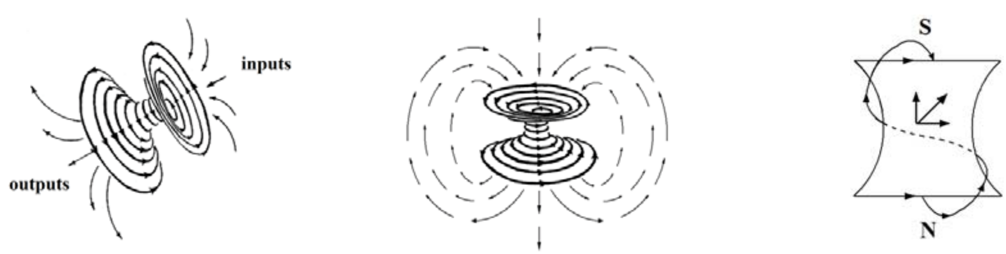
Historically, the concept of systems has been directly or indirectly introduced by scholars from different disciplines. For example, in the area of economics Rostow (1960) wrote that: The classical theory of production is formulated under essentially static assumptions … to merge classical production theory with Keynesian income analysis … introduced the dynamic variables: population, technology, entrepreneurship, etc. But … do so in forms so rigid and general that their models cannot grip the essential phenomena of growth … We require a dynamic theory … which isolates not only the distribution of income between consumption, savings, and investment (and the balance of production between consumers and capital goods) but which focuses directly and in some detail on the composition of investment and on developments within particular sectors of the economy.

In the area of biology von Bertalanffy (1924) points out that because the fundamental character of living things is their organization, the customary investigation of individual parts and processes cannot provide a complete explanation of the phenomenon of life. And others, such as Klir (1985), Lin (2009), Porter (1985), etc., also demonstrate how powerful holistic thinking and relevant methodology could be in producing conclusions regarding organizations and their behaviors that are realistically reliable and practically usable. That is, business entities, economies, and markets, as organizations, do have their individually different internal structures and interact externally with each other. As a matter of fact, since the 1920s (von Bertalanffy, 1924), such a holistic view of nature, organizations, and social events has permeated the entire spectrum of knowledge (Lin, 2009).

Based on what is discussed in the previous paragraphs, it can be seen readily that numbers and systems are concepts respectively abstracted out of the physical world, but from two different points of view. In particular, when an organization is seen as a set of non-interacting elements, numbers come into play, say, *n* employees, *m* buildings, etc. On the other hand, as soon the organization is treated holistically with internal structure systems emerge, where such elements of the organization of concern as employees, capital, properties, talents, etc., form an organic whole through various relationships. Absent of these relationships the organization does not exist. In other words, all business related disciplines are essentially about relationships of organizations (or systems), be they small economic agents, firms (large or small), markets (local, national or international), industries, or economies, and how organization interact with each other.

To summarize, the concepts of numbers and systems are very different in the following two main aspects: 1) the former is a small scale local concept, while the latter a large-scale organizational concept (Lin, 1988; 1999); and 2) numbers exist only post existence, while systems emerge at the same time when physical or intellectual existence comes into being (Lin, 2009).

The first difference tells the reason why systems methodology is a more appropriate tool than the classical theories developed on numbers and variables for the investigation of economic entities when their internal structures cannot be ignored. The second difference explains why business scholars and practitioners still cannot successfully make advanced predictions for imminent economic disasters (Lin & OuYang, 2010).



(a) Eddy motion model of the general system (b) The meridian field of the yoyo model (c) The typical trajectory of how matters return

Figure 1. The systemic yoyo model in 3-Dimensional Euclidean Space

As for systems science, it is simply the totality of studies of various kinds of systems. In the past century, the methods and thinking logic of systems science have been widely employed in scholarly works (Klir, 2001). Similar to how the Cartesian coordinate system – consisting of the crossing of two or more number lines – plays its role in the development of the traditional science and mathematics (Kline, 1972), in systems science the role is played by the systemic yoyo model (Lin, 2007), shown in Figure 1.

Specifically, the blown-up theory (Wu & Lin, 2002), a general theory of development, and discussions on whether or not the world can be seen from the viewpoint of systems (Lin, 1988; Lin, et al, 1990) have led to the development of this yoyo model for each object and every system imaginable. Speaking differently, each system can be theoretically seen as a multi-dimensional entity that spins about its axis. If such a spinning entity is fathomed in the 3-dimensional space within which we live, such a structure as artistically shown in Figure 1(a) appears. The input side pulls in *things*, such as human resources, materials, information, investment, profit, etc. After funneling through the "neck", *things*, such as products and services, are spit out from the output side. Some of the things, spit out as outputs, never return to the input side and some will (Figure 1(b)). Due to its general shape, such a structure is referred to as a yoyo.

What this systemic model says is that each physical or intellectual entity in the universe, be it a tangible or intangible object, a living being, an organization, a market, an economy, etc., can all be treated as a realization of a certain multi-dimensional spinning yoyo with an eddy and meridian field around. This yoyo remains in a spinning motion as depicted in Figure 1(a). When it stops its spinning motion, it will no longer be an identifiable system. What Figure 1(c) tells is that the interaction of the eddy field, which spins perpendicularly to the axis of spin, of the model, and the meridian field, which rotates parallel to axis of spin, makes *things* that are either new to the yoyo body or returning to the input side travel along a spiral trajectory.

Based on this systemic yoyo intuition, each market competition can be seen as a collection of yoyo fields struggling against each other for survival and for growth; each market, large or small, can be modelled abstractly as an ocean of yoyo fields that push against each other and pull similar fields together to form much larger and more powerful fields.

In order to actually develop useful insights and conclusions, let us follow the approach given by Lin (1999), where each system is described as a mathematical structure from which theoretically important and practically useful theorems can be established: S is a (general) system if S is an ordered pair (M, R) of sets, where R is a set of some relations on the set M. Each element in M is called an object of S, and M and R are called the object set and the relation set of S, respectively. A system S is discrete if $R = \emptyset$ or $R = \{\emptyset\}$ and $M \neq \emptyset$; it is trivial if $M = \emptyset$, where $\emptyset$ stands for the empty set.

Basic Assumptions and Terminology

To make logical reasoning in this paper valid, assume that each business firm exists for the purpose of satisfying a particular market niche through generating a positive cash flow, which can be profits from the marketplace, or investments from various investors, or both. In other words, the firm has to actively pursue after certain endeavors in order to meet some market demand(s).

By consumers, we mean the end users of products and/or services. By resource, it means an asset of a firm, be it tangible or not (Harmancioglu et al, 2009), which that firm can use to design and implement its strategies (Barney & Arikan, 2001). In other words, a resource stands for something, be it physical, financial, intellectual, or organizational, the firm can mobilize to accomplish its business goals. And, a resource can generally provide alternative services that differentially increase either the efficiency inside the firm or consumer value creation outside the firm.

By synergistic innovation, it stands generally for such an innovative strategy of a focal firm that systemically deploys and redeploys known elements that exist either within or outside that firm to produce additionally economic benefits. In particular, known elements can be resources - either tangible or intangible, established management routines, production processes, consumer preferences, market demands, etc.; and the word "systemically" means that a focal firm can develop a meaningful system or a set of systems that organically combine the known elements to produce new products with much improved functionalities, and /or new services that meet a forever evolving market demand or consumer preference. The following are some good examples of synergistic innovations in action on either producer-side or consumer-side synergies.

- Different combinations of known technological processes can produce positive synergy (Crossland & Smith, 2002).
- When knowledge across business units of a focal firm is shared, benefits from transferred skills can be anticipated (Hitt et al, 2001).
- When economies of scope and skill transfers are combined, the social network of a focal firm can greatly contribute to that firm's innovativeness (Tsai, 2001).
- Evolving consumer tastes stimulate firms to embark on technological development and innovation (Adner & Zemsky, 2006).
- The benefits consumers enjoy when their knowledge learned from using one product can literally reduce or eliminate the learning time required to use another product (Priem, 2007; Tanriverdi & Lee, 2008).
- The appearance of a disruptive technology can help reveal a new dimension or confirm an existing dimension of consumer preferences for various industries (Adner & Snow, 2010).

SYNERGISTIC INNOVATION AT THE PRODUCER SIDE

This section establishes relevant concepts and elementary properties regarding synergistic innovations at the producer side (Priem & Butler, 2001a, b). The concept of synergistic potential arising from resource relatedness has been introduced since at least the early 1970s (e.g., Rumelt, 1974; Palich et al, 2000) when Rumelt noted that firms, which diversify through employing respectively related resources, generally outclass those firms, which also diversify, but only doing so by utilizing unrelated resources.

Deployment and Redeployment of Resources

By synergistic innovation at the producer side, it means that a focal firm designs and employs an innovative strategy that systemically deploys available resources in such a way that the firm can produce an economy of scope in terms of products and/or services. By producer synergy, it means that through product diversification as a way to widen a firm's stock of assets and skills, the firm is able to expand the perimeter of its value activities (Porter, 1985, p. 380). By synergistic potential arising from resource relatedness, it means the potential of producing new products and/or services, which helps increase the economy of scope of a firm, by innovatively mobilizing related resources. When a mobilization of certain resources leads to positive economic benefits, then we say that the resources create a positive synergy. Otherwise, we say that the mobilization produces a negative synergy.

Proposition 1. If a firm is able to deploy and redeploy resources repeatedly in its effort to produce an economy of scope by making resources, be they tangible or intangible, available to all business units, then there is a potential for synergistic innovations to appear from the effort of diversification.

To see why this proposition holds true, let us model the firm of concern as a system $S = (M, R)$ such that the object set M consists of the resources the firm controls and each relation r in the relation set R stands for a product produced by mobilizing a subset of the resources in M. Now, the given assumption means that freedom and encouragement are given for the employees of the firm to establish possible associations among elements in any subset of M, where each element in M can be repeatedly used in as many associations as possible. That of course implies that a potential of designing and producing many additional products and/or services appear. This logic reasoning is well depicted in Figures 2(a) and 1(b), where the rectangle stands for the object set M, and in Figure 2(a) *A* and *B* are the two existing products of the firm, which are produced respectively by associating resources in their enclosed areas. When employees are encouraged to associate resources any way imaginable, additional enclosed areas, such *C* and *D* in Figure 2(b), can be produced.

(a) Existing associations of resources (b) Additional associations are created

Figure 2. Additional associations of resources are encouraged

This proposition can be shown rigorously by using the following theorem of systems science:

Theorem 1. If $S = (M, R)$ is a multi-level system with a finite object set M such that

- Each object system of S has a finite object set,
- Each object that appears in any relation in the system S or an object system of S only appears once in that relation; and
- S has at least one chain of object systems of more than one level and each object system on the chain contains more than one object,

and $M(S)$ the set of all fundamental objects in S, then $|M| < |M(S)|$.

The proof is very technical and is omitted.

Now, let us model the focal firm with business units strictly defined and resources divided according to the unit divisions as a system $S = (M, R)$, where each object m in M stands for the bundle of resources available only to a particular business unit and each relation r in R as a product or service of the firm. Then the set $M(S)$ of all fundamental objects of the system S

stands for the totality of resources the firm has control over. Now, the conclusion of Theorem 1 says that $|M| < |M(S)|$, which means that the number of available resources is greater than that of business units. Therefore, there are more ways to define relations (products) on *M(S)* than on *M*. That proves Proposition 1.

In terms of the literature, comparing to Proposition 1, a more specific conclusion is given by strategic management scholars. For example, it has been argued (e.g., Porter, 1985) that positive synergies from diversification can emerge if a firm is able to share tangible functions and intangibles, such as knowledge and skills, among business units.

In terms of when a mobilization of certain resources can lead to negative synergies, we have the following result.

Proposition 2. Assume that A and B represent two opposing business goals of a focal firm and that X and Y are mutually exclusive sets of resources that firm has control over, satisfying that resources in X support the realization of goal A and those in Y help actualize goal B. Then a mobilization of any resource in X and any resource in Y will generally produce negative synergies.

To illustrate how two business goals of a focal firm could be opposing to each other, let us consider the following situation (McGrath, 2013):

- A = the goal of implementing the strategy of exploiting the competitive advantages proven successful over time; and
- B = the goal of implementing the strategy of constantly designing and developing new competitive advantages.

Based on this illustration it can be seen that the set of resources employed to materialize goal A and the set of those used for goal B are not the same. All the involved resources can be written into three mutually disjoint sets X, Y, and Z, other than X and Y, as defined in the proposition, set Z includes all those resources that are needed for materializing both business goals A and B, Figure 3. The elements in set Z could include such commonly deployable resources in multiple directions as strong relationships that lead to information sharing, risk taking, and adoption of innovations (Dutta, et al, 1999). Now, it is ready to see that a joint mobilization of the special resources in X and those in Y generally leads to undesirable effects or negative synergies.

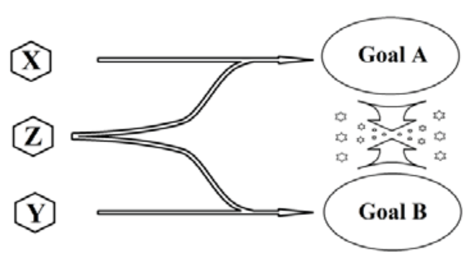


Figure 3. How resources are divided corresponding to business goals A and B

Inconsistent Resources and Core Resources

Two resources x and y are said to be inconsistent, if mobilizing these resources jointly leads to negative synergy. For example, any resource from set X and any resource from set Y in Proposition 2 will be inconsistent, because jointly they lead to undesirable outcome(s). Now, in terms of when a mobilization of certain resources can potentially lead to positive synergies, we have the following conclusion.

Proposition 3. Assume that X represents the set of resources that were used to generate a positive synergy in a focal firm's effort to create an economy of scope. Then by either adding another set of available resource into X or replacing some resources in X by another set of available resources the firm can potentially lead to positive synergies, if none of the new resources under consideration is inconsistent with the other remaining resources in X.

This result holds true, because altering set X is generally the way for the focal firm to produce additional versions of the product initially developed on X with varying degrees of functionality. Systemically, either adding another set of consistent resource into X or replacing some resources in X by another set of consistent resources mean that the new resources will alter the yoyo structure that underlies the original association of the resources in X in terms of spinning strength, the orientation of the spinning axis, the area the spin field covers, etc. The resultant yoyo structure of the updated set X of course means a different product or service, which is either very different from or somehow related to the original one. Depicting this situation, Figure 4 also demonstrates why the condition that the set of new resources used to alter X has to be consistent with the remaining resources in X, otherwise, the resultant yoyo body can be potentially broken into pieces, as what Proposition 2 shows. In Figure 4, the original X evolves into either X' or X", where some of the round dots are replaced by diamonds in the former case, while by starts in the latter case.

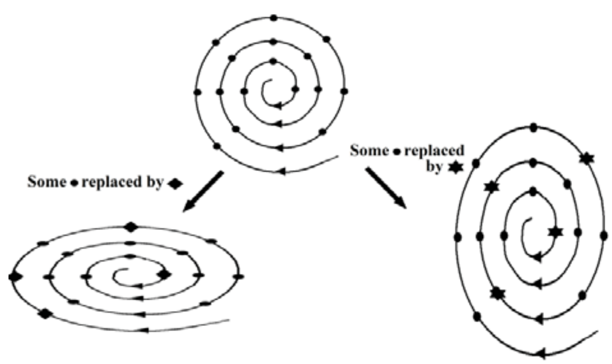

Figure 4. Altering an existing systemic field by changing its composition

A set of resources is said to be relatable, provided that the association of any two resources in the set does not lead to negative synergy, although the association might not produce a positive synergy, either.

Proposition 4. The most natural portfolio of products and/or services of a firm is bound together by a set of related resources that generate positive synergies.

From the point of view of development (Wu & Lin, 2002), any portfolio of products and/or services must start with the very first product or service. When a firm develops its first product or service that generates a positive cash flow (seen as a positive economic benefit), either from the marketplace or investors, there must be a set X of resources the firm has control or influence over that have jointly produced positive synergies for the firm. So, Proposition 3 indicates that a natural way to develop different products and/or services will be finding growth points out of the set X of once-already-proven resources through modifying X by either replacing some resources from X with new and consistent ones or adding additional consistent resources into X. That end is vividly shown historically by how industrial revolutions evolve over time and how one follows another (Forrest et al, 2018); and it is partially recognized by Robins and Weirsema (2003, p. 45) when they remarked that “contemporary view(s) of related diversification might be summarized by … that … a portfolio of businesses is bound together by some shared strategic resources or capabilities”.

As for why such a portfolio of products and/or services is considered most natural, it is because finding an organic association of another set of resources to produce positive economic benefits generally is much harder, which is equivalent to starting up a new business. Other than opportunities of luck, this is much more difficult to accomplish than simply finding growth points on top of the set X as described in the previous paragraph (Salamzadeh & Kawamorita, 2015).

Systemically, this result is quite intuitively straightforward: After a yoyo field emerges, as a new born business entity, in the turbulent ocean (a model of the business world) of countless incumbent yoyo fields that intensively combat against each other first for survival and then for further development, the best and most natural way for it to survive and to grow is to make itself stronger through strengthening what the new born has already achieved and acquiring additional elements so that new and enhanced associations of various resources will help the yoyo field of the new born spin faster and more powerfully than ever before.

Proposition 5. If a firm’s portfolio of products and/or services is bound together by a set of core resources, then there is a good chance for the firm to continuously exploit its established competitive advantages instead of constantly developing new advantages.

This result is a corollary of the previous propositions. In particular, if there is a set of core resources that underlies a firm’s portfolio of products and/or services, the superior value of those resources will be widely acknowledged by the stakeholders of the firm if not yet the case already. So, there will be a momentum for the firm to continue its current state of affairs based on the following first law on state of motion.

First law on state of motion (Lin, 2009): Each imaginable and existing entity in the universe is a spinning yoyo of a certain dimension. Located on the outskirt of the yoyo is a spin field. Without being affected by another yoyo structure, each particle in the said entity’s yoyo structure continues its movement in its orbital state of motion.

The scenario can be seen from a different angle: after putting in tremendous amounts of time and efforts in trying various combinations of resources to get a business operation going, the founders of the firm, as systems themselves with life cycles, can be most likely tired both mentally and physically. That explains why under such circumstances, there is a good chance for the firm to continuously exploit its established competitive advantages instead of constantly developing new advantages, unless new stimuli, either from competitors or from the changing market condition, appears to redirect the attention and energy of the founders and their successors.

SYNERGISTIC INNOVATIONS AT THE DEMAND SIDE

Since over 50 years ago when Penrose (1959) noted that when paying attention to the needs of consumers, companies grow, studies in strategic management have advocated for paying additional attention to the demand side in decision making (e.g., Adner & Zemsky, 2006; Priem, 2007). Riding on this trend of thoughts, this section investigates the concepts and elementary properties of synergistic innovations at the demand side (Ye et al, 2012) by placing end users of products and services in the square center.

When Consumers Are Willing to Pay Additional

Similar to how the concept of producer synergy is defined earlier in the previous section we have the following (Ye et al, 2012): By consumer synergy, it stands for an increased value created for consumers and captured by a firm through employing combination(s) of products and/or services that jointly expand consumer utilities beyond the sum of the consumer utilities offered individually by the products and/or services. For illustration purpose, let us look at an excellent example constructed by Ye at al (2012).

A state university in northern USA has a population of over 29,000 students, most of whom are unmarried undergraduates living on tight budgets. As most of the rental properties around the campus do not offer laundry facilities, self-service, coin-operated laundromats near the university compete for the students' business. Another successful kind of college-town business, attractive mostly to college women, is indoor tanning. Instead of offering these services separately, two entrepreneurs provide their independent, single-location businesses, each of which jointly provide coin-operated self-service laundry facility and indoor tanning service. Such business combination creates consumer synergies from diversification of commonly available assets – same or similar equipment –without much reduction in the overhead costs (from completely different sets of equipment) and labor costs (the combined business types require considerably different production and customer service skills). However, this business combination creates tremendous amount of demand-side synergies due to the following reasons:

(1) Students can start washing their clothes and then tan their skin simultaneously, saving the otherwise unproductive and costly waiting time; and
(2) Students are provided with a place for the potential of establishing relationships because the location of combined services provides opportunities for both males and females to meet, where women's greater participation in the tanning service attracts a larger number of men to the laundry service.

Consequently, the created consumer (or demand-side) synergies help respectively support higher fees collected from the laundry service than other standalone stores and maintain competitive prices for the much increased demand for the tanning service. In other words, a greater value is respectively created for consumers and captured by business providers because of the resultant consumer synergies from product-and-service diversification.

In general, if two or more market demands can be met simultaneously, such as the situation described in reason (1) above, while saving valuable resources for consumers, such as time and/or money, then we say that the diversification effort of meeting different market demands has created a simultaneous consumer utility effect. If two services, each of which attracts a different segment of consumers, although the segments might be overlapping, are collocated so that the increased traffic flow due to the joint offer of services from one segment of consumers attracts an increasing traffic flow from the other segment of consumers, while the latter does not have any adverse effect on the former, as described in reason (2) above, then we say that the diversification of services has created a two-sided market effect.

Proposition 6. When collocating diverse products and/or services leads to a simultaneous consumer utility effect, consumers will be willing to pay additionally for a product or service beyond the market norm.

First, when a simultaneous consumer utility effect is created by collocating diverse products and/or services, by definition it means that consumers have saved some of their valuable resources. That saving generally is convertible into consumers' willingness to pay more than what is expected on the average in the marketplace. When a two-sided market effect is developed by collocating diverse products and/or services, the alternatively reinforcing effects on the traffic flows of the different segments of consumers make the demand for the joint offer of products and/or services rise. That in turn supports rising prices.

Systemically speaking, each simultaneous consumer utility effect can be described by employing the yoyo model in Figure 5. In this systemic depiction, three market demands A, B and C can be satisfied by either three different business entities X, Y and Z separately or by one business firm whose yoyo field encompasses all those of the three entities X, Y and Z. The idea is kind like, but not exactly the same as that of one-stop shopping. The reason why consumers are willing to pay extra is demonstrated by the fact that the conflict zones existing in areas between the yoyo fields X, Y and Z no longer exist, if these small yoyo fields can be combined into a much larger field that encompasses those of X, Y and Z.

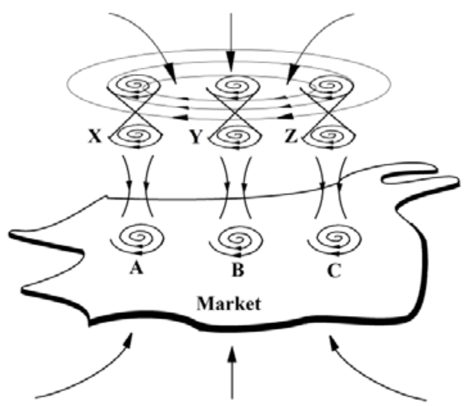

Figure 5. Meeting three market demands simultaneously

Proposition 7. When collocating diverse products and/or services leads to a two-sided market effect, consumers will be willing to pay additionally for a product or service beyond the market norm.

For two-sided market effects, the concept can be intuitively seen systemically in Figure 6. In this systemic intuition two different market segments A and B of consumers are identified, where consumers in B are closely attached to those in A who at the same time are particularly attracted to the service provided by firm X while can also take advantage of the service of Y. From such a realization of potentially creating a two-sided market through diversified offers of products and/or services, the business ideas of both X and Y are combined into one business practice, whose yoyo field encompasses those of both X and Y. This new business firm will attract the consumers in A, through which those consumers in B are also pulled over from the corresponding competitors.

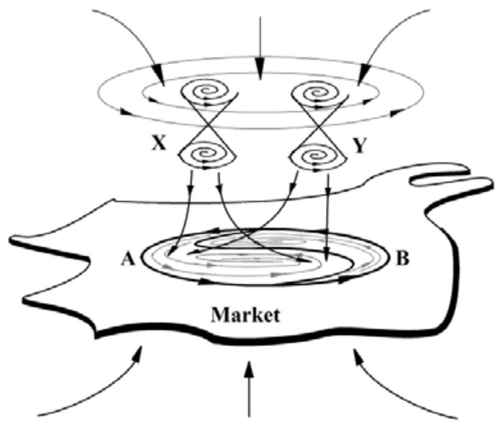

Figure 6. How a two-sided market effect appears

Corporate Growth and Improving Firm Performance

When consumers are willing to pay extra beyond the expected market fees for a product or service due to the reason that diverse products and/or services are provided to consumers as bundles, we say that the diversification has produced a demand-side or consumer synergy. Because at any given moment of time each human being has multiple needs from across different industries, Propositions 6 and 7 imply that demand-side synergy can be obtained via inter-industry diversification of seemingly unrelated products and services from the viewpoint of producers.

Proposition 8. Corporate growth and improving performance can be achieved simultaneously through diversification at either the producer side, or the consumer side, or both.

At the producer side, diversification or creating an economy of scope is most likely achieved in real life by making resources available to all business units (Proposition 1) so that these resources can be deployed and redeployed repeatedly for different purposes, leading to a rich portfolio of products and/or services, which are more or less related due to the resources employed (Proposition 4). From Proposition 1, it follows that diversification at the produce side leads to the potential for synergistic innovations to appear, which helps to grow the business and to improve the performance. This end is like what Porter (1985) argued that firms should consider the ‘fit’ of related diversification for better performance.

From the perspective of demand-side synergies, a synergistic fit of diversified offers can occur on the consumer side (Proposition 6), leading to increasing top lines of a firm. Hence, both corporate growth and improving performance can be simultaneously achieved through diversification.

By combining the previous analyses, it shows that if diversification occurs at both the producer and the consumer side, the chance for corporate growth and improving performance increases tremendously.

CONCLUSIONS

The present world of market economies has been turbulent. To successfully survive and grow in such a constant turbulence, a firm has to continuously look for potentials of different competitive advantages (McGrath, 2013). One way of doing so is to create economies of scope by diversification at either the producer side (Porter 1985; Santalo & Becerra, 2008) or the demand side (Ye et al, 2012) or both. If a firm adopts this approach of diversification, then the firm faces the challenge of how to develop the necessary ideas for diversification. It is around our attempt to address this challenge that this paper establishes a series of both theoretically and practically significant results.

By employing the thinking logic of systems science, this paper is able to develop urgently needed conclusions generally useful for managerial problem solving and decision making (Lockett et al, 2008) and to address some key issues in strategic management. In terms of applications, this paper provides practically significant recommendations for entrepreneurs, managers, and retailers, respectively.

In particular, for managers, entrepreneurs and retailers who focus on the demand side by considering collocating commonly available products and/or services, this paper shows that other than an intimate understanding of consumers' needs and the creativity to envision a novel collocation of commonly available resources (Ye at al, 2012), superior consumer benefits can still be created by offering consumer groups utilities that they were not previously aware. In particular, this paper shows why diversification helps firms with corporate growth and performance (Proposition 8); and when consumers are willing to pay extra for their needs (Propositions 6 and 7). Beyond theoretical results, this paper also provides practically applicable recommendations. For example, when strategically planning for collocations of commonly available products and/or services, a manager/entrepreneur should always keep in mind the potential of complementary consumer benefits (Propositions 6 and 7), where consumer interactions can create another dimension of growth and satisfaction and where a two-sided or even multi-sided market can emerge.

For managers of the producer side who intend to produce an economy of scope, beyond explaining why the idea of economies of scope will help with corporate growth and performance (Proposition 7), this paper also shows how to potentially create synergistic innovations by

- Making their limited resources available to all business units within their companies,
- Discovering what new ideas could be introduced through combining different resources,
- Naturally formulating a portfolio of diversified products and/or services,
- Staying alert about when their firms could likely become exploiters of existing competitive advantages instead of explorers of new advantages in the turbulent consumers' markets, and
- Avoiding negative synergies by not jointly mobilizing inconsistent resources.

To conclude this presentation, let us now look at the limitations of this paper. One limitation stems from the assumption of why a firm actually exists. In fact, firms in the business world behave widely differently from each other depending on why and how they are established. That will explain why results established will not be universally applicable to many actual situations. Although our attention in this paper is on how both conceptually and practically a focal firm can synergistically collocate available resources at the producer side or commonly available products and/or services at the demand side in its effort to create economies of scope, we did not consider the limitations that firm is subject to. These listed and unlisted limitations of this work should help point to future research problems in order to develop additional practically useful insights beyond what have been established in this paper.

ABSTRACT

In Behavioral Economics, "arbitrary coherence" is when an arbitrary, randomly chosen number, influences the amount purchasers are willing to pay for a product. Arbitrary coherence is similar to anchoring which marketers sometimes use to help set optimal prices. This paper examines how the arbitrary coherence effect influences individual decision making.

KEYWORDS: Arbitrary coherence, Anchoring, Semantic differential, Monadic testing, Random numbers

INTRODUCTION

A landmark article in Science (Tversky and Kahneman, 1974) reported a research track concerning decision-making that essentially created the field of Behavioral Economics. In that article, the authors noted that humans normally use heuristics ("rules of thumb") to interpret information and make decisions. Humans are especially prone to errors concerning representivity (judging instances more or less representative than they are; ignoring sample size, etc.), availability (e.g., bias of imaginability), and adjustment and anchoring (e.g., bias due to conjunctive and disjunctive events).

In the book *Predictably Irrational* by Dan Ariely (2008), a study is described which reveals something very interesting about the effect of context on how we make decisions. Knowledgeable and very intelligent people who were fully aware that certain numbers were chosen in a completely arbitrary, random fashion were still influenced by those numbers when making decisions about what they would pay for certain items. This phenomenon is described as "arbitrary coherence", a term also found in the behavioral economics literature. One of the authors was working for a large national marketing research firm at the time and thought that the results of the study could provide a valuable tool for marketing research professionals especially in the area of setting new product prices.

A first attempt at replicating the Ariely study using four different products confirmed the phenomenon. A second study, with different items, completely failed to replicate the effect. Thus, began a nearly ten-year journey into answering the question, "When and under what conditions does the arbitrary coherence phenomenon manifest itself?" This paper details five studies beginning with the one that replicated Ariely's findings and the second study that did not demonstrate the effect. Three follow-up studies with students and national samples are described in an effort to identify the underlying factors when arbitrary coherence is observed and when it is not.

LITERATURE REVIEW

Beyond the landmark article in *Science* (Tversky and Kahneman, 1974), the book *Thinking, Fast and Slow* (Kahneman, 2011) elaborated on forty years of research in the area by describing two mental “systems.” Kahneman appropriately cautions that thinking is not as simple as the two-system concept suggests, but the theory helps understand and describe the findings. System 1 is the heuristic-using operator that relies on bits of available data and draws conclusions; it is very good at perceiving patterns, even where there are none. System 2 is the thinking component – focus, concentration, work. System 1 only examines and operates on what is present. Kahneman summarizes its method with WYSIATI – an admittedly awkward acronym for “What You See Is All There Is”. System 1 does not consider unseen possibilities. It makes quick, easy decisions, often accurate in everyday life.

System 2 is the analytical function. It can explore possibilities and elements that are not present, but this requires thinking, which is hard work. So, if System 1 makes a judgment and nothing present (WYSIATI) conflicts with it, System 2 will likely “rubber stamp” it, taking the easy way out. Given this, decisions are subject to systematic biases.

The specific instance of bias of interest here is “arbitrary coherence.” In a summary of six experiments, Ariely, Loewenstein, and Prelec (2003) describe an anchoring phenomenon wherein a random, arbitrary number that respondents know is irrelevant to the decision influenced their judgments of amounts willing to pay and reactions to hearing painful sounds. The authors’ own words are the best succinct description of the phenomenon.

> *In six experiments, we show that the initial valuations of familiar products and some simple hedonic experiences are strongly influenced by arbitrary “anchors” (sometimes derived from a person’s social security number). Because subsequent valuations are also coherent with respect to salient differences in perceived quality or quantity of these products and experiences, the entire pattern of valuations can easily create an illusion of order, as if it is being generated by stable underlying preferences. The experiments show that this combination of coherent arbitrariness (1) cannot be interpreted as a rational response to information, (2) does not decrease as a result of experience with a good, (3) is not necessarily reduced by market forces, and (4) is not unique to cash prices. The results imply that demand curves estimated from market data need not reveal true consumer preferences, in any normatively significant sense of the term.*

The authors say this in a less precise but perhaps clearer way in their introduction.

> *In this paper, we show that consumers’ absolute valuation of experience goods is surprisingly arbitrary, even under “full information” conditions. However, we also show that consumers’ relative valuations of different amounts of the good appear orderly, as if supported by demand curves derived from fundamental preferences. Valuations therefore display a combination of arbitrariness and coherence that we refer to as “coherent arbitrariness.”*

Arbitrary coherence is also referred to in *Predictably Irrational* (Ariely, 2008), and is put in the broader context of anchoring in *Priceless* (Poundstone,2010). The latter also points to numerous examples of anchoring and arbitrary coherence in setting market prices and determining price changes. One example is lowering the volume of peanut butter by indenting the bottom of the jar, since consumers will, by and large, fixate on the familiar price, not the volume. Once an anchor price is established, all other pricing in that particular arena can be coherent with that price in some way. Luxury goods can especially benefit from a high anchor price point.

In a literature search aimed specifically at finding work on “arbitrary coherence” only two articles specific to the topic appear. In a pilot project with 41 fourth year medical students, Pouthier (2009) found that having them write the last two digits of their mobile telephone numbers influenced their subsequent responses to a series of questions concerning surgical training. The questions required estimating numbers, and the mean results by student correlated ($r = 0.36$, $p \leq .05$) with the irrelevant telephone number digits. The author warns that steps should be taken to minimize this unexpected potential bias.

A second article with students at Cambridge (Scott and Lizieri, 2011) tested two hypotheses. Paraphrasing, they were (1) an arbitrary anchor will reliably influence judgment of a property’s value, even when incentives are provided for accuracy; (2) subsequent judgments of property values will be influenced by the value immediately prior, so a single subject’s valuation set will be coherent. After significant data manipulation (“eliminating noise”) primarily by eliminating outliers, they more or less confirmed both hypotheses. Their research clearly has implications for pricing in real estate marketing.

As noted, arbitrary coherence is put into a broader context of anchoring in *Priceless* (Poundstone,2010), pointing to numerous examples of anchoring and arbitrary coherence in setting market prices and determining price changes. Another example besides the peanut butter jar is placing a very expensive item on display, so that other items of less expense look reasonable – the $9,000 Gucci purse displayed with many $2,500 to $3,000 purses available for purchase.

Fudenberg, Levine and Maniadis (2010), in “Reexamining Coherent Arbitrariness for the Evaluation of Common Goods and Simple Lotteries” found that the effects of the arbitrary coherence manipulation on the valuation of common market goods produced very weak anchoring effects, and no effects at all on the valuation of binary lotteries.

> *The assumption that people make decisions based on a constant set of preferences, so that choices should not depend on context-specific cues (anchors), is one of the cornerstones of economic theory. We reexamined the effects of an anchoring manipulation on the valuation of common market goods that was introduced in Ariely, Lowenstein and Prelec (2003). We found much weaker anchoring effects. We performed the same manipulation on the evaluation of binary lotteries, and we found no anchoring effects. This suggests limits on the robustness of strong anchoring effects. Hence, the evidence that people have "arbitrary preferences" may not be conclusive, and economic theory may still be valid in many cases of interest.*

The experiments conducted by Fudenberg et. al. took place in the California Social Science Laboratory (CASSEL) at UCLA, in August of 2009, and the subjects were UCLA students. The first of four experiments were paper-and-pencil as was the case in Ariely et. al. and reexamined the effects of random anchors on subjects' valuation for common market goods of interest to students.

One other consistency in the reviewed research and in the initial research by the authors should be noted. Nearly all were convenience samples, primarily college students, but our earliest studies included marketing researchers who were at hand and willing. The authors are not familiar with any research that attempted to show arbitrary coherence in a national, random sample. In this paper, two national samples of 400 each are detailed.

In an interesting precursor of arbitrary coherence, Wilson et. al. (1996) examined anchoring effects to determine conditions under which anchoring appears. The authors supported a number of hypotheses that relate to arbitrary coherence. Each of their five studies required numerical responses. They found numerical basic anchoring effects occur when uninformative numerical anchors influence judgment, even when people are not asked to compare that anchor to the target value.

Based on the finding from their second study, Wilson et. al. eliminated any subject claiming to be knowledgeable from the next three, so their conclusions must be qualified accordingly. Wilson et. al. focused on aspects of the conditions where anchoring impacts decisions. Following Wilson et. al., questions abound about the limitations of both anchoring and the arbitrary coherence effect.

The fourth study explores the differences in perceptions which might account for when the arbitrary coherence effect is observed by using semantic differentials, specifically, do differences in the perceptions of each item tested correlate in any way to the existence or lack of arbitrary coherence? There is a wealth of literature on semantic differentials and the research is beyond the scope of this paper. Briefly, one of the earliest publications was by Charles Osgood (1957). Mindak (1961) applied the semantic differential to marketing problems.

FIVE STUDIES EXAMINING THE IMPACT OF ARBITRARY COHERENCE ON DECISION MAKING

Study #1 (AC1) – The Initial Attempt to Replicate Ariely's "Coherent Arbitrariness"

In the Ariely study (2003), six items with an average retail price of $70 were shown to 55 MBA students during the first marketing research class meeting at the Sloan School. Students were asked if they would buy each item for the dollar figure equal to the last two digits of their Social Security Number. They were then asked if an auction was held, what is the highest price they would be willing to pay (WTP) for each item.

The goal of the first study we conducted was to see if the arbitrary coherence (AC) effect would be observed in a less "naïve" group of respondents. Four items were selected at random from advertisements in a Sunday paper, specifically: Teleflora Spring Pitcher Floral Display, Dr. Scholl's Hand-Stitched Leather Loafers, Irish Spring 12-bar Value Pack and a bottle of Bailey's Irish Crème (Appendix 1). There are a few differences from Ariely's original research, specifically, this study was conducted with 69 marketing research professionals and four items were tested using photos only, not the actual items. To further test the effect, two items with generally unknown values were tested with two items with generally known values below $30. The results from Ariely are shown in Table 1 as the reference for our first study (AC1).

The survey contained the following three questions (Appendix 2):

1. Enter the last two digits of your Social Security number (SS#) as if it were a price in dollars.
2. Indicate if you would be willing to pay that amount for the item by writing in a Y for “yes” or an N for “no”.
3. Pretend there is an auction for the item. In whole dollars, write in the maximum amount you would be willing to pay for it (WTP).

Table 1. Results from the Ariely (2003)

Products	Quintile 1	Quintile 2	Quintile 3	Quintile 4	Quintile 5	Correlation
Cordless Trackball	$ 8.64	$11.82	$13.45	$21.18	$26.18	.415 p=.0015
Cordless Keyboard	$16.09	$26.82	$29.27	$34.55	$55.64	.516 p<.0001
Average Wine	$8.64	$14.45	$12.55	$15.45	$27.91	.328 p=.014
Rare Wine	$11.73	$22.45	$18.09	$24.55	$37.55	.328 p=.0153
Design Book	$12.82	$16.18	$15.82	$19.27	$30.00	.319 p=.0172
Belgian Chocolates	$9.55	$10.64	$12.45	$13.27	$20.64	.419 p=.0013

As Ariely points out,

> … the impact of the social security number on stated WTP was significant in every product category… the top quintile subjects were willing to pay $56 on average for the cordless computer keyboard, compared with $16 on average for the subjects with the bottom quartile numbers. Alongside this volatility of absolute preference, we also observed a marked stability of relative preference. For example, the vast majority of subjects (>95 percent) valued a cordless keyboard more than a trackball, and the highly rated wine more than the lower-rated wine.

The results of AC1 are shown in Table 2. The arbitrary coherence effect was found to exist for the two higher-priced items where the actual price was uncertain. Even though most respondents would have a good idea of the actual retail price for the Bailey’s Irish Crème there was a positive correlation. As expected, there was no correlation for the Irish Spring, the one item most subjects knew was inexpensive.

Table 2. Results of Arbitrary Coherence (AC1) Study

	Last 2 Digits Social Security Number as $				
Products	Under $25	$26 - $50	$51 - $75	$76+	Correlation
Teleflora	$22.13	$43.29	$38.70	$40.79	+.33*

Dr. Scholl's	$34.13	$34.07	$49.45	$51.53	+.28*
Bailey's Irish Crème	$15.50	$16.93	$16.75	$20.42	+.16
Irish Spring 12 Pack	$5.63	$9.50	$6.10	$6.21	-.05

* = the correlation is statistically significantly different than zero, $p \leq 0.05$.

If a group of professionals were "impacted" by the random number anchoring, the next question was, "Is there something in the questions that produces the results?" A second study was conducted about six months later with the same, but larger group of 84 professionals.

Study #2 (AC2) – Different Item Set, Two Questions versus Three

For the second study, four different items, all of reasonable and unknown value, were used: Crocodile Wallet, Copper Bowl, Necklace of Pearls from Tahiti, The Complete Works of Lewis Carroll (Appendix 3). These were again selected from newspaper ads, this time to have prices that would likely be unfamiliar to subjects, since uncertainty is a precondition.

In this study (AC2) half the group were not exposed to the middle question "indicate if you would be willing to pay that amount for the item" (Appendix 4). The other half of the respondents completed all three of the original questions. Subjects were randomly assigned, so that half were asked the original three questions, and half were not asked the middle question (would they buy it for the specified amount).

Table 3. Results of AC 2 Study with Purchase Decision Question (Three Questions)

	Last 2 Digits Social Security Number as $				
Products	Under $40	$40 to $59	$60 to $79	$80 to $99	Correlation
Crocodile Wallet	$38.22	$42.50	$18.60	$22.69	-.24
Copper Bowl	$90.56	$112.90	$158.40	$151.54	+.10
Necklace from Tahiti	$26.33	$45.80	$25.50	$47.85	+.12
Complete L. Carroll	$65.56	$34.20	$25.50	$75.38	-.03

Table 4. Results of AC2 with No Purchase Decision Question (Two Questions)

	Last 2 Digits Social Security Number as $				
Products	Under $30	$30 - $59	$60 - $79	$80 - $99	Correlation
Crocodile Wallet	$13.10	$20.22	$23.17	$20.64	+.08
Copper Bowl	$161.50	$189.89	$117.58	$135.45	-.05
Necklace from Tahiti	$14.10	$36.00	$36.58	$15.91	+.04
Complete L. Carroll	$137.10	$97.44	$95.00	$64.36	-.18

In the second study, there was no arbitrary coherence effect in either subgroup. This lack of effect meant that it was impossible to shed light on the effect of the second question. It also raised new questions about the limitations of arbitrary coherence.

Did the lack of effect in the test cell that received exactly the same questions occur because the same subjects were used? But prior research, reported in *Priceless* (Poundstone, 2010), found that experience did not impact arbitrary coherence. In this case, though, one wonders if these informed researchers were “conditioned?” Alternatively, did the lack occur because of the items used? Were the items of little interest, limiting the effect? Or, was it just the random assignment of subjects presenting an effect of its own?

Study #3 (AC3) – Two Items Sets and Two versus Three Questions

The third study was conducted among 84 university students to attempt to resolve the questions from AC2; specifically:

1. Is the arbitrary coherence effect present when each set of items is tested with naïve subjects?
2. Is making a purchase decision (“the middle question”) causing a different effect?
3. Is there an interaction, such that making or not making a purchase decision yields different results for each set of items?

The age range for respondents was 18 to 47 years old and all had Social Security numbers. The mean age is 22 and the median is 21 with 71% between 18 and 22 years old. Thirty-two (38%) are female. There are 53 undergraduates (63%) and 31 (37%) graduate students.

Since there are two types of questionnaires, one with two questions and the other with three questions and two sets of items there were four test groups (Table 5). Four color coded surveys were created and distributed to four independent groups with between 19 and 22 different students per group. Group 3 (16) and Group 4 (14) contained almost all of the graduate students.

Table 5. Table of Groupings for the Third AC Study (AC3)

	Item Set #1:	Item Set #2:	Totals
Purchase Decision (3Qs)	Group 1: 22 students AC3, Set1, 3Qs	Group 3: 19 students AC3, Set2, 3Qs	41
No Purchase Decision (2Qs)	Group 2: 21 students AC3, Set1, 2Qs	Group 4: 22 students AC3, Set2, 2Qs	43
Totals	43	41	

Item Set #1 consists of three of the four original items from the first study. In deference to the fact that some subjects were underage for alcohol consumption, the original Bailey’s Irish Crème was changed to “Sandy Flats Pure Maple Syrup – 250ml” (Appendix 1). Item Set #2 is the same four items used in the second study (Appendix 3). To conduct the survey a one-page paper questionnaire, color-coded by cell, was handed out for subjects to complete. A picture of each item was projected on a screen all at one time. Half the students in the room received the two-question survey and the other half received the three-question survey.

For each item, the amount subjects were Willing to Pay (WTP) was examined in two different ways: by quartile grouping and by looking at the correlation between the SS$ and the WTP. If arbitrary coherence holds, the WTP should increase with increasing SS$.

Group 1 – Item Set 1 and 3Qs plus Comparison to AC1

Group 1 shows a clear arbitrary coherence effect. The pattern parallels the original AC1 study. The Irish Spring 12-pack of bar soap shows stronger tendency to arbitrary coherence than it did in the first study, but the correlation is still not statistically significant. Teleflora, which had the strongest correlation with the older researchers is somewhat weaker with these younger students.

Table 6. Group 1 - Item Set 1 with Purchase Decision Question plus Comparison to AC2

	Last 2 Digits Social Security Number as $					
	Under $25	$26 - $59	$60 - $80	$80+	AC3-3Qs Correl.	AC1-3Qs Correl.
Teleflora	$15.83	$25.50	$22.00	$25.00	+.28	+.33*
Dr. Scholl's Loafers	$39.83	$43.83	$67.00	$56.80	+.36**	+.28*
Maple Syrup-250ml	$5.17	$5.50	$10.00	$23.60	+.39**	
Irish Spring 12 pack	$8.00	$10.00	$11.80	$10.80	+.24	-.05
Bailey's Irish Cream						+.16

* = the correlation is statistically significantly different than zero, $p \leq 0.05$.
** = the correlation is statistically significantly different than zero, $p \leq 0.10$.

One question this research addressed was whether results would be replicated with new subjects. They were. The respondents in the AC1 study were experienced marketing researchers, which may explain why the results with the more naïve students are overall stronger. The researchers not only were older, but also had more experience with questionnaire studies like this, which may have made them slightly less susceptible to the AC effect.

Group 2 - Item Set 1 with No Purchase Decision Question (No Prior Study for Comparison)

While there was a clear effect with all four products when questioning with the three questions on Item Set 1 (Table 6), the arbitrary coherence effect vanishes in all but one item when the Purchase Decision Question is removed (Table 7). Teleflora has a statistically significant correlation while the effect is almost nonexistent for the other three items.

Table 7. Group 2, Item Set 1 with No Purchase Decision Question
(no comparable prior study)

	Last 2 Digits Social Security Number as $ (SS$)				
	Under $18	$19 to $41	$42 to $79	$80 to $99	Correlation
Teleflora	$6.67	$23.00	$8.60	$26.40	+.41*
Dr. Scholl's loafers	$31.67	$45.00	$39.40	$40.80	+.07

Maple Syrup-250ml	$6.67	$9.20	$3.80	$7.00	+.02
Irish Spring 12-pack	$5.83	$9.00	$5.60	$6.20	-.04

* = the correlation is statistically significantly different than zero, $p \leq 0.05$.

Group 3 – Item Set 2 with 3Qs plus Comparison to AC2

The student survey results for the second set of products and three questions are similar to the AC2 results; there was no arbitrary coherence effect. All the correlations are weak and three of four are negative. There is little consistency in WTP across the quartiles.

Table 8. Group 3, Item Set 2 with Purchase Decision Question plus Comparison to AC2

	Last 2 Digits Social Security Number as $					
Products	Under $23	$23 to $40	$41 to 70	$71 to $99	AC3-3Qs Correl.	AC2-3Qs Correl.
Crocodile Wallet	$48.00	$20.83	$19.50	$50.00	+0.13	-0.24
Copper Bowl	$60.60	$25.83	$24.17	$34.00	-0.14	+0.10
Necklace from Tahiti	$80.00	$249.17	$53.67	$86.00	-0.12	+0.12
Complete L. Carroll	$18.20	$126.67	$27.50	$46.00	-0.04	-0.03

Group 4 – Item Set 2 and 2Qs plus Comparison to AC1

Given that there was no effect with these items when a SS$ purchase decision is required, it is not surprising that there is none when there is no purchase decision. With correlations hovering near zero, the pattern is consistent with that found with Group 2, Item Set 1 with No Purchase Decision.

Table 9. Group 4, Item Set 2 with No Purchase Decision Question plus Comparison to AC2

	Last 2 Digits Social Security Number as $					
Products	$00-$25	$26-$60	$61-$70	$71-$99	Correl.	AC2-2Qs Correl.
Crocodile Wallet	$40.00	$26.00	$50.00	$33.00	+0.05	+0.08
Copper Bowl	$27.00	$20.00	$16.25	$24.00	-0.05	-0.05
Necklace from Tahiti	$128.00	$71.00	$128.75	$153.00	+0.04	+0.04
Complete L. Carroll	$22.00	$15.00	$22.50	$51.00	+0.17	-0.18

Observations and Summary of Results for AC3

In the Purchase Decision groups, an indicator of the willingness to buy is how many said “yes” to the second question, “In column B, indicate if you would be willing to pay that amount for the item.” How do the proportions saying “yes” compare between this study and the earlier studies?

In Item Set 1, the overall interest in either Bailey’s Irish Crème or Maple Syrup is low, as is interest in the Irish Spring soap. The interest among the AC3 students in Teleflora is not much higher than for the Irish Spring. About the only consistency is that the Dr. Scholl's loafers received more interest among the students than the researchers, and the correlation with SS$ is stronger with students than with researchers.

Table 10. Item Set 1 - Percent Who Would Buy Product for SS$

Items	AC2 researchers	AC3 students
Bases	69	22
Teleflora	43.5%	18.2%
Dr. Scholl	49.3%	63.6%
Bailey's/Maple Syrup	18.8%	9.1%
Irish Spring	4.3%	13.6%

Interestingly, the percentages who would buy for the SS$ prices are very similar for Item Set 2 (Table 11). In neither study with Item Set 2 was there an arbitrary coherence effect.

Table 11. Item Set 2 - Percent Who Would Buy Product for SS$

Items	AC2 researchers	AC3 students
Bases	42	22
Wallet	21.4%	22.7%
Bowl	38.1%	45.5%
Pearl Necklace	85.7%	86.4%
Carroll Book	38.1%	31.8%

Overall, there does not appear to be a strong relationship between interest and the presence of arbitrary coherence.

Research Questions Answered:

1. Is the Arbitrary Coherence effect present when each set of items is tested with naïve subjects?

    No. It is present in Item Set 1 in three of the items with the researchers and, to some extent, with all four among the students. But it is not present anywhere with the products in Item Set 2, even though the actual cost of these is likely uncertain and, as nearly as can be assessed, levels of interest are similar.

2. Does making a purchase decision causes a different effect?

    The similarities in the AC2 study and groups 2 and 4 in the AC3 study (where no purchase decision was made) certainly suggest that eliminating the purchase decision eliminates arbitrary coherence.

3. Is there an interaction, such that the making or not making of a purchase decision yields different results for each set of items?

    This seems to be the case. Making a purchase decision is in some way responsible for creating arbitrary coherence in Item Set 1, as the comparison between Group 1 (Item Set 1 with Purchase Decision) and Group 2 (Item Set 1 with No Purchase Decision) demonstrates. But the situation is more complex, since Groups 3 and 4 show the same “no arbitrary coherence” results regardless of the inclusion of the purchase decision question.

One of the original intentions of AC3 was to see if the AC effect existed with Group 3 (Set 2, with purchase decision question), which would imply that the prior failure to replicate was because knowledgeable subjects were used in that research. The AC2 group’s greater experience was obviously not the reason for the lack of effect. It also appears unlikely that lack of interest in Item Set 2 products is responsible. If it is not simply greater variability in interest, what it is about Item Set 2 that obliterates arbitrary coherence?

Study #4 (AC4) – National Sample, Two Items Sets and Two versus Three Questions

This study attempts to identify the underlying factors that explain why arbitrary coherence is found in some of the previously mentioned situations but not in others. Factors tested in this study were, would a national sample, rather than a local convenience sample, make a difference? Also, what would happen if each item was presented alone, not in any set? Could respondents’ perception of the test items help explain when arbitrary coherence is observed? A semantic differential measurement was included in the survey to quantify factors that might identify the casual factors that produce the inconsistency of arbitrary coherence reported in the literature.

This study was conducted with a nationally representative sample of 402 adults with the objective of determining if a national sample provides more consistent evidence of arbitrary coherence than found in the literature. The eight items from the prior studies were used for this study.

The arbitrary coherence part of the questionnaire for this research was like that used in prior research. However, experience had determined that asking consumers in an online panel anything about their Social Security number reduced response rates. To compensate for this, the first question, which established the arbitrary anchor, was changed to write the last two digits of your primary telephone number as if it were a price in dollars. The first four items were in the original Item Set 1 and the last 4 items were in Item Set 2 as shown in Table 12.

Table 12. Base Sizes of the Arbitrary Coherence Test Cells

The Eight Item Cells	Base -- Total per Cell
Teleflora	50
Dr. Scholl’s Loafers	51
Maple Syrup-250ml	51
Irish Spring 12-pack	50
Crocodile Wallet	50
Copper Bowl	50
Necklace from Tahiti	50

Complete Works of L. Carroll	50

The Semantic Differential attributes were added after the arbitrary coherence questions for each item. They were taken from a University of California Davis teaching website (Unknown 2017). The respondent saw the semantic differential scale shown in Figure 1. After examining the connotative meaning of thousands of concepts, Charles Osgood and his associates identified three major dimensions of meaning: *strength, value*, and *activity*. The first two examples below fit the theme of *strength.* The second two represent *value*, and the last two illustrate *activity*.

Discussion of the Arbitrary Coherence Effect

When these eight items are tested individually online with a sample national in scope, arbitrary coherence is greatly lessened. For only two of the eight items is there a clear statistically significant correlation ($p \leq 0.05$) between the last two-digit telephone dollars ($Phone#) and the amount respondents were willing to pay for the item, namely the Teleflora Flowers and the Crocodile Wallet. Note that arbitrary coherence was not seen with the Wallet in the second and third studies. The Pearl Necklace from Tahiti shows a directionally large correlation, but the correlation is weak for four of the other five items: Dr. Scholl’s Loafers, Sandy Flats Maple Syrup, Irish Spring Soap, and the Copper Bowl. It is modest for the Lewis Carroll Book.

For five of the items, the highest $Phone# group has a WTP that is greater than the lowest – Teleflora, Soap, Wallet, Necklace, and Book. For the other three (Scholl’s, Syrup, Bowl) the highest $Phone# subgroups will pay less than the lowest $Phone# would be willing to pay.

Table 13. Arbitrary Coherence: WTP by Quartile, Correlations

	$Phone#				
	$0 to $25	$26 to $50	$51 to $75	$76 to $99	$Phone# WTP Correlation

Teleflora	$11.16	$22.47	$27.75	$39.12	+0.36*
Scholl's	$41.67	$50.33	$44.58	$38.38	-0.01
Syrup	$20.82	$14.86	$11.42	$19.07	-0.11
Soap	$6.33	$9.83	$9.84	$7.69	+0.03
Wallet	$8.00	$26.19	$21.53	$40.00	+0.29*
Bowl	$18.00	$17.21	$27.22	$16.73	-0.01
Necklace	$31.00	$59.09	$56.83	$78.80	+0.26**
Carroll Bk	$9.43	$10.63	$32.67	$16.15	+0.19

* = the correlation is statistically significantly different than zero, $p \leq 0.05$.
** = the correlation is statistically significantly different than zero, $p \leq 0.10$.

A summary of the correlations from the four arbitrary coherence studies is shown below. Up to this point, items were always tested in sets. This study (AC4) is the only study in which the context was the single item. In all, there are 24 instances where arbitrary coherence might manifest; it is clearly evident in four of the 24, and possibly present in a total of seven of 24 instances.

Table 14. Summary of Correlations from Four Arbitrary Coherence Studies

	AC1	AC2	AC3	AC4
Item Set 1				
Teleflora	0.33*	na	0.28	0.36*
Scholl's	0.28*	na	0.36**	-0.01
Bailey's/Syrup	0.16	na	0.39**	-0.11
Soap	0.05	na	0.24	0.03
Item Set 2				
Wallet	na	-0.24	0.13	0.29*
Bowl	na	0.1	-0.14	-0.01
Necklace	na	0.12	-0.12	0.26**
Carroll Bk	na	-0.03	-0.04	0.19

na = Not Available.
* = the correlation is statistically significantly different than zero, $p \leq 0.05$.
** = the correlation is statistically significantly different than zero, $p \leq 0.10$.

Since arbitrary coherence is a sub-category of the well-known anchoring effect, data were examined across all four studies to see if the highest quartile gave a higher WTP than the lowest. This did occur in 19 of 24 instances. Three that did not are in the current study (AC4). One caution is that base sizes per quartile are small. In many of the earlier studies (and in a few instances here, in AC4) they are single-digits.

Even with one of the three items (Scholl's, Syrup, Bowl) that show a negative shift in WTP from the highest to the lowest quartile in AC4, two show evidence of some anchoring effect. With Scholl's, the lowest shift, from Quartile 1: $0-$25 to Quartile 2: $26-$50, shows an anchoring effect, going from $41.67 to $50.33, but the higher levels cancel any coherence effect. There is no anchoring effect at all, even at lowest-to-second lowest quartile for Syrup or the Bowl.

In the third study (AC3), there was directional evidence of arbitrary coherence with two of the eight items. Observationally, there is at least a modest anchoring effect evident in all four Set 1 items. In Set 2, with the Wallet and the Necklace, anchoring is again very modest, but at least possibly present. With the Bowl, there is no anchoring and no arbitrary coherence in AC3.

Only Set 2 items were used in the second study and no arbitrary coherence effect was found anywhere. There does appear to be some anchoring effect; even with the Wallet the WTP goes from $38.22 to $42.50 in going from the Quartile 1 to Quartile 2.

Table 15. Difference in WTP, Quartile 4 (Highest) Minus Quartile 1 (Lowest)

	AC1	AC2	AC3	AC4
Item Set 1				
Teleflora	$18.66*	na	$9.17	$27.96*
Scholl's	$17.40*	na	$16.97**	-$3.29
Bailey's/Syrup	$4.92	na	$18.43**	-$1.75
Soap	$0.58	na	$2.80	$1.36
Item Set 2				
Wallet	na	-$15.53	$2.00	$32.00*
Bowl	na	$60.98	-26.60	-$1.27
Necklace	na	$21.52	$6.00	$47.80**
Carroll Bk	na	$9.82	$27.80	$6.72

na = Not Available.
* = the correlation is statistically significantly different than zero, $p \leq 0.05$.
** = the correlation is statistically significantly different than zero, $p \leq 0.10$.

Semantic Differential Measures

As mentioned, there are three Semantic Differential dimensions: Strong-Weak, Good-Bad, Active-Passive. For this exercise, those adjectives were used plus three other pairs that echoed them; respectively; they are Decisive-Indecisive; Expensive-Cheap; Industrious-Lazy. The eight items were ranked on the mean ratings shown in Table 17. Essentially, the items for which arbitrary coherence appears all tend to be lower in rank on each of these attribute pairs, so they are viewed, relatively, as weak/indecisive, bad/cheap, and passive/lazy. That generalization is not perfect, since the Teleflora flowers are third on Decisive and fourth on Good, while the Wallet is rated Expensive and the Necklace is Active. Perhaps though, being relatively weak/indecisive, bad/cheap, and passive/lazy assists in generating the effect.

Table 16. Ranking of Items on Mean Seven-point Scale Values

Rank	Strong-Weak	Decisive-Indecisive	Good-Bad	Expensive-Cheap	Active-Passive	Industrious-Lazy
1	Soap	Bowl	Soap	Syrup	Soap	Soap
2	Bowl	Soap	Bowl	Bowl	**[Necklace]**	Bowl
3	Dr. Scholl's	**[Teleflora]**	L.Carroll	**[Wallet]**	Dr. Scholl's	Syrup
4	Syrup	Dr. Scholl's	**[Teleflora]**	**[Necklace]**	Bowl	Dr. Scholl's
5	**[Necklace]**	L.Carroll	Dr. Scholl's	Dr. Scholl's	L.Carroll	**[Wallet]**
6	L.Carroll	**[Necklace]**	**[Necklace]**	L.Carroll	Syrup	**[Necklace]**
7	**[Teleflora]**	Syrup	Syrup	**[Teleflora]**	**[Wallet]**	L.Carroll
8	**[Wallet]**	**[Wallet]**	**[Wallet]**	Soap	**[Teleflora]**	**[Teleflora]**

Note: items in bold and bracket indicate the Arbitrary Coherence effect is present

Table 17. Mean Values for Each Item on Seven-Point Scale

	Strong(7) Weak (1)	Decisive(7) Indecisive(1)	Good(7) Bad (1)	Expensive(7) Cheap (1)	Active(7) Passive(1)	Industrious(7) Lazy (1)
Teleflora	4.72	4.98	5.44	4.44	4.24	4.42
Dr. Scholl's	5.20	4.84	5.33	4.61	4.59	4.82
Syrup	5.10	4.67	4.92	5.29	4.53	4.88
Soap	5.72	5.08	5.80	4.22	5.34	5.42
Wallet	4.64	4.44	4.56	4.76	4.26	4.78
Bowl	5.64	5.10	5.54	5.26	4.58	5.34
Necklace	4.92	4.72	5.24	4.66	4.66	4.76
L.Carroll	4.92	4.80	5.52	4.46	4.56	4.60

AC 4 Research Questions Answered:

Is the arbitrary coherence phenomenon is found in a national sample of adults questioned about each of the eight items used in prior research?

> The best answer is “no.” Arbitrary coherence is clearly present in only two of eight items, weakly in a third. But over the quartiles, the average price willing to pay appears to randomly shift for all but the Teleflora, which rises consistently.

What happens if the eight items in the Sets are broken up and each article is tested individually?

> Apparently, the context of the sets matters in some nonspecific way. The reasonably strong effects seen with Set 1 items in prior research were lessened when the items were shown alone, and two of the items in Set 2, Necklace and the Wallet, were strengthened. Arbitrary coherence was not seen in Set 2 in two prior studies.

Does a semantic differential measurement of how each item is perceived shed light on the differences between items for which arbitrary coherence reliably appears and those for which it does not?

> The items for which arbitrary coherence appears generally tend to be lower in rank on each of these attributes, so they are viewed, relatively, as weak/indecisive, bad/cheap, and passive/lazy. The only item for which arbitrary coherence reliably appears is Teleflora, though not statistically significant in AC3, likely due to small base sizes. It is “middling” on the Semantic Differential and relatively weak, cheap, passive, and lazy. Other items were as well, so no conclusion about items for which arbitrary coherence reliably appears are possible.

Study #5 (AC5) – Arbitrary Coherence versus Monadic Testing

In addition to measuring the arbitrary coherence effect on an item from the original Ariely study, the objective of this final study was to examine the extent a price-demand curve based on AC results parallels one derived from more tradition monadic testing. Marketing researchers sometimes use monadic testing to determine price sensitivity and create a demand curve. If AC creates a similar demand curve, it might be a useful tool to more efficiently (i.e., fewer subjects, less expensive) create that curve.

This study is comprised of two groups which are compared to address the objectives. Group 1 completes a standard three question AC task, followed by a monadic purchase intent (PI) question including price, with the group split by four price points. Group 2 is the reverse, specifically the purchase intent question is first followed by the standard 3 question arbitrary coherence task. For this study, an item was needed with an ambiguous price and could easily be used by anyone, men or by women, young or old, etc. The Belgian chocolates used in the original Ariely article was selected.

The sample consists of 401 subjects (not the same sample as AC4) from across the United States. All were prescreened as having enjoyed chocolate in some form “recently.” Statistical testing shows that the two groups do not differ in terms of age, sex, race, education, or geographic distributions ($p > .05$). The highest percentages are older, between 50 and 69. Most, about seven in 10, are female. The majority, more than eight in 10, are White. Overall, 5% indicated they were Hispanic. The highest percent, just over a third, had some college, with about a fourth having a college degree. The respondents were fairly evenly split between Northeast, Midwest, South and West.

A Word version of the complete online questionnaire can be found in Appendix 5 and 6. After determining demographics, a question about whether or not the subject has enjoyed chocolate recently was asked in a blinded fashion to make certain only those who possibly would be interested in the Belgian Chocolates were questioned.

In Group 1, two hundred (200) were asked about a box of 24 Fine Belgian Chocolates, using the three arbitrary coherence questions with the last two digits of the telephone number used to determine the arbitrary anchor. Then, each respondent was randomly assigned to one of four price subgroups ($12.50, $37.50, $62.50, $87.50) and asked purchase intent (PI) for the same item. Price points were selected by taking the midpoints of the quartiles between zero and 100, after ensuring that some Fine Belgian Chocolates actually do sell for those amounts.

In Group 2, two hundred one (201) were randomly assigned to the four price points first. Each saw the same picture and description of the Belgian Chocolates used for Group 1, but were asked purchase intent (PI) using the traditional scale (Definitely Would Buy, Probably Would Buy, Might or Might Not Buy, Probably Would Not Buy, Definitely Would Not Buy). They were then asked the same arbitrary coherence questions as asked in Group 1.

Summary of Arbitrary Coherence Results for AC5

Given that the arbitrary coherence effect is often not found, it seemed reasonable to first learn if it could be found in either of these groups.

The effect was found in both groups. In Group 1 (AC task first) the correlation between the arbitrary number derived from the telephone number and the Willingness to Pay (WTP) amount is 0.31 (statistically significantly above zero) versus Ariely's .491. There is only one WTP reversal as one goes up the arbitrary telephone dollar quintiles, and that is at the highest level.

Table 27. Groups 1 Belgian Chocolates, Results When AC Task is First

	$Phone# for AC5 and $SSN for Ariely					
Products	Quintile 1	Quintile 2	Quintile 3	Quintile 4	Quintile 5	Correlation
AC5 Belgian Chocolates Average WTP (n=200)	$12.82	$18.15	$21.41	$30.08	$28.03	.310 $p<.05$
Ariely Belgian Chocolates Average WTP (n=55)	$9.55	$10.64	$12.45	$13.27	$20.64	.419 $p=.0013$

Similarly, the effect is found in Group 2, when the AC questions are asked after presenting one of the four prices and asking purchase intent. The effect is lessened, however, with a correlation of .20 and two reversals at the high end of the arbitrary price quintiles.

Table 28. Groups 2 Belgian Chocolates, Results When AC Task is Second

	Last Two Digits or Telephone Number Corresponding to the Monadic Prices					
	0 to $12	$13 to $37	$38 to $62	$63 to $87	$88+	Correl.
Average WTP	$14.13	$21.92	$33.92	$29.64	$29.44	0.20*

* = the correlation was statistically significantly different than zero, $p \leq 0.05$.

It appears that the lower stated prices in the purchase intent question had little effect on the lower quintiles, but restricted reactions to the higher quintiles. Seeing $87.50 in a purchase intent question and then being asked for a maximum bid may have biased those with arbitrary scores ≥$88.

Summary of Purchase Intent Results

Table 29 shows the results of the purchase intent (PI) questions for each group. An examination of the sum of those who said they definitely or probably would buy, ("top two buy" scores, or T2B scores), shows the order made little difference. In three of the four instances, the T2B scores are statistically the same in Groups 1 and 2. For the highest price, it is directionally different, suggesting completing the AC task first pulled interest down at the highest price.

Table 29. Purchase Intent Question Results by Price Points and Groups

	$12.50		$37.50		$62.50		$87.50	
	Grp 1	Grp 2	Grp 1	Grp 2	Grp 1	Grp 2	Grp 1	Grp 2
Base	*50*	*50*	*50*	*50*	*50*	*51*	*50*	*50*
Definitely buy	26%	22%	8%	18%	8%	6%	2%	14%
Probably buy	30%	20%	14%	16%	6%	12%	4%	4%
Might or might not	16%	32%	16%	22%	18%	20%	6%	20%
Probably not buy	10%	14%	32%	24%	16%	18%	20%	14%
Definitely not buy	18%	2%	30%	20%	52%	45%	68%	48%
Total	100%	100%	100%	100%	100%	100%	100%	100%
Definitely+Probably	56%	52%	22%	34%	14%	18%	6%	18%

One of the objectives of this final study was to examine the extent a demand curve based on AC results parallels one derived from more tradition monadic testing. Based on the results shown in Figures 2 and 3, it looks quite promising that an AC task can be employed to create a price-demand curve. Figure 2 is a graph of the percentages of respondents willing to pay the price range listed on the x-axis. In Figure 3, the same curve is shown, but with only the four price points (plus ≥$88) presented to Group 2 respondents. The curves are quite similar. It appears that if a product being tested is susceptible to arbitrary coherence, then the results would be reliable for creating a price demand curve.

The regression lines can be interpreted in the following manner. In Figure 2, for each $1 increase in price, the percentage of those willing to buy at that price drops by .284 times the log of the price. The regression is only valid over the data range of $0.00 to $99.00 (technically cannot be extrapolated beyond that range). In Figure 3, for each $1 increase in price, the percentage of those willing to buy at that price drops by .175 times the log of the price. From visual inspection of both graphs, the AC test shown in Figure 2 appears to provide a more reliable price-demand curve than the monadic price test shown in Figure 3.

Summary of AC5 Results

Under the carefully specified conditions created for this study the AC phenomenon is clearly present. Also, of interest is that whether the AC task was first or second had little effect on the results of the PI task, which were very similar regardless. The exception was at the highest price level asked in PI ($87.50), in which the AC task depressed the percent willing to buy. This may have been an anchoring effect, since most of the arbitrary numbers were lower than that price point.

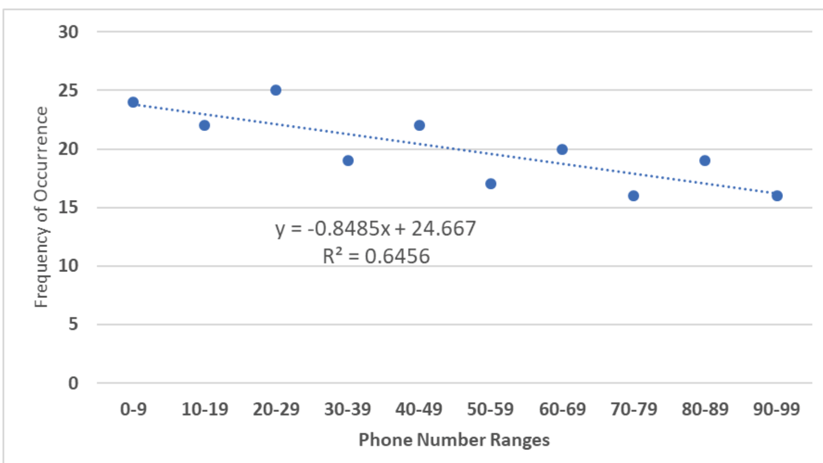
In the reverse order, half saw PI prices first that were lower than $63, so there appears to be an anchoring effect that way as well. The AC correlation was lessened, with the middle price point higher than when the AC task was first and those getting the AC task second indicating lower prices in the higher arbitrary number quintiles.

Observation on a Random Number Distribution

The original work by Ariely used the last two digits of the social security number as the random number which seems quite reasonable. With the more recent privacy concerns around social security numbers, it seemed reasonable to use the last two digits of a person's telephone number as the random number for testing purposes. While creating the tables for AC5 it was observed that the random numbers were not quite so randomly distributed. As shown in Figure 4, as the decile range increased the frequency of occurrence decreased.

This phenomenon does not adversely affect the results of AC4 or AC5 since any random number is sufficient for the study of arbitrary coherence. However, if this phenomenon is not an aberration, then research requiring a uniform distribution of random numbers using a telephone number may need to sample in such a way as to obtain a more uniform distribution of respondents.

Figure 4. Random Number Distribution from AC5 Study



It would be interesting to determine if the last two digits of one's telephone number is not as random as one would expect or if respondents are also reluctant to give their actual numbers. If respondents are making up a number, it seems remarkable that the distribution is so linearly predicable. It is unlikely however, that any more than a small percentage of people willing to cooperate in an interview of this nature would deliberately mislead. Even more amazing is that numbers beginning with 2, 4, 6 and 8 consistently deviate positively from the regression line and numbers beginning with 1, 3, 5 and 7 consistently deviate negatively from the regression line.

CONCLUSIONS

There are two aspects of arbitrary coherence. The first is that the anchor, which everyone knows is arbitrary, influences the judgment of subjects in the selection of a starting point when asked about pricing in an ambiguous situation. As noted, in our three-question work, we found (along with Wilson) that some processing of the arbitrary number must occur to see the influence. Hence, no effect when “question two,” the purchase decision, is not asked.

There are two hypotheses for why the arbitrary number has this effect. One is the “reach back” hypothesis proposed by Kahnemann. Subjects need something to think of when asked the third question (the auction question) and so they reach back for a handy recent number. The other is the “imprinting” hypothesis of Ariely et. al., similar to the “carry forward” alternative Wilson discusses. The idea is simply that since the arbitrary number is still in mind, it has an influence.

The second aspect of arbitrary coherence is sequentiality, or coherence. The first WTP influences all subsequent ones. However, the three-question demonstration does not show sequential or coherent impact. In it, each subject is exposed to a single arbitrary number and creates a single judgment. If the anchoring effect is not present, then there is no “coherence” using this method. Ariely et. al. did find evidence for sequential impact in the other five “annoying sound” experiments they conducted, since in those the subjects experienced repeated exposures to sounds of varying durations. However, the “arbitrary coherence” shown in their Experiment 1 and (where it appears) in our work only demonstrates an anchoring effect. Coherence (when it is found) is an artifact produced by anchoring across a group of subjects.

While the “coherence” in arbitrary coherence is weak or nonexistent for some items tested, the “arbitrary” reaction, i.e., anchoring, is present. As noted previously, data were examined across the first four studies to see if the highest quartile gave a higher WTP than the lowest. This did occur in 19 of 24 instances. The fact that 19 of 24 instances show an impact of the arbitrary value in raising WTP, most by more than five dollars, suggest the anchor influenced the respondent’s willing to pay price.

The Semantic Differential results are challenging to interpret. While being the strongest, best, and most active is not conducive to arbitrary coherence or consistency in anchoring, the conclusion is based on relative ranks within these eight items, and suffers that limitation. Finally, despite its limitations, it appears from AC5 that the three arbitrary coherence questions can be quite useful in exploring the price-demand relationship, one that is often challenging in the development of new products.

ABSTRACT

In this paper, we tackle in the newsvendor context a problem of optimal product allocation and pricing under uncertain demand in a prioritized multi-segment market for a monopolistic retailer. A mathematical programming model is developed and then solved via dynamic programming to find the optimal allocation scheme and determine the prices correspondingly. A numerical experiment is designed and performed to solve the model via the dynamic programming approach and examine the effects of the key model parameters upon the retailer's optimal expected total profit and allocation schemes.

KEYWORDS: Product allocation, Pricing, Prioritized segmentation, Optimization, Dynamic programming

INTRODUCTION

The classical news-vendor problem aims at finding a product's order quantity that maximizes the expected profit in a single-period probabilistic demand framework. Khouja (1999) classifies two approaches to solve this problem. The first approach intends to minimize the expected costs of overestimating and underestimating demand. The second approach is to maximize the expected profit. A general extension of this classical newsvendor problem in conjunction with the second approach in a retail setting is how to allocate a fixed quantity of a product for sale and set the price in a multi-segment market to maximize the expected profit. We focus on a profit-maximizing monopolistic retailer facing uncertain demand at the aggregate level. In this paper, we address three research questions stated as follows: (i) What is the optimal scheme for a monopolistic retailer to allocate and price K identical units of a product in a prioritized n-segment market under uniformly distributed uncertain demand during a single selling season so that her expected total profit is maximized? (ii) What is the sensitivity of the optimal expected profit to simultaneous variations in the key parameters of the mathematical programming model? (iii) What is the relative importance of each of these parameters upon the optimal allocation scheme?

We make the following basic assumptions while addressing the three strategic issues mentioned above:

(i) The price charged by the retailer in each segment is the only independent variable that affects the aggregate demand in that segment.
(ii) Consumers in each segment are well-informed of the price charged in that segment, which is set at the beginning of a selling season.
(iii) The demand in each segment is heterogeneous and independently follows a uniform probability distribution conditioned by the price charged in that segment.
(iv) The allocation decisions are made following a predetermined prioritized sequence.

Priority service, a form of product differentiation, is widely used in practice. Priority-based capacity allocation allows the market to be segmented into a spectrum of priority classes. For example, those customers willing to pay higher prices are assigned higher priority in receiving the product or service (Chao & Wilson, 1987). We analyze a model of *n* prioritized customer segments, in which higher priority segments are served before any lower priority segment. If capacity is exhausted by higher priority segments, the lower priority segment goes unfilled. We are not deriving optimal prioritization; rather we assume that priorities are set. Factors to consider in setting priorities may include willingness to pay higher prices, expected volume of business and expected customer satisfaction, among others.

The addressed problem is envisioned to belong to the class of “inverse newsvendor problems.” The classical newsvendor problem is one of optimally choosing a level of capacity to respond to a known demand distribution. The inverse newsvendor problem is one of optimally choosing a demand distribution with fixed capacity. In many firms, capacity is relatively more difficult to adjust than demand because of the time required to install new capacity (Carr & Lovejoy, 2000).

This paper is organized as follows. In the next section, we review the relevant literature and position our study afterwards within the reviewed literature to highlight its contributions. In the third section, a mathematical programming model is developed. The fourth section presents a dynamic programming (DP) formulation developed to solve the mathematical programming model. A numerical study is conducted for the model in the fifth section. Finally, the paper concludes in the six section with a summary of its contributions, managerial implications, and directions for future research.

LITERATURE REVIEW

The newsvendor problem of setting quantity to maximize expected profit has been extensively addressed for several decades. Khouja (1995) and Qin et al. (2011) provide lucid reviews of the newsvendor literature. In a classical newsvendor environment, a retailer has little control over the exogenously determined selling price. In practice, however, a retailer may adjust the current selling price in order to shift demand (Qin et al., 2011). There is a substantial body of newsvendor literature exploring the impacts of the price-dependent demand on the seller’s pricing and ordering decisions (e.g., Whitin, 1955; Mills, 1959; Karlin & Carr, 1962; Lau & Lau, 1988; Chen et al., 2004; Arcelus et al., 2005; Wang et al., 2017; Berenguer et al., 2017).

Wang et al. (2014) argue that the newsvendor literature has focused on the quantity decision, whereas the revenue management literature has focused on the pricing decision. In the newsvendor literature, three notable studies are more relevant to our current study. Ng and Lee

(2008), applying a game theoretic approach, analyze the optimal capacity allocation in a duopolistic two-segment market where demand is deterministic. A closed-form solution is obtained in their study. Carr and Lovejoy (2000) study an inverse newsvendor problem where demand distributions are chosen from an opportunity set, which represents the set of market opportunities for the firm. The firm's profit is formulated as a function of those demand distributions. The objective is to maximize the firm's profit by finding the optimal demand distribution from the opportunity set. The results of the solution are extended to cases of multiple prioritized market segments sharing the firm's capacity, where the priorities are taken as given. In the work of Deng et al. (2008), demand in each segment of the market is assumed to independently follow a Poisson distribution. A marginal-revenue-based capacity management model is formulated in their study to manage stochastic demand in a three-segment market and develop the policies for the firm to allocate capacity to those segments of higher revenue.

In the revenue management literature, two recent studies are related to our current paper. Zhang (2012) investigates a multiple-segment price discrimination problem with different segments' demand elasticity and supply constraints, where all segments are subject to the limited common capacity. In addition, each segment is subject to a limited segment-specific capacity, while the firm incurs segment-specific production and selling costs in each segment. In his model, the demand function of each segment is deterministic. The objective is to maximize the firm's profit by finding the optimal price for each segment. Zeng (2013) proposes multiple pricing strategies for a retailer who operates in a two-segment market composed of experienced and inexperienced consumers.

In recent years, there is a growing research stream that focuses on both quantity and price decisions. Three papers of this research stream are noteworthy. Gallego et al. (2011) address the problem of capacity allocation and pricing in a two-segment market where an entrant sells at a lower price to compete against an established incumbent. Their model is designed to study the competitive interactions between the two rivals for different assumptions about market structure, demand and available capacity. Wang et al. (2014) tackle a price-setting problem with partial information. Their study focused on robust capacity and pricing decisions for an innovative product with limited consumer valuation and market size information. The objective is to minimize the maximum loss in expected profit due to incomplete information on the probability distribution of demand. Closed-form expressions are derived for the optimal quantity and price. Duan et al. (2016) present a model as a three-stage dynamic game for the allocation of a limited spectrum capacity and the pricing decision in a wireless market with two segments for femtocell and macro-cell services.

Our present study possesses the following five characteristics that make it distinct from the articles cited above: First, a general n-segment market in a prioritized setting is taken into account in our modeling framework. Second, the uncertain demand in each segment is modeled as a continuous random variable following a uniform probability distribution. Third, a mathematical programming model is formulated and then solved via dynamic programing (DP) to find the optimal allocation scheme, which then determines the pricing strategy. Fourth, a numerical experiment is designed and implemented to solve the mathematical programming model with the DP approach. Fifth, we perform a global sensitivity analysis of the mathematical programming model using the approach proposed by Wagner (1995) and subsequently examine the relative importance of each key parameter on the model's optimal output as in Druehl et al. (2009).

MODEL DEVELOPMENT

Let us consider a monopolistic retailer who has K identical units of a product to be allocated in a general n-segment market during a single selling season. The n segments, denoted as segments i (i = 1, 2, …, n), are prioritized to receive their allocations of the product in such a way that the allocation decision pertaining to segment i is made prior to the allocation decision related to segment i + 1. Without loss of generality, we assume that the K units of the product are successively allocated to segments i (i = 1, 2, …, n).

The following notations are used to formulate the retailer's profit and price functions:

K	the quantity of the product available for sale in the n-segment market;
K_i	the quantity of the product available for sale in segment i;
y_i	the quantity of the product to be allocated to segment i (a decision variable);
P_i	the price per unit of the product charged in segment i ($P_i > 0$);
C_i	the cost per unit of the product allocated to segment i ($C_i > 0$);
S_i	the salvage value per unit of the product disposed of after the selling season in segment i ($S_i > 0$);
d_i	the aggregate demand of consumers in segment i;
ω_i	the demand parameter in segment i ($\omega_i > 0$);
$f(x\|\omega_i)$	the probability density function (p.d.f.) of d_i being a continuous random variable;
$E(d_i)$	the expected value of d_i;
π_i	the retailer's profit yielded from segment i;
$E(\pi_i)$	the expected value of π_i;
π	the retailer's total profit yielded from the entire n-segment market;
$E(\pi)$	the expected value of π.

Consumers' price sensitivity may substantially vary across segments, a thorough understanding of the dynamic interaction between price and demand is required to find the optimal allocation scheme and set the price accordingly in each segment of the market. Since consumers in segment i are assumed to be well-informed of the price charged in that segment, they would take the price into consideration while making their purchases. Thus, the uncertain demand of segment i, d_i (i = 1, 2, …, n) can be modeled as a random variable following a probability distribution conditioned by P_i. Following Azoury (1985), we model the aggregate demand, d_i, as a continuous random variable following a uniform probability distribution. The p.d.f. of d_i is given by

$$f(x|\omega_i) = \begin{cases} 1/\omega_i, & if \quad 0 < x < \omega_i, \\ 0, & if \quad x \geq \omega_i, \end{cases} \tag{1}$$

where $\omega_i > 0$. A price-dependent model proposed by Karlin and Carr (1962) is used in this study to define the functional relationship between the demand parameter ω_i and selling price P_i:

$$\omega_i = \alpha_i P_i^{-\beta_i} \tag{2}$$

where, $\alpha_i > 0$ and $\beta_i > 1$ (i = 1, 2, …, n).

In expression (2), the parameter, α_i, reflects the size of segment *i*. A larger value of α_i shows stronger demand in segment *i*. The power parameter β_i measures the responsiveness of the aggregate demand of segment *i* to the price charged in that segment. According to Huang et al. (2013), one of the advantages of this model is that it does not require a finite upper limit on price. The model is also called the constant elasticity model because the demand function exhibits a constant elasticity (i.e., $-\beta_i$) (see Huang et al., 2013).

The expected demand of segment *i*, based on expression (1), is given by

$$E(d_i) = \int_0^{\omega_i} \frac{x}{\omega_i} dx = \frac{\omega_i}{2}\,. \tag{3}$$

Expression (3) reveals that the demand parameter, ω_i, equals twice the expected demand, $E(d_i)$, and thus serves as an indicator of the aggregate demand in segment *i*.

From expressions (2) and (3), the expected demand of segment *i*, can be rewritten as follows:

$$E(d_i) = \frac{1}{2}\alpha_i P_i^{-\beta_i} \tag{4}$$

Cost-plus pricing is the practice of "adding a standard markup to the cost of the product" (see Kotler & Armstrong, 2004, p.357). Zeithaml et al. (1985) report that 63% of the studied firms base their prices primarily on costs. Also, there are studies in the literature that incorporate price markup in their modeling frameworks (e.g., Shah & Jha, 1991; Hanson, 1992). In this paper, the unit price charged in segment *i*, P_i (i = 1, 2, …, n), is set by a markup over the unit cost; that is, $P_i = \theta_i C_i$ where $\theta_i > 1$.

As the risk of larger orders is mainly carried by buyers, sellers are often more than willing to offer quantity discounts when inventory costs are high. Quantity discounts help sellers identify price-insensitive buyers from the price-sensitive ones to practice price discrimination (Qin et al., 2011). While implementing price discrimination, a retailer usually charges a higher price when the quantity of the product available for sale is relatively scarce and a lower price when it is relatively abundant. We may therefore assume that the price markup factor, θ_i, is a decreasing function of K_i :

$$\theta_i = \phi(K_i), \tag{5}$$

where, $d\phi(K_i)/dK_i < 0$. Accordingly, the price charged in segment *i* is a function of K_i :

$$P_i = C_i\phi(K_i) \tag{6}$$

In segment *i* (i = 1, 2, …, n), if the demand (d_i) exceeds the quantity of the product allocated by the retailer (y_i), the profit (π_i) will equal the profit per unit multiplied by the number of units sold. On the other hand, if d_i is smaller than y_i, a portion of the allocated quantity, $y_i - d_i$, will be unsold and disposed of after the selling season at the unit salvage value, S_i. Hence, the retailer's profit yielded from segment *i* (i = 1, 2, …, n) is stated as

$$\pi_i = \begin{cases} P_i d_i - C_i y_i + S_i (y_i - d_i), & d_i \le y_i, \\ (P_i - C_i) y_i, & d_i > y_i. \end{cases} \tag{7}$$

Since d_i is modeled as a continuous random variable, we obtain from expression (7) the expected value of π_i:

$$E(\pi_i) = (P_i - S_i)\int_0^{y_i} x f_i(x|\omega_i)dx - (C_i - S_i) y_i \int_0^{y_i} f_i(x|\omega_i)dx + (P_i - C_i) y_i \int_{y_i}^{\infty} f_i(x|\omega_i)dx. \tag{8}$$

Substituting (1) into (8) and carrying out the integrations, we obtain

$$E(\pi_i) = (P_i - C_i) y_i - \frac{(P_i - S_i)}{2\omega_i} y_i^2, \quad if \quad y_i < \omega_i; \tag{9}$$

$$E(\pi_i) = \frac{(P_i - S_i)}{2}\omega_i - (C_i - S_i) y_i, \quad if \quad y_i \ge \omega_i. \tag{10}$$

The derivations of expressions (9) and (10) are found in the Appendix.

The retailer's expected total profit from the entire *n*-segment market can be expressed as

$$E(\pi) = \sum_{i=1}^{n} E(\pi_i). \tag{11}$$

Given *K* identical units of a product, which is to be allocated by the retailer during a single selling season for sale in the *n*-segment market, we aim at finding the optimal quantity to be allocated to segment *i* (i = 1, 2, …, n), y_i^*, to maximize the expected total profit. The problem may therefore be formulated as the following mathematical programming model:

$$\underset{y_1, y_2, \ldots, y_n}{Max} \sum_{i=1}^{n} E(\pi_i)$$

$$\text{s.t.} \quad \sum_{i=1}^{n} y_i \le K,$$

$$y_i \ge 0 \text{ for } i = 1, 2, \ldots, n. \tag{12}$$

The model (12) can be cast into a dynamic programming (DP) formulation that is solved by applying the principle of decomposition. The DP formulation is presented next.

DYNAMIC PROGRAMMING FORMULATION

There are six key components in the DP formulation: (i) the sequence of decision stages, (ii) the input state variable of each stage, (iii) the decision variable of each stage, (iv) the transition function linking the input and output state variables of each stage, (v) the return at each stage, and (vi) the recursive relationship. These components, shown in Figure 1, are identified and discussed below.

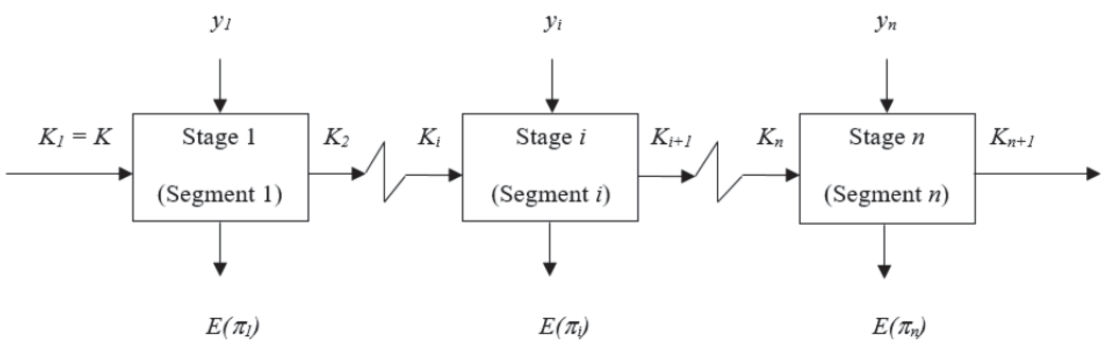

Fig. 1. A dynamic programming representation for the mathematical programming model (12)

Each segment of the market stands for a decision stage to which a certain quantity of the product is allocated. These consecutive stages are indexed corresponding to the indices of the segments defined in the previous section. The mathematical programming model (12) is decomposed into a sequence of smaller and computationally simpler sub-problems, as discussed in the remainder of this section.

The input state variable of stage i is the quantity of the product available for allocation at the beginning of the stage, K_i (i = 1, 2, …, n). As shown in Figure 1, each stage's output state variable K_{i+1}, serves as the input state variable of the next stage. In particular, K_{n+1} is the output state variable of the last stage, which is the quantity of the product unallocated for the purpose of maximizing the expected total profit. The quantity allocated to stage i, y_i (i = 1, 2, …, n), is a decision variable. As a whole, there are n decision variables in the DP formulation for the n-segment market. The transition function defines the linkage between the input and output state variables of a stage and the decision made for the stage, and may be expressed as

$$K_{i+1} = t_i\,(K_i, y_i),$$

where,
$K_1 = K$ is given;
$K_{i+1} = K_i - y_i$, $i = 1, 2, \ldots, n-1$;
$t_i(\cdot)$ stands for 'transition function of.'

Expressions (9) and (10) both show that the expected profit yielded from stage i (i.e., the return at stage i), $E(\pi_i)$, is determined by the decision variable y_i, where $y_i \le K_i$ and the price P_i. It is shown in expression (6) that P_i is a function of K_i. Hence, $E(\pi_i)$ is a function of K_i and y_i and can be expressed as $E(\pi_i\,(K_i, y_i))$.

A backward induction process is employed to formulate the recursive relationship, which links the optimal decision for a stage to the optimal decisions made in previously considered stages. Starting from stage n, the recursive relationship is given by expressions (13) and (14).

For stage n,

$$F_n^*(K_n) = \max_{\forall y_n \le K_n} E(\pi_n(K_n, y_n)). \tag{13}$$

For stage i = 1, 2, …, n-1,

$$F_i^*(K_i) = \underset{\forall y_i \le K_i}{Max}\{E(\pi_i(K_i, y_i)) + F_{i+1}^*(K_{i+1})\}, \tag{14}$$

where $K_{i+1} = K_i - y_i$.

The optimal solution to the DP model formulated above, y_i^* (i = 1, 2, …, n), is a function of the input state variable K_i and hence can be expressed as $y_i^*(K_i)$. The recursive optimization is carried out in backward fashion until the first stage is reached. At stage 1, the maximum total return (i.e., the expected total profit), $F_1^*(K_1)$, and the corresponding optimal quantity to be allocated to stage 1, $y_1^* = y_1^*(K_1)$, are both determined. $y_1^*(K_1)$ is a unique value because $K_1 = K$ is a given constant. Then, it is possible to backtrack from the first stage through the succeeding stages to obtain the optimal quantity to be allocated to each of the other stages in the following manner: At stage 2, we compute the optimal input value $K_2^* = K_1 - y_1^*$ and then determine the optimal quantity to be allocated to stage 2 through the function $y_2^* = y_2^*(K_2^*)$. Afterwards, for stage i (i = 3, 4, …, n), we compute the optimal input state value $K_i^* = K_{i-1}^* - y_{i-1}^*$ and then determine the optimal quantity to be allocated to stage i through the function $y_i^* = y_i^*(K_i^*)$. Using the optimal input state value K_i^*, the optimal price P_i^* (i = 1, 2…, n) is determined through the price function (6).

NUMERICAL EXPERIMENT

In this section, we design and conduct a numerical experiment to (i) find the optimal solution to the mathematical programming model (12) with the DP formulation presented in the fourth section, (ii) perform a global sensitivity analysis of the model, and (iii) examine the effects of eight key parameters on the optimal allocation scheme. In the numerical study, the price markup factor (5) in segment i, θ_i, is specified to take the following functional form:

$$\theta_i = \phi(K_i) = \frac{b_1 + K_i}{b_2 + K_i}, \tag{15}$$

where, $b_1 > b_2 > 0$. It can be easily shown that $d\phi(K_i)/dK_i < 0$ and $d^2\phi(K_i)/dK_i^2 > 0$, implying that $\phi(\cdot)$ is a convex decreasing function of K_i. We set b_1 = 2000, b_2 = 1 and, K = 10000, 15000, 20000, and 25000 units, respectively. Due to the RAM limit of the computer used to run the DP formulation, we consider $C_i = C$ and $S_i = S$ (i = 1, 2, 3) in our numerical study. The results of the numerical study for K = 15000 units are reported in this paper. All the unreported results for K = 10000, 20000, and 25000 units are available from the authors upon request.

Experimental Design and Implementation

Table 1 displays six marketing parameters, α_i and β_i (i = 1, 2, 3) and two operations parameters, C and S, encompassed in our factorial design. Three values (factor levels) are chosen for every single parameter. This factorial structure has a total of 3^8 = 6561 possible combinations (treatments), which makes our numerical experiment extensive and robust. Given K, b_1 and b_2, each treatment leads to a DP optimal solution.

Table 1. Factor levels of eight key parameters

Parameter	Factor levels
α_1	0.8×10^7 , 1.0×10^7, 1.2×10^7
α_2	0.8×10^7 , 1.0×10^7, 1.2×10^7
α_3	0.8×10^7 , 1.0×10^7, 1.2×10^7
β_1	1.8, 2.0, 2.2
β_2	1.8, 2.0, 2.2
β_3	1.8, 2.0, 2.2
C	20, 25, 30
S	0, 5, 10

The factor levels of α_i and β_i are chosen based on their domains defined by Karlin and Carr (1962). The levels of the parameter, C, are chosen to ensure that the cost per unit is smaller than the corresponding selling price. The choice of the factor levels for S reflects the assumption that the salvage value per unit is smaller than the cost per unit.

Profit Optimization

To improve exposition, we confine the decision variables y_i to take on nonnegative integer values. For each of the four levels of K mentioned above, the domain of the decision variable y_i (i = 1, 2, 3) is uniformly discretized as $\{500q \mid q = 0, 1, \ldots, K/500\}$. The mathematical programming model (12) is solved through the DP formulation for every single treatment of the factorial design. A computer program is developed by coding in C++ the recursive relationship characterized by expressions (13) and (14) and the backtracking procedure described in Section 4. Given the factorial design, we obtained 6561 optimal solutions of the model (12) for each of the four values of K along with the values of b_1 and b_2.

Table 2 displays the optimal solution for four treatments, respectively. For instance, given the combination of the parameters' values in Example 1, the retailer should allocate 8500, 5500 and 1000 units to segments1, 2 and 3, respectively. As a result, her expected total profit would be $55306.86, and the unallocated quantity of the product is zero unit. It is noted in Table 2 that the retailer could earn a higher expected total profit by allocating larger quantities of the product to satisfy the stronger demand of those consumers who are less price-sensitive. It is also found that the retailer may keep certain quantities of the product unallocated to maximize her profit if consumers are more price-sensitive.

Table 2. Examples of the DP optimal solutions
(K = 15000 units, C = 25, S = 5, $\alpha_i = 1.0\times10^7$, i = 1, 2, 3)

	β_1	β_2	β_3	y_1^*	y_2^*	y_3^*	$K-\Sigma y_i^*$
Example 1	1.8	1.8	1.8	8500	5500	1000	0
Example 2	1.8	2.0	2.2	5500	2500	1500	5500
Example 3	2.2	2.0	1.8	1500	2500	4000	7000
Example 4	2.2	2.2	2.2	1000	1000	1000	12000
	P_1^*	P_2^*	P_3^*	ω_1^*	ω_2^*	ω_3^*	$E^*(\pi)$
Example 1	28.33	32.69	74.93	24317.4	18798.3	4223.5	55306.86
Example 2	28.33	30.26	32.14	24317.4	10921.0	4836.7	14128.22
Example 3	28.33	28.70	29.54	6382.8	12139.2	22552.2	13502.21
Example 4	28.33	28.57	28.84	6382.8	6266.4	6135.9	5093.48

Parameter Effects Upon Profit

We follow the approach of global sensitivity analysis introduced by Wagner (1995) to investigate the effects of simultaneous variations of the parameters listed in Table 1 upon the retailer's expected total profit. A multiple linear regression is performed after all the 6561 treatments are completed with the eight parameters as independent variables in the regression and the expected total profit as the dependent variable. In order to circumvent potential multicollinearity, all the independent variables are centered around their respective means before the regression is run. The magnitude of the effect of each parameter on the expected total profit is gauged by the absolute value of the parameter's t-statistic generated by the regression. Table 3 summarizes the regression results with the R^2 value = 0.8414. As shown in Table 3, the expected total profit is positively impacted by α_i (i = 1, 2, 3) and S but negatively impacted by β_i (i = 1, 2, 3) and C.

Table 3. Regression results for the expected total profit as the dependent variable (K = 15000 units)

Parameter (Independent variable)	t-statistic
α_1	26.67229367*
α_2	22.09137115*
α_3	17.00855894*
β_1	-81.52676609*
β_2	-71.64766765*
β_3	-64.59967864*
C	-112.2403325*
S	68.72406362*

"*": p-value < 0.001.

Table 4. Regression results with interactions for the expected total profit (K = 15000 units)

Parameter (Independent variable)	t-statistic
α_1	44.195*
α_2	37.201*
α_3	28.641*
β_1	-137.287*
β_2	-120.651*
β_3	-108.782*
C	-189.006*
S	115.727*
$\alpha_1 \times \alpha_2$	0.898
$\alpha_1 \times \alpha_3$	1.513
$\alpha_1 \times \beta_1$	-24.410*
$\alpha_1 \times \beta_2$	-4.867*
$\alpha_1 \times \beta_3$	-8.550*
$\alpha_1 \times C$	-15.401*
$\alpha_1 \times S$	7.235*
$\alpha_2 \times \alpha_3$	1.344
$\alpha_2 \times \beta_1$	-3.697 *
$\alpha_2 \times \beta_2$	-16.049*
$\alpha_2 \times \beta_3$	-7.275*
$\alpha_2 \times C$	-10.575*
$\alpha_2 \times S$	5.399*
$\alpha_3 \times \beta_1$	-4.701*
$\alpha_3 \times \beta_2$	-4.475*
$\alpha_3 \times \beta_3$	-3.945*
$\alpha_3 \times C$	-7.068*
$\alpha_3 \times S$	4.900*
$\beta_1 \times \beta_2$	17.311*
$\beta_1 \times \beta_3$	26.071*
$\beta_1 \times C$	51.699*
$\beta_1 \times S$	-25.998*
$\beta_2 \times \beta_3$	23.837*
$\beta_2 \times C$	37.375*
$\beta_2 \times S$	-20.260*
$\beta_3 \times C$	28.417*
$\beta_3 \times S$	-20.220*
$C \times S$	-50.512*

"*": p-value < 0.001; otherwise, p-value > 0.1.

We also investigate the effects of two-way interactions among the eight parameters mentioned earlier. Table 4 shows that the three interaction terms among the segment-size parameters are insignificant, whereas all the other interaction terms turn out to be significant. Given the absolute values of their t –statistics in Tables 3 and 4, the eight parameters are ranked as $C > \beta_1 > \beta_2 >$

$S > \beta_3 > \alpha_1 > \alpha_2 > \alpha_3$ with respect to the importance of their effects upon the expected total profit. Apparently, the cost per unit exerts a leading influence on the expected total profit. The three price-sensitivity parameters, as a whole, are more influential than those segment-size parameters. The price-sensitivity and segment-size parameters of the segment of a higher priority have larger effects than their counterparts of a lower-priority segment, respectively.

Parameter Effects Upon the Allocation Scheme

Based on the factorial design, each level of a parameter is exclusively associated with 6561/3 = 2187 treatments. Out of the 2187 treatments associated with each level of a parameter, we now focus on the proportion of those treatments where the quantity K is not fully allocated based on the optimal allocation scheme. If a parameter's influence on the outcome of "partial allocation" is insignificant, then we should expect that the proportion of "partial allocation" is roughly equal across its three levels, classified as L (low), M (moderate), and H (high). This hypothesis is statistically tested. As shown in Table 5, the hypothesis of the equality of the three proportions is rejected for each of the eight parameters.

Table 5. Results of the 4084 treatments where $y_1^* + y_2^* + y_3^* < 15000$

Parameter	α_1	α_2	α_3	β_1	β_2	β_3	C	S
Frequency observed at the low level	1460	1449	1515	1014	1045	949	581	1614
Frequency observed at the medium level	1357	1360	1337	1408	1397	1270	1481	1359
Frequency observed at the high level	1267	1275	1232	1662	1642	1865	2022	1111
χ^2 – value †	36.3	29.5	79.6	414.9	350.5	840.6	2061.9	246.2

† For each parameter, the proportion of $y_1^* + y_2^* + y_3^* < 15000$ is significantly different across its three levels at p-value < 0.001.

For every single parameter, the Marascuilo procedure (Anderson et al., 2016) is used to make pairwise comparisons of the three proportions. Table 6 indicates that the proportions in each pair are significantly different from each other. This finding implies that each parameter plays a significant part in the outcome of "partial allocation." Furthermore, Tables 5 and 6 reveal that given K = 15000 units, the optimal partial allocation of the product by the retailer is more likely to occur at the lower levels of α_i (i = 1, 2, 3) and S and the higher levels of β_i (i = 1, 2, 3) and C.

The general results were found consistent with respect to the remaining three values of *K* not reported herein.

Table 6. Results of the Marascuilo procedure: The absolute differences in proportion pairs and the corresponding critical ranges (i.e., the numbers in parentheses)

Parameter	(L, M)	(L, H)	(M, H)

"**": p-value < 0.001; "*": 0.001 < p-value < 0.05.

SUMMARY AND CONCLUSIONS

In this paper, we tackle a general newsvendor problem of optimal product allocation and pricing for a profit-maximizing monopolistic retailer in a prioritized multi-segment market. A price-dependent demand model proposed by Karlin and Carr (1962) is employed to describe the functional relationship between the selling price and the aggregate consumer demand. A mathematical programming model is formulated and then numerically solved via dynamic programming for an exogenously given quantity of the product available for allocation over a three-segment market to determine the optimal allocation scheme and the corresponding pricing strategy for all the 6561 treatments of a factorial design.

The presented model is not only a valuable decision tool for making pricing and allocation decisions but also provides valuable insights on the roles of the six marketing parameters and two operations parameters. The effects of these parameters on the retailer's expected total profit and optimal allocation scheme are statistically investigated. The findings of the numerical study offer practical managerial implication for a retailer. Given a certain quantity of the product to be allocated to a multi-segment product, the optimal allocation scheme should be tilted towards those segments exhibiting low price-sensitivity. Reducing the cost per unit is the most important task to carry out due to its significant impact on profit. While enhancing the values of the marketing parameters of the same type to improve profitability, the retailer should focus her efforts on those segments of higher priorities. The price-sensitivity parameters as a whole deserve more enhancing efforts than the segment-size parameters. In addition, a partial-allocation scheme may maximize the retailer's profit.

This exploratory study suggests some possibilities for future research. First, we have addressed a problem of optimal product allocation and pricing for a monopolistic retailer in the newsvendor context. An interesting research direction would be to solve the problem in a competitive environment. Second, although the findings reported in this paper are appealing, their generalizability should be considered with care. Third, the mathematical programming model developed in this study is based on the uniformly distributed uncertain demand. Consumer demand following other probability distributions may be incorporated in the modeling framework in future research. Fourth, we employ a price-dependent demand model in this research. In future extensions, different demand models such as the price and lead time-dependent models could be considered for the profit-optimization framework.

APPENDIX

Derivation of Expression (9)

Given $y_i < \omega_i$, substituting (1) into (8) and carrying out the three integrations yield:

$$\begin{aligned} E(\pi_i) &= (P_i - S_i)\int_0^{y_i} \frac{x}{\omega_i}\,dx - (C_i - S_i)y_i\int_0^{y_i}\frac{1}{\omega_i}\,dx + (P_i - C_i)y_i\int_{y_i}^{\omega_i}\frac{1}{\omega_i}\,dx \\ &= \frac{(P_i - S_i)}{2\omega_i}y_i^2 - \frac{(C_i - S_i)}{\omega_i}y_i^2 + (P_i - C_i)y_i - \frac{(P_i - C_i)}{\omega_i}y_i^2 \\ &= (P_i - C_i)y_i - \frac{(P_i - S_i)}{2\omega_i}y_i^2. \end{aligned} \tag{A.1}$$

Derivation of expression (10)

Given $y_i \geq \omega_i$, substituting (1) into (8) and carrying out the three integrations yield:

$$E(\pi_i) = (P_i - S_i)\int_0^{\omega_i}\frac{x}{\omega_i}\,dx - (C_i - S_i)y_i\int_0^{\omega_i}\frac{1}{\omega_i}\,dx = \frac{(P_i - S_i)}{2}\omega_i - (C_i - S_i)y_i. \tag{A.2}$$

Engaging Millennials in Gig Economy: An Exploratory Study Using Direct Selling Association's National Survey on Independent Sales Representatives

Yulong Li
Simmons University
Email: yulong.li@simmons.edu

Ying Liao
East Carolina University
Email: liaoy17@ecu.edu

ABSTRACT

Based on data from DSA's 2018 National Salesforce survey, this study revealed a three sub-dimensional structure of the construct of engagement, different from findings in previous research. Additional cluster and discriminant analyses investigated factors related to gig workers' perceived work experience and their likelihood to stay with the same company.

KEYWORDS: Workforce engagement, Gig economy, Direct selling, Factor analysis, Discriminant analysis

INTRODUCTION

As organizations respond to the forces of globalization and technology innovation, they see the rise of "gig economy" and the career preference change of the Millennials, the generation that is "notoriously" known for their zest for entrepreneurship and more frequent job-hopping than any other generations before (Deal and Levenson, 2016). According to a recent employer survey by Ernst & Young, the global workforce has been transformed dramatically: one in two organizations in the U.S. indicated an increase in the use of contingent workforce in the last five years (EY Global, 2018). Intuit further predicted that 40 percent of American workers would be independent contractors by 2020 (Intuit, 2018).

The gig economy is defined as "a collection of markets that match providers to consumers on a gig (or job) basis, where gig workers enter into formal agreements with on-demand companies to provide service to the companies' clients" (Donovan, Bradley and Shimabukuru, 2016). For organizations, maintaining a highly flexible workforce gives them the agility to scale and descale resources rapidly depending on dynamic market demands. For contingent workers, also known as consultants, freelancers, independent contractors, independent professionals, or temps in various occasions, the gig economy offers them freedom, instant gratification, bridge employment opportunities and work-life balance that many Millennials rank highly on their career aspiration list (PWC, 2017). For researchers on the other hand, such drastic paradigm shift in employment context and structure challenges many fundamental beliefs and principles of workforce planning and management, thus calls for a re-examination of the applicability of many traditional theories and frameworks on employee management among Millennial in the new economy. Among them, employee engagement, a concept regularly used to attribute job performance to employee morale, motivation, and behavior, deserves exceptional research attention. This is because of three reasons: firstly, employee engagement has been documented in numerous previous studies in the literature as one of the most important enablers for potentially high organizational performances. Secondly, the alternative job arrangements and the temporary nature of contingent work significantly alter workers' sense of job security, work scheduling, and compensation structure. The bonds that customarily ties workers to the organization and to his or her bosses, colleagues and sometimes clients are thus believed to become much weaker than in a typical full-time employment environment, in which traditional employee engagement theories were developed (Donovan, Bradley and Shimabukuru, 2016). Organizations, those utilize a large number of contingent employees in particular, must develop new understandings on the challenges and possible strategies of engaging the new labor force population of Millennials in the new business landscape of the gig economy. Thirdly, the sheer size of the Millennial population, which will account for up to 75 percent of the entire labor force in the U.S by 2025 (Fry, 2018) and the impact and nationwide reach of gig work have even attracted attention from members of the U.S. Congress (Donovan, Bradley and Shimabukuru, 2016). All these three reasons combined make this current study interesting to explore, relevant to business practices, and impactful from a national policy perspective.

In the rest of this paper, we will first start with a literature review on employee engagement as a construct in section 2. In the next section on research methodology, we will conduct exploratory factor analysis using the data from the 2018 Direct Selling Association's National Salesforce Study Questionnaire to examine the conceptual dimensions of engagement among freelance contractors (referred as direct selling independent sales representatives or ISR in the direct selling industry). After that, we will conduct K-means cluster analysis and a series of discriminant analyses to evaluate various factors that are believed to have impact on ISR's work experiences and their intention to continue with their current sponsoring direct selling companies. The last section (#4) will discuss the implications of our findings and draw conclusions for this study.

LITERATURE REVIEW ON EMPLOYEE ENGAGEMENT

Built upon job characteristics theory (Hackman and Oldham, 1980) and growth theory (Alderfer, 1972), scholars in academic circles conceptually define *Employee Engagement* as the "harnessing of the organizational members' selves in their work roles that enables them to devote discretionary effort in achieving organizational intent*" (*Kahn, 1990, p 694). Engagement is a motivational state that employees develop a sense of meaningfulness (i.e. feeling work is valuable and worth doing), availability (i.e. having the physical and mental energy for work), and psychological safety (i.e. having the freedom of being oneself at work). Despite its preciseness and ability to delineate engagement from other similar but distinctive constructs (e.g. employee participation and empowerment), the academic definition lacks the level of clarity for measurement and practical application (Podskoff, Mackenzie, and Podskoff, 2016). Most researchers typically chose to define engagement by the characteristics or outcomes of engaged employees. For example, Sugirtha and Snehe (2017) argue that engagement makes employees feel cognitively and emotionally connected to their jobs, managers, co-workers and organization's vision, mission and objectives. Mathews (2010) describes engaged employees as those who "take pride in their organization and work; take ownership of projects; talk positively about themselves, their employer and the goods and services they help deliver; and view working for their organization as a career, not just a job" (p29).

Regardless of which way it is defined, engagement is universally perceived as a key enabler for potentially high-performing organizations, because engaged employees are more likely to go extra miles in their assignments, contribute vigorously and thus achieve greater productivity, higher customer satisfaction, and increase profitability of their employer. Numerous studies have demonstrated strong relationships between engagement and employee turnover (e.g. Shuck et al, 2014; *Smith & Macko, 2014*). More recently, additional studies have empirically observed the positive effects of engagement on reducing turnover intentions in specific industry sectors, such as among federal employees (Byrne, Hayes, and Holcombe, 2017), in public accounting firms (Carrillo et al., 2017), IT sector (Pandita and Singhal, 2017), and higher education (Chong and Lee, 2017).

A variety of approaches have been proposed in the literature on measuring engagement as a complex and holistic construct. The Gallup's Q^{12} Survey is one of the earliest and also commonly considered as one of the most influential. It consists of 12 simple one-sentence questions (Table 1) and has been used on more than 25 million employees in 3 million workgroups from 195 countries since 1996 (Gallup, 2018). Forbringer (2002) consequently categorized the Gallup Q^{12} into 4 discrete levels/dimensions: 1) basic job needs, 2) self-image and worth, 3) feeling of belongingness, and 4) opportunities for learning and growth. More recently, SurveyMonkey Business Solutions (2016) designed a different version of 12 questions (Table 1). As compared with the Gallup Q^{12}, which primarily focus on employees' perception about themselves, the SurveyMonkey questionnaire measures engagement at the organizational level. Besides the 6 questions about how engaged one feel about him or herself, it includes another 6 questions on the respondent's perception on co-workers' level of engagement. The assumption is that an engaged organization is one where all employees should feel engaged (rather than just felt by the individual who responded to the questionnaire). Following the same two-level approach (i.e. individual plus organization), the Society of Human Resource Management (SHRM) measures engagement in its Employee Job Satisfaction and Engagement survey (2016) that are administered to 600 U.S. employees annually. The engagement section contains 37 questions (Table 1), categorized into 3 separate dimensions: 1) *Conditions for Engagement* dimension captures the employee's satisfaction level to a wide array of job characteristics, which are considered as the capacity and reason for the employee to feel engaged. 2) The *Engagement Opinion* dimension depicts the personal reflection of employee's relationship with their own work. 3) The *Engagement Behaviors* dimension describes the "look" of engaged employees and workgroups and their "actions" that can positively contribute to the welfare of the organization. Despite the greater details and more straightforward verbiage of the questions, the foundation of the SHRM survey is similar to the 4 levels of Gallup Q^{12} as proposed by Forbringer (2002).

The applicability of traditional concept of employee engagement among Millennials in the gig economy has been questioned by many practitioners and researchers. Typical concerns are around: 1) the confusing definition of gig workers being employees vs. independent contractors and the associated legal rights, responsibilities and other ramifications (Donovan, Bradley and Shimabukuru, 2016); 2) the weaker bond and loyalty from contingent workers to employers (Klazema, 2018); 3) the typical part-time and temporary status of gig workers and their and spatial detachment (i.e. the lack of face-to-face interactions) with fellow employees and the geographic location of the company (ibid); 4) the shrinking differences between self-employment and external work in the gig economy so that companies have to compete for talents not only against other employers, but also with self-employment (McGuire, 2017); and 5) company's lack of understanding to the importance of gig worker engagement and the appropriate strategies to engage them (Thompson, 2017). We would thus like to use the secondary data from the 2018 Direct Selling Association's National Salesforce Study Questionnaire to help us develop a snapshot understanding to the current status of ISR engagement and compare its internal sub-dimensions with the traditionally defined construct of employee engagement.

Table 1. Literature review on the construct of Employee Engagement

Forbringer's Engagement levels	Gallup's Q[12] Survey	Survey Monkey's Professional Engagement Survey		SHRM's Employee Job Satisfaction and Engagement Study	
Level 1: Basic Needs (What do I get?) • Gallup Q1 • Gallup Q2	Q1. Do you know what is expected of you at work?	Self-perception	Q1. I am inspired to meet my goals at work.	Conditions for Engagement	• Relationship with co-workers • Opportunities to use skills/abilities • Meaningfulness of the job • The work itself • Relationship with immediate supervisor • Organization's financial stability • Contribution of work to organization's business goals • Autonomy and independence • Variety of work • Overall corporate culture • Communication between employee and senior management • Organization's commitment to corporate social responsibility • Management's recognition of employee performance • Job-specific training • Organization's commitment to professional development • Network opportunities • Career development opportunities • Career advancement opportunities within the organization
	Q2. Do you have the materials and equipment to do your work right?		Q2. I feel completely involved in my work		
Level 2: Self-image and worth (What do I give?) • Gallup Q3 • Gallup Q4 • Gallup Q5 • Gallup Q6	Q3. At work, do you have the opportunity to do what you do best every day?		Q3. I get excited about going to work.		
	Q4. In the last seven days, have you received recognition or praise for doing good work?		Q4. I am often so involved in my work that they day goes by very quickly.		
	Q5. Does your supervisor, or someone at work, seem to care about you as a person?		Q5. I am determined to give my best effort at work each day.		
	Q6. Is there someone at work who encourages your development?		Q6. When at work, I am completely focused on my job duties.		
Level 3: Feeling of belongingness (Do I belong here?) • Gallup Q7 • Gallup Q8 • Gallup Q9 • Gallup Q10	Q7. At work, do your opinions seem to count?	Perception of the organization / other employees	Q7. In my organization, employees adapt quickly to difficult situations.	Engagement Opinion	• I am confident to meet work goals • I am determined to accomplish work goals • I understand the organization's vision/mission • I am highly motivated by my work goals • While at work, I always completely focus on work projects • I am provided the resources to do job well. • I frequently feel that I am putting all efforts to my work • I have passion and excitement about my work • I am often so wrapped up in work that hours go by fast • I enjoy volunteering for activities beyond my job requirements • I feel completely plugged in at work, like I am always on full power.
	Q8. Does the mission/purpose of your company make you feel your job is important?		Q8. Employees here always keep going when the going gets tough.		
	Q9. Are your associates (fellow employees) committed to doing quality work?		Q9. Employees proactively identify future challenges and opportunities.		
	Q10. Do you have a best friend at work?		Q10. Employees in my organization take the initiative to help other employees when the need arises.	En ga ge	• Employees are encouraged to take actions when problem/opportunity arises
Level 4: Learning, growth and innovation (How can we all grow?) • Gallup Q11 • Gallup Q12	Q11. In the last six months, has someone at work talked to you about your progress?		Q11. Employees here are willing to take on new tasks as needed.		• My colleagues quickly adopt to challenging or crisis situations. • My workgroup never gives up despite difficulties • Employee deal very week with unpredictable or changing work situations. • My workgroup is constantly looking out for future challenges • People in my workgroup are always flexible • Others in my organization view unexpected responsibilities as opportunities • Other people in my organization often volunteer for new projects
	Q12. In the last year, have you had opportunities to learn and grow?		Q12. Employees in my organization willingly accept change.		

RESEARCH METHODOLOGY AND FINDINGS

Research Sample and Data

Direct Selling Association (DSA) is the national trade association for companies using direct selling business model. Serving nearly 200 member companies, DSA provides educational opportunities and support to advance the understanding and practice of direct selling. Every 3-5 years, DSA conducts a study on current direct selling salesforce to learn about their attitudes and opinions toward direct selling and outline demographic profile of workforce in the industry. The study may be completed in English or Spanish. As faculty fellows of the Direct Selling Education Foundation (DSEF), a 501(c)3 organization affiliated with DSA to advance direct selling-related research and teaching, we were granted access to the variable descriptions of the questionnaire and approximately 8,700 responses DSA had received from this study conducted in May 2018.

We first removed records 1) with incomplete data, 2) answered “Don’t know/Not Applicable” option in measurement items of ISR engagement, and 3) indicating company and upline “does not provide” training and support. In screening the data for outliers, we detected extreme values using Mahalanobis distance. As wide range of commitment to direct selling was represented in the data set, we further identified those have no other paid jobs and spend at least 10 hours per week on direct selling business. In addition, it has been recognized that engagement for success is different across cultures in arena of management and marketing (Akutsu, Haga, Fujikawa and Ono, 2013; Huang, Ma and Meng, 2018). To control the effect of ethnic culture in this study, we chose respondents whose primary language spoken at home is English. The resulted final research sample contains 267 responses.

Measurement and Analysis

To investigate the number of sub-constructs and structure of the measurement of engagement, an exploratory factor analysis (EFA) was conducted using SPSS on the 33 items about ISR's opinions on the direct selling company they represent and the upline agents who sponsor the ISR. Using principal component analysis, varimax rotation and extraction criterion of eigenvalue greater than 1.00, the analysis results recommended a five-factor solution that explained 67.78% of the variance. All measurement items with their factor loadings and reliability are reported in Table 2. Cross-loaded items were examined using the threshold factor loading value of 0.50, underlying structure in response to proposed construct and the impact on measurement item reliability (Cronbach's α). For example, if item # 10 (The sponsor and/or upline is honest and accurate about the effort required in direct selling and the rewards you can expect to receive) is cross-loaded on the engagement by upline and the basic engagement condition at corporate level, with factor loading of 0.62 and 0.47, respectively. The cross-loading could be because being "accurate" about effort required and potential reward makes ISRs feel that they know what to expect at work (the condition for engagement); while being "honest" manifests upline's willingness to enhance sense of ISRs' well-being and help them succeed. As the item reflects two levels of engagement and the Cronbach's α is not improved if the item is added, it was removed. Factors 4 and 5 revealed in the EFA were also removed because they obviously manifest inventory-related operations not engagement.

We thus eventually identified three sub-dimensions of ISR engagement as shown in table 2: 1) UPLINE: Emotional attachment with sponsor/upline (items 1-9); 2) OPR: Operational needs from company (items 13-20); and 3) BELONG: Feeling belongingness to the company (items 21-26). The cumulative variances for these three factors are observed to be 56.47%.

Cluster Analysis

To study the ISR's perception towards direct selling experience, we performed a K-means cluster analysis choosing experience comparing to initial expectation and the rating of actual experience in direct selling as clustering variables. It needs to be noted that the responses for initial expectation (on horizontal axis) was in a 1-3 scale; while the actual experience (on vertical axis) was in a 1-5 scale as shown in Figure 2.

The results of the cluster analysis revealed two groups with 82.5% and 17.5% share of the sample, respectively. As shown in Table 3, ISRs in Cluster 1 tend to have very good experience that above their expectations when they started direct selling. ISRs in Cluster 2 have fair to good experience but the experience doesn't meet their expectations in general.

Table 2. Construct items (Factor loadings and reliability)

Item	Factor Loading 1	2	3	4	5	Cronbach's α
How much do you agree that your sponsor and/or upline…?						0.94
1. Is interested in your personal development	**0.87**	0.20	0.20	0.03	0.04	
2. Has recognized your accomplishments appropriately	**0.86**	0.17	0.22	-0.01	0.02

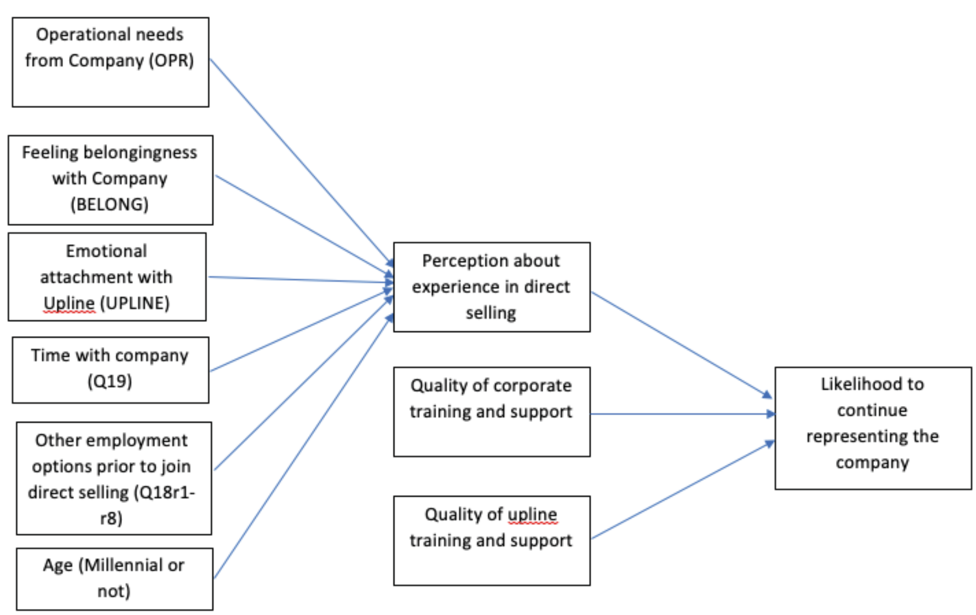
<u>Discriminant Analysis</u>

Based upon cluster analysis results, we conducted discriminant analysis to further investigate the effectiveness of engagement sub-dimensions and a host of demographic descriptors on ISR's perceptions about their experiences in direct selling. These descriptors include a) time with the company, b) ISR age (millennial vs. baby boomer) and c) a series of 8 employment options respondents had explored when deciding to join direct selling (labeled as Q18_n in table 4). The conceptual model was illustrated in Figure 2. As the analysis involved two groups of ISR, one function was derived and was significant at 0.01 level ($\lambda=0.868$, $\chi^2(df=13) = 34.43$, $p = 0.001$). The hit ratio was 84.9%, which was higher than 1.25 times that achieved by chance, suggested acceptable classification accuracy (Hair et al., 2010. Press's Q is another measure of predictive accuracy of a discriminant function. The value was calculated at 122.92 and significant at 0.01 level. All above indicates that the discriminant function was statistically significant.

Figure 2. Conceptual model



As shown in Table 4, the Univariate ANOVA assesses the significance between the means of the two groups, variables of engagement sub-dimension of feeling belongingness to the company (BELONG), time with company, age and employment option before deciding to become an ISR showed significant univariate differences between the two groups at 0.05 or 0.01 level. The other aspect of engagement (Operational needs from company or OPR) was significant at the 0.1 level. It is noteworthy that Emotional attachment with upline (UPLINE) was not significant (not reported in Table 4). In other words, ISRs who had high levels of engagement with their upline sponsors rated their perception of direct selling experience very similarly to those with low upline engagement. Hair et al. (2010) suggested discriminant loading as a valid parameter to interpret the discriminating power of an independent variable. To be consistent with previous research, we consider those with loadings absolute value of 0.3 or above as substantive in this study. The results thus indicated that those ISR who had considered other full-time employment options are most likely to have a better experience with direct selling, while those who had not made no other career plans would likely to have a bad experience in direct selling (a strong negative discriminant loading factor). Feeling belongingness to the company (BELONG) also appeared to have strong relationship with ISR experiences, so did their time with that company and being the Millennials generation.

Finally, we conducted an additional discriminant analysis to determine whether three variables - perception about experience in direct selling, quality of training and support provided by the company and upline, could anyhow predict an ISR's likelihood to stay with the company in direct selling (Figure 2). Although the data consists of four level of likelihood to continue representing the company for the next year. The sample size of those who were very unlikely or somewhat unlikely to continue were only 4 and 1, respectively. Therefore, the discriminant analysis was only performed on two groups of ISRs – those were somewhat likely or very likely to continue. All three variables - perception on experience, quality of training and support the company provides, quality of training and support the upline or sponsor provides, are primary source of differentiating the two groups (Table 6). The ISRs who obtained high quality training and support from upline and company were more likely to continue with the company (Table 5). The groups of ISRs with relatively good and poor perception about experience were automatically coded in reverse order as 1 and 2 in cluster analysis. The results demonstrated that ISRs who had better perception about their direct selling experience were also more likely to continue.

DISCUSSIONS AND CONCLUSION

This study has made the following contributions to practitioners and future researchers.

Firstly, our empirical analysis confirmed the uniqueness of millennial ISRs engagement in the gig economy. The factor analysis revealed three distinctive sub-dimensions of engagement that are very different from findings of earlier studies on this construct. The dimension of emotional attachment with one's sponsor or upline (UPLINE) recognizes the importance of the people element of the construct. In order to feel engaged with one's work, people need to develop connections and emotional involvement with colleagues at their workplace (Kapoor & Meachem, 2012). With the absence of typical coworkers and managers in the direct selling context, the upline sponsors become the "human figurehead" of the work that ISRs can relate to. Direct selling companies are thus advised to pay close attention to the role of these upline sponsors in developing ISR engagement. The other two company related engagement dimensions (OPR and BELONG) align relatively well with Maslow's need hierarchy. At the minimum level, the direct selling company must meet basic operational needs of ISRs so that they can function properly for their contracted work (OPR). For many gig workers who use their own equipment and facilities for their work (e.g. Uber drivers use their private vehicles and direct selling ISRs

Table 4. Discriminant Analysis on Experience in Direct Selling

	Discriminant loading	Standardized Function coefficient	F
Full time employment option before deciding to join direct selling (Q18_1)	0.639	0.425	15.491***
Nothing before deciding to join direct selling (Q18_8)	-0.549	-0.385	11.441***
Feeling belongingness with company (BELONG)	0.424	0.546	6.811**

set up sales parties at their own home), good quality products, clearly defined work flow, and easy-to-work-with supportive representatives from company are particular important, because these equipment and facilities are less standardized and more likely to cause confusion in the gig work environment. Once the basic needs have been met, gig companies should also look at the dimension of feeling belongingness to the company (BELONG) to engage their workforce. This dimension allows the company to move up the Maslow's hierarchy and address the needs of gig workers for personal development opportunities and the sense of ownership and pride. Meeting these higher-level needs helps gig workers align personal goals with the organizational goals, policies and practices, and is believed to be able to sustain a high level of engagement.

Table 5. Descriptive statistics for group statistics

Likelihood to continue		Mean	S.D.
Somewhat likely	Perception on experience	1.64	0.505
	Quality of training and support the company provides	4.36	0.674
	Quality of training and support the upline or sponsor provides	3.91	1.136
Very likely	Perception on experience	1.15	0.356
	Quality of training and support the company provides	4.89	0.352
	Quality of training and support the upline or sponsor provides	4.58	0.834

	Correlation Coefficient	Standardized Function coefficient	F
Quality of training and support the company provides	0.759	0.640	21.168***
Perception on experience	-0.718	-0.632	18.957***
Quality of training and support the upline or sponsor provides	0.426	0.140	6.671**

*p<0.1, **p<0.05, ***p<0.01

Secondly, our cluster analysis and discriminant analysis aim at understanding the factors related to gig workers' job experiences and their longevity in the gig professions. It is interesting to notice that being Millennial is indeed strongly related to having a good work experience in the gig economy. This is a confirmation to the findings from many generational studies in the literature. It is fortunate for the gig companies that the nature of gig work does seem to be perceived favorably among Millennials. They should continue their expansion in the Millennial generation.

Thirdly, another interesting finding from table 4 indicates that those people who have considered other full-time job opportunities and those who have considered no other career options (and jump straight into direct selling) are the ones more likely to have better perceived work experience at a later time. While others who have considered part-time employment opportunities, any type of self-employment, or those only consider direct selling as an "educational opportunity" prior to joining to direct selling are not found to have statistically significant relationship with high work experience. One possible interpretation to this result is that gig companies may want to rethink the strategy of billing themselves as a sector that offers people bridge employment or supplement income when attracting new contractors, because people with these expectations may find the actual gig work not meeting their expectations and drop out quickly. Only those who are serious with the gig work and would like to regard it as a long-term career path are more likely to feel engaged, enjoy their work experience, and deliver quality work results to the customers. When studying ISR's likelihood to stay with the company in direct selling, our results in table 6 indicated the importance of gig worker's perceived experience at work and the training and support they receive from both upline sponsors and the direct selling company. It thus highlighted another strategy for companies to sustain their gig workers: proper on-boarding at the commencement of contract work and ongoing training should never take lightly. Gig workers are still workers of your organization after all- they should have the same level of training and support as serious as you provide to any other employees.

Finally, we would like to acknowledge the challenges related to working with secondary data. The questionnaire was not designed specifically for this study nor even created/administered by the authors. The wording of some items was not as clear, the conceptual thoroughness of some questions less than ideal, and scales of different questions were not always constant. All these resulted in a lot of missing data and some difficulties for our model fitting. Despite these challenges, we appreciate the opportunity given by the DSEF. We hope our findings have stimulated more interest in studying Millennials in the burgeoning gig economy.

ABSTRACT

We model a supply chain in which the buyer audits the supplier's compliance with the code of conduct. We investigate the effect of buyer's upfront commitment to price and quantity on supplier's compliance. We also analyze implications of raising the standard of code of conduct on sustainability and financial performance.

KEYWORDS: Supplier's Social and Environmental Compliance, Sustainability Code of Conduct, Commitment to Contract Terms, and Game Theory

INTRODUCTION

Major brands in many industries outsource their production and hence lose direct control in managing sustainability in their supplier base. An overwhelming majority (i.e., as much as 70%) of sustainability issues (i.e., social and environmental violations) come from suppliers (UNGC 2015). Brands strive to reduce the likelihood of social and environmental violations in their supplier base. Many brands such as Nike, GAP, Wal-Mart and Apple have developed a code of conduct that sets expectations for their suppliers' social and environmental practices. These brands audit their suppliers' compliance (GIIRS 2014).

Yet suppliers' likelihood of compliance varies significantly across industries with significant consequences for the buyer. For example, a supplier of multiple fashion brands (i.e., GAP, Old Navy, and Banana Republic), released untreated wastewater into local streams and rivers in China that resulted in significant brand damage (Price 2017, Backhaus and Fischer 2017). In another incident, a supplier of Nike employed child labor and paid low wages. Consequently, the customers organized boycotts, which resulted in loss of revenue for Nike (Nisen 2013).

Brands face the challenge of engaging the supplier for improving social and environmental sustainability. Previous researches have investigated the efficacy of using various tools such as offering price premium (see Karaer et al. 2017), auditing (see Plambeck and Taylor 2016), and certification (see Chen and Lee 2016) to motivate suppliers to be more socially and environmentally responsible. We investigate the efficacy of a brands' use of commitment to contract terms in combination with auditing (i.e., committing to price and/or quantity prior to auditing) to enhance supplier's compliance to the code of conduct. We address the following research questions:

1) How does commitment affect the compliance to the code of conduct?
2) How does commitment affect the financial performance of buyer and supplier?
3) What is the relative value of different modes of commitment (i.e., price only, quantity only, or both, or neither)?
4) What are the implications of raising the standard of code of conduct on sustainability and financial performance?

MODEL

We develop and analyze multistage game-theoretic models. We consider a supply chain with a buyer and a supplier. The buyer sources a product from the supplier with a wholesale price contract and sells the product to the market. The supplier may misbehave socially or environmentally and cause the buyer to lose market revenue. The buyer audits the supplier with respect to the code of conduct. The supplier exerts an effort to comply with the code of conduct. To induce higher level of effort of the supplier, the buyer may commit to some or all the contract terms (i.e., price, quantity) before auditing.

RESULTS AND IMPLICATIONS:

We solve for the subgame-perfect equilibrium and characterize the contract terms, the buyer's auditing effort, and the supplier's compliance effort at the equilibrium. We also derive the overall compliance of the supply chain and the two parties' profits. To the first research question, our results confirm that increasing the level of commitment improves the supplier's compliance. Partial commitment to the price may decrease the overall compliance of the supply chain in comparison to the scenario of no commitment.

To the second research question, we find that increasing the level of commitment always increases the buyer's profit, but the supplier's profit may decrease. Interestingly, we find that when the buyer commits to price only, there exists a win-win-win outcome where both parties will be financially better off and overall compliance of the supply chain is improved, in comparison to the scenario of no commitment.

To the third research question, we find that there is a value for the buyer to commit to quantity only if the buyer has already committed to the price. Therefore, committing to the price and committing to the quantity are complementary to each other for the buyer. The supplier suffers a loss from buyer's commitment to quantity only if the buyer also commits to the price. Therefore, committing to price and committing to quantity are substitutes for the supplier. Also, we find that the change in the overall compliance of supply chain due to committing to quantity is positive only if the buyer also commits to the price.

To the last research question, our results show that when the buyer raises the standard of the code of conduct, interestingly, the supplier is more likely to be compliant with the code of conduct, even if the chance of passing the audit decreases. We show that when the auditing cost is very sensitive to increasing standard and the buyer commits to the price, an increases of the standard increases both the supplier and buyer's profit. We also find that as the standard of the code of conduct increases, the supply chain's total compliance and total profit may decrease.

NLP analysis of incidents descriptions in case of IT services

Attila Sóti Széchenyi István University of Hungary-soti.attial@hallgato.sze.hu

ABSTRACT

This article is an empirical approach to the linguistic analysis of incident description using natural language processing (NLP). Considering the customer feedback as texts are mainly written in an unstructured way, there is a need to use text meaning techniques to gain insight or perceive the focusing area of the text. The case is more complicated when events or incidents description is associated with a large organization providing a wide range of IT services. This article describes how to use semantic analysis with other data meaning techniques which can help in finding focus, patterns and trends in texts connected to user feedback.

Keywords: Statistical Natural Language Processing, User feedback, IT services

INTRODUCTION

It is estimated that 80% of business-relevant information is in unstructured and semi-structured text data. In other words, without the use of textual analysis, to discover the 80 percent of data, all business information and customer's behaviour data will be lost (Halevy, Norvig, & Pereira, 2009).

Incident descriptions are usually written by non-professionals and many times they are not formulated adequate to English, but they contain a lot of information.(Pan, Liu, Xiang, & Yang, 2011) Using this information in a thorough and systematic way, it is increasingly necessary to understand customer's behaviour and attitudes (Song & He, 2010). For example, if the cause of most incidents is known, measures can be taken to decrease their occurrences. There are no standard rules for writing customer's feedback so that the computer can understand them. The language and the meaning for every piece of text vary depending on the purpose (Dan Jurafsky & Martin, 2009). The only way to include accurately unstructured data in a data-meaning project is to understand the language and the context within which the text is created (Briscoe, 2011).

LITERATURE REVIEW

Understanding human language is based on linguistics, commonly referred to as Natural Language Processing (NLP) (Nadkarni, Ohno-Machado, & Chapman, 2011). NLP is a way for computers to analyse, understand, and derive meaning from human language in a smart and useful way (Turney & Pantel, 2010). By utilizing NLP, developers can organize and structure the knowledge to perform tasks such as automatic summarization, translation, named entity recognition, relationship extraction, sentiment analysis, and topic segmentation. (Briscoe & Carroll, 1993) NLP algorithms are typically based on machine learning algorithms (Reddy et al., 2015). Instead of hand-coding, large sets of rules, NLP can rely on machine learning to automatic learning these rules by analysing a set of (Chan & Franklin, 2011). A Statistical NLP approach seeks to solve problems by automatic learning lexical and structural preferences (Cohen & Dolbey, 2007) from corpora and if the existing dictionary is extended (rules, types, synonyms) to support this process we might be able to analyse our non-formal descriptions. (Majumder, Mitra, & Chaudhuri, 2002) (See Figures below 1, 2) as examples (Jordan & Mitchell, 2015). A system that incorporates NLP can intelligently extract terms, including compound phrases, and permit classification of terms into related groups (Le & David Jeong, 2017). Linguistic systems are knowledge-sensitive: the more information is contained in the linguistic resources (dictionaries), the higher is the quality of results (Yu, Li, Merigó, & Fang, 2016). Modification of the dictionary content, such as synonym definitions, can simplify the resulting information and focus attention on the most relevant concepts.

Figure 1 – Statistical NLP approach phase I

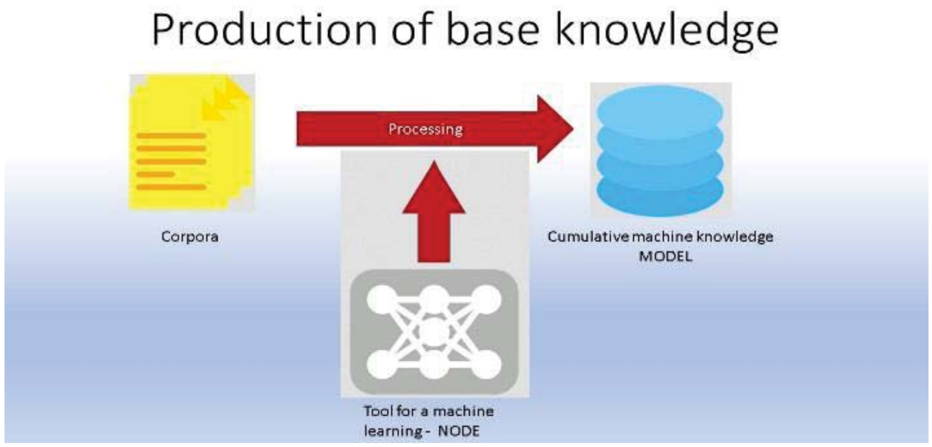

Figure 2 – Statistical NLP approach phase II

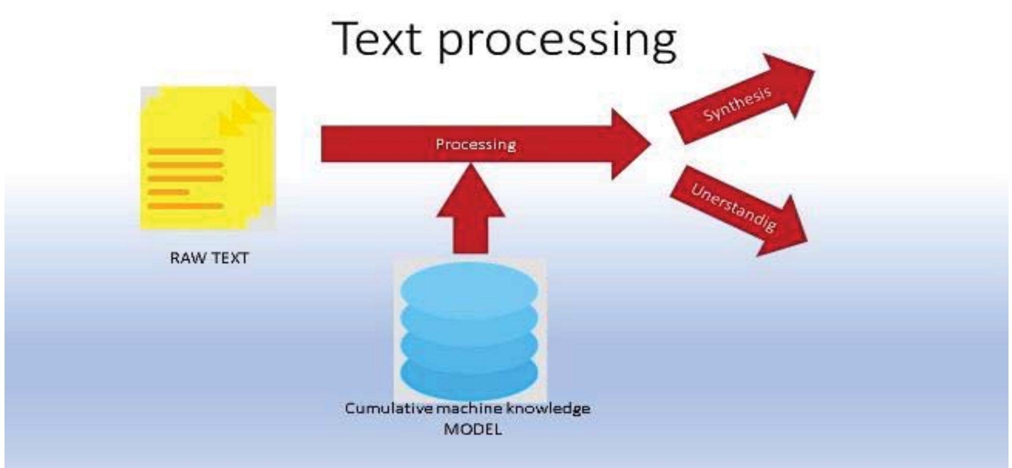


Text meaning must consider the universal fact that languages contain ambiguities (Kiss & Strunk, 2006). The same words can be different parts of speech (nouns, pronouns, verbs, adjectives, adverbs, etc.), and therefore play different roles in meaning (Goldberg, 2018). The same word, even when used as the same part of speech, can have different meanings depending on how it is used and the context within which it appears. The linguistic analysis involves the study of the elements, structure, and meaning of language: (Fraser & Hudson, 1992).

THEORETICAL DEVELOPMENT/MODEL

Text meaning is the process of extracting knowledge and information from natural language texts (Li, Zhou, Bruza, Xu, & Lau, 2008). There are several ways how NLP can help to gather insights out of any text description (Manning & Schütze, 2000). In this research are used segmentation of text description (by creating clusters) which can help to identify the problem area, where we can detect which parts of the service have the most impact (Alotaibi & Ahmad, 2019). This is the most difficult task for text meaning and involves in part the use of dictionaries, glossaries, lexicons, typologies, and so forth (Briscoe, Copestake, & Boguraev, 1990). The following steps were taken during text processing:(Yessenov et al., 2013).

Text preprocessing- Replacement of some special characters with spaces, and determination at the end of sentences and at the end of paragraphs.

The extraction step begins by attaching a label to each word and making the first attempt at the identification of candidate terms. Recall that terms are the building blocks of text analysis, corresponding to single or complex words that are considered relevant or interesting. During this step, the following actions are taken:

Text tokenization: A process that identifies character strings (tokens) from the input text, based on delimiters. Examples of delimiters are spaces, tabs, carriage returns, and punctuation marks.

Text normalization: Helps to manage poor punctuation in the text, such as improper use of a period, comma, semi-colon, colon, forward-slash, etc. The input text is "corrected" internally to place spaces around improper punctuation.

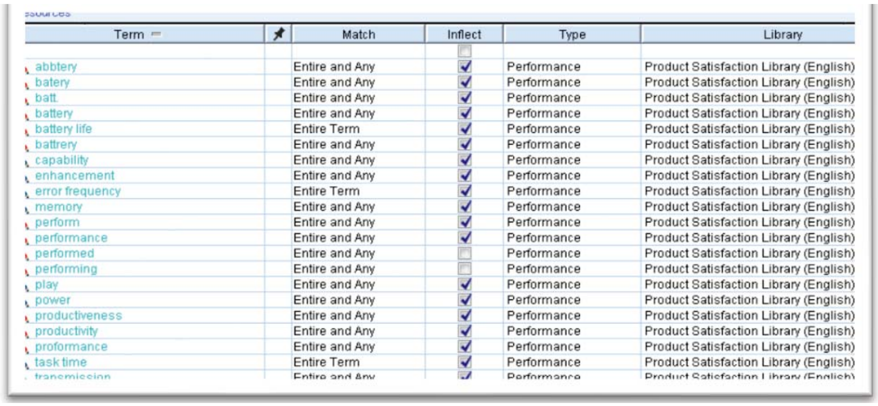
Candidate term extraction: Identifies relevant words and compound words from the input text.

Labelling the Part of the speech: Each token in the text stream is labelled by a Part of Speech tag, which comes from the base of the dictionary. Traditional English grammar classifies words based on eight parts of speech: verb, noun, pronoun, adjective, adverb, preposition, conjunction, and interjection. Each part of speech does not explain what kind of word is, but how the word is used.

Forcing / Excluding step: When we reviewed the text data after extraction, we should discover that some words or phrases were not extracted. While normally these words are verbs or adjectives that we are not interested in. These may be terms that are specific to an industry as product names, acronyms, etc. If we would like to have these words and phrases extracted, we can force a term into our dictionary, or we can exclude expressions that we no longer consider important.

Typing step: A type is a higher-level concept that contains one or more terms. There are default types for Organization, Product, Person. After extracting and modifying terms as described above, the extractor next assigns each concept to a type, wherever possible. See the example in figure 3.

Figure 3 -The type (Performance) and associated terms.



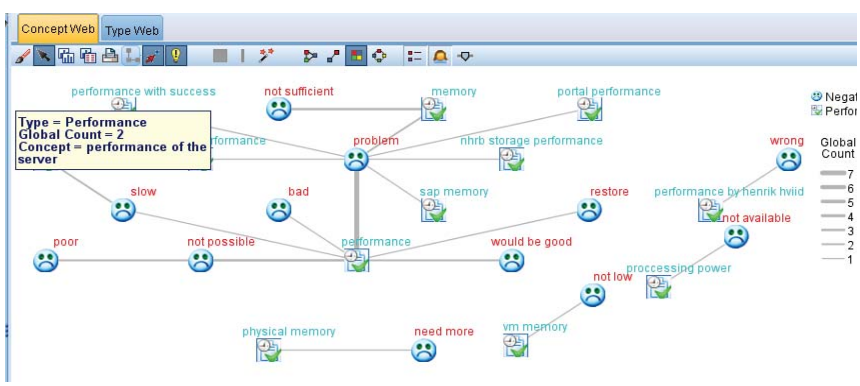
Term	Match	Inflect	Type	Library
abbtery	Entire and Any	✓	Performance	Product Satisfaction Library (English)
batery	Entire and Any	✓	Performance	Product Satisfaction Library (English)
batt.	Entire and Any	✓	Performance	Product Satisfaction Library (English)
battery	Entire and Any	✓	Performance	Product Satisfaction Library (English)
battery life	Entire Term	✓	Performance	Product Satisfaction Library (English)
battrery	Entire and Any	✓	Performance	Product Satisfaction Library (English)
capability	Entire and Any	✓	Performance	Product Satisfaction Library (English)
enhancement	Entire and Any	✓	Performance	Product Satisfaction Library (English)
error frequency	Entire Term	✓	Performance	Product Satisfaction Library (English)
memory	Entire and Any	✓	Performance	Product Satisfaction Library (English)
perform	Entire and Any	✓	Performance	Product Satisfaction Library (English)
performance	Entire and Any	✓	Performance	Product Satisfaction Library (English)
performed	Entire and Any		Performance	Product Satisfaction Library (English)
performing	Entire and Any		Performance	Product Satisfaction Library (English)
play	Entire and Any	✓	Performance	Product Satisfaction Library (English)
power	Entire and Any	✓	Performance	Product Satisfaction Library (English)
productiveness	Entire and Any	✓	Performance	Product Satisfaction Library (English)
productivity	Entire and Any	✓	Performance	Product Satisfaction Library (English)
proformance	Entire and Any	✓	Performance	Product Satisfaction Library (English)
task time	Entire Term	✓	Performance	Product Satisfaction Library (English)

Creation of categories step (grouping): The next step in text meaning is normally the creation of categories, which represent the information that we consider to be important in the responses. There are three categorization methods:

- concept inclusion,
- concept derivation
- semantic networks

The category refers to a group of closely related concept, opinion, or attitude used in text meaning. Each category is defined by one or more descriptors that are concepts, types, patterns, or conditional rules. Categories can only be created from a single concept or type, but it is common to combine multiple descriptors. The above-mentioned three language methods provide a natural language-based approach to categorization. For example, figure 3 presents the overlap for the categories to which the type (Performance) belongs according to the selection.

Figure 4 The overlaps for the categories



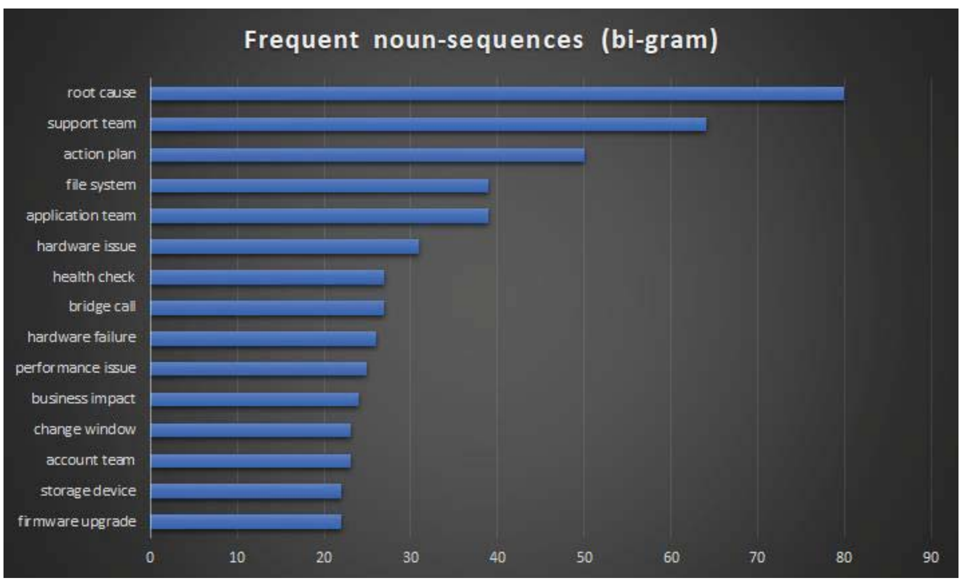
.

Indexing step: The types are indexed by establishing a pointer between a text position and the representative term for each equivalent class.
Matching patterns and events extraction step: NLP can discover not only types and concepts but also relationships among them.

RESULTS

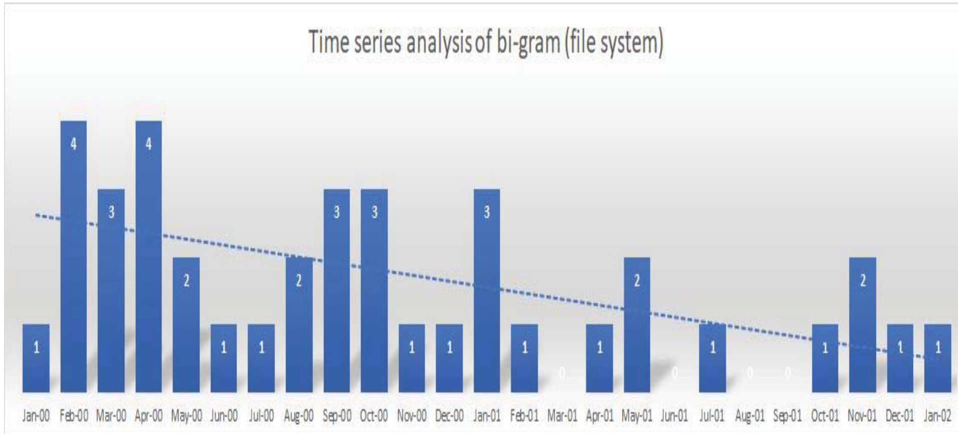
Semantic analysis has several advantages, it can detect connection among different tags, There are several combinations, which have powerful meaning like verb-noun connections (Huttenlocher & Lui, 1979). In the case of the noun, we can increase the significance if we identify not a single term, but a sequence. A typical noun sequence is a bi-gram, but that can be any number of nouns (n-grams) (Daniel Jurafsky & Martin, 2014; Majumder et al., 2002; Santos, Penya, Devesa, & Bringas, 2015). Advantage of the n-grams, that are comparing with the daily-speech environment occurrences of n-grams is relatively low (Gries & Mukherjee, 2010) while in the technical environments these occurrences are high (typically identifying technical terms or expressions) and have higher business meaning value, what we can use for analysis (Wang, McCallum, & Wei, 2007). One example, how bi-grams help to identify areas, what we can see here that several customer feedback refer to hardware problems or issues related to file systems or problems describing cases related to performance (See figure 5), In such cases, we need to look at the relationship between different IT environments where the problem occurs. We discovered, for example, that some types of databases could not work together with old operating systems (performance problem). In other cases, we have discovered that a poorly written application program in different IT environments has always caused a storage problem. The third case refers to the vulnerability of a hardware element.

Figure 5 – Frequent noun-sequence



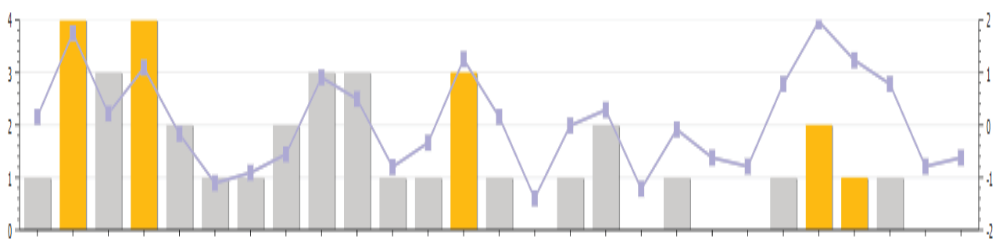
Since problems do not occur at the same time, so by enriching our data with time scales can easily help us to identify trends in some common grammar tags. For example, very often, the usage of some IT environments is not linear, but there are some frequent periods. In such cases, for example, periodical usage of the term "slow response time" can be observed. In another case, however, we can follow the elimination of the problem. For example, the mention of the "file system" bi-gram was reduced at the beginning of the year, because some applications started automatically to save the data. (See Figure 6)

Figure 6 – Time series analysis of bi-gram (file system)



At the same time series can be analysed from deviations points of view, which helps to identify those points in the time, which behave differently in time than what we would predict from previous data points (See figure 7). We could use this method as well in the case of problems with the smaller parts of the system. For example, a poorly formatted SQL query occasionally causes high memory usage. It is easy to found out which of the thousands of queries working badly with this method since only the running time of queries had to be compared with the time of deviation.

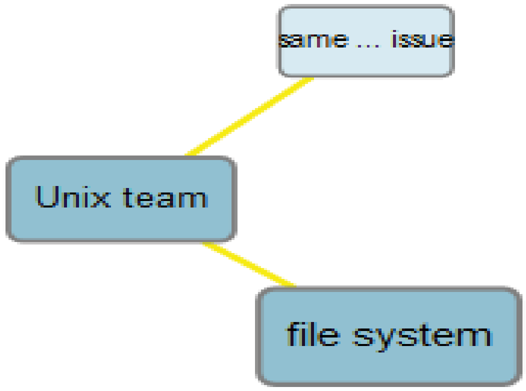
Figure 7 – Deviation detection



Semantic analysis can help to detect meaningful connections among different grammatical parts of the customer feedback.

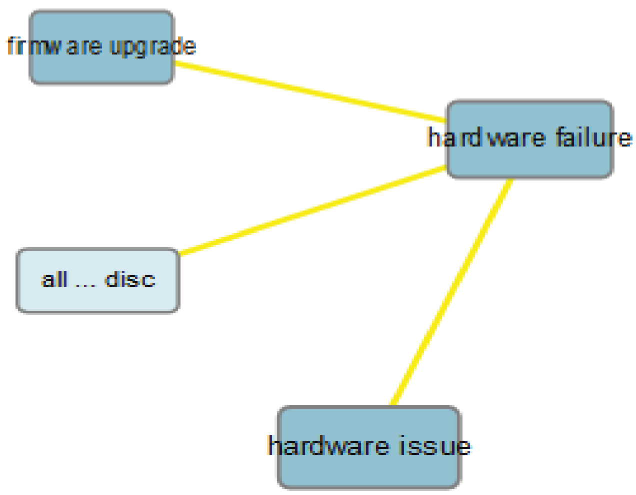
Let's see two examples of connection by detecting a correlation between noun sequences (bi-gram) and modified nouns (Chen, Seymore, & Rosenfeld, 1998). For example, we gain more insight by seeing that a larger part of file system issues is connected to Unix team (See figure 8). So we can identify that this problem occurs mainly around Unix environment. In such cases, the parts of a text ("same issue", "file system", "Unix team") are not necessarily mentioned sequentially. It may also happen that in different customer feedback only some synonyms of terms appear, nevertheless, we discover the relationships among the text elements.

Figure 8 - Connection network sample I



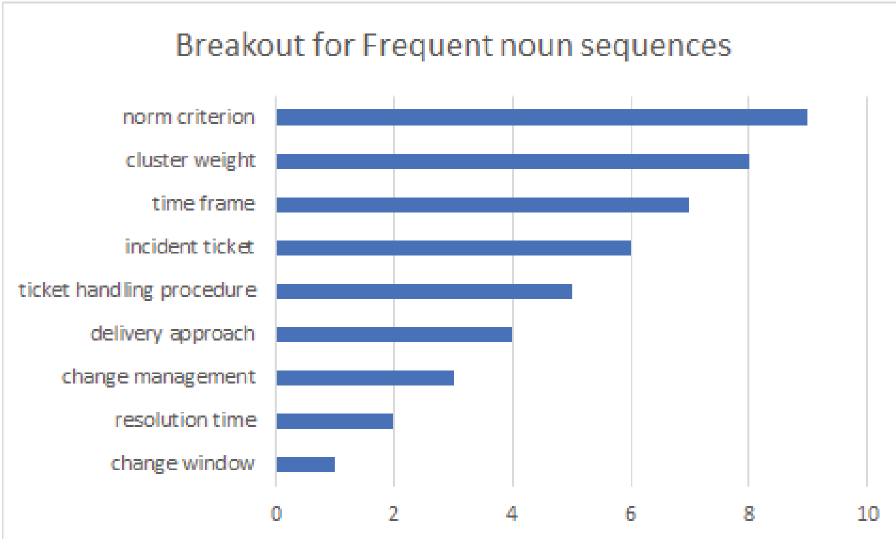
Another example shows that there is a correlation between hardware failure and firmware upgrade, (See figure 9) which can help us to identify common issues with firmware level. In this case, a correlation between the four elements of text occurs. The incorrect writing of "hardware" word does not cause trouble to recognize the connection among the text elements.

Figure 9 - Connection network sample II



Beyond the forms mentioned so far, we can identify structures such as noun sequences, modified nouns or nouns with predicates, which help us to identify more relevant text structures in describing our problem space (See figure 10).

Figure 10–Frequent noun sequences



The frequency of these terms and text structures may reflect the severity of the problematic area. In this case, we need to consider what solution shall we choose. For example, if many posts contain a "time frame" expression. That refers to a certain period when something planned is to happen in the IT system. In this case, we need to pay special attention to planning the introduction of changes in the future, because this is an important area for our customers.

DISCUSSION AND CONCLUSIONS

NLP is an efficient way to discover patterns on a large set of feedback descriptions, simply identifying grammatical structures supports to detect trends and deviations related to the provided service or the applied service components (Gao et al., 2007). There are grammatical structures, which are more valuable for this purpose, basically, nouns and verbs are the key language components from this point of view (Huttenlocher & Lui, 1979). Customers' feedback and incident descriptions individually should describe some parts of a customer' opinion but contains more information in a complex enterprise environment. These details are highly unstructured, and we need to apply techniques to extend information about them. By applying NLP procedures with other methods such as time series analysis, deviation detector connection, detecting, we can identify trends and deviations focusing on business-relevant expressions and terms.

Gamification in Entrepreneurial Education: Highlighting Major Concerns through a Systematic Mapping Study

Katalin Czakó
Széchenyi István University
Email: ckatalin@sze.hu

László Szendrői
Széchenyi István University
Email: szendroi.laszlo@sze.hu

ABSTRACT

Gamification is innovation in classroom instruction and consequence of following the global standards in university operations. In this study, through the application of systematic mapping, we screened empirical articles, where universities developed gamification in entrepreneurial education. Our goal is to present trends among the following questions: Who are the actors of applying gamification in entrepreneurial university atmosphere? How can we categorize the applied gamification tools? What research gaps can be defined? We observed that academics and institutional changes are less in focus of research. Categorization of gamification tools is constraint due to the dominance of serious games and online based (mobile) applications.

KEYWORDS: Games and Simulations, Classroom management, Gamification, Entrepreneurship

INTRODUCTION

Goal of this paper is to give an insight in present trends and research directions dealing with the efficient operations of higher education institutions and the application of gamification in entrepreneurial education.
Method applied in this paper is the mapping study, which is usually used as one of the first steps of comprehensive research in a given field and it is a useful method for defining the future research interest based on the findings of the systematic categorization of the existing research. Based on a systematic mapping study logic, represented in this paper, 20 papers were selected as suitable material for deeper data extraction.
We use the word “entrepreneurial education” once because of the logic of the analyses presented in this paper. Beside this under entrepreneurial education we understand all the courses, which are in field of business administration and economics. They are business or entrepreneurship related courses. We also focus on other courses, where developing the entrepreneurial mindset of students is the goal of the implemented gamification tools.
Literature of gamification in education provides several empirical analyses and can be categorized in sub topics. In order to be more specific, this analysis provides synthesis on two regularly researched topics – gamification and entrepreneurial university. General question of our interest is that is there any overlap among the two topics? If yes, what are the major elements and findings in this link. If no, what are the characteristics of the research gap? We know, that eventually we cannot separate two answers for the general question. In order to get closer insight to the extent of the assumed overlap, we highlight the following categories in the selected papers:

- Number of studies by disciplines or subjects.
- Course' types mentioned in the studies.
- Way of implementation of gamification tools.
- Examined variables in the studies.
- The mostly mentioned gamification tools in the studies
- General outcome or findings of the studies.

Recovering the common fields and elements in literature through the above listed categories may give more exact conclusions in the efficient operations of universities, which have the strategic focus to enforce the entrepreneurial spirit among students, faculty members and other shareholders of higher education operations. Since Clark's original definition (1998) there are changes in the role of entrepreneurial universities. In many cases, being an entrepreneurial university is not only a financial must, it is also a strategic and or differentiating goal, which is still in development phase in many cases (Czakó, 2017). Gamification is the tool to drive development processes and enforce different practices in operations of organizations in competitive sphere and also in education. Pelling (2011) was the first who coined the term of gamification when there were several authors used it before. He used it to describe those techniques which promote products and services. (Buckley and Doyle, 2017) The most common definition accepted by many researchers comes from Deterding et al., (2011) who defined gamification as a term for the use of video-game elements in the context of non-gaming systems to improve user engagement and experience. Since then, we can see several surveys, which general message is that applying gamification in education results better student performance, better experience, higher engagement and overall better teaching processes in educational institutions. Yilirdim (2017) focuses on students' attitude toward mathematic lessons. We would like to turn toward lessons of entrepreneurship and business and lessons in other topic, which improve the entrepreneurial skills of students. Basic assumption of us is that both of the topic of gamification in education and entrepreneurial university are upcoming areas among researchers and also in decision making processes of universities or other educational institutions. This gives the reasonability to make the synthesis, which arises several research questions.

In this paper we focus on the following questions: (Q1) Based on the categorization of this paper, what kind of tools are in the focus of the studies? (Q2) Who are the actors of gamification in entrepreneurial universities, how do they contribute to the usage of gamification tools? (Q3) Based on the synthesis of the paper, which research gaps can be identified?

This paper shows that the mapping study prospect is adequate to answer these questions. First part of the paper presents the major literature of gamification and entrepreneurial university with the goal of highlighting the link between the two topics. The theoretical model represents the main functions of mapping study and after this, the logic of mapping study process applied in this paper. Discussion part includes the extracted information from classification, which leads to the answering the above defined questions.

LITERATURE REVIEW

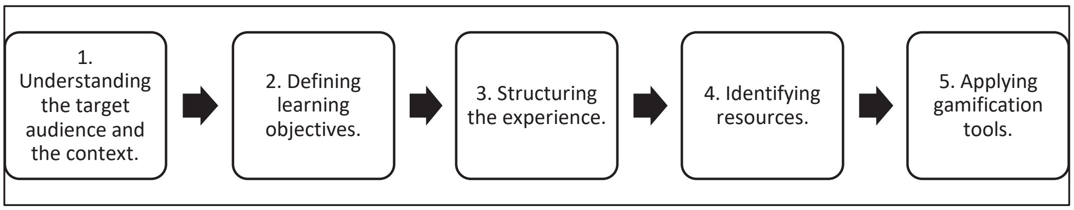
As it was mentioned before, this paper's theoretical framework has two pillars. The first important topic is gamification in education. The second is entrepreneurial university and more precisely, the integration of entrepreneurial practices in higher education.

Gamification in education

Huang and Soman (2013) elaborated a five-step process to apply gamification in education. Figure 1. gives shows those conditions, which are needed to the successful application

Understanding the target audience and defining the learning objectives are the very first steps before the application. Usually there are more versions of application. Structuring the experiences supports to collect needs or mistakes from previous applications. As it is sign in step 4. Application of gamification tools are strongly resource oriented actions. It is a basic requirement to provide equal availability to the members of the target audience.

Figure 1. The five-step process of applying gamification in education.



Source: Huang and Soman (2013)

Gamification can be found in the Oxford dictionary, which explains it in the following way: "The application of typical elements of game playing (e.g. point scoring, competition with others, rules of play) to other areas of activity, typically as an online marketing technique to encourage engagement with a product or service." (Oxforddictionaries, 2019).
Hamari et al. (2014) found the most common motivational terms related to gamification: points, leader boards, achievements/badges, levels, story/theme, clear goals, feedback, rewards, progress, and challenge. Dicheva et al. (2015) in an educational context found that the following gamification elements are the most commonly used: points, badges, leaderboards, levels, virtual currency, progress bars, and avatars. These elements have different motivational values; therefore, they have to be customized according to the environment and different types of individuals (Barata et al. 2015). According to Costa et al. (2017) it is difficult to define each gamification element as they are in many cases related to each other and sometimes researchers use them in different ways, meaning there are always overlaps between them.
There are both studies which examined the attitudes and knowledge of the teachers toward gamification (Adukaite et al., 2017; Fisher et al., 2014; Martí-Parreño et al., 2016) and studies investigating the student motivational effects and the learning outcome of using gamified classes (Antonio et al., 2015; Wintermeyer & Knautz, 2015).

Entrepreneurial universities – external and internal research perspectives

Clark (1998) gives the prototype criterions of entrepreneurial universities through a continuous operation analysis and case study building in the middle of 90's in chosen European Universities. There are internal criterions, which descript the changing mindset of students and faculty members toward entrepreneurial practices like taking part in common research activity or providing creative lessons and courses. Topic of entrepreneurial universities got great interest, it is showed by Mascarenhas et al. (2017), who gives a comprehensive literature review about the study of entrepreneurial universities from 1900 to nowadays. Considering external point of views Slaughter (1997) focuses on the effects of policy changes and centralized strategies on the corporatization process. Fekete (2015) collects economic development tools in governance of European cases and highlights the growing role of universities in industrial cities. (Abeles 2001) links external and internal point of views with the finding of growing number of university partnerships and other outsourcing processes can have also mainly cultural effects on internal university operations toward being more entrepreneurial.

Gamification and entrepreneurial universities

Basic assumption of us is that both of the topic of gamification in education and entrepreneurial university are upcoming areas among researchers and also in decision making processes of universities or other educational institutions. Gamification serves as supporting aspect in the transformation process to be entrepreneurial. This statement is supported by Troudt et al. (2017), who says that in order to turn entrepreneurship education into a semiautomated system of rewards, we must understand the actions of the entrepreneur. This statement can be strongly linked to the Criteria of Clark (1998) toward faculty members in an entrepreneurial transformation of a university.
Rippa and Scundo (2018) listing and summarize different types of technologic tools used in academic entrepreneurship, which has also clear focus in term of changing attitude of faculty members (e.g. thinking of Strike (2009); Normand (2016); Jessop (2017)). They refer to Galan (2013), whose case study illustrated that gamification is presented in these tools as improving factor of not only in the student learning experience but it is closely linked to research activity, which leads to effective community outreach.
Belotti et al. (2014) measures in European Universities, that serious games are welcomed by Students and the use of them and found them to be useful for introducing some difficult topics. Entrepreneurial motivation, business competence, and business acumen were identified as key entrepreneurial skills. There is a general question by the authors that what are the needed skills and competences by an educator to apply these games successfully. Are these competences closely linked to the entrepreneurial mindset? According to the above mentioned basic assumption, we think that applying gamification tools requires an entrepreneurial atmosphere. In order to strengthen this assumption, we provide the systematic mapping study to recover the literature was made in the topics of gamification and entrepreneurial university.

METHODS

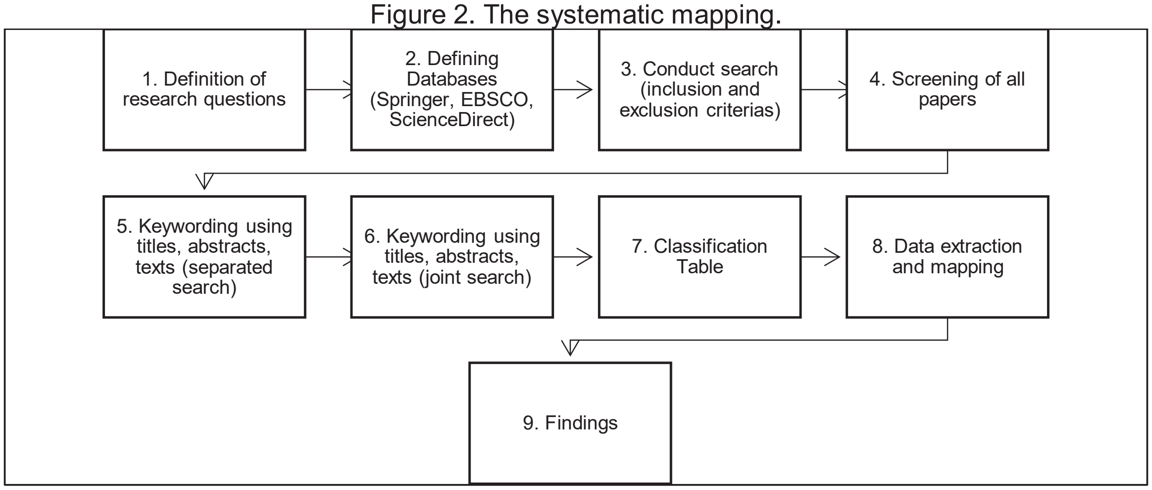
The mapping study methodology is usually used as a first step of the research and it is a useful method for defining the future research interest. It is similar to a systematic literature review, however, there are differences regarding the goals and other aspects between them. The mapping study focuses more on the classification of the collected studies and thematic analysis of literature and not the aggregation of the information from the comparative studies. The research questions are related more to research trends and not the outcomes of empirical studies. The scope of the research is broader, which means that all papers are selected to a topic area but only the classification data are collected from them and individual research outcomes are not extracted from each paper. The research strategy requirement is less stringent, because only trends are of interest, therefore authors may search only for journal papers or restrict themselves to only one or two search engines. So, it is not necessary to find all relevant studies like in a literature review (Kitcenham, 2011). Analysis of this paper is close to logic of Dicheva et al. (2015).
In this paper, we used more search engines and applied the definition of inclusion and exclusion criteria in the searching process. Another difference is that, we collected outcomes or findings from each paper after the screening process based on the inclusion and exclusion criteria.
A mapping study has several benefits for researchers. After a thorough mapping study, it is easier and less time-consuming to move forward in future research. As it provides a comprehensive overview of the literature it can also help in understanding the literature and to construct research questions. A theoretical contribution of a mapping study is usually the definition of the needed primary studies in sub-topics. The procedures, forms and experiences

can be also reused, and the results can provide a basis for comparison with the follow-on studies. Finally, the primary studies provided, can be used to validate further research and results (Kitcenham, 2011).

Mapping study of the topic of gamification in entrepreneurial universities

Analysis in the paper follows the logic mapping study process. Figure two shows the steps of the mapping study represented in the paper. Conducting the research, the process of the research was accomplished based to the systematic mapping steps, provided by Petersen et al. (2008).
The screening was conducted through the search in Springer, EBSCO and ScienceDirect. As it is visible on Figure 2, in the 4th step, there is a screening after defining inclusion and exclusion criteria. The used terms in screening is showed by Table 1.

Figure 2. The systematic mapping.



Own source based on: Petersen et al., (2008)

The inclusion criteria were the following:

- Where several papers reported the same study, only the most complete one is included.
- Where several studies were reported in the same paper, each relevant study was treated separately.
- Studies that answer at least one research question.

The exclusion criteria consisted the following:

- Studies that are not written in English.
- The study is not related to institutional education or learning.
- The study does not contain empirical research.

Screening of all papers

Firstly, the screening was conducted based on a separated mapping activity. In the first round, keywords “gamification” and “education” and key words of “entrepreneurial” and “university” or “universities” were screened in the databases (5th step in Figure 2). Our assumption was that entrepreneurial university is an older term. So, the keywords “gamification” and “education” were searched not only in titles of papers but also in abstracts or the whole text. Keywords “entrepreneurial” and “university” or “universities” were searched only in titles of papers. Through the separated search, we could extract data in the following fields:

- Number of selected papers by year,
- distribution by database,
- number of papers by journal,
- number of studies by education level, which is interesting input in case of “gamification”, but not in the focus of this paper and also recall low level of interest as this topic shows increasing number of studies year by year.

The second round of the searching activity was the joint search (6th step in Figure 2). Two ways were applied. In the first case „gamification” was searched in the title and „entrepreneurial” „university” or „universities” in the text - or „entrepreneurial university” or „universities” in the title and „gamification” in the whole text. In the second case, „gamification” or „entrepreneurial” or university” or „universities” words were searched in the whole text. Trough the joint search, we could reflect information in the following categories, represented in the introduction and later in Table 2. of this paper:

- Number of studies by disciplines or subjects.
- Course’ types mentioned in the studies.
- Way of implementation of gamification tools.
- Examined variables in the studies.
- The mostly mentioned gamification tools in the studies
- General outcome or findings of the studies.

RESULTS

In this section, we introduce the results from the step of the screening of all papers (4th step) and then the categorization phase (7th step in Figure 2) in order to represent the possibility of extracting information, which provide a general picture of the research trends. Based on the selection of articles. Table 1. Shows the numerical data of the screening:

Table 1. Number of the searched papers by database. Selection of articles

	FIRST ROUND – SEPARATED SEARCH		SECOND ROUND – JOINT SEARCH	
	„gamification” „education” in abstracts and the whole text	„entrepreneurial university” in titles	In the whole text: „gamification” and “entrepreneur” or „entrepreneurial” and „university”	Duplicates
Springer	269	35	3	1
EBSCO	246	167	11	9
ScienceDirect	194	60	14	10
SUM			28	20

Own source based on the screening process

After making the separated search of papers (5th step in Figure 2) it could be concluded that the number of articles are constantly growing in gamification and there is a continuous increasing trend that more and more empirical papers are written related to gamification in educational context. In case of entrepreneurial university, the first articles have been found from 1989. Number of articles are peaking for 2015. Dominating journals in case of separated search if the

topics can be defined. In case of entrepreneurial university Journal of Technology Transfer and Small Business Economics are the mostly screened Journals in the databases. In case of gamification, there are many Journals in field of IT.
We looked at the education level on this stage of the screening as well. Gamification related articles could be analyzed in term of education level. Most papers investigated the effects of gamification in higher education. In case of entrepreneurial university, this question is not relevant.

Gamification in entrepreneurial universities - specific categories

After making the joint search (6th step in Figure 2), the following information could be extracted to the Classification Table (Table 2) from 20 studies.

Table 2.: Classification Table

AUTHORS	FIELD	COURSE TYPE	WAY OF IMPLEMENTATION	VARIABLES/RESEARCH FOCUS	TOOLS	MAIN FINDINGS
Antonaci et al. (2015)	IT	Entrepreneurship	Stimulation	Students' perception	Serious games	Theoretical model supporting the choice of serious games.
Felker (2014)	IT	Library usage	Online platforms	Online and physical presence of users – Online usage	Information sharing (mobile) applications	Describing ways to gamify libraries and details the effect on students' attitudes to library usage
Holotescu et al. (2017)	Smart Cities	Entrepreneurship	Online platforms	Online usage	Open online courses	Effects of courses on smart city interventions.
Ciupe et al. (2018)	Career	Business and entrepreneurship - entrepreneurship	Simulation	Institutional elements	Virtual enterprise	Link between applying virtual enterprise and five practices in entrepreneurship and entrepreneurial competency model and responses in education.

Sanip & Rahman (2018)	Education	Medicine	Performance systems	Experiences of implementing the system – Professionals' experience	Integrated cumulative GPA	Needed competences and responses for the medical faculty members.
Bodnar et al. (2016)	Education	Engineering	Games	Student learning outcomes – Students' performance	Serious games	Undergraduate student learning was improved by game-based activities
Pianchi & Lió (2017)	Education	Medicine: genomics and bioinformatics - Medicine	Online platforms	Digital-genomic divine – Software performance	Community awareness platforms	Bottom-up development efforts in education. Role of bioinformaticians.
Naaji et al. (2015)	Education	Humanistic, economic, social, medical studies – Mixed courses	Online platforms	e-learning experience of Romanian educational system – exact case analysis	Flipped classrooms + social media	Listing related sciences. Standards required for evaluating the quality of online and blended courses.
Vaughan (2013)	IT	Library usage	Online platforms	Responses of members of the Association of Research Libraries – Library users' responses	Information sharing (mobile) applications	Suggestions to innovative solutions in libraries.
Dziob (2018)	Education	Physics	Serious games	Students' responses with control group's responses – Students' perception	Serious games	New method of student assessment.
Zaina & Alváro (2015)	IT	Entrepreneurship	Online platforms	End user requirements and needs – Users' requirements	Information sharing (mobile) applications	New ideas for software development.

Sousa et al. (2019)	Education	Business and ICT Entrepreneur trainings - Entrepreneurship	Online platforms and games – Mixed platforms	Perceptions of students and entrepreneurs about E-education methods. – Students' and Entrepreneurs' perceptions	Serious games	Gamification is more adequate in creating new ideas and market and product analysis. Skills, motivations, support from the HEI, barriers, difficulties and sociodemographic traits.
Mincha et al. (2018)	Education	Business – Entrepreneurship	Online platforms	Case based outcomes of implementing the program - Exact case analysis	GTP-global talent program	Effects of software usage: skills and competence development.
Seixas et al. (2016)	Education	Elementary school courses – Mixed courses	Online platforms and games – Mixed platforms	Students' engagement level – Students' perception	ClassBadges	Classification of student groups. Strong causality between more rewards and better performances.
Faghihi et al. (2014)	Education	Mathematics	Software	Difference in student performance – Students' performance	Serious games	Students, who used the gamified system reached greater scores Video game elements vs. AI tutoring system (MathDungeon).
Yen-Chun Jim Wu	Education	Entrepreneurship	Online platform, software –	Students' perception	Information sharing (mobile)	mobile-based CRS technology is a useful and

et al. (2017)			Online platforms		applications	effective tool for facilitating interaction among learners and content, enhancing students' engagement with entrepreneurial knowledge acquisition, and improving students' motivation toward increased entrepreneurial capability.
Severengiz (2018)	Education	Engineering education – Manufacturing - Engineering	Gamified class	Students' perception and performance	Gamified examination	Gamifying a classic MC test has no significant impact on the test results and does not influence the perceived level of difficulty of the test questions.
Reise et al. (2014)	Education	Manufacturing - Engineering	Games	Game elements	Serious games	Description of usage of the game
Belotti et al. (2014)	Education	Entrepreneurship	Games	Game elements	Serious games	Overview of relevant SGs available on the market and identifies, through an expert analysis, key benefits and issues concerning their adoption

						in teaching entrepreneurship for the target students.
Popoiu et al. (2012)	Education	Medical courses - Medicine	Social media – Online platforms	Medical educators' experiences – Professionals' experience	Blogs and microblogs	Best practices in teaching.

Own source

Number of studies by discipline or subject

The articles were categorized by the disciplines or fields of subjects in which context's researchers examined gamification tools in universities. Education (14 studies) Information Technology (4 studies), Career, Smart City (1-1 study). It is worth to note, that in empirical studies, in which students are the target, the findings are concluded to effective way of teaching and the positive effects of choosing a gamified process.

Number of studies by courses

In a wide aspect, seven courses could be identified. Obvious outcome is that entrepreneurship courses were represented in the highest number (8 studies) others are medical courses (3 studies), engineering courses (3 studies) and Library usage (2 studies). There were two studies, where more courses were mentioned and physics and math in one-one studies. The fact that entrepreneurship classes were overrepresented is not distorting the answers of the research questions of this paper.

Ways of implementation

It can be defined as novel result that in most of the studies the implementation of online platforms are presented. There are several offline ways of implementation gamification tools (competitions, offline badges, group games). In this focus of papers – in the topic of gamification in entrepreneurial teaching – online based games, social media platforms, other online communication channels are implemented. There are few cases, where gamified examination is presented or performance systems are implemented, but there is no exact information whether they are based on online platform or not. It is more surely that these are based on mixed – online and offline platforms.

Variables or quantifiable outputs

We tried to extract more precisely the variables or quantifiable research focuses in case of empirical researches. The following variables are presented in the selected papers:

- Students' perception.
- Student's performance.
- Students' and entrepreneurs' perception.

- Level of online usage.
- Institutional elements.
- Professionals experience.
- Software performance.
- Case analysis: exact case-based data.
- Library user's experience.
- User requirement: in case of a given program.
- Game elements.

Gamification tools mentioned in the papers

We can agree with the finding of Costa et al. (2017), that it is difficult to categorize gamification tools according to their function, because there are several games with licenced names, which have customized, for their own target. After this mapping, we focused on the followings when we categorized the tools: all the games, which had exact names or brands was categorized in the group of serious games. All the platforms, which had the only function of communication and interaction, were categorized in the group of information sharing "mobile" applications. All the others outside of these two major categories can be differ from serious games and information sharing mobile applications in their functions:

- Open online courses.
- Virtual enterprise.
- Integrated, cumulative GPA.
- Flipped classrooms (social media).
- Global talent program.
- Community awareness platforms.
- Blogs.
- Gamified exams.
- Class badges.

Logic behind this is that we did not want to list all the exact game names presented by several papers, but we did not want to be too general with creating big categories of tools. To do so, we focused on the function of the mentioned tools in the selected papers and categorized them based on it. As a result, we could conduct the list of gamification tools in entrepreneurial teaching based on their function.

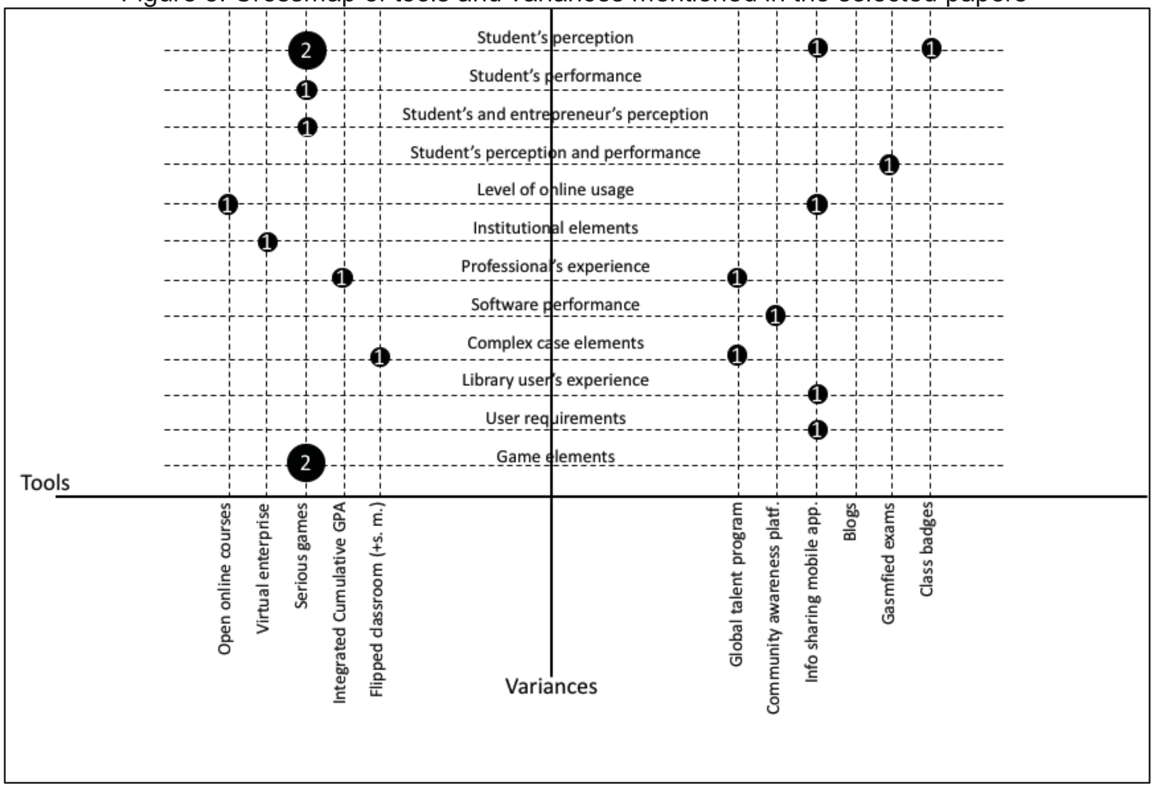
Outcomes or findings of the studies

As it is written in the methodological discussion of mapping study process, it is not needed to collect outcomes in case of each studies. In order to be more focused, thanks to the joint research, we could list the major findings, which can be valuable if they are in one table. Categorization in these ones was also not so direct, like in case of variables. Through the collection of outcomes and findings we were looking for whether gamification provided a positive effect on the different variables that were examined by authors in the articles. Authors represent most of the cases positive effects, which meant that gamification had an overall positive influence on each examined variable. The application of gamification tools in entrepreneurial teaching is presented as effect in the context of open innovation or technology-based entrepreneurship. Obvious, but worth to mention that in studies, where authors mentioned an exact tool (e.g.: exact program names in group of serious games), the applied methodology was case study and the findings were generalized less. There were studies, where the market of the given program was represented in the results (Belotti et al. 2014).

DISCUSSION

Figure 3 shows the mapping of gamification tools mentioned and variables analyzed in the studies in a crossmap. Beside answering the above-mentioned Q1 question of the paper, this figure makes us able to extract the actors of gamification applied in entrepreneurial education (Q2).

Figure 3: Crossmap of tools and variances mentioned in the selected papers



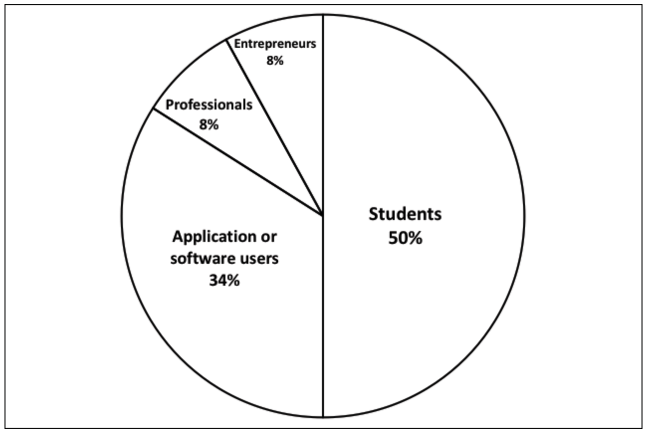
Own source based on the selected papers

Major group of actors, based on the in the selected papers:

- Students
- Professionals
- External users of apps and software applied by the university: entrepreneurs, customers

Main and dominant group of actors based on the analyzed studies are students on the courses, where a given gamification tool is applied. Their perception, performance, requirements, level of usage and soft variables like experience are measured in the studies, mostly in case-based dimension. To be keen on the papers in the final selection, we named customers as users and we can represent the ratio of actors taking part in studies of gamification in entrepreneurial education:

Figure 4: Representation of group of actors in the selected papers



Own source based on the selected papers

Figure 4. shows the ration of target audiences mentioned in the studies. There are an obvious inequality, which gives research gap in field of research on gamification.

Underrepresented fields of research

Through Figure 3, we can define also research gaps (Q3), which can validate new questions in present or further research trends, satisfying the function of mapping study (Kitcenham, 2011). If we look at the variables or the list of actors, studies did not name educator, lecturer or professor as an actor. We did not really find information about the changing role of them, which can be linked to the phenomena of the changing role of homo academicus in the entrepreneurial environment of universities. Advantages and disadvantages of homo oeconomicus has huge literature, while in these studies the focus is mostly the effect of application on students and professionals, who are able to apply the given tool on the classes or in other university operations like library usage. Relatively there are less studies, which are dealing with the needed skills and knowledge of using a gamification tool in in-class processes.
Variables of institutional elements are less represented. Based on this collection of papers a gap is indicated, which focus on the change of institutional elements of universities or their processes. Operational processes, structural changes can be assumed in many cases of implementing a gamification tool. For example, the usage of one software or online based application targets not only one department or course in a university. The implementation of the usage of the given tool requires horizontal management aspects in universities, where departments have high level of autonomy in each case, but they need to share sources in order to use this opportunity efficiently. Here is the question: what are the institutional requirements of an efficient implementation of a gamification tool?
As institutional variables were underrepresented in the extracted data, we can say that the overlap between the research of gamification and entrepreneurial university is not significant interest of researchers in this field. Perception of actors (students, professionals, entrepreneurs and software users- are the dominant focus of the selected articles.

CONTRIBUTION

Overall expectation of this analysis was to get some commonly examined trends both in topic of gamification and entrepreneurial university. We can say that logic of this mapping study process

was appropriate to find the final selected papers, which are the closest to the overlap of these topics.
The application of gamification tools in entrepreneurial teaching is presented as effect in the context of open innovation or technology-based entrepreneurship. Although there are growing number of analyzed studies in each topic, the overlap between applying gamification tools and examining their effects in entrepreneurial higher education institutions is relatively small comparing to the gamification effects on actors' perceptions or experience in them.
Through the application of mapping study, paper's theoretical contribution is visible. Applying the mapping study gives the novel result, that this method can contribute firstly to the reasonability of the synthesis of different research topics, which are linked together in one institution. Mapping study help to get an insight, whether different research topic is analyzed hand in hand or separately on empirical base. Secondly, this method also contributes to the validation of future research questions based on the logical screening and extraction of data of the papers.
This study was focusing on the fields, course types, gamification tools, ways of their implementation and examined variables. Classification behind this focus was enough to represent the actors of gamification in entrepreneurial universities with the exception of academic faculty members. It is an empirical gap, which was highlighted in this research.
Another empirical contribution we would like to mention is the underrepresented institutional aspects compared to actors' perception, requirements and experiences. Gamification tools are implemented in universities. Especially in case of online systems, most of the times, efficiency of them is based on the number of users. The higher the users number, the better is the given software or platform.
In case of this selection of the papers we could see that there is not unified vocabulary for gamification tools. In case of this mapping study the results can support the statement of Costa et al. (2017). Although mentionable research contribution can be that we extracted the gamification tools based on their functions. At the same time, we admit the difficulty of categorization of these tools:

Table 3. Tools and their functions of gamification in entrepreneurial education

TOOL	FUNCTION
Serious games	Learning
Info sharing (mobile) applications	Sharing information
TOOL WITH PLUS FUNCTIONS	PLUS FUNCTIONS
Open online courses	Recruiting
Virtual enterprise	Enterprising
Integrated, cumulative GPA	Testing
Flipped classrooms (social media)	Grouping
Global talent program	Sample tracking
Community awareness platforms	Grouping
Blogs	Testing
Gamified exams	Exam
Class badges	Rewarding

Own source based on the selected papers

Table 3 summarizes the functions of gamification in entrepreneurial education. As it was assumed previously, we realized overlap as serious games and info sharing applications have general functions in this grouping, which are represented by other tools listed under them.

RESEARCH LIMITS

In this research it was difficult to define each gamification tool. In many cases there were mixed tools. Offline ways of implementation were not visible in every cases. Categorization of gamification tools in this analysis lead to overlaps among gamification tools.
Other cross maps and Tables are available upon a request.

ABSTRACT

In this research, a chance-constrained bi-objective optimization model for hazardous materials (hazmat) distribution problem is developed. The goal is to find optimal links and routes to obtain a trade-off between the safe and fast distribution of hazmat through a transport network under customers' demand and service time uncertainty along with unknown probabilities for hazmat incidents in a link-based model. We also develop a solution method based on a hybrid Monte-Carlo simulation and compromise programming to determine the optimal solutions. Computational results of a real case study are also provided to illustrate the effectiveness of the model and the solution method.

KEYWORDS: Hazardous material, vehicle routing and scheduling problem, demand uncertainty, service time uncertainty, chance-constrained programming, multi-objective optimization

INTRODUCTION

The inherent properties of Hazardous Materials (hazmats) are such that its production, warehousing, and transportation activities impose serious risks to both society and its surrounding environment. A large proportion of hazmats shipments that are transported in-land is carried by trucks. In the United States, about 60% of the tonnage of total hazmat shipments are reported to be transported by trucking industry (U.S. Department of Transportation, 2017). Commercial carriers in the United States transport over 3 billion tons of hazardous materials each year. Such hazmat shipments can be highly risky and highly sensitive and if improperly handled, labeled, or packaged could result in the loss of life, property damage, and harm to national security interests.

Compared to the number of shipments and the amount of hazmat transported through the transport networks, the number of hazmat incidents, fatalities, injuries and economic loss compared to the flow of hazmats are diminutive, approximately 10^{-6} per vehicle-miles traveled (Harwood *et al.*, 1993). As such, hazardous material transportation planning has been categorized as Low-Probability-High-Consequence (LPHC) problem. Although the number of hazmat transportation incidents is a very small fraction compared to the total number of shipments, due to nature of hazmats, there will be tremendous societal costs as well as environmental impacts in a case of an incident. These consequences make hazardous materials transportation, routing, and scheduling operations very important and sensitive logistical decisions.

Hazmat incidents are rare events as such estimating the likelihood of their occurrence based on historical data is challenging. Moreover, the road network is naturally a dynamic system. The changes in the existing roads, expansion of the network, and the development of new roads mean that reliable historical data may not be available to be used for estimating the likelihood of incidents. As such, we encounter a transportation network in which incident probabilities are unknown or uncertain. Therefore, unlike the majority of the traditional literature, this research focuses on unknown incident probabilities. Risk and time (or cost) are the two indispensable objective functions of the Hazardous materials Vehicle Routing and Scheduling Problem with Time Windows (HVRPTW) that govern both path choice and routing (Pradhananga *et al.*, 2014). Despite the practical significance, HVRPTW-related research is not widely practiced. The present study is an effort to fill in the gap of the literature and aims for the development of an efficient optimization model for the HVRPTW addressing the practical aspects of hazmat transportation.

The remainder of this paper is organized as follows: the relevant literature is reviewed in Section 2. The detailed problem description along with its difficulty aspects and assumptions is presented in Section 3, and it is mathematically formulated in Section 4. Computational results including the presentation of a case study, and the practicality of the optimal solutions are discussed in Section 5. Section 6 concludes the paper by highlighting the contributions and provides direction for future research.

LITERATURE REVIEW

The traditional approach to model the routing and/or scheduling decisions assume that incident probabilities are known. The alternative approach is that these probabilities are unknown. One of the early studies to deal with unknown probabilities of hazmat incidents is found in (Bell, 2007). In that study, a two-player non-cooperative game is considered between the network user seeking a path to minimize the expected trip cost and on the other hand, an “evil entity” choosing link performance scenarios to maximize the expected trip cost. The applications of the classic two-player non-cooperative game are also found in (Szeto, 2013) and (Szeto *et al.*, 2017). However, all of these studies used single-objective optimization models to formulate the two-player non-cooperative games. Other recent significant studies that employed single-objective mathematical models can be found in (Dadkar *et al.*, 2010), (Hu *et al.*, 2017), and (Kumar *et al.*, 2018).

Combined routing and scheduling of hazmat shipments under multiple objectives in networks that have time-dependent attributes has also been studied in the literature (Androutsopoulos and Zografos, 2010), and (Androutsopoulos and Zografos, 2012). Chang *et al.* (2005) developed a method for finding non-dominated routes for multiple routing objectives in transport networks in which the routing attributes are uncertain and the probability distributions that describe those attributes vary by time of day. Pradhananga *et al.* (2014) developed a Pareto-based bi-objective optimization of hazardous materials vehicle routing and scheduling problem with time windows for a realistic case study. Esfandeh *et al.* (2016) investigated dual-toll setting as a policy tool to mitigate the risk of hazmat shipment in road networks by formulating the dual-toll problem as a bi-level program in which the upper level aims at minimizing the risk, and the lower level explores the user equilibrium decision of the regular vehicles and hazmat carriers.

The hazardous materials distribution problem involves the determination of the sequence of deliveries and the corresponding paths assigned to each truck. Erkut and Alp (2007) considered an integrated routing and scheduling problem in hazardous materials transportation where accident rates, population exposure, and link durations on the network varied with time of day and tried to minimize risk in the form of accident probability. Ma *et al.* (2012) investigated vehicle routing problem with time windows and link capacity constraints to transport hazardous materials using a tabu search heuristic with an adaptive penalty mechanism (TSAP) to help manage company’s vehicle fleet. Bronfman *et al.* (2015), Bronfman *et al.* (2016) and Garrido and Bronfman (2017) studied the hazmat routing problem from an origin to a destination in an urban area in order to maximize the distance between the route and its closest vulnerable center, weighted by the center’s population.

Applications of stochastic models have also been found to the hazmat routing and scheduling problem. Jia *et al.* (2011) formulated a hazmat problem to minimize the risks from a natural accident and the uncertainty of a terrorist threat and developed a fuzzy-stochastic constraint programming method to deal with multiple uncertainties. Desai and Lim (2013) employed a Stochastic Dynamic Programming (SDP) approach to solving the hazmat route selection problem to determine the optimal routing policies in a stochastic dynamic network. In order to expedite the process of obtaining optimal routing policies they proposed three techniques for pruning stochastic dynamic networks as (1) use of static upper/lower bounds, (2) pre-processing the stochastic dynamic networks by using the start time and origin location of the vehicle, and (3) a mix of pre-processing and upper/lower bounds. Pamucar *et al.* (2016) proposed a new approach for cost and risk assessment in the multi-objective selection of routes for the transport of hazardous materials on a network of city roads based on the application of an Adaptive Neuro-Fuzzy Inference System (ANFIS).

PROBLEM DESCRIPTION

The proposed integrated routing and scheduling problem involves three underlying definitions: loss, expected loss, and total expected loss. Loss (expected loss) is defined as the number (expected number) of people affected in the event of accidents. Expected loss can be defined on the link, route, and network levels. The expected loss on a link (route) is the expected number of people affected in the event of accidents on that link (or route). The sum of the expected loss on all links or routes gives the total expected loss in the network. For each link *ij*, $loss_{ij}$ is measured by the population inside a circle of given impact radius, centered at any point on link *ij*, in the event of an accident from node *i* to node *j*. The impact radius would depend on the hazardous material under consideration, and can vary from several feet to several miles (Erkut and Verter, 1998).

Link failure is usually rare, so as previously mentioned there is likely to be insufficient data from which to estimate failure probabilities. Hence q_{ij}, the conditional probability of an incident on link *ij*, is unknown. We assume that the dispatcher plans on the basis of one link failure. Multiple link failures are excluded from consideration in this study as they are too unlikely. However, they can be considered in a case of an extensive natural disaster such as earthquake, flood, or hurricane. Aside from the total expected loss, the dispatcher is interested in finding the shortest paths in the distribution network that can start from any of the origins and end at any of the destinations. So the dispatcher's problem involves in finding the safest links and routes with regard to the risk of population exposure and simultaneously determining the shortest paths within the distribution network.

The necessary underlying assumptions are listed as follows:

- The numbers and locations of the depots and customers are predetermined;
- The capacities of depots are known and deterministic while the demand and service time of customers are associated with uncertainty;
- Each customer can be served by multiple depots and multiple vehicles;
- The quantity of total supplies is greater than the quantity of total demands;
- Customers' demand must be serviced within pre-specified time windows and waiting due to early arrival is possible, while late arrival is not allowed at all;
- All vehicles must start and end their routes at the depots. The time of starting and ending the operations of the vehicle must be within the time windows specified at the depot;
- The probability of an incident on a link is unknown;
- The probability of using a link is unknown;

- Simultaneous hazmat incidents will not happen. The reason is that a hazmat incident is a low-probability event. Naturally, multiple link failures are very unlikely.

PROBLEM FORMULATION

Notation

In this section, we introduce the notation used in the paper to formulate the problem mathematically.

Sets

N	set of nodes in the network *G*
A	set of links in the network *G*
O	set of origin nodes in the network *G*
D	set of destination nodes in the network *G*
F	set of objective functions

Indices

i	Index for node *i* in the network *G*, *i* = 1, …, *N*
j	Index for node *j* in the network *G*, *j* = 1, …, *N*
k	Index for node *k* in the network *G*, *k* = 1, …, *N*

Parameters

$Loss_{ij}$	Loss, or population exposure, is defined as the number of people impacted in the event of an accident on link *ij*, $i \in N, j \in N$
$Dist_{ij}$	Travel distance (or time) from node *i* to node *j*, $i \in N, j \in N$
Dem_i	Demand for hazmat at node *i*, $i \in D$, random variable with mean μ_{Dem_i}, standard deviation σ_{Dem_i}, and the cumulative probability distribution of F_{Dem_i}
Tme_i	Earliest allowed arrival time at node *i*, $i \in D$
Tml_i	Latest allowed arrival time at node *i*, $i \in D$
Tmv_i	Stop or visit (i.e., service) time at node *i*, $i \in D$, random variable with mean μ_{Tmv_i}, standard deviation σ_{Tmv_i}, and the cumulative probability distribution of F_{Tmv_i}
Tmpm	Travel time per mile
Tmax	Maximum time for any trip
Dmax	Maximum distance for any trip
Vcap	Capacity of vehicles
Maxveh	Maximum number of vehicles
ε_{Dem}	Pre-determined satisfaction level of probabilistic demand constraints
ε_{Tmv}	Pre-determined satisfaction level of probabilistic service time constraints

Decision variables

x_{ij}	Binary variable equals to 1 if a vehicle travels from node *i* to node *j*, $i \in N, j \in N$; otherwise it is equal to 0.
p_{ij}	Probability of link *ij* selected for shipment, $i \in N, j \in N$
q_{ij}	Conditional probability of an incident on link *ij* given that an incident occurs, $i \in N, j \in N$
u_i	Accumulated deliveries of hazmat at node *i*, $i \in D$
td_i	Total travel distance for node *i*, $i \in D$
tma_i	Arrival time at node *i*, $i \in D$

Development of Mathematical Models

The routing and scheduling problem described above is a bi-objective decision problem. The first objective is to minimization transport risk associated with the unknown probability of incidents and links selection. In order to formulate the objective function, we employ a game theoretic approach in which it is assumed there is a two-player game between a dispatcher, who seeks a least cost tour, and nature (e.g., demon), with the power to cause one link to fail. This zero-sum, non-cooperative, two-player game mimics the mental process of a risk-averse dispatcher seeking the best route by considering a sequence of worst-case scenarios and his responses in each case. As *m* tends to infinity, the link use and failure probabilities tend to the mixed strategy Nash equilibrium as shown in the following bi-level *minimax* objective function.

$$Min_p\ (Max_q(\sum_{i=1}^{N}\sum_{j=1}^{N} Loss_{ij}.p_{ij}\ .q_{ij})) \tag{1}$$

Additionally, the second objective function tries to minimize the total travel distance determining the shortest paths within the distribution network as formulated in equation (2).

$$Min\ f_2 = \sum_{i=1}^{N}\sum_{j=1}^{N} Dist_{ij}.x_{ij} \tag{2}$$

In order to complete the mixed strategy Nash equilibrium, equation (3) indicates that there is only one link failure in the network. The risk-averse dispatcher, in general, will not wish to use one route but rather a mix of links so generally ($\sum_{i=1}^{N}\sum_{j=1}^{N} p_{ij} \geq 1$). Equations (4)-(6) impose the requirement of using a mixed strategy for link selection probabilities at the origin, destination, and intermediate points.

$$\sum_{i=1}^{N}\sum_{j=1}^{N} q_{ij} = 1 \tag{3}$$

$$\sum_{j=1, j\neq i}^{N} p_{ij} = 1 \quad \forall\ i \in O \tag{4}$$

$$\sum_{i=1, i\neq j}^{N} p_{ij} = 1 \quad \forall\ j \in D \tag{5}$$

$$\sum_{i=1, i\neq k}^{N} p_{ik} - \sum_{j=1, j\neq k}^{N} p_{kj} = 0 \quad \forall\ k \notin O, k \notin D \tag{6}$$

Equation (7) requires that inbound and outbound transported hazmat for intermediate nodes to be equal. In order to mandate that a link is available to transport hazmat whenever the link is included in a mixed strategy (its probability of selection is greater than zero), constraint (8) uses a very large number, *M*, enforcing the equivalent if-then-constraint is met. In addition, equation (9) ensures that a vehicle does not travel within the same node.

$$\sum_{i=1, i\neq k}^{N} x_{ik} - \sum_{j=1, j\neq k}^{N} x_{kj} = 0 \quad \forall\, k \notin O, k \notin D \tag{7}$$
$$x_{ij} \leq M.p_{ij} \quad \forall\, i \in N, j \in N \tag{8}$$
$$x_{ii} = 0 \quad \forall\, i \in N \tag{9}$$

Equation (10) requires that a vehicle can enter a destination node *k* from node *i* if it comes either from a depot that indicates it has enough supply to provide or from a destination node in which the total demand at both nodes does not exceed the vehicle's capacity. Similarly, equation (11) enforces that a vehicle must leave node *k* after service to a node *j* with the condition of the next node is either a depot or the vehicle has enough supply to serve the next demand node.

$$\sum_{\substack{i=1, i\neq k,\\ i\in O \text{ or } Dem_i + Dem_k \leq Vcap}}^{N} x_{ik} = 1 \quad \forall\, k \in D \tag{10}$$
$$\sum_{\substack{j=1, i\neq k,\\ j\in O \text{ or } Dem_j + Dem_k \leq Vcap}}^{N} x_{kj} = 1 \quad \forall\, k \in D \tag{11}$$

Constraint (12) restricts the probability of the accumulated hazmat deliveries at destination points to be greater or equal to the demand and less than or equal to the vehicles' capacity. If destination node *k* is visited after destination node *i*, then the probability of the difference of accumulated hazmat delivered at each node, $u_k - u_i$, should be bounded to the vehicle's capacity and fulfilled stochastic demand as formulated in constraint (13). On the other hand, if destination node *k* is the first stop after the depot then the probability of the entire demand for the node can be fulfilled, $u_k = Dem_i$ by constraint (14) otherwise, this probability of the demand will be provided by multiple vehicles coming from other nodes as formulated by constraint (15).

$$P(Dem_k \leq u_k \leq Vcap) \geq \varepsilon_{Dem} \quad \forall\, k \in D \tag{12}$$
$$P(u_k \geq u_i + Dem_k - Vcap + Vcap.(x_{ki} + x_{ik}) - (Dem_k + Dem_i)x_{ki}) \geq \varepsilon_{Dem} \quad \forall\, i \notin O, k \in D, i \neq k \tag{13}$$
$$P(u_k \leq Vcap - (Vcap - Dem_k)x_{ik}) \geq \varepsilon_{Dem} \quad \forall\, i \in O, k \in D \tag{14}$$
$$P\left(u_k \geq Dem_k + \sum_{i=1, i\notin O}^{N} Dem_i.x_{ik}\right) \geq \varepsilon_{Dem} \quad \forall\, k \in D \tag{15}$$

Constraints (16) and (17) calculate the total travel distance from depots to the destinations nodes and from each destination node to other destination nodes. Constraint (18) restricts the total distance traveled by each vehicle from depots to be less than maximum distance allowed on a trip.

$$td_j \geq Dist_{ij}.x_{ij} \quad \forall\, i \in O, j \in D \tag{16}$$
$$td_j \geq td_i + Dist_{ij}.x_{ij} - Dmax(1 - x_{ij}) \quad \forall\, i \notin O, j \in D \tag{17}$$
$$td_i \leq Dmax \quad \forall\, i \in O \tag{18}$$

Constraints (19)-(21) represent the time window requirements for the arrival and departure of vehicles to the destination nodes. Inequality (19) defines the probability of the arrival time of a vehicle at node *k* after it visited or served previous destination node *i* to be greater than or equal to the latest allowed arrival time at node *i* plus the service time at node *i* and travel time required to go from node *i* to *k*. Constraint (20) restricts the decision variable of arrival time to be within allowed early and late arrivals in which a vehicle is allowed to wait in order to arrive no earlier than early arrival time. Constraint (21) enforces the probability of the triangle inequality requirement of maximum trip time for arrival time, service time, and travel time between the origin points and destination points in the network to be greater than a specified satisfaction level.

$$P(tma_k \geq tma_i + (Tmv_i + Tmpm.Dist_{ik})x_{ik} - Tml_i(1 - x_{ik})) \geq \varepsilon_{Tmv} \quad \forall\, k \in D, i \neq k \tag{19}$$
$$Tme_k \leq tma_k \leq Tml_k \quad \forall\, k \in D \tag{20}$$
$$P(tma_k + Tmv_k + Tmpm.Dist_{ki}.x_{ki} \leq Tmax) \geq \varepsilon_{Tmv} \quad \forall\, i \in O, k \in D \tag{21}$$

In order to calculate the minimum number of vehicles to transport the hazmat from depots to the destination locations, $Vehf$, the following probability inequality (22) is formulated. Since $Vehf$ may be fractional in value so it will be rounded to the next integer using equation (23).

$$Vehf \geq P\left((\sum_{i=1, i \notin O}^{N} Dem_i)/Vcap \right) \tag{22}$$
$$Vehr = int(Vehf + 0.999) \tag{23}$$

The dispatcher is required to send enough vehicles from the depots to the destination nodes to ensure that demand for hazmat will be fulfilled by the coming vehicles. This requirement is formulated by constraint (24). Furthermore, constraint (25) requires that the number of dispatched vehicles is always less than the maximum number of vehicles available.

$$\sum_{i=1, i \in O}^{N} \sum_{j=1, j \in D}^{N} x_{ij} \geq Vehr \tag{24}$$
$$\sum_{i=1, i \in O}^{N} \sum_{j=1, j \in D}^{N} x_{ij} \leq Maxveh \tag{25}$$

Finally, constraints (26) and (27) restrict the probability of link selection, p_{ij}, and the conditional probability of link failure, q_{ij}, to be in the range of [0,1]. Constraints (28) and (29) mandate the requirement for decision variables, x_{ij}, to be binary variables and the decision variables $u_i, td_i, \text{and } tma_i$ to be positive.

$$0 \leq p_{ij} \leq 1 \quad \forall\, i \in N, j \in N \tag{26}$$
$$0 \leq q_{ij} \leq 1 \quad \forall\, i \in N, j \in N \tag{27}$$
$$x_{ij} \in \{0, 1\} \quad \forall\, i \in N, j \in N \tag{28}$$
$$u_i, td_i, tma_i \geq 0 \quad \forall\, i \in N, j \in N \tag{29}$$

M is a very large number

CASE STUDY AND COMPUTATIONAL RESULTS

Network and Data Setting

Chance-constrained bi-objective hazmat routing and scheduling is a new problem and no test instances have been developed for the problem yet. Therefore, we have adopted a real distribution problem encountered by a chemical plant and designed a new test problem capturing our new stochastic features to demonstrate an application of the developed model and the solution method. The case study problem is inspired by a distribution of sulfuric acid by our industry collaborator from a chemical plant in Chicago, IL (labeled in red) for industrial use in 11 major US cities (labeled in blue) located in the Midwest and the West Coast as shown in Figure 1. Sulfuric acid is an important chemical commodity, and it has been suggested that a nation's sulfuric acid production is a good indicator of its industrial strength.

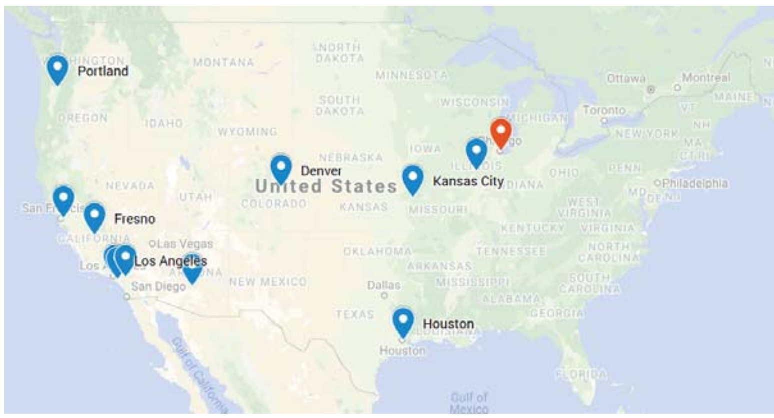

Figure 1. Location of the chemical plant (red label) and industrial facilities (blue labels)

The transportation network has 12 nodes and 66 bi-directional links which is equivalent to 132 unidirectional links (inside-the-city travel links are eliminated).The population of the cities was extracted from the estimates calculated by the United States Census for 2018. Demand for sulfuric acid at the industrial facilities is calculated based on the average consumption rate of the facilities. It also is assumed that there will be enough semi-truck tankers each with the capacity of 18,000 liters. Table 1 demonstrates the estimated population in cities, average and standard deviation of demand and service time, and the requirements for the earliest and latest allowed arrival time to the cities. All parameters are chosen in a realistic order of magnitude.

Table 1. Population and logistics data of the nodes in the distribution network

Node	City	Population	Average Demand (10000 L)	SD of Demand (10000 L)	Average TMV (hr.)	SD of TMV (hr.)	TME (hr.)	TML (hr.)
1	Chicago	9,533,040	0	0.00	0.00	0.000	0.00	1666.65
2	Denver	2,888,227	6	0.60	0.17	0.028	16.67	41.67
3	Fresno	972,297	3	0.33	0.20	0.040	46.67	48.33
4	Houston	6,313,158	7	1.68	0.17	0.040	33.33	50.00
5	Kansas City	2,159,159	7	1.05	0.17	0.030	30.00	65.00
6	Los Angeles	13,131,431	18	3.06	0.23	0.047	60.00	65.00
7	Oakland	425,195	4	0.48	0.17	0.037	58.33	65.00
8	Anaheim	352,497	5	0.50	0.17	0.017	40.00	63.33
9	Peoria	373,590	2	0.38	0.17	0.027	1.67	13.33
10	Phoenix	4,737,270	6	0.90	0.17	0.030	25.00	40.00
11	Portland	2,389,228	7	0.84	0.18	0.044	30.00	46.67
12	Riverside	303,871	2	0.28	0.20	0.036	31.67	63.33

In order to calculate the population loss in the distribution network, it is assumed that only a small fraction of the population would be impacted depending on how close and dense the population is scattered around the network's links. We used a gravity-based method to estimate the impacted population (i.e., population loss) in case of a catastrophe event. The travel distance between the cities was extracted from Google Maps.

For computational purposes, we can use either normal distributions or triangular distributions to represent demand and service time uncertainty. The reason to choose these two distributions in this study is that they are easy to understand and it is intuitive for practitioners to describe the uncertain demand and service times in these forms. The normal distribution is a common assumption and is easily described by two parameters, the mean and the variance. Like the well-known beta distribution used in PERT/CPM, the triangular distribution allows practitioners to describe the random demand and random service time in a limited region with three parameters; the minimum value, the most likely value, and the maximum value.

The average speed for semi-truck is assumed to be 50 mph (i.e., travel time per mile is 1.2 min/mile) and the maximum distance allowed on a trip for a vehicle is 5000 miles. Finally, we set $\varepsilon_{Dem} = \varepsilon_{Tmv}$ during the solution process. It is possible to explore the solutions with different ε_{Dem} and ε_{Tmv} values. However, the system's reliability level, described by different ε_{Dem} and ε_{Tmv} levels, is less meaningful for practitioners to interpret. We set $\varepsilon_{Dem} = \varepsilon_{Tmv} = 0.90$ to find the ideal solutions with respect to each objective function and Pareto optimal solutions for that level of reliability. LINGO optimization software (LINGO 18.0, unlimited version) is utilized to solve the compromise programming sub-model in the algorithm.

Properties of the Optimal Solutions for Individual Objective Functions

Table 2 shows the optimal routes and schedules with respect to the first objective function independently while ignoring the other objective function subject to the functional and operational constraints. It can be observed that the optimal solution for objective function (1) with the lowest possible value for the total expected loss, number of people affected, is 946 while the total travel distance is 29073 miles. In this case, it can be stated that the dispatcher tends to diversify the link selection probabilities as much as possible in order to reduce the negative effect of potential hazmat spillage due to possible link failures. It is found that the optimal solution consists of 58 (out of 132) candidate links with non-zero probability indicating the availability of a large selection poll. In addition, if a link has zero selection probability, it will not be advisable to use that link to transport any amount of hazmat. According to this optimal scenario, 20 candidate links are finally selected to transport sulfuric acid from the chemical plant to the industrial facilities. The modeling approach also enables the dispatcher to choose different vehicles to distribute hazmat shipments. Table 2 also illustrates that there are nine vehicles required through 20 different routes for safest distribution of sulfuric acid in the network while meeting demand and service time requirements.

Table 2. Optimal routes for the objective function of total expected loss ($f_{1,min}$ = 946 people and f_2 = 29073 miles)

Vehicle	Routes	Arrival Time (hr.)
1	Chicago → Denver	19.9
	Denver → Chicago	40.0
2	Chicago → Kansas City	30.0
	Kansas City → Houston	44.4
	Houston → Chicago	65.9
3	Chicago → Los Angeles	60.0
	Los Angeles → Chicago	101.3

Vehicle	Routes	Arrival Time (hr.)
4	Chicago → Oakland	65.0
	Oakland → Chicago	107.8
5	Chicago → Anaheim	61.5
	Anaheim → Chicago	102.7
6	Chicago → Peoria	3.0
	Peoria → Chicago	6.2
7	Chicago → Phoenix	34.3
	Phoenix → Chicago	68.7
8	Chicago → Portland	41.7
	Portland → Chicago	83.5
9	Chicago → Riverside	40.1
	Riverside → Fresno	46.7
	Fresno → Chicago	90.1

Table 3 shows the optimal routes and schedules with respect to second objective function independently while ignoring the first objective function (total expected loss) subject to the functional and operational constraints. The optimal solution with respect to the total travel distance results to the minimum 15,997 miles of travel but it affects 125,181 people of the population. Under this optimal scenario, the travel distance can be improved by 45% at most, while the total expected loss is increased by 132 times. The link selection probabilities in this situation reveal a different pattern as the optimal solution enforces the dispatcher against diversification as there are only 38 (out of 132) candidate links with non-zero probability. However, only 15 candidate links are finally selected to transport sulfuric acid from the chemical plant to the industrial facilities. Table 3 indicates that to meet the customers demand and their required service time restrictions only 4 vehicles are required through 15 different routes for the fastest distribution of sulfuric acid in the network. This pattern of optimal solution indicates that if the dispatcher goal is to only minimize the total travel distance, the optimal solution narrows down the dispatcher's choice to fewer candidate links from the distribution network, but these links will have a much higher likelihood for selection resulting to a significant increase of impacted population.

Table 3. Optimal routes for the objective function of total travel distance (f_1 = 125181 people and $f_{2,min}$ = 15997 miles)

Vehicle	Routes	Arrival Time (hr.)
1	Chicago → Denver	19.9
	Denver → Portland	46.7
	Portland → Oakland	65.0
	Oakland → Chicago	107.8
2	Chicago → Los Angeles	60.0
	Los Angeles → Chicago	101.3
3	Chicago → Peoria	3.0
	Peoria → Kansas City	30.0
	Kansas City → Houston	44.4
	Houston → Chicago	65.9
4	Chicago → Phoenix	34.5
	Phoenix → Fresno	48.3
	Fresno → Anaheim	53.5
	Anaheim → Riverside	60.1
	Riverside → Chicago	100.4

CONCLUSIONS AND FUTURE RESEARCH

This research developed an integrated routing and scheduling hazmat transportation problem with multiple supply and demand locations and unknown link incident probabilities. A new chance-constrained bi-objective network optimization model was formulated to minimize the total expected loss (based on the risk of population exposure) and the total travel distance for a hazmat distribution problem with time windows in which uncertain demand and service times are captured by well-known probability distributions. In order to illustrate the effectiveness of the developed mathematical model and the solution method in obtaining Pareto-optimal solutions, a real case study was solved and analyzed. For future research, exact and heuristic approaches that include novel mathematical programming components can be examined especially for very large-scale problems. In addition, possible extensions can be made to the window reduction and partition approach originally developed for the multiple traveling-salesman problems with time windows. Incorporating of some more realistic constraints (e.g., special-line transportation, temporary warehousing, fatigue driving, and government rules of banning road accessibility, among others) may also be taken into account to reflect more practical aspects.

ABSTRACT

As a necessity of life, smartphones have become rapidly popular in China in recent years. Chinese consumers' never-ending demands for superior function, performance and appearance push them to replace smartphones more frequently, bringing in huge market opportunities for smartphone marketers. In contrast to the previous studies that focus on cognition, this research takes an affective approach to consumer's decisions of replacing consumer and analyzes the impacts of consumers' anticipated regret on their smartphone replacement decisions based on empirical data collected in China. The respective moderating effects of consumers' novelty seeking and need for uniqueness are subsequently examined.

KEYWORDS: Anticipated Regret, Intention to Upgrade, Intention to Switch Brands, Novelty Seeking, Need for Uniqueness, Moderation

INTRODUCTION

Nowadays, smartphones have become an indispensable part of people's life. According to a report quoted by US technology media Mashable, the smart phone penetration rate in China was 58% in 2016 and the figure reached 89% in 2018. Zenith's research report in 2017 showed that the number of smartphone users in China would reach 1.3 billion in 2018, ranking first in the world. As people become more and more dependent on smartphones, they become more demanding for functions, specifications and other attributes. As a result, people's consumption of smartphones is rapidly increasing, and the frequency of replacement is getting faster. With the increasing market saturation, the business competition becomes gradually fierce. Therefore, the decisions of consumers on smartphone replacement have become the focus of business and a challenge for all smartphone manufacturers. According to the "2017-2022 China Smart Phone Market In-depth Evaluation and Development Trend Research Report", consumers are not as sensitive to the monetary cost of replacing smartphones as they used to be. The frequency of smartphone replacement among consumers remains high, with 32% of consumers willing to replace their phones within 6 months.

For smartphone manufacturers, the huge smartphone replacement market has become a major battleground. There is a profound difference in marketing for manufacturers between attracting a new consumer and persuading an existing consumer to replace his/her product. Nevertheless,

the previous literature makes no distinction between the first purchase decision and the replacement decision in discussing consumer decision of purchasing smartphones. Most of existing studies address the cognitive aspect of consumer replacement and upgrade decisions (cf. Bellezza, Ackerman, & Gino, 2017). Fewer studies that discuss the replacement decision of consumers are mainly from the perspective of affective psychology, ignoring the fact that consumers may not be completely rational ones and they make decisions with affect. A direct relationship between affect and action may appear obvious (Frijda, 2010). Actually, affective judgments are fairly independent of, and even precede, the perceptual and cognitive activities in consumer behavior (Zajonc, 1980). It is evident that consumers' affect plays an important role in consumer behavior. For instance, Westbrook (1987) indicated that consumers' affect is highly associated with post-purchase behaviors such as complaint and word of mouth as well as with purchase intention (Ruth, Brunel, & Otnes, 2002). Affect has not been fully empirically studied and discussed in the durable replacement literature. This research incorporates the affective psychology of consumers, i.e. anticipated regret, into the analysis of consumer replacement decision. Specifically, it hopes to explore the impact of consumers' anticipated regret on their product upgrading and brand switching decisions. Novelty seeking and need for uniqueness are selected as moderators because these two factors are the most important consumer traits that may affect the affect- behavior linkage.
The main research objectives are summarized as follows:

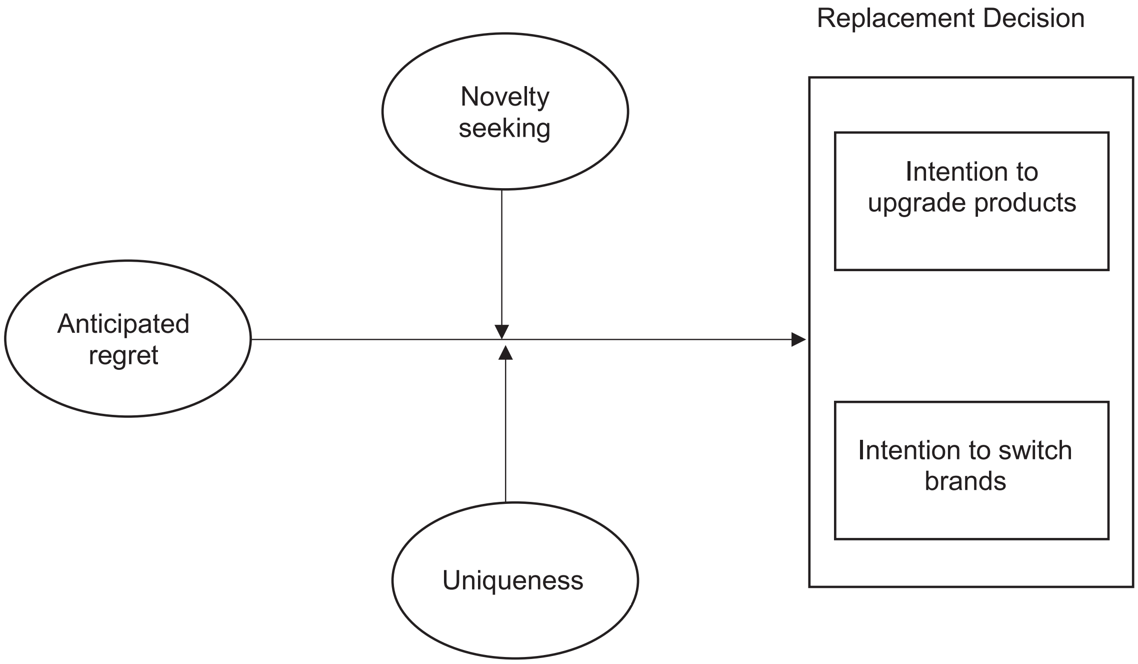
1. To investigate the impact of consumers' anticipated regret on smartphone upgrade and brand switching decisions.
2. To explore the moderating effects of consumers' novelty seeking and uniqueness on the relationship between anticipated regret and replacement decisions.

Empirically, it is hoped that this study can provide guidance for the marketing of smartphone.

LITERATURE REVIEW AND THEORETICAL DEVELOPMENT/MODEL

A research framework is therefore proposed, as shown in Figure 1, to analyze the relationships between consumers' anticipated regret and their intention to upgrade and switch brands. The relationships are expectedly moderated by novelty seeking and need for uniqueness. According to Dickson (1982), the interactionist perspective is the theoretical basis of the moderating effects, and it advocates that consumers' behaviors depend on the context, the individual differences and the interaction between them. These two moderators are used to reflect the contingency about the heterogeneity of consumers. Novelty seeking (Tse & Crotts, 2005) and need for uniqueness (Snyder & Fromkin, 1977) are both consumer traits that are the manifestations of individual differences and may have moderating effects on consumers' behaviors. At the same time, in order to avoid other confounding influences on dependent variables, this study uses consumer satisfaction as a control variable when analyzing the proposed direct and moderating effects.

Figure 1. Research Framework: Anticipated regret and the Intention to upgrade and to switch brands



Anticipated Regret and the Intention to Upgrade and Switch Brands

In the context of consumer purchase decision making, regret will not only occur when purchase is realized but may also appear before purchase. Researchers in psychology have found that, when people face counterfactual comparisons, they learn to anticipate the regrets they will have and try to minimize this kind of future regret in various ways (Meller et al., 1999; Zeelenberg & Beattie, 1997). This kind of regret of pre-purchase illusion is called anticipated regret, as opposed to experienced regret, which is felt through actual comparison after purchase. Janis and Mann (1977) used anticipated regret as an allusion to the main psychological effect of various worries about loss, which is, the materialized loss that troubles decision-makers before their decisions. Anticipated regret is usually divided into upward anticipated regret and downward anticipated regret (Roese, 1997). The upward anticipated regret usually restrains consumers' emotions when making their purchase decisions, which accordingly increases their preferences for conservative purchase. In his research on the decision-making behavior of consumers, Simonson (1992) found that after knowing that they made a wrong decision, consumers would like to buy guaranteed products and try to avoid regret in the future. For consumers, product upgrade decisions usually represent better performances and higher specifications of new products, which is a more secure conservative consumption. Therefore, consumers with stronger anticipated regrets are more willing to upgrade their products.

H1a: The consumers' intention to upgrade should increase as their anticipated regret increases.

In the process of brand switching, consumers will be faced with such problems as conversion cost and search cost, etc. These problems enable consumers to perceive the risks of brand switching and thus to reduce their intention of brand switching (Colomb & Morrison, 1989). When the anticipated regret of consumers is stronger, consumers are more reluctant to make risk-taking choices, thereby reducing the intention of brand switching in the face of the risks brought by brand switching.

H1b: The consumers' intention to switch brands should decrease as their anticipated regret increases.

Moderation of Novelty Seeking

Tse and Crotts (2005) indicates that human curiosity is a strong internal force that can drive people to explore the world around them and the changes among individuals. Curiosity is one of the main concepts of behavioral motivation, which can drive people to learn, execute, verify, explore and experience. In some literature related to behavioral science, novelty seeking is also regarded as a kind of curiosity drive, perceptual pursuit and exploration drive. Novelty is an inherent psychological trait of consumers. A logical explanation for a large difference in people's purchase behavior mainly comes from the individual's different desires for novelty (Bello & Etzel, 1985). Therefore, the hypothesis is put forward:

H2a: The positive relationship between anticipated regret and intention to upgrade increases as novelty seeking increases.

Novelty seeking is a key motive underlying the purchase of smartphones. Consumers are likely to buy them because they want to experience things different and innovative, satisfying their desire for novelty and excitement (Lee & Crompton, 1992). According to the relationship between novelty and exploratory behavior proposed by Berlyne (1966), the exploration behavior is a manifestation of the individual's curiosity awakened by the novel environment. The more time a person likes to spend in exploring novelty and excitement, the less time he will spend in those have been experienced before. That is, the stimulation of novelty heightens the exploration behavior. Therefore, the hypothesis is put forward:

H2b: The negative relationship between anticipated regret and intention to switch brands increases as novelty seeking increases.

Moderation of Need for Uniqueness

Snyder and Fromkin (1977) found that, when individuals feel that their own uniqueness is threatened, there will be a need to differentiate themselves from others and it will compete with other demands. In short, individuals want to be able to show others what they are different from others or beyond others in the real world. This kind of demand is called need for uniqueness. Uniqueness has various patterns and means of expression. For instance, individuals can manifest their uniqueness by displaying their belongings (Belk, 1988), by expressing their own interpersonal interaction style (Maslach et al., 1985), or by demonstrating their own knowledge and expertise in a certain field (Holt, 1995). As one of the important possessions of consumers, the upgrade decision of smartphone can reflect the consumers' professional knowledge and expertise in the field of electronic technology to a certain extent. So the hypothesis is:

H3a: Uniqueness strengthens the positive relationship between anticipated regret and intention to upgrade.

The theory of uniqueness (Snyder 1992) indicates that, under the premise of avoiding serious social punishment due to violation of social norms, some forms of material expression can satisfy the individual's need to express his uniqueness. Some customer behaviors, e.g., the purchase of certain products, showing others their unique consumption characteristics, have become a typical manifestation of individual in the context of the market economy. Burns and Warren (1995) also illustrated in their study that, consumers with higher need for uniqueness would choose shopping mall far away from home in order to purchase goods different from their neighbors. However, the development of a brand usually goes from less commonly used and less known to more and more popular, which is just contrary to the needs of consumers with strong uniqueness. Therefore, it is hypothesized that:

H3b: Need for uniqueness weakens the negative relationship between anticipated regret and intention to switch brands.

RESEARCH METHODS

This research adopted an online survey for testing the proposed model. Among a variety of surveys, online surveys enjoy low cost, high anonymity, high convenience, rapid diffusion and high response speed (Wright 2005). Smartphone is used as the object of this research. Anticipated regret is examined herein because a large proportion of consumers possess this particular affect when they purchase smartphone. Consumers on WeChat platform in China are legitimate respondents for they use smartphones daily. They were asked to fill out the questionnaire, which consists of all of the measurement items of the six constructs, along with behaviors and experience in using smartphones. After a series of snowball data collection, 470 usable questionnaires were secured for the subsequent data analysis.

Among the 470 usable samples, roughly 58.1% are unmarried people, followed by the married with children (34.5%), the married without children (5.3%), the divorced (1.3%), and the widowed (0.9%). In terms of age, only 3.2% of the samples are under 20 years old, 56.2% are between 21 and 30 years old, 9.8% are between 31 and 40 years old, 18.7% are between 41 and 50 years old, and 12.1% are above 50 years old. In terms of educational background, only 1.1% are junior high school or below, 7.9% are senior high school or technical secondary school, 12.1% are junior college, 37.9% have bachelor degree (the most), 36.4% have master's degree, and 4.7% have doctoral degree. As for occupation, white collar worker holds the largest proportion (47%) of the samples; students constitute 38.9%; the rest of respondents are selfoperated businessmen, retirees, freelancers that only account for a very small proportion. The mode of the respondents' monthly income is 8,000 yuan (about 1165 USD) or less, accounting for 81.4% of all samples, while 27% earn less than 2,000 yuan (about 291 USD). 32.1% of the samples are with monthly income between 2,000 yuan and 4999 yuan (about 727 USD), as opposed to 22.3% with monthly income between 5,000 yuan and 7999 yuan.

The most often used smartphone brands is Apple (48.5%), followed by Huawei (24%) and xiaomi (10.9%). In terms of operation systems, Android and iOS account for 50.4% and 48.1% respectively. As for replacing smart phone, 96% of the respondents have had replaced their phones, and the main reason for replacement is “the original mobile phone is broken”, accounting for about 44.3%. In addition, replacing the old version for “the new mobile phone specifications/performance” also accounts for about 21.3%, followed by about 15.7% for “the function of new mobile phone is better/more”. Finally, in terms of average inter-purchase interval, 18-24 months represent the largest proportion (33.2%), followed by 30-36 months (31.3%). Over 83.4% of the respondents choose to replace their smart phones within an average duration of 18-48 months.

We measure all the constructs in the research hypotheses by following Churchill’s (1979) approach. All responses were expressed on 5-point Likert scales. Six measures of interest were included in the final instrument. Anticipated regret is captured by a 16-item scale by adopting the study of Janis and Mann (1977). The intention to upgrade is adopted from the 6-item scale in Tseng and Lo’s (2000) research. The intention to switch brands is measured in terms of a 8item scale adopted from Jones and Tremblay (2000) and Söderlund and Julander (2003). As for moderators, novelty seeking and need for uniqueness are respectively measured by a 12-item scale and a 28-item scale. The former is based on the studies of Hirschman (1980) and Hsiao and Yang (2010), while the latter on those of Knight and Kim (2007) and Tian and McKenzie (2001). Satisfaction with the current brand is the control variable related to consumers’ purchase and use of smartphones.

After a series of confirmatory factor analyses (CFAs), convergent validity, reliability and discriminant validity are established. The CFAs use LISREL 8.80 to purify the reflective scales. Overall, all the CFA models show reasonably good fit, in terms of ^{2}/df (equaling to 3.377) and other model fit indicators as follows: Root Mean Square Error of Approximation (RMSEA) value is .074, Normed Fit Index (NFI) is .93, and both Comparative Fit Index (CFI) and Incremental Fit Index (IFI) are equaling to .95 (Bollen, 2014). The Cronbach’s Alpha values of each construct are greater than 0.8, indicating that questionnaires of the same construct are homogenous, and the reliability and unidimensionality of each construct are quite high (Nunnally, 1978). To be specific, the alpha values are 0.911 and 0.877 for the two sub-dimensions of novelty seeking, while 0.957, 0.851 and 0.954 for the three sub-dimensions of uniqueness. The intention to upgrade and the intention to switch brands have alpha values of 0.893 and 0.915 separately. Cronbach’s Alpha for the two lower level traits of anticipated regret are 0.950 and 0.940.

According to Sharma et al. (1981), the research uses the moderated regression analysis to test the hypotheses mentioned above. This model consists of the main effects of one control variable, one independent variable, two moderator variables, together with two relevant independent variable × moderator interactions. The satisfaction with current brand is the control variable in the regression analysis. The scores for all constructs are calculated by use of the corresponding questionnaire responses in the equally weighted scales. Before creating the interaction terms, the independent variables and moderator variables, anticipated regret, novelty seeking and uniqueness, have been mean-centered, so multicollinearity will not be a serious problem in this research.

Table 1 shows the results of the moderated regression model. In Model 1, the control variable accounts for 0.4% of the variance in current brand satisfaction (F=1.680, p> .10). Model 2 means the variance of current brand satisfaction is 19%, with the F-value of 27.285 (p< .01).

Between Model 1 and Model 2, there is a significant difference in R^2 with F equaling to 35.695 and p< .01, which means that the main effect makes sense. The effect of anticipated regret on intention to upgrade is positive and significant (= .643, p < .05), so Hypothesis 1a is supported.

Table 1 Results of Moderated Regression Analysis

Dependent Variable	Intention to Upgrade			Intention to Switch Brands		
	Model 1	Model 2	Model 3	Model 4	Model 5	Model 6
Control Variable						
Satisfaction with Current Brand (SCB)	.060	.039	.038	-.222***	-.238***	-.237***
Independent Variable (Main Effect)						
Anticipated Regret (AR)		.105**	.643**		-.096*	-.779***
Moderator Variables (Main Effects)						
Novelty Seeking (NS)		.415***	.772***		.076	-.378**
Need of Uniqueness (NU)		-.039	-.037		-.242***	-.246***
Moderating Effects						
AR NS			-.731**			.929**
AR NU			.132**			-.175***
R2	.004	.190	.202	.049	.125	.145
R2		.187	.012		. 076	. 020
F-value	1.680	27.285***	19.506***	24.178***	16.573***	13.063***
F		35.695***	3.388**		13.398***	5.413***

*Significant at p < .10; **Significant at p < .05; ***Significant at p < .01

This research uses an incremental F-test to test the moderating effects (Aiken et al., 1991) in Hypotheses 2a and 3a. The approach is to compare Model 3 with Model 2. Between Model 2 and 3, the F-value is 3.388, with p < .05. Both of two interaction terms are statistically significant according to the test of individual interaction terms. In the H2a above, we predict that the positive relationship between anticipated regret and intention to upgrade increases as novelty seeking increases. As the regression coefficient of interactive term in H2a is significantly negative (= -.731, p < .05), the hypothesis is rejected. As for H3a, it predicts that need for uniqueness increases the positive relationship between anticipated regret and intention to upgrade. The corresponding interaction term, which is anticipated regret uniqueness, is positive and significant (= .132, p < .05), so H3a is supported.

As for Model 4, 5 and 6, the same approach is used to test. In Model 4, the control variable accounts for 4.9% of the variance in current brand satisfaction, with the F-value equals to 24.178 and p < .01. Model 5 means the variance of current brand satisfaction is 12.5% (F=16.573, p < .01). There is a significant difference in R^2 with F equaling to 13.398 (p < .01) between Model 4 and 5. Thus, the main effect is certainly present. Hypothesis 1b is supported according to the findings, because the effect of anticipated regret on intention to switch brands is significantly negative (=- .779, $p < .01$).

The F-value is 5.413 ($p < .01$) between Model 5 and Model 6. The test of individual interaction terms shows that both of these two interaction terms are statistically significant. Consistent with the expectation of H2b, the negative relationship between anticipated regret and intention to switch brands increases as novelty seeking increases. The data findings support it because the regression coefficient of interactive term is positive and significant (= .929, $p < .05$). Hypothesis 3b predicts that uniqueness decreases the negative relationship between anticipated regret and intention to switch brands. Finally, it is confirmed because the corresponding interaction term (anticipated regret need for uniqueness) is significantly negative, with = -.175, $p < .01$.

CONCLUSIONS

This research shows that the need for uniqueness has a significant moderating effect on the relationship between anticipated regret and the intention to upgrade and switch brands, while novelty seeking does not. Alternative explanations can be considered for such seemingly conflicting results. The development of smartphone in China has reached such a relatively mature stage that smartphones can mostly meet the daily needs of consumers in this market because of the fast speed of upgrading products. In China, manufactures often launch new products within only a few months and many updated functions and technologies for consumers become dispensable. As a result, even for novelty-seeking consumers, their anticipated regret psychology won’t affect their intention to replace any more. Furthermore, smartphones becomes a necessity partly due to the rapid growth of consumers’ personal income and their consumption level in China. The decisions to purchase and replace smartphones are not difficult for Chinese consumers. The economic value of smartphones is no longer critical in the purchase/repurchase decisions, especially for novelty-seeking consumers, who seldom worry about value declining. As a result, the moderation of novelty seeking on consumers’ affect-replacement linkage becomes relatively nonsignificant.

The findings of this study confirm the proposed model of consumers’ upgrade and brand switching decision, based on affective psychology. The research can make up for the gap in our understanding of anticipated regret, which refers to an allusion to the main psychological effect of various worries about loss, the materialized loss that troubles decision-makers before their decisions (Janis & Mann, 1977), and the impact of anticipated regret on consumers' intention to upgrade products and switch brands. Therefore, emotional process, instead of cognitive process, may drive the purchase behavior of consumers (Verhagen & van Dolen, 2011). It is clear, however, that current research on consumer decision-making is largely rooted in the cognitive domain, with little regard for affect. Therefore, the research content of this study shifted from general consumer cognition to consumer affect, and explored the mechanism of consumers' decision to upgrade and switch brands with the influence of anticipated regret in high-tech durable products. An investigation into the main effect of anticipated regret on consumers' intention to upgrade products and switch brands has been done, along with the moderating effects of novelty seeking and uniqueness. Studying the bahaviors of Chinese smartphone consumers may offer some theoretical and practical insights. The empirical results will help to better understand consumers' replacement decisions for high-tech durable products, even predict their behaviors in upgrading current products and switching to other brands. Several managerial guidelines can be provided for managing and launching high-tech consumer products. According to the data collected from the questionnaires in the paper, 96% of the samples have replaced their smartphones, so it can be judged that the current smartphone market is basically saturated, and the most important customers of smartphone are consumers who need to replace their products. However, in the current market with numerous smartphone brands, manufacturers should encourage to shorten the holding time, stabilize their own consumers and attract potential consumers from other brands, which is the key to their success. Therefore, the current research concludes that smartphone manufacturers should formulate appropriate and purposeful marketing strategies based on the characteristics, personality and behavior patterns of different consumers for the consideration of the uniqueness demand of consumers. Manufacturers can provide exclusive products, purchasing channels and characteristic advertisements for specific target groups to meet the personalized needs of consumers.

With limited human, material and financial resources, the research tries to complete the research step by step in a rigorous way. However, there are still rooms for improvement. There are more than 1.3 billion people in China. Such an extremely large population represents an obstacle for random sampling. In this study, questionnaires were distributed through the WeChat platform, from which the samples are inevitably students and young white collar workers. As a result, demographic variables such as age and occupation of the respondents could not be completely controlled .Furthermore, consumers are affected by many situational factors when making replacement decisions for smartphones. A logical step to advance our knowledge is to extend our study by incorporate both cognitive and affective aspects into the explanation and prediction of consumers’ replacement decision.

Regulatory Uncertainty in Operating Environments: Slack as a Coping Mechanism

ABSTRACT

This paper considers how operations decision makers employ excess organizational resources known as slack to manage regulatory uncertainty. Slack will be oriented toward either preserving or altering workflows depending on perceptions about the direct and indirect influences of regulatory uncertainty. Findings highlight important contingencies associated with slack-related decisions made in regulatory contexts.

KEYWORDS: Resource Management and Allocation, Environmental Management, Innovation Process, Contracts, Outsourcing, Process Change, Supply chain management, Conceptual modeling

INTRODUCTION

To cope with uncertainty in external environments, organizations develop sources of strategic flexibility that enhance adaptive capability (Aaker & Mascarenhas, 1984; Collis, 1992; Wernerfelt & Karnani, 1987). The resilience of workflows that produce critical organizational resources is a common focus of these efforts. Improving the adaptability of core workflows often involves building reserves of flexibility known as slack. Slack is a collection of excess resources that is not used in routine production but can be marshalled when necessary to facilitate adaptation in uncertain settings (Azadegan et al., 2012; Bourgeois, 1981).

Slack enables operations to navigate uncertain environments through two seemingly contradictory mechanisms. Slack can *preserve* existing workflows by cushioning an organization from external shocks. Inventory, for example, is a form of slack that buffers operations from unforeseen volume-related changes that might otherwise motivate sweeping modifications to production processes (Thompson, 1967; Galbraith, 1973). Enabling the maintenance of status quo workflows in uncertain settings is an attractive feature of slack because of the high cost of altering work processes—particularly those that employ specialized assets. Slack can also *alter* workflows when external change forces cannot be buffered. For instance, slack in the form of research and development activities offers creative resources for innovation and experimentation that support reconfiguration of work when status quo operations are unable to satisfy changing market demands (Cyert & March, 1963).

The level and nature of uncertainty present in operating environments influences slack-related decisions. Generally, higher levels of environmental uncertainty motivate the creation of more slack (Ford, 2017). Because uncertainty stimulates adaptive response (Lawrence & Lorsch, 1967), managers employ slack resources in turbulent settings to increase maneuverability. Failure to fortify operations with enough slack to cope with external uncertainty can foster rigid, maladaptive work processes. Slack's precise shape depends on the nature of uncertainty in the operating environment (Ford, 2017). For example, market forces create uncertainty about supply chain volume requirements as well as about technological requirements necessary for production (Walker & Weber, 1984). When volume uncertainty dominates the environment, slack is likely to be oriented toward preserving workflows in the event of volume-related shocks. When technological uncertainty dominates, slack is oriented toward altering workflows that would otherwise be rendered obsolete in the face of technological change.

Because production and trade are commonly subject to government oversight, regulatory uncertainty is often present in operating environments as well. Processes that develop regulations in addition to the regulatory outcomes themselves create uncertainty that requires attention when making operating decisions (Duncan, 1972). Regulatory uncertainty can be amplified by lack of working knowledge about the bureaucratic machinations that shape regulatory settings (Art, 1973). Because penalties associated with regulatory non-compliance can be complex and apportioned by politically interested actors, the outcomes of regulatory processes and their consequences on operating environments are often difficult for managers to discern (Besley & Coate, 1998; deLeon, 1992; Pettigrew, 1973). It is also possible that regulations, once implemented, fail to achieve their intended or anticipated purposes (Carrigan, 2017) which could consequently introduce additional episodes of uncertainty that must be managed.

Extending slack's utility for managing uncertainty into regulatory environments seems intuitive. Yet, the literature is unclear about how operations develop and deploy slack to cope with regulatory uncertainty. A sizeable stream of research suggests that, in uncertain regulatory settings, organizations generally prefer to postpone investments and assume a "wait-and-see" posture until uncertainty is resolved (e.g., Bittlingmeyer, 2001; Fuss et al., 2009; Marcus, 1981; Yang et al., 2004). On the other hand, some researchers propose that investments made during periods of regulatory uncertainty, particularly those that focus on reversible commitments using flexible resources, can create valuable strategic options for producers as the uncertainty subsequently dissipates (Aragon-Correa & Sharma, 2003; Doh & Pearce, 2004; Hoffman et al., 2009; Rugman & Verbeke, 1998). If investments in slack are in fact made, then questions arise about how that slack should be shaped to address regulatory uncertainty. Because slack can generally be oriented toward preserving workflows or toward altering them (Bourgeois, 1981; Ford, 2017), the shape of slack may depend on the particular nature of regulatory uncertainty at hand. Research, however, has yet to focus on this possibility.

In the operations management literature, there is little discussion that managers should possess competence for coping with unstable institutional settings. Regulatory issues are often seen as beyond the control of operating managers. Although employing slack to manage external uncertainties is intuitive, researchers have largely ignored the idea in the context of operating in hostile political and regulatory environments.

This paper advances a contingency-based framework to clarify the relationship between regulatory uncertainty and slack employed by operations to manage that uncertainty. Building on work from Hoffman et al., (2008), we conceptualize regulatory uncertainty along two dimensions—one related to uncertainty about the direct characteristics and consequences of regulations themselves, and the other related to uncertainty about the indirect consequences of regulations once implemented. We then develop a series of propositions linking the two dimensions of regulatory uncertainty to the development of different slack orientations for purposes of either preserving workflows or altering them. Because it increases the cost of process modification and change (Williamson, 1975), asset specificity is considered as a moderator in the relationship between regulatory uncertainty and slack. Our primary contribution is the development of an improved conceptual foundation for how operations decision makers employ slack to cope with regulatory uncertainty.

DIRECT AND INDIRECT REGULATORY UNCERTAINTY

Regulation is the imposition of rules by government, often backed by penalties for noncompliance, meant to guide or control economic or social behavior (Jones & Thompson, 1984). Regulations can be narrow or broad in scope. In some cases, regulations target specific industries, production processes, or types of output, as in the case of particular air, water, and product quality and safety rules. In other cases, regulations touch many industries and impact producers across borders, as in the case of tariff, exchange rate, and central bank policies. Viewed from a supply chain perspective, regulations commonly influence the broad sequence of events from upstream raw material development and product assembly through downstream transportation, distribution, and sale of finished goods. Table 1 shows representative regulations often present in an operation's environment.

Managers consider regulation among the socio-political factors of the external environment to be taken into account when making decisions (Duncan, 1972). When information is scarce, time lags are long, and relationships between variables are difficult to grasp, uncertainty about the external environment increases, reflected by the inability to confidently assign probabilities to future events or to predict outcomes of forthcoming decisions (Lawrence & Lorsch, 1967; Duncan, 1972; Knight, 1921). In decision-making contexts, environmental uncertainty is generally considered to be perceptual in nature because decisions are based mainly on what individual decision makers sense about their surroundings (Downey & Slocum, 1975; Hambrick et al., 2005; Milliken, 1987; Perrow, 1970; Weber & Mayer, 2014).

Table 1: Representative Regulations in an Operation's Environment

Location	**Representative Regulations**
Upstream (inputs from suppliers)	Material requirements and restrictions Laws that restrict sourcing choices Input quality, inspection, and testing
Production processes	Work safety standards Minimum wage laws Hiring requirements (e.g., anti-discrimination laws) Environmental regulations and standards Required production practices Limits to what can be produced (e.g., market power restrictions)
Downstream (output to customers)	Product safety Product quality, inspection, and testing Product purity and cleanliness Pricing laws and restrictions Limitations on selling, who can be customers Information/disclosure requirements to buyers
General environment	Tariffs Trade restrictions and sanctions Laws governing mergers and acquisitions

Licensing/qualification requirements
Transportation rules and regulations
Exchange rate policy
Interest rate policy

Perceived uncertainty related to regulatory aspects of the environment can be tied to Milliken's (1987) notion of state uncertainty. State uncertainty involves the inability of managers to understand how factors in the external environment are changing. Managers may be unable to identify key events or changes in the environment, or they may be uncertain about the likelihood that future events or changes will occur. In the regulatory context, managers may not know, for instance, what regulations incoming political regimes might support, or be able to confidently predict whether proposed regulatory schemes will subsequently be approved. State uncertainty can also involve incomplete understanding of interrelationships between elements in the environment. For example, managers might be uncertain about the impact of newly imposed regulations on supply markets, or about how competitors will respond to those regulations.

Regulatory uncertainty, then, is a form of state uncertainty that manifests in perceptions about processes that develop regulations and the outcomes resulting from those processes. Hoffman et al. (2008) argued that regulatory uncertainty can be separated into two components: one related to uncertainty about the direct characteristics and consequences of regulations themselves, and the other related to uncertainty about the indirect consequences of regulations once implemented. Although we label these dimensions differently than Hoffman et al. (2008) for purposes of clarity, we define them similarly. *Direct regulatory uncertainty* is the inability of managers to predict the future state of the regulatory environment. It is linked to particular regulatory policies and their characteristics such as legislative direction, specific rules and measures, implementation plans, and interdependencies with other regulations (Lopez et al., 2017). *Indirect regulatory uncertainty* is the inability of managers to predict the state of the nonregulatory environment caused by a regulation. It is consistent with Milliken's (1987) observation that state uncertainty can sometimes involve incomplete understanding of interrelationships between elements in the environment. In the regulatory context, uncertainty about the state of the regulatory environment (i.e., direct regulatory uncertainty) often clouds knowledge about how regulatory changes will touch aspects of the non-regulatory environment (i.e., indirect regulatory uncertainty). The specter of new tariff impositions, for example, may create doubt not only about the precise shape and scope of the tariffs themselves, but also about how those tariffs might affect market-oriented dimensions of the environment such as those related to monetary exchange rates and trade patterns.

Although indirect regulatory uncertainty flows from regulatory uncertainty brought about by a changing regulatory state, it is possible that these two types of uncertainty may not coexist (Hoffman et al., 2008). Direct regulatory uncertainty is subject to abrupt, discontinuous resolution as segments of the regulation development process are completed. Sticking with our above tariff example, doubts about the shape and scope of upcoming tariffs are likely to fade once those tariffs are approved and implemented. The "punctuated equilibrium" nature of direct regulatory uncertainty differentiates it from market-related uncertainties that tend to diminish gradually over time. While direct regulatory uncertainty is often resolved abruptly, indirect regulatory uncertainty may persist for considerable time (Hoffman et al., 2008). While direct regulatory uncertainty associated with our tariff example is likely to decline once the details of the tariff have been determined and enacted, the indirect regulatory uncertainty associated with the tariff's effects on trade and other aspects of the non-regulatory environment may linger for great length of time after the tariff is implemented.

SLACK AND REGULATORY UNCERTAINTY

The temporal, multi-dimensional nature of regulatory uncertainty presents unique managerial challenges. Direct regulatory uncertainty threatens status quo production and process management with the prospect of rules and requirements that can force reconfiguration of workflows, alteration of work procedures, and installation of abatement equipment. Managers are unlikely to preemptively alter their production processes while direct regulatory uncertainty is present. They will be reluctant to do so not only due to the cost of making process changes, which could involve substantial irreversible commitments, but also because an abrupt end to direct regulatory uncertainty can be anticipated. Once the regulatory development process concludes, the direct consequences of the regulatory outcomes on production processes will become apparent. The risk of making a poor remedial decision is reduced at that point.

This does not mean that managers will necessarily assume a classic “wait-and-see” stance where no investment is made until the direct regulatory fog lifts. Because they may need to react quickly to regulatory outcomes once they become known, managers will favor a state of operational flexibility that permits maintenance of status quo operations while loosening core rigidities (Leonard-Barton, 1992) that might otherwise impair adaptation should it be mandated by the new regulatory environment. Reinforcing managerial preference for flexibility is the realization that, while direct regulatory uncertainty is likely to dissipate with the conclusion of the regulatory development process, doubts about the effects of newly imposed regulations on aspects of the non-regulatory environment will be prone to persist and perhaps even increase. The enduring presence of indirect regulatory uncertainty motivates managers to maintain a state of operational flexibility in order to facilitate adaptation until clarity can be achieved.

Creating a state of operational flexibility to cope with the multi-dimensional nature of regulatory uncertainty should precipitate the use of slack. Slack represents what Ghemawat and del Sol (1998) termed usage-flexible resources. Usage-flexible resources can be employed in various ways and applications. For example, usage-flexible resources can be used to change production volumes in response to demand fluctuations, alter the attributes of existing products, or to introduce new products (Ghemawat & del Sol, 1998). Slack’s usage flexibility provides strategic options for coping with regulatory uncertainty (e.g., Aragon-Correa & Sharma, 2003; Doh & Pearce, 2004; Hoffman et al., 2009; Rugman & Verbeke, 1998). Because managers can shape it at their discretion, slack can be deployed to correspond with particular junctures in the regulation development process. If that particular form of flexibility is no longer deemed necessary or effective, then those slack resources can be redeployed toward other uses. For example, once the regulatory development process concludes, then slack previously deployed to manage direct regulatory uncertainty might be reshaped to address lingering indirect regulatory uncertainty.

Higher levels of regulatory uncertainty should invite greater use of slack. Regulatory environments perceived as benign and predictable are unlikely to motivate investment in usage flexible resources since such flexibility is unnecessary in stable settings. On the contrary, slack deployed in stable environments can be a source of bureaucracy and waste (Bourgeois, 1981; Cheng & Kesner, 1997). As the regulatory environment becomes more unpredictable, however, managers will sense more value in accumulating usage-flexible resources to increase adaptive capacity. As regulatory uncertainty grows, so should the intensity of slack utilization.

Proposition 1: The higher the regulatory uncertainty, the greater the utilization of slack to cope with that uncertainty.

SLACK ORIENTATION AND DIMENSIONS OF REGULATORY UNCERTAINTY

As a usage-flexible resource, slack can, by definition, assume various forms. This variety can be categorized according to the two primary orientations that slack assumes when employed as a strategic environmental coping mechanism. Slack can be oriented toward either preserving workflows or toward altering them. In the section that follows, we describe these two categories of slack in some detail and propose how managers employ them to address direct and indirect regulatory uncertainty.

Preserving Orientations

When its purpose is to maintain status quo workflows, slack assumes a preserving orientation. Preservation-oriented slack insulates or protects workflows from external shocks. A traditional form of preservation slack is the operating buffer. Operating buffers, such as inventory and spare capacity, act as shock absorbers to cushion production processes from volume-related uncertainties that would otherwise disrupt workflows (Bourgeois, 1981; Galbraith, 1973). For example, managers might build inventories in advance of prospective regulations that threaten to shut down production facilities so that pollution abatement equipment can be installed.

In some cases, however, operating buffers may be unable to preserve status quo operations in the face of regulatory uncertainty. Excessive buffering can create suboptimal structural arrangements that align more with personal managerial preferences rather than with economic efficiency (Child, 1972; Yasai-Ardekani, 1986). Additionally, the excess buffering can slow managerial response to external conditions that demand quick action (Cheng & Kesner, 1997). Moreover, because uncertainty generally threatens the flow of resources between interdependent organizations in the supply chain (Oliver, 1991; Pfeffer & Salancik, 1978), operating buffers may not sufficiently protect the interorganizational linkages that govern resource exchange. To protect those linkages, managers will seek to create negotiated environments that govern exchanges in manners that secure those resources (Cyert & March, 1963; Dyer, 1997; Eisenhardt, 1989; Poppo & Zenger, 2002; Williamson, 1991). In the regulatory context, a necessary resource for unencumbered exchange includes government permission to engage in trade in a manner that other vital resources can be obtained. Managers can exploit the usage-flexible nature of slack to create preservation-oriented forms that foster negotiation and governance of interorganizational exchange so that resource flows can be stabilized in uncertain regulatory times.

Preservation-oriented slack that governs interorganizational exchange can be either formal or informal in nature (Ford, 2017). Formal exchange governance features the use of contracts that buttress exchanges to withstand adverse effects of unforeseen change (Williamson, 1991). In market contexts, contractual agreements are traditionally established between buyers and sellers in supply chains of goods and services. In regulatory contexts, contractual agreements can also be established between producers and government. For example, producers might provide personnel to sit on panels that co-develop new regulations with government bureaucrats. To develop formal governance mechanisms with trading partners, operations require slack resources that can be deployed for contracting activities and their subsequent enforcement. These preservation-oriented resources can be used in activities that enable the establishment of formal agreements and managing across organizational boundaries to stabilize resource exchange and maintain status quo workflows.

Formal governance of interorganizational transactions may not be effective in all environmental contexts (Ford, 2015; Poppo & Zenger, 2002). For instance, prospective regulatory changes may threaten to upset measures and standards that form the basis for control and improvement, making it difficult to enforce formal agreements over significant periods of time and driving up re-contracting costs (Handley & Benton, 2012; Heide & John, 1990). Uncertainties that arise in some environments can also widen information asymmetries between exchange partners that increase risk of strategic behavior and opportunism

(Eisenhardt, 1989; Nilikant & Rao, 1994), leading to less willingness to enter into formal commitments.

As an alternative to formal governance, slack resources can also be applied toward informal, relational governance. Relational governance mechanisms foster trust, parallel expectations, joint action, and procedural fairness that build cooperative, flexible alliances between exchange partners (Benton & Maloni, 2005; Dyer & Singh, 1998; Geyskens et al., 2006; Heide, 1994; Kanter, 1994). Slack deployed in relational governance manners commonly assumes the form of joint planning and steering committees, inter-organizational problem solving teams, and customer/supplier training programs (Ford, 2017). In regulatory contexts, slack could similarly sponsor special studies, white papers, lobbying and other efforts aimed at influencing institutional participants in the regulation development processes (Bonardi & Keim, 2005; Hillman & Hitt, 1999; Kingsley et al., 2012). Slack that builds relational governance capability, such as proficiencies for boundary spanning and interorganizational teamwork, helps stabilize resources flows and strengthen competitive positions in technologically uncertain contexts. Because they do not depend on particular standards or specifications, relational governance mechanisms are capable of enduring high levels of environmental uncertainty while encouraging mutually beneficial collaboration on matters affecting resource stability. Table 2 includes the various forms of preservation-oriented slack and some examples of each.

Table 2: Slack Orientations and Examples in the Regulatory Context

Preservation Orientation	Altering Orientation
Operating Buffers:	*Scanning:*
Inventory	Monitoring of regulatory media
Spare capacity	Networking with regulatory officials
	Performing competitive analysis
Formal Exchange Governance:	
Contract development and oversight	*Workflow Reconfiguration:*
Regulatory committee participation	Research and development
	Human resource training
Relational Governance:	Project management skills
Coalitions, trade groups	Team-based problem problem-solving
Interorganizational planning/problem solving	
Lobbying	
Conducting special studies	
Regulatory committee participation	

Higher levels of direct regulatory uncertainty should invite use of more preservation-oriented slack. As direct uncertainty increases, doubts grow about the impact of prospective regulations on workflows. Use of slack to protect workflows should intensify as managers create a state of flexibility until they can gain clarity about what durable remedies for the new regulatory environment might look like.

Proposition 2: The higher the direct regulatory uncertainty, the greater the utilization of slack oriented toward preserving existing workflows.

Altering Orientations

Although preserving workflows is generally preferred due to the high cost of process change, several factors may motivate managers to consider the possibility of modifying core workflows under conditions of regulatory uncertainty. As uncertainty increases, preservation-oriented slack may not provide enough capacity for buffering external forces from upsetting resource flows. On the other hand, because excessive buffering capacity could render decision-makers less responsive to environmental stimuli (Cheng & Kesner, 1997; Modi & Mishra, 2011), managers might consider large measures of preservation-oriented slack as imprudent. Of course, it is also possible that managers simply perceive the nature of regulatory uncertainty to be such that status quo workflows will not enable adaptation and consequently must be modified (Rindova & Kotha, 2001).

When its purpose is to modify or change workflows, slack assumes an altering orientation. Because environmental uncertainty creates discrepancies and challenges to the skills upon which operating tasks are based (Fredrickson & Mitchell, 1984), dynamic capabilities are necessary that enable the alteration of production processes (Teece et al., 1997; Winter, 2003). Dynamic capabilities facilitate workflow modification by increasing organizational capacity for innovation and adaptation (Helfat & Winter, 2011; Rindova & Kotha, 2001; Teece, 2014). Since slack can provide resources for creative behavior (Bourgeois, 1981), dynamic capabilities for innovation are furnished by slack with an altering orientation.

Dynamic capabilities involve skills for scanning environments and reconfiguring workflows (Cohen & Leventhal, 1990; Collis, 1994; Pavlou & El Sawy, 2011; Teece, 2007). In the regulatory context, alteration-oriented slack must develop aptitude for scanning regulatory environments for opportunities, threats, and changes. Aptitude must also be acquired for experimentation and for modifying work processes to better meet external demands so that vital resources can be secured. Table 2 includes the various forms of alteration-oriented slack and some examples of each.

Due to their preference for maintaining status quo workflows until outcomes of regulation development processes are known, managers are unlikely to employ large amounts of alteration-oriented slack in response to direct regulatory uncertainty. Instead, managers should view altering orientations as more attractive as indirect regulatory uncertainty grows and lingers. Higher levels of indirect regulatory uncertainty increase doubt about how prospective regulations will impact the non-regulatory environment and everyday production processes. Because this uncertain state may persist for some time, managers are likely to orient more slack toward the possibility that workflows may require modification in order to adapt.

Proposition 3: The higher the indirect regulatory uncertainty and the longer it persists, the greater the utilization of slack oriented toward altering existing workflows.

ASSET SPECIFICITY

In economic contexts, specialization is the extent to which individuals, groups, or organizations perform a narrow range of activities (Schilling et al., 2003). The benefits of specialization on productivity have been recognized for some time (e.g., Fayol 1916; Smith, 1776; Taylor 1911), and include learning effects from repetition and efficiency gains from low switching costs. Most operations adopt at least some degree of specialization to realize a portion of these benefits.

Specialized production fosters specificity in labor as well as in assets such as machinery, facility location, and brand name capital (Williamson, 1991). Asset specificity refers to the degree to which an asset can be redeployed to alternative uses without loss of productive value (Williamson, 1975). The redeployment costs associated with highly specific assets make them riskier than general purpose assets. Because they require commitment to specific assets that can be difficult to modify or trade, specialized operations are inherently rigid and unresponsive in uncertain environments (Ghemawat, 1991; Leonard-Barton, 1992; Williamson, 1975). Asset specificity forces operations decision makers to protect existing production by increasing slack due to the limited ability of an alternative use for specialized assets.

Degree of asset specificity should moderate the relationship between regulatory uncertainty and use of slack. When responding to a given level of regulatory uncertainty, highly specialized operations are likely to employ more slack than operations with lower degrees of specific assets. The rigid nature of specialized workflows requires additional resources to create a state of flexibility to cope with both direct and indirect regulatory uncertainty. Greater use of slack increases the likelihood that specialized operations will adapt in uncertainty regulatory settings.

Proposition 4: At a given level of regulatory uncertainty, higher degrees of asset specificity will be associated with greater utilization of slack.

DISCUSSION

This study examines the relationship between regulatory uncertainty and slack employed by operations decision makers. Generally, higher levels of regulatory uncertainty should motivate greater utilization of slack. When direct regulatory uncertainty is elevated, managers are likely to prefer slack oriented toward preserving workflows. When indirect regulatory uncertainty increases, managers are more likely to employ slack oriented toward altering workflows. Specialized operations, which contain high degrees of specific assets that are difficult to modify and trade, should utilize slack more in order to cope with regulatory uncertainty than should operations composed of general-purpose assets. Our primary contribution is the development of an improved, contingency-based foundation for how operations employ slack to cope with regulatory uncertainty.

In the operations management literature, the notion that managers must possess competence for coping with unstable institutional settings remains largely novel. Regulatory settings are often seen as beyond the control of operating managers. Although employing slack to manage external uncertainties is intuitive, researchers have largely ignored the idea in the context of operating in hostile political and regulatory environments. Hopefully, this paper will encourage dialogue and work in this direction.

The conceptual framework proposed in this study must be tested and validated. Empirical research might extend Lopez et al.'s (2017) work that considered how direct and indirect regulatory uncertainty affected corporate investment decisions. Because supply chains continue to lengthen across country borders, future studies should also investigate situations where managers must cope with a portfolio of regulatory uncertainties that accrue from operating in multiple political regimes simultaneously.

From a practical standpoint, previous work has alerted managers to contingencies linked to employing slack for managing environmental uncertainty. Ford (2017), for example, suggested that how slack is oriented to address uncertainty is likely to depend on whether volume or technological uncertainty dominates market environments. This study extends the contingency notion to the external environment. Managers will be prone to orient slack toward either preserving or altering workflows depending on direct and indirect regulatory uncertainties that threaten the production status quo.

ABSTRACT

Multinational Enterprises (MNEs) with operations in emerging countries seek to adjust to institutional uncertainty. This paper seeks to understand how MNEs respond to market changes caused by the uncertain environment through a coevolutionary perspective, guided by the following research question: how does the uncertain institutional environment affect capabilities' coevolution process? This study follows a multiple case study research strategy in seven MNEs. The results suggest that a high level of uncertainties affect companies directly or indirectly in this institutional environment. In critical levels of uncertainty severity, result in new capabilities development (exploitation strategy), or strengthen existing ones (exploration).

KEYWORDS: Coevolutionary theory, Uncertain environment, Ambidexterity, MNEs, and Multiple case study

INTRODUCTION

In the management field, the coevolutionary theory seeks to understand the selection and adaptation processes of firms in their environments (Mckelvey, 1997). Regarding a firm's environment, this theory assumes it as a complex set of relationships amongst supply chain partners, industry competitors, entities, and institutions that influence firms' corporate strategy. Therefore, the aim of firms is not only to adapt themselves to the environment and actors they interact with but also to influence it (Cantwell, Dunning, & Lundan, 2010).

To be capable of influence or to be influenced by their environment, firms need to make decisions about their internal resources. They can address this issue by creating new practices and capabilities which can impact on their business. One way is by improving internal resources and capabilities, and/or by being able to put them together to get influence over its competitors, partners, and institutions.

We assume that uncertain institutional environments are more susceptible to market volatility, changes in legislation and regulation, theft, fraud, and corruption. Regarding the former, information asymmetry arose by the uncertain environment, mainly during transitions, making way for high levels of opportunism when dealing with third-parties (Peng, Lee, & Wang, 2005). Firms may suffer from opportunistic, unfair or unlawful behaviors (Su, Peng, & Xie, 2016), as well as vulnerability to sudden institutional disruption, market reforms and political backlash (Yamakawa, Peng, & Deeds, 2008). Companies also tend to rely on relationships and networks more intensely if institutions are weak, since formal rules are fragile, forcing them to develop strategies to face uncertainty and institutional idiosyncrasies (Meyer & Peng, 2016).

Mair, Marti, and Ventresca (2012) argue that the institutional environment affects business' infrastructures to the extent that it can be considered as market failures, influencing all stages of the supply chain. For instance, emerging markets have institutional idiosyncrasies that are not usually found in advanced economies, leading them to an uncertain environment, thus, forcing companies to adapt their strategy to the institutions they are subject to, and also to influence them. In that sense, we question: “How does the uncertain institutional environment affect operational capabilities’ coevolution process?”.

To address the question proposed in this study, we follow a qualitative approach by multiple case studies (Eisenhardt, 1989; Yin, 2014), and seek to understand how companies develop capabilities to respond and adapt to externalities caused by the uncertain institutional environment in a coevolutionary perspective. The use of a case study is justified because this phenomenon is not very well understood, also it is indicated to analyze complex subjects (Meredith, 1998). In this research, seven companies were selected; leaders in the national and global market, of the automotive (3 companies), beverage (2 companies), cosmetic (1 company), and tobacco (1 company) sectors.

This research seeks to understand the strategies adopted by MNEs in uncertain institutional environments to reduce the impacts on their operations. For that matter, this study uses coevolutionary theory to understand the process of interaction between companies and the external environment, and the concept of ambidexterity to identify the influences that companies generate in the external environment.

The sequence of this paper follows the subsequent order: the second section presents a literature review of Coevolutionary Theory and Institutional Theory, and how institutional uncertainty context generated changes in capabilities coevolution. The third section describes the methodological steps used in the case study based on Eisenhardt (1989). The fourth section presents the results of the within-case and cross-case analyses, followed by a section to discuss our findings with the literature. Finally, the main conclusions and orientations for future studies are presented in the last section.

LITERATURE REVIEW

Coevolutionary Theory

The coevolutionary theory was born from natural science arguing a joint evolution between organisms, species of animals and plants (Ehrlich & Raven, 1964). The coevolutionary approach was brought to the strategy field to understand the selection and adaptation of companies to a competitive environment (McKelvey, 1997). According to Lewin and Volberda (1999), the coevolutionary process would be shaped by a large and complex process of coevolution that would involve influences through different levels of management.

These influences could come from the corporate, the supply chain, the industry and the country (or region) levels (Lewin & Volberda, 1999). However, they differ regarding the (immersion) embeddedness level of a company in an environment and its relationship level with those players. Thus, this approach allows analyzing the company's choices at micro, meso or macro levels, which creates a possibility to broaden the understanding of the different strategies adopted in operations. Simultaneously, the company’s capabilities can be influenced by competitive and institutional environments, and the company itself, through an innovative resource or process, can affect the external environment from a new capability (Rodrigues & Child, 2003). From this perspective, the organizations’ strategy is not only to adapt themselves to the institutions, but also to influence them (Cantwell, Dunning, & Lundan, 2010).

Multinational enterprises (MNE’s) are ideal for coevolutionary theory application because they integrate a set of distinct environments and contexts. They put together the role of institutions for creating new policies and the effect of corporate strategies over subsidiaries (macro-environment), the role of suppliers, customers and competitors and their activities (meso-environment), and the set of resources and capabilities of subsidiaries (micro-environment) (Madhok & Liu, 2006).

According to Lampel and Shasie (2003), the coevolutionary theory presupposes that the mobilization of resources and the creation of competences are self-determined. The concept of ambidexterity considers that resources exploration can result in two distinct processes. The first of them, exploitation, the company mobilizes its internal resources to fulfill a short-term change (Kristal, Huang, & Roth, 2010). However, in the second process, exploration, the company uses its resources with a focus on the future, generating new capabilities (O'Reilly & Tushman, 2004). According to Birkinshaw and Gupta (2013), these two processes are not necessarily excluding, but acting together can offer present gains and anticipation of future changes.

For that matter, the coevolutionary theory suggests that are four strategies that companies can respond to external changes. We related each one of that strategy with ambidexterity concept.

- Naive selection - A random and unconscious choice of practices occurs, these being little connected with the institutional or competitive environments. The selection of a new competence is only to minimize the impacts of some change in the external environment at its current level of performance. It would be equivalent to Stage 1 proposed by Wheelwright and Hayes (1985) and focus on the exploitation process.
- Managed selection - Occurs in complex internal environments in which it is necessary to select practice or routine in front of the others in the market. An analysis of the times and resources spent in practice or routine is carried out. In this case, it would be equivalent to Stage 2 proposed by Wheelwright and Hayes (1985) and a major focus on the exploitation process.
- Hierarchical Renewal - The choice of practices and routines are strategic elements of the business. Thus, the process is proactive, well-defined and with clear objectives to achieve strategic goals, however, all guidance is top-down. It would be equivalent to Stage 3 proposed by Wheelwright and Hayes (1985) and a combined exploitation and exploration processes.
- Holistic Renewal - There is collective learning at the different levels of the company, in the top-down and bottom-up perspectives, which aims at cyclically renewing various aspects of the organization, including beliefs, cultures, and practices. In this case, it would be equivalent to Stage 4 proposed by Wheelwright and Hayes (1985) and focus on the exploration process.

Institutional Uncertain Environment

According to Meyer and Rowan (1977), the organizational structure is not only composed of available resources but is the result of the interaction of these resources with the current institutional environment. The institutional environment determines and limits the opportunities of new business for the companies (Bruton, Ahlstron, & Li, 2010). According to Scott (2008), the institutional environment can be defined as "rules, norms, and belief systems [which] undergird all stable social systems, including economic systems." Government actions and social norms, therefore, can create a restrictive environment, which becomes an obstacle to the development of a new business or even to the maintenance of current business performance.

According to DiMaggio and Powell (1983), this environment generates external pressures on these organizations, through norms, coercion or adequacy. However, organizations cannot be seen as passive agents in this process. For Oliver (1991), economic agents interact with the institutional environment. Their reactions, nonetheless, are not only restricted to adjusting to external pressures, but they can also avoid, challenge, compromise and/or manipulate these pressures.

The differences between institutions of emerging and developed economies are noticeable (Meyer et al., 2009). In the former, information asymmetry arose by the uncertain environment, mainly during transitions, making way for high levels of opportunism when dealing with third-parties (Peng, Lee, & Wang, 2005). Firms may suffer from opportunistic, unfair or unlawful behaviors (Khanna & Palepu, 1997; Su, Peng, & Xie, 2016), besides vulnerability to sudden institutional disruption, market reforms and political backlash (Yamakawa, Peng, & Deeds, 2008). Companies also tend to rely more intensively on relationships and networks if formal rules are fragile, developing strategies to face uncertainty and institutional idiosyncrasies (Meyer & Peng, 2016).

Emerging economies have less sophisticated institutional frameworks and inconsistent institutional pressures sometimes (Meyer & Peng, 2016). The lack of certain market-supporting institutions leads to the existence of “institutional voids” (Khanna & Palepu, 1997), reducing the tendency for isomorphism (Meyer & Peng, 2016). Those “voids” can be filled or lessened by Government support, for example (Su, Peng, & Xie, 2016). When present, firms should redesign their organizational forms (Meyer & Peng, 2016) and also ponder decision-making processes to face such “institutional voids”.

Not all emerging markets are the same. Meyer et al. (2009) classify the emerging economies institutional framework into two categories: developed (strong) and underdeveloped (weak). For them, those countries "show substantial variation in formal and informal institutions (Meyer et al., 2009: 62), which makes them an interesting subject of analysis.

In this complex scenario, emerging economies are significant markets, due to their supply of raw materials, labor at low prices or market size, although they might present many peculiarities (Rottig, 2016). International business scholars have been comparing MNEs’ operations in both home and host country in several aspects (Ramamurti, 2012; Estrin, Meyer, & Pelletier, 2018). Recently He, Brouthers, and Filatotchev (2018) point out that when an MNE from an emerging country acquiring facilities in a developed country it needs to develop and to upgrade its capabilities to the new market. It means that capabilities development occurs in both directions when moving to a different institutional context.

On the other hand, investing in emerging economies may be much more challenging for companies than they usually expect, particularly, in their supply chain activities (Karamchandani, Kubzansky, & Nishant, 2011). Companies must deal with the occurrence of institutional voids in its different forms (labor, regulatory and contracting mechanisms) in the raw material, manufacturing, distribution and marketing activities of the value chain (Parmigiani & Rivera-Santos, 2015).

The lack of efficient institutions demands firms to make strategic choices to operate in institutional voids environments (Peng, 2003). From an institutional perspective, these emerging markets have considerable institutional idiosyncrasies that usually are not found in advanced economies (Rottig, 2016). Doh, Rodrigues, Helmhout, and Makhija (2017) argue that institutional voids might enhance opportunism and corruption, among other institutional failures.

METHODS

As presented in the introduction, this research question guided our study: “How does the uncertain institutional environment affect operational capabilities’ coevolution process?”. This study follows a qualitative approach through multiple case studies (Yin, 2014), and seeks to understand how MNEs develop capabilities to respond to institutional uncertainties in emerging markets. The use of this research strategy is justified because this phenomenon is not very well understood (Meredith, Raturi, Amoako-Gyampah, & Kaplan, 1989), also that it is indicated to analyze complex subjects. According to Barratt, Choi, & Li (2011: 330), a case study based on the “how” question takes an explanatory approach because: [..] “the context and experiences of actors are critical and especially the experiences of managers so as to increase the practical relevance of the findings."

This section was structured according to the five stages of a study case, initially proposed by Eisenhardt (1989) and continually improved (Eisenhardt, 1991; Stuart, Mccutcheon, Handfield, Mclachlin, & Samson, 2002). According to this model, the analysis of the case study should follow these steps: research question (already presented); case selection, data gathering; data analysis; and replication. In this way, the next subsections were structured following the one proposed by this author.

Case selection

We decided to select MNEs that have greater power of adapting capabilities and also the power of influencing their respective markets. According to Eisenhardt (1989), a multiple case study should select between four and ten cases to be considered effective. In this research seven companies were selected, leaders in the national and global market, of the sectors automotive (3 companies), beverages (2 companies), cosmetics (1 company), and tobacco (1 company). After identifying the most appropriate cases to fulfill the purposes of our research, the managers of these companies were invited to participate by e-mail or telephone. Then, the objectives and scope of this research were presented, and, when requested, the semi-structured interview protocol also. Also, a confidentiality agreement was sent indicating that we would not disclose the companies or the participants' names.

Therefore, the following cases were selected:

- Case 1 - AUTO1 - An automotive multinational that operates in a host country. In addition to Brazil, this company operates in more than 40 countries with a global annual revenue above US$ 100 billion.
- Case 2 - AUTO2 - An automotive multinational firm that operates in a host country. It has assembly, manufacturing, distribution, office, or warehousing operations in more than 60 other countries with a global annual revenue above US$ 140 billion.
- Case 3 - AUTO3 - An automotive multinational firm that operates in a host country. The company manufactures popular and luxury cars, sports cars, trucks and commercial vehicles with a global annual revenue above US$ 200 billion.
- Case 4 - BEER1 - A home country beverage multinational firm. The production and distribution of beer is the main activity but also operates in the non-alcoholic soft drinks with a national revenue above 13 billion.
- Case 5 - BEER2 - A beverage multinational firm operating in a host country. The company produces beers, distillates, wines and soft drinks with global revenue above US$ 20 billion.
- Case 6 - COSM1 - A home country cosmetic multinational firm. The company manufactures skincare, fragrances, and bath products with annual revenue above US$ 3 billion.
- Case 7 - TOBC1 – A tobacco multinational firm that bought a national company. The company produces cigarettes in more than 200 countries. In Brazil, firm´s market share is 80% of the legal market (Bloomberg, 2018).

Data gathering

Data gathering was performed through in-depth interviews from a semi-structured protocol (Barratt et al., 2011). Managers from several operational functions (purchasing, logistics, IT, product development, among others) were invited, and at least three interviews were conducted per company, that provided a broader view of the institutional pressures perceived in each organization. This resulted in greater reliability in the information collected, reducing the risk of limited understandings by the areas of performance or subjective factors of the interviewee.

Table 1: Interviews done

Case	Company	Interviewee ID	Operational functions	Time
Automotive	AUTO1	AUTO1E1	Product development	60 minutes
		AUTO1E2	Product development	70 minutes
		AUTO1E3	Logistics	40 minutes
		AUTO1E4	Information management	40 minutes
Automotive	AUTO2	AUTO2E1	Product development	60 minutes
		AUTO2E2	Purchasing	40 minutes
		AUTO2E3	Purchasing	40 minutes
		AUTO2E4	Logistics	40 minutes
		AUTO2E5	Logistics	30 minutes
Automotive	AUTO3	AUTO3E1	Planning	30 minutes
		AUTO3E2	Planning	50 minutes
		AUTO3E3	Product development	70 minutes
Beverage	BEER1	BEER1E1	Logistics	40 minutes
		BEER1E2	Transport management	40 minutes
		BEER1E3	Manufacturing	30 minutes
Beverage	BEER2	BEER2E1	Distribution	40 minutes
		BEER2E2	Distribution	40 minutes
		BEER2E3	Logistics	40 minutes
		BEER2E4	Process management	60 minutes
		BEER2E5	Process management	60 minutes
		BEER2E6	Process management	60 minutes
		BEER2E7	Distribution	40 minutes

Table 1: Interviews done				
Case	Company	Interviewee ID	Operational functions	Time
Cosmetics	COSM1	COSM1E1	Supply chain management	40 minutes
		COSM1E2	Logistics	30 minutes
		COSM1E3	Product development	30 minutes
Tobacco	TOBC1	TOBC1E1	Logistics	60 minutes
		TOBC1E2	Logistics	40 minutes
		TOBC1E3	Transport management	40 minutes
		TOBC1E4	Security management	60 minutes

Thus, we interviewed 29 professionals working in these seven companies, with an average duration of approximately 40 minutes per interview (Table 1). Of these interviews, 24 were permitted to be recorded, while the other 5 were not allowed by the interviewees. In these, the record was made through field notes. The data collection period occurred between August 2017 and February 2019. After the data collection, the recorded interviews were transcribed.

Data Analysis

Thereafter, all transcriptions and notes were coded and analyzed according to Corbin and Strauss (2008) by open coding strategy through Atlas IT software, using the techniques of individual and cross-case analysis (Eisenhardt, 1989). These techniques presuppose that the researcher follows these steps: detailed transcription and notes of the interviews, the codification of concepts, tabulation, analysis of the data, and, finally, interpretation of the results. The inductive method was adopted as a way of exploring the phenomena in this research. This considers the process of theorization from the emergence of constructs coming from the field under study, and not being guided by any theoretical model (Randall & Mello, 2012). Three steps were used to compile the data analysis. First, the researchers identified the categories present in the interviews and their respective subcategories through the Atlas TI software. Second, according to these categories, they were refined to follow a convergence in the presentation of the results. Third, the microanalysis of relationships and meanings was used to report the phenomenon. Thus, a unique analysis model emerged, allowing the phenomenon to be understood more broadly, simultaneously, reinforcing the internal validity of the analysis (Patton, 2002).

Replication

One concern of the researcher in conducting a case study is to ensure the accuracy of the information collected. According to Yin (2014), this process begins before the researcher goes to the field. The construction of the research protocol and case selection are factors used to ensure the reliability of the study results. We also conducted some qualitative criteria to ensure the quality of the multiple case study (Table 2), in a positivistic approach (Lincoln & Guba, 1985).

Table 2: Quality criteria application		
POSITIVISTIC CRITERIA	DEFINITION	HOW TO COPE WITH THE CRITERION
Internal validity	The degree to which findings correctly map the phenomenon in question (Lincoln & Guba, 1985).	- Seven leading MNEs from four important industries; - Interviews with professionals from different operational areas, with at least three interviews per company; - Propositions presented; - The theoretical framework presented.
External validity	The degree to which findings can be generalized to other settings similar to the one in which the study occurred (Lincoln & Guba, 1985).	- Specification of the unit of analysis and the context; - Dense context description (within-case analysis)
Reliability	The extent to which findings can be replicated or reproduced by another investigator (Lincoln & Guba, 1985).	- Research protocol provided in the Appendix, including the semi-structured questionnaire; - Documentation of all the procedures performed during the case studies; - Data Analysis through proper software (Atlas TI); - Transcription of the interviews; - Use of multiple researchers.
Objectivity	The extent to which findings are free from bias (Lincoln & Guba, 1985).	- Raw material presented, including interviewees quotation; - Create a case selection criterion.

Thus, we selected companies from different sectors representative of the Brazilian economy. To avoid that the findings in the survey did not represent the entire company, we tried to do at least three interviews per case. Besides, we looked for profiles from different areas of operations. Finally, the research protocol used in this study was made available in the Appendix.

RESULTS

The data analysis of this research was divided into two sections following Eisenhardt (1989): the first one, a within-case analysis, each of the six cases context were deeply analyzed; and in the second section, a cross-case analysis will be presented, where the main categories and subcategories that emerged from the interviews were evaluated, and an analytical model and interaction between constructs will be presented. Citations throughout this section are referenced at the end by a code that refers to the code of the respondent of origin.

Within-case Analysis

<u>AUTO1 - Multinational of the Automotive Industry</u>

Historically, this company has defined the location of its operations based on the tax incentive policies offered by local governments in less developed areas of the country. Unlike other

companies, that settled in the more industrialized region, it was necessary to create a supplier base of their own.
AUTO1 today is […] off the map of most suppliers, it has a belt of (near) suppliers here, it is a risk because with the falling market as we had a while ago, suppliers could break. It could paralyze the production line and everything, but it is a risk assessed as low for people compared to competitors, even because it is off-axis there in São Paulo, Rio, and other regions, it is isolated here and we have more control over it (suppliers) (AUTO1E1).
With the opening of new plants, more distant geographically, the risk of rupture increased dramatically, which led the company to build facilities for its suppliers within the plant. That strategy was a way to mitigate the risk of rupture of the production line, also the company created a supplier evaluation system to monitor the financial health of local suppliers.
When it was opened here (a place far from the industrialized area), it was decided to build what we call of "Supply Park". The Supply Park is a total of 9 strategic suppliers, which we bring here. So, we set up the plant, […], we gave them these buildings and they got the technology (AUTO1E1).
The company deals with a series of pressures from the national institutions that regulate its activities. To mitigate these external pressures, several systems have been created that mitigate uncertainties in regulation. Therefore, it takes a great effort to adjust to government changes.
Every time the government changes the legislation we have to make a systemic adjustment and the legislation changes, literally speaking, every day. To give you an idea, 25% of the commercial area effort is these adjustments, (the government) is the largest single client of our company (AUTO1E4).
Another important influence is the market instability generated by the national economic crisis, which changes the profile of the final consumer. Despite a generalized drop in sales, there was a steeper decline in cheaper products, with the luxury goods segment gaining importance in this time of crisis. This has brought internal changes by valuing the quality of the product more than seek for reducing costs.
I think the market has dropped a lot. But it also changed a lot, cars getting more expensive, AUTO1 betting more on quality, so when I joined the group was already undergoing this modification. Today it is much stronger. When we went to the maintenance of material we were under a very great pressure that was to choose the cheapest things. Today, we have a much greater pressure to choose the things that work, it does not matter so much. Obviously, that it has cast management, but we are not as tied to the cost (AUTO1E2).
Therefore, the company uses different processes of exploration resources to remain competitive. The exploitation process is used by the company to accommodate some direct pressures from the institutional environment such as regulations. Thus, the company creates systems and routines that can mitigate these changes, however, without generating improvement in competitiveness. On the other hand, the installation of factories in remote regions has generated the company's need to develop a strategy to mitigate logistics problems. Thus, the creation of the structure for the suppliers near the factory generated productivity gains, by offering greater control of the company production process. Therefore, the company uses both exploitation and exploration processes in the hierarchical renewal strategy.

AUTO2 - Multinational of the Automotive Industry

This company was greatly affected by the 2008 economic crisis. Because of this, it underwent a long process of global restructuring, including processes, products, and costs in its all subsidiaries. Since the Brazilian national crisis, the company has taken the lead in production and has already announced several investments in the country. Despite this, political instability is still viewed with caution.

I see the AUTO2 appearing, we learned from mistakes (that lead to crises in 2008) and now we are the market leader and we will not give up easily, we will fight tooth and nail. We are investing a lot of money […]. We have had a crisis in recent years in Brazil and we are announcing a lot of investment in Brazil. Take advantage of the opportunity of having a crisis, to have an idle capacity of the supplier, tooling supplier and manage to negotiate better prices for us because we have money. And he who has the money to invest ends up doing good business. […] (AUTO2E4).

The disruption in supply has become the biggest pressure for this company. As a result of the Brazilian economic crisis, several suppliers went bankrupt or became indebted. The market has shrunk approximately 70% in the last 3 years, and the local suppliers were very threatened by this drop in the market.

For example, there is a hole in the car and you have to plug the hole to not let in water, so it's this type of plastic or air ducts. So, the plastic industry, for example, is an industry with few players and many (of those) players with financial difficulties. This is a risk, it is a delayed chain compared to outside of the country (AUTO2E2).

To mitigate this pressure, the supplier's financial instability, the company has been conducting its evaluation through an external consultancy. Those suppliers who are in trouble are indicated for a recovery plan. As an alternative, the company seeks new suppliers, national and international. Therefore, as a way to maintain its national operations, the company increases its dependence on international suppliers.

Those (suppliers) who are at financial risk we do have (evaluation system). We have a score, we hire a consultancy that does this evaluation. We try to develop some plan to recover this supplier or to develop a plan B (another supplier), a secondary source. Or eventually, in certain cases, we develop a final alternative source and we leave that supplier (AUTO2E2).

Today the risks we have are lack of qualified suppliers. [...] then today here in Brazil we have less productivity, some suppliers of medium quality, compared (to international suppliers) ... Of course, all of the level, but out there the level is higher than here and productive is much higher. So, the risk today is the supplier in the chain, a (quality) little below the market out there (AUTO2E2).

The main pressure of the external environment is suppliers' bankruptcy. The company uses the exploration process by creating supplier assessment mechanisms and financial assistance. Thus, the company uses internal resources to strengthen the supply chain, gaining competitiveness, adopted a managerial selection strategy.

AUTO3 - Multinational of the Automotive Industry

This company was one of the first to install facilities in Brazil in 1950, and still has its main operations in the most industrialized region of the country. One of its plants works with a model called modular, in which strategic suppliers were invited to develop the plant together, which ended up generating managerial skills aimed at flexibility. This allows the company to deals better with the instability of the domestic market.

We have the flexibility/agility to tailor our volume up and down. When you have a need for fitness, you divide that responsibility into 8 partners. So, you work with agility to solve the issues very fast and on the other hand, you have a constant struggle, in a good way, to reduce costs, because everyone wants to. In fact, reduce costs with the same qualities to be able to generate, for the customer, a value-added perception of our product. This as competitiveness is a big differential (AUTO3E2).

This type of model is seen by the interviewees as something irreversible, that is, the skills generated in this plant cannot be copied in the other plants owned by the company. Despite that, the financial health of national suppliers is considered a great pressure for this company also.

We have suffered from 2 or 3 suppliers there because of financial risk. It turns out, the guy stops giving you the piece and says "I do not have the money to buy the raw materials". It's almost a knife in your neck, from where we come in with money to buy the raw material for the guy, some suppliers are at that level. Of course, you start a plan to change supplier because you cannot live like this (AUTO3E3).

For the interviewees, the contribution of foreign capital differentiates the capacity of the multinational in overcoming an economic crisis in front of the local suppliers. Thus, multinationals can deal with market fluctuations in a given country, since the other subsidiaries do not suffer directly from national crises in other countries.

A problem of the economic crisis here, the corporate headquarters inject capital, they make a capital contribution to hold the fight. A normally global supplier also has this benefit. I worked with a supplier, I say this with propriety, in a moment of crisis there was a capital injection, so you can ride the wave in the moment of crisis, taking damage, but you will not close because the market oscillates. Today you are losing and tomorrow you win again. That's what happens with automakers, but there are many domestic suppliers where the guy has no cash flow and many suppliers have broken into many crises (AUTO3E3).

The factory modular model offers the company the ability to flex production quickly, which brings efficiency to deal with abrupt market reductions, which fits as an exploration process. Regarding supplier bankruptcy, no supplier assistance mechanisms were identified, only evaluation mechanisms, identifying an exploitation process. Thus, we can identify that a hierarchical renewal strategy has been adopted.

<u>BEER1 - Brazilian Multinational in the Beverage Industry</u>

The case presents a company that has an operational competence in costs based on a standardized process, as well in logistics of distribution in the interred country. However, the risks production stoppages caused by suppliers increase over time but was reported that occur mainly because of the low quality of the inputs. Therefore, it was necessary to create a national supplier assessment system, which mitigated this pressure.

Employing this evidence, the company developed a ranking system of the suppliers, to mitigate the risks of delivery in terms of inputs quality. This system is centralized in the matrix, although there are local rankings due to variations of deliveries by regions and quality delivered from the same supplier. On the one hand, the ranking helped the company to monitor the inputs received; on the other hand, this ranking has now demanded a higher level of quality management and supplier deliveries (BEER1E3).

Also, this company noticed a movement of small companies boosting the beverage market from the consumption of the artisanal brewery. As a response to this market, the company started to acquire an ample amount of handcrafted companies located in Brazil, the United States, and Europe. With an already established distribution system, the company now has handicraft products in addition to traditional mass-produced products.

But, finally, [...] there are several sectors, but as the Brazilian profile is changing more for craft beer we started to invest more in craft beer and premium beer. [...] If you have a market you have to invest. Until, for example, they are thinking ahead, I do not know if they have even started selling, for example, hops malt for handmade producers (BEER1E2).

Additionally, this company deals with problems related to the lack of public security, such as cargo theft. To do this, the company contracts insurance and makes use of monitoring systems that were initially purchased to reduce distribution costs. Despite this, there is no more active mitigation by the company, due to the wide distribution network and the costs associated with the use of armed escort, for example.

BEER1 does not have such aggregate value within the product. So, I think the cost of an armed escort and the risk it brings to people is too great. We work with insurance for freight, for distribution and transfer to the center. We do armed escorts at the factory park. In the distribution, it doesn't. It is not worth financially and not worth in for the operations. We have a very large operation to have an armed escort for everyone (BEER1E2).

To deal with cargo theft pressure, the company adopted a strategy of selecting systems and practices that were not initially developed to deal with this problem. Thus, the company does not gain competitiveness in the distribution over its competitors, using an exploitation process and a naive selection strategy.

BEER2 - Multinational of the Beverage Industry

The second case in the beverage industry deals with a multinational company that has aggressively entered the national market in the last five years. This company strategy was to buy local breweries, besides bringing their original brands to the national market. Compared with direct competitors, the company shows high-quality products. However, the merger gives rise to some pressures concerning the brand, the processes, and quality levels.

We talk a lot about departments and each department has a strategy and sometimes this strategy is a bit out of alignment with reality, and now that it is merging, there is still a lot of internal alignment problems of just in terms of production, which product is produced and which is not (BEER2E1).

Given the risk of reputation (image to the customer), the company started to develop its processes with rigid standard procedures, enlargement and greater participation of the laboratory in the control of the process to guarantee normality in production batches over time. Considering a set of biological elements involved in the manufacture of beverages, the laboratory-raised the quality control of the process, and in turn, allowed to raise the quality management of the final product (BEER2E4; BEER2E5; BEER2E6).

Since the acquisition by the multinational, the national plants have developed a more effective preventive maintenance in order to ensure a reduction in unforeseen losses and higher standards of product quality. This allowed the company to affirm its image of product quality in the Brazilian market.

Despite this, the company handles problems common to the national beverage market. According to an interviewer (BEER2E1), there are cases of product counterfeiting in the industry where lower value products are changed with the more expensive product labels. This practice, although not very significant, is very difficult to restrain, since clients and employees of the company do not perceive the falsification through simple verification of the product.

If we discover a product of ours, as (brand of the multinational), which is a widely used brand (for counterfeiting). It is the most used brand. In fact, they buy our product to transform into another. The guy buys (brand of the same group) to turn it into (a premium brand of the same group), or in (a mainstream brand of BEER1). What happens? Selling a cold beer in the bar is impossible to detect. We say it's impossible because we have a tasting panel there, trained people, master brewer, who have difficulty differentiating one beer from the other. It is very easy this forgery, the perception of the end customer is very difficult. We help, always have police investigation, etc., we contribute, obviously do not agree, but this happens in the market (BEER2E1).

The product counterfeiting does not aggressively affect the company, no new practices or system was adopted to mitigate this pressure. Thus, the company does not affect the external environment, adopting a naive selection strategy.

COSM1 - Brazilian Multinational of the Cosmetics Sector

This case deals with a company that acts with high levels of sustainability. With their suppliers located in several regions of the country, there is a strong pressure related to the climatic issue. This pressure does not only affect the probability of a disruption of the production flow, but also the distribution based on direct sales. "[...] A region that has large levels of flooding, or regions that are subject to landslides, this makes it difficult for the consultant to deliver" (COSM1E1). Quality is seen as the company's main performance as well as its delivery capability. To ensure the quality of the inputs, the company started to buy inputs from local suppliers in the Amazon Forest. As these inputs are part of its market positioning, the company seeks to develop these suppliers. Thus, the company sought to open a plant near these suppliers. To this end, it sought fiscal benefits from the local government because the region has a low level of development and a large demand for investments and employment.
That's why I told you, not only the tax aspect, the monetary aspect, in the first place and the rest of the world that gets screwed up (in deciding where to install a factory). It has a variable that the company looks at. We had a small base in (Amazonian city) where we processed all the oils that came from Amazonia. [...] In this ecosystem, we collected rainwater, the treatment of the water is made entirely natural, only with the plant, has no chemical, a whole structure on top of that factory. [...] So we went to the government and said, "Look, we have this strategic vision of a factory in [the Amazonian city], near the forest, then minister, what profit do we get?" It is not that I build the factory that the incentive will be given (COSM1E2).
However, this geographic dispersion also generates problems related to the strategic positioning of the company as a sustainable organization. Thus, any activity that increases the company's carbon emissions goes against the internal guidelines, which causes the company to seek new ways to distribute.
This indicator (related to sustainability) for us greatly affects the environmental impact ... we already have goals for that. The annual employee bonus is tied to the percentage of carbon emissions, cost, quality, and normal supply chain (which allows) to know how we can reduce environmental impact. Then there is the concern if I send something to Bahia (northeast state) by boat or by car or I deliver in the region with electric car or bicycle and not with a Fiorino (a type of truck) (COSM1E2).
The strategy of positioning as a sustainable company has generated a series of long-term internal changes. In this way, the company's routines had to deal with changes to suit the company's new standards. The result was that the company gained prestige in the market, using products from the Amazon Forest produced by local communities. Thus, we can understand that the company used an exploration process adopting a hierarchal selection strategy.

TOBC1 - A Tobacco Multinational Firm that Bought a National Company

This is a national origin company that was acquired by an MNE. It is the leader in the tobacco industry with over 80% of the market share. However, the legal market represents only 60% of tobacco sales in the country. The other products are illegally imported by the Brazilian border with Paraguay. Thus, the company had to develop systems that help the national security forces to counter this external pressure.

These management systems have become very useful when cargo theft started to increase in the industry. In particular, the cities of Rio de Janeiro and São Paulo, this pressure became so strong that it was necessary to create a system of convoys protected by an armed escort. However, there were conflicts between thieves and security agents that resulted in death. Because of that, this system had to be reviewed in the city of Rio de Janeiro.
The company, therefore, has the power to influence the institutional environment by working together with the government agency to mitigate the problems related to cargo theft. These strategies, along with enhancing distribution security, improve your positioning against competitors. Thus, the company adopts the strategy of hierarchical renewal, as it manages to develop systems and new routines to deal with this pressure. Also, it manages to include internal partners and government agencies in its strategy.

Cross-case Analysis

After analyzing the cases individually, an analysis of all cases was carried out (Corbin & Strauss, 2008). Thus, we began the analysis of the open coding of the 29 interviews, and of the more than 100 different codes found. It evolved into a final model with three main categories, six properties, and twelve dimensions, present in the following tables. The main results pointed to a concern of the managers regarding the competences adaptation to the uncertain institutional environment. In the view of the managers, there is a general uncertainty with the actions taken by the government, especially in public policies and regulations. This uncertainty has become more serious when the country has entered an economic crisis in recent years.
Therefore, the competencies of these multinationals needed to adjust to the unstable environment, and this has become an important competitive advantage for the success of these companies' strategies in that country. Thus, we decide to pursue this path of understanding how the process of coevolution takes place. To interpret the results, we proposed three relevant categories: (1) Institutional environment influence; (2) Capability adaptation; and (3) Companies' influence.
This section continues to analyze in-depth each of the three categories encountered, and the relationships between their respective properties and dimensions. The tables summarize this information based on a sample of proof quotes. From these relationships, the prepositions of this study emerge in the next section (Discussion and Conclusions).

<u>Institutional Environment Influence</u>

The institutional environment is the source of several influences for the companies located in emerging countries (DiMaggio & Powell, 1983; Sapienza, Autio, Geoge, & Zahra, 2006). The institutions of these countries are distinct (Meyer et al., 2009), and may generate different pressures in MNEs (Meyer & Peng, 2016). Lewin and Volberda (1999) argue that the corporate strategy is defined by the influence of these pressures.
Uncertainties can be perceived differently by different industries because they generate pressures that affect them differently. For example, cargo theft strongly affects the tobacco company (TOBC1), has been identified as less harshly in the cosmetics industry and has little influence on the automotive industry. Infrastructure, however, seems to affect all companies located in regions far from the economic center of the country (AUTO1; BEER1; BEER2; COSM1). These factories are attracted by tax benefits offered by the home state or by the central government to develop the poorer regions. However, in addition to increasing the distance to the consumer market, these regions are lacking in quality infrastructure.
Once the pressures were identified, it was possible to identify which of them had more influence, and the level of impact on operations. Some institutional pressures, such as union

power (BEER2), had little power of influence and impact on operations (AUTO1). In contrast, public policies had a high level of influence and impact on operations. An example of this was in the automotive sector, which received tax incentives and increases in capacity. After the national economic crisis, the government couldn't maintain this policy, the demand was reduced, and the companies are now overcapacity (AUTO1E3).

Table 3: Institutional Environment Influence, its properties, and dimensions

Properties	Dimensions	Proof quotes
Uncertainty level	Low level	*In some regions, we do have unions that are more active for everyone and everything, and some localities have a stronger alignment. I have an alignment very close to the union, and one of the ways I managed to resolve the workday was to bring the union into the Distribution Center […] That is very much the way it is handled and how it is negotiated, but it has serious interventions (by the union) in some regions, especially in the transport area* (BEER2E3). *Generally, what is always being discussed in these (union) protests that I see is usually always related to salary. I've never seen any kind of advertisement, no kind of protest regarding non-labor rights. [..] I've never seen any kind of fight, nothing offensive, police, nothing* (AUTO1E2).
	High level	*... and you talk about financial risk, yes because (tax legislation) changes so much, it's very complex, we buy more than 6, 7 thousand pieces to make a car. So, you have (different legislation in) several countries around the world including here from Brazil, and in Brazil states that have different legislation* (AUTO2E4). *Inovarauto's (national public policy for the automotive sector) energy efficiency program aimed to have more than 15% improvement in energy efficiency. [..] Unfortunately, the government linked the program to steps in the productive process and this gave a feeling of a kind of protection to the local market. Which caused this measure to be questioned in WTO and we lost* (AUTO1E4). *We do not have tax benefits and every market works like this. One minute you have it, and the next it is gone. Then it's a problem. It may also be as the country is, in crisis, increasing the tax on beer. It is possible too, I am speaking more about the past. In fact, many tax increases were for alcoholic beverages. Alcoholic beverages and soda. In fact, these products are not essential for survival, so it makes sense for the government to raise taxes (BEER2E6).*
Influence impact	Direct impact on operations	*[..] law labor risk is one of the things that most change the factory. There is a case here that is emblematic, a woman came to work in high hills. Then she stumbled onto a sidewalk in the factory. [..] (Government) work safety time came and lowered a rule so no one else could use high hills (in the factory). We had to change all the sidewalks in the facility. So, labor risk always influences and drives a lot of big companies and, especially, an automotive company*

Table 3: Institutional Environment Influence, its properties, and dimensions		
Properties	Dimensions	Proof quotes
		(AUTO1E4). *There are tax classification rules that determine the percentage of nationalization of an item accordingly... and each has a tax rate, so ascertaining this correctly also is a significant job (AUTO1E4).* *I will give you an example, the government has created a program called the employment support program, which is a PES that allows companies to negotiate, with their class unions, a reduction in working hours and wages, and subsidized 50% of this reduction. [..] This alternative is one that allows you to make the journey more flexible, making the volume of production more flexible at an attractive cost for you, the employee and the government. For the government, because it guarantees employability, for us we can adjust the volume of production according to the market, at an attractive cost, and for the employee who has the guaranteed job and continues to receive more than he works. This is an example* (AUTO3E2).
	Indirect impact on operations	*So, it is extremely critical (supplier bankruptcy). What happens is that in Brazil there are many national suppliers. Nationals (suppliers) have a strong cash flow problem. Recently AUTO3E4 even promoted a meeting between suppliers and BNDES (government national bank) to encourage it to grant credit to these suppliers* (AUTO3E4).

However, the pressure does not impact all sectors in the same way. For example, TOBC1 and BEER2 identified that cargo theft was a risk affecting their distribution. Thus, through the routing, the most recurrent places of this event were identified. The same risk was not considered relevant by the companies AUTO1, AUTO2, and AUTO3, therefore, they do not carry out actions of the same nature.

In general, institutional pressure with a lower degree of severity tends to have a timely monitoring process, and any mechanism for effective monitoring is implemented. Unlike risks that impact the operations and flow of the company's products, monitoring is constant and, in general, accompanied by other mitigation mechanisms. For example, AUTO3 identified that outdated infrastructure was a lifetime risk for its products, causing the engineering team to increase the accuracy of quality tests before putting the trucks on sale (AUTO3E1o). According to Cuervo-cazurra et al. (2018), the MNEs evolve their practices due to the pressures of different institutional environments, which suggests a capability development.

The severity of the operational impacts is evaluated by managers to define their adaptation efforts (Carney, Dieleman, & Taussig, 2016). For example, the economic crisis had a very strong impact on suppliers in the automotive sector, with the risk of supplier failure becoming critical. Thus, several actions were carried out, such as the financial monitoring of suppliers. The same risk was identified as low by the beverage and cosmetic sectors, with little effort in that direction.

Capability Adaptation

The process of capability adaptation happens when a company performs actions to deal with the identified pressures. However, different strategies to deal with unique pressure could lead to different results. It was identified that some companies agreed to set up their factories in isolated regions of the country to receive a tax incentive from the state that promotes this policy (AUTO1; BEER2; COMS1). Due to this, these companies reacted to a government incentive without taking measures to reduces the logistics risk (BEER2). This not necessarily contributing to an improvement of their strategic positioning or a capability creation, but it reduces operational cost.

Table 4: Capability Adaptation, its properties, and dimensions

Properties	Dimensions	Proof quotes
Capabilities adaptation level	Low level	*AUTO1 engineering we develop radio, an instrument panel that are the ones we say are the original factory, but the same person who develops these radios too develops alternative radios that we call (incomprehensible). Then we develop the originals and know that they will be in the cars and everything else and we also develop other brands. Then AUTO1 itself develops the radios that it sells as alternatives. So maybe it's even to avoid counterfeiting in the parallel market and everything. The same engineer who developed the original, he also develops a similar cheaper* (AUTO1E2).
	High level	*Obviously, the road infrastructure is a problem for the trucker. In general, our products undergo the most rigorous tests here, and some of them simulating rough and/or poor paving, and the idea is always to have a product fit to work with the real conditions of Brazil. Obviously, everything has its limits. So, I would say that, in a general way of infrastructure, we have authorized stations, we have dealerships spread all over Brazil and our products undergo the most rigorous tests before they enter the field. The field is also faithfully accompanied by our group of technical and quality assistants, and when necessary, the engineering team also enters to be able to make the evaluations (AUTO3E1).*
Uncertainty severity	Little impact	*[…] the radios are assigned to work in a specific car. If you take one car and put it in another it does not work, so this ends up inhibiting the interest of theft. […] So, it happens, but it's punctual or something that worries us. I can tell you that it's one or two trucks that happen a year and the guy (thief) sometimes even sees the load and gives up the theft* (AUTO2E4). *Yes, but I think it is not in such a large proportion (forgery of products). We have already seen some seizures here and it is not a volume that justifies so much action on this (BEER2E3).*
	Critical impact	*We already had there in 2011, 2012 reduction of IPI that gave a boom in the market and I think even harmful because we had a significant increase in sales, increase in productive capacity, in*

Table 4: Capability Adaptation, its properties, and dimensions		
Properties	Dimensions	Proof quotes
		investments and it did not stay like that. Today we have idle capacity. AUTO1, for example, works with 60% of total capacity (AUTO1E3). *The Brazilian market was already the 5th largest car market in the world and was turning into 4th when [the factory] came to be. The market experts predicted that by 2018 we would reach 5 (million) units, this was much more than the installed production capacity of all manufacturers at the time, and everyone started to build factory after factory. Unfortunately, all forecasts were wrong, and we went 12 years back in terms of production volume, with several factories becoming idle (at the production level) as well* (AUTO1E4).

The same incentive, fiscal benefit, was used by COSM1 to strengthen its cosmetics production in the Amazon. Thus, the plant was installed close to its local suppliers, through the strategy of positioning itself as a sustainable company and defender of the Amazon Forest (COSM1E2). Here, the company acted actively in the use of public policy to reinforce its strategy, creating an institutional capability (Carney, Dieleman, & Taussig, 2016). On the other hand, AUTO1 mitigate the supply risk by created facilities for strategic suppliers in its own factories, which brings them more control to the entered process (AUTO1E1).

Companies' Influence

As predicted by the coevolutionary theory, firms do not act as passive agents to the environment but influence it (Cantwell, Dunning, & Lundan, 2010). This influence can only be reacting to the environmental pressures to contain these influences (exploitation), but it can undergo profound changes in its competences that have generated competitive advantages (exploration).

Table 5: Companies' Influence, its properties and dimensions		
Properties	Dimensions	Proof quotes
Ambidexterity process adopted	Exploitation	*For example, our factory in [distant state] today has its incentives and it's worth it for us to be there. If we are there, it is because there is a reason, certainly when we talk about costs. In the first place of any project, BEER2 considers taxes. I think for everyone, there is no longer an option to overlook taxes, tax incentive, concerning to planning a project* (BEER2E5).
	Exploration	*Suppliers are divided into groups. When [the factory] was opened [in a distant state], it was decided to build what we call supply park. Supply park is a total of 9 strategic suppliers, which we bring here. So, we set up the plant, built and supplied them with*

Table 5: Companies' Influence, its properties and dimensions		
Properties	Dimensions	Proof quotes
		the structures, and they came in with the technology (AUTO1E1). *The guy (supplier) is here on your side, the guy stays inside our park. So, he goes on to say so, our rules, such as uniform is the same pattern like ours, follows our standard of quality, the restaurant they eat is the same as ours… Such interaction is very great for us. So, it is very easy to solve a problem, it gave a problem you automatically in 2 minutes is already in the supplier's factory to solve. He has a great relationship* (AUTO1E1).
Influence impact	Direct	*It is an institutional relationship. We visit the police stations [..] present what we have done for safety and what we need to support them, in a reaction force, in research work* (TABC1E4).
	Indirect	*No, so much so that the government's role ... we always treat the government as a partner for the company in terms of activity, we had a financing with the BNDES recently that is still in force, that is important for the development of new products, in short, the sector regulation, as I said before, it goes through discussions in ANFAVEA, that is, they put an intermediary to meet or discuss market actions and in general I would for operation, government participation is more in terms of financing or something of that nature* (AUTO3E1).

This process is associated with each company's absorptive capacity strategy. Short-term decisions that do not imply future benefits, such as reducing operational costs with fiscal incentive, are associated with exploration strategies. However, when the company reacts to external pressure and manages to create a capability that brings competitive advantages, this is associated with the exploitation strategy (Birkinshaw & Gupta, 2013).
The influence of corporate strategies on the institutional environment can happen indirectly or directly. Indirectly, in general, it happens in sectors that have stronger associations, such as the automotive sector. This sector defines jointly with the government public policies through its national association, the ANFAVEA. In sectors in which a company has great market share, like tobacco, it acts individually, defending only the corporative interests of that company.

DISCUSSION AND CONCLUSIONS

Abrupt changes in legislation, economic crises, or changes in government public policies can aggravate information asymmetry and long-term strategy (Meyer & Peng, 2016; Yamakawa, Peng, & Deeds, 2008). Companies with operations in an uncertain institutional environment, as emerging countries, seek to adjust practices and strategies to respond to those pressures (Oliver, 1991).
To avoid disruptions in the companies' activities, all cases show some perception of potential institutional pressures. These pressures are perceived by the company according to their level

of operational impact. Institutional pressures can lead to capabilities adaptation (Carney, Dieleman, & Taussig, 2016). However, your findings suggest that pressure considered more important (high level of impact) is associated with greater effort to adaptation. Therefore, the choice of the process of exploitation of resources occurs in the function of the impact that the pressure in the company. Thus, it is possible to establish the following propositions:

Proposition 1. Uncertainties in the institutional environment are highly associated with direct and indirect impacts on the company.

Proposition 2. The choice of resource exploration process is highly associated with the level of impact of uncertainties.

The results of the research also suggest that companies exert influence in the institutional environment in two ways. This influence can occur directly, in which the company plays a decisive role in the promotion of public policies such as financing (AUTO2) or security strategy (TOBC1). However, companies may use industry associations to exert influence on public policies, such as the automotive sector. This suggests that the composition of the market can determine the channels of influence, therefore, very representative companies in their industry (TOBC1 and BEER1) tend to seek direct channels. Thus, it is possible to establish the following proposition:

Proposition 3. The type of market composition is highly associated with the direct or indirect influence of the company in the institutional environment.

In this research, we investigated how MNEs responded to pressures caused by institutional uncertainty, identifying how the influence between companies and institutional environment affects capability development in emerging countries. The main findings suggest that the impact level of uncertainty leads companies to develop new capabilities (exploration) or strengthen existing ones (exploitation).

As a limitation of this paper, the analysis does not allow for speculation on the difference of pressure response between national and international MNEs. Only in the beverage industry the selected cases reflecting this dichotomy. Another possibility is to understand how incoming companies adapting their capabilities to foreign markets in the first years. Another possibility for future research would be the monitoring of a single company during a longitudinal period, observing the creation and adaptation of its operational capabilities. These non-answered gaps could be subjects to be explored in future related research.

APPENDIX

Research Protocol

1) Research proposal

This paper aims to understand how the capabilities development process in MNEs is affected by the uncertain environment in a Coevolutionary Theory approach.

2) Search question

The research question of this study was: how does the uncertain institutional environment affect operational capabilities' coevolution process?

3) Theoretical bases of the research

- Coevolutionary Theory;
- Ambidexterity
- Institutional Theory.

4) Selection of cases

The main criteria for the selection of companies were:

- MNEs that have greater power of influencing in their respective markets;
- Leaders in the national and global market, of the automotive (3 companies), beverages (2 companies), cosmetics (1 company), and tobacco (1 company) sectors.

5) Data collection

- Interviews with managers recorded and transcribed;
- At least three interviews by each company.

6) Data Analysis

- Definition of codes in an open way through the technique of content analysis;
- Analysis based on within-case and cross-case analysis.

Semi-structured Questionnaire

Introduction
Full name
Position
The interviewee history in the company
How do you see the company in the market: Leader? In what categories? Who are the main competitors?

Part 1 - INTERNAL FACTORS
1) What are the main internal risks that the company manages?
2) What does the company do internally to manage them?
3) What competencies were created/adapted from risk management? Examples.
4) What motivates the company to develop such skills? Describe internal and external factors (internal factors: managers, processes, supply chain, etc.).

Part 2 - EXTERNAL FACTORS
5) What factors outside the firm motivate the creation/adaptation of company skills? What is the role of each? (Competitors, suppliers, sector, institutions, regulatory etc.).
6) How does the company respond to external influences?

Part 3 - PERFORMANCE
7) Regarding the operational performance such as cost, quality, flexibility, and delivery, which of them do you consider that your company performs better than your competitors? Why?
8) How did the risk capability development contribute to this performance? How did internal and external factors contribute to this?
9) In those who think that they perform better, which practices do they support? How do you use such practices? Give examples.
10) How the risks described influence the performance of the business or the business unit.

Part 4 - INSTITUTIONAL ASPECTS
1) How does labor legislation affect the competitiveness of the company? Is there a risk to trade unions?
2) Is there any risk concern to tax regulation?
3) How the sector legislations are defined? Does the company have an active voice in this definition?

4) Has there been any change in your operations to deal with crime? (Theft of cargo; counterfeiting).
5) How does the issue of infrastructure affect your operations?

Optimum Buffer Size of Steel Strip Coils in a Continuous Pipe Production System

Md. Shahriar J. Hossain

Bhaba R. Sarker
Louisiana State University
Email: bsarker@lsu.edu

ABSTRACT

The performance of a continuous steel pipe manufacturing system can be improved by solving different operational problems in the system. One of the important problems involves determination of buffer capacity of the coil accumulator which acts as an inter-stage buffer storage of steel strip that slowly feeds into the rolling benders to form the steel pipes. This research work is oriented in modeling this part of coil-feeding operation before forming the pipe and solving this by ensuring minimum costs for building and maintaining the sufficient buffer storage space to keep up the normal flow of raw materials to the system.

KEYWORDS: Buffer Inventory, Cost minimization, Operations management, of Continuous production system.

INTRODUCTION

Continuous seam welded pipes are produced from steel strip coils. These steel strips are first uncoiled and straightened. Then the steel strip is welded with the end of preceding strip to maintain a continuous flow of it as needed by processes. In order to avoid any disruption of production due to this joining operation a buffer inventory is held in between joining and forming stations [Figure 1] (Hossain and Sarker 2018). This buffer zone is known as coil accumulator which can hold steel strips for future use as a safety stock.

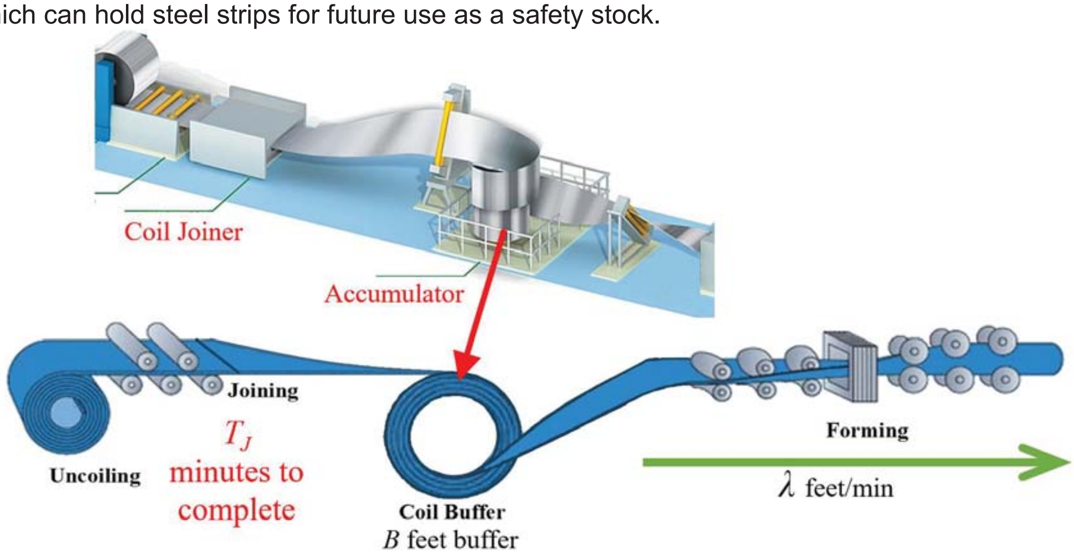

Figure 1. Buffer storage (accumulator) before the forming station.

The coil feeding system comprises of coil joining and coil accumulation. While a new steel coil is fed into the line through a welding joint, the process needs not to be stopped, rather the steel strip is continuously delivered to the main manufacturing line from a coil accumulator. The size of the allowable buffer inventory (buffer capacity) directly depends on the strip joining time. When feed rate of the line (roughly the pipe production rate) is given by λ feet/hour and the coil accumulator (buffer) can accommodate *B* feet (buffer size) of steel strip, the operators at the joining station gets maximum B/λ hours to complete their job. If they fail to complete the joining process by this time, the whole line must be stopped.

In order to avoid the line stoppage or downtime, the runout time of steel strips at the coil accumulator should be kept within an acceptable limit. High buffer inventory at the coil accumulator provides higher flexibility of time to carry out the joining operation. However, an increased buffer capacity results extra holding and operational cost, in addition to the initial fixed cost for buffer accumulator construction. So, an appropriate buffer capacity can be traded off between the buffer holding cost for maintaining the strip flow and downtime cost for potential loss of production. On the other hand, the time required for coil joining process is not deterministic rather shows some variabilities. Now, the problem is, therefore, to find an appropriate buffer capacity of the coil accumulator that can minimize the total cost of coil feeding facility. The buffer runout probability which in fact directly affects the buffer runout cost, eventually affects the value of optimum buffer capacity. Hence, determining an acceptable limit for buffer runout probability is another objective of this research work.

LITERATURE SURVEY

When needed, the in-line buffer storage is an intermediate stock of materials in the line that helps maintain a continuous flow of the material to the next subsequent station. An in-line buffer provides flexibility to avoid the shortage of raw material supply (here, strip of coil) for a station, and hence, reduces the disruption of the continuous process. Oversized buffer causes higher cost for holding the materials (in addition to initial large erection/commission cost), whereas a small buffer can cause station idleness due to lack of material leading to lower throughput and efficiency. The optimum size of the buffer capacity varies depending on the process and system parameters. Several research works were conducted in last few decades, in order to investigate the effect of the buffer storage on the line efficiency and to obtain an optimum size and location of the buffer in different production systems.

Effect of Buffer Storage on the Line Efficiency

The buffer storage in the multistage series production systems has been analyzed for more than fifty years. In the early stage, Hillier and Boling (1966) presented a detailed discussion and mathematical analysis about the effect of buffer storage on the production rate of two, three or four station production line. Next year, Buzacott (1967a) claimed that the efficiency of an automatic transfer line can be increased by dividing the line into a number of stages and providing buffer stocks between the stages. He (1967b) presented a model for predicting the line efficiency and showed how the line efficiency depends on the buffer capacity. Knott (1970) also considered a production line as a series of finite buffer at each station and developed a simple formula for determining the inefficiency of the line. N. P. Rao presented analytical studies for several aspects of two-stage (Rao 1975) and three-stage (Rao 1976a) production systems with inter-stage buffer storage. He presented the mathematical analyses for Erlang service times (Rao 1976b), as well as generalized distribution of service times (Rao 1975, 1976a). In a study, Panwalkar and Smith (1979) devised an expression to predict the average output rate of a series of multiple workstations with inter-stage finite buffers and exponential service times.

The intermediate buffer storage in a continuous process is analyzed in literatures for last few decades. Alvarezvargas *et al.* (1994) discussed about some simulation results to compare the production rate of the continuous flow model as an approximation of the asynchronous model. They considered manufacturing flow lines with deterministic processing times, unreliable machines, and finite buffers are considered. Tan and Gershwin (2009, 2011) used the fluid flow models to evaluate the performance of a two-stage production line with an intermediate finite buffer. They determined the production rate and the expected buffer level from the steady-state distributions. However, Bierbooms *et al.* (2013) analyzed continuous production lines consisting of a number of machines in series with a finite buffer between each pair of machines. They precisely estimated the throughput and the mean buffer content of the production line. Ozdogru and Altiok (2015) proposed a decomposition approximation method to study the steady-state behavior of a continuous material flow system operating in bulk port marine terminals, in terms of down time probabilities and the system throughput.

Buffer Allocation and Optimization

The optimization of buffer capability and location was one of the important topic in several researches. Anderson and Moodie (1968) analyzed the steady-state production line systems using simulations, to develop a total cost model. They derived an expression for an optimum capacity of the buffer storage that minimizes the total cost. Basu (1977) also developed a total cost model, for exponential service time, in order to optimize the buffer storage capacity. Sarker (1984) presented a critical review and a comparative study of some design aspects of the series production systems with a special emphasis on the design of inter-stage buffer stocks. Seong *et al.* (2000) formulated a non-linear programming for the buffer allocation problem in a continuous flow production and proposed an algorithm to solve the problem. Fu and Xie (2002) derived estimators of throughput sensitivity to changes in buffer capacity for continuous flow models. Rajaram and Tian (2009) formulated a non-linear integer program for optimizing the location and size of buffers in semi-continuous manufacturing processes.

Turki *et al.* (2013) presented continuous and discrete flow models for a single-product manufacturing system with a buffer storage and stochastic demand. The objective of their study was to find optimal buffer level, which minimizes the total expected cost. Kolb and Gottlich (2015) dealt with the buffer allocation problem consists of a production process combined with stochastic processing times. They derived a time-continuous model supplemented with a stochastic process. Gebennini *et al.* (2015) dealt with the performance evaluation of a two-machine one-buffer production line with restart policy modeled as a continuous time Markov process. The mathematical model was described along with its analytical solutions. Fitouhia *et al.* (2017) considered a two-machine continuous flow manufacturing system with a finite buffer capacity. They developed methodology to analyze the trade-off between the preventive maintenance of the machine and the buffer size. Hosseini and Tan (2017) presented a mixed-integer linear programming approach for determining the minimum buffer capacity that achieves a desired production rate and maximizes the profit for a continuous-flow production system. On the other hand, Dolgui *et al.* (2017) presented an optimization problem for determining the size of discrete product buffers to minimize the total cost of a production line. In that constrained optimization problem, they considered average production rate, costs for installing buffers, and the inventory cost, as process parameters. They solved the problem with metaheuristics.

Limitations of Previous Researches on Buffer Capacity

Though several research works are found on buffer storage optimization in continuous process flow, the available models are either approximated from discrete product flow or focused in performance evaluation of the process. In the continuous steel pipe manufacturing process, the buffer storage of steel strips in the line involves huge expenses for space, power and maintenance. It also involves, acceleration, deceleration of the input, random joining time and line stoppage due to buffer stock out. None of the available literature specifically addressed these issues in optimization of buffer capacity, especially matching with the continuous pipe production system. Hence, an analytical formulation of a buffer storage (coil accumulator) with random processing time, is needed to be developed and solved optimally.

ASSUMPTIONS

The mechanics of buffer operation at the coil accumulator is further clarified with some specific assumptions summarized below.

(a) The coil joining time follows a normal distribution with known mean and standard deviation.
(b) An acceptable limit for line stoppage or down time is specified by the level of significance for buffer runout.
(c) All coils that are fed into the line, are of the same strip length.
(d) Input rate to the coil accumulation is higher than the output rate from the accumulator.
(e) The strip input process involves the same value (α) for acceleration and deceleration, which incurs a power consumption cost proportional to the absolute value of α .
(f) The steel strip accumulator can be built in any dimension.

NOTATIONS

The buffer accumulation problem is formulated mathematically using some notations. Before illustrating the problem formulation, these notations are defined in four categories.

(a) System Parameters

λ	Strip output rate from the coil accumulator (feet/hour)
c_J	Cost of coil joining (dollars/hour)
c_λ	Unit cost for strip feeding to the coil accumulator [dollars/hour/ (feet/hour)]
c_α	Unit cost for acceleration/deceleration change [dollars/hour/ (feet/hour^2)]
h_B	Buffer strip holding cost at the coil accumulator (dollars/feet/year)
c_B	Operational cost for the buffer storage in coil accumulator (dollars/feet/year)
c_{td}	Line stoppage or downtime cost ($/hour)
D_c	Demand of coils (coils/year)
f_{T_J}	Probability density function (pdf) of T_J
L_c	Length of a coil (feet/coil)
T_J	Coil joining time (hours/coil)
$\bar{T}_J$	Mean time to join a coil (hours/coil)
σ_T	Standard deviation of joining time (hours/coil)

λ_{in}	Rate of strip feeding to the coil accumulator (feet/hour)
α	Acceleration for strip input to the coil accumulator (feet/hour^2)

(b) Intermediate variables

λ_{net}	Resultant rate of coil accumulation (feet/hour)
$\bar{I}_B$	Average buffer inventory level (feet)
T_c	Cycle time (hours/coil)
F_{T_J}	Cumulative density function (cdf) of T_J

(c) Variables

B	Buffer capacity (feet)
β	Level of significance for buffer runout

(d) Performance measures

TC^B	Expected total cost for the buffer storage system (dollars/year)

MATHEMATICAL MODEL FOR TOTAL COST OF COIL FEEDING SYSTEM

The coil feeding system includes fixed operational cost and the cost of capital for the coil accumulator, holding cost for the buffer, coil joining cost, power consumption cost involved in acceleration-deceleration and input-rate of steel strips to the coil accumulator, and downtime cost for strip runout.

The time gap between two consecutive coil joining operations determine one feed-cycle of the coil accumulation process. Throughout the cycle, the output rate (λ) of steel strip from the coil accumulator remains constant, which is the same as the feed rate of steel strips to the main manufacturing line. In a complete feed-cycle, the coil accumulation (in the coil accumulator) process can be segmented into six different timeslots over the time scale. Each of these timeslots are indicated graphically in Figure 2. The feed-cycle in Figure 2 starts at time $t = 0$ and end at time $t = t_6$, where the points of time t_1 , t_2 , t_3 , t_4 , t_5 and t_6 make partitions for the six time-slots containing six different patterns of coil accumulation.

(i) *Acceleration*: At time $t = 0$ the joining of previous coil is completed and input of a new steel strip to the coil accumulator is started. An acceleration (α) of coil input (to the accumulator) is started at $t = 0$ and continues until a desired coil input rate (λ_{in}) is achieved at the time point t_1 . Thus, when $0 < t \le t_1$ the resultant coil accumulation rate is found as $\lambda_{net} = \alpha t - \lambda$.

(ii) *Constant accumulation*: In the second time-slot of $t_1 < t \le t_2$, the strip input to the accumulator follows a constant rate λ_{in} . At the same time the output rate (λ) of the strip is consistently maintained. Hence, the resultant accumulation rate becomes $\lambda_{net} = \lambda_{in} - \lambda$.

(iii) *First deceleration*: A deceleration ($-\alpha$) of strip input is maintained in the time-slot $t_2 < t \le t_3$. At the end of this deceleration process, the input rate becomes same as output rate, resulting $\lambda_{net} = 0$.

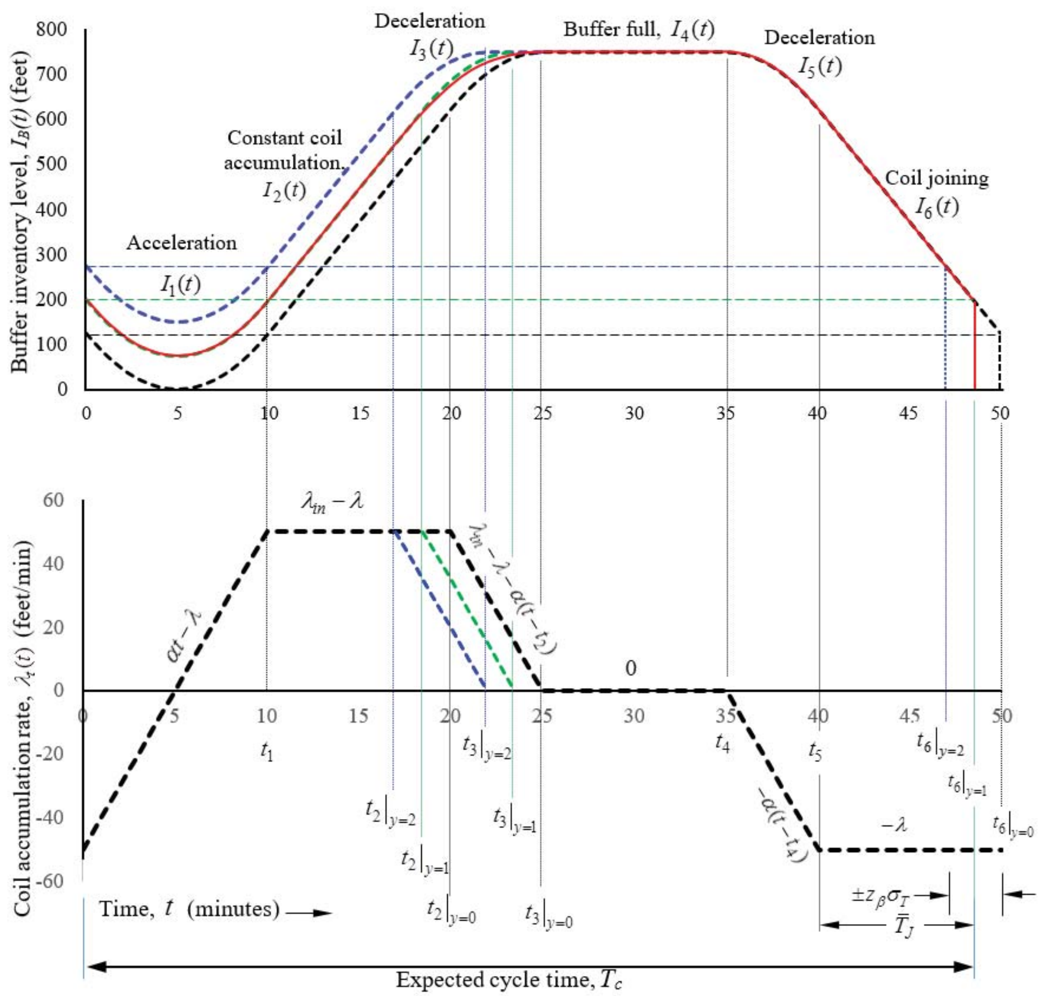

Figure 2. Buffer inventory level and coil accumulation rate over time.

(iv) *Buffer full*: At the time point t_3 input rate become equal to the output rate λ; hence, the resultant rate of coil accumulation become $\lambda_{net} = 0$. This steady state condition continues until the end of the next time segment $t_3 < t \le t_4$.

(v) *Second deceleration*: Now, in order to join a new coil with the continuing steel strip in the line, the feeding of strips to the coil accumulator has to be stopped. So, a deceleration is imposed. The deceleration continues until the input rate reaches to zero. This stage of deceleration results $\lambda_{net} = -\alpha\left(t - t_4\right)$, in the time-slot $t_4 < t \le t_5$.

(vi) *Coil joining*: At the last timeslot $t_5 < t \le t_6$, the feeding of the steel strip to the coil accumulator remains ceased, and the joining operation is conducted. This joining operation takes T_J time units. Once the joining of a new coil is completed the cycle re-starts again.

The complete expression for the resultant rate of coil accumulation, λ_{net} is expressed in Eq. (4.1).

$$\lambda_{net} = \begin{cases} \alpha t - \lambda, & \text{when } 0 < t \le t_1 & : \text{Acceleration} \\ \lambda_{in} - \lambda, & \text{when } t_1 < t \le t_2 & : \text{Constant accumulation} \\ \lambda_{in} - \lambda - \alpha\left(t - t_2\right), & \text{when } t_2 < t \le t_3 & : \text{First deceleration} \\ 0, & \text{when } t_3 < t \le t_4 & : \text{Buffer full} \\ -\alpha\left(t - t_4\right), & \text{when } t_4 < t \le t_5 & : \text{Second deceleration} \\ -\lambda, & \text{when } t_5 < t \le T_J + t_5 & : \text{Coil joining} \end{cases} \tag{1}$$

Now, expressing the size of the coil accumulator, B in terms of the length (feet) of steel strip, the total *operational* cost for the coil accumulator becomes $c_B B$ dollars/year, where c_B (dollars/feet/year) is the unit operation cost for the accumulator. Again, the *holding* cost for the buffer storage at coil accumulator depends on the expected buffer inventory level, $\bar{I}_B$. Hence, total expected holding cost can be written as $h_B \bar{I}_B$ dollars/year.

When the demand of coils for the pipe manufacturing plant is given by D_c coils/year, and the joining cost is denoted as c_J (dollars/hour), total *joining* cost in one year can be written as $D_c c_J \bar{T}_J$ where $\bar{T}_J$ (hours/coil) is the expected joining time. On the other hand, *feeding* of steel strip to the coil accumulator continues for the time-slot $0 < t \le t_4$, for which a cost of $c_\lambda \lambda_{in} t_4$ is accessed. Again, the input is accelerated and decelerated at a rate of α in the time-slots $0 < t \le t_1$, $t_2 < t \le t_3$ and $t_4 < t \le t_5$. For the *acceleration* and deceleration of the feeding, a cost of c_α {dollars/hour/(feet/hour^2)} is accessed which yields a cost of $D_c c_\alpha \alpha(t_5 - t_4 + t_3 - t_2 + t_1)$ dollars/year.

Besides these costs of operation, holding, joining, feeding and acceleration, an additional cost is incurred when the line needs to be stopped due to buffer storage runout. As the joining time (T_J) in reality is probabilistic with mean $\bar{T}_J$ and standard deviation σ_T, a runout duration can be obtained as $\{T_J - (\bar{T}_J + z_\beta \sigma_T)\}$ hours under a normal assumption. Hence, for a known probability density function $f_{T_J}\left(T_J\right)$ of joining time T_J, the total expected runout cost becomes $D_c c_{td} \int_{\bar{T}_J + z_\beta \sigma_T}^{\infty} \left(T_J - \bar{T}_J - z_\beta \sigma_T\right) f_{T_J}\left(t\right) dt$. Here, β denotes the level of significance for buffer runout, and z_β is denoted for the corresponding variable of standard normal distribution. Considering all costs involved in the coil accumulator and the coil joining process, the total expected cost $TC^B(B)$ is formulated for the coil feeding and accumulation system.

In order to avoid the buffer runout with level of confidence $1-\beta$, a minimum buffer capacity in the coil accumulator should be maintained, so that enough strip can be supplied to the main production line during, decelerations, coil joining and starting of the next cycle. The required amount of steel strip during the time-slot $t_4 < t \le t_5$ (decelarartin-2), is obtained as $(\alpha/2)(t_5 - t_4)^2$. The required amount of steel strip is $(\bar{T}_J + z_\beta \sigma_T)\lambda$, while a new coil is joined. In addition to these, an additional amount of steel strip with length $\lambda^2/2\alpha$, is needed to maintain an uninterrupted feeding to the main line when a new feed-cycle is started. Thus, a constraint is formulated as in [Eq. (2a)] that defines the minimum buffer capacity in the coil accumulator. Hence, the coil accumulation problem (CAP) becomes

CAP Problem: $\text{Min. } TC^B(B) = c_B B + h_B \bar{I}_B + D_c \left\{ c_J \bar{T}_J + c_\lambda \lambda_{in} t_4 + c_\alpha \alpha (t_5 - t_4 + t_3 - t_2 + t_1) \right\}$

$$+ D_c c_{td} \int_{\bar{T}_J + z_\beta \sigma_T}^{\infty} \left(T_J - \bar{T}_J - z_\beta \sigma_T \right) f_{T_J}(t)\, dt \tag{2}$$

Subject to $$B \ge \frac{\alpha}{2}(t_5 - t_4)^2 + (\bar{T}_J + z_\beta \sigma_T)\lambda + \frac{\lambda^2}{2\alpha} \tag{2a}$$

and $$0 < \beta < 1,\ B \ge 0. \tag{2b}$$

The buffer inventory level $I_B(t)$ in a specific feed-cycle depends on the joining time during the previous cycle. The upper and lower limits of joining time are $\bar{T}_J + z_\beta \sigma_T$ and $\bar{T}_J - z_\beta \sigma_T$, respectively. Three levels of the joining time T_J are represented with an indicator variable y defined as

$$y = \begin{cases} 0, \text{ if } T_J = \bar{T}_J + z_\beta \sigma_T \\ 1, \text{ if } T_J = \bar{T}_J \\ 2, \text{ if } T_J = \bar{T}_J - z_\beta \sigma_T. \end{cases} \tag{3}$$

Based on the definition of y, the buffer inventory level $I_B(t)$ can be obtained by integrating Eq. (1) over time t. The expressions for $I_B(t)$ can be written as

$$I_B(t)\big|_{y=0,1,2} = \begin{cases} I_1(t) = \dfrac{\lambda^2}{2\alpha} + y z_\beta \sigma_T \lambda + \dfrac{\alpha t^2}{2} - \lambda t, & \text{when } 0 < t \le t_1 \\ I_2(t) = I_1(t_1) + (\lambda_{in} - \lambda)(t - t_1), & \text{when } t_1 < t \le t_2 \\ I_3(t) = I_2(t_2) + (\lambda_{in} - \lambda)(t - t_2) - \dfrac{\alpha}{2}(t - t_2)^2, & \text{when } t_2 < t \le t_3 \\ I_4(t) = I_3(t_3), & \text{when } t_3 < t \le t_4 \\ I_5(t) = I_4(t_4) - \dfrac{\alpha}{2}(t - t_4)^2, & \text{when } t_4 < t \le t_5 \\ I_6(t) = I_5(t_5) - \lambda(t - t_5), & \text{when } t_5 < t \le \bar{T}_J + (1-y) z_\beta \sigma_T + t_5 \end{cases} \tag{4}$$

From this expression the total buffer inventory can be found as

$$\int_0^T I_B(t)dt = \int_0^{t_1}\left(\frac{\lambda^2}{2\alpha}+yz_\beta\sigma_T\lambda+\frac{\alpha t^2}{2}-\lambda t\right)dt+\int_{t_1}^{t_2}\left\{I_1(t_1)+(\lambda_{in}-\lambda)(t-t_1)\right\}dt$$

$$+\int_{t_2}^{t_3}\left\{I_2(t_2)+(\lambda_{in}-\lambda)(t-t_2)-\frac{\alpha}{2}(t-t_2)^2\right\}dt+\int_{t_3}^{t_4}I_3(t_3)dt+\int_{t_4}^{t_5}\left\{I_4(t_4)-\frac{\alpha}{2}(t-t_4)^2\right\}dt$$

$$+\int_{t_5}^{T_J+t_5}\left\{I_5(t_5)-\lambda(t-t_5)\right\}dt, \qquad (5)$$

Now, the average buffer inventory level $\bar{I}_B(t)$ at any time t can be calculated as

$$\bar{I}_B(t)=\frac{I_B(t)\big|_{y=0}+I_B(t)\big|_{y=2}}{2}. \qquad (6)$$

In case of probabilistic joining time, buffer stock is increased by a safety stock $z_\beta\sigma_T\lambda$. If $B_{\min}$ is the minimum buffer capacity without considering the safety stock such that $B_{\min}=\frac{\lambda^2}{\alpha}+\bar{T}_J\lambda$, then the required size of the coil accumulator is $B=B_{\min}+z_\beta\sigma_T\lambda$. Now, from Figure 2 it can be written as

$t_1=\frac{\lambda_{in}}{\alpha}$, $t_2-t_1=\frac{B_{\min}-I_1(t_1)}{\lambda_{in}-\lambda}-\frac{\lambda_{in}-\lambda}{2\alpha}$, $t_3-t_2=\frac{\lambda_{in}-\lambda}{\alpha}$, $t_4=\frac{L_c}{\lambda}-(t_5-t_4)-\bar{T}_J$ and $t_5-t_4=\frac{\lambda}{\alpha}$. Hence, $t_2=\frac{B_{\min}}{\lambda_{in}-\lambda}+\frac{\lambda}{\alpha}$, $t_3=\frac{B_{\min}}{\lambda_{in}-\lambda}+\frac{\lambda_{in}}{\alpha}$, $t_4=\frac{L_c}{\lambda}-\frac{\lambda}{\alpha}-\bar{T}_J$, and $t_5=\frac{L_c}{\lambda}-\bar{T}_J$.

The inventory level $I_1(t_1)$ after the acceleration period $0<t\le t_1$, can be found as $I_1(t_1)=\frac{\lambda^2}{2\alpha}+\frac{\alpha t_1^2}{2}-\lambda t_1=\frac{(\lambda_{in}-\lambda)^2}{2\alpha}$. So, from Eq. (5) and Eq. (6) the expected buffer inventory level $\bar{I}_B$ at the coil accumulator is found as

$$\bar{I}_B=\frac{1}{T}\int_0^T \bar{I}_B(t)dt$$

$$=\left(z_\beta\sigma_T\lambda+\frac{\lambda^2}{\alpha}+T_J\lambda\right)+\frac{\lambda^4}{6L_c\alpha^2}-\frac{\lambda\left(\frac{\lambda^2}{\alpha}+\bar{T}_J\lambda\right)^2}{2L_c(\lambda_{in}-\lambda)}-\frac{\left(\frac{\lambda^2}{\alpha}+\bar{T}_J\lambda\right)\lambda(\lambda_{in}+\lambda)}{2\alpha L_c}-\frac{\lambda^3}{6\alpha L_c}\left[\frac{\lambda}{\alpha}+3\bar{T}_J\right]-\frac{\lambda^2\bar{T}_J^2}{2L_c},$$

which reduces to

$$\bar{I}_B=B-\frac{\lambda^2\lambda_{in}\left(\alpha\bar{T}_J+\lambda\right)\left(\alpha\bar{T}_J+\lambda_{in}\right)}{2L_c\alpha^2(\lambda_{in}-\lambda)}. \qquad (7)$$

Again, $t_5 - t_4 + t_3 - t_2 + t_1 = \frac{\lambda}{\alpha} + \frac{\lambda_{in} - \lambda}{\alpha} + \frac{\lambda_{in}}{\alpha} = \frac{2\lambda_{in}}{\alpha}$, $t_5 - t_4 = \frac{\lambda}{\alpha}$ and $t_4 = \frac{L_c}{\lambda} - \frac{\lambda}{\alpha} - \bar{T}_J$. Hence, from Eq. (2), the final version of the revised RCAP Problem becomes

Problem RCAP:

$$\begin{aligned} \text{Min. } TC^B(B) = {} & c_B B + h_B \left\{ B - \frac{\lambda^2 \lambda_{in} \left(\alpha \bar{T}_J + \lambda\right)\left(\alpha \bar{T}_J + \lambda_{in}\right)}{2 L_c \alpha^2 \left(\lambda_{in} - \lambda\right)} \right\} \\ & + D_c \left\{ c_J \bar{T}_J + c_\lambda \lambda_{in} \left(\frac{L_c}{\lambda} - \frac{\lambda}{\alpha} - \bar{T}_J \right) + 2\lambda_{in} c_\alpha \right\} \\ & + D_c c_{st} \int_{\bar{T}_J + z_\beta \sigma_T}^{\infty} \left(T_J - \bar{T}_J - z_\beta \sigma_T \right) f_{T_J}(t)\, dt \end{aligned} \tag{8}$$

Subject to

$$B \geq \frac{\lambda^2}{\alpha} + (\bar{T}_J + z_\beta \sigma_T)\lambda \tag{8a}$$

$$0 < \beta < 1 \text{ and } B \geq 0. \tag{8b}$$

This is a non-linear programming problem, along with a constraint (8a). The non-linearity exists for the buffer runout probability β, when β is a decision variable. For a given value of β, the objective function $TC^B(B)$ is a linear function of B. In that case, the total cost decreases with buffer capacity B. However, the value of β directly affects the buffer runout cost. In other words, the total cost increases as β increases. As a result, lower value of β is desired. The value of β is also controlled by the constraint (8a). In constraint (8a) the buffer capacity B and the standard normal variable z_β are linearly related, while z_β increases with the decrease of β. So, higher value of B is necessary to reduce the buffer runout cost. These two contradicting scenarios are addressed in the formulation, from where an optimum value of B is needed to be determined.

In addition to the optimization of buffer capacity, some additional results are observed regarding the minimum limit for acceleration of strip feeding (α). These results are presented in Theorem 1.

Theorem 1: $\alpha > \max \left\{ \frac{\lambda^2}{L_c - \bar{T}_J \lambda}, \frac{\lambda_{in}\left(\lambda_{in} - 2\lambda\right)}{\lambda \bar{T}_J} \right\}$.

Proof: For time segment $t_4 > 0$, $\frac{L_c}{\lambda} - \frac{\lambda}{\alpha} - \bar{T}_J > 0$ which reduces to $\alpha > \frac{\lambda^2}{L_c - \bar{T}_J \lambda}$. Similarly,

$t_2 - t_1 = \frac{B_{\min}}{\lambda_{in} - \lambda} - \frac{\lambda_{in} - \lambda}{\alpha} > 0$, where $B_{\min} = \frac{\lambda^2}{\alpha} + \bar{T}_J \lambda$. This yields $\frac{\lambda_{in}\left(\lambda_{in} - 2\lambda\right)}{\lambda \bar{T}_J} < \alpha$. ■

SOLUTION METHODOLOGY

It is observed that, for a given value of buffer runout probability β, the total cost $TC^B(B)$ is a linear function of B for which a zero buffer (B =0) should be the optimum solution to this problem. However, a boundary condition for B is defined by the constraint (8a) which fixes the lower limit for buffer capacity as $B_l = \frac{\lambda^2}{\alpha} + (\bar{T}_J + z_\beta \sigma_T)\lambda$. Now, embedding this boundary condition in Eq. (8) the mathematical formulation of the problem becomes

$$\text{Min. } TC^B(B) = c_B B + h_B \left\{ B - \frac{\lambda^2 \lambda_{in} \left(\alpha \bar{T}_J + \lambda\right)\left(\alpha \bar{T}_J + \lambda_{in}\right)}{2L_c \alpha^2 \left(\lambda_{in} - \lambda\right)} \right\}$$

$$+D_c \left\{ c_J \bar{T}_J + c_\lambda \lambda_{in} \left(\frac{L_c}{\lambda} - \frac{\lambda}{\alpha} - \bar{T}_J \right) + 2\lambda_{in} c_\alpha \right\} + D_c c_{td} \int_{\frac{B}{\lambda} - \frac{\lambda}{\alpha}}^{\infty} \left(T_J - \frac{B}{\lambda} + \frac{\lambda}{\alpha} \right) f_{T_J}(t)\, dt, \quad (9)$$

and $B \geq 0$.

Thus, the objective function in Eq. (8) along with boundary condition in constraint (8a) forms a single variable non-linear programming problem, as shown in Eq. (9). The holding cost and the buffer stock runout cost (that causes line stoppage) can be controlled by changing the buffer capacity B (i.e., the size of the coil accumulator). Higher buffer capacity B increases holding cost whereas this increase of B reduces the buffer runout cost. These conflicting scenarios conclude that there is a optimum point for B that minimizes total cost for the coil feeding system.

The first and second derivatives of $TC^B(B)$ in (9) with respect to B are obtained as

$$\frac{d(TC^B)}{dB} = c_B + h_B - \frac{c_{td} D_c}{\lambda} \int_{\frac{B}{\lambda} - \frac{\lambda}{\alpha}}^{\infty} f_{T_J}(t)\, dt \quad (10)$$

and $\frac{d^2(TC^B)}{dB^2} = \frac{c_{td} D_c}{\lambda^2} f\left(\frac{B}{\lambda} - \frac{\lambda}{\alpha} \right) > 0$, respectively. (11)

The second derivative is positive definite for any $\alpha > 0$. So, $TC^B(B)$ is a convex function in B.

The minimum value of $TC^B(B)$ can be found by setting $\frac{d(TC^B)}{dB}$ = 0 which yields

$$\frac{d(TC^B)}{dB} = c_B + h_B - \frac{c_{td} D_c}{\lambda} \left[1 - F_{T_J}\left(\frac{B}{\lambda} - \frac{\lambda}{\alpha} \right) \right] = 0, \text{ or } F_{T_J}\left(\frac{B}{\lambda} - \frac{\lambda}{\alpha} \right) = 1 - \lambda \frac{c_B + h_B}{c_{td} D_c}.$$

The coil joining time is assumed to be normally distributed as $T_J \sim N(\bar{T}_J, \sigma_T^2)$. So $\left[\left(\frac{B}{\lambda} - \frac{\lambda}{\alpha} \right) - \bar{T}_J \right] \Big/ \sigma_T = F_{T_J}^{-1}\left[1 - \lambda \frac{c_B + h_B}{c_{td} D_c} \right]$, which finally leads to

$$B^* = \lambda\left[\frac{\lambda}{\alpha} + \bar{T}_J + \sigma_T F_{T_J}^{-1}\left(1 - \lambda\frac{c_B + h_B}{c_{td} D_c}\right)\right]. \quad (12)$$

This solution for B^* in Eq. (4.12) is optimum when a specific value of β is not assigned. On the other hand, if a particular value of β is given and the solution of B in Eq. (12) does not satisfy constraint (8a), the optimum solution will be dominated by the constraint. In the latter situation, the optimum solution B^* is thus obtained as

$$B^* = \frac{\lambda^2}{\alpha} + (\bar{T}_J + z_\beta \sigma_T)\lambda \text{ , where } z_\beta = F_{T_J}^{-1}(\beta). \quad (13)$$

The process for obtaining the optimum solution B^* is stated with a flow diagram in Figure 3. It is noticeable from Eq. (12) that the optimum buffer capacity (or the coil accumulator) B^* does not depend on coil joining cost (c_J), strip feeding cost (c_λ) , acceleration cost (c_α), rate of coil feeding to the accumulator (λ_{in}) and the length of a coil (L_c). However, these parameters affect the total cost of the coil joining and buffer accumulation. When other parameters are known, the optimum buffer capacity B^* can be directly obtained from Eq. (12).

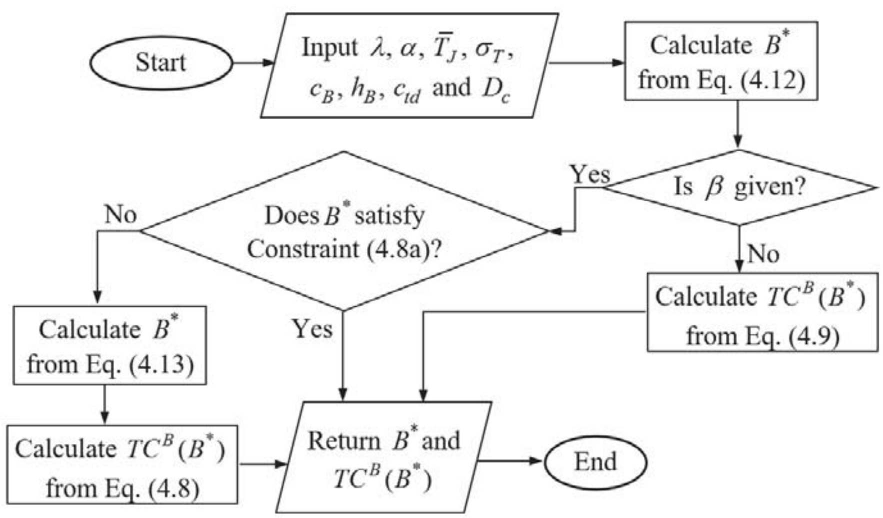

Figure 3. Flow diagram of optimum solution search.

Some numerical instances are presented in the next section for describing the solution and the sensitivity of the solution with respect to some system parameters is presented subsequently.

NUMERICAL EXPERIMENTATION

The continuous steel pipe manufacturing process involves a special type of buffer storage facility known as a coil accumulator. The size of the coil accumulator determines the buffer capacity of the system. The optimum solution for the buffer capacity can be obtained by following the flow diagram in Figure 3. A numerical illustration of this process in presented here.

Example 1: Optimum buffer capacity (size of coil accumulator)

In a steel pipe manufacturing system the coil joining time (T_J) is normally distributed such that $T_J \sim N(10,\ 0.5^2)$ in minutes. All other parameters involved in the feeding stage, are listed in Table 1.

Table 1. Input parameters for Example 1

c_B $/feet/year	c_J $/hour	c_λ $/feet	c_α $-hour/feet	α feet/hour^2	λ feet/hour	λ_{in} feet/hour	c_{td} $/hour	h_B $/feet/year	D_c coils/year	L_c feet/coil
10	600	0.10	1/30	36,000	3,000	6,000	600	20	1000	2500

The probability of buffer runout (β) is not assigned here. Hence, the optimum solution for the buffer capacity B^* can be calculated from Eq. (12). It becomes $B^* = 775.91$ feet which yields $TC^B(B^*)$ = $867,665.79 per year from Eq. (9). This optimum solution indicates that the coil accumulator should have enough space to hold a steel strip of length 775.91 feet. Both higher and lower capacity than 775.91 feet will increase the total cost for the coil joining and buffer storage facility. The optimum solution is graphically represented in Figure 4.

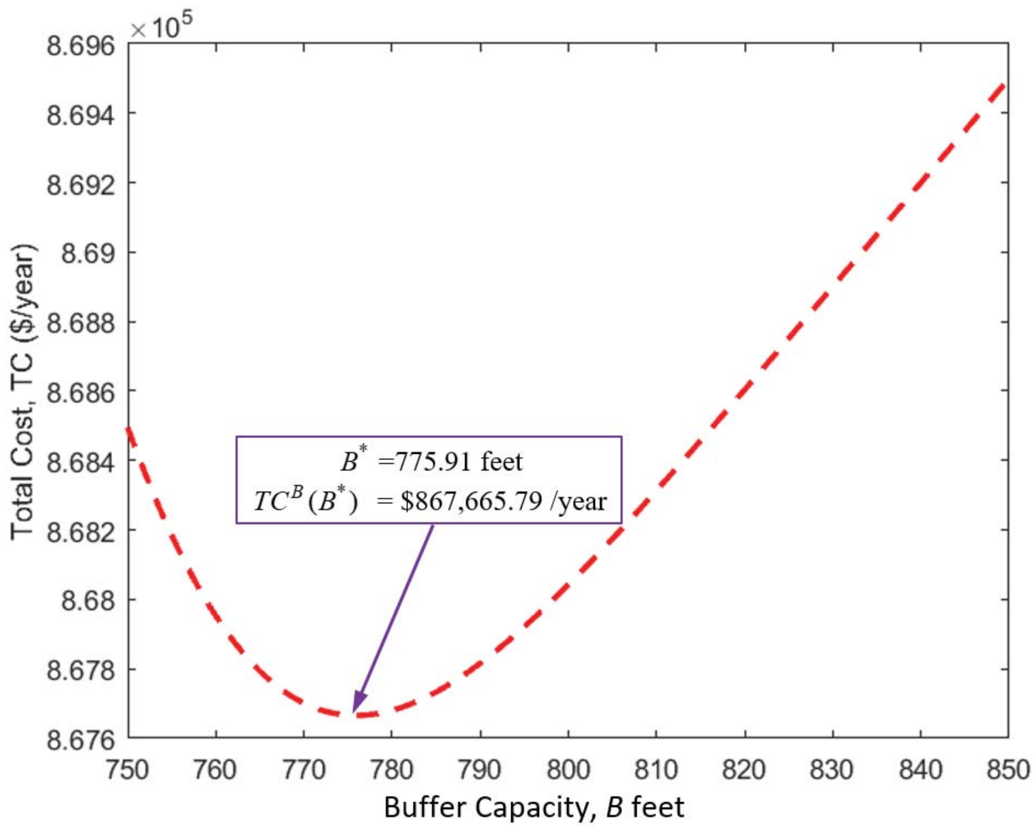

Figure 4. Optimum solution of Example 1.

SENSITIVITY OF THE SOLUTION

From Eq. (12) and Eq.(13) it is observed that, the optimum buffer capacity B^* largely depends on buffer runout probability (β), the output rate of steel strips from the coil accumulator (λ), acceleration rate of strips input (α) and coil joining time (T_J). The effects of these parameters on the optimum solution are analyzed in the following sub-sections.

Effect of β

Now, the probability of buffer runout can be calculated from the optimum solution found. From Eq. (13), $B^* = \left(\lambda^2/\alpha + \bar{T}_J\lambda\right) + \left(z_\beta \sigma_T \lambda\right)$. Here, $B_{\min} = \lambda^2/\alpha + \bar{T}_J\lambda$ is the minimum buffer capacity which is essential for continuing the pipe manufacturing process during the coil joining operation. The minimum buffer capacity is computed as $B_{\min} = 750$ feet. So, $z_\beta \sigma_T \lambda = B^* - B_{\min}$ = 25.91 feet is the amount of safety stock for handling uncertainty in joining time. From this, the standard normal variable z_{β^*} is found as $z_{\beta^*} = \left(B^* - \lambda^2/\alpha - \bar{T}_J\lambda\right)\Big/(\sigma_T\lambda) = 25.91/(\sigma_T\lambda)$ =1.0364. Thus, from the standard normal table the probability of buffer runout is found as β^* = $F_{T_J}(z_{\beta^*})$ = 0.1515. This result indicates that, if the buffer capacity in the coil accumulator is set at $B^* = 775.91$ feet, the buffer storage in the accumulator will runout 15.15% times. Though this probability is noticeably large, yet the total cost for the coil joining, coil accumulator and line stoppage (due to buffer runout) is minimum at $TC^B(775.91)$ = \$867,665.79 per year.

Any deviation from the optimal $B^* = 775.91$ feet will lead to an increase to the total cost until other related system parameters are changed. If the production manager is not happy with the runout probability β^* = 0.1515, he/she sets a different acceptable value of β = 0.10 (for example). With this new value, the solution for the buffer capacity B = 775.91 does not satisfy constraint (8a). Hence, constraint (8a) becomes effective and dominating to the optimum solution. When, under this condition, the optimum solution B^* is evaluated using Eq. (13) [See Figure 3] as B^* =782.04 feet. In this case, the total cost becomes $TC^B(782.04)$ = \$867,697.89/year which is obtained from Eq. (8).

Table 2. Optimum solutions for different limiting values of β.

SL	β	B^* feet	$TC(B^*)$ \$/year	SL	β	B^* feet	$TC(B^*)$ \$/year
1	0.0001	842.97	869,289.38	6	0.0500	791.12	867,838.10
2	0.0005	8.3226	868,968.55	7	0.1000	782.04	867,697.88
3	0.0010	827.25	868,819.06	8	0.1500	775.91	867,665.79
4	0.0100	808.16	868,261.70	9	0.1515	775.75	867,665.79
5	0.0200	801.34	868,077.03	10	0.2000	775.75	867,665.79

The effect of β-value on the solution is presented in Table 2, which is more visualized in Figures 5 and 6. Figure 5 presents a joint effect of B and β on the total cost. When a low value is imposed to the probability of buffer runout β, the optimum buffer capacity B is dominated by constraint (8a). Thus, a certain threshold value β^*, of can be determined for a given set of system parameters. Below β^* the constraint becomes tight and above β^* the constraint becomes relaxed.

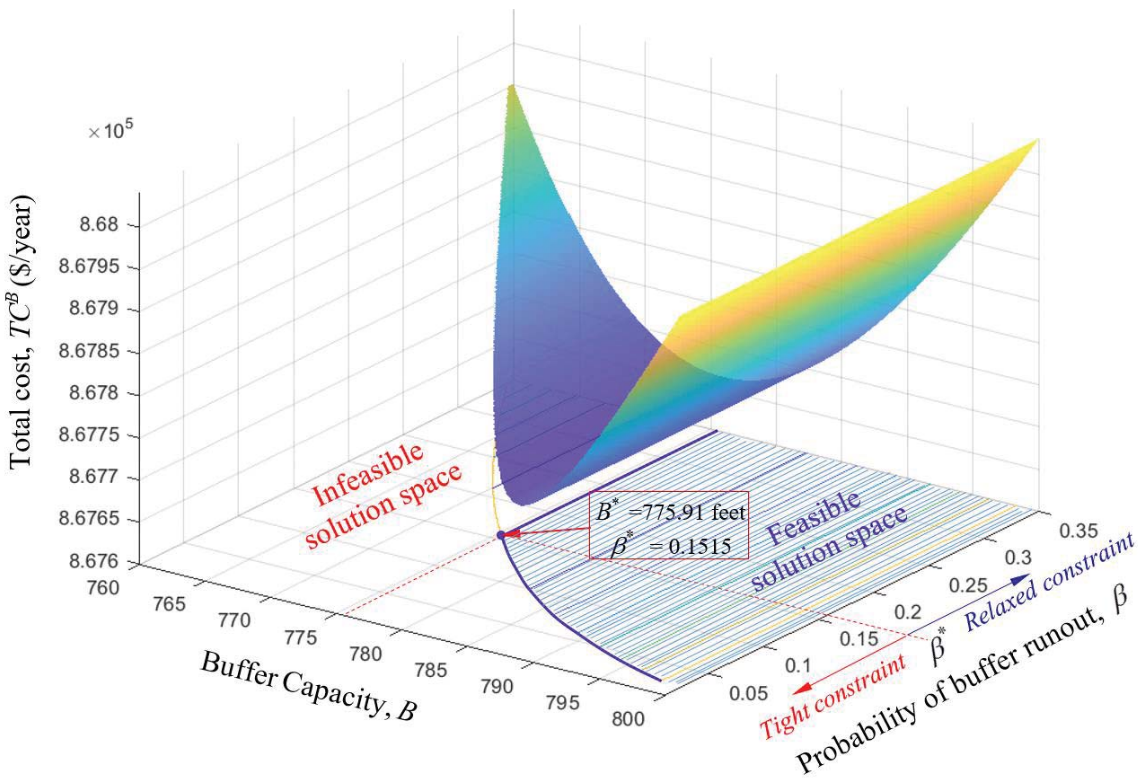

Figure 5. Variation in solution for different β value.

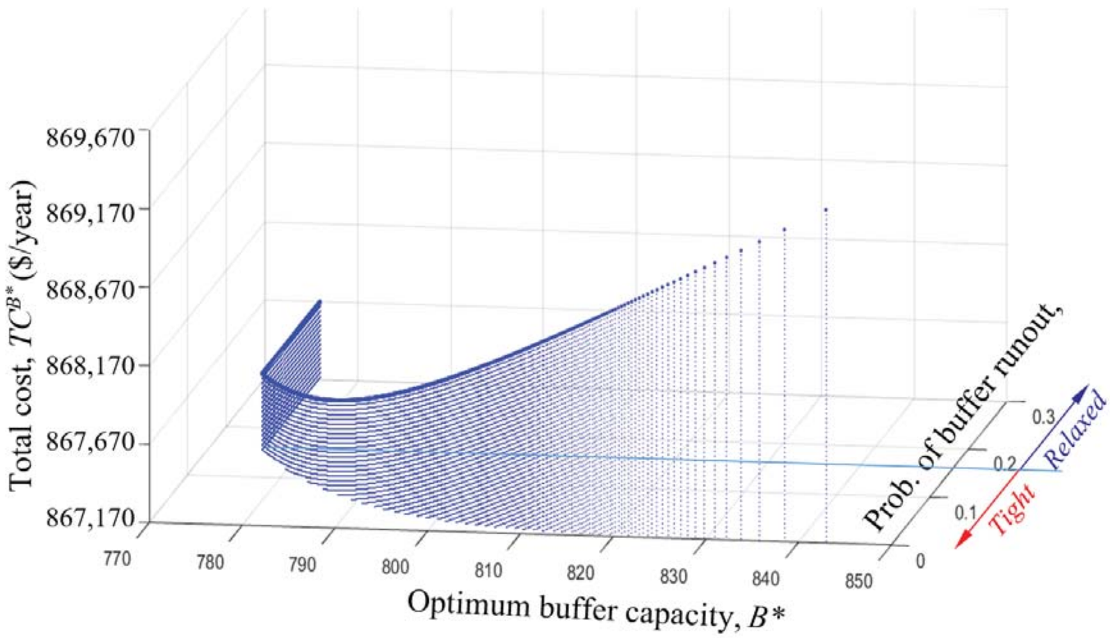

Figure 6. Effect of β value on the optimum solution.

Sensitivity of the Solution with Respect to Joining Time

The mean time for joining a coil (T_J) is a random value with known probability distribution. Both the mean ($\bar{T}_J$) and the standard deviation (σ_T) of joining time have direct effect on the optimum solution. In order to see the effects of joining time on the optimum solution, $\bar{T}_J$ and σ_T in Example 1 are varied individually. Six different values of $\bar{T}_J$ are taken; these are 5, 10, 15, 20, 25 and 30 minutes. For each of the values of $\bar{T}_J$, several solution points of B and the corresponding $TC^B(B)$ are measured. The solution points for each of the six values of $\bar{T}_J$ are plotted in Figure 7 with different colors. It is observed that, if $\bar{T}_J$ increases, the optimum total cost $TC^B(B^*)$ also increases. The increasing trend of $TC^B(B^*)$ with respect to $\bar{T}_J$ seems to be asymptotic [Figure 7].

Similarly, Figure 8 is plotted for six different values of σ_T; these are 0.5, 1.5, 2.5, 3.5, 4.5 and 5.5 minutes. The solutions corresponding to each of the values of σ_T, are represented with different colored lines in Figure 8. It is found that the optimum solutions follow a linear increasing trend with σ_T.

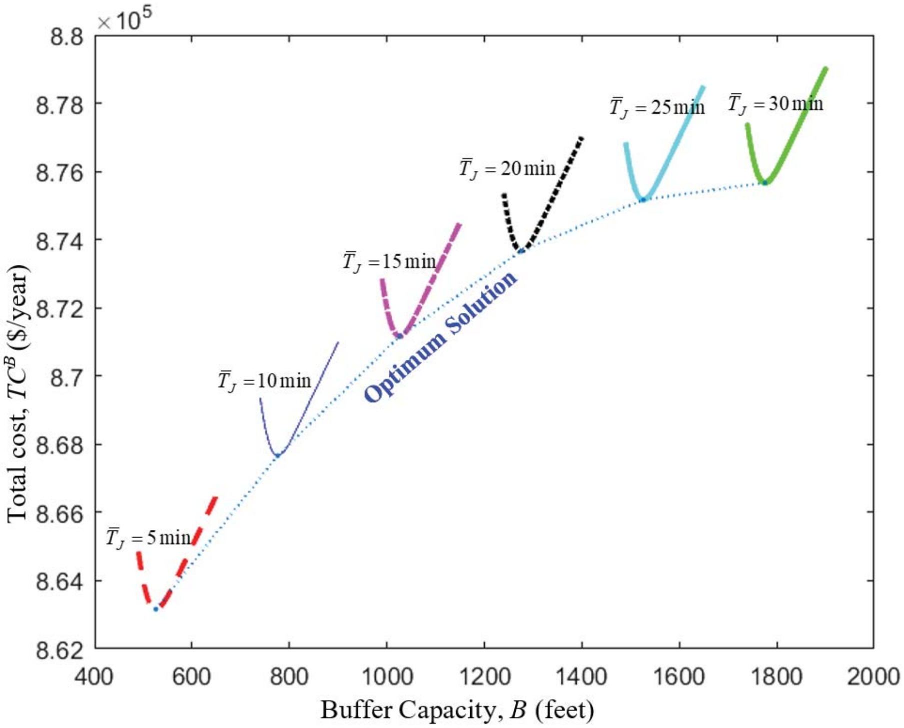

Figure 7. Sensitivity of the solution with respect to $\overline{T}_J$.

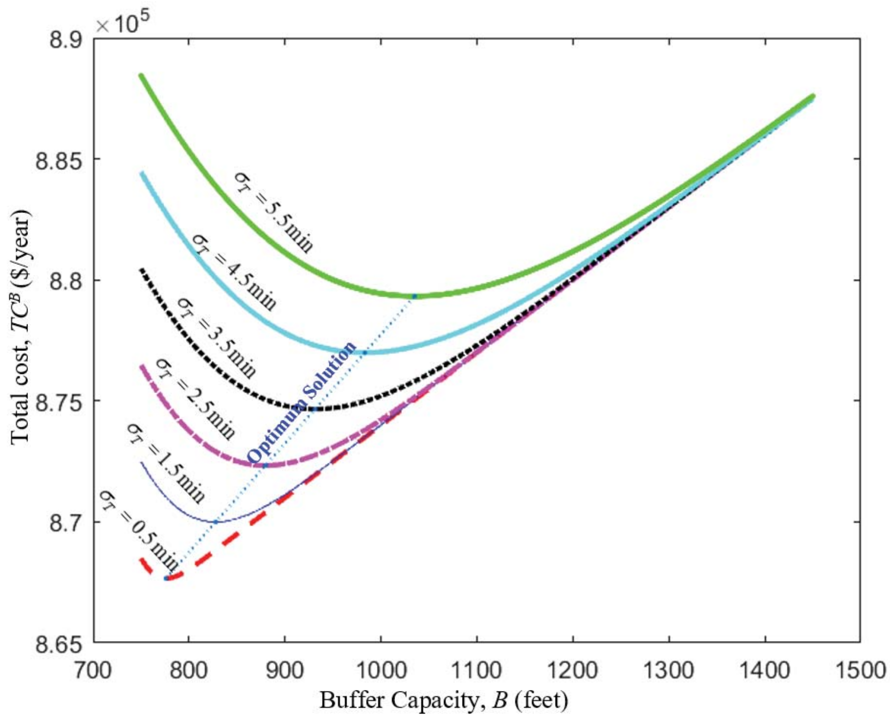

Figure 8. Sensitivity of the solution with respect to σ_T .

Sensitivity of the Solution with Respect to Acceleration

The acceleration and/or deceleration of steel strip input (α) to the coil accumulator should satisfy the condition in Theorem 1. This condition defines the minimum value of α that is needed to be ensured for achieving a desired input rate of strips to the coil accumulator. Now, for the given parameters in Table 1, it is calculated that, $\lambda^2 / \left(L_c - \bar{T}_J \lambda\right) = 1.25$, and $\lambda_{in}\left(\lambda_{in} - 2\lambda\right) / \left(\lambda \bar{T}_J\right)$ =0. Hence, from Theorem 1, the minimum value of α is found as $\alpha = \max(1.25, 0)$ =1.25.

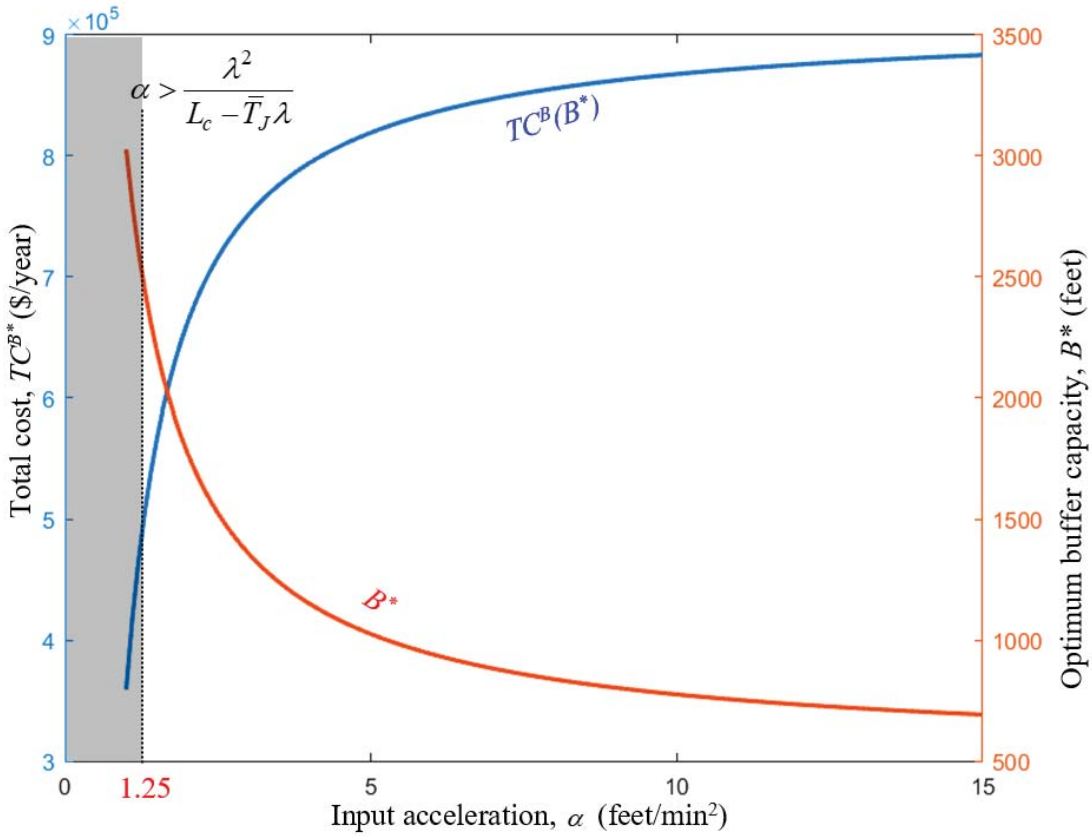

Figure 9. Effect of input acceleration α on optimum solution: 2D represntation.

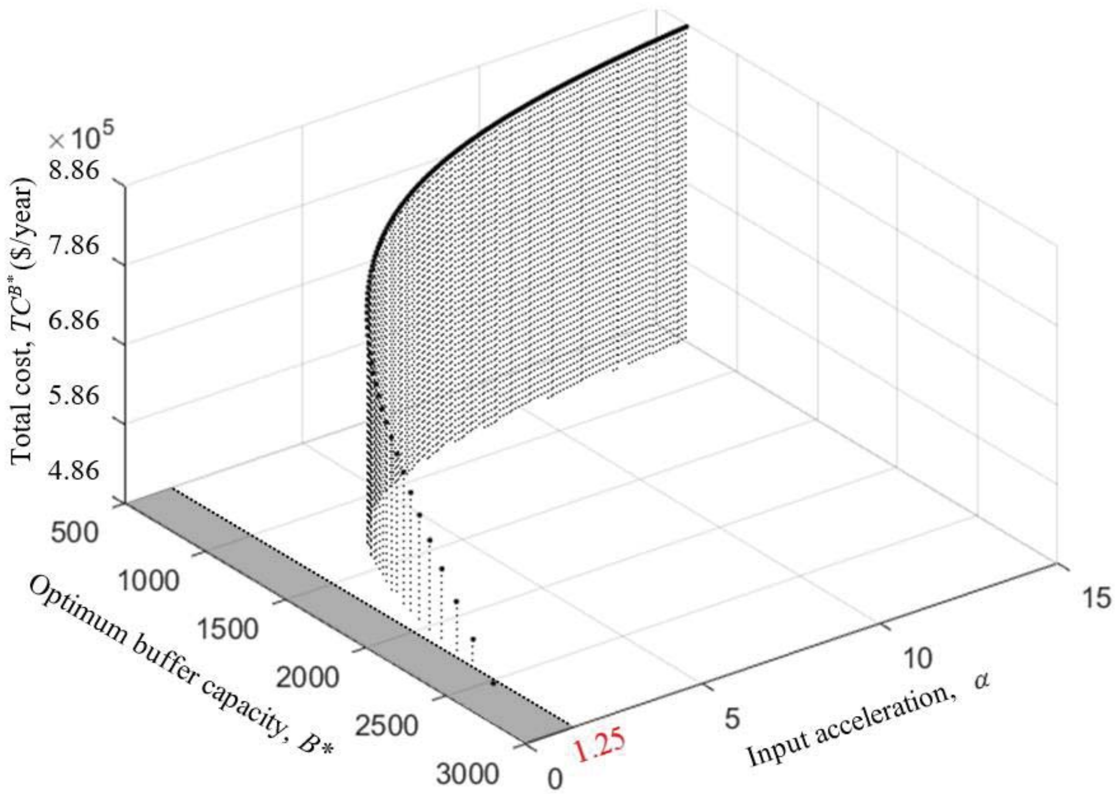

(b)

Figure 10. Effect of input acceleration α on optimum solution: 3D represntation.

So, in Example 1 the value of α is varied from 1.25 to 15 feet/min^2. For several values of α the optimum solution, B^* and the corresponding total cost, $TC^B(B^*)$ are calculated. The optimum solution points are plotted in Figures 9 and 10. Both Figure 9 and 10 are representing the same results, but in different ways. In Figures 9 and 10, it is shown that, with the increase of α the optimum buffer size decreases; whereas the total cost increases asymptotically. So, in order to obtain a lower value of total cost, the input acceleration should be kept as low as possible if the corresponding B^* is attainable with the available coil accumulator.

CONCLUSION

In continuous steel manufacturing process, steel strips are fed into the line through a coil accumulator. The coil accumulator acts as a buffer storage that helps avoid disruption of the continuous process during joining a new coil with the previous strip in the line. This research problem concerns about the capacity of buffer storage in the coil accumulator. The problem is formulated as a constrained non-linear programming problem, for which an optimum solution is obtained in closed form.

The optimum solution is dominated by the constraint at some pre-determined low value of the buffer runout probability. On the other hand, the optimum solution can be calculated by a closed form expression, if the buffer runout probability is relaxed or set at a higher value. The optimum solution for buffer capacity is not affected by input rate of the strip to the coil accumulator, the length of the steel strips in a coil, and the unit costs for the input velocity, acceleration and coil joining. It is observed that, optimum solution for the total cost increases linearly with joining time variability. The optimum total cost increases with the mean joining time as well. Some other observations of the solution conclude that the buffer runout probability decreases with increase of buffer capacity. Acceleration of strips input should be kept low for the resulting lower total cost.

In a more realistic situation, the company faces a constraint for capital expenditure, and only a few sizes of the coil accumulator are available in the market. So, an extension of this research can be done while considering the budget constraint and discrete size of coil accumulator. However, the outcome of this research develops a basis for reducing the cost for buffer storage in coil accumulator. It also helps reduce the downtime of the pipe mill, which is resulted by the line stoppage due to longer joining time.

Examining the impact of contract design on supplier performance: A theoretically-informed, multi-criteria, decision analysis

Ilias Vlachos
La Rochelle Business School, Excelia-Group
Email: vlachosil@excelia-group.com

ABSTRACT

Contracts has been studied extensively, yet how contract design influences supplier performance is largely unexplored. This study reviewed 18 contract design factors according to contract, relational, and contextual theoretical views. Multi-criteria methods (DEMATEL/ANP) were used to uncover the impact of the contract design on 3 supplier groups: average-, over-, and under-performers.
Results show that in the case of over- performers, contracts have a dual, yet discrete, transaction and relational role: at transaction level, they emphasise formality, protect from opportunism and include both liquidated damages and legal action clauses. At relational level, they focus on relational learning and incentivizing suppliers.

KEYWORDS: Contract Design, Supplier performance, Multi-criteria decision making (MCDM) methods, DEMATEL, ANP

INTRODUCTION

Interfirm contracts have been extensively researched in economics (Argyres et al. 2007; Ryall and Sampson 2009), yet few empirical studies on the actual process of contract design exist in the management literature (Ariño et al. 2014; Selviaridis and van der Valk 2019). Interfirm contracts (or simply contracts hereafter) have four characteristics: (i) they are idiosyncratically incomplete and, often, are too incomplete (Williamson 1987), which exposes companies to opportunism and conflicts with trading partners (Cabral 2017); (ii) Contracts are often ambiguous, which makes its interpretation depending on contextual factors (Gilson et al. 2014); (iii) Contract design is considered as a complex process; a wide number of factors play a role such as performance standards, firm strategy, business environment, the type of service or goods contracted, and the decision-making process itself (Weber and Mayer 2011); (iv) Contracts may evolve over time which makes their design a path-dependent, dynamic process (Argyres, Bercovitz, and Mayer 2007).
To deal with inherent incompleteness, complexity, ambiguity, and dynamism, one research view, based on efficiency theories, argues that contracts are interfirm governing mechanisms that aim to manage and reduce transaction costs (Benaroch et al. 2016; Williamson 1987): according to this view, contracts should be as less incomplete as possible which also minimises the supplier opportunism, yet at the expense of complexity. However, this view overlooks the potential use of contracts as mechanisms that frame and develop interfirm relationships: another view, the relational view, argues that by building trust and incentive partners, contracts can frame an interfirm relationship which allows companies to build relationship capital and generate mutual benefits (Möhring and Finch 2015; Ariño et al. 2014). A third view argues that the context defines contracts (Gilson, Sabel, and Scott 2014; Goorha 2018):

competition, force factors beyond firm control, such as force majeure and competitive forces, dictates what to include or not in a contract.

Few studies have attempted to synthesise these views and provide empirical support in order to improve procurement and supplier performance via effective contract design (Wang 2010; Vlachos 2012). This study empirically integrates these three views to answer the following research question: How contract design can improve supplier performance? To answer this question, this study examined a global firm with hundreds of supplier and procurement contracts annually. It compared 3 groups of suppliers: under-performers, average, and over-performers to uncover differences and similarities in the contract factors between them. Improving supplier performance by theoretically informed, yet affluent and easily applicable, contracting can have significant practical implications. Furthermore, this study provides empirical evidence to help bridge the gap between theory and praxis: First, it reviews 18 contract factors under three theoretical views: efficiency, relational, and contextual factors. Then, analysis shows that contract and relational factors influence more than contextual factors the contract design with over-performing suppliers.

The remainder of the study is organised as follows: The next section reviews the literature on theoretical views on contract design. Then, the research methods section presents the research design and case study. The research findings follow and the study concludes with discussion of the findings, presentation of managerial implications, and research limitations and recommendations for further research.

LITERATURE REVIEW

Contract Design Factors

In order to uncover the factors influencing contract design, prior literature was reviewed under three research views: contract, relational, contextual. In total, 18 factors were uncovered.

Efficiency factors

According to efficiency theories such as transaction cost economics, contracts act as mechanisms that minimise costs in interfirm transactions (Benaroch, Lichtenstein, and Fink 2016). Transaction costs arise because of limited information, industry dynamics, market uncertainty, and the prospect of opportunistic behaviour stemming from incomplete contracts (Williamson 1987). To minimise costs, firms design contracts that are formal, law-binding texts that include clauses regarding liquidated damages and legal actions. However, to minimize post-contractual opportunism, firms must incur higher transaction costs by designing more complex contacts to cover all aspects and contingencies in the interfirm interactions (Wacker et al. 2016). However, increased contract complexity may reduce incompleteness, yet it might increase transaction costs, particularly for contracts with long duration, which indicates that designing contracts based on transaction factors may result in suboptimal contracts and poor supplier performance.

Formality

Contracts as governing mechanisms of formal interfirm arrangements are formal, lawful texts (Carson et al. 2006). However, formality in contracts could undermine interfirm trust and therefore inspire the same opportunistic actions they are formally designed to depress (White et al. 2018; Watanabe et al. 2017). Mellewigt et al. (2007) propose that formality and trust can substitute or complement each other depending on contractual complexity. A formal contract still can be incomplete. For example, Cavusgil et al. (2004) suggest that cultural and geographical distances can reduce the effectiveness of contracts, thus those clauses should be excluded in a formal contract. Poppo and Zenger (2002) propose that formality and relational governance can be complements when contracting parties can improve their exchange performance and use contracts as a key mechanism in the governance of the improving interfirm relations.

Contract duration

Prior literature has examined the impact of duration on contract characteristics such as complexity and completeness, yet results are inconclusive (Iyer and Sautner 2018). Longer-duration contracts can be more complex since more contingencies can emerge over a longer period of time (Schepker et al. 2014). Further, longer duration implies higher costs in negotiating and agreeing on terms including exchange hazards that induce partners to engage in longer-term contractual commitments (Weber et al. 2011). Despite the higher complexity and the derived processing and transaction costs, the economic value of long-term collaborations is typically greater than that of short-term relationships, making investments in complex contracts economically more feasible (Brown et al. 2016; Wang et al. 2016).

Post-contractual opportunism

Post-contractual opportunism is considered one of the most concerning threats in interfirm relationships (Tahawy and Ibrahim 2015). Opportunistic behaviour is hard to detect in the pre-contractual stage, thus, when parties foresee a possibility of opportunism, they mitigate it by designing interfirm contract accordingly. For example, contracts with price adjustment clauses, which decrease the gap between contract and market prices compared to fixed-price agreements, can mitigate ex-post motivations to behave opportunistically (Casas-Arce et al. 2018). Grant (2007)'s study on vulnerability to post contractual opportunism in supply chain partnerships shows that, although long time horizons can negate the propensity for opportunistic behaviour, yet, without commitment to partnership, suppliers become sceptical and lose credibility of their partners.

Studies on IT outsourcing arrangements also provide insights on post-contractual opportunism since asset transfers to vendors incentivizes them to continue to invest in the transaction-specific assets to improve service (Dhillon et al. 2017). However, following transaction cost economics (Williamson 1987), the asset transfer increases bilateral dependence and would elevate the risk of post-contractual opportunistic behaviour (Bhattacharya et al. 2014). Therefore, contracts should specify terms that mitigate post-contractual opportunistic risks and at the same time provide the required incentives to make partnership work for both parties beneficially. Chang et al. (2017) study on IT outsourcing find that asset transfer does significantly affect contract design, manifested in the inclusion of clauses that protect both clients and vendors.

Liquidated damages

Most contracts include clauses of Liquidated Damages, which refer to a fixed or determined sum agreed by the contracting parties to be payable on breach by the other party. Lee et al. (2018) compare bonus contracts with penalty contracts in a cross-country experiment and find that they affect contract effectiveness while national culture moderates these effects. Wilkinson-Ryan (2009) suggest that a contract with a liquidated damages clause is more likely to default than one without it since firms will try to comply with moral and social norms to meet their obligations. Morgan et al. (2018) examine strong contracts as a tool to control supplier opportunism in outsourcing settings and found that threats of liquated damages became an accepted tool of behavioural control across all actors in a case study of the defence sector. Wacker, Yang, and Sheu (2016) argue that performance ambiguity can open the door for both parties to sue for liquidated damages, therefore companies should complement relational governance with contractual governance. However, compliance may impede the potential success of outsourcing contracts when collaboration is required to deal with future demand uncertainty (Delbufalo and Bastl 2018).

Legal actions
Similar to liquidated damages, legal actions refer to un-liquidated damages aim to fairly compensate the buyer for their loss as a direct result of the supplier not meeting their contractual obligations (Yang et al. 2018). Legal actions follow a contractual breach and they are calculated by the court based on: (i) Loss of Expectation within reasonable *contemplation. This is usually the most financially beneficial and popular method to calculate the compensation and provides the supplier incentive to meet their contractual obligations because there is no financial gain from breach; (ii)* Reliance loss: similar to liquidated damages, it incurs the value that spent or lost as a direct result of the supplier's default. (iii) Restitution: the value of any benefit a customer may have forsaken as a direct result of the supplier's default.
Legal actions can be costly, time-consuming and damaging to trustful supplier relationships: Ring and van de Ven (1994) point out that the reliance on trust at the interpersonal level may be conditioned by legal systems or organizational role responsibilities. When trust is low, contracts enhance legal obligations of the contracting parties. Formal contracts lead to greater levels of trust, out of which, over time, and by abiding legal actions, stem informal psychological contracts between buyers and suppliers which can supersede formal legal contracts (Handfield and Bechtel 2002). Legal actions may affect not only trust but also trading terms. Ranjan and Lee (2007) examine contracts in the context of global trade and found that contract enforcement directly affects trade volume and product differentiation. Weber and Mayer (2011) highlight that contracts may induce certain behaviours; thus indirectly affecting supplier performance and categorising contracts into two groupings: (i) promotional contracts that endorse trust and take a partnership approach; and (ii) prevention contracts that dictate high conformance to avoid contract default; this type of contracts are expected to rely more on legal actions than trust.

Relational factors
A growing number of studies recognise the pivotal role of contracts in framing and developing interfirm relationships (Möhring and Finch 2015). In sharp contrast to penalty clauses and legal actions, the relational view of the contracts proposes supplier incentives and building trust to create a successful interfirm relationship (Poppo and Zhou 2014; Ariño et al. 2014; Selviaridis and van der Valk 2019). As such, firms should consider relationship-building factors during contract design such as trust, incentives, relationship learning, partnership type, and supplier re-organisation.
Trust
A significant number of studies have examined the role of trust in formal contracts, yet results are inconclusive (Poppo and Zhou 2014). Three factors appear to mediate the effect of trust on contract effectiveness: flexibility, cost, and complexity. Contracts may vary in their degree of flexibility, which is the extent to which the contract is, deliberately or unintentionally, subject to different interpretations and adaptations (Arve and Martimort 2016; Furlotti 2007). Contract flexibility can be particularly valuable when partners face a high degree of (demand or supply) uncertainty, or unanticipated contingencies which allows them to adopt without incurring expensive costs of renegotiation and revision of agreed contract terms (Schepker et al. 2014; Boeh 2011). In general, negotiating and drafting contracts can be costly especially in complex contracts; when partners trust each other they may agree on flexible contracts that reduces the transaction and relationship cost and contract complexity (Ariño et al. 2014).

Incentives
Narayanan and Raman (2004) argue that incentives in contracts are an essential part of supply chain alignment such as Selviaridis and van der Valk (2019) who find that the framing of contractual performance incentives influences supplier behavioural and relational responses. Gunasekaran et al. (2015) review studies of green supply chain

collaboration and incentives and found various types of incentives while Iossa and Martimort (2016) suggest that contracts containing few incentives are open to corruption in the context of Public–Private Partnerships. Several studies have modelled the impact on contractual incentives on supply chains i.e. Wang and Shin (2015) examined the impact of contracts and competition on upstream innovation in a supply chain.

Partnership type

Contracts as a governing mechanism reflect the type of partnership between the contracting parties. Supply chain literature has extensively researched the types of collaboration and integration among chain partners: partnerships may vary from spot markets to vertical integration and strategic alliances (Yeung et al. 2013). Partnership-specific contracts and relational governance can be both substitutes and complements depending upon contingencies posed by environmental and behavioural (Abdi and Aulakh 2017). Hagedoorn and Hesen (2007) present how different modes of inter-firm technology partnering (i.e. equity joint ventures, non-equity partnerships, and licensing contracts) align with their contractual implications. Reuer and Arino (2007) investigate the contractual features of strategic alliances and show that contractual provisions depend on asset specificity and alliance's duration type (pre-specified or open-ended). Furlotti (2007) contractual incompleteness is associated with the partnership type and the control parties agree to exert.

Supplier reorganisation

Interfirm relationships are dynamic and evolve over time, which contracts should also reflect. Coltman et al. (2009) reviewed the evolution of supply chain contracts and suggested that contract design is a process that initially produces inefficient and inequitable contracts, yet, over time, by building trust and accumulating knowledge, firms improve contracts. This process evolution may affect the contracting parties directly by forcing them to re-organise their processes and functions to meet contractual agreements, especially when small and medium enterprises deal with larger, powerful partners (Ghosal 2015). This process re-organisation and resource re-configuration, which can take the form of business process re-engineering, continuous improvement and total quality management, can be a source of competitive advantage and result in contract renewal, yet it can also backfire with increased contract complexity and ambiguity and subsequently higher transaction costs (Arndt and Pierce 2018).

Relationship learning

Relationships offer valuable learning opportunities (Myers 2018). An organization can access knowledge from a partner to learn new skills (Preston et al. 2017). For example, a supplier may possess market and consumer knowledge (forecasts and trends, consumer performances); this knowledge can be valuable to a byer- its trading and contracting partner-in order to adopt its processes, produce new products etc (Lui 2009). A contract can serve as a mechanism to acquire this knowledge by embedding relationship learning into contract clauses (De Luca and Cano Rubio 2019).
Relationship learning is not always guaranteed: partners may refuse to share knowledge or protect against knowledge spill-overs which can allow an opportunistic partner to become a competitor (Yuan et al. 2018). Relationship learning also depends on the duration of the contract, the length and history of past relations and the expectation of continued exchange in future (Lui 2009; Myers 2018). As a result, how contracts deal with relationship learning may vary significantly (Dekker and Abbeele 2010). Ryall and Sampson Ryall and Sampson (2009) review the key terms from 52 technology development contracts in telecommunication companies and found high variance on contract purposes and relational governance.

Contextual factors
The context that companies operate, including the industry, market, and competitive landscape, is unavoidable complex, unpredictable and dynamic (Goorha 2018). By reflecting these realities, contact design becomes more incomplete and complex in the need to incorporate these contextual factors which are beyond the control of the trading parties (Gilson, Sabel, and Scott 2014).

Force majeure
An event is characterised as 'Force majeure' when it and its effects cannot be anticipated nor controlled, and it can be a result of either an act of nature or people (Tanenbaum 2006). Force majeure is the most common contractual term and refers to circumstances beyond the control and without the fault or negligence of the non-performing party (Chopra and Sodhi 2014). A force majeure clause aims to protect the supplier from being reprimanded in situations where they cannot meet their contractual obligations due to an event beyond their control. Despite their popularity, Tanenbaum (2006) stresses that force majeure clauses could increase the risk of default when suppliers are not adequately prepared to mitigate disruptions and suggested combining force majeure clauses with disaster recovery and business continuity provisions to ensure the supplier anticipates force majeure events.

Change in policies
Raj et al. (2018) examine how companies can design their supply contracts to meet external pressures for more sustainable operations. Liu and Cetinkaya (2009) focus on how leadership, contract flexibility, and information asymmetry affect the designing of supply contracts in supplier vs buyer-driven channels and find that, contrary to common wisdom, leadership is not necessarily beneficial for either party under conditions of information asymmetry. Since procurement is increasingly becoming international, contracting with foreign parties can expose to information asymmetry on government policies of that foreign country (Fang et al. 2017), the case of banning Huawei devices and restricting their access to software platforms being a recent example.
Dekker et al. (2018) examine contract design in cross-border business relationships, which are characterised by significant risk due to information asymmetry and complexity, and find that host country contracts have a shorter duration, more renewal provisions, less flexibility, and relatively greater contracting costs. Esmaeili et al. (2016) investigate the short- and long-term behaviour of agents in a two-echelon CLSC and demonstrate that anticipating policy changes affect pricing decisions.

Supplier technology
Changes in supplier's technology e.g. subcontracting, changes in sub-tier supplier' technologies and standards cannot be anticipated in a contract yet they may adversely affect the supplier performance (Casas-Arce, Kittsteiner, and Martínez-Jerez 2018).
Knowledge misappropriation (Colombo and Piva 2018) and usage of non-proprietary technology (Kauremaa and Tanskanen 2016) can expose contractual partners with conflicting interests to disputes and hazards. Contracts should appropriate risks and benefits in order to mitigating risks deriving from changes in supplier technology (Yeung et al. 2013). Ryall and Sampson (2009) review the key terms from 52 technology development contracts from 36 telecommunication companies and find great variance in the contract structure depending on contract purpose and type of relational governance.

Competitive factors
Contracts have to reflect and protect the competitive position of a firm within an industry. One of the most applied models of competition, Porter (2008) five forces model determines the competitiveness of a firm against five forces: buyer power,

supplier power, the competitive threat posed by current rivals, the availability of substitutes, and the threat of new entrants (Porter 2008). One characteristic of five forces model that makes it applicable to contract design is its completeness in considering all potential forces that would threaten the competition position of a firm.

Clauses in a formal contract oblige suppliers and customers not to exploit their powers, which make contracts a mechanism to control competitive forces. A monopolistic or oligopolistic supplier holds a lot of power and may demand higher prices or have little incentive to excel if the customer cannot easily switch suppliers. On the other hand, a powerful customer may have a significant influence over a supplier's operations. Reliance on a powerful customer make impact contract characteristics such as type of partnership, incentives, trust and duration.

A previously poor performing supplier may react to the threat of rivals, new entrants or substitutions by investing in supply chain improvements in order to meet their contractual obligations. They may also become suddenly interested in developing long term customer supplier relationships in an attempt to minimise the risk of contract termination.

Figure 1 presents the conceptual framework of this study which also used to guide the network modelling using multi-criteria decision analysis.

METHODOLOGY

Research design

The research design employed a single case study with a mixed methods data collection and analysis. Case studies are appropriate to explore emergent organizational and inter-organizational phenomena to develop an in-depth understanding of their nature and complexity (Yin 1989), allowing researchers to intertwine theory and empirical data to test existing theories in the light of empirical data.

The case study was an international manufacturing company with its headquarters in France. A multi-billion-dollar, global corporation with more than 1,800 suppliers over 30 countries, the company designs and runs thousands of contracts every year. Contract design involves different departments and managers including procurement leaders, legal advisers, contract managers, and financial officers. An experienced researcher conducted informal interviews with experts followed by structured data collection.

Data collection and analysis

Initially, semi-structured interviews were conducted with key personnel. Procurement leaders provided their support and input on supplier history and relationship status. Other procurement personnel were also interviewed for their general views on supplier performance including On-Time-Delivery (OTD), which was a critical performance indicator for this company. In total, 17 employees participated. The majority of participants have 10+ years direct experience in procurement. Most of the procurement leaders had been responsible for their supplier for the entire period that was studied. The interviews had the objective to confirm the relevancy to this company of contract factors found in the literature, provide insights of all suppliers in a specific product category, and give input for the quantitative analysis.

All suppliers were classified as minor or major. Suppliers were major if their annual spend was deemed significant based on an undisclosed formula. Minor suppliers were omitted in this study. The company classed twelve suppliers as major in a specific product category from about forty in total.

After initial interviews, six suppliers were selected, and their performance was evaluated based on their monthly OTD for three consequentially years starting from 2010. Other performance metrics were the same i.e. product quality. Two of them were grouped together as over-performed suppliers and the other two as under-performed

suppliers, based on the actual data. The selection of more than one supplier reduced the single-case bias in subsequent analysis. OTD analysis was triangulated with interviews and company reports.
The next step was the collection of qualitative data. The procurement leaders of the over- and under-performed suppliers were provided inputs for the suppliers they overlook, and nine other procurement leaders and managers were asked to provide input for a typical, average supplier they deal with.

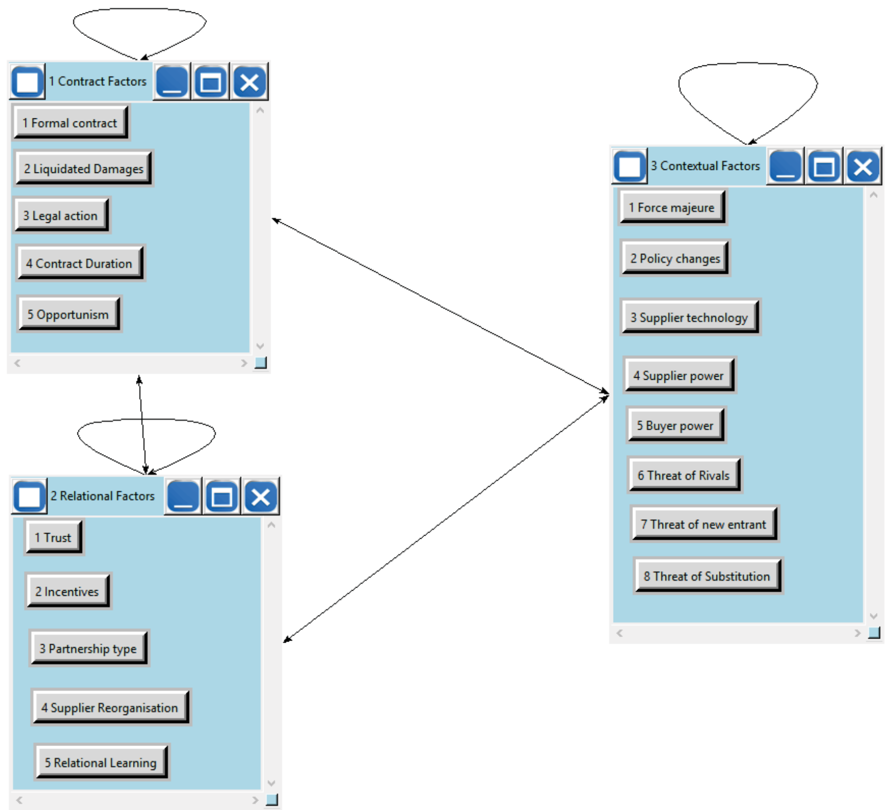

Figure 1 Conceptual Framework and Network model.

Justification of DEMATEL/ANP method
Contract design is a multi-criterion, decision-making problem (MCDM), per se, since contract clauses need to incorporate contract, relational, contextual, and completive factors. An advantage of MCDM methods is that they rely on a relatively small number of experts' opinions rather than a large-scale (Mangla et al. 2018). This advantage makes them suitable when empirical data derive from a single case study. MCDM methods include Data Envelopment Analysis (DEA), linear programming, goal programming (GP), DEMATEL, analytic hierarchy process (AHP), analytic network process (ANP), simple multi-attribute rating technique, and fuzzy set theory (Lee et al. 2011), yet no prior study has applied MCDM in contract design process.
The DEMATEL method takes into account the interrelations between attributes and divides the relevant attributes into cause and effect groups in a visual structural map. The method has been widely applied in a range of studies usually in combination with other MCDM methods, such as ANP. The ANP handles dependence within a criterion (inner dependence) and among different criteria (outer dependence). In a hybrid model

of DEMATEL and ANP, the key interdependences of variable clusters are obtained via DEMATEL, and the ANP algorithm determines the interdependences between the clusters of variables (Wu et al. 2017).

DEMATEL analysis
The following steps were applied for each of the three supplier groups.
DEMATEL Step 1: Generating the direct-relation matrix.
The comparison scale among the criteria has four levels: 0 (no influence), 1 (low influence), 2 (high influence), and 3 (very high influence). Experts are given pairs of factors and make wise comparisons in terms of influence and direction between criteria. The expert evaluations are the initial data obtained as the direct-relation matrix that is a n×n matrix A, in which a_{ij} is denoted as the degree to which the criterion i affects the criterion j (equation 1).

$$A = \begin{pmatrix} a_{11} & \cdots & a_{1n} \\ \vdots & \ddots & \vdots \\ a_{n1} & \cdots & a_{nn} \end{pmatrix} \quad (1)$$

DEMATEL Step 2: Normalizing the direct-relation matrix.
The normalisation of the direct-relation *matrix* A produces the normalized direct-relation matrix X obtained through formulas (2), (3) and (4).

$$X = A/k \quad (2)$$

$$k = Max\left[\max_{1\le i\le n}\sum_{i=1}^{n} a_{ij}\,,\ \max_{1\le j\le n}\sum_{j=1}^{n} a_{ij}\right] \quad (3)$$

$$X = \begin{bmatrix} a_{11}/k & \cdots & a_{1j}/k & \cdots & a_{1n}/k \\ \vdots & & \vdots & & \vdots \\ a_{i1}/k & & a_{ij}/k & & a_{in}/k \\ \vdots & & \vdots & & \vdots \\ a_{n1}/k & & a_{nj}/k & & a_{nn}/k \end{bmatrix} \quad (4)$$

DEMATEL Step 3: Compute the total-relation matrix.
Having calculated the normalized direct-relation matrix X, the total relation matrix T can be acquired by using formula (5), in which I denotes the identity matrix (6).

$$T = X + X^2 + X^3 + \cdots + X^p = X(I - X)^{-1}, p \to \infty \quad (5)$$

$$I = \begin{bmatrix} 1 & 0 & \cdots & 0 \\ 0 & 1 & & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & 1 \end{bmatrix} \quad (6)$$

The totals for each row and each column in formula (4) can be obtained as follows:

$$r_i = \sum_{i=1}^{n} t_{ij}\,, i = 1,2, \dots, n \quad (6)$$

$$c_j = \sum_{j=1}^{n} t_{ij}\,, j = 1,2, \dots, n \quad (7)$$

where r_i represents the direct influence value which is given by the factor a_i; c_j represents the indirect influence value which is given by the factor a_j. Vector D and vector R, respectively denote the sum of rows and the sum of columns from total- relation matrix **T** respectively.
DEMATEL Step 4: Set a threshold value and obtain the impact-relation map.
The total relation matrix contains the values of impact between the factors. However, the structural relations in the matrix should not take into account unsuitable effects

between the factors. Based on the matrix ***T***, each aspect *tij* of matrix ***T*** provides information about how aspect *i* influences aspect *j*. If all the information from matrix ***T*** converts to the network relation map (NRM) the map will be too complex to show the necessary information for decision-making. A threshold value (P) is necessary to remove those effects from consideration in matrix T. Only those aspects, whose influence level in matrix T is higher than the threshold value, can be chosen and converted into the impact-digraph-map. Typically, experts discuss how to decide each factor's threshold to make the rational decisions.

In this study, the frequency of t_{ij} was decided by the experts, yet the T value was also decided to cut off less than 30% of values. To do so, the frequencies of t_{ij} were calculated and the T threshold was found. If the threshold value is too low, the map will be too complex to reveal the necessary information for decision-making. If the threshold value is too high, many aspects will be presented as independent aspects without revealing the relationships with other aspects. Therefore, a number of trial-and-error attempts were pursued to justify the correct T value. Each time the threshold value increases, some aspects or relationships will be removed from the map. After the threshold value and relative impact-digraph-map are decided upon, the final influence result can be illustrated.

The sum of rows and the sum of columns are respectively denoted as vector D and vector R through formulas (6)– (7). The horizontal axis vector (D+R) named as ''*Prominence*'' is calculated as the sum of D and R. Prominence signifies the importance of each factor. The vertical axis (D-R) named as "*Relation*" is calculated by subtracting D from R. *Relation* classifies factors into two groups: a cause group and an effect group. When a factor has positive in the vertical D-R axis, then it belongs to the cause group, otherwise it belongs to the effect group. Therefore, the causal diagram can be acquired by mapping the dataset of the (P=D + R, L=D - R) as a dispersion graph, providing valuable insight for decision making.

Analytic Network Process (ANP)

The purpose of the Analytic Network Process (ANP) approach is to solve problems involving interdependence and feedback among criteria or alternative solutions. ANP is the general form of the AHP, which has been used in multi-criteria decision-making (MCDM) in order to consider non-hierarchical structures.

The ANP handles dependence within a criterion (inner dependence) and among different criteria (outer dependence). DEMATEL method is not going to be used only to calculate the level of impacts among different groups of factors, but the normalised total-influence matrix will be incorporated into un-weighted supermatrix W in the ANP to calculate the level of interdependences of different factors.

Although key interdependences of clusters can be obtained via DEMATEL, the ANP algorithm determines interdependences between clusters. The total-influence matrix acquired by DEMATEL is similar to the concept of ANP, which confirms the importance and influence of criteria through questionnaires. The ANP algorithm runs in four steps and it was repeated for each supplier group:

ANP Step 1: Construct the structure of the network and establish its objectives. Then, the network is decomposed into network hierarchical structure.

<u>ANP Step 2: Calculate the unweighted supermatrix W.</u>

Since DEMATEL produced the total-influence matrix, the unweighted supermatrix W can be calculated by normalizing the sum of influence for each criterion in each hierarchy under the criteria of total-influence matrix. To normalize the total-influence matrix produced by DEMATEL, the criteria total-influence matrix T_c (8) yields T_c^a as shown in equation (9) where T_c^{a11} is obtained by equations (10) and (11). T_c^{aij} to T_c^{ann} are calculated with the same equations (10,11). In the normalized criteria total-influence matrix, the interdependence relationship among clustering is incorporated into the un-weighted supermatrix W as shown in equation (12). The equation (9) shows the calculation of W_{11} and the calculation of element W_{ij} to W_{nn} are based on the same way.

$$T_c = \begin{array}{cc} & \begin{array}{cccc} D_1 & D_2 & \cdots & D_n \\ c_{1_1}\ \cdots\ c_{1_{m1}} & c_{2_{m2}}\ \cdots\ c_{2_{m2}} & \cdots & c_{n_1}\ \cdots\ c_{n_{mn}} \end{array} \\ \begin{array}{cc} D_1 & \begin{array}{c} c_{1_1} \\ c_{1_{21}} \\ \vdots \\ c_{1_{m1}} \end{array} \\ \begin{array}{c} D_2 \\ \vdots \\ \vdots \end{array} & \begin{array}{c} c_{2_1} \\ c_{2_2} \\ \vdots \\ c_{2_{m2}} \\ \vdots \end{array} \\ D_n & \begin{array}{c} c_{n1} \\ c_{n2} \\ \vdots \\ c_{nm_n} \end{array} \end{array} & \begin{bmatrix} T_c^{11} & T_c^{12} & \cdots & T_c^{1n} \\ T_c^{21} & T_c^{22} & \cdots & T_c^{2n} \\ \vdots & \vdots & \ddots & \vdots \\ T_c^{n1} & T_c^{n2} & \cdots & T_c^{nn} \end{bmatrix} \end{array} \tag{8}$$

$$T_c^{\alpha} = \begin{array}{cc} & \begin{array}{cccc} D_1 & D_2 & \cdots & D_n \\ c_{1_1}\ \cdots\ c_{1_{m1}} & c_{2_{m2}}\ \cdots\ c_{2_{m2}} & \cdots & c_{n_1}\ \cdots\ c_{n_{mn}} \end{array} \\ \begin{array}{cc} D_1 & \begin{array}{c} c_{1_1} \\ c_{1_{21}} \\ \vdots \\ c_{1_{m1}} \end{array} \\ \begin{array}{c} D_2 \\ \vdots \\ \vdots \end{array} & \begin{array}{c} c_{2_1} \\ c_{2_2} \\ \vdots \\ c_{2_{m2}} \\ \vdots \end{array} \\ D_n & \begin{array}{c} c_{n1} \\ c_{n2} \\ \vdots \\ c_{nm_n} \end{array} \end{array} & \begin{bmatrix} T_c^{a11} & T_c^{a12} & \cdots & T_c^{a1n} \\ T_c^{a21} & T_c^{a22} & \cdots & T_c^{2n} \\ \vdots & \vdots & \ddots & \vdots \\ T_c^{an1} & T_c^{an2} & \cdots & T_c^{ann} \end{bmatrix} \end{array} \tag{9}$$

$$d_j = \sum_{j=1}^{n} t^{ij}\ , j = 1,2,\ldots,n \tag{10}$$

$$T_c^{a11} = \begin{bmatrix} t_{c^{11}}^{11}/d_1^{11} & \cdots & t_{c^{1j}}^{11}/d_1^{11} & \cdots & t_{c^{1n}}^{11}/d_1^{11} \\ \vdots & & \vdots & & \vdots \\ t_{c^{i1}}^{11}/d_2^{11} & & t_{c^{ij}}^{11}/d_2^{11} & & t_{c^{in}}^{11}/d_2^{11} \\ \vdots & & \vdots & & \vdots \\ t_{c^{n1}}^{11}/d_n^{11} & & t_{c^{nj}}^{11}/d_n^{11} & & t_{c^{nn}}^{11}/d_n^{11} \end{bmatrix} = \begin{bmatrix} t_{c^{11}}^{a11} & \cdots & t_{c^{1j}}^{a11} & \cdots & t_{c^{1n}}^{a11} \\ \vdots & & \vdots & & \vdots \\ t_{c^{i1}}^{a11} & & t_{c^{ij}}^{a11} & & t_{c^{in}}^{a11} \\ \vdots & & \vdots & & \vdots \\ t_{c^{n1}}^{a11} & & t_{c^{nj}}^{a11} & & t_{c^{nn}}^{a11} \end{bmatrix} \tag{11}$$

$$W = \begin{array}{cc} & \begin{array}{ccccccccc} & D_1 & & & D_2 & \cdots & D_n & & \\ c_{1_1} & \cdots & c_{1_{m1}} & c_{2_{m2}} & \cdots & c_{2_{m2}} & \cdots & c_{n_1} \cdots & c_{n_{mn}} \end{array} \\ \begin{array}{cc} & c_{1_1} \\ D_1 & c_{1_{21}} \\ & \vdots \\ & c_{1_{m1}} \\ D_2 & c_{2_1} \\ \vdots & c_{2_2} \\ & \vdots \\ \vdots & c_{2_{m2}} \\ & \vdots \\ & c_{n1} \\ D_n & c_{n2} \\ & \vdots \\ & c_{nm_n} \end{array} & \begin{bmatrix} W^{11} & W^{12} & \cdots & W^{1n} \\ W^{21} & W^{22} & \cdots & W^{2n} \\ \vdots & \vdots & \ddots & \vdots \\ W^{n1} & W^{n2} & \cdots & W^{nn} \end{bmatrix} \end{array} \tag{12}$$

$$W_{11} = \begin{array}{cc} & \begin{array}{cccc} c_{11} & c_{12} & \cdots & c_{1m_1} \end{array} \\ \begin{array}{c} c_{11} \\ c_{12} \\ \vdots \\ c_{1m_1} \end{array} & \begin{bmatrix} t_{c^{11}}^{a11} & \cdots & t_{c^{21}}^{a11} & \cdots & t_{c^{m1}}^{a11} \\ \vdots & & \vdots & & \vdots \\ t_{c^{12}}^{a11} & & t_{c^{22}}^{a11} & & t_{c^{m2}}^{a11} \\ \vdots & & \vdots & & \vdots \\ t_{c^{1m_1}}^{a11} & & t_{c^{2m_1}}^{a11} & & t_{c^{mm_1}}^{a11} \end{bmatrix} \end{array} \tag{13}$$

<u>ANP Step 3: Obtain the weighted supermatrix</u>

by normalizing the sum of impact for each hierarchy and each dimension in the dimensions total-influence matrix as illustrated in equation (14). Normalizing the total influence matrix T_D yields T_D^a (15). The weighted supermatrix is obtained by incorporating the unweighted supermatrix into the normalized dimensions total-influence matrix (16).

$$T_D = \begin{bmatrix} t_D^{11} & \cdots & t_D^{1j} & \cdots & t_D^{1n} \\ \vdots & & \vdots & & \vdots \\ t_D^{i1} & & t_D^{ij} & & t_D^{in} \\ \vdots & & \vdots & & \vdots \\ t_D^{n1} & & t_D^{nj} & & t_D^{nn} \end{bmatrix} \tag{14}$$

$$T_D^a = \begin{bmatrix} t_D^{11}/d_1 & \cdots & t_D^{1j}/d_1 & \cdots & t_D^{1n}/d_1 \\ \vdots & & \vdots & & \vdots \\ t_D^{i1}/d_2 & & t_D^{ij}/d_2 & & t_D^{in}/d_2 \\ \vdots & & \vdots & & \vdots \\ t_D^{n1}/d_n & & t_D^{nj}/d_n & & t_D^{nn}/d_n \end{bmatrix} = \begin{bmatrix} t_D^{a11} & \cdots & t_D^{a1j} & \cdots & t_D^{a1n} \\ \vdots & & \vdots & & \vdots \\ t_D^{ai1} & & t_D^{aij} & & t_D^{ain} \\ \vdots & & \vdots & & \vdots \\ t_D^{an1} & & t_D^{anj} & & t_D^{ann} \end{bmatrix} \tag{15}$$

$$W = \begin{bmatrix} t_D^{a11} \times W_{11} & t_D^{a21} \times W_{12} & \cdots & \cdots & t_D^{an1} \times W_{1n} \\ & & & & \vdots \\ t_D^{a12} \times W_{21} & t_D^{a22} \times W_{22} & & & \vdots \\ \vdots & \vdots & & & \\ \vdots & \cdots & t_D^{aij} \times W_{ij} & \cdots & t_D^{ani} \times W_{ni} \\ \vdots & \vdots & & & \vdots \\ t_D^{a1n} \times W_{n1} & t_D^{a2n} \times W_{n2} & & & t_D^{ann} \times W_{nn} \end{bmatrix} \quad (16)$$

ANP Step 4: Obtain the limited supermatrix,
by multiple productions of the weighted supermatrix until the vector values in the limited supermatrix become stable (equation 17, with W being the limited supermatrix and z tending to infinity). The vectors of the limited supermatrix represent the relative weights of each factor in relation to the defined objective. Sorting the limited supermatrix W according to the relative weights of each factor gives insights on the significance and contribution of each factor as well as each cluster to the objective of network.

$$\lim_{z \to \infty} = W_w^z \quad (17)$$

FINDINGS

Contract Factor Inter-relationships

Table 1 presents the sums of influences of contract factors by supplier group on DEMATEL analysis. Figure 2 presents the Relation-Prominence Map for average-, over- and under- performing suppliers.
Prominence (p, D+R in Table 1) illustrates the strength of influences that are given and received of a given factor indicating the degree of central role that the factor plays in the system. For over-performers, the highest prominence scores were: Formality (p_o=8.54), Contract Duration (p_o=8.03), Partnership type (p_o=7.96) and Relationship Learning (p_o=7.74), while the lowest scores were: Force majeure (p_o=8.03), Supplier Reorganisation (p_o=8.03), and Supplier technology (p_o=8.03). On the other hand, for under-performers, the highest prominence scores were: Formality (p_u=5.39), Contract Duration (p_u=5.18), Trust (p_u=4.96), and Partnership type (p_u=4.84) while the lowest were: R Supplier Reorganisation (p_u=0.45), T Force majeure (p_u=0.57), T Supplier technology (p_u=1.53), and C Opportunism (p_u=1.75). Firms put more emphasis on Relationship Learning when contracting over-performers and on trust for under-performers respectively.
Relation (r, D-R in Table 1) shows the net effect that a given factor contributes to the system; a factor with positive relation scores has a net influence on the other factors and it should be grouped into *cause* group while negative effect shows that other factors have a stronger effect of the factor causing it to be grouped into the *effect* group. The highest cause factors for over-performers were: Opportunism (r_o=1.73), Supplier power (r_o= 0.91), Policy changes (r_o= 0.85), and Buyer power (r_o= 0.81) while for under-performers were: Supplier power (r_u=1.07), Opportunism (r_u=0.98), New entrant (r_u=0.80), Buyer power (r_u=0.62), which indicates that although both groups had similar cause factors, under-performers focused on contextual factors including the risk of new entrants, while for over-performers, post-contractual Opportunism had the highest effect on other factors. Another striking difference was in the effect groups: for over-performers Liquidated Damages (r_o= -1.29) was derived from other contract factors while for under-performers, Relational Learning (r_u=-0.79) was a low-score effect factor. Therefore, Relational Learning was a high-score Prominence factor for companies contracting over performers but a low-score Relation factor for under-performers, who also relied more on trust than over-performers.

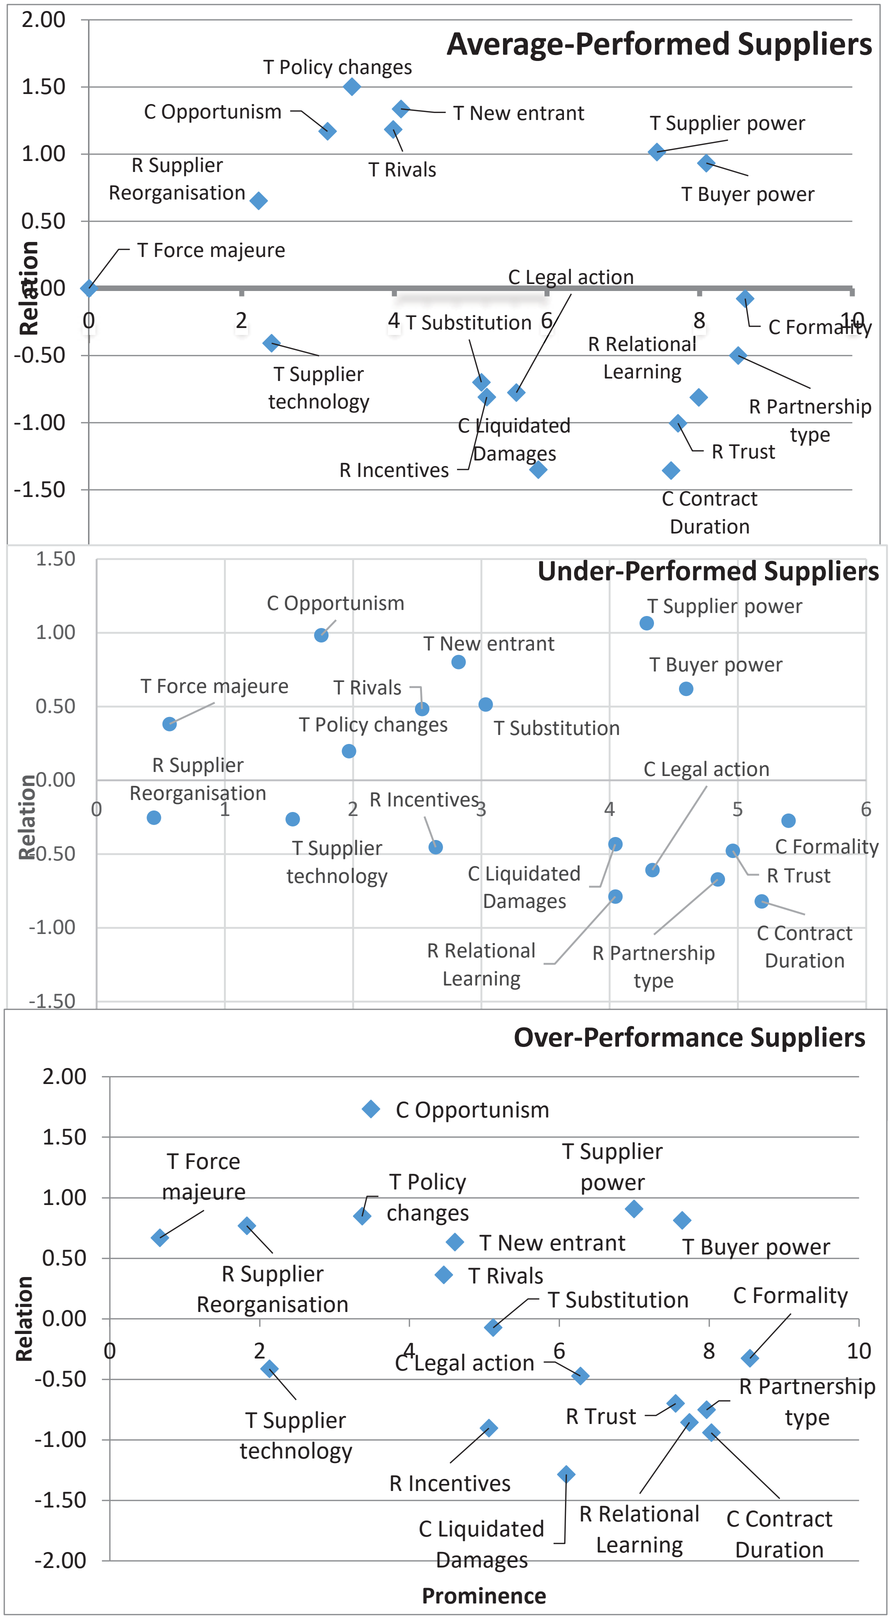

Figure 2 Relation-Prominence Map for 3 groups of suppliers

Contract Factor Rankings
Table 2 presents the rankings of contract design factors by supplier group derived from ANP analysis. Average-performing suppliers and over-performing suppliers has similar rankings while there were differences between over- and under-performing suppliers. Specifically, according to the limiting (l) values, the most important factors were for over performers: Formality (l_o= 0.077), Partnership type (l_o=0. 074286), and Relational Learning (l_o=07411) while for under-performers were: Trust (l_u=07411), Partnership type (l_u =07411), and Formality (l_u =07411). Therefore, trusting their suppliers produced less than expected performance. Contracts with under-performing suppliers showed also lower scores and emphasis on Incentives, and Relational Learning, and higher scores in most competitive factors (rivals, substitution, buyer and supplier power), which indicates that focusing on the context and not on the relationship itself results in poor performing suppliers.
Contracts that produced exceptional performance had a dual role: they put more emphasis on contractual and relational factors than contextual ones. This supports the theoretical views that contacts are governing mechanisms that reduce transaction costs but at the same time they can build and frame interfirm relationships. Specifically, the top contract factors with over-performing suppliers were contact and relational factors and the factors with les influence were contextual (Table 2). On the contrary, contracts with under-performing suppliers ranked contextual factors higher than over-performing and average-performing suppliers: i.e. Buyer power 9th vs 10th , Supplier power 8th vs 11th, rivals 14th vs 15th and Substitution 12th vs 14th respectively.
Interviews with key personnel confirmed the results of DEMATEL/ANP analysis. Procurement leaders emphasised the ineffectiveness of contractual tools such as liquidated damages, ranging from them being difficult to adequately calculate and cover damages sufficiently to discourage default, to the potential damage implementation can have on the customer- supplier relationship. Procurement managers reported that suppliers may prefer to pay liquidated damages rather than fixing the root cause of problems until it reaches a critical level. It was also highlighted that incentives were effective but not consistent especially when procurement personnel feel it unfair to reward the supplier in addition to payment for meeting their contractual obligations. Building interfirm relationships was desirable, yet beyond a point it could be less feasible or costly to tie-up in a specific supplier in the long run.

DISCUSSION
There is a rich literature on contracts (Liu and Cetinkaya 2009) but relatively few studies attempt to understand the contract design process and synthesise contract factors from different theoretical perspectives (Lumineau et al. 2011; Williamson 1987). Results show that even within the same company and same department, there are differences among the factors that influence contract design and these differences are related to supplier performance. Findings indicate that despite many commonalities, the contracting with under- and over- performers presents significant differences: In the case of over- performers, contracts have a dual, yet discrete, transaction and relational role: at transaction level, they reduce cost and complexity, and ambiguity by emphasising formality, protecting from opportunism and include both liquidated damages and legal action clauses. At relational level, they focus on relational learning and incentivizing suppliers. However, in the case of under-performers, contracts appear to focus on contextual factors, which can be a source of ambiguity particularly in complex environments. Furthermore, under-performing contracts emphasise trust, in contract to relationship learning, which appears to have a negative impact on supplier performance. These results have important theoretical and managerial implications.

Table 2 ANP Analysis: Rankings of contract design factors by supplier group

	Over-Performed Suppliers			**Under-Performed Suppliers**			**Average-Performed Suppliers**		
Name	**Normalized**	**Limiting**	**rank**	**Normalized**	**Limiting**	**rank**	**Normalized**	**Limiting**	**rank**

Theoretical Implications

Due to inherent contract complexity and incompleteness (Kalkanci et al. 2014), findings support that organisational learning improves contract design by overcoming contract inefficiencies due to bounded rationality, complex technical clauses, cultural distances and unforeseen contingencies (Ariño et al. 2014; Lui 2009).

Following transaction cost economics, asset-specific investments reduce transaction costs (Williamson 1987), therefore, formality and clauses to avoid post-contractual opportunism would reduce costs. Both factors were found to relate to overperformers in this study. Trust can be also considered as an asset- specific investment (Chiou and Droge 2006). However, one fundamental principle of relationship marketing, which is that trust improves interfirm relationships and can create loyalty (Ravald and Grönroos 1996; Ariño et al. 2014), is not confirmed. Findings do not support that trust improves supplier performance, rather the opposite: trusting suppliers relates to supplier under-performance. Previous studies have warned of the dark side of interfirm relationships (Oliveira and Lumineau 2019) including the fact that trusting suppliers may backfire by motivating them to post-contractual opportunism or make them assume that poor performance will be tolerated (Lumineau 2017).

On the other hand, incentives and relationship learning did relate to over-performance, which can be explained by the fact that contracts evolve over time (Argyres and Mayer 2007) by reflecting the relationship dynamics in which business partners are engaged and the business environment they interfirm relationships are embedded. To this respect, learning reflects the contract dynamism and frames the contract respectively, in the way formality reduces complexity and ambiguity.

Managerial Implications

Contract design is a complex process that involves managers and experts from different departments and backgrounds. Contract design is a process that it is affected by many factors that are related to each other. For example, there are trade-offs between trust and formality, trust and opportunism, contextual factors and complexity and so on. One way to deal with this inherent contract complexity and incompleteness, it to understand the interrelationships between the contract factors that affect the supplier performance. By applying multi-criteria decision making tools, like DEMATEL/ANP demonstrated in this study, companies can reveal the underlying relationships and assumptions when they design contracts and then link them to supplier performance. In this study, one key performance metrics was used, but companies may evaluate suppliers across different sets of key performance indicators that better reflect their strategic priorities.

This method allows to: (i) synthesise expert opinions from different backgrounds and expertise (ii) remove bounded rationality often present in human decision making (iii) uncover cause and group effect factors as well as prominence factors that lead the contract design (iv) rank contract factors in order of significance and (v) associate contract design factors to supplier performance.

This study also shows that companies should also keep regular face-to-face supplier management workshops on both management and working levels to align goals and expectations and to develop a good working relationship. In this way, companies will be able to crystalize what type of expectations they have from each supplier and adopt their contract accordingly.

Findings show that contracts have a dual role: reduce transaction costs and foster relationship learning. Managers should to educate staff and develop policies and appropriate techniques that enhance relational learning. Contextual factors appear to make contracts more complex and ambiguous.

Limitations and Recommendations

This study employed a single case study, which can present methodological limitations in terms of generalisation of results and reliability of data collected. Multi-criteria decision-making methods rely on evidence provided by experts in their field. When experts come from the same company, this may create a common method bias. Information from external experts would reduce the common bias effect. Future studies should apply the research design to more companies and industries, for example a multi-country, multi-industry of contract design factors and their effects on supplier performance. Although this study examined 18 contract factors, other factors may be relevant to specific industries, sectors or countries. Future studies should examine contract factors in more detail.

This study chose DEMATEL/ANP to analyse the empirical data. Multi-criteria methods are useful in codifying and analysing explicit knowledge, yet they have limitations in tacit knowledge. Future research should replicate the study with other multi-criterial methods such as fuzzy DEMATEL and compare the results across different methodologies. Although not illustrated in this case study, this method can be used as a diagnostic tool in case of disputes or service failures to uncover topics that require improvement.

ABSTRACT

This paper investigates the motivations behind investment for reliability on availability of the systems and total service cost in performance-based logistics contracts. The effects of interactions between reliability, spare parts, and the length of the contract on availability and service costs were analyzed with a simulation using BlockSim.

KEYWORDS: Performance-based logistics, performance-based contracts, reliability improvement, spare parts

INTRODUCTION

In the late 1990s, DoD came up with a new logistics model based on paying for performance rather than a transactional model to overcome these problems (Geary & Vitasek, 2005). The DoD called this model a performance-based logistics (PBL), which is also known as "power by the hour" and “outcome-based service contracts” in the private sector, is a paradigm shift in the DoD’s management (Ng and Nudurupati, 2010; Ong et al., 2005). The DoD defined PBL as a “… the purchase of support as an integrated, affordable, performance package designed to optimize system readiness and meet performance goals for a weapons system through long-term support arrangements with clear lines of authority and responsibility” (DAU, 2005).

The problems started with the overuse of the systems which bring about high life cycle costs in DoD, because of extended maintenance, hardware extinction, and structural tiredness (Berkowitz, Gupta, Simpson, & McWilliams, 2005; Devries, 2005; Kratz & Buckingham, 2010). Additionally, considering projected life of the systems, this longevity causes more maintenance time that reduces readiness of systems. These problems result with spending 72% of the total funds of the life cycle costs for sustainment of the systems (Berkowitz, Gupta, Simpson, & McWilliams, 2005). Furthermore, considering the continued budgetary pressure in addition to this high operation and maintenance costs, DoD required looking for new approaches to decrease life cycle costs while maintaining readiness of systems (Kobren, 2009; Kratz & Buckingham, 2010).

A transaction-based logistics approach, which is the traditional approach of DoD, is getting more inefficient, because of the 31% increase in the cost of sustainment in a transaction-based logistics approach in one year (Randal, Pohlen, and Hanna, 2010; GAO, 2005). Labor and material costs are the main components of these high expenses in the transaction-based logistics. (Gansler & Lucyshyn, 2006). Due to the high profit in after sales support for providers, the transaction-based approach could not align the customers' requirements with contractors' preferences (Keating & Huff, 2005). Thus, the transaction-based approach places the burden of risk on customers (Quick, 2011). Because of opportunism of contractors whose business model depends on the spare parts, contractors are not concerned with the life cycle cost of systems, thereby the reliability growth. (Hunter; 2006b; Gansler & Lucyshyn, 2006; GAO, 2005; Quick, 2011).

PBL contracts differ from transaction-based contracts in that the suppliers are rewarded when they achieve the desired performance objectives (Berkowitz, Gupta, Simpson, & McWilliams, 2005; Geary and Vitasek, 2005). This approach makes increasing system performance and reducing life cycle cost of systems possible (Berkowitz, Gupta, Simpson, & McWilliams, 2005; Geary and Vitasek, 2005; Jin, Tian, and Xie, 2014; Kim, Cohen, and Netessine, 2007; Randal, Pohlen, and Hanna, 2010).

The DoD is able to share the risk with a supplier with the advantage of this new logistics support strategy based on the pay for performance strategy (Gansler & Lucyshyn, 2006). PBL contracts motivate suppliers to make an investment to increase the reliability of systems that result in high operational readiness of systems (Gansler & Lucyshyn, 2006; Vitasek et al., 2007). This upfront investment by suppliers improving affordability over the remaining life of the supported system is affecting the spare and repair strategy (Kim, Cohen, and Netessine, 2007; Randal, Pohlen, and Hanna, 2010).

However, besides these advantages, PBL consists of some potential risks, such as supplier opportunism, selection of the wrong supplier (Gardner, 2008). In PBL, the contract identifies what is required such as target availability of systems, but the supplier determines how to attain the objectives (Kim, Cohen, and Netessine, 2007). How to get the required outcome is dependent on provider's decisions about strategies, such as making an upfront investment to increase reliability, holding spare parts to increase readiness, and increasing service capacity to reduce mean time to repair. In PBL, customers expected a high level of product reliability which is the one of the three fundamental features of enabling mission capability, along with availability and maintainability (DoD 2005). However, considering to supplier opportunism and uncertainties in long-term contracts, suppliers reluctant to increase the reliability of components (Stauss et al. 2010).

The primary purpose of this study is to understand the motivations behind upfront investment for reliability growth and the effects of reliability improvement on availability of the systems and total service cost in PBL. The other goal of this study is to understand the effects of interactions between reliability, spare parts, and the length of the contract.

The primary research question of this study is 'What is the consequences of reliability growth in PBL?' As secondary research questions, we will investigate these issues: How can we minimize design cost of systems while increasing the reliability of systems in PBL? What are the consequences of reliability growth on the availability of systems and service cost in PBL?

The remainder of this paper is organized as follows. The literature review will be presented in Section 2. In Section 3, research methodology and mathematical models are represented. In Section 4 and 5, a numerical example is described for optimum reliability allocation, and the effects of reliability growth on the availability of systems and service cost in PBL, respectively. The paper will be concluded in Section 6 with a discussion of limitations, future research, and conclusion.

LITERATURE REVIEW

PBL offers an exceptional model, win-win-situation, for customers and suppliers (Stauss, Hypko, et al. 2010). All efforts in PBL, such as maintenance programs and inventory management, are designed to reduce the cost of ownership for sustaining systems (Gansler & Lucyshyn; 2006; Vitasek et al., 2007). Fewer maintenance actions in PBL create more high-profit margins for suppliers, because of the high availability rates (Ong et al., 2005). Additionally, the supplier is motivated by incentives to invest the reliability of systems that result in high operational readiness of systems (Gansler & Lucyshyn, 2006; Vitasek et al., 2007). This investment for reliability will increase availability and readiness of systems while reducing total service cost, spare parts acquiring, holding costs, and logistic footprint (Cohen, M. A., & Netessine, S., 2007; Devries, 2005; Gansler, 2006).

Many studies are conducted about a trade-off between spare parts and reliability. Kumar et al. (2007) developed a multi-objective optimization model (goal programming model) to optimize reliability, maintainability and supportability that are important in PBL support contracts under PBL (Kumar, Nowicki et al. 2007). Sols et al. (2007) proposed a framework for PBL contracts and describes the fundamental features of a successful PBL initiative. In their study, which is based on the literature survey and the interviews, they come up with three essential characteristics - will, purpose, and reward - for efficient and effective PBL contractual agreements. They also proposed that successful implementation of PBL contracts depend on the appropriate selection of the metrics that show the effectiveness of systems and the adoption of a fair reward scheme (Sols, Nowicki et al. 2007). Nowicki et al. (2008) developed an optimization model for the spare asset allocation problem under three different revenue functions: step, exponential and linear revenue functions. They found that an optimal spares asset allocation can not be sustained without considering the associated profit stream (Nowicki, Kumar et al. 2008). Kim et al. (2010) analyzed the efficiencies of two contract types used in PBL, based on sample-average downtime and based on cumulative downtime, using a principal-agent contracting framework. They found that when a component is highly reliable, implementation of performance-based contracts (PBCs) may create high agency cost (Kim, Cohen et al. 2010). Mirzahosseinian and Piplani (2011) investigated how do component reliability, maintenance facility, and inventory management affect the availability of systems under the PBL. They found that the base stock level of the spare parts had an insignificant impact on the system availability. Thus, to attain a minimum target availability level, the supplier has to enhance the component reliability and the repair time, rather than increase the stock of spares (Mirzahosseinian and Piplani 2011). Jin et al. (2012) investigated the main factors that affect the system performance, and how they interact with each other to achieve the operational availability under PBC. They found that there is strong relationship amongst system cost, reliability, and spare parts stocking (Jin et al., 2012). They showed that under a longer service agreement in PBC, suppliers as OEMs are eager to invest in reliability improvement. Also, they revealed that increasing the spare parts inventory has less impact on the availability of highly reliable systems (Jin et al., 2012). Guajardo et al. (2012) showed in his experimental study, which was based on the real data of the Rolls-Royce company, how product reliability was impacted by the use of two various support strategies: time and material based (T&MC) strategy and performance-based strategy. They found that the reliability of products is much higher (25%–40%) under PBC than under T&MC (Guajardo, Cohen, et al., 2012). Jin and Tian (2012) investigated how operational availability can be achieved while minimizing the logistics footprint through increasing reliability under PBC. In their study, trade-offs between the reliability design and the spare part level are examined and compared in different scenarios. They showed that the multi-phase replenishment policy is effective to allocate spare parts to a changing installed base (Jin and Tian 2012). Kim et al. (2015) developed a game-theoretical model to investigate the interaction investment in spare assets and product reliability under the traditional resource-based contract (RBC) and PBC. They found that PBC motivates suppliers to make the upfront investment for reliability improvement by powerful incentives, which creates savings in acquiring and holding spare assets (Kim, Cohen & Netessine, 2015). On the contrary, under the RBC, the supplier invests more in inventory and less in reliability (Kim, Cohen & Netessine, 2015). Bakshi and Kim et al. (2015) developed the game-theoretical model, a principal-agent model, to investigate the interaction between reliability signaling and the vendor's unrestricted investment in spares inventory. They found that customers are eager to accept PBC when mature technologies are available for acquired products rather than products with newly developed technology (Bakshi, Kim, et al. 2015).

Although there are many studies about a trade-off between spare parts and reliability, there is no study that directly investigates the effects of the reliability of systems on availability and service cost in PBL. Also, unlike the previous studies, target reliability allocation of systems was attained considering a minimum and a maximum reliability of subsystems under the various feasibility rates. Supplier's reservation utility and supplier's utility function were conducted under the agency theory perspective based on the two different contract types: Fixed Firm Price (FFP) and Cost Plus Award Fee (CPAF). The 7other contribution of this study is the investigation of the direct impact of reliability growth to availability rates and service costs.

THEORETICAL DEVELOPMENT and MATHEMATICAL MODEL

Nomenclature

A	System or subsystem availability
$A\min$	Availability target
$MTBF$	Mean time between failure
MDT	Mean downtime
$MTTR$	Mean time to repair
$MLDT$	Mean logistics delay time
C_T	Total service cost
$c_i\ (sc_i)$	Spare cost of component/subsystem i
$c_i\ (mc_i)$	Maintenance cost of component/subsystem i
$c_i\ (shc_i)$	Holding cost of component/subsystem i
C_D	Total system design cost
$c_i\ (R_i)$	Design cost of component/subsystem i
R_i	Reliability of component/system i,
n	Number of components within the system considered in the optimization
$R_{i,min}$	Minimum reliability of component/subsystem i
$R_{i,max}$	Maximum achievable reliability of component/subsystem i
R_S	System reliability
R_T	System reliability target
f_i	Feasibility of increasing the reliability of subsystem I
I_r	Reliability importance

β_i Weibull shape parameter of component/system i,
α_i Weibull scale parameter of component/system i,
a, b_1, b_2 Fixed price, reward, and the penalty for suppliers, respectively.

In this study, we conducted a mixed methodology of quantitative research. The effects of reliability growth, spare parts, and the length of the contract in PBL will be analyzed with simulation (BlockSim).

In PBL, the customer outsources the task of delivering the system's performance to the supplier (Helander and Moller, 2008). This relationship between the supplier (agent) and customer (principal) creates the agency problem that emerges when the preferences and goals of the principal and agent are in conflict (Eisenhardt, 1989). Although customers have information about supplier's capability, such as service capacity, technological capability, and technical ability, they cannot forecast the supplier's action in the performing of the contract (Bergen et al., 1992). Because of the imperfect information about the agent's performance, it is getting hard to detect whether the agent performs according to the principal's interest or not (Eisenhardt, 1989).

The performance-based payment tied to achievement of the outcomes transfers risks from the principal (customer) to the agent (supplier) (Eisenhardt, 1989; Firchau, 1987). Even if the incentives inherent to performance-based payment in PBL transfers risks from the customer to the supplier, it still contains risks, which mentioned above, for customers. Considering customers' inability to observe suppliers' actions in PBL, because of the imperfect information, customers need to mitigate this risk in PBL, especially in long-term contracts. To reduce the risks that emerge from agency problems, in PBL, the payment based on the outcome enable alignment of the customers' goals with the supplier's preferences. Customers conduct incentives in the various contract types such as fixed price incentive fee (FPIF), cost plus incentive fee (CPIF), and cost plus award fee (CPAF) (Sols, Nowicki, and Verma, 2007). With these contract types, customers want to motivate the suppliers to act in agreement with the customers' preferences (Firchau, 1987).

One of the fundamental characteristics of PBL tied to arrangements, which is called as tenets of PBL, to get desired objectives is meaningful and significant incentives to supplier tied to achievement of the outcomes (DoD, 2014; UT, 2012). Therefore, it is significant for the customer to propose reasonable incentives and to make effective contracts align the preferences of supplier and his/hers. In our study, we show the relationship between reliability growth and motivation in different contract types.

Mathematical Model

In PBL, customer's incentives to motivate the supplier to make the upfront investment should be meaningful and significant for the supplier. The supplier will seek for a design that will sustain the target reliability of the system at a minimum cost. From the perspective of agency theory, considering the constraints involving the supplier, the customer must ensure that the agent gets at least a reservation level of utility. In that point, the customer can only influence the provider by his choice of the incentive payment.

We modeled the performance-based contract as a principal-agent game-theoretical model. Two players involved in the game are the supplier and the customer. The supplier behaves as an agent whose goal is to minimize the total design cost of the system while achieving the reliability target. Furthermore, the provider's ultimate goal with the result of this reliability growth is to maximize his service profit. The customer is the principal who wants to achieve reliability growth criteria by stipulating the reward function.

With the following models, denoted as Problem P1 and Problem P2, we will show the optimum reliability allocation to reach desired availability target while minimizing total design cost. For the purpose of the first research question, the minimization function will be used to find the objective reliability of systems subject to minimum and maximum reliability of subsystems, agent's reservation utility function, and agent's utility function. These functions depend on the agency theory and reliability theory.

Problem 1:

To find the optimum reliability allocation for supplier with a minimum cost; considering to achieve reliability target with implementation of Firm-Fixed-Price (FFP) contract is shown below:

The customer (principal) has utility function $\mathrm{B(y)}$ for reliability.

- If the outcome is R_T and the supplier (agent) is paid a,
- The customer's utility is $\mathrm{B}\,(R_T\ - R_S)$ (1)

In this equation, R_T is the target reliability of the system, after reliability enhancement; R_S is the current reliability if the system, without reliability improvement.

The supplier's (agent's) utility function is given by (adapted from Jin et al., 2012 and Mettas A., 2000),

$$Min\ C_D = \sum_{i=1}^{n} B_i * c_i(R_i) \ , \tag{2}$$

where

$$c_i\left(R_i; f_i;\ R_{i,min};\ R_{i,max} = e^{\left[(1-f_i)\frac{R_i - R_{i,min}}{R_{i,max}-R_i}\right]}\right) \tag{3}$$

In this equation, $R_{i,max}$ is the maximum achievable reliability of the subsystems or components while $R_{i,min}$ is the minimum inherent reliability of the subsystems or components. R_i represents the current reliability of the subsystems or components. f_i describes the feasibility of increasing the reliability of subsystem or component i and takes values between 0 and 1. It represents the difficulties, such as design complexity, technological limitations, etc., in increasing the subsystem/component's reliability relative to the others. The small feasibility rate indicates the reliability growth of the subsystems or components are difficult to improve. Additionally, this small feasibility rate results in a high design cost to increase the reliability of the subsystems or components (Mettas A., 2000). B_i represents the basic design cost of the subsystems or components.

Reliability of the system

$$R_s(t) = \prod_{i=1}^{n} R_i\ (t) = R_1(t) * \ R_2(t) * \ R_3(t) * \dots * R_n(t) \tag{4}$$

where

$$R(t) = e^{-(\alpha t)^{\beta}} \tag{5}$$

β_i and α_i Weibull shape and scale parameters of component/system i, respectively.

$$R_{i,min}(t)\ \le\ R_i\ (t) \le R_{i,max}(t),\ \ i = 1,2 \dots, n. \tag{6}$$

From equation 2 to 6;

$$Min\ C_D = \sum_{i=1}^{n} B_i\ *\ e^{\left[(1-f_i)\frac{R_i - R_{i,min}}{R_{i,max}-R_i}\right]} \tag{7}$$

Subject to

$$R_s(t) = R_1(t) * R_2(t) * R_3(t) \geq R_T(t) \quad (8)$$

$$R_{1,min}(t) \leq R_1(t) \leq R_{1,max}(t), \quad (9)$$

$$R_{2,min}(t) \leq R_2(t) \leq R_{2,max}(t), \quad (10)$$

$$R_{3,min}(t) \leq R_3(t) \leq R_{3,max}(t), \quad (11)$$

Problem 2:

To find the optimum reliability allocation for supplier with a minimum cost; considering to achieve reliability target with implementation of Cost Plus Incentive Fee (CPIF) contract is shown below:

The customer (principal) has utility function $\mathrm{B(y)}$ for reliability.

- If the outcome is R_T and the supplier (agent) is paid b_1,
- The principal's utility is $\mathrm{B}\,(R_T - R_S)$

Where the linear revenue functions are (adopted from Nowicki et al. (2008))

$$r(R_S) = \begin{cases} a + b_1(R_S - R_T) \ for\ R_S \geq R_T \\ a + b_2(R_T - R_S) \ for\ R_S < R_T \end{cases} \quad (12)$$

Here R_T is the target system reliability designated by the customer. a, b_1 and b_2 are positive parameters determined by the customer. In particular, a is the fixed payment; and b_1 and b_2 are the reward and penalty rate, respectively (or the piece rate in game theory). A larger value of $b1$ (or $b2$) implies that the OEM receives more compensation (or penalty) given the same level of R_S depending on whether $R_S \geq R_T$ or $R_S < R_T$.

The supplier's (agent's) utility function is given by

$$u\,(b_1, C_D) = b_1(R_S - R_T) - C_D \quad (13)$$

where C_D is the level of effort the supplier chooses to increase reliability and b_1 is the award in PBL that the supplier receives.

The agent has reservation utility $u0$ is given by

$$u0\,(b_2, C_D) = C_D - b_2\,(R_T - R_S) \quad (14)$$

where b_2 is the penalty in PBL that the supplier receives.

From equation 2 to 6 and 12-14;

$$Min\ C_D = \sum_{i=1}^{n} B_i * e^{\left[(1-f_i)\frac{R_i - R_{i,min}}{R_{i,max} - R_i}\right]} \quad (7)$$

Subject to

$$R_s(t) = R_1(t) * R_2(t) * R_3(t) \geq R_T(t) \quad (8)$$

$$R_{1,min}(t) \leq R_1(t) \leq R_{1,max}(t), \quad (9)$$

$$R_{2,min}(t) \leq R_2(t) \leq R_{2,max}(t), \quad (10)$$

$$R_{3,min}(t) \leq R_3(t) \leq R_{3,max}(t), \quad (11)$$

$$u\ (b_1, C_D) = b_1(R_S\ - R_T) - C_D \geq 0 \tag{15}$$

$$u0\ (b_2, C_D) = C_D - \ b_2\ (R_S\ - R_T)\ \leq 0 \tag{16}$$

Problem 3:

To minimize the total service cost is essential for the supplier. All of the suppliers' efforts concentrate on reducing this cost in PBL while achieving the desired outcomes. However, how this cost is affected by suppliers' action still not clear, especially in long-term contracts. With the third problem, we will investigate the effects of reliability growth on the availability of systems and service cost in PBL. For this purpose, simulation (BlockSim) will be used to find the consequences of reliability growth on the availability of systems and service cost. Our assumptions are; normal distribution will be utilized for maintenance time and logistic delay time.

$$C_T(s, R_S, t) = \sum_{i=1}^{n} c_i(R_i) + \sum_{i=1}^{n} c_i(sc_i) + \sum_{i=1}^{n} c_i(shc_i) + \sum_{i=1}^{n} c_i(mc_i) \tag{17}$$

$$A = \frac{MTBF}{MTBF+MDT} \tag{18}$$

where

$$MDT = MTTR + MLDT \tag{19}$$

The comparison of the effects of system reliability on system availability and total service cost will be made as a result of this problem. In this issue, C_T is the total service cost for the supplier and it is affected by the reliability of the system, number of spare parts, and length of contract. In this equation, $c_i\ (R_i)$ is the design cost of component/subsystem i, $c_i\ (sc_i)$ is the spare cost of component/subsystem i, $c_i\ (mc_i)$ is the maintenance cost of component/subsystem i, and $c_i\ (shc_i)$ is the holding cost of component/subsystem i. Availability is the primary performance metric and defined as where MTBF is the mean time between failures. MDT is the mean downtime which is the sum of mean time to replacement (MTTR) of a part and mean logistics delay time (MLDT) (Jin et al. 2014).

SIMULATION AND NUMERICAL EXAMPLE

Reliability Allocation

The system consists of three components connected in a series configuration. The system will fail if any of its subsystems fails (i.e., series configuration). Each system has different reliability and different feasibility rates. Each system has different reliability and different feasibility rates. The target reliability of the system is 90% within the time consideration of 200 hours. The Weibull shape, scale parameters, feasibility, and basic design cost of component/system i are shown in Table 1:

Table 1: Reliability and Cost Parameters of Components

Parameter		Value
β_i	β_1 (HardDriveBlock_1) β_2 (Main BoardBlock_2) β_3 (PowerSupplyBlock_3)	1,3 1,35 2,1
α_i (hours)	α_1 , α_2 , α_3	420 – 650 - 590
f_i	f_1 , f_2 , f_3	0.2 - 0.8 - 0.5
B_i (dollars)	B_1, B_2 , B_3	240.000,60.000,150.000

Analysis of Current Reliability of System/Subsystems:

The reliabilities, probability of failure rates, and importance of each component and reliability of system for 200 hours are shown in Table 2:

Table 2: Current Reliability of System and Components			
Mission End Time (Hr)	200		
	Block Outputs		
Block Name	*Reliability*	*Prob. of Failure*	*Importance*
HardDriveBlock_1	0.683064	0.316936	0.735789
Main BoardBlock_2	0.81572	0.18428	0.616132
PowerSupplyBlock_3	0.902012	0.097988	0.557189
	Reliability	*Prob. of Failure*	
System	0.502591	0.497409	
Failure Rate (Hr) =	0,004935/Hr		
Mean Life (Hr) =	231,947982 Hr		

Analysis of Target Reliability of System/Subsystems:

According to results of the first problem; the reliability allocation of the system considering minimum design cost is shown in Table 3-4. New total reliability of the system is presented in Table 5. Block and system reliability versus time shown in Figure 1-2.

Table 3: Reliability Allocation of System						
Block Name	$R_{i,max}$	$f_{i,}$	Reliability importance of component i (200 hr)	$R_{i,C}$ (200 hr)	$R_{i,T}$ (200 hr)	$B_{i,DC}$ (200 hr) (dollars)
PowerSupplyBlock_3	0,999	0,5	0,557189	0,902012	0,973752	35.457
Main Board Block_2	0,999	0,8	0,616132	0,81572	0,953352	12.075
HardDrive Block_1	0,999	0,2	0,735789	0,683064	0,969485	621.072
System	0,999	-	-	0.502591	0,90	668.604

$R_{i,max}$: Maximum achievable reliability of component i.
f_i: Feasibility of component i.
$R_{i,C}$: Current reliability of component I (200 hr).
$R_{i,T}$: Target Reliability of component i (200 hr).
$B_{i,DC}$: Design cost of component of component i (200 hr) (dollars).

Minimum total design cost of the system for R_T (0.90) is $668.604. Therefore, customers should have to consider this minimum total design cost of the system for award and penalty amount in the contract to motivate them to make the upfront investment to increase the reliability of systems. Additionally, this total design cost can reduce the fleet size. Thus, fleet size of the systems directly affects these amounts, design cost, award, and penalty. With this solution, meaningful and significant incentives (award and penalty), which are the one of the tenets of PBL tied to arrangements (DoD, 2014; UT, 2012), become more predictable for the customer.

The long-term effects of this reliability growth on system availability and total service cost will be analyzed below with Problem 3 and Problem 4.

Table 4: Target Reliability of System and Components

Block Name	Reliability	Prob. of Failure	Importance
HardDriveBlock_1	0,969487	0,030513	0,928324
Main BoardBlock_2	0,953579	0,046421	0,943811
PowerSupplyBlock_3	0,973516	0,026484	0,924482
	Reliability	Probability of Failure	
System	0,90	0,10	

Figure 1: Block Reliability versus Time

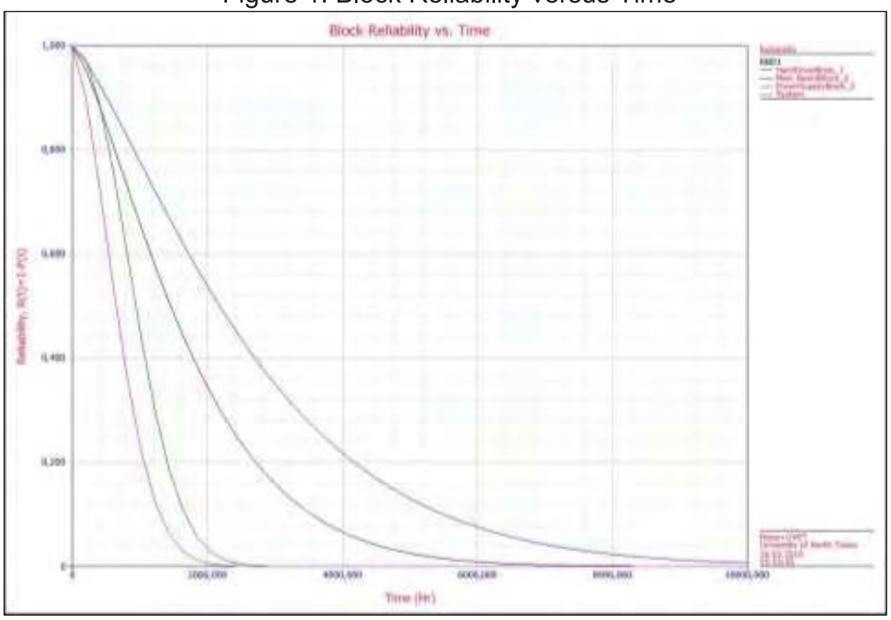

Figure 2: System Reliability versus Time

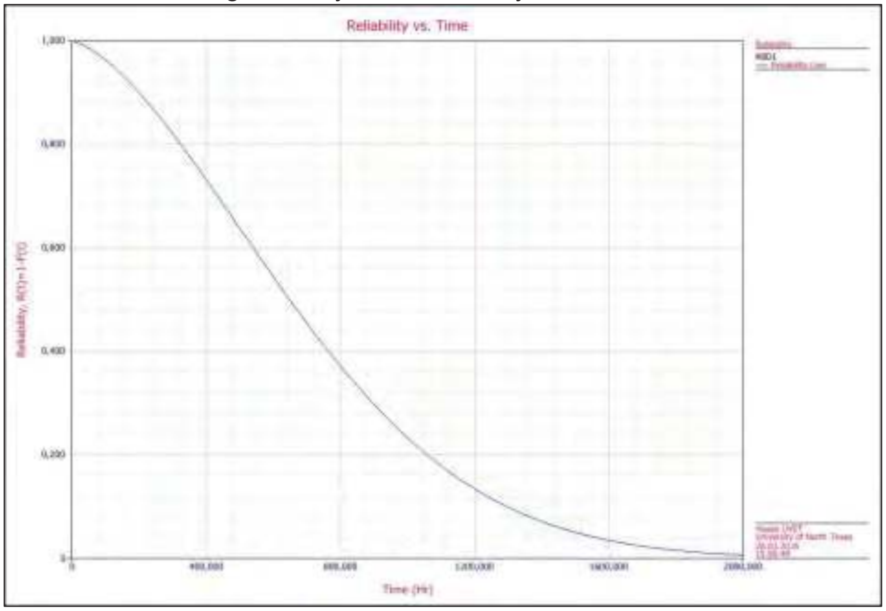

The Effects of Reliability Growth on Availability and Service Costs

In this study, we adopt a single-echelon service supply chain to support the operation of repairable systems. There are many studies have been conducted in the area of service parts inventory systems. The multi-echelon technique for a recoverable item control (METRIC) model, which was introduced by Sherbrooke (1968), is one of the first studies of repairable inventory model, and it is necessary for controlling expensive critical parts that are replaced correctively (Driessen et al., 2010). The goal of the METRIC model is to minimize inventory investment and to lower the holding or backorder cost subject to service level requirement (Sherbrooke, 1968). The stock holds various levels of spare parts per type in multi-item systems in which consists of several component types. In the event of failure, parts are sent to the repair center for reconditioning or repair. After maintenance, they are sent back to the stockroom under the one-for-one replenishment policy. The spare parts cost, maintenance cost, holding cost, and the other variables of each component/subsystem used in the simulation are shown in Table 5.

Table 5: Cost and Maintenance Data of component/subsystem i

	HardDriveBlock_1	MainBoardBlock_2	PowerSupplyBlock_3
$c_i\ (sc_i)$ (\$)	25000	27000	20640
$c_i\ (shc_i)$ (\$)	2000	2000	2000
Downtime Rate	Weibull Distribution		
Task Duratıon	Exponential Distribution		
Logistic Delay	Normal Distribution (Mean: 11; Std.: 4; Unit: Hour)		
Crew Task	Exponential Distribution (limit of tasks this crew can perform: 1)		
Cost Per Task	Normal Distribution (Mean: 250; Std.: 50; Unit: Dolar)		

$c_i\ (sc_i)$: Spare parts cost of component/subsystem i (\$)
$c_i\ (shc_i)$: Holding cost of component/subsystem i (\$)

Simulation (BlockSim) results with current reliability of the system

This simulation was conducted with current reliability, without enhancement of reliability of components, under the four various time considerations - 200 hr, 500 hr., 1000 hr., one year- with one spare capacity for the each part of the system. The results of this simulation were presented in Table 6.

Table 6: Simulation results for current reliability (spare parts =1)

System Overview	t=200 hr, s=1, current R_S	t=500 hr, s=1, current R_S	t=1000 hr, s=1, current R_S	t=1 year, s=1, current R_S

Number of Failures:	0.576	1.971	4.723	45.244
System Cost Summary				
Misc. Corrective Costs:	$3,649	$13,263	$32,198	$315,524
Costs for Parts (CM):	$14,400	$49,275	$118,075	$1,131,100
Total CM Costs:	$18,049	$62,538	$150,274	$1,446,624
Block Consequential Costs:	$16,777	$55,891	$131,679	$1,248,137
Pool Holding Costs:	$1,930	$5,551	$11,196	$97,484
Total Cost (Service and Spare Costs):	**$36,757**	**$123,981**	**$293,149**	**$2,792,245**

The results of simulation show that the availability of the systems decreases with the increase of the length of the contract. While the availability rate was 93% under the time consideration of 200 hr., this availability rate drops almost 7% to 86% under the one-year contract. On the other hand, the total cost of supplier increases from $36.757 to $2.792.245 in a year. This cost is not utility function of the supplier since it does not include incentives (penalty and reward) for the provider based on to attain the target objectivity of contract in PBL. Considering to 90% target availability was determined by the customer in PBL contracts, then depending on the results of the simulation, the supplier will be penalized for the low availability rates under the 500 hr-1000 hr- 1-year length of contracts. Therefore, provider’s total cost will increase with the penalty cost under the PBL. We can conclude that, besides the incentives (award and penalty) for the supplier, also, the length of contract and target availability rates are significant for the supplier’s decision to make the upfront investment to increase the reliability of the system.

According to results of simulation under the time consideration of current reliability, 500 hr., and one spare capacity the graphs of availability and reliability versus time, total service cost versus time, and system failures are shown in Figure 3, 4, and 5.

Figure 3: Availability and Reliability versus Time (R_C, 500 hr.,1)

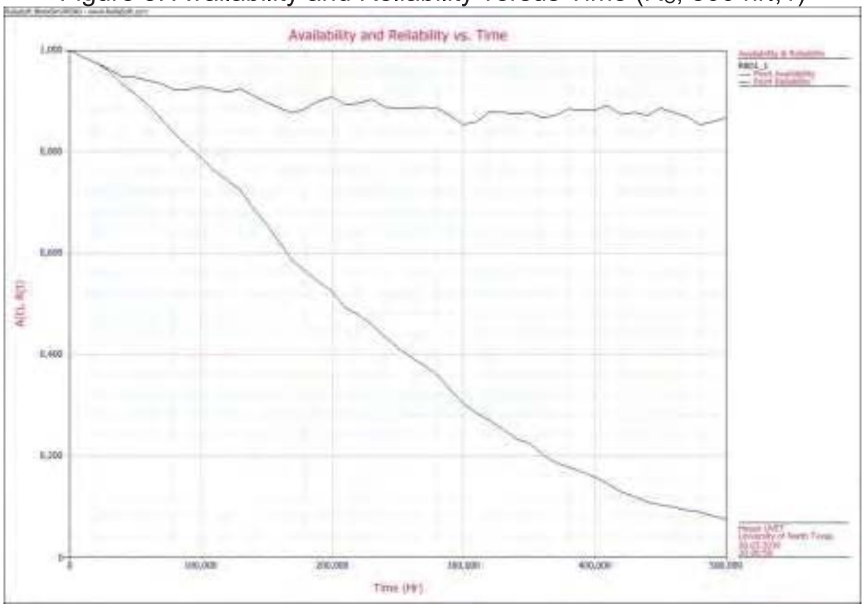

Figure 4: Total Service Cost versus Time (R_C, 500 hr.,1)

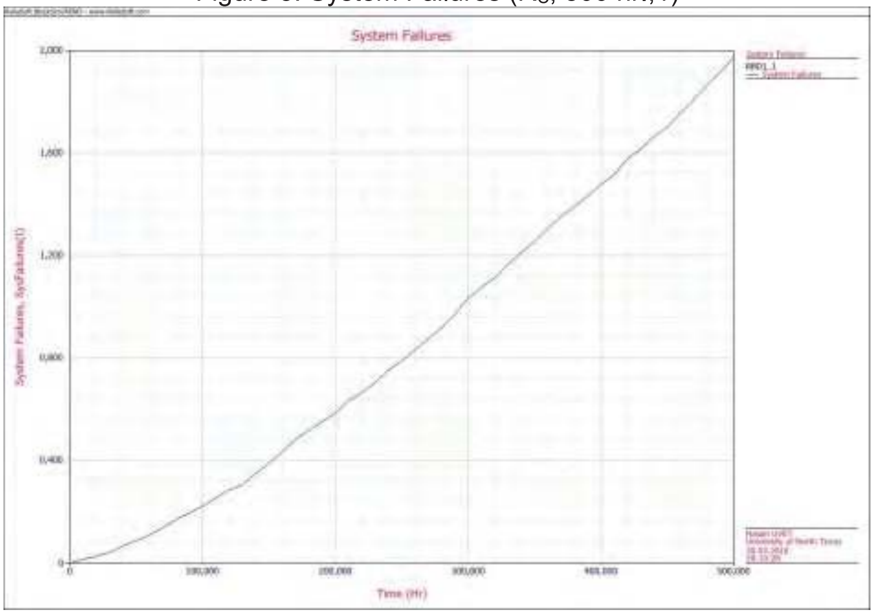
Figure 5: System Failures (R_C, 500 hr.,1)



The second simulation was conducted with current reliability, without enhancement of reliability of components, under the four various time considerations - 200 hr, 500hr., 1000 hr., one year- with spare acquisition type, fixed probability (0.1) of stock out for the each component of the system. The results of this simulation were presented in Table 7.

Table 7: Simulation results for current reliability (spare acquisition type: fixed probability (0.1) of stockout)

System Overview	t=200 hr, s=0, R_S (200hr)	t=500 hr, s=0, R_S(200hr)	t=1000 hr, s=0, R_S(200hr)	t=1 year, s=0, R_S(200hr)
Mean Availability (All Events):	**0.923873**	**0.888037**	**0.869557**	**0.853627**
Reliability(200):	0.519	0.066	0.001	0
MTBF (Total Time) (Hr):	336.134	243.664	213.949	192.384
Number of Failures:	0,595	2,052	4,674	44,905
System Cost Summary				
Misc. Corrective Costs:	$3,958	$14,515	$33,794	$327,478
Costs for Parts (CM):	$1,300	$4,825	$11,350	$111,375
Total CM Costs:	$5,258	$19,340	$45,144	$438,853
Block Consequential Costs:	$17,419	$58,112	$131,227	$1,247,450
Total Costs (Service and Spare Costs)	**$22,677**	**$77,452**	**$176,371**	**$1,686,303**

The results of simulation show that the availability of the systems decreases with the increase of the length of the contract. While the availability rate was 92.4% under the time consideration of 200 hr., this availability rate decreases to 85.3% under the one-year contract. On the other hand, the total cost of supplier increases from $ 22.678 to $1.686.303 in a year. The results of the simulation show that considering to 90% target availability was determined by the customer in PBL contracts; the supplier will be penalized for the low availability rates under the 500 hr-1000 hr-1 year length of contracts.

Comparison of two simulations under the different spare parts (1 and 0) shows that the availability rates did not change significantly. There is almost 0.6 % decrease in this availability rates. On the other hand total cost of the supplier, severely affected with the spare parts. Under the one-year contract length, the total costs of provider reduced from $2.792.245 to $1.686.303. To be able to show this comparison clearly, we put the results of two simulations in one table which are presented in Table 8.

Table 8: Simulation results for current reliability under the two different spare parts

System Overview	t=200 hr	t=500 hr	t=1000 hr	t=1 year
s=1, current R_S				
Mean Availability (All Events):	0.929974	0.897894	0.875977	0.859233
Total Costs:	$36,756	$123,981	$293,149	$2,792,244
s=0, R_S (200hr)				
Mean Availability (All Events):	0.923873	0.888037	0.869557	0.853627
Total Costs:	$22,.677	$77,452	$176,371	$1,686,303

<u>Simulation (BlockSim) results with target reliability of the system:</u>

This simulation was conducted with target reliability, after enhancement of reliability of components, under the four various time considerations - 200 hr, 500hr., 1000 hr., one year- with one spare capacity for the each part of the system. The results of this simulation were presented in Table 9.

Table 9: Simulation results for target reliability (spare parts =1)

System Overview	t=200 hr, s=1, R_T(200hr)	t=500 hr, s=1, R_T(200hr)	t=1000 hr, s=1, R_T(200hr)	t=1 year, s=1, R_T(200hr)
Mean Availability (All Events):	**0.987722**	**0.978038**	**0.967664**	**0.951943**
Reliability(200):	0.901	0.636	0.231	0
MTBF (Total Time) (Hr):	1904.76	1168.22	818.33	561.85
Number of Failures:	0.105	0.43	1.22	15.38
System Cost Summary				
Misc. Corrective Costs:	$641	$2,854	$8,391	$107,671
Costs for Parts	$2,625	$10,700	$30,550	$384,400
Total CM Costs:	$3,266	$13,554	$38,941	$492,071
Block Consequential Costs:	$2,765	$10,952	$30,712	$382,553
Pool Holding Costs:	$1,766	$5,315	$11,192	$97,942
Total Service and Spare Costs:	$7,797	$29,821	$80,845	$972,566
Design Cost	*$668,604*	*$668,604*	*$668,604*	*$668,604*
Total Costs:	**$676,401**	**$698,425**	**$749,449**	**$1,641,170**

The results of simulation show that there is an apparent growth in the availability rates. The availability of the systems decreases with the increase of the length of the contract. While the availability rate was 98.7% under the time consideration of 200 hr., this availability rate drops only 3.5% to 95.2% under the one-year contract. This decreased rate is the almost half of the reduce under the R_S (200hr). On the other hand, the total cost of supplier increases from $676.401 to $1.641.170 in a year. This cost is not utility function of provider since it does not include incentives (penalty and reward) for the supplier based on to attain the target objectivity of contract in PBL. According to results of the simulation, the supplier will be awarded for the high availability rates under the 200 hr.-500 hr-1000 hr-1 year length of contracts, considering to 90% target availability was determined by the customer in PBL contracts.

Because of the design cost, the total cost of the length of 200 hr.-contract is pretty high while comparing with the cost $36.757 under the R_S (200hr). However, this total cost under the one-year contract decreases from $2.792.245 to $1.641.170. Considering incentives, penalty and reward costs for these contracts, the decline in the total cost will be much higher than this amount. Therefore, provider's total cost will drop with the incentives under the PBL. We can conclude that the length of the contract is the most significant factor for the suppliers to increase the reliability of the systems.

According to results of simulation under the time consideration of target reliability, 500 hr., and one spare capacity (R_T, 500 hr.,1), the graphs of availability and reliability versus time, total service cost versus time are shown in Figure 6 and 7.

Figure 6: Availability and Reliability versus Time (R_T, 500 hr.,1)

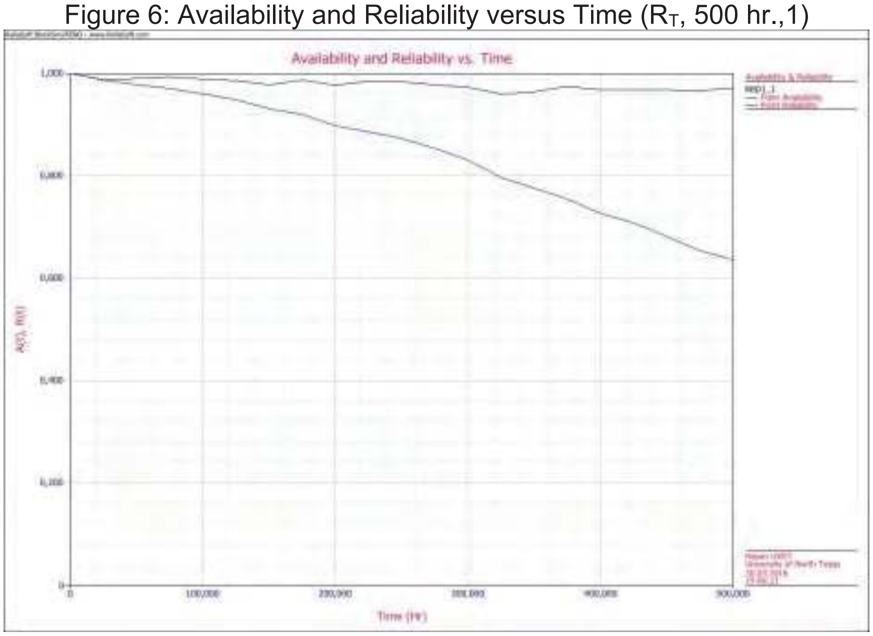


Figure 7: Total Service Cost versus Time (R_T, 500 hr.,1)

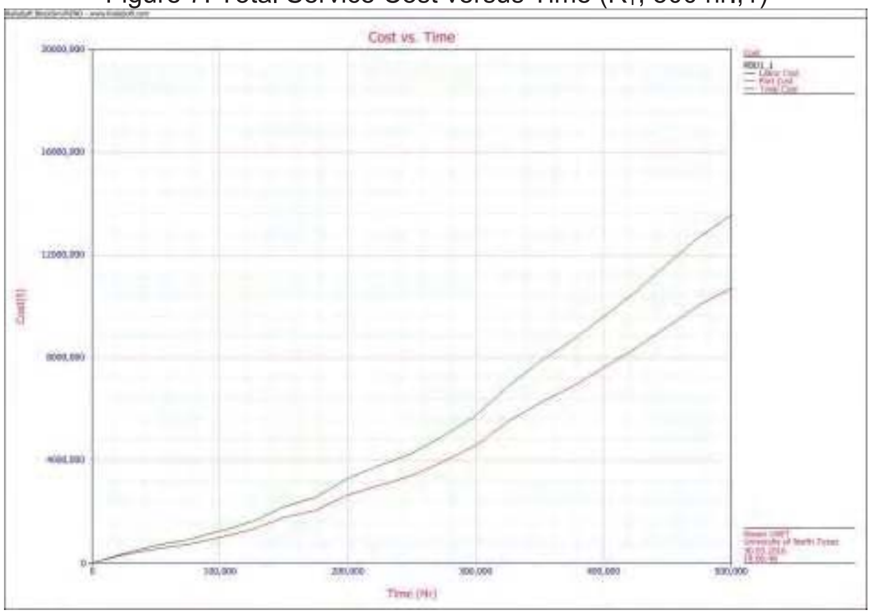

The second simulation was conducted with target reliability, after enhancement of reliability of components, under the four various time considerations - 200 hr, 500hr., 1000 hr., one year- with spare acquisition type, fixed probability (0.1) of stock out for the each component of the system. The results of this simulation were presented in Table 10.

Table 10: Simulation results for target reliability (spare acquisition type: fixed probability (0.1) of stock out)

System Overview	t=200 hr, R_T(200hr)	t=500 hr, R_T(200hr)	t=1000 hr, R_T(200hr)	t=1 year, R_T(200hr)
Mean Availability (All Events):	**0.986716**	**0.978143**	**0.966223**	**0.949386**
Reliability(200):	0.898	0.653	0.235	0
Expected Number of Failures:	0.103	0.409	1.221	15.369
MTBF (Total Time) (Hr):	1941.7	1222.5	819	562.1
Number of Failures:	0.103	0.409	1.221	15.369
System Cost Summary				
Misc. Corrective Costs:	$690	$2,836	$8,754	$113,219
Costs for Parts (CM):	$275	$875	$2,650	$37,475
Total CM Costs:	$965	$3,711	$11,404	$150,694
Block Consequential Costs:	$2,837	$10,767	$30,786	$383,302
Pool Holding Costs:	$0	$0	$0	$0
Total Service and Spare Costs:	$3,802	$14,477	$42,190	$533,996
Design Cost	*$668,604*	*$668,604*	*$668,604*	*$668,604*
Total Costs:	**$672,406**	**$683,081**	**$710,794**	**$1,222,599**

The results of simulation show that there is an apparent growth in the availability rates. The availability of the systems decreases with the increase of the length of the contract. While the availability rate was 98.7% under the time consideration of 200 hr., to 94.9% under the one-year contract. From this results, we can conclude that increasing the spare parts inventory has less impact on the availability of highly reliable systems. On the other hand, the total cost of the supplier increases from $672.406 to $1.22.599 in a year. Also, this price does not include incentives (penalty and reward) for the provider based on to attain the target objectivity of contract in PBL. Considering to 90% target availability was determined by the customer in PBL contracts, then we can see the results of the simulation, the supplier will be awarded for the high availability rates under the 200 hr.-500 hr-1000 hr-1 year length of contracts.

CONCLUSION, LIMITATIONS, AND FUTURE RESEARCH

In our study, we investigated the effects of reliability growth in PBL. We analyzed how reliability decision of the supplier was affected with incentives of customers. Additionally, we examined the relationship between spare parts, the length of the contract and reliability growth which are essential decision factors in PBL.

We found that there was strong relationship amongst system design cost, reliability, spare parts stocking, and incentives. The main contribution of this study is the effects of upfront investment for reliability growth in PBL become more predictable for suppliers. In our study, we managed to build the game-theoretical model to analyze the relationship between reliability growth and design cost. We found that customers should have to consider the minimum total design cost of the system for award and penalty amount in contracts to motivate them to make the upfront investment to increase the reliability of systems. Our study shows that meaningful and significant incentives; which is the one of the tenets of PBL tied to arrangements (DoD, 2014; UT,2012); has become more predictable for the customer in our game-theoretical model.

Also, we revealed that increasing the spare parts inventory has less impact on the availability of highly reliable systems. This result also consistent with the Jin et al., (2012)'s and Mirzahosseinian and Piplani (2011)'s findings.

Additionally, the results of simulation show that the availability of the systems reduces with the increase of the length of the contract. Additionally, we found that this decreased rate of the availability in longer contracts was reduced with the high reliability of the systems.

We showed that under a longer agreement in PBL, suppliers are eager to invest in reliability enhancement. While high design cost of the systems increases the total cost of supplier under the short-term length contract, this total cost of provider significantly decreases the whole cost with the long-term contracts.

In our study, not only we put forward the impacts of reliability enhancement on the availability and total costs suppliers but also we showed that how suppliers' decisions about reliability improvement are affected by the contract features, such as length of the contract and incentives.

One of the limitations of this research is the effects of system fleet size did not consider in this study. Suppliers' motivation for reliability enhancement will be affected directly with the fleet size of the system. In the future studies, this impacts of the fleet size to design cost, reliability, spare parts, and availability rates can be analyzed. In future research, besides the linear reward scheme which is applied to the second problem, also, exponential and serial award rate can be used in the game-theoretical model (Nowicki et al. (2008). One of the other limitations of this study is we ignore the manufacturing cost of the new systems with increased reliability. Since the production cost will be affected with reliability enhancement, the impacts of this cost can be examined in the future studies. Also, future research can be done with real data.

Finally, we can conclude that PBL contracts motivate suppliers to make the upfront investment for reliability improvement by powerful incentives, which able to make savings in acquiring and holding spare assets.

ABSTRACT

Over the years, Web 2.0 and its successor – Web 3.0 promote and prosper user-generated content, ease of use, interoperability, and virtual communities. Consequently, a growing number of companies start to leverage virtual communities for sharing knowledge, solving problems, and creating value. To that end, understanding members' motivations for participation in virtual communities is the primary purpose of the current research. We found that, "Trust" and "Shared Vision" can extensively affect individuals' knowledge sharing in virtual communities. Also, men and women's knowledge sharing tends to be divergent, in terms of "Norm of Reciprocity" and "Identification."

KEYWORDS: Knowledge Sharing, Virtual Communities, Motivations

INTRODUCTION

Advances in Internet and social network technologies have enabled people to access to information and knowledge easily, in different places, and at different times. Through virtual communities, one can simply pursue knowledge beyond traditional information sources, such as colleagues at work and peers in school. Chiu and colleagues (2006) indicated that virtual communities are providing numerous opportunities for knowledge sharing and social interactions, in particular, for individuals with common interests, goals, or practices. Similarly, knowledge is crucial for companies, who attempt to convert knowledge into competitive advantages. Slow and sluggish companies, often, are deficient in knowledge generation and diffusion among their employees. Many myopic managers immersed themselves and subordinates in relatively static and isolated legacy systems. In contrast, astute executives are likely to build and/or upgrade knowledge-based virtual communities, which allow their companies to tap collective wisdom while addressing enterprise-wide problems (Chiu et al., 2006). One famous example is Enterprise 2.0, a strategic integration of Web 2.0 into a company's networks and business processes, aiming at deep and wide organizational

collaboration and knowledge sharing (cf. McAfee 2006). Community activities can be oriented toward marketing, commerce and education (cf. Teo et al. 2003). Regardless of the theme and fashion of virtual communities, the viability and proliferation of a virtual community depend mainly on the sustained individual participation and knowledge sharing (Nov et al., 2009). Without adequate knowledge exchange, communities are likely to decline and demise (Chiu et al., 2006). As such, it is imperative to understand individuals' motivation for sharing knowledge in order to design and develop an efficient virtual community. One main category of virtual communities is termed *transactional virtual communities* (Sun et al., 2012), where people post questions and compensate other(s) who are able to answer. Also, another type of virtual communities are operated for public good, without financial incentives. We argue that the assumptions that have been used for transactional virtual communities cannot simply be applied in research on free virtual communities. Therefore, there is a need to understand individuals' motivation for participation in free virtual communities. The question of why people share their knowledge in virtual communities has been the subject of many studies (Burke et al., 2009; Butler, 2001; Chiu et al., 2006). They draw on different theories, such as social cognitive theory, social capital theory, social exchange theory, expectancy-value theory, and self-efficacy theory, to investigate the effect of different factors on the knowledge sharing in virtual communities (Chen & Hung, 2010; Chiu et al., 2006; Sun et al. 2012). Our study, hence, aims to integrate the fragmented constructs from prior research in order to get a better understanding of the knowledge sharing process in virtual communities.
The rest of this paper is organized as follows. First, theoretical background on influential factors on virtual community activities are reviewed and hypotheses are thus developed. Second, research methodology and data analysis are illustrated. Third, the implications for theory and practice, and limitations are discussed. Finally, the conclusion and future research directions are discussed.

THEORETICAL BACKGROUND

Motivation and self-determination theories distinguish intrinsic motivation from extrinsic motivation based on different reasons or goals that give rise to an action (Ryan & Deci, 2000). Intrinsic motivation refers to "doing something because it is inherently interesting or enjoyable," whereas extrinsic motivation refers to "doing something because it leads to separable outcome" (Ryan & Deci, 2000). Prior research has illustrated that extrinsic and intrinsic motivations can result in different performance (Ryan & Deci, 2000). Intrinsic motivation contains two distinct components: enjoyment-based intrinsic motivation (i.e., fun) and obligation/community-based intrinsic motivation (i.e., love of community) (Lindenberg, 2001). Most of the times, people perform tasks that they are extrinsically motivated, even if they are not intrinsically motivated (Kaufmann et al. 2011). In crowdsourcing area, extrinsic motivation can be categorized into three components: immediate payoffs (i.e., earning money), delayed payoffs (i.e., improving ones skills), and social motivation (such as building a network with other creative people) (Kaufmann et al., 2011). Researchers who work on participation in online communities and open source software projects also have applied these motivations in their studies (e.g. Lakhani & Wolf, 2003). Most of the researchers have used social cognitive theory, social capital theory, and social exchange theory to construct a model for investigating individuals' motivations for knowledge sharing in virtual communities. Social cognitive theory has been widely used for validating individuals' knowledge sharing behaviors (Compeau & Higgins, 1995a). According to social cognitive theory, contextual factors, personal factors, and behavior have interacting relationships (Wood & Bandura, 1989). Social capital theory refers to "the sum of the actual and potential resources embedded within, available through, and derived from the network of relationship by an individual or social unit" (Nahapiet & Ghoshal, 1998). Nahapiet and Ghoshal (1998) also argued that "the fundamental proposition of the social capital theory is that network ties provide access to resources." Tsai and Gholshal (1998) found that social capital facilitates knowledge sharing in organizations. Researchers in virtual communities also found that social capital stimulates members to share their knowledge (Chiu et al., 2006). Social exchange theory explains human behavior in social exchange and it demands that both producer and user benefit from their interaction (Anderson et al., 1999). According to social exchange theory, the norm of reciprocity motivates individuals to share their knowledge in virtual communities (Hall, 2001). In the following, the factors from the literature are discussed and hypotheses are developed.

Norm of Reciprocity

One of the important motivational factors for individuals' knowledge-sharing in virtual communities is the norm of reciprocity. That means people share their knowledge since they believe that they can receive benefits from others (Chen & Hung, 2010; Chiu et al., 2006). Although obligation of reciprocity between two individuals is difficult, some researchers believe that balanced reciprocity may occur within a group as a whole which is called generalized exchange (Ekeh, 1974). Davernport and Prusak (1998) in their paper stated that norm of reciprocity and trust are significant factors driving knowledge sharing. Wasko and Faraj in their study on three Usenet newsgroups found that people share their knowledge in the online community because of moral obligation that they have to the other members in the group (Wasko & Faraj, 2000). Wang and Fesenmaier in their study on members of a virtual tourism community also found that future reciprocation is a major motivation of individuals' contribution. Lin in his study on 172 employees from 50 organizations found the significance association of reciprocal benefits with employees' knowledge sharing attitudes and intentions (Lin, 2007). Fehr and Gachter in their study differentiated norm of reciprocity from altruism in the way that norm of reciprocity shows a pattern of behavior in which people respond to the actions of others with the similar actions (Fehr & Gächter, 2000). These arguments lead to:

Hypothesis 1: the norm of reciprocity is positively associated with the quality of knowledge sharing.

Trust

Mayer and David (1995) defined Trust as follows:
"The willingness of a party to be vulnerable to the actions of another party based on the expectation that the other will perform a particular action important to the trustor, irrespective of the ability to monitor or control that other party."

The importance of trust has been discussed in various disciplines, such as IS group performance (Nelson & Cooprider, 1996), marketing (Geyskens et al., 1998), organizational value creation (Uslaner, 2000), online transactions (Chang et al., 2005), knowledge sharing in virtual communities, communication, leadership, management, marketing (Geyskens et al., 1998), and Information technology artifacts (Vance et al., 2008). In management and sociology literature, trust has been identified in two dimensions: 1) "a business view based on confidence or risk in the predictability of one's expectations" and 2) "a view based on confidence in another's good will" (Smeltzer, 1997). Nahapiet and Ghoshal suggested that trust has significant effect on the willingness of individuals to engage in cooperative interaction (Nahapiet & Ghoshal, 1998). Chiu and colleagues (2006) in their study find that trust has influence on individuals' knowledge sharing behavior. The belief that the other party will not take advantage of the situation is known as Trust (Gefen, Karahanna, & Straub, 2015). When there is no rule to make the members to be sure that others in the community will behave as they are expected, trust will be a substitute to the rules. Nonaka (1994) stressed the importance of trust for creating an atmosphere for knowledge sharing. Many studies have examined the effect of trust on the knowledge sharing of the individuals in virtual communities and identified it as a key element in fostering the level of knowledge sharing in virtual communities (Butler & Cantrell, 1994; Ridings et al., 2002). In a study on 73 members in several knowledge discussion forums hosted by PChome online (www.pchome.com.tw), Chen and Hung (2010) found the significant effect of interpersonal trust on knowledge sharing attitude. These arguments lead to:

Hypothesis 2: trust is positively associated with the quality of knowledge sharing.

Personal Outcome Expectation and Community Related Outcome Expectation

Based on social capital theory, "outcome expectations refer to the expected consequences of one's own behavior" (Bandura, 1997). Positive outcome expectation has been found to incentivize individuals to participate (Bandura, 1997). Members of virtual communities may share knowledge for their self-interest (such as having fun, self-satisfaction, improving performance, and etc.), or they may share knowledge for virtual community rather than self-interest (such as success of virtual community, enriching knowledge in virtual community, and etc.) (Wasko & Faraj, 2000). Therefore, members' outcome expectations can be divided into two dimensions: personal outcome expectations and community related outcome expectations (Hsu et al., 2007).

Enhancement of career opportunities is a personal outcome expectation which has been discussed as motivational factor for individuals' knowledge-sharing and participation in various communities. One of the most cited reasons for individuals' participation in open source communities is the enhancement of career opportunities (Lakhani & Von Hippel, 2003). Also social capital research in the context of organizations shows that collective action of individuals is driven by instrumental motivations, such as career advancement (N. Lin, Ensel, & Vaughn, 1981). Lin (2007) found the significance association of enjoyment in helping others with employees' knowledge sharing attitudes and intentions. Contribution to the community's knowledge and enhancing the community have been found in previous research as a motivation for individuals' knowledge sharing (Bock & Kim, 2001). These arguments lead to:

Hypothesis 3: personal outcome expectations are positively associated with the quality of knowledge sharing.

Community related outcome expectations can be extended to two perspectives. One of the perspectives reflects the values of sharing knowledge in the virtual community, such as how the individuals think they can benefits from the virtual community. The other perspective is the perceived compatibility. Gerrard and Cunningham (2003) defined compatibility as "the degree to which an innovation is perceived as being consistent with existing values, previous experiences, and potential needs, where existing values involve lives style/habit, work attitude/relevance, and concepts in knowledge sharing"(Gerrard et al., 2003), which indicates whether the virtual community shares the benefits that the individual needs. Researchers in various studies on virtual communities found the significant effect of perceived compatibility on individuals' motivation for knowledge sharing (Bock & Kim, 2001; Chiu et al., 2006; Hsu et al., 2007; Wasko & Faraj, 2000), where the fulfillment of perceived compatibility shows the another aspect of community related outcome expectation. These arguments lead to:

Hypothesis 4: community related outcome expectations are positively associated with their quality of knowledge sharing.

Shared Language and Shared Vision

Shared language addresses “the acronyms, subtleties, and underlying assumptions that are staples of day-to-day interactions” (Lesser & Storck, 2001). Shared codes and language cause individuals to understand each other’s goals (Tsai & Ghoshal, 1998). Shared vision “embodies the collective goals and aspirations of the members of an organization” (Tsai & Ghoshal, 1998). Tsai and Ghoshal showed that organizational members who share a vision are more likely to share their knowledge with each other (Tsai & Ghoshal, 1998). These arguments lead to:

Hypothesis 5: Shared vision is positively associated with the quality of knowledge sharing.

Hypothesis 6: Shared language is positively associated with the quantity of knowledge sharing.

Identification

Identification refers to “conception of one’s self in terms of the groups’ defining features”. Bagozzi and Dholakia (2002) found that identification has significant effect on individuals’ participation in virtual communities. Hogg and Abrams (1988) found that identification is a motivational factor for individuals’ engagement in virtual communities. These arguments lead to:

Hypothesis 7: identification is positively associated with the quality of knowledge sharing.

Moderating Effects

Moderating effects on the relationships between variables have attracted many researchers’ interest in online communities and crowdsourcing contests (Nov et al. 2009, Sun et al. 2012). Researchers argue that the contribution to model development will be larger if moderating variables are included in the research model. Previous research on knowledge sharing among bloggers in online social networks indicates that the impact of identification and reciprocity on knowledge sharing varies by gender (Chai et al., 2011). In this study, we would like to identify how gender moderates the effect of independent variables on knowledge sharing. Based on the theoretical background and the hypotheses discussed above, this study establishes a research model which suggests seven primary links and two moderating links for gender involved in understanding the motivations of sharing knowledge in a virtually community. In order to test the hypotheses, Table 1 is represented.

Table 1. Research Hypothesis

		Moderator (Gender)
Dependent Variable	Knowledge Sharing	
Independent Variables	Norm of Reciprocity	Yes
	Trust	No
	Personal Outcome Expectation	No
	Community Outcome Expectation	No
	Shared Language	No
	Shared Vision	No
	Identification	Yes

RESEARCH METHODOLOGY

Setting and Participants

Data were collected through a field survey at a large public university behavioral research lab. The participants were undergraduate students in business school who voluntarily registered to participate in the survey to earn extra credits for their participations. Indeed, virtual community is very popular among college students since they are highly active in online communities, especially in social networks. Therefore, this study focuses on examining the motivations among the young college students. We obtained a total of 100 responses from the students.

Measurement Development

All measurement items where adopted from the related literature. By reviewing previous studies, we figured out that the combination of the items from different studies is complementary and would result in better scale development. Therefore, multiple items from different studies have been used in the survey, and the most reliable measurements have been selected for the analysis process. The independent variable norm of reciprocity is measured by 2 items, trust is measured by 5 items, personal outcome is measured by 13 items, community outcome is measured by 4 items, shared language is measured by 3 items, shared vision is measured by 3 items and identification is measured by 4 items. The dependent variable is measured by the quality of knowledge sharing which includes three measurement items.

Factor Analysis

Exploratory factor analysis (EFA) is used to discover factor structure of the constructs. Latent root criterion is used to decide on the number of factors to extract. Using eigenvalue for establishing cutoff point is reliable for our dataset, since the number of variables is 35 which is within the acceptable range of 20 to 50 (Hair et al., 2013). The Kaiser–Meyer–Olkin (KMO) measure of sampling adequacy(MSA) was used to determine the appropriateness of using factor analysis. Overall, MSA value equals 0.744 that meets 0.50 criterion. Individual variables' MSA values are all above 0.50 in the factor matrix which indicates that using factor analysis is appropriate (Hair et al., 1995). Bartlett's Test of Sphericity value (which is approximately Chi-Square) was 2210.213, which is significant at $p = 0.0001$. This test showed that a significant correlation exists among at least some of the variables which indicates the appropriateness of factor analysis solution. Principal Component Analysis of factor analysis was used with VARIMAX rotation to identify the variables associated with the virtual community. To make sure that this is the best factor solution, different methods such as latent root criterion, scree-plot, and parallel analysis are used to extract number of factors. The results showed that latent root criterion gives the number of factors which leads to the constructs with the highest reliability in comparison to the other methods. The factor analysis identified 35 items with factor loadings greater than 0.45. But, we chose 0.7 as the threshold for factor loading since in the literature for the sample size around this study's sample size, the same threshold has been used. Table 2 shows an excessive consistence among items under each factor with all the factor loadings, where 23 items are used in this study.

Table 2. Finalized Indicators

	Component							
	1	2	3	4	5	6	7	8

Identification_2							0.734	
Identification_3							0.812	
Quality of Knowledge sharing_1								0.853
Quality of Knowledge sharing_2								0.790
Quality of Knowledge sharing_3								0.770
Extraction Method: Principal Component Analysis. Rotation Method: Varimax with Kaiser Normalization.								

The Exogenous Construct 1 (Norm of reciprocity) includes two variables: “members' helping in return of my help” and “being fair by helping others when they help me”. Construct 2 (Trust) includes five variables: members' “not taking advantage of other members”, “keeping promises”, “truthfulness”, “non-disruptiveness”, and “behaving consistently”. Construct 3 (Personal Expectations) is identified by communication and Joy which includes: “reputation”, “respect”, “strengthening tie between members”, “making friends” and “improve status between members”. Construct 4 (community-related outcome expectation) includes three variables: “enriching community's knowledge”, “successful functioning of community”, and “community's continuous operation”. Construct 5 (shared language) includes two variables: members' “using understandable communication pattern” and “using understandable narrative forms for posting messages”. Construct 6 (shared vision) includes three variables: members' shared vision of “helping others is pleasant”, “helping others solve their problems”, and “learning from each other”. Construct 7 (identification) includes three variables: “sense of belonging to the community”, “positive feeling toward community”, and “feeling proud for being member of the community”. The Endogenous construct (quality of Knowledge sharing) includes three variables: “Knowledge shared by members is accurate”, “Knowledge shared by members is complete” and “knowledge shared by members is reliable”.

Reliability and Validity

Confirmatory factor analysis is employed to test the reliability and validity of the measurement model (Hair et al., 2013). The ratio of number of factors to the number of observations meets the acceptable ratio of 1:10, and the cumulative variance is 76.76% which is satisfied with the standard level 60% (Hair et al., 2013). Reliability focuses on the consistency of the subjects' responses to a set of items. In fact, it means that the items of the instrument measure the same phenomenon. We assessed reliability using construct reliability. As recommended by Nunnally, we use 0.60 as a minimum value to ensure that our measurements are reliable and are free from measurements' error (Nunnally et al., 1967). All of the constructs in this study have construct reliability greater than 0.7 which means that they are reliable. Construct validity is the extent to which a set of measured variables represent the theoretical latent constructs they are designed to measure. Convergent and discriminant validity are terms used to distinguish between two aspects of construct validity. Results showed that the model fits the data well. The correlation matrix between factors also proves discriminant validity because the correlations among the constructs are significantly less than one with all of the correlations are less than 0.001, which indicates that none of the constructs have significant relationship with the others, therefore this test provides evidence for discriminant validity. As Table 3 indicated, all eight constructs have strong convergent validity and discriminant validity. Consequently, well-defined constructs are used in the next stage of structure equation model, and Partial Least Squared Model is used for exploring the results in this study.

Table 3. Confirmatory Factor Analysis for Eight Constructs

Component	Composite Reliability	Cronbach's Alpha	Average Variance Extract
Norm of Reciprocity	0.911	0.805	0.837
Trust	0.948	0.931	0.784
Personal Outcome	0.915	0.883	0.682
Community Outcome	0.906	0.845	0.764
Shared language	0.889	0.749	0.799
Shared Vision	0.912	0.855	0.775
Identification	0.931	0.888	0.817
Quality of Knowledge Sharing	0.902	0.836	0.755

Data Analysis and Results

Table 4 summarizes the results of the hypotheses tests for the dependent variable – Quality of Knowledge Sharing. The results show that Trust and Shared Vision have positive significant effect on quantity of the submissions. Trust means that members of virtual communities who are not taking advantage of other members and behaving consistently and non-disruptiveness for being a member of the community, and shared vision expressed the members whom self believe that members also will learn from each other, are more interested to share contributed knowledge with the other members of the community. Also, “Norm of Reciprocity”, “Personal Outcome”, “Community Outcome”, “Shared Language” and “Identification” do not have significant effect on quality of the knowledge sharing.

Table 4. Results of hypothesis tests with quality of knowledge sharing			
	Coefficient	P Value	VIF
Norm of Reciprocity	0.132	0.119	1.397
Trust	0.249	0.011**	1.827
Personal Outcome	-0.051	0.327	1.842
Community Outcome	0.029	0.401	1.432
Shared language	-0.1	0.187	1.148
Shared Vision	0.315	0.002***	1.531
Identification	0.006	0.478	2.077

Moderator Tests

In this section, we test moderator effect of gender and evaluate whether the effect of norm of reciprocity and identification differ for Men and Women. The results are shown in Table 5. Gender significantly moderates the effect of norm of reciprocity on the quality of knowledge sharing. The results indicate men share high quality knowledge compared to women when there are higher norm of reciprocity and identification, which implies that men and women have different attitudes toward knowledge sharing in virtual communities. Moreover, the results shows that men have more sense of belonging to the virtual community and believe that if they help the other members, the other members also will help them.

Table 5. Gender moderator effect of quality of knowledge sharing			
	Coefficient	P Value	VIF
Norm of Reciprocity	0.092	0.207	1.404
Trust	0.224	0.020**	1.941
Personal Outcome	-0.055	0.314	1.964

Identification	0.011	0.461	2.182
Gender*Reciprocity	-0.155	0.081*	1.235
Gender*Identification	-0.157	0.078*	1.254

DISCUSSION AND IMPLICATIONS

Key findings

There are a couple of intriguing findings in this study. First, individuals' knowledge sharing behavior is positively associated with their attitude toward knowledge sharing. This study supports that "trust" and "shared vision" have significant positive effect on individuals' quality of knowledge sharing. Members who have positive feeling toward the virtual community and feel that other members do not take advantage from each other, are more likely to share their high quality knowledge with other virtual community members. Moreover, members share their knowledge in the virtual community because they believe that members in the virtual community would help them if they need it. The results also shows the moderating effect of gender on the relationship between norm of reciprocity and quality of knowledge sharing and the relationship between identification and quality of knowledge sharing. It shows that women and men have different attitudes toward sharing knowledge in the virtual communities.

Limitations

Before discussing the implications, the limitations of this study should be notified. First, the study's sample is limited to 100 students whose age ranges from 19 to 27, which constitutes a main concern of the current paper. The findings of this study may not be generalizable to all members of virtual communities. For instance, senior citizens or teenagers can behave differently from adults. In order to enhance our external validity, in the future research we should increase the sample size and variety. However, the student sample that we used can well represent the population of virtual community participants. They were "born and raised" in the Internet age and actively and ardently participate in various online activities.

Implications

The empirical results of our study show that "Trust" and "Shared Vision" have significant effect on individuals' quality knowledge sharing behaviors. It indicates that members who have a strong sense of belonging to the virtual community and who feel that they can be helped as long as they help others, are likely to share their knowledge in the community. Also, the results show that men and women have different attitudes toward knowledge sharing in virtual communities. Women are more willing to share their knowledge in virtual communities because they enjoy from participation and feel happy while helping each other. On the other hand, men have the feeling of belonging to the community and because of that they like to participate and share their knowledge. For practical applications, the findings of this study will help the online community sponsors to understand individuals' motivations and enhance online community platforms to motivate more people to participate in these communities and share high-quality knowledge.

Conclusion

Prior studies have found various factors that can motivate participants to share knowledge with others in virtual communities. Different constructs have been developed to measure individuals' motivations. In this study, we adopted items from various studies in prior literature and used them in designing our questionnaires that are distributed to the students. The results show that Trust and Shared Vision have significant positive effect on the quality of knowledge sharing in virtual communities. Also, gender moderates the impact of "identification" and "norm of reciprocity" on the "quality of knowledge sharing" in the virtual communities. It indicates that, individuals with sense of belonging tend to share more knowledge in the virtual community. Also, Women perform differently from men such that they like to share their knowledge in virtual community because of enjoyment they receive from helping others. Instead, men who have stronger sense of belonging to the virtual community are more willing to help others.

ABSTRACT

Eco-labels not only help consumers take environmental concerns into purchasing decisions, but also may help companies increase profit performance through enhanced environmental quality. This research studies the dynamics in the establishment and adoption of an eco-labeling program through a Stackelburg game between the third-party committee who designs the eco-labeling program and the company who adopts the program. Managerial insights are generated. We find that with complete information, a well-designed single-level eco-labeling program is sufficient, a sophisticated multi-level eco-labeling program is not necessary. Numerical tests are conducted to further investigate how the market responses to an eco-labeling program.

KEYWORDS: Eco-Labeling Program, Environmental Quality, Sustainability, Corporate Social Responsibility

INTRODUCTION

This paper studies the design and adoption of the eco-labeling program in an industry. An eco-labeling program commonly includes one or multiple levels of eco-standard in an industry. Products or services with environmental quality level exceeds certain standard level will be granted the respective eco-label, which demonstrates the product's performance in environmental quality to consumers, and in return influences consumers' purchasing decisions.

Eco-labeling programs have a wide range of applications in construction, agriculture, fashion, tourism, and consumer products industries (Burnett, 2007; Loureiro, McCluskey, & Mittelhammer, 2001; Nimon & Beghin, 1999; Font, 2002; Tang et al, 2004). Eco-labels such as "Green Stickers" and "Energy Star" have been very popular in food industry and consumer products. Take the Energy Star program for example. It was first established by the U.S. Environmental Protection Agency (EPA) in 1992. Since then Energy Star has successfully identified and promoted energy-efficient products and has been recognized as an umbrella of voluntary programs (Banerjee & Solomon, 2003). From 1993 to 2012, it is estimated that families and businesses have prevented 1,903 million metric tons of greenhouse gas (GHG) emissions and saved more than $239 billion on utility bills while using Energy Star products (Energy Star, 2014).

Unlike enforced regulations and policies, such as carbon taxes and emission trading programs, eco-labeling programs are voluntary programs. It acts as a form of sustainability measurement directed at consumers and intends to make it easy for consumers to take environmental concerns into account when making a purchasing decision. Through its influence on consumers, it performs as a "soft" policy instrument, which motivates companies to voluntarily adopt higher eco-standard in their products and services (Tang et al, 2004). The wide range of applications and the success stories of eco-labels prove the flexible, effective and less costly nature of this voluntary program. A properly designed eco-labeling program will likely attract more environmentally cautious companies to participate in the program; it will also demonstrate the authoritativeness and trustfulness to consumers to choose eco-labeling products. Ultimately, the consumer behavior will lead to higher market penetration of products with eco-labels and higher environmental performance of the industries.

An eco-labeling program is usually designed and examined by non-governmental organizations (NGOs), government offices, independent quality control organizations, or a combined force of the above. In this paper, we refer to the program designer as the third-party committee or the third-party. In order to make the eco-labeling program adoptable in the industry, the third-party often consults some major companies in the industry when making decisions in the design process. The third-party has the authority to design the eco-labeling program; the major companies have the resource, knowledge, and technology in leading the adoption of the eco-labeling program and implementing the eco-performance improvement in the industry. For the third-party, its goal is to promote eco-products and to improve the overall eco-performance of the industry. For a major company, its goal is to enhance company financial performance and to take corporate social responsibility in an affordable way.

The purpose of this paper is to analyze the third-party's decision making in designing the eco-labeling program and the major industry company's decision making in adopting the eco-labeling program. Under different situations of the cost structure, pricing strategy, consumer eco-awareness, and consumer distribution, the goal of the third-party and the goal of the major companies sometimes integrate together and sometimes set apart from each other. In this research, we aim to understand how companies respond to an eco-labeling program in determining the pricing strategy and the eco-performance level of its products, and how should the third party design an eco-labeling program incorporating the expectations of the company's decisions. We also attempt to quantify how consumers evaluate the products with different eco-labels and make their purchasing decision based on the price and eco-labels of the products. Game Theory is used to analyze and understand the complication and dynamics in the design and adoption of an eco-labeling program. Our analysis as well as the managerial insights generated from the research will help both the third-party and the major company in setting, compromising, and approaching their goals in the process. The ultimate goal of this research is to build sustainable supply chain through the eco-labeling programs. In particular, we aim to address the following research questions:

- How is the company eco-performance and its pricing strategy influenced by the consumer response to an eco-labeling program?

- How do the third-party and the major company interact through the design and adoption of the eco-labeling program?

- How should the third-party and the major company act pre-actively and dynamically in pursuing their goals given their different knowledge level in predicting the cost of technological advancement and consumer distribution?

The remainder of this paper is organized as follows. We review the related literature in Section 2. Then we introduce our modeling framework and main findings in Section 3 and Section 4 respectively. Numerical studies are conducted in Section 5. Finally, we conclude the paper with implications and limits of our research in Section 6.

LITERATURE REVIEW

In recent years, eco-labeling programs have attracted increasing attention among scholars. Many research projects in eco-labeling focus on various applications of eco-labeling programs and provide solid base to testify the application of eco-labeling programs in wide range of industries (Hartling, 2018; Yang, 2013; Burnett, 2007; Tang et al, 2004; Font, 2002; Loureiro et al, 2001). Their work justifies the importance and the implementation value of this research. In this section, we provide a brief review of the related literature.

The Implementation Value of Eco-Labeling Programs

Consumers in general prefer environmental quality in products and services. Positive environmental quality information of a brand tends to yield higher product evaluation and increased brand choice (Cho et al, 2017). However, observing environmental quality of a product and correctly evaluating its value is not an easy task for regular consumers. Unlike product quality attributes such as appearance, flavor, and functionality, which are usually revealed either pre-purchase or soon after purchase, environmental consequences of production processes and utility consumption of products are generally difficult to observe at purchase. Therefore, to promote eco-friendly products in the market, and to let consumers induce market changes by “voting” for green products with their shopping dollars (Dauvergne & Lister, 2010), an eco-friendly product needs to clearly demonstrate its environmental quality level. Eco-labeling programs provide consumers a way to easily collect and analyze such information and make their purchasing decisions accordingly.

Increased market demand is an essential motivation for companies to produce eco-friendly products. Higher demand of greener products will create a strong financial incentive for companies to improve their products’ eco-level in order to capture new market initiatives, increase their market shares, and perhaps generate higher profits on their eco-labeled products (Dauvergne & Lister, 2010). Eco-labeling programs provide opportunities for companies to demonstrate their products’ eco-quality to attract market attention, and in return eco-labels stimulate the eco-quality comparison and improvement effort in the industries (Xia et al, 2015).

A company’s products’ environmental performance is also positively correlated with its corporate social responsibility performance, which is a form of business behavior that leads companies to voluntarily contribute to a better society and a cleaner environment (Mir & Shah, 2018). Economic performance, environmental performance and social responsibility performance are three interrelated dimensions of corporate sustainability performance. Therefore, to protect the environment and fulfill their social responsibilities, and even to enhance their economic performance, companies are motivated to produce and redesign more environmentally friendly products. The voluntary adoption of the eco-label programs and the labels placed on their products not only highlight the product’s environmental quality, but also demonstrate the company’s effort in taking its social responsibility. Production of eco-labeled products can eventually be one of the best ways of pursuing competitive strategy (Orsato, 2006; Roy & Vezina, 2001).

From the third-party’s perspective, eco-labels inform consumers about the environmental impacts of the product’s manufacturing, usage, and disposal processes, thus may change consumer purchasing behaviors (Teisl et al, 2002). A significant change in consumer behavior may increase the demand of green products with eco-labels and motivate a company to adopt the eco-labels, which differentiate the company from its competitors and market its products with an environmental characteristic. An increasing supply of these green products may enhance consumer purchase simply through greater availability without even changes in individual awareness, and consequentially reduce ecological footprint of the products in the whole industry.

An Overview of Eco-Labeling Systems and Eco-Labeling Design

Eco-labels have been observed in the market for many years, although using eco-labels to promote carbon footprint reduction or sustainability is a more recent phenomenon (Banerjee & Solomon, 2003). While eco-labeling alone will not improve environment, experience has shown that a properly designed eco-labeling mechanism can be a significant stimulus for market transformation towards environmentally preferable products. Moreover, designing and introducing an appropriate eco-labeling program brings strategic benefits to companies, industries and society in general as we discussed in the earlier section.

Eco-labels are of different types. Salzman (1997) describes three types of eco-labels: single-issue voluntary labels, single-issue mandatory labels, and third-party voluntary labels. Single-issue voluntary labels, such as “Recyclable” mark, are self-claimed by manufacturers and rarely verifiable and accurate. Single-issue mandatory labels, such as “flammable” and “eco-toxic”, are a much smaller class and are required by law and by many governments. Third-party voluntary labels, which are observed as an environmental seal of approval, present the overall environmental quality of the products (Salzman, 1997). Fet and Skaar (2006) further categorize the third-party voluntary eco-labels into three sub-types based on the ISO 14000-series: Type I programs are multiple-criteria third-party programs awarding labels claiming environmental preferability. Type II programs contain a lot of self-declared environmental information on products. They are required to take into account of life cycle considerations. Type III programs need to conduct a life cycle assessment (LCA) of the product following the ISO 14040-standards. They consist of quantified environmental data on significant impacts of the product. The information should enable comparisons between products fulfilling the same function. Other requirements of type III programs include the LCA approval and the third-party verification of the declaration (Fet & Skaar, 2006). In this paper, we focus our discussion on the Type III eco-labeling programs of the third-party voluntary labels, so that we can compare product environmental quality on one criterion that set by a third-party. Note that earlier research has shown that eco-labeling system created by a third-party is more likely to be environmentally beneficial than the eco-labeling system created by the industry itself (Fischer & Lyon, 2014). Future study can be extended on more complicated eco-labels and eco-label programs.

The general procedure of designing a Type III eco-labeling program can be described as follows. The third-party committee determines the category of products to be covered and the specific objective standard that products must meet to obtain the label or labels. Given the standard, companies then determine if they would voluntarily participate in the program by submitting their products for evaluation. If a product meets the predetermined standard, the company pays a licensing fee and places the eco-label on the qualified products (Salzman, 1997). While the eco-labeling process seems straight-forward, there are two foremost design issues need to be addressed beforehand: whether to setup one level of label or multiple levels of labels in the program and what should be the proper standard level or levels.

Blengini and Shields (2010) point out that single-level eco-label is a binary indicator and it serves as an easy and clear standard for both the consumers and the manufacturers, and thus possesses marketing and managerial advantage. The concern of having one eco-label is that a product either meets the criteria (thus gets a label) or not. Therefore, receiving the eco-label only represents reaching the minimum predetermined eco-standard; it does not show the relative environmental performance among the products who receive the label. While in a multi-level eco-labeling program, products with various environmental quality performances obtain different levels of eco-labels, which inform the consumers more details about their relative green quality levels. On the other hand, multi-level eco-labeling system is usually more complicated in design and adoption, and it may cause confusion among consumers. Bleda and Valente (2009) develop a simulation model to show that competition drives the market toward cleaner technological patterns in the presence of multi-level eco-labels. Fischer and Lyon (2016) model competing eco-labels sponsored by an industry trade association and an environmental group. They find multi-level labeling system more attractive in a market with many producers and high production cost gap between different quality levels. Heys and Martin (2017) discover that the entries and competition of the third-party committee may affect the setting of eco-labels. Rysman et al, (2018) study the adoption of a multi-level environmental building certification system. They simulated the impact of switching from the three-level eco-label system (with four difference tiers) to the single-level eco-label system (with high-tier and low-tier), and found single-level system more efficiently stimulate environmental investment of low-tier builders to reach to the high-tier; however, the overall investment of all builders is higher in multi-level system.

Standard levels should be very cautiously set. The standard level or levels should effectively and efficiently promote carbon footprint reduction in the industry and proficiently transfer eco-labeling adoption into economic benefits for the companies that adopt the eco-labeling program. Too high the standards may eliminate participation from the majority of the companies due to the high cost of achieving such standards. However, if a standard is set too low and too easy to reach, the labeling program may lose credibility among consumers and reduce or even eliminate the value for companies to adopt the eco-label system (Harbaugh et al, 2011), and will not be able to truly promote carbon footprint reduction.

A successful eco-labeling program should bring economic benefit to the adopting companies, so that company's ability to become eco-friendly can be sustainably translated to their willingness to make the efforts. Till now, it remains a controversy whether environmental and financial goals are compatible or conflicting. Sammer & Wüstenhagen (2006) report empirical data on how the consumer behavior for household appliances is influence by eco-labels. Houe & Grabot (2009) suggest the label users a method in checking a product' compliance of an eco-label. Rysman et al (2018) show that vertical differentiation in adoption of building certification eco-label system generates economic benefits for builders and motivates them to invest in reaching higher eco-levels. Research works in sustainable supply frame work link company eco-performance with its economic performance to reach the goal of sustainability (Xia et al, 2015; Brandenburg, Govindan et al, 2014; Reuter, Foerstl et al, 2010). These research results provide support and evidences to transfer eco-labeling adoption into economic benefits, the idea we embrace in our model setup to evaluate an eco-labeling system.

In this research, we start with modeling analysis of the general multi-level eco-labeling system, seek to understand the game between the third-party committee who design the labeling program and the company who adopts the program. From the third-party's perspective, we examine the design of the labeling program on improve the eco-quality of the industry. From a company's perspective, we inspect its decisions on adopting various eco-quality levels and determining pricing strategy of its product/service according to the labeling program. Our analysis generates some interesting managerial insights in understanding the eco-labeling systems and improving the functionality of the system.

ECO-LABELING MODELING FRAMEWORK

We study a supply chain with a major company that provides a product and many consumers who make their purchase decisions based on both the price and the eco-quality level (such as water assumption for washing machine and gas-mileage for trucks in transportation) of the product. A third-party committee design the eco-labeling program for the industry of product. The company determines whether to adopt the eco-labeling program or not, and the eco-quality level to reach if it adopts the program. The decisions are made based on the analysis of its own cost structure and estimation of the market response. In the market, consumers observe the label on the product to evaluate the product's eco-quality level and make their independent purchasing decisions. For the third-party, its goal is to improve the overall eco-performance of the industry. For the major company, its goal is to enhance its own economic performance and to take affordable company social responsibility. For the consumers, they want good eco-quality product with affordable price. The third-party has the authority to design the eco-labeling program; the major company has the resource, knowledge and technology to adopt the eco-labeling program and implement the eco-performance improvement of the industry; the consumers make their purchasing decisions. The three groups all target at different goals, however their decisions influence each other consequently. In this paper, we focus on the game between the third-party committee and the major company. Consumers' aggregative decision is described as the overall market response to the eco-quality price and the price set by the company.

Without loss of generality, we assume the current mandatory industry eco-quality standard to be $L_0 > 0$ and normalize the highest eco-quality level reachable in the market as "1". We assume that the company can choose its product/service to reach any eco quality level q in between the mandatory and highest reachable standards ($L_0 < q \leq 1$). In order to reach eco-quality q, it endures a unit production cost $C = f(q)$. Without loss of generality, we assume $f(q)$ to be a convex increase function of q, e.g., $f'(q) > 0, f''(q) \geq 0$, since it is common knowledge that quality improvement at higher quality level tends to cost more than quality improvement at lower level (Craig, 2012). The third-party designs the eco-labeling program to includes n levels of eco-standards, each set to be L_i ($i = 1, \dots, n$ and $L_i < L_{i+1}$). We denote the designed labeling program as $\Psi' = (L_1, \dots, L_n)$. Incorporating the market mandatory eco-quality level L_0, we define the labeling program as $\Psi = (L_0, L_1, \dots, L_n)$. Clearly, the company should set its product service eco-quality level to be at-the-levels instead of in-between-levels as in-between-levels only adds additional cost, wouldn't be recognized by the eco-labeling program.

A cooperative advertising model is used to describe the market response to the eco-labels from consumers' perspective. Cooperative advertising model is well accepted in marketing and operations literature when market is influenced simultaneously by brand quality recognition and product price (Yue et al, 2006; Huang et al, 2002; Li et al, 1996). Here, the eco-label acts as the recognition of the product's eco-quality level. Therefore, the market share of the company when it chooses eco-level L_i and unit product price p can be described as

$$S(q = L_i, p|\Psi) = \left(1 - bL_i{}^{-\delta}\right)(p)^{-\theta}, i = 0,1, \dots n. \quad (1)$$

In the above equation (1), without loss of generality, we unify the potential market demand as "1". $b\ (0 < b < {L_0}^{\delta})$ is a market scaling parameter for the quality effect. Since we assume that products with eco-quality level lower than L_0 is not acceptable by the market. $1 - b$ represents the highest market potential of the company. We further define two positive constants δ and θ as the quasi-quality elasticity of demand and the quasi-price elasticity of demand respectively. To ensure the market demand sufficiently responsible to eco-quality and price changes, we assume both $\delta > 1$ and $\theta > 1$.

We now investigate the Stackelberg Game of the eco-labeling system with the third party setting up the labels and the company deciding whether to adopt the labeling program consequently. We first assume that the company has adopted level $i\ (i = 0, 1, .. n)$ of the ecolabeling system; $i = 0$ represents the scenario that the company maintains its eco-quality level to the minimum requirement of the market and does not adopt the eco-labeling system. The company's expected gross profit at label level i is then

$$\Pi_i(q = L_i, p_i\ |\Psi) = \left(1 - b{L_i}^{-\delta}\right)(p_i)^{(-\theta)}(p_i - f(L_i)),\ \ i = 0,1, \dots n. \tag{2}$$

Therefore, if the company adopts an eco-quality level, the following lemmas help up understand the setting and adoption of the quality levels. All proofs of this paper are included in the Appendix of this paper.

Lemma 1. At a desired enhanced eco-quality level L_i, the company would set its enhanced product price to

$$p_i = \frac{\theta}{(\theta-1)} f(L_i),\ \ i = 1, \dots, n. \tag{3}$$

and maximize its profit at the enhanced quality eco-level as

$$\Pi_i = \left(1 - b{L_i}^{-\delta}\right)\frac{1}{\theta-1}\left(\frac{\theta-1}{\theta}\right)^{\theta} f(L_i)^{-(\theta-1)},\ \ i = 1, \dots, n. \blacksquare \tag{4}$$

Lemma 2. The profit function of the company is a concave function of the eco-quality level. The maximum of Π_i is reached at $\hat{L}$, which satisfy the condition that $\left(\hat{L}^{\delta} - b\right)\frac{f'(\hat{L})\hat{L}}{f(\hat{L})} = \frac{\delta b}{\theta-1}$ $\blacksquare$

It is important to know that the profit function $\Pi\ (L)$ has only one optimal solution $\hat{L}$. Any eco-quality levels $L_i > \hat{L}$ will result in a lower profit than the profit at $\hat{L}$, are thus not attractive to the company and won't be approached by the company. Those eco-levels ($L_i > \hat{L}$) are infeasible quality levels for the company.

MAIN FINDINGS

The timing of our model frame can be explicated as a Stackelberg Game. Step 1, the third-party committee designs the eco-labeling program, hence set L_i, $i = 1, \dots, n$. Step 2, the major company chooses its product/service eco-quality level ($q^* \in \{L_i,\ i = 0, 1, \dots, n\}$) and price (p^*) of the product/service. Step 3, the market responds to the company's decision. In this section, to analyze the decision process and identify the equilibriums with the backward induction.

We start with the market's response, which is specified by the cooperative advertising model as stated in equation (1) of this paper. Assuming that the company choose eco-label level L_i, its profit is thus estimated by equation (2). Based on the profit function, the company should choose its pricing strategy as in equation (3). The company would not choose any higher eco-level which generates lower profit for it. Therefore, $\Pi_i > \Pi_{i-1}$ and $\Pi_i > \Pi_{i+1}$. The third-party committee has enhanced the eco-quality of the company by $L_i - L_0$, which is defined as the as program benefit $B(\Psi)$. The following Lemmas describe the choices of the eco-quality levels.

Lemma 3. The feasible quality levels of the labeling programs satisfy the condition that $L_i \leq \hat{L}$. ■

In other words, for an eco-labeling system with $L_k \leq \hat{L} < L_{k+1}$, only the eco-levels L_i, $(i \leq k)$ are feasible. Levels L_i $(i \geq k+1)$ are unnecessary quality levels and possess no practical value to the system. In addition, in the special case that $k = 0$, the labeling program does not engage the company to participate in the program. Therefore, the improvement of the eco-performance cannot be achieved, the program is thus a failed eco-labeling program. The analysis can be organized in the following Lemma.

Lemma 4. The maximum program benefit is $B^*(\Psi) = \hat{L} - L_0$. If $L_1 > \hat{L}$, the eco-labeling program fails to promote eco-quality improvement in the system. ■

Clearly, how should the third-party design the labeling program is determined by its knowledge of $\hat{L}$. If the third-party has the complete information of the company's cost structure $f(L)$ as well as the market parameters (b, δ and θ), we can easily find the following Proposition that describes the equilibrium of the game in terms of the pricing strategy and profit function for the company and the setting of labeling program for the third-party.

Proposition 1. With complete information shared in the labeling system, the third party should design a one level eco-quality labeling as $\Psi: (L_1^* = \hat{L})$. The company should choose to enhance product eco-quality level to $\hat{L}$ and set its optimal price as $p^* = \frac{\theta}{(\theta-1)} f(\hat{L})$, and generate the highest profit as

$$\Pi^* = \left(1 - b\hat{L}^{-\delta}\right)\frac{1}{\theta-1}\left(\frac{\theta-1}{\theta}\right)^{\theta} f\left(\hat{L}\right)^{-(\theta-1)}. \blacksquare \tag{5}$$

Corollary 1. A single level of labeling program is sufficient if complete information is shared in the labeling system. ■

Corollary 2. A labeling program are not functional and should not be introduced if $\hat{L} < L_0$. ■

To better understand the labeling program, we now investigate the case that production cost of the company is quadratic with respect to eco-quality level $f(L) = \alpha L^2$. A quadratic cost function is well accepted in literature. αL^2 is a convex increase function of L since quality improvement at higher quality level tends to cost more than quality improvement at lower level (Craig, 2012).

Corollary 3. With the quadratic production cost function, the third-party committee should set the optimal quality level as $L_1{}^* = \hat{L} = e^{\frac{1}{\delta}ln\left[b+\frac{\delta b}{2(\theta-1)}\right]}$*. As long as* $L_0 < L_1{}^*$*, the labeling program can improve quality in the industry, and a multi-level labeling mechanism is not necessary.* ■

Clearly, if $L_0 > L_1{}^*$, the company's profit drops if it adopts eco-program. A labeling program based on the voluntary adoption of the company is not feasible to promote higher eco-quality in the market. Corollary 3 shows that the optimal quality level $L_1{}^*$ decreases monotonically with the quasi-price elasticity θ. If consumers are very sensitive to price, the company should adopt a relatively low eco-quality level. On the other hand, $\frac{\partial L_1{}^*}{\partial \delta} = e^{\frac{1}{\delta}ln\left[b+\frac{\delta b}{2(\theta-1)}\right]} \times \left[-\frac{1}{\delta^2} ln\left[b + \frac{\delta b}{2(\theta-1)}\right] + \frac{1}{\delta} \cdot \frac{1}{2(\theta-1)+\delta}\right]$. Higher consumer environmental awareness may or may not leads to a higher eco-quality level equilibrium of the system. Due to the compacity of the market responses, we use numerical test to investigate the market as in Section 5. Notably, the quality function coefficient α possess no impact on the quality level decision.

Corollary 4. Assuming the company holds quadratic production cost function, the third-party committee doesn't need to know the cost function coefficient to set the labeling program. ■

The above result is very important since operational details are usually considered business secret of the company. It is very difficult and many times impossible for the third-party to collect the related information and make an accurate estimation. On the other hand, market survey to understand δ, θ, and b are relatively easier task for the third-party before it designs or adjusts the labeling program.

When the third-party can only guess a wide range of $\hat{L}$, e.g., $\hat{L} \in (\underline{L}, \overline{L})$, a multi-level of labeling program Ψ: $(L_1 \leq \underline{L}, \ldots, L_n \geq \overline{L})$ should be introduced in order to promote higher eco-quality product and capture the optimal labeling level. Depending on the information, the design of the multi-level labeling program requires further in-depth investigations.

From the company's perspective, the labeling program provide an opportunity for it to further enhance its profitability through eco-quality improvement. Its pricing strategy at any of the quality level L_i can be simply executed by the Equation (3) as long as it understands its own cost structure $f(L_i)$. It can also understand the market through the Third-party's design of the labeling program.

NUMERICAL STUDIES AND MANAGERIAL INSIGHTS

In this section, we use numerical examples to investigate the market response with respect to different parameters, and gain further insight into the company's eco-quality level desicison. We test the following base parameter set: $b = 1/10$, $\alpha = 2$, $\delta = 1.5$, and $\theta = 1.8$. All the following results are obtained by modifying the base set by one or two parameters at a time.

Earlier analysis tells that that the optimal quality level $L_1{}^*$ set by the third-party is a monotonic function with the price elasticity θ. However, the profitability of the major company may not be monotonic with θ or δ. The group of charts in Figure 1 demonstrate that the maximal profit decreases with δ, but interestingly the maximal profit decreases first with θ and then increases with it. So the company may be able to exploit the consumer's price sensitivity by adopting the labeling system designed by the third-party. Furthermore, the 3D figure reals that consumers' environmental awareness (shown by δ) have a larger impact on the company's profit when the consumers are more price sensitive.

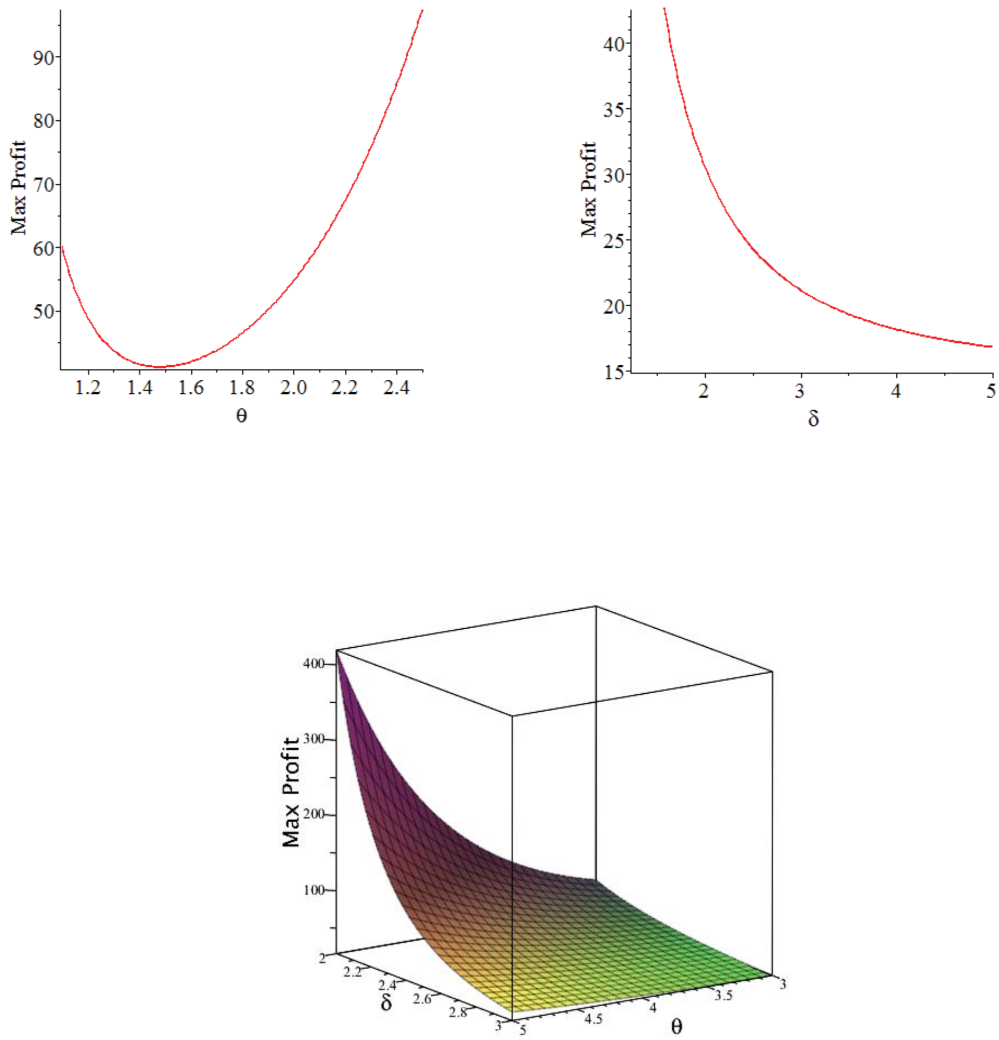

Figure 1 Relationship Between Maximal Profit and Two Elasticity Parameters

Because consumers are reacting more strongly to environmental concerns, their environmental awareness may increase over time. Figure 2 illustrates how such a trend on consumers' behaviors changes optimal decision of the third-party. As δ increases, the third-party should apparently design a higher eco-quality level. Therefore, if considering the evolving of consumers' environmental awareness, designing a multi-level labeling system might be a wise future-oriented solution for the third-party committee.

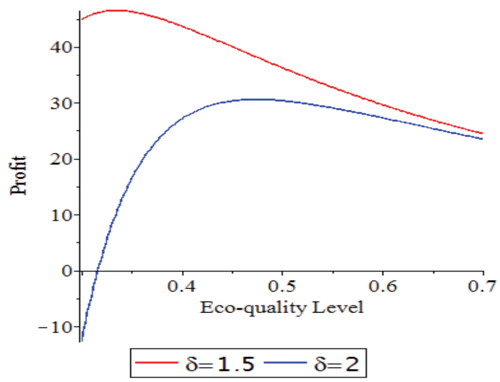

Figure 2 Impact of Consumers' Environmental Awareness

CONCLUSIONS AND FUTURE STUDIES

In this paper, we examine the strategies on how to design an eco-label program. We proposed the pricing strategy if a company wants to achieve certain eco-quality. We also provide the third-party committee with the insight on how to design the eco-labeling program to motivate the companies to enhance eco-quality. In addition, we also investigate how the market parameters influence the design and adoption of eco-labeling program. In particular, if consumers are very sensitive to price, a relatively low eco-quality level will be adopted by the company; on the other hand, if consumers' environmental awareness increases, a higher eco-quality level could lead to more profit for the company. Although multi-level eco-labeling programs are established to promote green quality, we find that it is not necessary to include in the program design and a one-level eco-labeling is enough if complete information is shared in system. This finding justifies the business practice that the majority of eco-labels only contain one level.

However, this paper has its limitations. First, we only consider one major company in the system to focus on the adoption of the eco-labeling program. In reality, it is quite common that there exist several companies competing together. Therefore, the competition among the companies and the impact of the competition deserves further investigation. In addition, because service quality is also a significant factor when consumers make choices, analyzing eco-labeling program design in together with service quality will certainly enrich our understanding on consumers' choices.

APPENDIX : SOME PROOFS

Proof of Lemma 1:

$$\Pi_i(q = L_i, p_i \,|\Psi) = \left(1 - bL_i{}^{-\delta}\right)(p_i)^{(-\theta)}(p_i - f(L_i)),$$

At $q = L_i$, calculate

$$\frac{\partial \Pi}{\partial p} = \left(1 - bL_i{}^{-\delta}\right) \cdot \left[-\theta p^{-\theta-1}(p - f(L_i)) + \, p^{-\theta}\right]$$
$$= \left(1 - bL_i{}^{-\delta}\right) \cdot \left[(1-\theta)p^{-\theta} + \, \theta p^{-\theta-1} f(L_i)\right].$$

Let $\frac{\partial \Pi}{\partial p} = 0$, therefore, $p_i = \frac{\theta}{(\theta-1)} f(L_i)$

Then, substitute it into the profit function, the optimal profit at the voluntary product price is

$$\Pi_i = \left(1 - bL_i{}^{-\delta}\right)\left(\frac{\theta}{\theta-1} f(L_i)\right)^{-\theta}\left[\frac{\theta}{(\theta-1)} f(L_i) - f(L_i)\right]$$
$$= \left(1 - bL_i{}^{-\delta}\right)\left(\frac{\theta}{\theta-1} f(L_i)\right)^{-\theta} \frac{1}{(\theta-1)} f(L_i)$$
$$= \left(1 - bL_i{}^{-\delta}\right)\frac{1}{\theta-1}\left(\frac{\theta-1}{\theta}\right)^{\theta} f(L_i)^{-(\theta-1)}$$

Q.E.D.

Proof of Lemma 2

$$\frac{\partial \Pi_i}{\partial L_i} = \frac{1}{\theta-1}\left(\frac{\theta-1}{\theta}\right)^{\theta}\left[-(\theta-1)\left(1 - bL_i{}^{-\delta}\right)f'(L_i) + \delta b L_i{}^{-(\delta+1)} f(L_i)\right] f(L_i)^{-\theta}$$

Since $f'(L_i) > 0$, $f''(L_i) \geq 0$, we can easily find the condition for $\frac{\partial \Pi_i}{\partial L_i} = 0$ and prove that $\frac{\partial^2 \Pi_i}{\partial L_i{}^2} > 0$.

Q.E.D.

Consequences of Sustainability Orientation in Service Firms

Sandeep B. Jagani
Illinois State University
Email: SBJagan@ilstu.edu

ABSTRACT

Recently, internal and external sustainability drivers have increasingly mandated firms to improve their engagement with the two previously less exploited dimensions of sustainability, social and environmental dimensions. Sustainability orientation, an evolving strategic intent, has enabled firms to develop blueprint of policies and procedures of corporate sustainability for various business functions in their organizations. Manufacturing sector has received fair attention from the researchers because of their reputation for emissions of greenhouse gasses, polluting natural water sources and callous social practices across the globe. However, there has been very little research on implications of sustainability orientation on business practices and sustainability outcomes in service sector. Unlike, tangible goods, services need to be produced at the place of its consumption. Process alterations and tradeoffs, that a service system design makes to accommodate sustainability practices, will be noticed by the customers in service system unlike a manufacturing system. Customers can develop mixed perception about the company or the brand in their minds. This research investigates the role of sustainability orientation of service firms and its impact on the customers' readiness to adhere to the sustainability initiatives. The research tries to identify the sustainability outcomes in the form of social, environment and economic goals that are realized based as a result of sustainability orientation. As future research agenda, this paper suggests to conduct a survey of senior practitioners in service sector of United State of America using a comprehensive questionnaire on sustainability strategies, practices and outcomes designed from the thorough literature review to find empirical evidence of the propositions.

KEYWORDS: Sustainability orientation, environmental performance, social performance, sustainability implementation, sustainability outcomes, consumer perceptions

INTRODUCTION AND LITERATURE REVIEW

Increasingly, companies in manufacturing and service sector are positioning themselves as advocates of sustainability by designing strategies that enables business functions to use stainability practices (Hong, Kwon, & Roh, 2009; Kleindorfer, Singhal, & Wassenhove, 2005; Linton, Klassen, & Jayaraman, 2007; Wu & Pagell, 2011). Strategic intent for sustainability (sustainability orientation) is the result of the all the stakeholders' pressure (government compliances, customer preferences, labor unions' requirements, order qualifying criteria, etc.) on the firms to deliver products and services in more environment friendly operations, considering the frugal use of natural resources and becoming more socially responsible while guaranteeing profits. Sustainability orientation is translated to sustainability practices that transforms the traditional way of operations to realize the perceived sustainability outcomes.

Over past three decades, manufacturing sector has incorporated sustainability initiatives in their operations leading to noticeable sustainable outcomes in the terms of economic, social and environmental benefits (Chen et al., 2017; Hong, Jagani, Kim, & Youn, 2019; Tachizawa & Wong, 2015). However, there is a prominent difference in incorporating sustainability practices in manufacturing firms and that in service firms. This is because frontend activities (activities that happen in front of customers) and backend activities (activities that happen without the presence of customer) are very distinct in manufacturing and service operations. Modification of a process design in manufacturing firm to include a sustainability initiative will be less eminent to a customer or user of its product unless that initiative has modified the product design. The same is rarely true for a service firm. Services are different from tangible goods in many ways. Production of services requires involvement of customers. Services cannot be stored for later use. Services are produced at the location where they are delivered. The production and consumption of services occur simultaneously. Thus, the incorporation of sustainability initiatives in service form will alter both, the service system design as well as the service offering. Changes in service operations for sustainability can impact the customer perception about the company and their likelihood of making a repeat purchase.

The review of literature suggests that several researchers have attempted to study sustainability of service firms. In service sector, there are more conceptual papers and case studies on sustainability. Very few empirical studies in the field emerged from the literature review. Three of the most comprehensive studies on sustainability in service sector are briefed here. Hussain et al., (2016) reveals a framework for supply chain sustainability in service industry. However, (1) they look at the sustainability from a firms supply chain perspective not operations perspective. (2) They do not consider the service delivery process and service offerings inseparable. Finally, (3) They concentrate more on sustainability orientation (strategic intent of sustainability) and fail to address the practices related to sustainability that mediated the relationship between strategic intent and outcomes. Goodman (2000) uses case study of Scandic Hotels in Nordic Europe to find that environmental information systems, employee training programs and collaboration with suppliers are the mechanisms that enabled this hotel chain to be leader in sustainable operations. This study concentrates specifically on hotel industry and discusses service operations limited to sample size of one organization. Though this study identifies few mechanisms through which company implements sustainability initiative, it fails to discuss implementation of sustainability on customer perceptions. Lastly, Rothenberg (2007) argues that more manufacturing businesses are moving toward including services in their portfolio using the service dominant logic (Vargo & Lusch, 2008). She presents a series of case studies of manufacturers who have realized sustainability benefits on moving to the service sector. Though she argues about the practices these firms use to be more sustainable, her sample size is limited and her arguments are difficult to generalize across different industries in service sector. In summary, despite an exhaustive attempt by previous researchers, there are certain research gaps that will enable service firms to understand consumer behavior as a result of sustainability orientation and sustainability implementation.

RESEARCH MODEL AND PROPOSITIONS

This research intends to answer three questions related to sustainability orientation, sustainability implementation, sustainability outcomes and consumer perceptions.

1. What is the role of sustainability orientation in service firms in translation of generic service operations into sustainable service operations?

2. How the sustainable operations translate to measurable outcomes in service firms?

3. How customers' perception about service firm changes as the firm moves towards more sustainable practices?

Sustainability orientation and sustainability implementation is service firms

According to Hamel & Prahalad (2005), companies gain competitive advantage by clearly defining a roadmap or a blue print of new functionalities and acquisition of competencies. Sustainability orientation is one such type of strategic intent to redefine existing service process and products to attain sustainability goals. When companies develop clear policies for their economic intents, environmental intents and societal intents, it is actually building orientation on sustainability. Sustainability of a firm is the combination of how well a firm performs in three dimension; economic, environmental and social (Dyllick & Hockerts, 2002; Markard, Raven, & Truffer, 2012). However, given the nature of the service system design, considering that there is involvement of customers in production of services and heterogeneity in delivering services, implementation of sustainability action plans has its own challenges compared to manufacturing systems. Nevertheless, action plans of sustainability implementation are the result of the sustainability polices and standard operating procedures defines in sustainability orientation. Therefore, I propose:

P1. Sustainability orientation will positively influence sustainability influence sustainability implementation.

Epstein & Buhovac (2010) argues that effective implement sustainability action plans need the formal and informal mechanisms. But, most companies do not possess both mechanisms. However, sustainability orientation is a phenomena to build such mechanisms. Measureable performance outcomes enable companies to quantify their efforts onto success criteria. Though the perishable nature of service products offer a new challenge in measuring sustainability outcomes, specifics sustainability practices should reveal several sustainability outcomes. Therefore, action plans of earning high revenues, conservation of reserves, being less detrimental or environment, and inclusiveness of society will enable companies to achieve sustainability goals. Thus, I propose:

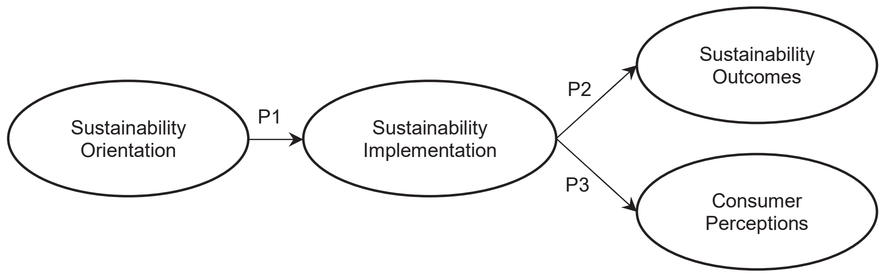
P2. Sustainability implementation will positively influence sustainability outcomes

Unlike manufacturing firms, service firms have a unique challenges. Services need to be produces at the place of consumption. Additionally, in service process design and product design are strongly tried together and are always done simultaneously. Implementation of sustainability orientation will require service firms to build and incorporate policies and standard operating procedures in their existing process and product design. This may require the companies to alter their existing processes and consequently change the specifications of the service offerings. This may result in change of consumer perception about the product and about the company. Consumer perception is a positive or a negative feeling associated with a brand or product (Carpenter & Nakamoto, 1989; McDonald & Oates, 2006). Altering a service process or service offering in order to incorporate sustainability practices may cultivate mixed consumer perceptions. However, in a controlled experiment of manufactured products, Choi & Ng, (2011) demonstrate that consumers favor sustainability in both dimensions by giving positive evaluations of the company and purchase intent. Therefore, I propose:

P3. Sustainability implementation will create positive consumer perception.

The research model is as shown in the below Figure 1 along with the three propositions.

Figure 1: Conceptual framework for the research



FUTURE SCOPE OF RESEARCH

To find empirical evidence of the relationships among the constructs in Figure 1, there is a need to conduct a survey of US firms of service sector. First, one should aim to develop valid and reliable measurement instrument for the constructs and sub-constructs used in the proposed conceptual framework in Figure 1. Next, using with Dillman (2000) and Huang (2012) methods, use four step approach to investigate the relationship: item generation, pre-test and structured interviews, pilot study using Q-sort, and finally launch large-scale survey and conduct data analysis.

IMPLICATIONS AND CONCLUSION

Sustainability outcomes and consumer perceptions are the key goals companies expect from the exercises of designing a sustainability strategy and implementing the action plan of sustainability practices. Linking consumer perception to the sustainability practices in a service production process of which consumers are co-producers will enable companies to decide the intensity of sustainability practices. Consequently, the results of the empirical investigation will allow companies to discover the tolerance of consumers' acceptance of alteration of services system design to incorporate sustainability criteria. This study attempts to fill the gap in the literature by focusing on service systems and linking strategic intent of sustainability to the measureable outcomes and consumer perceptions.

A Student Engaged Project for Undergraduate and Graduate Introductory Financial/Managerial Accounting Courses

Judith A. Sage
Sage & Sage
Email: lloydsage@aol.com

Lloyd G. Sage
Sage & Sage
Email: lloydsage@aol.com

ABSTRACT

A student engaged Project was examined in introductory financial/managerial accounting for a midwest undergraduate course [MW]) and a southwest graduate course [SW]. This Project included many of the Pathways Commission (2015) Learning Objectives and AICPA Framework Core Competencies (2017/1999). The Project involved teamwork, written reports, oral presentations, and peer evaluations. The students strongly agreed/agreed (mean scores of 4.75 [MW] and 4.89 [SW]) that this Project increased understanding of selected financial/managerial accounting topics. It appears that this Project can be successfully used for teaching these topics in undergraduate and graduate courses.

KEYWORDS: Engaged project, Introductory financial/managerial accounting, Alternative teaching method

INTRODUCTION

Various committees for more than three decades have called for change in the accounting curriculum and teaching approaches. Recently, the Association of International Certified Professional Accountants discussed the skills needed by managerial accountants in the *CGMA Competency Framework: 2019 Update* (2019). Earlier, the *AICPA Pre-Certification Core Competency Framework* (2017) advocated for a skills-based curriculum for accounting students (public/industry/government/not-for-profit). Our research investigated a project that engaged students in activities to assist them in experiencing several needed skills.

Previously, the Pathways Commission (2012) indicated that accounting educators have responsibilities that comprise both curricular dimension (what we teach) and pedagogical scope (how we teach). Also, this Commission (2012) has endorsed, under the pedagogical scope pillar, approaches or learning experiences that are designed to help students in thinking, performing, and making decisions comparable to accounting professionals. Our research study examined a learning method that should assist students to think and make accounting decisions.

Apostolou *et. al.* (2013) advocated that accounting research should be conducted to identify approaches and/or methods to teach or learn core professional competencies (e.g., communication skills). In 2014 the Pathways Commission recommended that quality education should encompass the use of a variety of teaching techniques that stimulate students to enhance their ability to utilize professional judgment in decision-making. Also, Bandura and Lyons (2012) proposed that instructors should incorporate different learning approaches (e.g., lecture, problem-solving, or engaged learning) in their courses. In addition, Wessels (2010) indicated that the instructor's primary responsibility is to motivate students to use learning activities that will accomplish the desired learning course outcomes. This research paper explored whether a project that engaged the students was a good method of teaching selected financial and managerial topics to undergraduate and graduate students enrolled in introductory financial/managerial accounting courses.

In 2008 Jackson and Durkee suggested that the instructor's role must shift from being the presenter of facts to facilitator of active (engaged) learning to help students to achieve the essential professional skills. Previously, Albrecht and Sack (2000) underscored the need to transform the accounting education delivery methods. According to Helliar (2013), a vital component of accounting education should entail teaching methods that engage (enable) students (e.g., role playing, real-world case studies, and group activities). In this research our project involved group work and the use of real-world data (i.e., financial and nonfinancial data from two corporations in the same industry).

The Pathways Commission (2015) proposed the use of Schulman's (2005) five signature pedagogies criteria. Three of these criteria specified that students: (1) should be held accountable for their work to clients, student peers, and faculty; (2) must be active and interactive; and (3) should experience adaptive anxiety. In this research our project incorporated group work and required the students to actively engage in the learning process. Also, this project held the students accountable to their peers. In addition, the students in the preparation of their projects may experience some anxiety (e.g., uncertainty and complexity).

The Chartered Global Management Accountant (CGMA) in the CGMA Competency Framework [CGMA Framework] (2019) discussed five skilled knowledge areas. In addition, the Pathways Commission (2012) in Action Item 4.1.1 advocated the development of an accounting body of knowledge. The Pathways Commission's Knowledge and Pedagogy Task Force in November 2015 proposed a "Common Body of Knowledge Learning Objectives" for accounting. Earlier, the *AICPA Core Competency Framework for Entry into the Accounting Profession* [Framework] (1999) endorsed a set of essential competencies (encompassing100 elements) for accounting students who plan to enter the profession. These competencies are similar to the skill sets discussed by educators and practitioners in Albrecht and Sack (2000), Canadian Institute of Chartered Accountants [CICA] (2010), the Institute of Management Accountants (1994), Institute of Internal Auditors (1999), and the Accounting Education Change Commission [AECC] (1990). Our project was developed to help the students in undergraduate and graduate introductory financial/managerial accounting courses to experience several of the CGMA skilled knowledge areas, many of the Pathways Commission's learning objectives, and about one-half of the AICPA Framework (1999) elements.

THEORY

Learning-to-Learn

The Association of International Certified Professional Accountants (2019) recommended that accountants should recognize the necessity for lifelong professional learning and experience. Earlier, the CPA Vision Project (2017) indicated that there is a need for lifelong learning in the profession (i.e., continuous acquisition of new skills and knowledge). Also, the Pathways Commission (2014) stipulated that high-quality accounting education should prepare students for a lifetime of learning.

In addition, Albrecht and Sack (2000) stated that accounting educators should assist students in development of their ability-to-learn skills. Previously, the Accounting Education Change Commission (AECC) in 1990 indicated that the accounting curriculum "should lay the base on which life-long learning can be built." Further, Gammie and Kirkham (2008) suggested that the ability to "learn to learn" is a key competency that is essential for accountants to adapt to the rapidly changing business environment. Our financial/ managerial project should give the students an opportunity to develop or expand their ability to “learn to learn.”

Under the constructive learning theory, the role of students is to actively participate (engage) in activities that construct their knowledge base. According to this theory the learning environment should be aligned with learning outcomes, which should develop into independent learning. Seifried (2012) and Tan and Ferreira (2012) found that constructive alignment occurs when learning outcomes, teaching and learning activities, and assessment are carefully coordinated. Students need to “learn to learn” so that they will be able to discover needed tacit knowledge for their professional careers. The importance of life-long learning is reinforced as it is one of the top five core values recognized in the AICPA Vision Project (2017). Our learning project allowed the students to participate (engage) in an activity that should help them construct their knowledge base and to learn to learn.

Johnstone and Biggs (1998) advocated supplementing existing textbook material with real world activities (e.g., analysis of realistic data). Many cases have been created using companies’ annual reports and/or SEC 10-K reports for financial accounting courses [e.g., Taylor *et al.* (1998), Kern (2000), Stuart and Karan (2003), Williams and Koch (2004), and Williams (2005)]. However, only a relatively few cases have been developed for cost accounting or graduate managerial accounting courses [e.g., Carter (1999), Dikolli and Sedatole (2004), and Bamber and Bamber (2006)]. Both the Bamber and Bamber (2006) and the Adams *et al.* (1999) cases require an entire semester commitment to complete a series of mini-cases and involve only one company within an industry. Our project was developed to include both financial and managerial accounting topics for undergraduate and graduate students that required the students to analyze financial and nonfinancial data for business decision making.

This study contributes to the accounting literature by presenting an assignment (Financial/ Managerial Accounting Project) that exposes students enrolled in introductory financial/ managerial accounting courses to both financial and managerial information found in publicly traded company annual reports and/or SEC 10-K reports. For example, it was necessary for the students to identify what needs to be measured in the calculation of financial/managerial accounting ratios. Also, the project entailed obtaining managerial accounting information from the Management Discussion and Analysis (MD&A) section of the companies’ annual reports. Our project involved the analysis of two companies within one industry for each team.

Further, the project permitted the students to develop or refine the Pathways Commission’s Common Body of Knowledge Learning Objectives (2015), the CGMA Competency Framework (2019) knowledge areas, and the core competency strategies and techniques enumerated by the AICPA in1999 and again in 2017 while analyzing, writing, presenting, and evaluating their project. This study also contributed to the accounting literature by utilizing value added assessment to evaluate the effects of this learning exercise. In addition, student opinions of this project were obtained and analyzed.

Learning Objectives and Skills

The CGMA Competency Framework (2019) discussed interdependent knowledge areas (i.e., technical skills, business skills, people skills, leadership skills, and digital skills). For example, financial ratio analysis is utilized to assess the performance of the organization, preparation of analysis for decision-making purposes, and participation in teams and groups.

In addition, the Common Body of Knowledge (i.e., Accounting Competencies, Professional Foundational Competencies, and Broad Management Competencies), which was developed by the Pathways Commission (2015), has incorporated measurable learning objectives. Specifically, the Pathways Commission’s Common Body of Knowledge Learning Objectives suggested that accounting students should be able to interpret financial and nonfinancial data

located in external corporate annual reports (e.g., ratio analysis or trend analysis) for decision-making purposes (e.g., investment or credit decisions).
Previously, Albrecht and Sack (2000) specified that accounting courses should emphasize financial statement analysis instead of preparation of the statements. In addition, these authors recommended that an undergraduate accounting curriculum could utilize accounting information (e.g., annual reports) from different industries. Our project required each team to analyze and present information from a different industry for decision-making purposes.

Communication

The ability of the accounting students to communicate (both written and oral) is vital to the profession. Various professional committees have consistently advocated over many years that accounting education should place more emphasis on writing skills, oral skills, and critical thinking skills. More recently, the CGMA Framework (2019), the AICPA Framework (2017) and the Pathways Commission (2015) have indicated that beginning accounting professionals should be able to communicate clearly to the intended audience. Earlier, the AICPA in the Framework (1999) project listed communication as an element of "Personal Competencies." Our learning project permitted the students to write, make oral presentations, and employ critical thinking in making business decisions.
As previously mentioned, the Pathways Commission (2012) recommended that accounting students must possess professional skills (e.g., the ability to communicate effectively). In a follow-up report, the Pathways Commission (2014), stated that quality accounting education should result in an improvement in the students oral and written communication skills. In a survey, Bui and Porter (2010) found that employers considered communication skills to be indispensable for accounting graduates.
According to Conrad and Newberry (2012), despite the educators' best attempts, there still appears to be a gap between practitioners desired communication skills of graduates and what is presently possessed by new graduates. Taking into account this disparity, the Pathways Commission (2015) included under "Professional Foundational Competencies" learning objectives related to communication. Recently, the CGMA Framework (2019) included communication under its "People Skills—Proficiency Level." As suggested by both the CGMA Framework (2019) and the Pathways Commission (2015), our project gave the students an opportunity to make oral presentations and to write on financial statement analysis topics. Specifically, the students were assigned two different types of writing exercises (a team report and an individual report) and an oral presentation as part of their project requirements.
Further, the International Federation of Accountants (IFAC) in its International Education Standard 3 (IES3), *Professional Skills and General Education* (2008) identified the essential skills that are needed by individuals desiring to enter the accounting profession. The IFAC in IES3 emphasized that accountants entering the profession should have interpersonal and communications skills. In addition, the Institute of Chartered Accountants in Australia (ICAA) and Certified Practicing Accountants of Australia (CPA Australia) in their *International Accreditation Guidelines for Accounting Degree Programs* (ICAA/CPA Australia, 2009) indicated that cognitive skills (e.g., writing skills and thinking critically) and behavioral skills (e.g., interpersonal skills) are essential for accounting graduates to succeed. Our project required the students to write, make oral presentations, work in teams, and utilize critical thinking in making business decisions.

Analytical Thinking

The Pathways Commission (2014) denoted that high-quality education encompasses deep learning beyond memorization. The managing partners of the then "Big 8" CPA firms

(“Perspectives . . .”) (1989) indicated that accounting education should place emphasis on analytical and conceptual thinking instead of rote memorization. In addition, the Accounting Education Change Commission [AECC] (1990) recommended that students should actively participate in the learning process and not be just passive recipients of information. Both the Wilkin and Collier (2009) and the Flood and Wilson (2008) studies suggested that accounting programs should deviate from the traditional practice of communicating large amounts of technical knowledge and, instead, facilitate students’ understanding of the principles and concepts involved with accounting/business practices. Our project was designed to encourage the students to do some analytical and conceptual thinking and writing.

The CPA Vision Project (2017) indicated that one of the top five core competencies involves linking data, knowledge and insight to offer strategic decision-making advice. Also, the CGMA Framework (2019) suggested that professionals are expected to capture data, analyze information, advise and influence decision makers, and assist in ensuring required outcomes are achieved.

Earlier, the Pathways Commission (2012) indicated that to be competent an accountant must possess professional skills such as the capability to utilize knowledge to make reasoned judgments. Also, the Broad Business Perspective Competencies category of the *AICPA Core Competency Framework for Entry into the Accounting Profession* [Framework] (1999) suggested that strategic/critical thinking is a necessary component for professional success. In addition, Albrecht and Sack (2000) recommended that accounting education delivery methods be modified to allow students to develop critical skills. Further, students should learn to critically examine and interpret information and ideas according to the Canadian Institute of Chartered Accountants (CICA) in its *CA Skills and Competencies* (2010) report. Classroom techniques (e.g., student engaged projects) should be created to achieve these objectives.

The Pathways Commission’s Common Body of Knowledge Learning Objectives (2015) stated that accounting students should be able to locate appropriate accounting information for guidance in determining accounting measurement methods. Albrecht and Sack (2000) emphasized the importance of “teaching students how to find answers and how to learn.” Also, the AECC (1990) believed that students should have the ability to locate, obtain, and organize information. In addition, the need for entry-level accounting professionals to be able to organize and evaluate information was suggested in the AICPA Framework [Functional Competencies category under Decision Modeling] (1999). Our project required the students to locate, organize, and evaluate financial, managerial, and nonfinancial information.

One of the top five core competencies of the CPA Vision Project (2017) entailed interpretation of both financial and nonfinancial information. Also, in 2017 the CGMA in *Global Management Accounting Principles* stated that one of the main practice areas should involve an integrated and comprehensive view of the organization’s financial and nonfinancial performance along with evaluation of risks and strategy.

The CGMA Framework (2019) indicated that foundational skills (entry-level proficiency) encompass financial ratio analysis to evaluate the organization’s performance. In 2015 the Pathways Commission suggested that students should be able to interpret both financial and nonfinancial data to determine an organization’s operating efficiency and effectiveness. Previously, Albrecht and Sack (2000) recommended that an undergraduate accounting curriculum should include analysis and use of accounting information in making decisions. Also, accounting graduates should be able to analyze the information gathered and form an opinion on the impact of the information for a particular situation according to the CICA in its *CA Skills and Competencies* (2010). Our project required the students to analyze company financial/ nonfinancial accounting information (e.g., MD&A reports) as a basis for decision-making purposes (e.g., the choice of company in which to invest).

Leadership and Human Relations

Another one of the top five core competencies of the CPA Vision Project (2017) encompasses influencing, inspiring, and motivating others to accomplish results. Recently, the CGMA Framework (2019) indicated that accountants should encourage team performance, train and advise others, and motivate and inspire others. Previously, Albrecht and Sack (2000) suggested group activities should be used to teach both leadership and how to work together.

Under Professional Competencies of the AICPA Framework (2017), students should be able to work effectively with diverse individuals, promote inclusion, and enhance performance to accomplish objectives. Under Leadership Skills in the CGMA Framework (2019), entry-level professionals should welcome diverse ideas, interact effectively with everybody, contribute to groups or teams, and value the contribution and efforts of group or team members. Also, the IFAC in IES3 (2008) indicated the need for students to learn to work with others, to negotiate acceptable solutions, to listen effectively, and to solve any conflicts that may occur. Further, both the Kavanagh and Drennan (2008) and the Kennedy and Sorensen (2006) studies stated that employers expect accounting graduates to be able to successfully work on a team, in addition to having technical and analytical accounting skills. Our project involved students working together on teams.

Students should learn to think and perform as professionals during their educational experience according to the Pathways Commission (2015). Prior to this report, Sin, Reid and Jones (2012) advocated that accounting education should assist students in developing transferable skills that will help them to make the transition from their present learning environment to the work environment. These transferable skills include report writing and interpersonal skills. Stone and Lightbody (2012) found that interpersonal skills need to involve both listening and oral communication. Our project required the students to not only prepare a written report and make oral presentations, but also, to encourage them to learn to listen.

According to Schulman (2005) signature pedagogy should provide learning experiences that hold students accountable for their work (e.g., to clients, peers and faculty). In addition, the AICPA Framework [Personal Competencies category under Professional Demeanor] (1999) advocated that students should objectively respect the professional assessment or evaluation of others. Also, Boud *et al.* (2010) suggested that students should learn to make judgments about their own work and the work of others (i.e., peer review) in order to become successful continual learners and future accounting professionals. Our financial/managerial project gave the students an opportunity to evaluate their classmates' presentations (i.e., to perform peer review). As a result, the students received feedback/criticism from their peers.

Value-Added Assessment

One technique to evaluate students' learning is to use pre- and post-study measurements. According to Angelo and Cross (1993), the purpose of utilizing pre- and post-assessment techniques is to determine whether students have benefited from class discussions and assignments. The pre-test allows the instructor to establish a benchmark of what the students know on the subject matter being investigated before the study technique (project) is utilized. Gordon (1998) used the pre- and post-assessment technique to evaluate students' knowledge of social responsibility accounting.

In our study, Exam II, which was administered after discussing the homework problems on financial/managerial accounting topics (before the project was assigned), was designated as the pre-test. After Exam II there was no other class discussion or homework involving financial/ managerial accounting ratios or other questions included in the project. The Final Exam, which was given after the students completed the project, was considered to be the post-test.

In summary, the literature suggests that student engaged learning exercises can enrich the learning process and that writing projects can be utilized as a learning tool. The following hypothesis was used to test the benefit of this engaged learning technique (project):

> H_1: The distribution of exam scores for undergraduate (graduate) students on the financial/managerial accounting questions for Exam II (before the engaged learning exercise) and for the Final Exam (after the engaged learning exercise) are the same.

Student Perceptions

Ennis (1987) stated that attitudes strongly determine the ability to apply intellectual skills (e.g., written communication skills). Stout and Rebele (1996) indicated the need to examine student attitudes toward a teaching method. According to Ennis (1987), if students do not have positive attitudes toward a teaching method, desired learning outcomes (e.g., intellectual skills) may not occur.

Stone and Shelley (1997) used survey questions to measure student perceptions of the instructional processes. Ramsay *et al.* (2000) utilized a survey to determine the students' preferences for a cooperative learning method. Sawyer *et al.* (2000) administered a survey after the students received their grade and assessment sheet for a case to determine if they believed that the case was useful in meeting specified skills. Chu and Libby (2010) utilized a post-assignment questionnaire to evaluate an active learning assignment.

In this research study, students' opinions of the usefulness of the Financial/Managerial Accounting Project in accomplishing selected Pathways Commission's Common Body of Knowledge Learning Objectives (2015) and the AICPA's Framework Core Competencies (2017 and 1999 versions) were measured using a survey. This survey was given after the students received their project results.

Pathways Commission – Common Body of Knowledge

The Pathways Commission's Common Body of Knowledge Task Force began by examining the AICPA Core Competency Framework (1999) along with the work of other accounting task forces (e.g., Chartered Professional Accountants Canada, Chartered Accountants Australia, Institute of Management Accountants, and International Accounting Standards Board Education Initiative) to develop learning goals for accounting education (i.e., undergraduate, graduate, and beyond). To concentrate on undergraduate accounting education, a new task force of the Pathways Commission was formed (Knowledge and Pedagogy Task Force). This task force translated the goals of the Common Body of Knowledge Task Force into measurable undergraduate learning objectives.

The learning objectives were categorized into three competency areas (i.e., Accounting, Broad Management, and Professional Foundational). The Accounting Competency was divided into six subsections (i.e., external reporting and analysis; planning, analysis and control; taxation compliance and planning; information systems; assurance and internal control; and professional values, ethics, and attitudes). There are five subsections under the Professional Foundational Competencies (i.e., communication; quantitative methods; analytical thinking and problem solving; human relations; and technology). Finally, there are also five subsections under the Broad Management Competencies (i.e., leadership; organizational ethics and social responsibility; process management and improvement; governance, risk, management, and compliance; and additional core management competencies). The project's desired accounting learning objectives have been classified by the researchers into appropriate subsections of the Pathways Commission's (2015) Common Body of Knowledge Learning Objectives.

About half of the subsections of the Accounting Competencies have at least one project learning objective that the students were exposed to while preparing their engaged learning project. Specifically, all of the learning objectives of the professional values, ethics and attitudes subsection were integrated into our project. For the Professional Foundation Competencies, all of the subsections had at least one learning objective incorporated in the assigned project. At least half of the learning objectives were expected to be accomplished with our project for the communication; analytical thinking and problem solving; and human rights subsections. Of the Broad Management Competencies, all except one of the subsections were expected to have at least one learning objective reflected in the project. More than half of the learning objectives for the organization, ethics and social responsibility subsection were assimilated into our engaged learning project.

AICPA Framework

The AICPA Framework (2017 and 1999 versions) each provided a set of needed competencies for all students preparing to enter the accounting profession and/or the business world. The Framework (2017) competencies were divided into accounting, professional, and business. Our project encompassed elements in all of these competencies.

The Framework (1999) competencies were classified as functional, personal, and broad business perspective. Our project incorporated elements of the functional competencies category. Also, our project was expected to permit the students to experience elements of the personal and broad business perspective categories.

The team Financial/Managerial Accounting Project (project) was expected to result in elements of all three categories of the Framework (2017 and 1999 versions) competencies being integrated into introductory financial/managerial accounting courses (an undergraduate course and a graduate course) with a minimum of two to three hours of class time.

As previously mentioned, students' opinions of the usefulness of the project in accomplishing selected Pathways Commission's Learning Objectives (2015) and selected AICPA's Framework Core Competencies (2017 and 1999 versions) were measured using a survey. Our survey requested the students to indicate their opinions as to whether the competencies/learning objectives were accomplished in preparing, presenting, and evaluating the project.

Two Different Universities

One of the limitations of educational research that is conducted at only one university is whether the results will apply to other university settings. Accounting instructors are interested in teaching techniques or methods that might be successfully utilized in different university environments. One of the objectives of this research study was to determine if there would be different Final Exam score results when the outside of class project was used at two universities located in different regions of the country (midwest regional and southwest regional [95% English second language students]).

Another objective of this study was to determine whether there would be a different result when the introductory financial/managerial course was taught at the undergraduate level as compared to the graduate level. An additional objective was to ascertain whether the student-perceived benefits from using the engaged learning project vary between these two different university settings.

RESEARCH METHODS

One of the researchers taught both of the introductory financial/managerial accounting classes used in the research experiment. One of the universities was a midwest regional state university and the other was a state university with 96% minority students [95% English second language], which is located in the southwest. At the midwest university (MW-U) the students were undergraduate sophomores, while the students at the southwest university (SW-G) were graduate MBA students with no previous accounting knowledge.

The project involved financial/managerial accounting analysis for the two most recent years of annual reports and/or SEC 10-K reports for two companies in the same industry (e.g., Goodyear and Cooper Tire) for each team. Each team (consisting of 3-5 students) analyzed a different industry (e.g., office furniture, petroleum industry, or wireless components).

Project and Team Selection

The students at both universities were allowed to select the industry from pairs of companies identified by the instructor. The researchers have found that students are more motivated to do this project if at least one of the firms is a regional firm or at least a nationally recognized firm (e.g., Caterpillar and Deere).

In addition, if the company's annual report does not incorporate the SEC 10-K report, the project required the students to access their company's SEC 10-K report on the Internet. Other than the selection of the industry by the team, the entire project was designed to be prepared outside of class.

Written Reports and Oral Presentations

The students at both universities were required to prepare a written team report. This report had three parts. First, the team was required to calculate ten financial/managerial accounting ratios for the two most recent years. Then, the students were expected to use the ratio analysis results as the basis for answering a set of questions. For example, "Which company has the more favorable inventory turnover?" Another example was "Which company has the more favorable gross profit percentage trend?"

Finally, for the most recent year, each team was required to answer another set of questions related to each company's annual and SEC 10-K reports. For example, "What inventory valuation methods does each company use?" Another question required the students to identify two segments (e.g., product lines) reported by each firm and indicate if there was a product line or business segment that they would want to consider dropping in the future.

The third part of the team report was designed to expose the students to other sections of the company's annual report in addition to the financial statements and accompanying notes (e.g., Management's Discussion and Analysis (MD&A) report). The students were requested to use the MD&A section to determine if the company management made forward-looking or projection statements. Then, if company projections were presented in the MD&A section, the students were asked to identify two factors related to the projections that would also affect the preparation of a budget for each company. For example, "What assumptions discussed in the MD&A section were related to the development of sales forecasts?"

In addition, to assure that each student had writing experience during preparation of the project, each student was required to write a one-page report. This individual report required the students to give their opinions as to the firm they would select for investment purposes. They were expected to support their conclusions based on the team data developed in the first three parts of the project requirements.

Also, each team was required to orally present their analysis to their classmates. The students were expected to dress as if they were presenting to clients. The teams were informed that their presentations should be 15 to 20 minutes in length. The other classmates were expected to act as the client and were encouraged to ask questions of the presenting team.

Evaluations

As the Pathways Commission (2012) recommended, the project was designed to promote deep engagement of the students by holding them accountable to the instructor and fellow students through the use of an evaluation form during their oral presentations. Each student's presentation was evaluated as well as the team as a whole.

The students at both universities received (one week before the presentation) a copy of the evaluation form, which was to be used during their presentations. Upon reviewing the evaluation form, the students knew that they would be scored (5-1 Likert scale with 5 being the highest) based on (1) the content of their segment or topic presented, (2) the organization of their presentations, (3) the use of visual aids during their presentations, and (4) the effectiveness of the delivery of their presentations. These grading characteristics were defined on the evaluation form. For example, the characteristics for effectiveness of the delivery of the individual student's presentation were listed as: "Did the presenter's voice enhance the effectiveness of the presentation?" "Did the presenter maintain good eye contact?" "Did the presenter sound natural and professional?"

In addition, the evaluation form defined the characteristics on which the teams were evaluated. The team score was based on (1) the content of the team project presented; (2) the organization of the entire team presentation; (3) the coordination of visual aids used by the team; and (4) the cohesiveness of the team presentation.

The instructor evaluated the team and each individual on the team. As mentioned above, the non-presenting class members were also required to complete the evaluation form. Each classmate and the instructor had equal evaluation weight in determining the student scores for the presentations. This helped the students to consider the presentations more seriously.

The students were asked to keep the evaluation forms confidential and were told that only the instructor will compute the presenter's scores. The evaluation form permitted the evaluators to write comments and suggestions for each presenter and for the team presentation as a whole. One of the purposes of the evaluation form was, as suggested by the Pathways Commission (2015), to hold the presenting students accountable to their student peers and the instructor. Also, as implied by the Pathways Commission (2012), it was expected that the students will benefit from peer evaluation/observation and comments.

When the written reports were returned, each student at both universities also received his or her project score and the written instructor/peer comments for the individual and team presentations. The total score for the project was 70 points (team report, 40; individual report, 15; individual presentation, 10; and team presentation, 5).

Testing

Approximately a week following the discussion of the homework problems on the financial/managerial analysis topics, Exam II was administered. Exam II was given before the students started their engaged learning exercise (i.e., Financial/Managerial Accounting Project). In our study, Exam II was designated as the pre-test.

About a week after the students made their presentations and completed their team and individual reports, the Final Exam was administered. The Final Exam had questions related to the financial/managerial analysis topics that were different than those that were given on Exam II but were similar in the level of complexity. The Final Exam was considered as the post-test in our study. The results of Exam II and the Final Exam were used to measure the effect of this engaged learning exercise technique.

Student Perceptions – Pathways Learning Objectives – AICPA Framework

This study used a survey to measure student perceptions of this engaged learning technique as Stone and Shelly (1997) did in their research. The survey was utilized to measure the students' opinions of the usefulness of the Financial/Managerial Accounting Project in accomplishing selected Pathways Commission (2015) Learning Objectives and the AICPA Framework Core Competencies (2017 and 1999 versions). In addition, the survey was used to ascertain the opinions of the students on the usefulness of the project in understanding the financial/ managerial accounting analysis topics.

Like the Sawyer *et al.* (2000) study, our survey was given after the students received their project results (i.e., their grade and assessment sheet). The survey requested the students to rank (strongly agree = 5) whether selected Pathways Commission Learning Objectives and AICPA Framework Core Competencies were accomplished during their project preparation, team presentation, individual presentation, completion of the peer evaluation form, and reviewing peer evaluations.

RESULTS

The students at both universities were tested twice on the financial/managerial accounting analysis topics. First, an exam (Exam II) was administered after discussing the homework problems on these topics, but before the Financial/Managerial Accounting Project (project) was assigned. Exam II was considered as the pre-test. As previously discussed, there was no other class discussion or homework involving financial/managerial accounting ratios or other questions included in the project after Exam II. The second exam (Final Exam) was given after the students had completed the project. The Final Exam was designated as the post-test. Different questions related to the project topics were given on these exams.

At both universities, the majority of the student exam scores related to the financial/managerial accounting analysis topics increased or stayed the same after the project was completed. For the undergraduate midwest university (MW-U) course, the mean score increased from 43.2% on Exam II to 55.2% on the Final Exam. The mean score for the graduate southwest university (SW-G) course increased from 29.7% on Exam II to 53.0% on the Final Exam.

The students' Exam II and Final Exam scores were matched by names. The Wilcoxon signed rank test was utilized to test H_1 (EII ≥ FE). Since there was a significant difference ($p = .01$ at MW-U and $p = .05$ at SW-G), H_1 was rejected. The students' exam scores appeared to have significantly increased at both universities as a result of this engaged learning exercise. Thus, it appears that this type of learning exercise can be successfully used as a teaching method for financial/managerial accounting analysis topics at both the undergraduate and graduate levels.

Like Sawyer *et al.* (2000), the researchers administered a survey after the students received their grade and assessment sheet for the project. The survey was used to determine whether the students felt that the assigned project was useful in meeting specified Pathways Commission Learning Objectives and AICPA Framework skills while analyzing, writing, presenting, and evaluating this project.

Generally, the students stated that they "strongly agree" or "agree" that the selected core competencies were accomplished by the project. The average mean score for the students at MW-U was 4.109 and the median score was 4.125. At SW-G the average mean score for the students was 4.356 and the median score was 4.440. The scores ranged at MW-U from 4.750 to 3.500 and at SW-G from 4.780 to 3.560.

Pathways Commission Common Body of Knowledge Learning Objectives

The Pathways Commission Common Body of Knowledge Learning Objectives were categorized into Accounting Competencies, Broad Management Competencies, and Professional Foundational Competencies. Many of the Accounting Competencies subsections were included in our project. The “external report and analysis” subsection of the Pathways Commission Accounting Competencies was one of the main reasons for this project with most MW-U students indicating a ranking of 4.13 or higher and a mean score of 4.32 and most SW-G students indicating a ranking of 4.10 or higher and a mean score of 4.32. Generally, both the MW-U and SW-G students believed that the “planning, analysis, and control” subsection was accomplished with a mean score of 4.13 for MW-U students and 4.36 for SW-G students. Another purpose of the project was to introduce the students to ethics and social responsibility. Therefore, the researchers were interested in the results of the questions for the “professional values, ethics, and attitudes” subsection. Both the MW-U and SW-G students generally believed this project overall improved their knowledge of this subsection with most of the related questions having a ranking of 4.00 or higher for the MW-U students and 4.10 or higher for the SW-G students and a mean score of 4.27 (MW-U) and 4.50 (SW-G). The difference between these two groups could have resulted because there was a dysfunctional team at the MW-U university.

Also, the students’ opinions of the project’s exposure to all of the subsections of the Pathways Commission Professional Foundational competencies were examined. Our project was designed to increase student communication skills, which is not normally part of an Introductory Financial/Managerial Accounting course. Thus, the results of the “communication” subsection were important. The majority of the MW-U students’ scores were 4.00 or higher and all of the SW-G students’ scores were 4.11 or higher with a mean score of 4.13 for the MW-U students and 4.38 for the SW-G students. The difference between the MW-U and SW-G students could be because the MW-U students (sophomores) may not have had to make presentations in their freshman level courses (which made the students feel less confident) while the graduate students at SW-G probably had made presentations prior to this course.

Another learning objective of our engaged learning project was to motivate the students to do some analytical and conceptual thinking and writing. Specifically, it was hoped that the students in the project preparation would learn to critically examine and interpret information [as suggested by the Canadian Institute of Chartered Accountants (2010)]. Explicitly, our project expected the students to analyze company financial/nonfinancial accounting information [as recommended by The Pathways Commission (2015)] as a basis for decision-making purposes (e.g., the choice of company in which to invest). As a result, the student opinions of the “analytical thinking and problem solving” subsection were examined. Most of the MW-U students’ scores for these questions were 4.00 or higher and the majority of the SW-G students’ scores were 4.11 or higher with a mean score of 4.17 for the MW-U students and 4.37 for the SW-G students.

One of the advantages of the team project was the opportunity for the students to develop better “human relations” than is normally possible in an Introductory Financial/ Managerial Accounting course. Most of the MW-U students’ opinion scores were 4.00 or higher and the majority of the SW-G students’ scores were 4.33 or higher for the human relations subsection questions with a mean score of 4.19 for the MW-U students and 4.44 for the SW-G students. Probably the lack of previous teamwork experience by the MW-U students may explain the resulting score differences between the undergraduate (MW-U) and the graduate (SW-G) students.

Our project required some use by the students of technology (e.g., locating and downloading their companies’ annual reports and/or SEC 10-K reports). For the MW-U students, the majority

of their opinion scores were 4.00 or higher and all of the SW-G students' scores were 4.11 or higher with a mean score of 4.15 for the MW-U students and 4.36 for the SW-G students.
The Pathways Commission's final Common Body of Knowledge competency is the Broad Management category. Because the project involved teams, it was hoped that the students would have some leadership opportunities while working on the project. Most of the MW-U students' scores related to this competency were 4.00 or higher and the SW-G students' scores were 4.22 or higher with a mean score of 4.16 for the MW-U students and 4.43 for the SW-G students.
Another subsection of the Broad Management category relates to "governance, risk management, and compliance," which was not emphasized in the project. As a result, the student opinions were relatively low with a mean score of 3.79 for the MW-U students and 3.93 for the SW-G students.

AICPA Framework Core Competencies

As previously discussed, this Financial/Managerial Accounting Project should facilitate the students in accomplishing elements of all three of the AICPA Framework's broad skills categories (Functional Competencies, Personal Competencies, and Broad Business Perspective). Specifically, the researchers expected about one-half of the AICPA Framework's skills to be achieved by the students.
Of the elements that the researchers expected to be accomplished, the students ranked 70.49% and 93.44% as either "strongly agree" or "agree" at MW-U and SW-G, respectively. The ten highest elements at MW-U had a score of 4.50 or higher. Because of ties the 20 highest elements at SW-G had a score of 4.56 or higher.
The majority of the core competency elements achieved by this project were related to the personal competencies category. Personal competencies may be more difficult to achieve with traditional activities in an undergraduate or graduate introductory financial/managerial accounting class. Of the top ten elements at MW-U, 80% are from the personal competencies category. Of the top 20 elements (because of ties) at SW-G, 80% are from the personal competencies category.
The survey also requested the students to rank (strongly agree = 5) whether preparing the Financial/Managerial Accounting Project greatly assisted them in understanding the financial statement analysis and managerial accounting topics. The students "strongly agreed" or "agreed" (4.75 mean score at MW-U and 4.89 mean score at SW-G) that this project increased their understanding of these topics.

SUMMARY

Many of the students received higher scores on the Final Exam related to the financial statement analysis and managerial accounting topics after they completed the project than they did on Exam II, which involved only regular class discussion and homework assignments. There was a significant difference at p = .01 for MW-U (undergraduate course) and at p = .05 for SW-G (MBA graduate course) between the mean scores on Exam II (before the project) and the Final Exam (after the project). The students' exam scores appear to have significantly increased at both universities as a result of this project. Therefore, this engaged learning exercise (project) appears to be beneficial for both undergraduate and graduate students.
Many of the specified Pathways Commission (2015) Learning Objectives and the AICPA Framework Core Competencies (1999 and 2017 versions) were accomplished when the students prepared, presented, and evaluated their projects. On the survey, the SW-G students ranked 93% of the learning objectives/core competencies that the researchers expected to be accomplished as either "strongly agree" or "agree." The SW-G students' average mean score

was 4.37 and the median score was 4.44. The scores ranged from 4.78 to 3.56 for the SW-G students.

Of the expected elements, about 80% of the top scores at both universities were from the learning objectives/personal competencies category. This project gave the students an opportunity to experience types of skills recommended by the Pathways Commission (2015) Learning Objectives and the AICPA Framework Core Competencies (1999 and 2017 versions) that may not normally be accomplished in a typical undergraduate or graduate financial/ managerial accounting course (e.g., professional foundational/personal competencies). Further, the students indicated that they “strongly agreed” or “agreed” (4.75 mean score at MW-U and 4.89 mean score at SW-G) that this project increased their understanding of the financial statement analysis and managerial accounting topics.

Also, in the preparation of this project the students were active participants in the learning process as suggested by Schulman (2005) and the AECC (1990). The use of actual company data in this project permitted the students to analyze and interpret financial information as advocated by Albrecht and Sack (2000). Further, as recommended by both the Pathways Commission (2015) and the AECC (1990), the students were required to locate, obtain, and organize/analyze financial and nonfinancial information.

This project can be accomplished using a minimum of two to three hours of class time. Of course, the amount of class time spent on the project will vary depending on the size of the class. In conclusion, it appears that this engaged learning exercise (project) can be successfully used as a teaching method for financial statement analysis and managerial accounting topics in an undergraduate or graduate financial/managerial accounting course.

ABSTRACT

Using cluster analysis, we present research examining the characteristics of lean operations by U.S. manufacturing industries based on U.S. Economic Census data. From an end-to-end supply chain perspective, we aim to develop insights into the learning practices by industry groups based on a set of industry characteristics related to lean operations, including manufacturing worker productivity, fuel consumption, capital expenditures, inventory, waste, etc.

KEYWORDS: Lean operations, Economic Census, Cluster analysis, Manufacturing industries

INTRODUCTION

Simply put, lean manufacturing in terms of a management philosophy is all about relentless efforts to eliminate waste from the manufacturing process. In lean manufacturing, waste is broadly defined to include any activity that does not add value to the end-to-end supply chain, including wasted materials, defected products, overstocked inventory, emissions, underutilized capacity, underutilized skills, lost efficiency and lost productivity due to unevenness of the workflow, etc. According to UK Lean Enterprise Research Center (LERC), nearly 60% of production activities in a typical manufacturing process are waste since they do not add value to the end customers.

Ford may be the first company to implement the pristine form of lean manufacturing by using standardized processes in the assembly line of the Model T automobiles where each stage was fitted together tightly to ensure a continuous and consistent production flow. However, it is Toyota that perfected the manufacturing process through its innovative "Toyota Production System" which identifies and eliminate expenditures of material, effort and time that do not generate value for customers in late 1990s. Toyota identified eight forms of waste from a customer's perspective, including transport, inventory, motion, waiting, overproduction, over processing, defects and underutilized workers. Those activities may be necessary steps in delivering final products to the end customers; however, customers do not appreciate their value and may be unwilling to pay for them. Therefore, manufacturing companies shall try their best to eliminate or minimize those wasteful activities.

In terms of best practices, lean manufacturing includes just-in-time production (JIT), which means "making only what is needed, only when it is needed, and only in the amount that is needed", total quality management (TQM), Six Sigma, automation and avoidance of human errors, 5S (Seiri, Seiton, Seiso, Seiketsu, and Shitsuke in original Japanese terms; Sort, Set in order, Shine, Stanardize, and Sustain in English translation), Kanban (pull systems), Kaizen (continuous improvement), total productive maintenance (TPM), supplier relationship development, value stream mapping (VSM).

Based on U.S. Economic Census data, in this research we set out to map the state of lean manufacturing for the U.S. manufacturing industries using cluster analysis. In the following sections, our paper progresses with literature review of lean philosophy and lean practices. We then propose a supply chain perspective of lean practices and methodologies. In the section of research methodology, we introduce data collection process and conduct cluster analysis to map the lean operation status of all U.S. manufacturing industries, complemented by case studies of selected industries in each cluster.

LITERATURE REVIEW

We review lean production literature from three perspectives: definition and evolution of lean production as a management philosophy; lean practices and methodologies; and performance indicators of lean operations.

Definition and Evolution of Lean Manufacturing/Production

Womack, Jones and Roos (1990) prescribed that lean production uses less of everything compared to mass production, including less human effort in factory, less manufacturing space, less investment in tools, fewer engineering hours in new product development, less inventory, fewer defects, more flexibility, greater variety of products, and greater efficiency. Shah and Ward (2007) defined lean production as an integrated socio-technical system whose main objective is to eliminate waste by concurrently reducing or minimizing supplier, customer and internal variability.

Garza-Reyes, Kumar, Chaikittisilp and Tan (2018) operationalized lean manufacturing as five methods and tools, including TPM, VSM, Automation, Kaizen/CI, and JIT and used four indicators to measure the environmental impacts of lean manufacturing: material use, energy consumption, non-product output and pollutant release. Material use goes beyond raw material to include water consumption, packing material, hazardous material and the use of recycled material. Energy consumption refers to the use of fuel and electricity. Generally, the use of electricity generates less waste. Non-product output and pollutant releases refer to waste and hazard for disposal, air emissions and landfill.

Aqlan and Al-Fandi (2018) provides a summary of waste considered by lean operations, including inadequate processing, unnecessary transportation, excess motion, defects, waiting, over production, and inventory. When waste activity is eliminated in a process, cost is reduced and the process becomes more efficient. Believing that lean production focuses on the elimination of waste and creation of value for customers, Womack and Jones (1996) identified three additional waste, including underutilization of people, environmental waste, and underutilization of facilities, and five critical elements of lean implementation, including value, value stream, flow, pull, and the pursuit of perfection. Value is emphasized to keep customer focus. Value stream analysis is used to identify non-value-added activities. The flow element is to ensure a smooth and leveled process without interruption and too much variation. Pull ensures that firms only produce what customers want and are willing to pay for. Perfection encourages firms to continue to improve.

First introduced by Motorola in the 1980s, Six Sigma is a process improvement philosophy aimed to reduce variation in the process and seeks to identify the causes of defects and develop effective corrective actions through "Define, Measure, Analyze, Improve, and Control" (DMAIC). Lean operation does not use statistical tools to achieve process capabilities; Six Sigma is not designed to optimize the process flow. Lean Six Sigma combines both lean operations and Six Sigma methodology.

Business sustainability and social and environmental responsibility in the 21st century call for companies to seek innovative solutions for cleaner technologies. Taddeo, Simboli, Di Vincenzo and Ioppolo (2019) claimed that environmental issues have gradually required manufacturers to pursue a more rational use of resources and a reduction in wastes production. The emerging Lean and Clean Production suggests that firms should create more value with less impact and that environmental eco-efficiency is of the same importance to companies as operational efficiency and market effectiveness. Based on a bibliometric and network analysis of lean and clean production literature, this study identifies keywords, key constructs, subject areas, author collaboration in Lean and Clean Production research.

Benefits of lean manufacturing include increased productivity, reduced cost, shortened lead times, increased volume flexibility and enhanced competitiveness (Shah and Ward, 2003).

Identification of Lean Manufacturing Practices/Methods

However, not all organizations have achieved desired outcomes and success when implementing lean production (Wickramasinghe & Wickramasinghe, 2017; Doolen and Hacker, 2005). Wickramasinghe & Wickramasinghe (2017) provided two interesting findings which may well account for performance variation of lean operations. First, lean operational practices complement each other and only a systematic implementation of all lean operation methodologies may achieve desired outcomes. Second, lean duration moderates the relationship between adoption of lean production practices and lean performance outcomes. Essentially, it takes time for firms to implement lean manufacturing and for lean manufacturing to generate benefits. Lean manufacturing is not an effective tool to solve short-term competitive problems.

Another underlying factor for performance variation is the unfortunate fact that there is no consensus on what qualifies as lean practice. James-Moore and Gibbons (1997) summarized five methods, including general waste elimination, flexibility, people utilization, process control, and optimization. Koufteros (1998) identified seven categories of lean operations, including shop floor employee involvement in problem solving, re-engineering set-up, cellular manufacturing, quality improvement, preventative maintenance, dependable suppliers, and pull production.

Flynn, Schroeder, and Flynn (1999) defined ten kinds of lean practices to include employee development, management technical competence, design for customer needs, worker participation, proprietary equipment, continuous improvement, process control, feedback of information, pull system, and JIT supplier relationship. Panizzolo (1998) proposed six broad categories: process and equipment, manufacturing planning and control, human resources, product design, supplier relationships, and customer relationships. Shad and Ward (2007, JOM, 25/4)'list includes supplier feedback, JIT delivery by suppliers, customer involvement, pull, continuous flow, setup time reduction, TPM, statistical process control, and employee involvement.

Hayes and Wheelwright (1984) summarized lean production methods into two major categories: structural, which includes capacity, facilities, technology, and vertical integration, and infrastructural, including workforce, quality, production planning, and organization. Sakakibara, Flynn, Schroeder, and Morris (1997) proposed slightly different two categories: infrastructure practices include quality management, workforce management, manufacturing strategy, organizational characteristics, product design; JIT practices, including setup time reduction, scheduling flexibility, maintenance, equipment layout, Kaban and JIT supplier relationships.

Wickramasinghe & Wickramasinghe (2017) complies a comprehensive list of lean manufacturing practices, including cellular manufacturing, multitasking workforce, lot size reduction, JIT, work delegation, total productive maintenance (TPM), set-up time reduction, total quality management (TQM), continuous flow production, agile manufacturing. Lean production also covers process capability measurement, safety improvement programs and human resource management.

Performance Effects of Lean Manufacturing

Manufacturing performance can be described in multiple dimensions, including manufacturing plant's labor efficiency (Arthur, 1994), manufacturing plant productivity (Ichniowski et al., 1997), machine efficiency (Youndt et al., 1996), on time delivery (Swink et al., 2007), inventory management (Hofer et al., 2012), production volume flexibility (Cua et al., 2001), and manufacturing cost efficiency (Bozarth et al., 2009). The ultimate benefit of lean manufacturing is to enhance a firm's manufacturing competitive capabilities (Jabbour et al., 2013). (Wickramasinghe and Wickramasinghe, 2017) applied seven measures for manufacturing plant performance, including waste elimination, defects minimization, cross-functional teams, continuous improvement, JIT and pull, information availability and employee involvement. Garza-Reyes, Kumar, Chaikittisilp and Tan (2018) examined the environmental performance of manufacturing firms that implemented lean methods and tools. Those performance measures include materials use, energy consumption, non-product output and pollutant releases.

Not surprisingly, many of those performance measures are interchangeably used with lean practices, such as waste elimination, cross-functional teams, continuous improvement, JIT, etc. To overcome those shortcomings in the literature, in this study we decide to use more objective measures for performance effects, such as inventory, waste releases, fuel consumed, etc.

CONCEPTUAL FRAMEWORK

In this study, we set out to map lean manufacturing practices from an end-to-end supply chain perspective. A manufacturing supply chain is comprised of upstream suppliers, internal operations and downstream customers. Lean manufacturing is a systematic approach for the entire supply chain. A supply chain is as lean as the fattest section. Therefore, it is meaningful to understand lean manufacturing practices from a supply chain perspective.

Based on our survey of lean operations, we find that some lean practices are more used to deal with supplier relationship management, such as JIT delivery; some are more likely to be used in internal operations, such as plant capacity utilization, machine setup time and down reduction, utilization of labor skills; and a few other practices deal with downstream customers, including design for customer needs, pull, and customer involvement. Therefore, lean practices are classified as follows from a supply chain perspective (Figure 1).

RESEARCH METHODOLOGY

Han & Nag   Lean Supply Chain: A Cluster Analysis of U.S. Manufacturing Industries

We collect archival data and perform cluster analysis to map the lean operation status of all U.S. manufacturing industries, complemented by case studies of selected industries in each cluster.

Data Collection

We collected the most recently available data on U.S. manufacturing industries from U.S. 2012 Economic Census (note that 2017 Economic Census data will be published until late 2019). The U.S. Economic Census includes all manufacturing establishments classified in sectors 31-33 with one or more paid employee at any time during the year. The unit of analysis in this study is six-digit North American Industry Classification System (NAICS) manufacturing industries. There are 364 six-digit NAICS manufacturing industries ranging from 311111 9 (Dog and cat food manufacturing) to 399999 (all other miscellaneous manufacturing, including candles, lamp shade, hot tubs, pet supplies, etc.).

Below is the complete list of variables captured in U.S. 2012 Economic Census data for manufacturing industries:

- Number of companies
- Number of establishments
- Establishments with 0 to 19 employees
- Establishments with 20 to 99 employees
- Establishments with 100 employees or more
- Number of employees
- Annual payroll ($1,000)
- Total fringe benefits ($1,000)

- Employer's cost for health insurance ($1,000)
- Employer's cost for defined benefit pension plans ($1,000)
- Employer's cost for defined contribution plans ($1,000)
- Employer's cost for other fringe benefits ($1,000)
- Production workers average for year
- Production workers for pay period including March 12
- Production workers for pay period including June 12
- Production workers for pay period including September 12
- Production workers for pay period including December 12
- Production workers annual hours (1,000)
- Production workers annual wages ($1,000)
- Total cost of materials ($1,000)
- Cost of materials, parts, containers, packaging, etc. used ($1,000)
- Cost of resales ($1,000)
- Cost of purchased fuels consumed ($1,000)
- Cost of purchased electricity ($1,000)
- Cost of contract work ($1,000)
- Quantity of electricity purchased for heat and power (1,000 kWh)
- Quantity of generated electricity (1,000 kWh)
- Quantity of electricity sold or transferred (1,000 kWh)
- Total value of shipments and receipts for services ($1,000)
- Value of resales ($1,000)
- Value added ($1,000)
- Total inventories, beginning of year ($1,000)
- Finished goods inventories, beginning of year ($1,000)
- Work-in-process inventories, beginning of year ($1,000)
- Materials and supplies inventories, beginning of year ($1,000)
- Total inventories, end of year ($1,000)
- Finished goods inventories, end of year ($1,000)
- Work-in-process inventories, end of year ($1,000)
- Materials and supplies inventories, end of year ($1,000)
- Gross value of depreciable assets (acquisition costs), beginning of year ($1,000)
- Total capital expenditures ($1,000)
- Capital expenditures for buildings and other structures ($1,000)
- Capital expenditures for machinery and equipment ($1,000)
- Capital expenditures for automobiles, trucks, etc. for highway use ($1,000)
- Capital expenditures for computers and peripheral data processing equipment ($1,000)
- Capital expenditures for all other machinery and equipment ($1,000)
- Total retirements ($1,000)
- Gross value of depreciable assets (acquisition costs), end of year ($1,000)
- Total depreciation ($1,000)
- Total rental payments or lease payments ($1,000)
- Rental payments or lease payments for buildings and other structures ($1,000)
- Rental payments or lease payments for machinery and equipment ($1,000)
- Total other operating expenses ($1,000)
- Temporary staff and leased employee expenses ($1,000)
- Expensed computer hardware and other equipment ($1,000)
- Expensed purchases of software ($1,000)

- Data processing and other purchased computer services ($1,000)
- Communication services ($1,000)
- Repair and maintenance services of buildings and/or machinery ($1,000)
- Refuse removal (including hazardous waste) services ($1,000)
- Advertising and promotional services ($1,000)
- Purchased professional and technical services ($1,000)
- Taxes and license fees ($1,000)
- All other operating expenses ($1,000)

Cluster Analysis

Based on literature review and out conceptual framework, we believe that the following variables from the dataset can be used to capture the lean characteristics of U.S. manufacturing industries.

Productivity-related variables:
- output per worker per hour
- value added per worker per hour

Variable related to green operations:
- Cost of purchased fuels (non-clean energy)
- Cost of purchased electricity (clean energy)

Inventory variables:
- Raw material inventory
- Work-in-Process Inventory
- Finished goods inventory

Variables related to capital expenditures on PPE:
- Capital expenditures for buildings and other structures
- Capital expenditures for machinery and equipment
- Capital expenditures for automobiles, trucks, etc. for highway use
- Capital expenditures for computers and peripheral data processing equipment
- Capital expenditures for all other machinery and equipment

Waste variables:
- Refuse removal including hazardous waste

To map lean operations of all U.S. manufacturing industries, we conduct a cluster analysis based on lean-related variables listed above.

In cluster analysis, a cluster is considered a group of observations such that the distance of the observation from the cluster centroid is the shortest of the distances between that observation and the centroids of all the clusters. Typically, the assignment of an observation to a cluster is a result of an iterative process during which the cluster centroids may change as more observations are added to a given cluster, and some observations previously assigned to one cluster may be reassigned to another cluster.

There are multiple ways to start cluster analysis. In this research, we follow Nag et al. (2015) to employ non-hierarchical, *k-means* clustering, a process that demonstrates stability and relatively low sensitivity to data outliers. *K-means* clustering typically starts with a user-defined or randomly generated number of *k* initial clusters.

Each six-digit NAICS industry in the dataset is assigned to one cluster with the nearest Euclidean distance to the centroid of the cluster. As one cluster gains an observation, the centroid of the cluster is recalculated, and observations may be reassigned accordingly. The iterative algorithm stops when the within-group sums of squared errors, as measured by Euclidean distances from each observation, are minimized.

Our objective is to group U.S. manufacturing industries of similar lean characteristics into clusters so that manufacturing industries in the same group have the most commonality of lean operations and manufacturing industries across different groups differ most from each other in terms of lean operations.

Case Studies

We will conduct case analysis of selected industries in each of the clusters identified in the stage of cluster analysis. We believe that a multiple case study will provide further insights into the lean operations of U.S. manufacturing industries.

DISCUSSIONS AND CONCLUSIONS

This study aims to map the lean operations of all U.S. manufacturing industries based on cluster analysis of U.S. Economic Census data. This paper has completed literature review and conceptual development. We have also collected data, identified research methodologies appropriate to our research objectives and data. It is promising when data analysis is complete at a late stage. We then shall be able to conduct further case studies to complete cluster analysis and provide further insight into the lean operations of U.S. manufacturing industries.

Alignment of Benchmarking Performance Metrics: A Perspective on Managerial Positions

(Full Paper Submission)

Mohammad Z. Meybodi
Indiana University Kokomo
mmeybodi@iuk.edu

ABSTRACT

This focus of this article is to examine consistency of benchmarking performance metrics at various levels of an organization. The article also examines the role of managerial positions on deployment of consistent strategic and tactical benchmarking performance metrics. Statistical results show evidence of misalignment between organizational strategy and proactive development of organizational core competencies. The results indicate that managers at the higher-level positions typically place more emphasis on strategic benchmarking performance measures while managers at the lower level of the organization place more emphasis on tactical benchmarking performance metrics. Utilizing consistent benchmarking performance metrics require a thorough understanding of organizational strategy and deployment of the strategy into tactical strategies.

KEY WORDS: Benchmarking Performance Metrics

INTRODUCTION

In today's global competitive market, world-class organizations consistently utilize benchmarking to improve their competitiveness in the market by improving elements such as cost, quality, delivery, agility, and customer service. Benchmarking may be defined as the process of learning from the best-in-class organizations, determining how the best-in-class achieve those performance levels, and utilizing the best practices to their own company to achieve superior performance (Ferreira de Castro and Frazzon (2017), Watson (1992), Camp (1989), Whiting (1991)). Benchmarking is a flexible tool that can be used for gradual continuous improvement, as well as for major changes of process reengineering. Benchmarking is an effective means for learning and change because it exposes employees to new approaches, systems, and procedures (Welch (1993), Kuebler (1993)). Deming (1982) and other quality advocates (Graham (1993) and Venetucci (1992)) have strongly recommended the use of benchmarking as an essential component of continuous improvement.

The use of benchmarking as an effective quality improvement tool was started by Xerox in the early 1980's to overcome severe international competition. Also, since 1987, benchmarking has been a major component of the Malcolm Baldrige National Quality Award criteria. Since 1987, out of a total of 1000 Baldrige points, benchmarking has consistently influenced more than 500 points, Bogan and English (1994). No other quality elements, such as process management, employee involvement, and quality planning, have had such a broad influence on the Baldrige criteria than benchmarking. More recently, the practice of benchmarking is being widely used by

six sigma process, agile manufacturing, supply chain management, and for organizations seeking ISO 9000 certification (Arya et.al (2017), Faisal et.al.(2017).
Since the early 1980's, application of benchmarking in various businesses, ranging from manufacturing to health care, marketing, supply chain, human resources, and accounting has been widely reported. Harrison (1999) presents a detailed analysis of the evolution of different aspects of benchmarking activities. A comparison of the Xerox and Kodak benchmarking process has been reported by Bogan and English (1994). Although the two benchmarking methods utilize different numbers of steps, their overall logic is quite similar. Zairi and Whymark (2000) report successful results of the application of benchmarking at British Royal mail. Applications of benchmarking to world-class purchasing and to US service sectors have been reported respectively by (Newman, Hanna, and Duffett (1995) and Roth et.al. (1997)). The use of benchmarking as an effective organizational learning tool has been presented by (Tasopoulou and Tsiotras (2017), Souliotis et.al. (2017), Senge (1990), Garvin (1993), Ford and Evans (2001), Smith (1997), Hambly (1997), Watson (2001), Chen and Paetsch (1995), O'Dell and Grayson (2000), Routroy and Pradhan (2013), and Evans and Dean (2003)). A comprehensive list of legal and ethical issues of benchmarking is presented by Brue (2002), Vaziri (1992), and Bogan and English (1994)).
Although the content of the above articles is diverse, their primary focus, however, has been on short term financial and operational aspects of benchmarking. These articles generally address the technical aspects of departmental benchmarking along with limited success stories. As argued by (Furey (1987), Goldwasser (1995), Kaplan (1992), and Talluri and Vazacopoulos (1998)) effective benchmarking is more than comparative analysis of quantitative metrics from one company to another. To take full advantage of benchmarking, the benchmarking activities need to be integrated into organizational strategy and the process employs a broad range of performance measures consistent with organizational strategy.
The aim of this article is to examine consistency of organizational strategy and to investigate the impact of managerial positions on the alignment of benchmarking performance metrics. Specifically, the focus of the article is to answer the following questions:

1. Are long term corporate goals and objectives consistent with their core competencies?
2. Are long term corporate goals and objectives consistent with detecting environmental factors?
3. Are corporate competitive priorities consistent with their long-term strategies?
4. Are corporate competitive capabilities consistent with their competitive priorities?
5. Are there relationships between managerial positions and selection of benchmarking performance metrics?

BENCHMARKING AND PERFORMANCES MEASREMENTS

Total quality management (TQM), Just-in-time (JIT) systems, proliferation of new technologies, and a number of other important events during the last two decades have helped organizations to recognize the importance of benchmarking and performance measurements in managing complex processes. Managers across various industries have recognized the importance of managing processes and the truth that what gets measured is what gets managed and improves. Special focus of Malcolm Baldrige National Quality Award on benchmarking and performance measurements is a clear indication of the critical role of these elements in managing and improving organizational processes (Ferreira de Castro and Frazzon (2017), Dewan et al. (2013), Potdar et al. (2017), Kafetzopoulos, Gotzamani, and Psomas (2013)).
In the past, organizations generally used performance measurements that contributed mainly to short-term financial and technical results. How the organization achieved those results and their impact on the entire organization was unimportant Eccles and Nohria (1992). Today, managers understand that focus on short-term financial and technical results without consideration to

overall organizational strategy could produce devasting results over the long term. As a result, organizations are learning to manage the system in a way that crosses traditional departmental boundaries. In this new horizontally integrated system, organizations need to accept a long-term perspective and utilize balanced, financial and nonfinancial performance measures to carefully improve the competitiveness of the entire organization. The approach requires that benchmarking organizations develop a complete understanding of their own business strategy and deployment of the strategy into functional strategies. This process will ensure that there is a consensus within the organization about long term and short-term performance measures that are consistent with organizational mission and goals (Papke-Shields et. al. (2000), Madigan (1992)).

METHODOLOGY

A questionnaire-based survey was used to examine the above questions. The part of the survey related to this article contains a series of questions on the use of strategic and tactical benchmarking metrics. Strategic questions are concerned about organizational mission and goals, as well as attitude toward customers, competition, technology, globalization, quality, and employee developments. Tactical items are related to specific technical performance measures such as cost, quality, and delivery.
The target population for this study consisted of manufacturing firms in the Midwestern United States. A sample of manufacturing firms with more than 50 employees was chosen from Midwestern manufacturers' directories. The sample covers organizations in a variety of industries ranging from fabricated metal, communication, electronics, automotive, toots, chemicals, rubber, and paper products. In addition to general organization and managerial profile items, the survey contained a series of questions regarding organizational goals and objectives, competitive priorities, manufacturing performance objectives, and manufacturing action plans.
The survey data indicates majority of respondents had various high level managerial positions from organizations with less than 500 employees. Presidents and vice presidents accounted for 29% and plant managers accounted for 30% of the sample. About 35% of the sample had other managerial positions such as operations/production managers, quality managers, and the remaining 6% were production line supervisors. In terms of manufacturing experience, about 28% of the respondents had between 10 to 20 years and 60% had more than 20 years of manufacturing experience.

RESULTS

Table 1 shows the ranking of the mean importance score for each element of corporate goals and objectives and. Table 2 also shows the mean importance rating for corporate core competencies and elements of environmental factors. The respondents were asked to rate each element based on the degree of importance (1=low importance, 5=high importance) to their company for the next five years.

Table 1. Mean Importance Rating for Corporate Goals and Objectives
(1=low importance, 5=high importance)

Element	Mean	SD
Build market share	4.76*	1.27
Maximize profits	4.61*	1.32
Focus on customer satisfaction	4.52*	1.15

SD = Standard Deviation, * = Statistically larger than the Means in Table 2 at α = 0.05

Table 2. Mean Importance Rating for Core Competencies and Environmental Factors

Element	Mean	SD
Build and exploit core competencies	3.74	1.39
Understand competitors' strategy	4.14	1.21
Understand global strategies	3.88	1.37
Understand technology	3.91	1.32

SD = Standard Deviation; The means are statistically smaller than the means in Table 1 at α = 0.05

Table 1 indicates that the respondents' top three corporate goals and objectives are building market share, maximizing profits, and focusing on customer satisfaction. Being in a better competitive position with respect to quality and customer satisfaction are reasonable explanation for market expansion and profit making. However, the mean rating for the four elements of core competencies and environmental factors in Table 2 are significantly lower than the mean rating of the three elements of corporate goals and objectives in Table 1 at 0.05 level of significance. This is perhaps an indication of traditional reactive strategy in which the primary focus of managers is on marketing and financial goals. Understanding external environmental factors such as competition, global issues, technology, and development of core competencies to effectively deal with these factors is considered to be secondary. This is a rather disturbing posture because in today's global market world-class organizations focus more on building core competencies than on achieving marketing and financial goals. They develop core competencies first, then utilize a proactive strategy and look for opportunities to exploit their core competencies to achieve a competitive advantage. Understanding the causes for such strategic misalignment between corporate goals and objectives and proactive development of core competencies is extremely important.

Table 3. Mean Importance and Capability Rating for Competitive Priorities
(1=low importance, 5=high importance) (1=weak strength, 5=strong strength)

	Importance		Capability			
Element	Mean	SD	Mean	SD	t-value	p-value*
Product reliability	4.69	1.16	3.56	1.24	4.21**	0.000
Conformance quality	4.58	1.28	3.84	1.14	1.34	0.090
Delivery reliability	4.47	1.24	3.78	1.32	2.57**	0.005
Product customization	4.35	1.36	3.42	1.09	3.46**	0.000
NPD speed	4.29	1.23	3.35	1.36	3.50**	0.000
Price	4.16	1.34	3.96	1.25	0.75	0.230
Fast delivery	4.03	1.32	3.82	1.19	0.78	0.210
Performance	3.98	1.22	4.22	1.28	0.89	0.190
Service after sales	3.84	1.44	4.18	1.23	1.27	0.100
Volume flexibility	3.62	1.31	4.32	1.37	2.61**	0.005

* Small p-value indicates the difference between two means is statistically significant
** Mean strength is less than mean importance at alpha = 0.05

Table 3 shows the mean importance and capability rating for each element of competitive priorities. The importance rating is similar to the one stated earlier. From Table 3, the respondents ranked product reliability, conformance quality, delivery reliability, product customization, and new product development speed as the top five important competitive priorities. The ranking of product reliability and conformance quality as the top two competitive priorities is consistent with corporate goals and objectives. It indicates that managers believe that quality factors are still important elements of competitive advantage. However, the ranking of delivery reliability, product customization, and new product development speed as the next three competitive priorities indicate that the respondents also believe on the importance of time based competition and product customization. Overall, one can argue that the importance ranking of top five competitive priorities is consistent with recent manufacturing literature and with organizational strategy of market expansion, profitability, and customer satisfaction. Table 3 also shows that low price as an element of competitive priorities ranked sixth. This rather interesting result indicates, unlike traditional thinking, the responding managers believe that low price is no longer the primary elements of competitive advantage. Relative low ranking of price along with the last four competitive priorities is perhaps an indication that these elements represent order qualifiers and the top five factors are order winners. In other words, competitive market considers the last five competitive priorities as given. To attract customers, organizations need to perform on the basis of top five competitive elements.

To understand organizational competitive capabilities, the respondents were asked to rate relative competitive capabilities of their organization with respect to the competitors who are doing best in that area. A five-point scale, where 1 corresponds to weak and 5 corresponds to strong, is used to indicate managers' perceptions of the company's current competitive capability relative to the best competitors. The mean competitive capability scores for each element of competitive priorities are shown in Table 3. Statistical tests indicate that, for the top five competitive priorities, the mean competitive capability is significantly lower than the mean importance. This is evident because with the exception of conformance quality, the p-value for other four competitive priorities is less than 0.005. This indicates, although managers ranked product reliability, conformance quality, delivery reliability, product customization, and new product development speed as the top five important competitive priorities, organizational competitive capability for those elements, however, is not that strong. On the other hand, the mean competitive capability for the last three competitive priorities is greater than the mean importance indicating that managers believe their competitive capabilities in the areas of performance quality, service after the sales, and volume flexibility are quite strong. This imbalance between importance and actual capability for the top five competitive priorities is perhaps a critical area that needs to be investigated.

Table 4. Strategic and Tactical Benchmarking Performance Elements

Strategic Elements	**Tactical Elements**
Develop mission and goals (DMG)	Reduce percent defects (RPD)
Develop core competencies (DCC)	Reduce percent errors (RPE)
Understand competitors' strategies (UCS)	Reduce labor costs (RLC)
Develop global strategies (DGS)	Reduce materials costs (RMC)
Develop technology strategies (DTS)	Reduce overhead costs (ROC)
Focus on customer satisfaction (FCS)	Reduce inventory costs (RIC)
Adopt TQM philosophy and practices (TQM)	Reduce set-up/changeover costs (RSUC)
Change organizational culture (COC)	Increase labor utilization (ILU)
Improve interfunctional communication (IIFC)	Increase equipment utilization (IEU)
Improve employee training (IET)	Improve process capability (IPC)
Improve employee empowerment (IEE)	Improve quality circle practices (IQCP)
Improve employee team work (IETW)	Utilize quality improvement tools (UQIT)
Install continuous improvement (ICI)	Utilize statistical process control charts
Adopt quality at the source (AQS)	Increase delivery speed (IDS)
Improve supply chain management (ISCM)	Increase product development speed
Improve supplier relationships (ISR)	Reduce manufacturing lead time (RMLT)
Eliminate wastes (ELW)	Increase delivery reliability (IDR)
Reengineer new product development (RNPD)	Increase new product customization

Table 4 shows the listing of strategic and tactical benchmarking metrics. Table 5 and 6 lists respectively the mean importance score for strategic and tactical benchmarking metrics. Each Table shows the mean and the standard deviation of importance rating for two managerial positions. In Tables 5 and 6, the responses from the presidents, vice presidents, and plant managers are grouped under managerial positions at the higher level of the organization and the responses from operations/production managers, quality managers, and supervisors are grouped under managerial positions at the lower level of the organization.

Table 5. Ratings for Strategic Benchmarking Performance Elements
(1=low importance, 5=high importance)

	Managerial Positions				
	Higher		Lower		
Element	Mean	SD	Mean	SD	t-value
DMG	4.63	1.92	3.56	2.11	2.34*
DCC	4.32	1.83	3.24	1.74	2.70*
UCS	4.65	1.76	3.76	1.85	2.21**
DGS	4.51	1.85	3.52	1.63	2.54*
DTS	4.49	1.68	3.46	1.75	2.69*
FCS	4.72	1.64	4.53	1.67	0.51
TQM	4.62	1.55	3.66	1.64	2.69*
COC	4.32	1.87	3.34	1.62	2.51*
IIFC	4.46	1.78	3.82	1.83	1.59
IET	3.92	1.66	4.20	1.47	0.80
IEE	3.75	1.45	4.14	1.69	1.33
IETW	4.51	1.62	3.78	1.85	1.88**
ICI	4.57	1.34	4.43	1.95	0.37
AQS	4.34	1.40	4.53	1.68	0.55
ISCM	4.47	1.87	3.67	1.48	2.12**
ISR	4.56	1.74	3.98	1.78	1.47
ELW	4.58	1.67	3.55	1.57	2.84*
RNPD	4.46	1.66	3.53	1.52	2.61*

SD= standard deviation, * = significant at 0.01, ** = significant at 0.05

In Tables 5 and 6, the respondents were asked to rate each element based on the degree to which they believe the factors are important (1=low importance, 5=high importance) to be used for benchmarking performance metrics. Table 5 indicates that overall managers at the higher level positions rated strategic elements higher than the managers at the lower level positions. This is evident because, with the exception of two, the mean ratings for these elements are above 4.00. Also, statistical tests indicate that out of 18 tests, 11 were statistically significant at least at a 0.05 level of significance; meaning for the strategic elements managers at the higher level positions rated these elements significantly higher than the managers at the lower level positions. For the strategic elements such as customer satisfaction, inter-functional communication, employee training, employee empowerment, continuous improvement, quality at the source, and supplier relationships, the mean ratings for managers at the higher level positions were not significantly different than the ratings for mangers at the lower level positions. One possible explanation for such result would be the popularity of these elements. Since these are well known TQM elements, managers at both levels believe on the importance of these strategic benchmarking elements. However, believing on the part of the managers at the lower levels does not necessarily translate to consistent actions. It is interesting to note that managers at the lower level positions rated the strategic elements employee training, employee empowerment, and quality at the source higher than the managers at the higher level positions.

This result was expected because managers at the lower levels are closer to employee related issues than managers at the higher levels.

Table 6. Ratings for Tactical Benchmarking Performance Elements
(1=low importance, 5=high importance)

	Managerial Positions				
	Higher		Lower		
Element	Mean	SD	Mean	SD	t-value
RPD	4.02	1.83	4.73	1.87	1.74**
RPE	4.07	1.65	4.75	1.86	1.75**
RLC	3.65	1.92	4.63	1.72	2.40*
RMC	3.54	1.82	4.58	1.69	2.65*
ROC	4.22	1.75	4.71	1.58	1.25
RIC	4.13	1.62	4.75	1.69	1.82**
RSUC	4.52	1.73	4.69	1.67	0.45
ILU	4.64	1.48	4.42	1.83	1.13
IEU	3.83	1.67	4.68	1.76	1.72**
IPC	4.13	1.59	4.76	1.55	1.79**
IQCP	3.63	1.78	4.71	1.58	2.87*
UQIT	4.05	1.59	4.73	1.93	1.72**
USPC	4.08	1.73	4.78	1.61	1.87**
IDS	4.22	1.68	4.37	1.72	0.39
IPDS	4.23	1.71	4.38	1.57	0.41
RMLT	4.04	1.84	4.78	1.73	1.85**
IDR	4.66	1.42	4.14	1.76	1.45
INPC	4.55	1.72	3.62	1.81	2.36*

SD= standard deviation, * = significant at 0.01, ** = significant at 0.01

Table 6 shows, unlike strategic elements, overall managers at the lower level positions rated tactical factors higher than the managers at the higher level positions. With the exception of one, the mean ratings for managers at the lower level positions are above 4.00. Also, statistical tests indicate that out of 18 tests, 12 were statistically significant at least at a 0.05 level of significance, meaning for tactical elements, managers at the lower level positions rated these factors significantly higher than the managers at the higher level positions. This result is consistent with manufacturing literature because managers at the lower levels positions have tendency to focus more on tactical cost cutting and quality improvement measures. This is perhaps due to miscommunication with the higher level managers or the result of inconsistent evaluation and reward system for managers at the lower levels. That is, regardless of organizational strategy, managers at the lower levels are often rewarded based on their cost cutting measures or efficiency in capacity utilization. The ratings for the tactical elements reducing overhead and set-up costs, increasing delivery and product development speed, and increasing delivery reliability for the two managerial levels were not significantly different. Perhaps due to popularity of these elements, managers at both levels believe on the improvement of these tactical benchmarking elements.

CONCLUSION

This article demonstrates how understanding organizational strategy is crucial to improve the effectiveness of benchmarking metrics. The article investigates the impact of managerial positions on the deployment of strategic and tactical benchmarking performance metrics. Five questions were asked to investigate the consistency of the decisions and to examine the relationship between managerial positions on the selection of strategic and tactical benchmarking performance metrics. Summary of the results indicate: 1) Possible misalignment between corporate goals and objectives and proactive detection of environmental factors. 2) Inconsistencies between corporate goals and objectives and development of corporate core competencies to effectively deal with the environmental factors. 3) Potential mismatch between organizational competitive priorities and their core competencies. 4) Overall, managers at higher level positions rated strategic elements significantly higher than the managers at the lower level positions. 5) Managers at the lower level positions rated tactical elements higher than the managers at the higher level positions. This result is consistent with manufacturing literature because lower level managers often have tendency to focus more on tactical cost cutting and quality improvement measures. 6) For strategic elements such as customer satisfaction, interfunctional communication, employee training, employee empowerment, continuous improvement, quality at the source, and supplier relationships the mean ratings for managers at the higher level positions were not significantly different than the mean ratings for managers at the lower level positions. Since these are well known TQM elements, perhaps managers at both levels believe on the importance of these strategic benchmarking factors. 7) The mean ratings for tactical elements of reducing overhead and set-up costs, increasing delivery speed and delivery reliability for the two managerial levels were not significantly different. Since these are well-known just-in-time elements, perhaps managers at both levels believe on the improvement of these tactical benchmarking elements.

In summary, the article showed evidence of misalignment, inconsistencies, and lack of consensus among managers at different levels of organization in choosing benchmarking performance metrics. To be effective, managers must develop a complete understanding of their own strategy and choose long term and short term benchmarking performance metrics that are consistent with organizational strategy.

ABSTRACT

Lean Six Sigma (LSS) rises as a viable alternative with its ability to aid in transforming a culture through continuous improvement and saving on cost. In order to provide data on its application and impact, this case study considers an injection molding process and demonstrates how to improve the quality of manufactured plastic components, eliminate waste, reduce the component variation and increase the output yield by applying Lean Six Sigma methodology. Design of Experiment (DOE) is used to identify the key process input variables (KPIVs) which have significant influence on the output of the plastic component.

KEYWORDS: Lean Six Sigma, customer satisfaction, design of experiment, molding, technology management.

INTRODUCTION

As global competition continues to rise, the pressure to improve efficiency becomes more and more intense. Under constant pressure to achieve more with less, only the firms that deliver superior value and produce world class quality in its all processes will remain competitive in the market. Corporations that can reduce costs, eliminate waste, minimize defects, decrease lead times, improve quality, enhance customer satisfaction, and transform a culture through continuous improvement will be the ones to operate successfully in the long term (Zhang et al., 2016b). To ensure their sustainability many of these corporations today are turning to process improvement methodologies such as Lean Six Sigma to improve and sustain their business operations. Lean Six Sigma is a continuous improvement methodology that combines two of the most powerful improvement disciplines. Lean was developed by Toyota Motor Corporation (Jiang et al., 2004) and Six Sigma was developed by Motorola (Dakhli et al., 2016). Lean focuses on elimination of waste, non-value added activities and increasing process efficiency through a focus on improvement in speed and cost. Six Sigma on the other hand, focuses on reduction of process variation and drastic elimination of defects with an emphasis on improvement in quality (Ben Ruben et al., 2017). The two methodologies are harmonized, and there is strong evidence that total improvement in a process is greater if Lean and Six Sigma are implemented together (Zhang et al., 2016b).

Lean Six Sigma is a well-established methodology for improvement the organizational effectiveness. The goals of Lean Six Sigma include building a world-class organization, developing leaders, creating a culture of continuous improvement (Erdil et al., 2018). Lean Six Sigma consists of five basic phases, Define, Measure, Analyze, Improve, and Control (Desai, D. A., 2006), and hence the process is also known as DMAIC(Antony et al., 2017).

Lean Six Sigma has been implemented very successfully in many large corporations such as Honeywell, Johnson & Johnson, General Electric, Boeing, Merck, Aetna, and Quest Diagnostics (Chakrabarty and Tan, 2007) and in some small and medium sized manufacturing enterprises (SMEs) (Kumar et al., 2006).There is, however, still a gap when it comes to the applications of Lean Six Sigma tools (Vo et al., 2019), specifically on how Lean Six Sigma is implemented in small organizations (Lande et al., 2016). The objective of this research is to investigate the steps and effects of Lean Six Sigma program on a consumer packaging company which is located in the United States.

LITERATURE REVIEW

Lean Manufacturing

Lean manufacturing is considered to be a long term philosophy that aims at continuous growth by creating value for the customer, societies, and economy by decreasing costs, improving quality and delivery through the elimination of waste (Houborg, 2010). Lean production system, aka Toyota Production System, is a world renowned production system developed and practiced by Toyota for a long time (Jiang et al., 2004). As Jones et al. (1999) points out the principles of 'lean thinking' aim at eliminating waste and focusing on those activities which add value for the customers (Jones et al., 1999). Waste, often known as muda, consists of seven types: Defects, Overproduction, Transportation, Waiting, Inventory, Motion, and Processing (Sternberg et al., 2013). Apparently, eliminating of waste relatively looks simple and straightforward, but it is often difficult to identify what is waste and what is not in most organization (Ghosh, 2013).

Six Sigma

Six Sigma is a management philosophy developed by Motorola to improve processes by reducing process variation and eliminating defects (Antony et al., 2017). The Greek letter sigma is used to denoted variation from a standard. In order for the organization to achieve Six Sigma Process, it can't produce more than 3.4 defects per million opportunities or 99.99966% defect free over the long-term. Six Sigma methodology makes use of many tools and techniques to enable continuous improvement. The most frequent statistical tools used are pareto chart, histogram, gage R&R, attribute agreement analysis, and process capability (Prashar, 2014).

Lean Six Sigma

Lean Six Sigma is a process improvement approach that consists of tools and methods of both Lean and Six Sigma (Zhang et al., 2016a) and aims to provide customers with the best possible quality, cost, and speed (Dakhli, et al., 2016). In the recent years, there has been a noticeable increase in LSS popularity and deployment in manufacturing and service industry (Lim et al., 2015). A synergy between Lean and Six Sigma would maximize the strengths and minimize the weakness of both methodologies when used alone (Timans et al., 2012)

Design of Experiments (DOE)

Design of Experiments (DOE) and statistical analysis of variance approach were developed by Fisher in 1930 (Box, 1980). DOE is commonly used to optimize industrial process (Dowlatshahi, 2004) and in this study it is utilized to optimize the injection process. Optimization is a mathematical approach to tackle the problems and widely used in many different areas. A full factorial design DOE with replicate and center points are suggested for a study if applicable. The next section explains how to carry the DOE design and analysis needed to identify the factors that have the most influence on the injection molding process (Timans et al., 2014).

METHODOLOGY

The purpose of this research is to explore Six Sigma tools and techniques that were applied to improve the process capability of torque retention for a cosmetic pump. The case study describes the impact of Lean Six Sigma on reducing component defects by optimizing the injection molding process. Rigorous use of the Lean Six Sigma methodology and application of each step of the DMAIC roadmap are essential in process improvement implementation. The design of the study and the type of data are clearly defined and described for the injection molding process. The statistical analysis, interpretations of the statistical results and graphical tools are presented along with the conclusions and recommended actions at the end of this article.

The execution of Define process for this project included approved project charter, a process map/SIPOC, and project Y's. During Measure phase, C&E matrix, FMEA and project baselines were established. Analysis included basic statistics and graphical summary, and hypothesis testing. The Improve phase included the identification of the solutions implemented above. Finally, pFMEA, validation and verification, and control plan were updated during the Control Phase.

CASE STUDY

The company in this case study was founded over half a century ago and is publicly held. It provides consumers all over the world with state-of-the art packaging materials in the beauty, health care, personal care, home care, food, medical, and prescription drug segments. The product in focus is a dispensing pump system which comprises of dust cap, actuator, insert, fixture, gasket, cartridge, and dip tube. All plastic components were molded and assembled into a finished pump by the company which recognizes as a leader in the global packaging and dispensing industry.

Recently, the company received a high count of customer complaints related to dust cap separated from the pump during transportation. In addition, it has been noticed that a number of lots failed to meet a minimum torque retention at the final inspection. The project was initiated to decrease the customer complaints and reduce cull/rework related defects. The Lean Six Sigma methodology was applied to identify the root causes of the defects and unitized design of experiment (DOE) to improve the process to achieve higher customer satisfaction and to reduce operational cost.

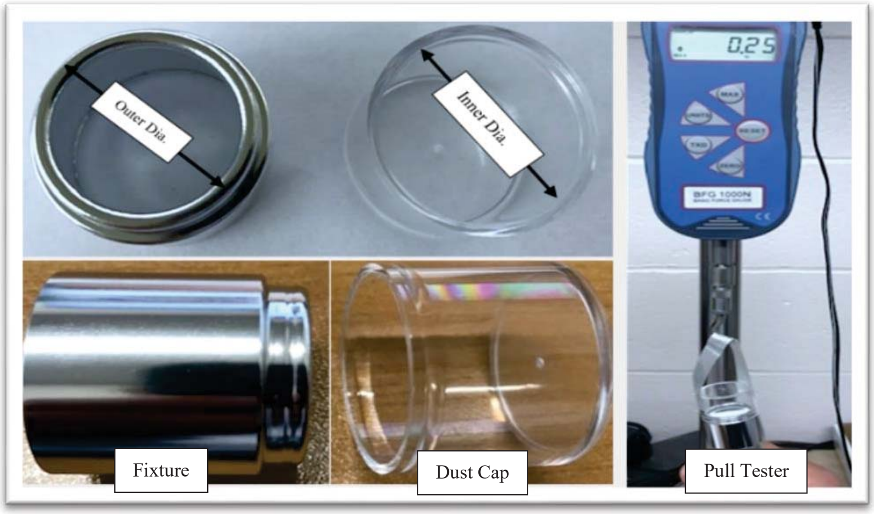

Fig. 1: Product

Table 1: Product specifications

Torque retention specification	1.5 – 4.0 lbf
Product scrap rate (OOS)	15%

The resin material which used to mold the dust cap is Polypropylene (PP) with 35 percent glass reinforced which is a high impact grade PP resin for injection molding. The mold has 32 cavities in which every cycle of the injection molding process produces 32 dust caps. The process of injection molding of the dust cap comprises a combination of heat, pressure and time parameters. The resin is compressed in a heated cylinder by means of a reciprocating screw and injected into a mold cavity. The mold is cooled to solidify the part before it is ejected out of the cavity.

Define Phase

The first phase of the DMAIC methodology is to define the problems through the voice of the customer/business, SIPOC, and project map. The critical to quality (CTQ) characteristics in the study is an interference fit of two components (dust cap and fixture) in which the inner diameter of the dust cap slightly exceeds the outer diameter of the fixture (Fig. 1). It is critical that the dust cap must be applied tight enough to maintain a good seal to the fixture, and there is a gentle pull onto the dust cap to remove it from the fixture. The customer specification of cap removal (torque retention) is from 1.5 lbs. to 4 lbs.
Given the mold design and material resin, the goals of the project are defined as follows in the Define phase:

- Identify the process parameters that have impact on torque retention
- Establish a range of the process parameters for those significant parameters.
- Determine optimal set-points for the process parameters.

Furthermore, a SIPOC map of an injection molding process, the Suppliers (the 'S'), the Inputs (the 'I'), the Process (the 'P'), the Outputs (the 'O'), and the Customers (the 'C'), was used to identify all pertinent elements of a process improvement project before work began. The project team consisted of the facility manager, the Director of Quality, the Manager of the Advanced Quality Planning, the floor supervisor, and the machine operator. The map allowed the team to identify the areas of opportunity for improvements and determined where resources should be allocated.

Suppliers (S)	Inputs (I)	Process (P)	Outputs (O)	Customers (C)
Resin supplier Colorant Supplier	Materials Machine Personnel Equipment Mold	W/O & Schedule ↓ Pickup Mold from Tool ↓ Hang Mold ↓ Mold & Machine ↓ Mold & Machine ↓ First Run ↓ Visual Inspection 1 ↓ Run ↓ Final Inspect ↓ Packaging	Molded components Quality records	Assembly Manufacturing

Fig. 2: SIPOC

Measure Phase

In order to determine the mutual relationships and contributing causes, a cause and effect (C&E) diagram was created for the injection molding process. The C&E identified which process inputs of the molding process had the most impact on the customer requirements. The Key Process Output Variables (KPOVs) from the process mapping were streamlined into project goals, and the numbers from 1 to 10 were scaled the importance to the project. Each of the input process steps was rated on a scale of 0, 1, 3, and 9. The highest scores were then determined to be included in the process failure modes and effects analysis (pFMEA). This funnel tool is a highly effective way of focusing on priorities of the project. The pFMEA, was then completed for the injection molding process to identify and evaluate the failure modes. The severity, occurrence, and detection multiplied together to form the risk priority number (RPN) which was used to rank and to focus the team on specific action items (Sekar and Santhosh, 2012). Any items with high RPNs, the recommended actions were identified to reduce the RPN, and the control plan was created to sustain corrective actions. Once the actions were implemented; the RPN was recalculated.

As part of the analysis, 100 samples were randomly collected and measured for the torque retention quality characteristic from the current multiple production lots. The torque retention data was then used in the process capability analysis to identify whether the process was producing results outside the specification limits to prevent further production of unacceptable products. Based on the results, Cp and Cpk indices are 1.64, and 0.41 respectively. These values indicated that the process is capable but is not centered and not performing within the specification limits, the process needs to be improved. Consequently, a high number of pumps failed to meet the torque retention specification as shown in Fig. 3.

Table 2: Summary Statistics

Variable	Count	Mean	StDev	Min	Median	Max	Data Normal?	Cpk
Torque Retention (N*m) (Current Production)	100	1.8	0.24	1.2	1.8	2.3	Yes	0.41

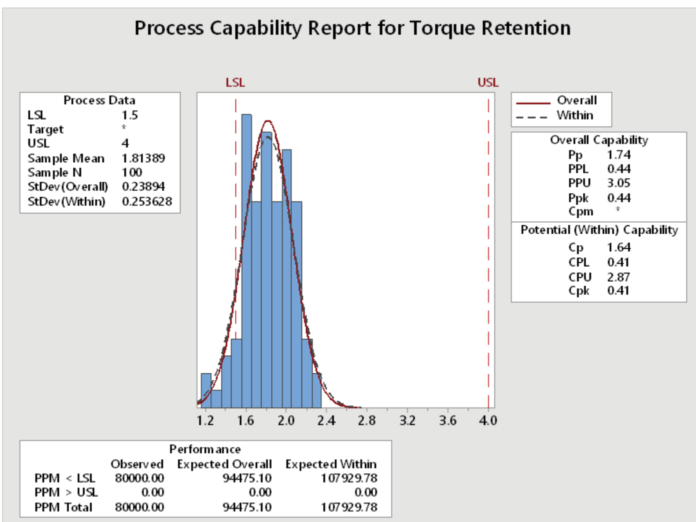

Fig. 3: Cpk Analysis of Torque Retention before Implementing DMAIC Methodology

Analyze Phase

In the analysis phase, the team identified the potential causes of variations in the process that affected the retention force using a cause and effect diagram. Figure 4 depicts all possible major causes that involve the injection molding process, i.e., temperature, pressure, speed, and time, and speed. Based on the resin material, mold design, flow mold analysis, pFMEA, and the data gathered from additional statistical analyses, the team determined four process parameters to be included in the design of experiments.

- Barrel Temperature (Tbarrel)
- Injection Pressure (Pinjection)
- Injection Speed (Sinjection)
- Hold Time (Thold)

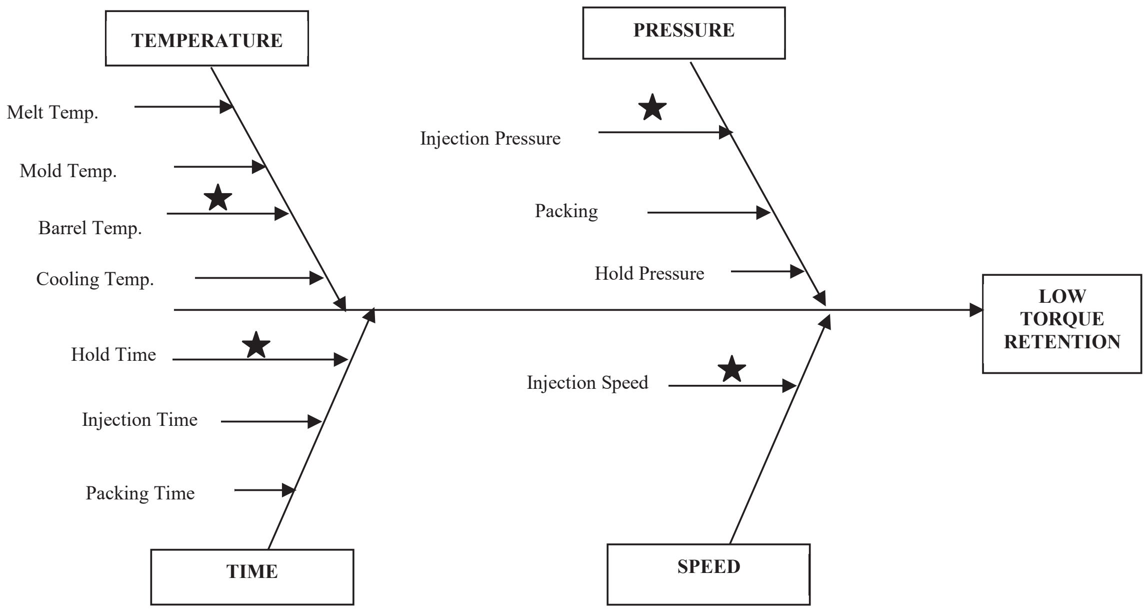

Fig. 4: Cause and Effect Diagram

Improve Phase

In order to study the effects of process parameters on the quality characteristics of interest, a design of experiment was carried out. A full factorial design consisted of four factors with two levels (low and high). Due to the production constraint, one replicate was applied in this study. A full factorial of 16 runs ($2^4 = 16$) was set. The quality characteristic of interest for this study was torque retention measured in pound-force unit. The torque retention will be the response output in the study.

Table 3: Level Values of Input Factors

Factors		Levels		Units
		Low	High	
A	Barrel Temperature (Tbarrel)	215	235	Degree
B	Injection Pressure (Pinjection)	30	45	PSI
C	Injection Speed (Sinjection)	40	50	ml/sec
D	Holding Time (Thold)	1.5	2.5	second

Table 4: Full Factorial Format with Torque Retention Data Applied

StdOrder	RunOrder	Barrel Temperature	Injection Pressure	Injection Speed	Holding Time	Torque Retention (lb-f)
16	1	235	45	50	2.5	2.3
12	2	235	45	40	2.5	2.3
2	3	235	30	40	1.5	2.4
1	4	215	30	40	1.5	0.7
6	5	235	30	50	1.5	2.8
13	6	215	30	50	2.5	0.9
8	7	235	45	50	1.5	2.9
15	8	215	45	50	2.5	2.5
10	9	235	30	40	2.5	2.6
7	10	215	45	50	1.5	2.6
3	11	215	45	40	1.5	2.5
11	12	215	45	40	2.5	2.5
5	13	215	30	50	1.5	0.6
4	14	235	45	40	1.5	2.7
9	15	215	30	40	2.5	0.8
14	16	235	30	50	2.5	2.7

Table 4 shows a total of 16 runs for each setting condition. Each trial was carried out by allowing the machine to run at least 10 cycles to stabilize the process condition before samples to be collected for testing. For instance, the first run order of the experiment, the process parameters were set for Barrel Temperature at 235, Injection Pressure at 45, Injection Speed at 50, and Hold Time at 2.5. All samples from the 16 runs were collected and stored for at a minimum of 24 hours at the ambient environment. The dust cap was assembled onto the pumps and then tested using the pull tester. The results were calculated and analyzed using Minitab v18.

To validate the data before analyzing, normality assumption was selected and checked for the error variables have a normal distribution. The normal probability plot was generated and showed that the data was normally distributed (Fig. 5). This plot illustrates that normality assumption is met for torque retention.

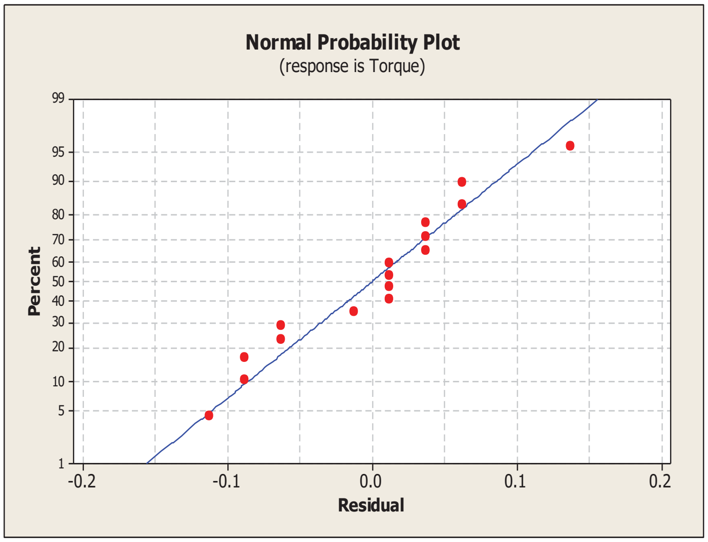

Fig. 5: Normal Probability Plot

The first step in the analysis was to identify any main and interaction factors that have influence the mean of torque retention. According to the Pareto chart of the standardized effects in Fig. 6, factors A (Tbarrel), B (Pinjection), AB (Tbarrel and Pinjection), BD (Pinjeciton and Tholding), and AD (Tbarrel and Tholding) have significant effect on the response. Since C, D, AC, CD, and BC terms are insignificant, these terms can be removed from the model. The design can be reanalyzed by choosing only significant factors A, B, AB, BD, and AD.

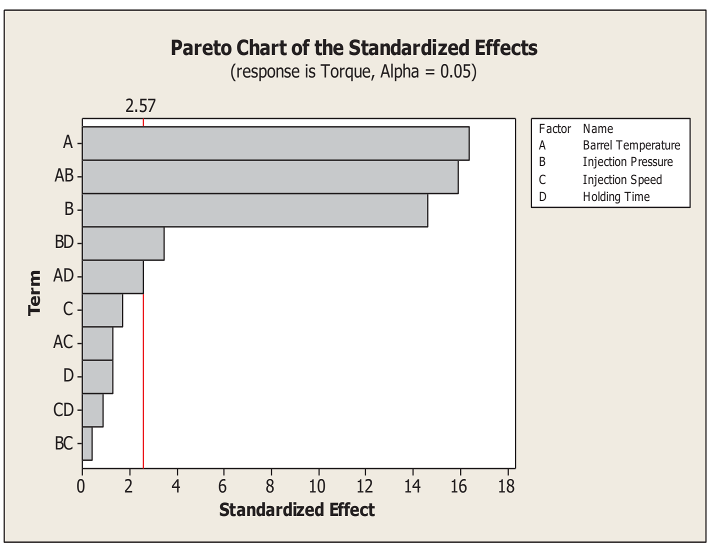

Fig. 6: Pareto Chart of the Standardized Effects

After eliminating the insignificant factors, the analysis which was rerun using significant factors that were identified in Fig. 6. The results confirmed that the factors A (Tbarrel), B (Pinjection), AB (Tbarrel and Pinjection), BD (Pinjeciton and Tholding), and AD (Tbarrel and Tholding) remained as significant factors. Given that factor AD had significant interaction; factor D is included in the analysis (Fig. 7)

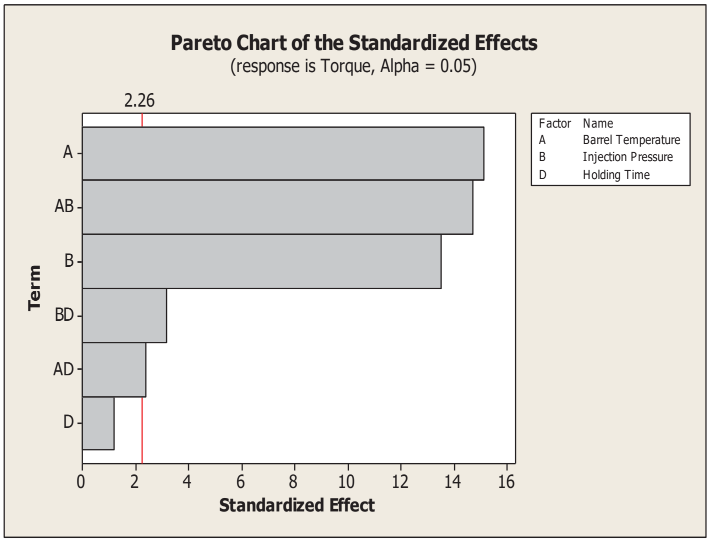

Fig. 7: Pareto Chart of the Standardized Effects

Next, since there are various factors that affect the response, an analysis of variance (ANOVA) was performed to determine the influential ones. If p-values were less than or equal to 0.05 (95% confidence level) they were considered as significant factors. According to the ANOVA output, the following factors were influenced to the torque retention: Two factors (Barrel Temperature and Injection Pressure) were significant. In addition the three interaction factors, “Barrel Temperature” and “Injection Pressure”, “Barrel Temperature” and “Holding Time”, and “Injection Pressure” and “Holding Time” were also significant.

Interpreting the ANOVA Results

Estimated Effects and Coefficients for Torque (coded units)

Total	15	10.3375			

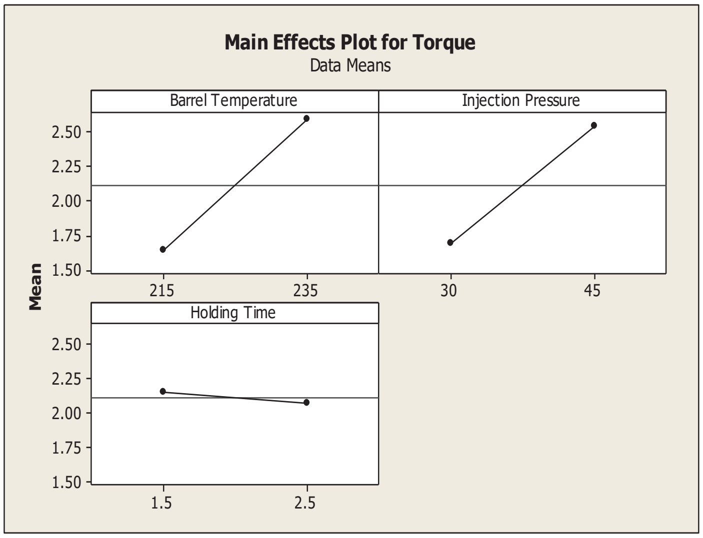

Fig. 8: Main Effects Plot

The Main Effects Plot in Fig. 8 indicates that A (Tbarrel) and B (Pinjection) affected the torque retention because the lines of mean were not horizontal. Both factors showed torque retention increased when the factors moved from the low level to the high level. In contrast, D (Thold) factor had no effect to the torque retention due to horizontal line (parallel to the x-axis).

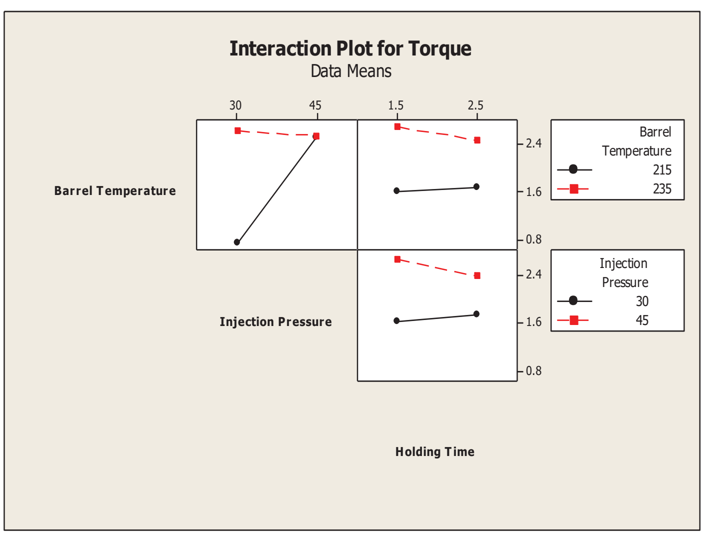

Fig. 9: Interaction plot

From the interaction plot in Fig. 9 it can be observed that the torque retention increases when A (Tbarrel) and B (Pinjection) are high.

The contour plot in Fig. 10 predicted that the torque retention response with the highest yield obtained when both A (Tbarrel) and B (Pinjection) factors were set at the high conditions.

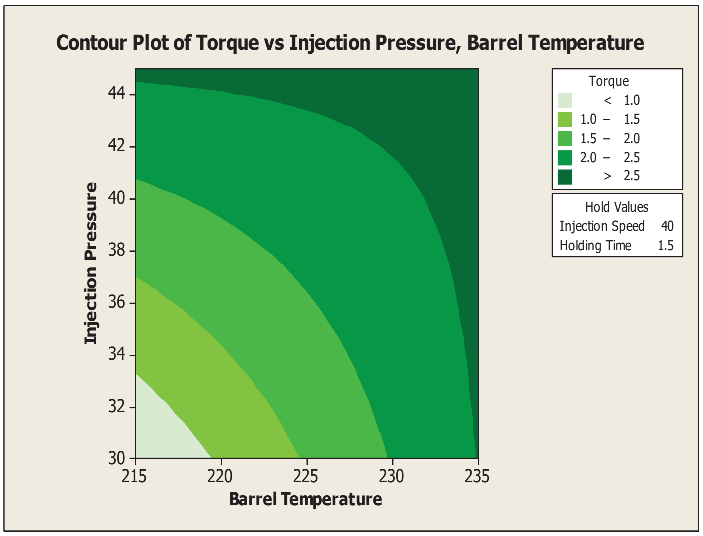

Fig. 10: Contour Plot

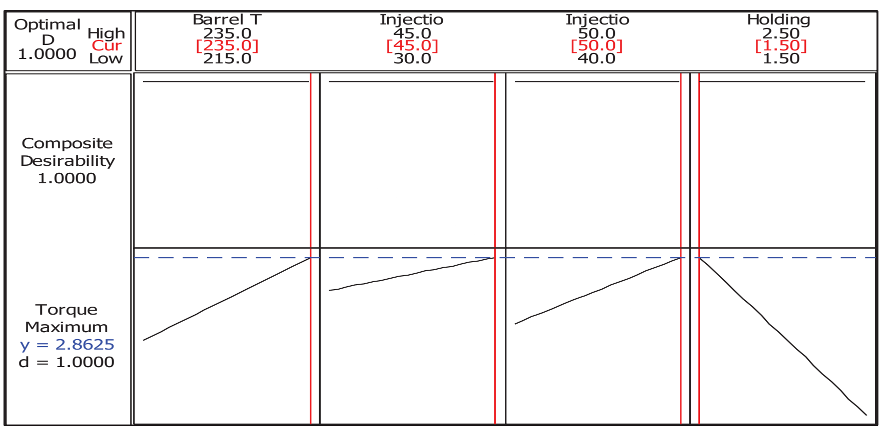

Fig. 11: Optimizer Plot

Applying the response optimization analysis, the process parameter settings at optimal conditions are as specified in Fig. 11. The composite desirability value was at 1 which is close to the best possible prediction.

In order to obtain the value of 2.86 lbf torque retention, the following process parameter settings should be set as follows; Factor A (Tbarrel) at 235º, Factor B (Pinjection) at 45 PSI, Factor C (Sinjection) at 50 seconds, and Factor D (Thold) at 1.5 seconds.

Control Phase

Update pFMEA

The pFMEA was updated to reflect the new process, including the changes, which eliminated several process steps. In addition, the incorporation of the recommended actions reduced the highest risks associated with the process.

Validation and Verification (V&V)

The injection molding process of the fixture is validated under change control request, including Installation Qualification (IQ), Optimization Qualification (OQ), and Performance Qualification (PQ). Proven Acceptable Range (PAR) challenges are completed and verified the process/product capability within specifications throughout the listed process ranges. These process parameters and their ranges are shown below:

Table 5: Proven Acceptable Ranges

Process Parameter	Low	Nominal	High
Barrel temperature (°C)	230	233	235
Injection Pressure (PSI)	42	44	45
Injection Speed (ml/sec)	45	47	50
Hold Time (sec)	1.5	1.6	1.8

Pilot run

One lot was run at the optimized settings of Barrel temperature would be set at 233º, Injection Pressure at 44 PSI, Injection Speed at 47 seconds, and Hold Time at 1.6 seconds. Quality Assurance collected and tested approximately 100 samples and recorded the results. The results are not only used to compare against the baseline data to show the process improvement but also are to validate if the desirable response (torque retention) is met.

Table 6: Individuals of Torque Retention (before vs. after) Improvement

Variable	Count	Mean	StDev	Min	Median	Max	Data Normal?	Cpk
Torque Retention (lbf) (Current Production)	100	1.8	0.24	1.2	1.8	2.3	Yes	0.41
Torque Retention (lbf) (After improvement)	100	2.9	0.20	2.3	2.8	3.4	Yes	1.87

2-Sample T-test

H_0: Torque Retention baseline ≥ Torque Retention after improvement.
Ha: Torque Retention baseline < Torque Retention after improvement.

Two-Sample T-Test and CI: Torque, Stage

```
Stage        N   Mean  StDev  SE Mean
After      100  2.853  0.200    0.021
```

```
Baseline   100  1.814  0.239    0.024

Difference = μ (After) - μ (Baseline)
Estimate for difference:  1.0388
95% CI for difference:  (0.9764, 1.1013)
T-Test of difference = 0 (vs ≠): T-Value = 32.81  P-Value = 0.000  DF = 189
```

Since the p-value= 0 and is less than .05, reject the null hypothesis. It can be concluded that the torque retention mean after improvement is higher than the torque retention baseline. Furthermore, the individual (I-Chart) clearly showed a step change after improvement (Fig. 11).

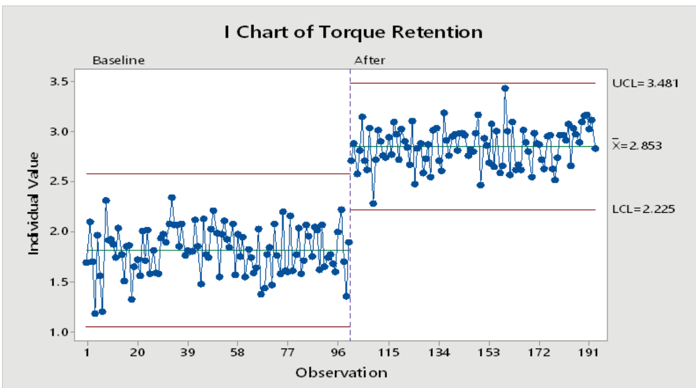

Fig 12: Individual Chart of Baseline vs. After Improvement

Lastly, Process capability analysis was re-analyzed for both Baseline and After Improvement. Both Cp = 2.037 and Cpk = 1.87(After Improvement) were achieved quality level and centering the specification range. This meant that the pumps passed torque retention specification, and the process was capable.

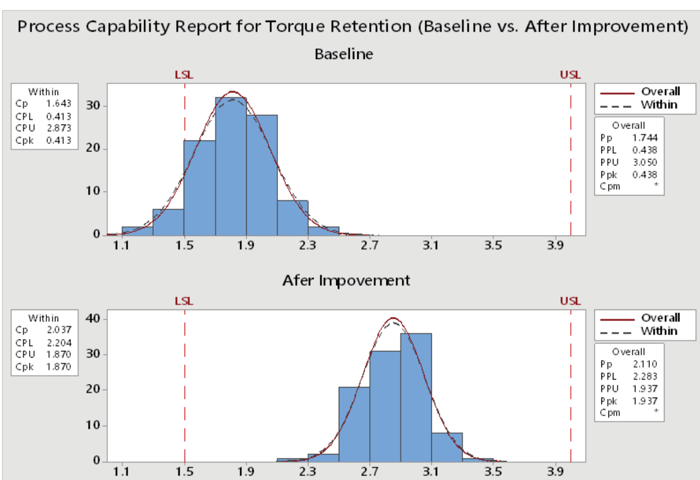

Fig. 13: Cpk Analysis of Torque Retention Baseline vs. After Improvement

Control plan

The optimal process parameters were confirmed after the study and documented in Standard Operational Procedure (SOP) including reaction plans to make corrective actions when the injection mold process is out of the control, especially torque retention will not meet specification limit. Control charts are trended for torque retention, and the results are reported in a monthly KPI review meeting. The control limits are re-calculated on a quarterly basis and revised as needed.

CONCLUSION

The five phases of the Lean Six Sigma were successfully implemented in the injection molding process. The design of experiment case study illustrated the effective use of Lean Six Sigma methodology to reduce process variation and to improve the torque retention output. The design of experiment analysis is applied to the injection molding process using full factorial design. The main and interaction factors are identified. Based on the DOE analysis, it is found that the Barrel Temperature and Injection Pressure had significant impact on torque retention; Injection Speed and Holding Time did not. The design of experiment technique also allows practitioners to run all possible combinations with different levels instead of running one-factor-at-a-time (OFAT) and missing-out the factor interactions. The optimization analysis indicated that parameter settings have led to significant improvements in the torque retention quality characteristics. With the optimized settings, the injection molding process became capable of producing a stable torque retention greater than 2.86 lbf. Lean Six Sigma proved to be a valuable tool to reduce defects and to improve yield of the manufacturing processes. This study provided a manufacturing case study to technology management practitioners detailing a step by step application of Lean Six Sigma techniques. Statistical analysis of the findings is also provided to validate the results. Moreover, the case study reiterates the significant impact of Lean Six Sigma as a tool that can help companies achieve their business objectives to deliver superior levels of performance to overcome operational and strategic challenges.

ABSTRACT

Quality Management Analytics (QMA) is a comprehensive quality improvement approach for (current & future) professionals to increase organizational performance by leveraging the power of the analytical and analytics methodologies. Specifically, Quality Management Analytics (QMA) program focuses on teaching students and professionals on how to: 1) Enhance the organizational performance by reducing business process inefficiencies through the proven systematic quality improvement methodologies; and 2) Promote excellence in business decisions and operations using modern analytics tools, increasing the chance of delivering quality services and products for their customers. This article describes the program for its unique approach, the curriculum structure, and the analytics methods utilized.

KEYWORDS: Quality Management, Performance Improvement, Organizational Excellence, Exploratory Analytics, Predictive Analytics, Prescriptive Analytics

QUALITY MANAGEMENT ANALYTICS (QMA)

Quality Management Analytics (QMA) is a comprehensive quality improvement approach for (current & future) professionals to increase organizational performance and meet demanding customer expectations by creating high quality processes for services and products. It achieves this goal by leveraging the proven power of the integrative analytics methodologies so as to reduce business process wastes and operational variations.

Specifically, Quality Management Analytics (QMA) enables practitioners to: 1) Enhance the organizational performance by reducing business process inefficiencies through the proven systematic quality improvement methodologies; and 2) Promote excellence in business decisions and operations using modern analytics tools, increasing the chance of delivering quality services and products for their customers. Program participants will gain knowledge and skill sets in quantitative and qualitative decision making practices to solve complex business operational problems and quality issues.

Intuitive data analytics tools and qualitative techniques are used to effectively deliver performance improvement solutions. Hands-on exercises and software packages are extensively utilized to help participants learn the concepts and applications in real world problems. In summary, the QMA program aims at facilitating organizational excellence by engaging professionals in data-driven analytics decision practices. The program places emphasis on the fact organizational performance is largely defined by how business entities create, manage, and utilize data related to their business and operation processes. Student will gain knowledge in extracting and analyzing data from business processes and confidence in presenting their findings.

QMA PROGRAM STRUCTURE & CONTENTS

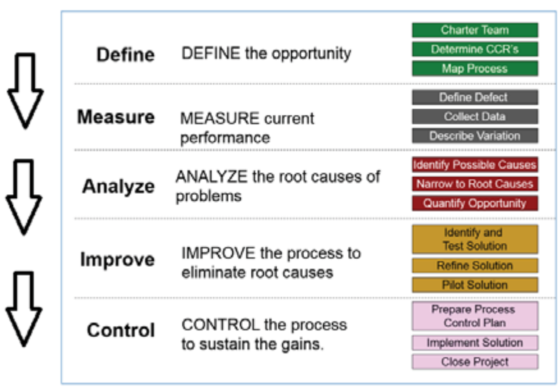
QMA program focuses on providing solutions for industry managers to efficiently handle four major organizational performance issues: 1) System Variations; 2) System Wastes; 3) System Risks; and 4) System Predictions. To this end, the program offers a structured curriculum as summarized below in Figure 1 with conceptual frameworks and analytical/ analytics methods. In the following sections of this article, each curriculum category will be described in detail.

Curriculum Category		Application Domain	Course Name
I. Organizational Excellence (System Performance **Management**)	(Business Functions)	- Organizational Decisions <Integrated Functional Decisions>	TEC xxx
	(Operational Functions)	- Quality Management & Project Management <Operational Excellence & Lean Six Sigma >	TEC xxx
II. Exploratory Analytics (System Performance **Description**)		- Insight Analytics <Visual Mining>	TEC xxx
		- Process Analytics <Process Mining>	TEC xxx
III. Predictive Analytics (System Performance **Prediction**)	A. Inductive Prediction	- Predictive Analytics <Machine Learning>	TEC xxx
	B. Deductive Prediction	- Decision Simulation <Monte-Carlo Simulation>	TEC xxx
		- Process Simulation <Discrete-Event Simulation>	TEC xxx
		- Behavior Simulation <Agent-Based Modeling>	TEC xxx
		- System Alternatives <System Dynamics>	TEC xxx
IV. Prescriptive Analytics (System Performance **Solution**)		- System Optimization <Stochastic Optimization Method>	TEC xxx

Figure 1. QMA Program Structure and Topical Contents

CURRICULUM CATEGORY I: ORGANIZATIONAL EXCELLENCE

In this part of the curriculum, the focus is on how important customer satisfaction is to the business success of any organizations. Students need to understand that the “quality” of any products/ services is one of the major factors in the customer satisfaction. Students also learn how to operationalize quality management as part of any regular business processes. Quality is not a concept but rather a measurable performance indicator by constantly comparing business performances against customer expectations. Students learn how companies can establish and implement such quality management practice using the Lean Six Sigma (LSS) methodology. The methodology aims at explaining how system variations and system wastes lead to customer dissatisfaction and how these fundamental issues can be resolved. QMA students follow the entire quality improvement process, the DMAIC (*Define-Measure-Analyze-Improve-Control*) methodology as a way of systematically and analytically investigating system performance issues and proposing solutions as depicted in Figure 2. Based on a real case or a scenario, students define a quality-related business problem, measure the current level of performance using KPIs, analyze the root causes of variations and sources of inefficiencies, and provide alternative solutions to improve and control system behaviors. At the end of the course, students have learned the fundamental concepts and tools that can be used to improve business system performance.



Define	Measure	Analyze	Improve	Control
Project Charter	Key Performance Indicators (KPI)	Process Mapping	Design of Experiments (DOE)	Statistical Process Control (SPC)
Voice of the Customer	Measurement System Analysis (MSA)	Cause & Effect Diagram	Theory of Constraints	Standardized Processes
House of Quality	Gauge R&R	Hypothesis Testing	Pugh Matrix	Control Plans
Kano Analysis	Process Capability	Confidence Intervals	5S	Total Preventative Maintenance
Critical to Quality (CTQ) Trees	PPM & DPMO	Failure Mode and Effect Analysis (FMEA)	Kanban	Project Report
SIPOC Map	Short/ Long Term Variation	Affinity Diagram	Work Flow Improvement	Procedures and Work Instructions
Gemba	Data Collection Methods	Correlation & Regression	Visual Management	Training Requirements

Figure 2. DMAIC Improvement Methodology and Conventional LSS Analytical Tools

If you are a manager responsible for improving the system performance of a factory, a distribution center, a supply chain, or any business systems, you have a daunting task because these systems are complex, dynamically changing, operating under uncertainties, and heavily influenced by your decisions. Because of these reasons, finding the source of poor system performance and providing the solutions to quality problems are very time-consuming and costly endeavors. In fact, typical analytical and statistical methods and tools used in the conventional Lean Six Sigma (LSS) practices have created these bottlenecks to the level that companies consider the LSS non-agile.

To overcome this very issue, the QMA program integrates various modern analytics and modeling methods as a way of facilitating the DMAIC process to make the quality management practice to be significantly nimble and comprehensive. As shown in Figure 1, these methods are organized into the exploratory, predictive and prescriptive analytics categories in the QMA curriculum to describe, estimate, and direct system behaviors. Specific methods covered include: insight visual analytics; process mining; predictive machine learning; monte-carol simulation; discrete-event simulation; and agent-based modeling. Emphasis on hands-on experience with computer applications is to ensure students to acquire working knowledge beyond the concepts and theories in making decisions in business and operations. Various industry-based decision situations are modeled and analyzed throughout the courses. Let us take a look first how the exploratory analytics is used in the quality management context.

CURRICULUM CATEGORY II: EXPLORATORY ANALYTICS

In this part of the curriculum, the focus is on finding potential reasons and sources of system variations and efficiencies. To illustrate, Figure 3 shows a process analytics methodology, called a process mining (the figure was generated using DISCO by fluxicon), to describe the system behaviors and its embedded wastes. The process map shown, automatically generated from a set of transaction dataset of business operations, allows users to identify typical system wastes such as reworks, dropped cases, and bottlenecks by navigating to various areas of the system in question. Tools such as this are much more powerful and time-saving than the conventional cause-effect tools such as fishbone diagram because users do not have to guess where the inefficiencies come from.

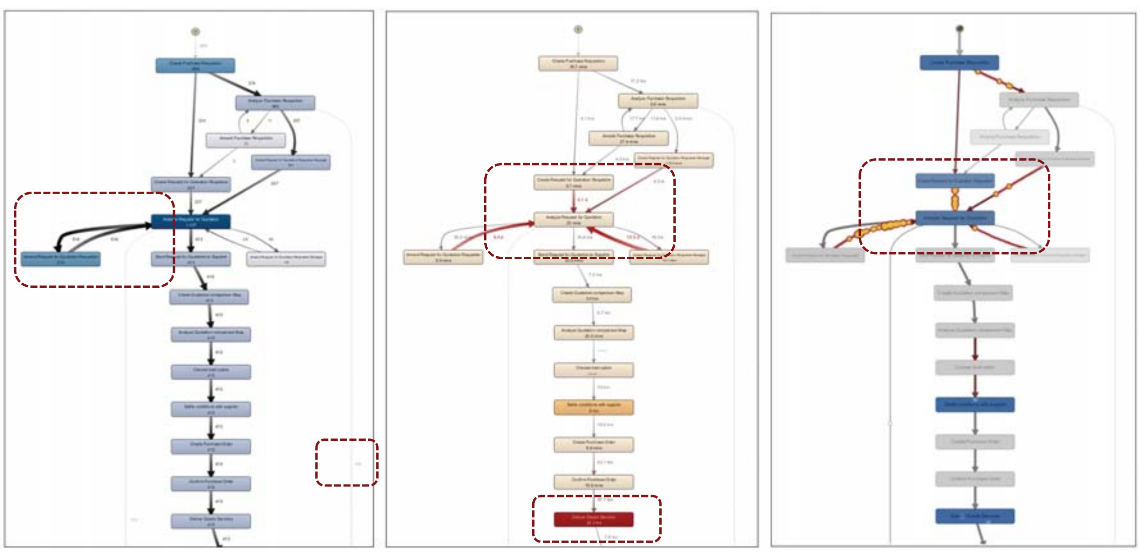


Figure 3. Process Analytics to Identify Wastes and Efficiencies

Figure 4 demonstrates another example of how a visual analytics technique can be used as a quality management tool. If you are a manager overseeing the sales in US and you know the sales in the Eastern states has been a struggle, the visual insight below (created by Tableau) indicates more specific sources of the struggle in terms of location and time in an objective and quantitative fashion instead of relying on the manager’s qualitative judgment. Again, the emphasis is on the speed and accuracy that can be adopted in the quality management practice.

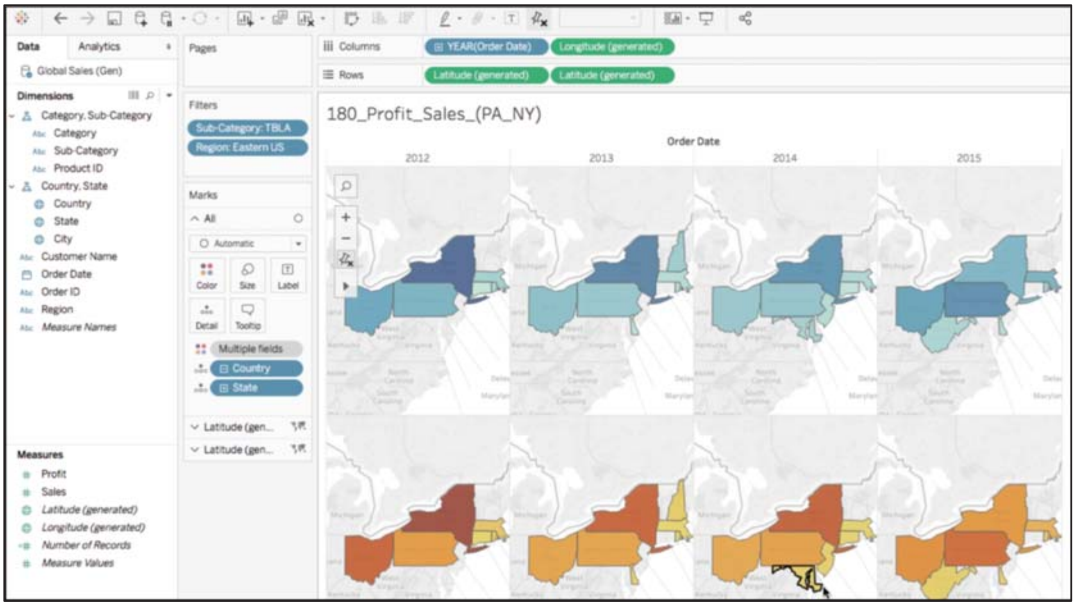

Figure 4. Visual Insights on Sources of Sales and Profit Declines

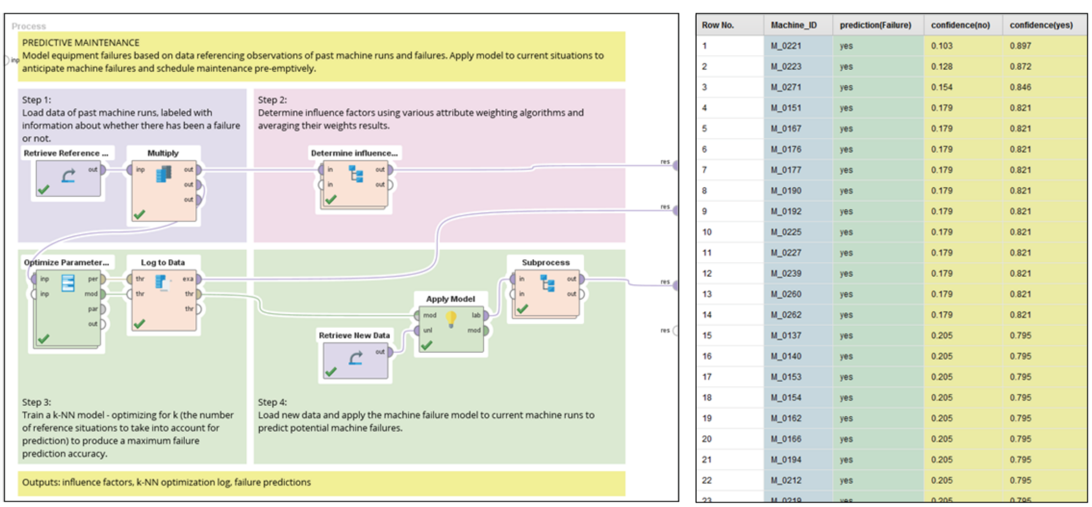
CURRICULUM CATEGORY III-A: PREDICTIVE ANALYTICS (INDUCTIVE PREDICTION)

If you care for system performance at a certain level, it is always a good idea to predict what could/ would happen before it happens. This may be the best quality management practice after all, if possible at all. One possibility is that now as a manager you have a lot more data that you can turn into a predicting machine. Figure 5 shows a predictive analytics model (created by the RapidMiner software) based on an operational data to take a preventative measure on potential machine failures. This type of analytics use will bring in a completely different managerial mindset in that now you want to be proactive in improving quality of product or services.



Row No.	Machine_ID	prediction(Failure)	confidence(no)	confidence(yes)
1	M_0221	yes	0.103	0.897
2	M_0223	yes	0.128	0.872
3	M_0271	yes	0.154	0.846
4	M_0151	yes	0.179	0.821

12	M_0239	yes	0.179	0.821
13	M_0260	yes	0.179	0.821
14	M_0262	yes	0.179	0.821
15	M_0137	yes	0.205	0.795
16	M_0140	yes	0.205	0.795
17	M_0153	yes	0.205	0.795
18	M_0154	yes	0.205	0.795
19	M_0162	yes	0.205	0.795
20	M_0166	yes	0.205	0.795
21	M_0194	yes	0.205	0.795
22	M_0212	yes	0.205	0.795

Figure 5. Predictive Analytics for Machine Failure

CURRICULUM CATEGORY III-B: PREDICTIVE ANALYTICS (DEDUCTIVE PREDICTION)

In this category, the approach is to put together a model closely emulating the behaviors of the business system. This is a deductive analytics approach because the system itself is replicated as a digital model or twin to describe and predict its behaviors. (*Note that in the previous categories, the focus is on analyzing the data produced from the system under consideration for prediction of its behavior. This is an inductive approach.*) Various simulation methodologies are used to support the deductive prediction modeling practice and some of the powerful ones include: agent-based modeling (ABM), monte-carol simulation (MC), and discrete-event simulation (DE) techniques. They provide more convincing and quantitative solutions to system improvement questions. Traditionally, this is where the conventional DMAIC LSS tools such as Pugh Matrix and FMEA (Failure Mode Effect Analysis) are used. Though analytical, they are qualitative and subjective in their analysis capabilities and they are incapable of handling complex business systems.

On the other hand, a simulation-based application such as the discrete-event simulation shown in Figure 6 (created by AnyLogic) can represent individual system components and interactions as precisely as the system understanding allows. The simulation is capable of predicting how the system would operate in dynamically changing and uncertain conditions.

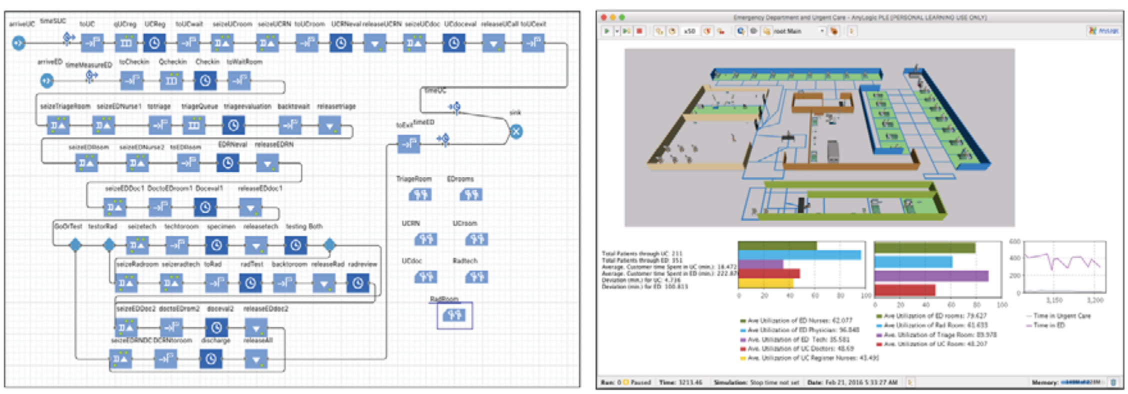

Figure 6. Discrete Event Simulation to Predict the System Behavior of Healthcare Provider

CURRICULUM CATEGORY IV: PRESCRIPTIVE ANALYTICS

In this category, the focus is to provide more definite directions on what parameters of the system need to be changed and how much they have to be modified to achieve the best overall quality. Since the simulation tools in the previous section have the capability to generate multiple scenarios, they are also capable to compare them and choose the best scenario for the users to adopt for optimum system performance. They often use the stochastic optimization techniques to provide more realistic solutions to users who operate the business system in risky and uncertain environments. This is another area where the conventional LSS tools do not provide convincing solutions.

Figure 7 below describe a Monte-Carlo simulation model (created by Palisade's @Risk) where an optimum production level is prescribed based on uncertainties.

	A	B	C	D	E	F	G	H	I	J
1	**Ski Jacket Production Simulation**

Figure 7. Prescriptive Analytics for Production Quantity

SUMMARY

The Quality Management Analytics (QMA) program is a new approach to change how the quality management practice can be done more effectively by leveraging the power of analytics capability to make quality improvement analysis and solutions robust and agile. In this article, various analytics applications are described to demonstrate how they can complement and improve the conventional DMAIC LSS tools. As analytics technologies evolve rapidly, professionals and academics seek to embed the analytics capability in their own domains. In QMA, the various analytics are actively used to deliver solutions to performance issues related to system variations; system wastes; system risks; and system predictions.

ABSTRACT

We investigate holistically a business system, consisting of market invitations, a firm's supply-chain ecosystem, innovative recognition of market signals, and consequent challenges the ecosystem faces. We show that a firm's upstream component and downstream complement challenges place respectively a cap on the 'value' the firm can create and capture; a firm's capability of identifying challenges is positively correlated to its adeptness in creating and sustaining marketplace advantage and imposing challenges on its ecosystem. A firm's strong capability to learn and act accordingly is an advantage.

KEYWORDS: capability, market invitation, performance, systemic yoyo, value creation/ capture

INTRODUCTION

Systemically speaking, when a firm recognizes a market invitation in an epoch-making way, the firm has an opportunity to develop a significant competitive advantage over its competitors. However, other than internal reasons other players in the ecosystem of the firm's supply chain greatly affect the enhanced performance the firm consequently enjoys (Adner et al, 2013). For example, the difficult daily commuting problem, confronting those individuals who live in a suburban area and commute to work inside a major U.S. metropolitan, necessarily invites politicians and entrepreneurs alike to come up with a solution. One possible resolution to this challenge, for example, is to design, produce, and offer flying cars (Lemoussu et al, 2018) to these frustrated commuters. To manufacture realistically such cars, a firm has to have appropriate components supplied to it in its assembling of the imagined product. However, the value created for commuters is practically realizable until the appropriate road conditions and air traffic controls, as key complements, are constructed and installed in order for such cars to move and fly around freely and orderly. So, a natural question arises: After a firm receives a market invitation for innovation, how will the consequent success of the firm be dependent on the success of other players in its ecosystem?

This paper seeks to address this question, which is important both theoretically and practically, by randomly selecting a firm as our focal firm and by using the thinking logic and methodology of systems science. To accomplish this end, we first distinguish suppliers and complementors so that suppliers provide their outputs for the focal firm to integrate in its effort to offer a complete product to its customers and complementors facilitate necessary conditions for customers to fully utilize the product. Then we develop the following main conclusions amongst others:

- The upper limits of value the focal firm can create and capture are respectively constrained by its upstream component challenges and downstream complement challenges; and
- The more adept a focal firm is at learning and acting, the greater the challenges that will face the ecosystem of the firm's supply chain.

The remainder of this paper is organized as follows. The following section provides a literature review while showing how this work contributes to established knowledge. The next section lists the necessary background information to make this paper self-contained. Following this is the construction of the ecosystem of an arbitrarily chosen business firm. Then studied are the relationship between the firm's capability of learning and its consequent challenges imposed on the ecosystem. The final section concludes the presentation of this work with managerial recommendations and open problems for future research.

LITERATURE REVIEW

Due to the power of systems thinking and methodology, this paper contributes to an array of different literatures, simultaneously covering business ecosystems, value capture and creation, learning capabilities, competitive advantage, and customer adoption of innovation. In this section, we review relevant works in each of these discrete literatures.

In the literature of ecosystems, Adner et al (2013) publish a collection of papers addressing how system players collaborate and compete with each other. Refuting the common beliefs that knowledge ecosystems in technology hotspots leads to business ecosystems in which there are competitive advantages for each of the players in the ecosystem, Clarysse et al (2014) find a particular case where a structured knowledge ecosystem is concentrated around only a number of central players. The result is an imagined business ecosystem that is nearly non-existent. When a business ecosystem includes well-established companies and new ventures, Zahra and Nambisan (2012) claim that success of that ecosystem requires collaboration and competition that demands strategic thinking to leverage a firm's resources and capabilities. Kapoor and Agarwal (2017) study how platform firms in a business ecosystem orchestrate the ecosystem's functioning by providing platforms and setting the rules for participation by complementor firms. They develop a reason for how the ecosystem's structural and evolutionary features may shape the extent to which participating complementor firms can sustain their superior performance. Instead of using technical interdependencies, Hellström et al (2015) explore how firms in an energy business ecosystem collaborate by using a business model lens, pointing to the importance of locating the factors that drive the business models of collaborating firms to facilitate system transitions and change in the logic of an industry. Attour and Lazaric (2018) emphasize that transformation of a knowledge ecosystem can lead to the emergence of a technological platform that provides the resources required especially for firm startup. By conceptualizing the construct of ecosystems, Adner (2017) offers an examination of the relationship between ecosystems and a host of other constructs, such as business models, platforms, coopetition, multisided markets, networks, technology systems, supply chains, and value networks.

In the literature on value creation and capture, Chemmanur et al (2014) analyze how entrepreneurial firms differ when they are corporate venture capital (CVC) based or independent venture capital (IVC) based in terms of their innovativeness. What is found is that CVC-backed firms are more innovative, although they are younger, riskier, and less profitable than those backed by IVC. Kagermann (2015) discusses the impact, challenges and opportunities of digitization and finds that the two key instruments for greater value creation in the Age of Industry 4.0 are platform-based cooperation and a dual innovation strategy. By looking at how the usage of big data analytics (BDA) affects value creation, Chen et al (2015) conceptualize BDA use as an information processing capability that brings competitive advantage to organizations and identify paths through which factors influence the actual usage of BDA.

In terms of learning capability, Camps et al (2016) test hypotheses that link organizational learning capability (OLC) and individual employee performance, OLC and employee flexibility, and employee flexibility and individual performance, and show that employee flexibility fully mediates the relationship between OLC and individual performance under the influence of environmental turbulence. Altinay et al (2016) investigate the interface between OLC, entrepreneurial orientation (EO), and small business performance, and find a positive relationship between EO and sales and market share growth and OLC and EO, but not between EO and employment growth. Kalmuk and Acar (2015) emphasize the mediating role of OLC on the relationship between innovation and company's performance and attempt to demonstrate how multiple types of innovations could contribute to firm performance through OLC. Sung and Choi (2014) examine how training and development affect organizational innovation and suggest that investments in training and development do exert influence on firms' innovative performance through promotion of various learning practices.

Regarding performance and competitive advantages, Yadav et al (2017) look at the association between a firm's environmental efforts and the sustainability of its competitive advantage through analyzing how changes in the firm's environmental performance affect the persistence of its profitability growth. These authors find that environmental resources permit superior financial performing firms to maintain their competitive advantage, while complementing poorly performing firm's efforts to recover. This study empirically supports the proposition that economic value can be created through benefiting the environment. Prajogo and Oke (2016) examine the effect of human capital (HC) on service innovation advantage (SIA) and business performance (BP), and how external environmental factors play a role. These authors show that HC is positively correlated to the creation of value or SIA which in turn results in rent generation for firms, and that the effect of SIA on BP is influenced by environmental factors such that it is strengthened by dynamic environments and weakened by competitive environments. Chang et al (2016) consider the inconsistent relationship between supply chain integration (SCI) and firm performance by proposing that the inconsistency may be associated with selection bias, failure to consider the mediating routes of how SCI affects financial performance, and lack of investigation of moderators. Their findings confirm the early claim that each dimension of SCI indeed improves financial performance.

In terms of market adaptation of innovation, Oliveira et al (2016) aim to identify determinants of mobile payment adoption by proposing a new model. These researchers find that compatibility, perceived technology security, performance expectations, innovativeness, and social influence have significant effects on consumer adoption. This work provides a basis for further refinement of individual models of acceptance. Bilgicer et al (2015) study the role of social contagion in customer adoption of new sales channels by focusing on two aspects of social contagion (i.e., local contagion and homophily), as they influence a consumer'spreference for either an internet channel or a brick-and-mortar store. Bilgicer et al find that social contagion does indeed play a major role with long-term versus short-term customers being less inclined to consider alternate sales channels. By recognizing the importance of downstream activities of the innovation process, specifically marketing and commercialization, Brem and Viardot (2015) consider the adoption of innovations by the market by providing conceptual insights and manners that appear to stimulate and facilitate the adoption of every kind of innovation. Laukkanen (2016) posits that all innovations meet consumer resistance and overcoming this unfriendliness needs to occur prior to product adoption. He examines how five adoption barriers – usage, value, risk, tradition, and image – and three consumer demographics – gender, age, and income – influence consumer adoption versus rejection decisions in internet and mobile banking. Laukkanen finds that value is the strongest barrier, while image slows adoption; and that both gender and age significantly predict adoption and rejection decisions.

This paper contributes to the literature in several different ways. First, it establishes general propositions that are practically applicable with reliability and certainty. Second, it introduces a new methodology for investigating important issues relating to the distribution of challenges across the ecosystem of a focal firm. Third, this paper develops a general theory of business ecosystems without suffering from the constraints and limitations of anecdotes and data analyses (or data mining). In other words, the results established in this paper are universally true within the system of our cohesive theory constructed on top of a few basic assumptions and logical reasoning.

PREPARATION

To make this presentation self-contained, this section briefly introduce the relevant basics and facts of systems science and methodology, the dishpan experiments and the list necessary assumptions and terminology.

Basics of Systems Science and Methodology

Systems are everywhere, especially in investigations of economic issues and business decision making. For example, each person is a complex biological system that is made up of numerous smaller systems. Additionally, that person also belongs to many social and economic systems, such as families, neighborhoods, communities, etc., and that person interacts with a range of systems, such as a car, a smart device, retail stores, the organization the person works for, etc. Because of the existence of such individuals, these systems constantly interact with one another. Hence, other than using numbers and variables to investigate problems and issues regarding organizations, which is mostly reflected in the literature of social sciences, there is a need to employ the concept of systems and relevant methods to study how organizations evolve and how they interact with each other in order to obtain insightful understandings and conclusions that can potentially lead to tangible conclusions in real life.

Historically, the concept of systems has been directly or indirectly introduced by scholars from different disciplines. For example, in the area of economics Rostow (1960) wrote that: The classical theory of production is formulated under essentially static assumptions … to merge classical production theory with Keynesian income analysis … introduced the dynamic variables: population, technology, entrepreneurship, etc. But … do so in forms so rigid and general that their models cannot grip the essential phenomena of growth … We require a dynamic theory … which isolates not only the distribution of income between consumption, savings, and investment (and the balance of production between consumers and capital goods) but which focuses directly and in some detail on the composition of investment and on developments within particular sectors of the economy.

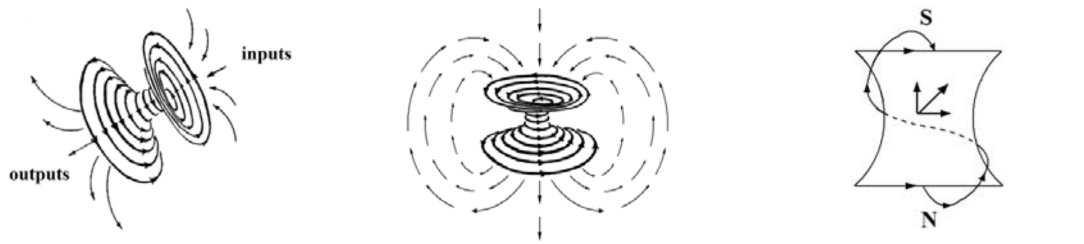
In the area of biology, von Bertalanffy (1924) points out that because the fundamental character of living things is their organization, the customary investigation of individual parts and processes cannot provide a complete explanation of the phenomenon of life. And others, such as Klir (1985), Lin (2009), Porter (1985), etc., also demonstrate how powerful holistic thinking and relevant methodology could be used in producing conclusions regarding organizations and their behaviors that are realistically reliable and practically usable. That is, business entities, economies, and markets, as organizations, do have their individually different internal structures and interact externally with each other. As a matter of fact, since the 1920s (von Bertalanffy, 1924), such a holistic view of nature, organizations, and social events has permeated the entire spectrum of knowledge (Lin, 2009).

The concepts of numbers and systems are respectively rooted in the physical world from two different points of view. For example, when an organization is seen as a set of elements, numbers come into play, such as *n* employees, *m* buildings, etc. However, when the organization is treated holistically, systems emerge, where elements such as employees, capital, properties, etc., form an organic whole through various relationships; without these relationships the organization does not exist. That is, studies in business related disciplines are essentially about relationships of organizations (or systems), be they small economic agents, firms (large or small), markets (local, national or international), industries, or economies.

To summarize, the major differences between the concepts of numbers and systems include: 1) the former is a small scale local concept, while the latter is a large-scale organizational concept (Lin, 1988; 1999); and 2) numbers exist only post existence, while systems emerge at the same time when physical or intellectual existence comes into being (Lin, 2009).

The first difference tells the reason why systems methodology is a more appropriate tool than the classical theories developed on numbers and variables for the investigation of economic entities when their internal structures are being investigated. The second difference explains why business scholars and practitioners still cannot successfully make advanced predictions for imminent economic disasters (Lin and OuYang, 2010).

As for systems science, it is simply the totality of studies of various kinds of systems. In the past century, the methods and thinking logic of systems science have been widely employed in scholarly works (Klir 2001). Similar to how the Cartesian coordinate system – consisting of the crossing of two or more number lines – plays its role in the development of traditional science and mathematics (Kline, 1972), in systems science the role is played by the systemic yoyo model (Lin, 2007), shown in Figure 1.



(a) Eddy motion model of the general system
(b) The meridian field of the yoyo model
(c) The typical trajectory of how matters return

Figure 1. The systemic yoyo model in 3-Dimensional Euclidean Space

Specifically, the blown-up theory (Wu & Lin, 2002), a general theory of development, and discussions on whether or not the world can be seen from the viewpoint of systems (Lin, 1988; Lin et al, 1990) have led to the development of this yoyo model for each object and every system imaginable. Speaking differently, each system can be theoretically seen as a multi-dimensional entity that spins about its axis. If such a spinning entity is fathomed in the 3-dimensional space within which we live, such a structure as artistically shown in Figure 1(a) appears. The input side pulls in *things*, such as human resources, materials, information, investment, profit, etc. After funneling through the "neck", *things*, such as products and services, are spit out from the output side. Some of the things, spit out as outputs, never return to the input side and some will (Figure 1(b)). Due to its general shape, such a structure is referred to as a yoyo.

What this systemic model says is that each physical or intellectual entity in the universe, be it a tangible or intangible object, a living being, an organization, a market, an economy, etc., can all be treated as a realization of a certain multi-dimensional spinning yoyo with an eddy and meridian field around. This yoyo remains in a spinning motion as depicted in Figure 1(a). When it stops its spinning motion, it will no longer be an identifiable system. What Figure 1(c) tells is that the interaction of the eddy field, which spins perpendicularly to the axis of spin, of the model, and the meridian field, which rotates parallel to axis of spin, makes *things* that are either new to the yoyo body or returning to the input side travel along a spiral trajectory.

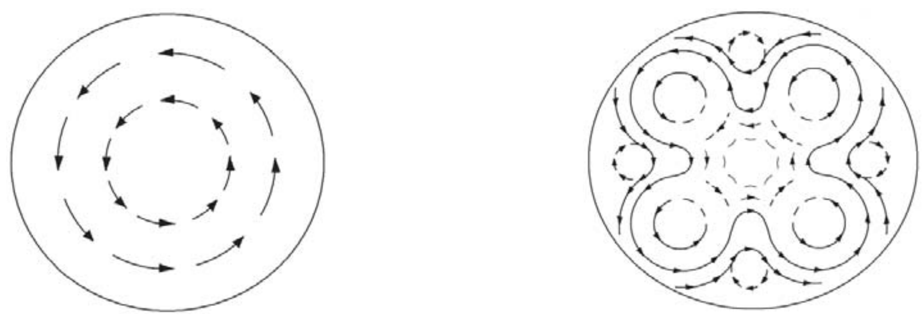
The Dishpan Experiment

In order to understand how the yoyo model (Figure 1) can be applied to the studies of evolution and development of systems, organizations, etc., this subsection will look at the well-known dishpan experiment.

Dave Fultz, University of Chicago, and his colleagues in late 1950s (Fultz et al, 1959) constructed the following experiment: they partially filled a cylindrical vessel with water, placed it on a rotating turntable, and subjected to heating near the periphery and cooling near the center. The bottom of the container is intended to simulate one hemisphere of the earth's surface, the water the air above this hemisphere, the rotation of the turntable simulates the earth's rotation, the heating and cooling simulate the excess external heating of the atmosphere in low latitudes and the excess cooling in high latitudes.

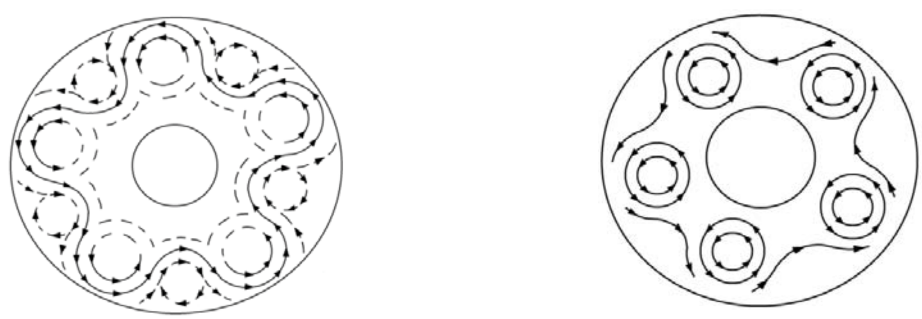
In order to observe flow patterns at the upper surface of the water, which was intended to simulate atmospheric motion at high elevations, Fultz and his colleagues sprinkled some aluminum powder. A special camera that effectively rotated with the turntable took time exposures so that a moving aluminum particle would appear as a streak and sometimes each exposure ended with a flash, which could add an arrowhead to the forward end of each streak. The turntable generally rotated counter clockwise, as does the earth when viewed from above the North Pole.

Even though everything in the experiment was arranged with perfect symmetry about the axis of rotation, such as no impurities added in the water, the bottom of the container was kept flat, etc., Fultz and his colleagues observed more than they had bargained for. First, both expected flow patterns (as shown in Figure 2) appeared, and the choice depended on the speed of the turntable's rotation and the intensity of the heating. Briefly, with fixed heating, a transition from circular symmetry (Figure 2(a)) would take place as the rotation increased past a critical value. With a sufficiently rapid, but fixed rate of rotation, a similar transition would occur when the heating reached a critical strength, while another transition back to symmetry would occur when the heating reached a still higher critical strength.



(a) Symmetric flow at the upper surface (b) Asymmetric flow at the upper surface

Figure 2. Patterns observed in Fultz's dishpan experiment



(a) One flow pattern (b) Another flow pattern

Figure 3. Streak patterns of the flow at the upper surface of Hide's dishpan experiment. (a) is followed by (b) after 8 rotations; and (b) is followed by (a) after another 8 rotations

A few years before the previous dishpan experiment was conducted in Chicago, Raymond Hide, Cambridge University, did a similar experiment in England (Hide, 1953). Instead of a dishpan, Hide used two concentric cylinders with a fluid placed in the ring-shaped region between the cylinders. He discovered similar transitions between symmetric and asymmetric flow patterns. In this experiment, the asymmetric flow was often regular and consisted of a chain of apparently identical waves, which would travel around the ring-shaped region without changing their shapes. What's more remarkable about what Hide found is that a chain of identical waves would appear. But, as they traveled along, they would alter their shapes in unison in a regular periodic fashion and after many rotations of the turntable, they would regain their original shape and then repeat the cycle (Figure 3).

What's important about these experiments is that structures, such as jet streams, traveling vortices, and fronts appear to be basic features in rotating heated fluids, and are not peculiar to atmospheres only.

Basic Assumptions and Terminology

To make our logical reasoning valid, we assume that each and every firm in the business world exists for the purpose of satisfying a particular market niche through generating a positive cash flow. The positive cash flow can be a result of profits from the marketplace, or investments from various investors, or both.

By a *value system*, we refer (Porter, 1985) to associated activities that jointly transform raw materials into products or services for end users. These activities are usually performed by various firms with end users known as *consumers*. In contrast, intermediate, B2B purchasers in a value system are referred to as *customers* instead of consumers. When a firm delivers its products and/or services to both customers and consumers simultaneously, for the sake of convenience of communication, we will just refer to both of these users as customers.

Assume that value creation is the principal objective of any business enterprise, where the outputs are more valuable than the sum of the inputs. It consists of two components: creating value for customers as well as creating value for shareholders. The former helps sell products and services, while the latter, in the form of a rising stock price, insures the future availability of investment capital to fund the operations or to help with the positive cash flow of the enterprise. The *value creation* of a value system is determined by the expected benefits that consumers will receive from their purchases, as represented by their willingness-to-pay (WTP). Due to the lack of perfect price discrimination, consumers generally maintain a consumer surplus, because consumers' spending with payments into the value system is mostly less than the aggregate WTP.

After value has been created, the business enterprise whose efforts led to the value creation needs to capture the value in order to achieve its financial goal of first surviving and then thriving in the economic world. For example, value is created when farmers plant and grow crops; however, these farmers have to capture their created value by harvesting and selling their crops. Value capture by an individual firm is usually determined by its ownership of resources and power status within the value system, as well as by the firm's cost structure and negotiating skill in relation to other firms in the value system (Bowman & Ambrosini, 2001; Priem, 2007).

THE ECOSYSTEM OF AN ARBITRARILY CHOSEN FIRM

This section looks at why market invitations can be at least partially answered and establishes some basic properties of an arbitrarily chosen focal firm in relation to its ecosystem.

The Ecosystem and a Systemic Modeling

The success of our focal firm primarily depends on how well other firms are doing in its input-output environment because of their economic interdependence, where the inputs of one firm are the outputs of some other firms. That is, by using the flow of inputs and outputs we can talk about the ecosystem within which the focal firm resides with other firms seen as either upstream components or downstream complements of the system (Adner & Kapoor, 2010). In particular, suppliers represent some of the upstream components of the focal firm; customers, supporters and assistants who help to make the product of the focal firm usable by consumers are the downstream complements. Supporters and assistants are called complementors because although they are outside the focal firm’s direct supply chain they need to invest and develop new infrastructure to make the focal firm’s product practically usable by the ultimate consumer. Governments, regulators, etc., are examples of complementors that help to build and to regularly maintain, for instance, the roads necessary for transporting products, or the specification of new safety procedures, etc. With this explanation in place, we can see that the set of components of the focal firm also includes upstream complementors that help to make the outputs of the suppliers usable by the focal firm.

Figure 4 depicts the systemic structure of this ecosystem, where the focal firm utilizes the inputs, which will be called components, from *n* supplies and delivers its outputs to customers with the support and assistance of *m* complementators, *m*, *n* = 1, 2, 3, … These support and assistance are called complements. As shown in Figure 4, only first-tier components and complements are given, although this structure in real life should be extended forward and backward along the chain of value creation to include actors of other tiers, such as suppliers' suppliers, customers' customers, complementors’ complementors, etc. And when the full range of all players of different tiers is included in the ecosystem, one actually develops a practical situation of linked systems (Lin & Ma, 1987). (To make the figure intuitively clear, all upstream complementors of the focal firm are omitted.) In other words, the ecosystem of the focal firm possesses the characteristics of the yoyo model in Figure 1(a), where the firm’s internal working is around how its employees with adequate organizational supports can innovatively integrate the components from suppliers in order to deliver its functional product(s) to its customers. Note that similar systemic constructs such as this one has also attracted the attention of academics and practitioners (Iansiti & Levien, 2004; Adner, 2006; Intel Corporation, 2004; SAP Corporation, 2006).

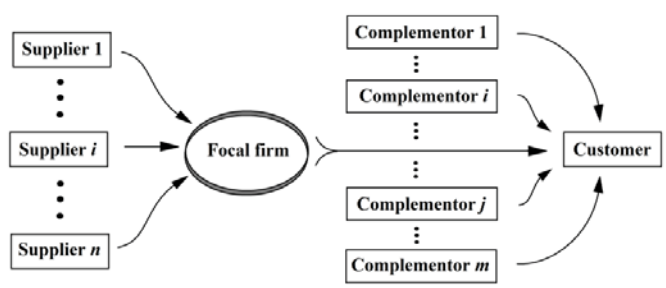


Figure 4. The ecosystem of any focal firm

By modeling each firm in the ecosystem of the focal firm and the market as a system, and a mapping ℓ_{ts} from an upstream supplier firm S_s to a downstream customer firm S_t as the linkage of how S_s’s component m_s is applied in S_t’s product m_t, we have the following result.

Theorem 1. Assume that *T* is a given partially ordered set of type α and that *S* is an α-type hierarchy of systems over *T*, satisfying that each state S_t is a nontrivial system, for $t \in T$. Then *S* can be made into a linked hierarchy by a family $\{\ell_{ts}: t, s \leq T, s \geq t\}$ of linkage mappings of *S*.

The proof of this result is very technical and is omitted.

One interpretation of this theorem of systems science can be given as follows: When the focal firm receives a market invitation for innovation, meaning that the partially ordered set *T* has a set of minimal elements (representing the various market demands related to the invitation), then each and every firm within the ecosystem of the focal firm will be challenged one way or another to provide a resolution to their respective challenges in order to jointly answer the market call. Although the initial market invitation might not be answered perfectly, some combinations of individual firms' resolutions to their respective challenges would provide at least a partial solution to the market demand.

Success and Challenge of the Focal Firm

Based on the ecosystem of the focal firm constructed previously, this subsection establishes a few fundamental conclusions about the focal firm in terms of its market success, the values it creates and captures, and the magnitude of challenges it faces in the marketplace.

Proposition 1. The success for the focal firm to meet its challenges that appear when the firm decides to answer a market invitation is often dependent on the successes of the other firms within the ecosystem to meet their respective challenges that arise out of the focal firm's desire to answer the market invitation.

In fact, this result follows from how the ecosystem of the focal firm is constructed, as shown in Figure 4. In particular, this ecosystem organically relates the firm's performance with not only the challenges the firm faces (Henderson & Clark, 1990; Christensen, 1997), but also those that confront the external partners. For instance, to meet a challenge, the focal firm may very well need to acquire certain special upstream components, which may in turn represent challenges to the relevant suppliers and their corresponding complementors. At the same time, a solution to the challenge, as identified by the focal firm, may likely require downstream complementors to successfully meet their corresponding challenges in order for the focal firm's new product to be fully usable by the customers. In other words, this ecosystem, as a systemic model of the environment of the focal firm, explicitly explains how the network of challenges centered on that particular challenge the focal firm faces needs to be successfully resolved by different actors in the ecosystem in order for the ecosystem to create value.

On the practical front, there are many real-life instances that support the conclusion of Proposition 1. For example, direct current (DC) generation technologies declined because of unconquerable bottlenecks in the development of DC distribution technology (Hughes, 1983), while in the semiconductor lithography industry optical lithography dominates all non-optical approaches as a consequence of the fact that suppliers, customers, and complementors played roles in meeting their respective challenges in optical lithography technology (Henderson, 1995). On a more personal level, when one of the co-authors of this paper had to convert her house to gas heating from its original 100% electric home, although the conversion was possible and done successfully without any trouble, the system became louder than before. Apparently, the duct work in electrical homes is not directly (1 to 1) compatible with that of gas-heated homes.

The duct work of the former homes is narrow so that the newly installed gas system pushes more air through a smaller space, and hence, lending itself to a noisier output.

Proposition 2. The upper limit of the value the focal firm can *create* when it answers a market invitation is constrained by the upstream component challenges the suppliers consequently confront, while the upper limit of the value the focal firm can *capture* from its effort to answer the market invitation is constrained by the downstream complement challenges.

In fact, the first conclusion follows from the fact that the focal firm's ability to actually make a product that is expected to be competitive in the marketplace is constrained by the challenges the upstream components faces. The second conclusion is a consequence of the fact that how much of the full benefit of the focal firm's offering the customer can enjoy from consumption is influenced by the downstream complements.

By the magnitude of a challenge the focal firm faces, it means how much the challenge requires the current approach of problem solving of the firm to change. In other words, the magnitude of a challenge to the focal firm corresponds to the degree to which this firm is charged with changing its approach to problem-solving.

Proposition 3. The greater the magnitude of a challenge the focal firm faces in the marketplace, the greater change the entire ecosystem of the firm will be required to undergo in order for the focal firm to resolve the challenge.

When the focal firm confronts a challenge in the marketplace, it has to make certain necessary changes in its adopted way of problem-solving in order to come up with a resolution beneficially. Now, the required changes necessary to produce the desired resolution could be in:

- The discovery of market trends, the consequent design of brand new ideas, and the development of competitive products (Tushman & Anderson, 1986; Henderson & Clark, 1990), or
- The identification of how some environmental elements can be integrated into firms' internal structures (McGrath, 2013; Takeishi, 2002; Brusoni, Prencipe, & Pavitt, 2001), or
- The determination of how to scale up the production and delivery of identified solutions (Argote, 1999; Hatch & Mowery, 1998).

However, for the ecosystem's purpose of creating value, the focal firm's current approach of problem-solving has achieved a dynamic equilibrium with those of the other players in the ecosystem. In other words, in their effort of achieving the common goal of value creation, all players in the ecosystem are in a state of mutual forbearance. That is, the players, be they firms, complementors or consumers, mitigate the overall challenge of creating and capturing value by dividing the series of necessary activities into bundles, each of which is manageable by one player according to its strength (Bernheim & Whinston, 1990). They cede efforts in less efficient areas to other more capable players, while in exchange the latter do the same in areas where the former are more efficient (Li & Greenwood, 2004). The players' codependence gradually makes the ecosystem stable in their concerted effort of value creation and value capture (Yu & Cannella, 2012). Eventually, the association of the players becomes strengthened (Fuentelsaz & Gómez, 2006) and the network of adopted approaches of problem-solving by different players reaches equilibrium (Haveman & Nonnemaker, 2000). Therefore, when the focal firm is forced to make changes in its adopted approach of problem solving, the stability and equilibrium of this network has to be broken; and at the same time, the greater the change the focal firm has to make, the greater alteration the entire ecosystem will have to make in order for the system to reach another equilibrium.

In terms of the systemic yoyo model, the situation implied by the setup of Proposition 3 can be depicted in Figure 5, where one linear branch of the supply chain is shown as the horizontal curve with the arrows indicating the direction of movement of inputs and outputs of the firms along the chain, and the vertical arrowed curves stand for the combined eddy field of the individual eddy fields of the firms along the supply chain. When a certain amount of value is created and captured by the firms, an equilibrium and stability between the vertical and horizontal fields are established. However, when the focal firm faces a challenge from the marketplace, it means that its outputs need to be altered, which in turn implies that components from suppliers different from before will be needed. That consequently means that the suppliers' outputs have to be different from before. At the same time, the outputs of the downstream firms will in turn be changed accordingly. Such a domino effect quickly rises upward affecting all the suppliers and the suppliers' suppliers as well as downward exerting demands for downstream firms to alter their offers accordingly. So, once again, this analysis indicates that the more a change is required of the focal firm, the greater change the entire ecosystem will have to go through.

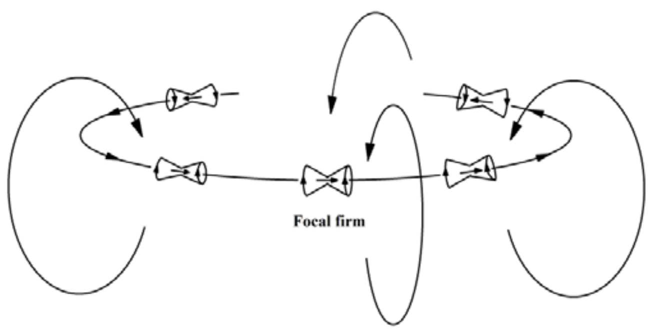

Figure 5. One linear branch of the supply chain within the ecosystem of the focal firm

CAPABILITY OF LEARNING AND CHALLENGE ON THE ECOSYSTEM

As the title suggests, this section studies how the market signals for additional competition, new innovation and how the focal firm's capability to learn and act accordingly leads to challenges to its ecosystem other than improved advantages. In particular, as shown in Figure 6, the systemic yoyo field of the market includes inputs, which are reflected in such terms as new kinds of products and/or services supplied into the market, and outputs, which could be conceived as demands for improved products and/or services. Although various upstream supplies are available to the focal firm, when the firm learns what the market is calling for, it designs innovative products, which in turn requires the upstream suppliers to provide different kinds of innovative components.

Theorem 2 (Forrest et al, 2017). In the coordinately monopolized market described below, if the magnitude of the market segment of switchers – those consumers who make purchases based on which firm's price is most competitive – is greater than α, then at least one new enterprise would enter the market profitably, as a competitor of the existing firms. The said market consists of m incumbent firms, m = 1, 2…, which provide consumers with mutually substitutable products such that

- Each of the incumbent firms has developed its respective share α of loyal consumers who purchase the products from their respective firms only as long as the price is not more than their reservation price, which is set to be 1;
- The incumbent firms compete over the switchers with adjustable prices charged to their consumers; and
- The managements of these *m* firms are well aware of the pricing strategies employed by the firms and have established their best responses by playing the Nash equilibrium through pure self-analyses.

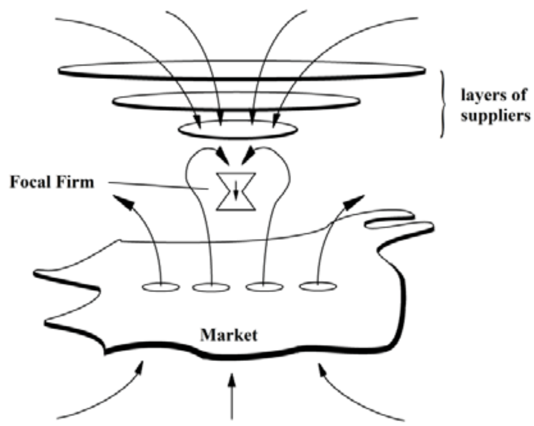

Figure 6. The interaction between what the focal firm learns and what is demanded by the firm from the upstream suppliers

In particular, the condition of this theorem – the magnitude of the market segment of switchers is greater than the average market share of the incumbent firms – is such a key that it is subject to different understandings of the market players. For instance, other than frugality or other thousands of reasons, one explanation for the existence of these switchers is that they are not totally satisfied with the features of the existing products. Aiming at such an understanding of the market cue, our focal firm could potentially come up with an innovative idea on how to improve the functionalities and features of the existing products. However, such an idea could most likely post challenges to the upstream suppliers for them to design and produce relevant components for the focal firm to integrate in order to make its imagined offer to the marketplace. Additionally, at the same time, the idea could potentially post challenges to the downstream complementors, too, in order for customers to enjoy the full benefit of the revolutionary offer of the focal firm. That is, the entire ecosystem now confronts a challenge, the magnitude and location of which depends on the first innovative idea of the focal firm. At this junction, a natural question arises: Would being an early mover be advantageous for the focal firm?

Intuitively, a leader (or first mover), by virtue of having beaten all rivals in the marketplace, should be able to enjoy non-existing or reduced competition when presenting its offer to the market, as documented by Lieberman and Montgomery (1988). That would naturally provide the leader with an advantageous exclusivity although it might be only temporary. However, from Theorem 2, this intuitive understanding, even so it is empirically supported, suffers from one practical problem – the existence of the desired market. In other words, if the imagined offer is too much ahead of its time, there might not be any readily available market for the product. So, first movers/leaders or pioneers in this sense will have to spend their time, efforts, and resources to first explore and define the market for their products. This end explains why studies, see (Lieberman and Montgomery, 2013) and references there, suggest that time can also benefit later entrants by helping to improve risk estimations, clear uncertainties, improve capability gaps, and facilitate learning from the costly mistakes of earlier entrants.

So, in terms of market entry timing as defined by (Zachary et al, 2015), Theorem 2 implies that market characteristics (or invitation) beget the entry of new comers with the potential of making more profits than any of the earlier movers. Therefore, the general symmetry assumed in Theorem 2 indicates that new entrants have at least the same amounts of capabilities and resources as the earlier movers. That simply implies that established firms should not strive to be early movers in any new market until the early movers have established the market with sufficient depth. This end theoretically confirms what Golder and Tellis (1993) find empirically: pioneers enjoy an average of 10% of the market share with nearly half of them failing outright, while early followers take roughly 28% of the market share with failure rates around 8%.

Practically speaking, Theorem 2 explains why large, multi-business enterprises generally exploit slack resources and complementary capabilities to scale up their operation and bypass early entrants (Markides & Geroski, 2005). In other words, size advantage, be it small or large, can make a firm more fitting for a later entry, as noted by Zachary et al (2015).

Systemically, Theorem 2 can be seen readily from the systemic yoyo model. For example, the entire market of concern can be modelled as the spinning dish in Figure 2(b), and each of the *m* incumbent firms aa a regional eddy pool. As such, the assumed symmetry in the market place, just like that that exists in the dishpan experiment, suggests that it is impossible that a blank space, which is at least as big as the area occupied by one of the local eddy leaves, would appear within the circular chain of the local eddy pools. Furthermore, the total area between adjacent local eddy leaves and between the periphery of the dish and circular chain of the local eddy leaves will be too large due to the fact that the local eddy leaves are created by uneven distributions of forces that act on the fluid particles located at different distances from the center of the dish.

What has just been discussed in the previous paragraphs actually explains theoretically why the key challenge underlying the early mover advantage is the opportunity for the focal firm to experiment innovative conceptual products, search for potential customers, and eventually form a market of sufficient depth. If successful, the firm would have acquired very valuable knowledge on production exploitation and market experience, while increasing its added value by improving its offer’s performance and/or costs (Spence, 1981; Lieberman, 1984, 1989; Argote, 1999). At the same time, it also illustrates the reason why pioneers tend to occupy small market share with nearly half of them failing outright (Golder & Tellis, 1993) because of the prohibitive difficulties existing first with the design and production of innovative conceptual products and then with the formation of the relevant market of sufficient depth.

Proposition 4. The more capable the focal firm is to learn and to discover, the greater advantage the firm is able to create and the greater the challenge the firm imposes on its ecosystem.

In fact, the previous analysis shows that the firm’s capability to learn and to discover is required in the understanding of market cues, in the formation of innovative concepts, and in the development and production of competitive products to satisfy the emerging market need. Therefore, the more capable the focal firm is in terms of learning and discovery, the more likely the firm will come up with innovative concepts and the consequent design and production of epoch-making products. Now, Proposition 3 implies that in this case the ecosystem will confront greater challenges in order to supply for the focal firm's design and production of new products and facilitate the delivery of the firm's products to customers.

Speaking systemically, when the focal firm is very capable of learning and discovering, it means that it is more convenient and ready for the firm to sense opportunities and emerging demands in the marketplace. That sensitivity in real life generally means that the firm has an established mechanism for learning and discovering and for how to benefit from what is learned and what is discovered, otherwise any such sensitivity would be dulled either consciously or unconsciously because resources are needed to maintain the said sensitivity. That implies that the firm's output will be replaced with improved or brand new products based on new knowledge and discovery, which consequently imposes challenges, Figure 5, on the upstream suppliers to provide different and, more likely, innovative outputs from before and on the downstream complementors to develop appropriate supports and assistance in order for customers to fully enjoy the new focal offers. Such chain effects rise quickly upward affecting all the suppliers and the suppliers' suppliers and downward disturbing all the complementors and the complementors' complementors. So, once again, this analysis indicates that the more a change is required of the focal firm by new knowledge and discovery, the greater advantage the firm is able to create and the greater change the entire ecosystem will have to go through.

Proposition 5. For the focal firm, its strong capability to learn and to act accordingly is an advantage of the firm over its competitors.

In fact, beyond what is given in the reasoning of Proposition 4, the level of learning capability depends on both the magnitude and the scope the focal firm needs to make changes. It is the emerging mastery of new routines of operation, different ways of thinking and forever changing processes of production that underpins the firm's success with its rides on the waves of transient competitive advantages in the increasingly turbulent economic market (McGrath, 2013). If little or no change from the status quo is necessary, as one of those incumbent firms described in Theorem 2, then there is not much for the firm to learn and to discover so that the motivation for learning and the relative advantage gained from learning and corresponding actions will be either low or nonexistent. In contrast, when the focal firm needs to bring its constantly different and supposedly better offers to the market, it has to overcome related uncertainties and complexities. That explains why a strong capability for the firm to learn and to act accordingly represents a unique advantage of the focal firm.

CONCLUSION

One important characteristic of the business landscape of the modern world is that successful firms have to ride waves of transient competitive advantages (McGrath, 2013). To do so, a firm faces challenges first in learning what the market is signaling, second in deciphering what innovative solution the firm can come up with to answer the market call by mobilizing its resources, and third, in how to deal with considerable challenges in resolving uncertainties appearing with upstream suppliers and downstream complementors.

The literature has provided a rich collection of factors, each of which represents a challenge facing business enterprises with respect to innovativeness and good performance outcomes for a firm (Christensen, 1997; Marzi et al, 2017). However, as pointed out by (Adner & Kapoor, 2010) and as shown in this paper, challenges that surround an innovative design, consequent production and movement of the product out to the market are often situated both inside a focal firm and within the firm's ecosystem. This paper propels us beyond the traditional analysis of the literature of innovative firms' internal and environmental challenges by theoretically establishing a series of generally true conclusions on systemic logic reasoning and relevant intuition.

By holistically looking at the ecosystem of a focal firm that recognizes an invitation from the market, this paper provides a systemic framework by focusing on input-output threads located throughout a supply chain. Within this framework, we show that the focal firm's innovative idea introduced to answer the market invitation generally posts challenges to upstream suppliers and downstream complementors. We illustrate that suppliers' resolutions to component challenges help the focal firm to produce its ideal product, while complementors' success with their challenges facilitates the necessary conditions for the focal offer to reach customers with full potential of value creation. We examine how an epoch-making understanding of a market invitation by a focal firm can simultaneously challenge both suppliers and complementors with asymmetrical levels of effects on the performance of the focal firm. Specially, we establish the following main results among others:

- Upstream component challenges and downstream complement difficulties can respectively constrain the values a focal firm can create and capture; and
- When a focal firm is more capable to learn and to act accordingly, that firm's ecosystem will experience greater challenges.

Other than developing a series of practically useful conclusions, this paper expands the traditional toolbox of reasoning and analysis through demonstrating the power and usefulness of systems science and methodology. By utilizing holistic thinking and logic reasoning, we are able to investigate the dynamics of the ecosystem of a focal firm, and produce different while more insightful understandings than those in the literature on the distribution of challenges, appearance of uncertainties, evolution of technologies, and performance of a focal firm, (e.g. Utterback & Abernathy, 1975; Anderson & Tushman, 1990; Cusumano et al, 1992).

The conclusions established in this paper provide a practical managerial guideline on how to manage investments in meeting challenges originated from market calls. In particular, we have the following recommendations:

- A firm's investment in speeding up the commercialization cycles when pursuing first mover advantage has to carefully consider whether other firms in the firm's ecosystem can promptly meet their respective challenges or not.
- When introducing an innovative product to answer a market invitation, the more upstream suppliers and the less downstream complementors are challenged, the greater value the product is expected to create and capture.
- If a perceived innovative product posts challenges, downstream complementors will likely have difficulty in meeting the market's need in a timely manner. Consequently, the innovative product needs to be modified to ease the expected difficulty confronting complementors.
- Any firm that desires to be succeed in its market domain needs to focus on improving its capability to learn and to discover. Potential performance advantages of the firm originate from such capability.

In other words, a firm can estimate the levels of relative challenges across its ecosystem well in advance of the commercialization of the firm's innovative idea.

As for the limitations of this work, the first one stems from the assumption of why a firm in the business world exists, because not all firms aim at generating positive cash flows. Firms, developed for reasons beyond generating positive cash flows, can behave in different ways than what is described in this paper. Second, although this paper looks at the distribution of challenges across the ecosystem of a focal firm, we did not consider the innovation challenges the focal firm faces in its core activities. These internal challenges might possibly alter some of the established results if they are somehow correlated with external challenges. Third, this study stays within the context of a single supply chain; however, in real life supply chains, as systems, also interact with each other. That interaction of a higher systemic level could very possibly affect the distribution of challenges within each of the interacting supply chains. In other words, this study only presents a baseline structure on top of which other factors and considerations need to be overlaid.

Corresponding to these listed and other unlisted limitations, future studies should incorporate additional contingencies and antecedents in order to produce more practical useful insights than what have been established in this paper.

ABSTRACT

This paper aims to study the impact of resource Constraint on accelerating innovation by leveraging external knowledge. We find the effects of resource constraints on innovation performance are varied on the types of resource constraint. This result differs from the results in some of the previous literature.

KEYWORDS: Open Innovation, Resource constraints, External knowledge search, and Knowledge Management

INTRODUCTION

The 21st century is the era of knowledge-based economies, where innovation is the principal focus of national policy. While companies attempt to enhance competitiveness and expand their market size, innovation can promote continuous business development for companies. It ensures the survival and development of companies that survive in viciously competitive environments. In recent years, innovation has become widespread due to its simplicity and the need to reduce costs. However, most innovations, at least at the grassroots level, are temporary devices created by indigenous creativity that achieve their goals under the constraints of various resources (Balkrishna C. Rao, 2018)

In knowledge-based theory, knowledge is characterized as a key corporate resource and a source of competitive advantage with great strategic value as a tool for creating value (Spender & Grant, 1996; Teece, Pisano, & Shuen, 1997). The continuous pursuit of new knowledge is essential for innovation and to achieve long-term profitability and competitiveness. Open innovation advocates that the strategic application of external resources outweighs the benefits of the confined use of internal knowledge in facilitating innovation (Chesbrough, 2003). Smith et al. (2005) found that the knowledge acquired by dedicated units within an organization is usually authentic, valuable, and difficult to imitate. Internal knowledge fundamentally helps companies discard unimportant information during the knowledge searching process. However, internal research and development (R&D) requires immense time and monetary investments and contains considerable risks. Therefore, companies can use external knowledge searches (EKS) to complement internal knowledge.

EKS strategies can help companies in their innovation efforts (Laursen & Salter, 2006; Levinthal & March 1981; Zhang & Li, 2008). Katila and Ahuja (2002) expressed that during technical and market uncertainty, the most effective action that companies can take is EKS to adjust and restructure internal organizations. The acquisition of external information and technical resources reduce the cost and complexity of technical company is insufficient to support rapid responses to market changes. Companies must appropriately utilize external sources or channels to acquire the latest resources and innovation information. Laursen & Salter (2006) also pointed out in his research that the more open and breadth or depth of search an organization has, the more innovative its ability is. Because openness plays an extremely important role in the innovation performance of an enterprise, There should be a focus on openness, good connections with Communities and Networks, but too much breadth or depth of EKS can actually be counter-productive to spend too much time and money. Different forms of organizational slack divergently influence a firm's open search strategy, contributing to the understanding of the relationship between organizational slack and knowledge search behavior in a broader context, as well as the understanding of the moderating effect of absorptive capacity. Many scholars have suggested that different external knowledge search strategies may produce different results (Chen et al., 2011; Laursen and Salter, 2006), which may be the cause of inconsistencies in past empirical results. In the depth and breadth of external knowledge search, past empirical results show that the breadth and depth of external knowledge search has no significant impact on innovation performance (Ferreras-Méndez et al., 2015), and some research results show that external knowledge breadth and radical Innovation has an inverted U-shaped relationship (Ardito & Petruzzelli, 2017), and some results show that breadth of external knowledge has only an inverted U-shaped relationship with incremental innovation, and has no significant impact on radical innovation (Hwang & Lee, 2010).

The objectives of this paper are: a) to analyze the relationships of the EKS strategies companies adopt on their innovation performance, and b) to evaluate the influences that companies' resource constraints have on their EKS strategies and innovation performance. In collation of the preceding research motivation, this paper examines the following issues: (1) Relationships of EKS on innovation performance. (2) Relationships of resource constraints on innovation performance. (3) Relationships of resource constraints on EKS.

LITERATURE REVIEW AND HYPOTHESES

External Knowledge Search and Innovation

Knowledge-based theory emphasizes that enterprises must demonstrate sufficient internal competency to manage knowledge effectively. It also focuses on the effects of knowledge acquisition models on the learning performance of organizations (Grant, 1996; Tidd & Trewhella, 1997; Poppo & Zenger, 1998).
Abeson and Taku (2009) categorized knowledge into internally generated knowledge (R&D) and externally acquired knowledge (cooperation and purchase). Probst et al. (2000) proposed the knowledge gap model and asserted that the key objectives of knowledge management are to bridge the knowledge gap in strategies and determine the internal and external knowledge required by enterprises, the knowledge enterprises currently have, the knowledge enterprises lack, and whether enterprises are able to self-generate the knowledge that they lack. When enterprises are unable to generate the necessary knowledge through R&D, they are required to acquire the knowledge externally. Innovation processes consist of actors searching for knowledge, and of combination and integration processes of that knowledge (Savino et al., 2015). Martini et al. (2016) .Laursen & Salter (2006) combines the ways in which researchers access knowledge and works on the relationship between external knowledge search and innovation performance and establishes a solid foundation for an open innovation strategy. Its strategy of depth and breadth is proposed for external knowledge search. "External search of breadth" refers to the number of enterprises 'innovation activities relying on external sources or search pipelines, while "deep external search" refers to enterprises' diversification from different external sources or Laursen & Salter also proposed 16 sources of knowledge (search pipeline) such as upstream suppliers, customers, competitors, governments, academic institutions, research institutes and so on.Open innovation advocates that the strategic application of external resources outweighs the benefits of the confined use of internal knowledge in facilitating innovation (Chesbrough, 2003). However, a number of scholars argue that knowledge-rich environments are able to reinforce the innovation capability of enterprises, even if they do not actively employ search strategies (Garriga, von Krogh, & Spaeth, 2013).
Innovation, defined as the application of unique methods to incorporate novel concepts into new products, services, or manufacturing processes (Urabe, 1988), involves a linear conversion of scientific knowledge into technical knowledge to improve product development outcomes (Gomory & Schmitt, 1988). Hence, innovation transforms creative ideas into useful products, services, or operating methods that are profitable for enterprises.
Enterprises can eliminate or change the current organizational protocols and routines through knowledge acquisition. Knowledge enables enterprises to make different decisions and achieve innovation by redefining existing markets or creating new markets (March, 1991; Miner et al., 2001). Enterprises engage in external searches to acquire external knowledge. They then use external knowledge sources to achieve innovation and reap immense profit (Menon & Pfeffer, 2003). EKS enhance enterprise innovation. However, such searches incur costs. Excessive knowledge searches (including excessive broad and in-depth knowledge searches and excessive outward exploration and exploitation knowledge searches) may cause an enterprise to waste unnecessary energy, time, and money, hindering enterprise performance.
Companies are increasingly competing in an open innovation environment. Therefore, the search strategy of external knowledge is decisive for the success of the company. Existing research distinguishes the breadth (diversity) and depth (strength) of firms dealing with external sources of knowledge (Iferd, Younes; Plötz, Patrick,2018). Laursen & Salter (2006) examines UK manufacturing knowledge search depth and breadth. The two search strategies for innovation performance (new product revenue share of business turnover), found that both exist inverted U-shaped relationship. In other words, the external search strategy can improve the

innovation performance of an enterprise, but accumulate to an extent without any subtraction because the extensive knowledge source pipeline or the deep search of too many source pipelines not only leads to cost increase, but also complexity Increase, so that enterprises can not absorb the huge external information. In addition, Laursen & Salter believes that in the general environment, the appropriate depth and breadth search lead the enterprise to achieve the highest level of innovation performance. The depth and breadth of external knowledge have different effects on innovation. The depth of external knowledge helps to generate groundbreaking ideas, novel ideas, and different past solutions and is therefore particularly helpful for radical innovation (Cohen & Levinthal, 1990; Schilling & Green, 2011), while a breadth of external knowledge Are more conducive to the gradual and progressive progress of the organization. However, it is also more difficult to solve the fundamental problem of breakthrough than the high possibility of novelty (Schilling & Green, 2011)

Although EKS helps to improve the innovation performance of enterprises, some costs still exist. With the improvement of EKS, enterprises may have a negative correlation between EKS and performance due to the increase of pipeline complexity, the increase of transaction costs and the increase of information needs and information processing costs. Therefore, "excessive" knowledge search, including excessive depth and breadth of knowledge search, may cause enterprises to waste too much energy and time costs, resulting in the Performance and performance reduction. In summary of the aforementioned discussion, the following hypotheses were proposed:

H1a: Depth EKS has inverse U-shaped relationship with radical innovation.
H1b: Depth EKS has inverse U-shaped relationship with incremental innovation.
H2a: Breadth EKS has inverse U-shaped relationship with radical innovation
H2b: Breadth EKS has inverse U-shaped relationship with incremental innovation

Resource Constraints and Innovation

The daily routines of enterprises, such as production, marketing, labor allocation, R&D, and finance, require various tangible and intangible resources to sustain normal operations. Previous studies concerning the resource constraints of enterprises proposed a variety of descriptive, explorative, conceptual, and qualitative variables. Hewitt-Dundas (2006) indicated that a type of interrelation exists between the constraint variables that affect innovation.The intensity of innovation in an enterprise depends on the availability of resources, primarily financial and human resources constraints (Trajkovski & Jovan, 2018).

However, studies on cognitive psychology have found that when resources are restricted, individuals are more able to be creative and resolve innovation-related problems (Durham et al., 2000; Moreau & Dahl, 2005). Iammarino et al. (2009) found a positive correlation with the cognitive constraints and innovation tendencies of enterprises. These findings suggest that resource constraints may facilitate enterprises’ innovation activities. From a macro-environment perspective, the application constraints of corporate resources refer to intrinsic conditional constraints, external regulatory constraints (e.g., the human genome research in the field of life science), and country backgrounds (e.g., lack of professionals or lack the requirements to enter key markets). These forms of constraints may affect the enterprises’ innovation behavior (Shan, 1990). Garriga, von Krogh, and Spaeth (2013) found a negative correlation between resource application constraints and enterprise innovation. Moreover, national and regional regulatory restrictions are also factors obstructing innovation.

A consensus has yet to be reached concerning the impact of resource constraints on innovation. However, the findings of most studies indicated negative correlations between resource constraints and innovation. Vossen (1998) asserted that a number of enterprises

encounter personnel constraints when engaging in external searches. Large companies are able to attract highly specialized professionals and are therefore more capable of innovation. For SMEs, Resources are often limited and these constraints can interfere with their ability to innovate. Therefore, in order to meet research objectives, it is crucial to analyze the theory of the impact of corporate resources on innovation(Woschke, Tino; Haase, Heiko; Kratzer, Jan, 2017). Barber et al. (1989) asserted that it can be a challenge for smaller companies to recruit experienced, highly skilled employees and to have to continuously invest in personnel training and technology development, thus restricting innovation performance (Brown et al., 1990). Moreover, the lack of R&D professionals and/or experienced professionals may impact enterprises' innovation behaviors (Shan, 1990). The execution of EKS and the acquisition of external knowledge require R&D teams and innovation professionals. Therefore, enterprises that lack such teams and professionals are less able to engage in innovation. Hence, the following hypothesis was proposed:
H3: Personnel constraints has a negative effect on radical innovation and incremental innovation.
Knowledge constraints are also an issue that organizations cannot easily overcome and solve because innovation-related knowledge is often tricky and not readily available and not easily understood, therefore, it will not be conducive to the radical innovation activities of enterprises, but will promote some systems and processes depending on incremental innovation of the previously-used search channels and methods (Ahuja & Lampert, 2001; Carlile, 2004). Keupp & Gassmann (2013) assumes that there is a negative impact between knowledge constraints and radical innovation. The following hypothesis was proposed:
H4a: Knowledge constraints has a negative effect on radical innovation.
H4b: Knowledge constraints has a positive effect on incremental innovation.
Capital adequacy helps companies accelerate the introduction of new products without missing out on opportunities and creating maximum benefits (Patzelt et al., 2008). Therefore, companies without adequate funding will not be able to support relevant organizational activities, improve their products, conduct small-scale key technological improvements, introduce attractive products, and gain solid market share (Hsu-Hua et al., 2011) . From a financial resource point of view, the source of funding is a significant consideration for firms before they engage in innovation activities. Keupp & Gassmann (2013) assumes that financial constraints have a positive impact on radical innovation. Hewitt-Dundas (2006) also stated their relationship in the findings, arguing that there is a gap between financial constraints and innovation positive relationship, companies that face financial constraints or have experienced financial distress find themselves under pressure and enable organizations to engage in innovation-related activities, both in product development and business strategy, and companies can take advantage of this The chance of success of its innovation.
H5a: Financial constraints has a positive effect on radical innovation.
H5b: Financial constraints has a negative effect on incremental innovation.

Resource Constraints and External Knowledge Search

Laursen (2012) asserted that enterprises are met with resource constraints when they engage in EKS. Therefore, enterprises must take into account limited organizational resources and current conditions when engaging in broad and in-depth external searches in order to make accurate fit and trade-off decisions (Liu & Chen, 2013). Moreover, the majority of scholars believe that enterprises with resource constraints do not have adequate support and are less able to engage in in-depth EKS. The reason is because such searches are costly. However, internal resources also affect trade-offs and dilemmas concerning exploration and exploitation

(Argote & Ingram, 2000). Therefore, resource application constraints may form different search strategies and modes (Argote & Ingram, 2000). In terms of resource constraints, personnel and knowledge constraints are key aspects of knowledge acquisition. Hence, negative innovation resource constraints may hinder enterprises' EKS.

For many businesses, knowledge constraints are a problem that cannot easily be overcome because innovation-related knowledge is often not readily available and not easily understood (Ahuja & Lampert 2001; Carlile 2004) In the absence of knowledge, innovation-related people may not know how to obtain market information, technology, etc. Zhang et al. (2008) indicated that enterprises may be detrimental to finding out-of-industry knowledge when limited by the use of resources. Hewitt-Dundas (2006) argues that there is a correlation between the limiting variables that affect innovation. From a knowledge point of view, for example, Roberts (1999) finds that an organization's R & D-related resources will affect knowledge restrictions and their innovations, ie, not enough Of the research funding, cannot support the R & D team to get more technology and knowledge and further breakthroughs, because R & D always requires constant trial and error, and the opportunity cost is high, therefore, knowledge restrictions will not be conducive to external knowledge search activities .The following hypothesis was proposed:

H6: Personnel constraints has a negative effect on depth EKS and breadth EKS.

H7: Knowledge constraints has a negative effect on depth EKS and breadth EKS.

Studies on cognitive psychology have found that when resources are restricted, individuals are more able to be creative and resolve innovation-related problems (Durham et al., 2000; Moreau & Dahl, 2005). Iammarino et al. (2009) found a positive correlation with the cognitive constraints and innovation tendencies of enterprises. These findings suggest that resource constraints may facilitate enterprises' innovation activities. From a macro-environment perspective, the application constraints of corporate resources refer to intrinsic conditional constraints, external regulatory constraints (e.g., the human genome research in the field of life science), and country backgrounds (e.g., lack of professionals or lack the requirements to enter key markets). These forms of constraints may affect the enterprises' innovation behavior (Shan, 1990). Garriga, von Krogh, and Spaeth (2013) found a negative correlation between resource application constraints and enterprise innovation. Moreover, national and regional regulatory restrictions are also factors obstructing innovation. In the absence of internal finance, firms are more inclined to conduct knowledge search activities abroad because organizations need financial support for many activities, such as research and development, marketing or innovation activities. Therefore, Survival and competitiveness are often accelerated by the introduction of new products as the faster the introduction of new products, the more profit can be derived from them, thereby reducing the overall risk and stress (Keupp & Gassmann, 2013).Although financial limitations contribute to external knowledge search, personnel limitations and knowledge restrictions are an important part of knowledge-related knowledge. Therefore, the negative effect will lead to the overall resource limitation is not conducive to external knowledge search. The following hypothesis was proposed:

H8: Financial constraints has a positive effect on depth EKS and breadth EKS.

Based on the concept of Laursen & Salter (2006), this study divides external knowledge search into depth and breadth and discusses its impact on innovation performance. In addition, this study attempts to explore the impact of resource constraints on external knowledge search and innovation performance of enterprises. Including the impact of financial resource constraints, knowledge resource constraints and personnel resource constraints on innovation performance and the depth and breadth of external knowledge search. The research frame is illustrated as figure 1.

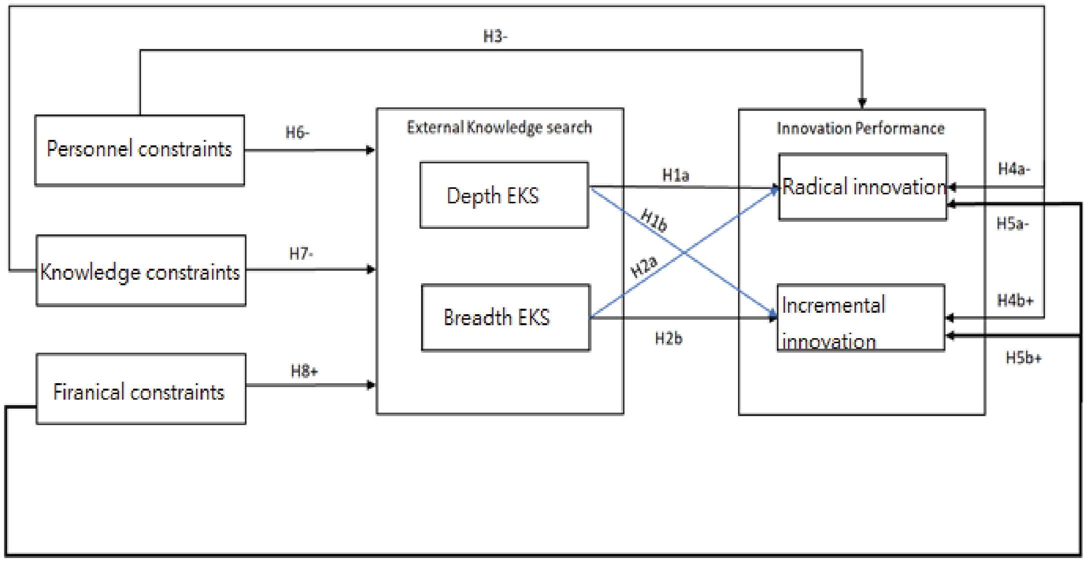

Figure 1. Research Framework

METHODOLOGY

Sampling

In this paper, the top one-thousand Taiwanese manufacturers reported in *Common Wealth Magazine* in 2015 were selected as the targets for a questionnaire survey. The reasons for selecting manufacturers are as follows: (1) Taiwan's economic growth is largely based on manufacturing, and the development of the manufacturing industry is a key aspect of future innovation and investment (*Common Wealth*, 2015). (2) The manufacturing industry centers heavily on developing new techniques and products. (3) Laursen and Salter (2006) selected manufacturers in England as the sample population. The questionnaires were administered via surface mail. One thousand questionnaires were sent and 118 were received, among which one invalid questionnaire was omitted. The final number of valid questionnaires was 117, with a recovery rate of 11.7%. In the second round of the survey, a convenient sampling approach was adopted in the form of an online questionnaire. A total of 65 questionnaires were received. Therefore, a total of 182 valid questionnaires were collected for the second sampling round.
A test for non-responsive bias was performed to identify the potential non-responsive biases in the questionnaire recovery process. The recovery channels of the questionnaires were first classified in chronological order. An independent *t*-test and chi-square test were performed to make a pair-wise comparison of the samples and determine whether biases existed in the research variables and demographics. The samples collected in the first sampling round, that is, those collected from the top one-thousand Taiwanese manufacturers via surface mail were characterized as the early recovery group, which comprised 117 samples. Those collected in the second sampling round, that is, those administered electronically to friends and relatives in the manufacturing industry, were characterized as the late recovery group, which comprised 65 samples. Significant effects confirmed in the *t*-test and chi-square test outcomes denoted that

the significant differences existed between the early and late recovery groups. Actual test results indicated no significant differences between the various variables and demographics in the two groups.
To prevent the subjectivity of a single respondent from creating common source biases in the questionnaires, the questionnaire was evaluated using research program design theory before administration (i.e., eliminate underlying preferences in the item descriptions) to reduce common source bias. Once the questionnaires were recovered, Harman's one-factor test was performed to evaluate the severity of common source bias (Podsakoff & Organ, 1986). A principal component analysis was adopted as the factor analysis without rotation. A total of 15 eigenvalues greater than 1 were extracted and examined. No one-factor conditions were observed. The explanatory variance of the first principal component was 23.121%. Hence, it was unable to explain the majority of the variance, implying that the research data did not contain significant common source biases

Sample Characteristics

Taiwanese manufacturers were the research participants in this paper. In terms of industry distribution, the majority were metal production and processing vendors (N=26; 14.3%). In terms of company age, almost half of the manufacturers (48.9%) have been in operation for over 31 years, suggesting that most of the samples were from sustainable enterprises. In terms of scale, most of the samples (51.6%) were large companies with more than 250 employees, suggesting that most of the companies engaged in large-scale operations. In terms of position, most of the respondents were managers or deputy managers (32.4%), suggesting that the majority of the respondents were in management roles and demonstrated adequate managerial experience

Variable Measurement

The EKS scale was developed based on the findings of Laursen and Salter (2006). The scale comprised 11 knowledge sources, including upstream suppliers (e.g., raw material, equipment, and software suppliers), clients, competitors, consultants, exhibition/display organizers, trade unions (e.g., export and fair trade unions), government-owned research institutes (e.g., Academia Sinica, Industrial Technology Research Institute, Institute for Information Industry, and National Health Research Institutes), other public/government departments (e.g., Ministry of Economic Affairs, Ministry of Labor, and Directorate-General of Budget, Accounting, and Statistics), professional conferences (e.g., domestic/foreign conference and international forums), university research institutes, and private research institutes. The respondents measured the innovation contribution of the knowledge and information acquired by the 11 knowledge sources to their companies. A four-point scale was used for scoring, where 0 denotes that the knowledge source made no innovation contribution to the company, 1 denotes a slight innovation contribution, 2 denotes some innovation contribution, and 3 denotes a large innovation contribution. A higher score signified a more extensive knowledge search.
The resource constraints scale was developed based on the findings of Keupp and Gassmann (2013), Hewitt-Dundas (2006), and Garriga and Spaeth (2013). The scale comprised six items to measure personnel constraints, financial constraints, and knowledge constraints. A Likert five-point scale was used to measure the items (1=very unsatisfied and 5=very satisfied). A higher score signified higher resource constraints perception.
Managerial ties refer to the individuals' external contact through their relationships and interpersonal networks. The managerial ties scale was developed based on the findings of Qin et al. (2010) and Li et al. (2014). The scale comprised nine items. A Likert five-point scale was

used to measure the items (1=very unsatisfied and 5=very satisfied). A higher score signified stronger ties between the respondents and external experts.
The innovation performance scale was developed based on the findings of Leal-Rodríguez et al. (2014) and Kim et al. (2012). The scale comprised nine items to measure radical product, service, and procedural innovation, and six items to measure incremental product, service, and procedural innovation. A Likert five-point scale was used to measure the items (1=very unsatisfied and 5=very satisfied). A higher score signified a higher innovation performance perception.
The control variables comprised industry type, number of employees, technical uncertainty, and market uncertainty. Industry type was set using dummy variables and chategorized into high-technology industries and ultra-high-technology industries. Damanpour (1992) asserted that company size and employee size could affect innovation performance in one of two ways. One is the generation of laziness because the company is too large to change, reducing innovation performance. The other is the increase in innovation performance because large companies contain adequate resources. Atuahene-Gima and Li (2004) examined past innovation-related issues and found that technical uncertainty and market uncertainty are the two key factors influencing IP. The technical uncertainty scale was developed based on the findings of Atuahene-Gima and Li (2004). It comprised four items. The market uncertainty scale was developed based on the findings of Jaworski and Kohli (1993). It comprised three items.

Reliability and Validity

Reliability measures the consistency and stability of evaluation and measurement tools and tests the internal consistency of the scale composition. In this paper, the Cronbach's α coefficient was adopted as the reliability measure. An increased coefficient signified a higher internal consistency. Nunnally (2010) proposed that the reliability reaches an acceptable range when the Cronbach's α coefficient is greater than 0.7. Based on this standard, the Cronbach's α coefficients for the various variables are tabulated in Table 1. The table shows that the Cronbach's α coefficients for all the variables were higher than 0.749, suggesting that the scales used in this paper achieve excellent reliability.

Table 1. Reliability Analysis

Variables	Items	Factor loading	Cronbach's α	CR	AVE
Personnel constraints	1. The company lacks "R & D personnel"	0.84	0.749	0.799	0.665
	2. The company lacks "management professionals"	0.79			
Financial constraints	1. The Company lacks "funds (including self-financing or borrowing money from banks)"	0.83	0.847	0.892	0.805
	2. The Company lacks R & D funding	0.96			
Knowledge constraints	1. The company lacks "technical knowledge"	0.96	0.799	0.881	0.789
	2. The Company lacks "market knowledge"	0.81			
Radical Innovation	1. Our"technological competitiveness" is higher than that of our competitors	0.70	0.901	0.953	0.692

	2.	Our "speed of technological innovation" is faster than our competitors	0.85			
	3.	Our "process, method update faster than competitors	0.89			
	4.	Our products / services have the latest technology	0.86			
	5.	We can grasp the most innovative processes, methods	0.87			
	6.	Our "new level of product / service" is great	0.87			
	7.	Our "new product development speed" is very fast	0.83			
	8.	We often introduce new products to the market	0.80			
	9.	Our products / services are unique, novel	0.80			
Incremental Innovation	1.	We have made minor improvements in "technology and technology"	0.68	0.877	0.900	0.547
	2.	Our products / services are further improvements on the original products / services	0.70			
	3.	We introduce new products that are more incremental (ie, less innovative) than our peers	0.84			
	4.	The proportion of our incremental innovation products, higher than their peers	0.91			
	5.	The Company's revenue from incremental innovative products has been growing year by year	0.88			
	6.	For customers, we are famous for progressive product innovation	0.88			

Content validity measures the appropriateness and representation of the scale content, or rather whether the scale encompasses all desired research aspects. All variables measured in this paper contained theoretical bases and were formulated based on an extensive literature review and an empirical questionnaire survey. Prior to formal testing, an expert scholar and six industry experts were invited to review and revise the questionnaire. Therefore, the scales used in this paper achieved excellent content validity.

Moreover, a confirmatory factor analysis was performed to test the convergent validity and discriminant validity of the scales. For convergent validity, the standards proposed by Fornell and Larker (1981) were adopted. They were: (1) the standardized loading between the items and their latent variables must be greater than .5; (2) the average variance extracted (AVE) must be greater than .5; and (3) the composite reliability (CR) must be greater than .6. The CR values for all the variables were between .8 and .95, meeting the recommended value of .6, and the AVE values were between .5 and .87, meeting the recommended value of .5. Hence, all variables converged at their respective factor dimensions, suggesting excellent convergence validity.

RESULTS

A regression analysis was performed to validate the proposed hypotheses and examine the associations among the variables. The Durbin-Watson (DW) value was adopted to determine whether the errors were auto-correlated. The DW values for the models ranged between 1.746 and 2.294, suggesting no severe autocorrelation in the errors. A regression analysis was performed on the variables to validate the hypotheses proposed in this paper.
H1a claims that depth EKS has an inverted U-curve relationship with radical innovation. The regression results are tabulated in Table 2. The results in the Model 2 column indicated no inverted U-curve for the relationship between depth EKS and radical innovation (β =0.141). Therefore, H1a is rejected. The results in the Model 4 column indicated a U-shaped curve for the relationship between depth EKS and incremental innovation (β =0.277). Therefore, H1b is supported the results in the Model 2 column indicated an inverted U-curve for the relationship between breadth EKS and incremental innovation (β =1.420; P<0.05). Therefore, H2a is supported. The results of the Model 4 column in Table 2 indicated Breadth EKS has inverse U-shaped relationship with incremental innovation (β =0.500; P<0.001). Therefore, H2b is supported. H3 claims that personnel constraints has a negative relationship with radical innovation and incremental innovation (β = -0.46,-0.076). Therefore, H3 is rejected. H4a claims that knowledge constraints have a negative relationship with radical innovation The results of the Model 2 column in Table 2 indicated a significant and negative correlation between personel constraints and innovation performance (β =-0.259; P<0.001). Therefore, H4a is supported. H4b claims that knowledge constraints have a positive relationship with incremental innovation (β =0.080). Therefore, H4b is supported. H5a claims that financial constraints has a postive relationship with innovation (β =0.0100). Therefore, H5a is supported. H5b claims that financial constraints have a negative relationship with innovation (β =-0.132). Therefore, H5b is supported.

Table 2. Effects of Resource Constraints and External Knowledge Search on Innovation Performance

	Radical Innovation		Incremental Innovation

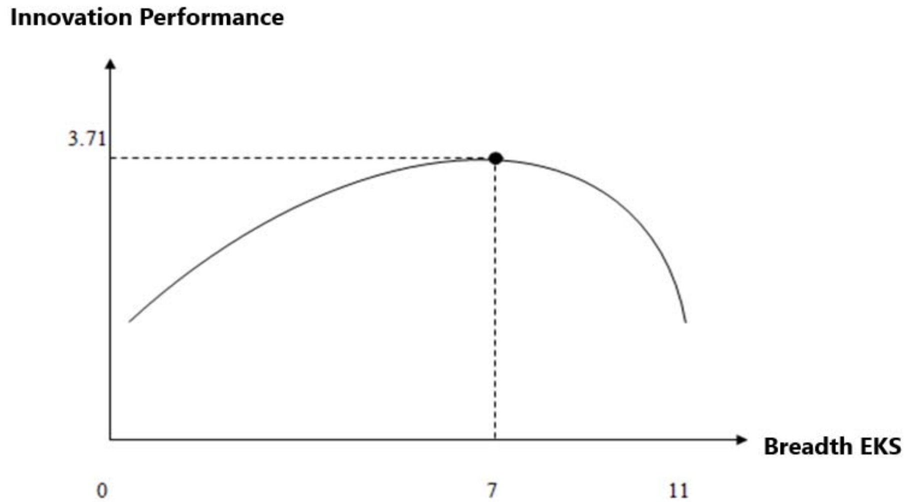

Figure 3. Breadth of external knowledge search and innovation performance

CONCLUSION AND FUTURE RESEARCH

Conclusion and Implications

This paper aims to elucidate the effects of resource constraints, breath and depth of EKS on innovation performance. The conclusion and theoretical contributions of this paper are presented in this section.

Empirical findings show that different EKS strategies affect radical and incremental innovation performance differently. This paper hypothesizes that depth and breadth of EKS has an inverted U-curve relationship with innovation performance; wherein an increase in EKS would initially improve innovation performance , but excessive EKS would reduce innovation performance. Empirical results showed that depth of EKS and innovation performance failed to has a significant inverted U-curve relationship (H1a was rejected); depth of EKS has an inverted U-curve relationship with incremental innovation (H1b was supported); and EKS and radical innovation failed to has an inverted U-curve relationship, but rather a U-shaped curve relationship (H1a was rejected). The inverted U-curve relationship exhibited between depth of EKS, and incremental innovation was similar to the findings of Laursen and Salter (2006). However, the relationship between depth of EKS and radical innovation was inconsistent with the results proposed by Laursen and Salter (2006). Rather, a U-shaped curve relationship was observed. The reason for the rejection of H1a may be the offset of contradicting effects between radical innovation and incremental innovation and EKS. Because EKS exhibited opposite effects on radical and incremental innovation, the offset of the two effects confirms that the effects of EKS on innovation performance are insignificant.

The most appropriate external search strategy for a business will depend on the type of business innovation (Garriga & Spaeth et al., 2013). When a company adopts incremental innovation, the use of external sources of knowledge will be more important than radical innovation (Moon, 2014). That is, incremental innovation relies more on the use of open EKS, which requires more breadth of EKS pipeline than depth of EKS. Although EKS helps to improve the innovation performance of enterprises, some costs still exist. With the improvement of EKS, enterprises may have a negative correlation between EKS and performance due to the increase of pipeline complexity, the increase of transaction costs and the increase of information needs and information processing costs. Therefore, "over-performing" knowledge search, including excessive depth and breadth of knowledge search, may cause enterprises to waste too much energy and time costs, resulting in lower business performance.

Although many scholars have previously investigated the success factors of corporate innovation, the competencies required to achieve innovation, and the importance of organizational learning, few have examined the internal resource constraints that could potentially threaten enterprises' innovation activities. In this paper, the empirical results personnel constraint rejected H3, indicated no significant correlation between personnel constraint and innovation performance. These results are inconsistent with a number of previous studies (Hewitt-Dundas, 2006; Garriga et al., 2013). From a resource-based perspective, enterprises are able to perform internal audits to determine the relationship between input resources and innovation performance (Hadjimanolis, 1999). Although large manufacturers have considerably more resources at their disposal, they may still be challenged with resources inadequacy. These constraints may affect organizations' innovation performance.

Few scholars have investigated the relationship between internal resource constraints and the knowledge activities of organizations. Based on the conclusion of Laursen et al. (2012), this paper argues that enterprises may be constrained by limited resources while engaging in EKS. In this paper, the empirical results resource constraints partially supported hypotheses, suggesting that resource constraints failed to significantly affect EKS. These results are prompted by one of two reasons. First, resource constraints may have a positive influence on EKS. A number of studies have indicated that certain resource constraints facilitate enterprises in implementing external search strategies (Gupta et al., 2006; Zhang Li, 2008; Schilling & Green, 2011). Because the effects of resource constraints on EKS activities contain positive and negative aspects, they offset each other. Second, different types of resource constraints produce different effects. For example, financial resource constraints may produce positive effects, while labor and knowledge resource constraints may produce negative effects. These effects offset one another, thereby partially supporting hypotheses.

Practical Implications

In terms of resource constraints, this research can help administrators to identify key internal resources and understand the effects of these factors on search strategies before they engage in depth and breadth of EKS or innovation activities. This paper also helps future scholars elucidate the effects of resource constraints on EKS strategies and highlight the relationships and contradictions between innovation activities and performance. For example, the provision of an open education environment to foster employees' perseverance and willingness to engage in lifelong learning, encourage further education, and/or participate in social exchanges, and suitably provide encouragement and incentives, can generate substantial knowledge sources and foster highly technical employees, thereby improving organizational performance.

Empirical results showed that EKS strategies facilitate innovation performance. Therefore, enterprises should utilize their information sources and channels from various levels, such as establishing R&D alliances and participating in conferences to help them overcome the problem of narrow search ranges and enhance innovation performance. However, excessive broad and in-depth searches could harm the enterprise by wasting the energy and time cost of the organization. Therefore, enterprises must seek to balance and trade-off searches. Before engaging in external searches or innovation activities, enterprises must evaluate their type of innovation they wish to achieve, such as incremental or radical innovation; wherein the former requires a shorter amount of time with relatively lower risk but less beneficial, or the latter, which requires more time and is riskier and costly but yields greater results. Moreover, successful innovation relies on the external searches of innovators. Once external knowledge sources are acquired, innovators can determine whether these sources can be internalized and their ideas commercialized. This process requires a series of market surveys and repeated trial and errors.

Limitation and Future Research

The design of this paper sought to meet the criteria of scientific research. However, several research limitations were apparent. First, a list of Taiwanese manufacturers proposed by *Common Wealth Magazine* in 2015 was used as the population for data collection. However, because the respondents were largely executives from the manufacturing industry, the research results may not apply to other industries. In addition, this paper adopts a cross-sectional research design, implying that the dynamic changes of resource constraints, depth and breadth of EKS, and innovation performance could not be determined. Future researchers can adopt a similar research framework and use a more diverse set of samples. Alternatively, they can also adopt a longitudinal research design coupled with qualitative analysis to examine the long-term development of the research variables.

Second, the questionnaire survey was administered via surface mail; wherein each enterprise was sent a copy of the questionnaire. The questionnaires were completed by executives or R&D teams. However, answers may be subjected to the subjectivity of the respondent. Therefore, the common source bias problem must be taken into account. Therefore, a statistical method was applied to elucidate whether common source bias existed in the recovered questionnaires. To prevent the problem of subjectivity, future researchers can survey a wider range of respondents, where one questionnaire is provided to different employees within the enterprise. This process can generate more objective results and reduce the effects of common source bias.

Third, the cause and effect variables influencing depth and bread of EKS and innovation are abundant and complex. This paper only adopts a resource-based perspective to analyze internal resource constraints such as personnel constraints, financial constraints, and knowledge constraints. Future researchers can collect a wider range of variables influencing resource constraints and categorize these variables into internal and external variables, tangible and intangible variables, and/or controllable and uncontrollable variables to facilitate their research.

ABSTRACT

We develop a soft operational research heuristic called the CURVO Grid for IT vendors for competitive strategizing that combines real options logic with several theories of competitive advantage, including Porter's competitive forces model, the resource-based view (RBV), dynamic capabilities approach, core competence theory, and the theory of the ambidextrous firm.

KEYWORDS*:* Information technology strategy, real options, resource-based view, dynamic capabilities approach, core competency theory, theory of the ambidextrous firm

INTRODUCTION

Real Options (RO) is both a conceptual framework and a quantitative valuation methodology and it is here to stay. The chief difference between RO and traditional capital budgeting methodologies, such as the net present value (NPV), is that RO treats investment opportunities as options (Dixit and Pindyck 1995, Luehrman 1998). When investment opportunities are viewed as options, then timing is everything. One does not necessarily have to make the decision now. It is eminently reasonable to keep the option of investing in that opportunity open to gather more information on the value of the opportunity. This stands in stark contrast to the traditional NPV analysis, which takes a "now-or-never" approach to investing (Dixit and Pindyck 1995, Luehrman 1998). In the RO approach, the investment decision does not necessarily have to be made at time $t = 0$. If the uncertainty surrounding the investment opportunity is high, one could wait till time $t = 0 + \Delta t$ to make the decision and use the time Δt for more information to arrive, which resolves some of the uncertainty surrounding the investment opportunity. For example, new information could arrive about how some other firm fared with making a similar investment; or it could be about a technology standard related to the investment that emerged as the winner among several competing standards.

The time Δt need not necessarily be spent passively waiting for new information to arrive from the external environment that resolves some of the uncertainty. This time could well be spent in actively learning about new technologies associated with the investment. For example, if a firm is contemplating investment in some complex information technology (IT) such as the service-oriented architecture (SOA) and Web Services (Erl 2005, Krafzig et al. 2005), a firm without deep roots in this technology could use the time Δt in doing a small pilot project to acquire knowledge about the benefits and pitfalls of SOA. Hence, the RO approach to capital budgeting inherently has the element of timing when it is best to make the investment in much the same way that a holder of a financial call option is timing when to exercise the call option (Dixit and Pindyck 1995, Luehrman 1998).

As our literature review shows later, RO logic in the information systems (IS) discipline has been applied mainly from the standpoint of a user or buyer of technology to value the investment in the face of uncertainty and managerial flexibility to change course depending on how the future unfolds. RO logic has not been used from the perspective of the IT vendor on how to gain competitive advantage in the markets of their products and services. In this paper, we develop a software operational research heuristic called the CURVO Grid to help IT vendors with developing competitive strategy. Within an RO framework, we integrate various theories of competitive advantage including Porter's five competitive forces model (Porter 1980, 1985), Barney's resource-based view (RBV) (Barney 1991, 2001), the dynamic capabilities approach (Teece et al. 1997), the core competency theory (Prahalad and Hamel 1990), and ambidexterity theory (O'Reilly III and Tushman 2004). The CURVO Grid is a normative repertory grid (Eden and Jones 1984) that can be used to guide managerial decision-making on the right options and option chains to exercise depending on the state of the firm and the environmental uncertainties the firm faces. The CURVO Grid thus helps management avoid the pitfalls of pursuing misguided strategies.

LITERATURE REVIEW

The power of the RO approach is manifested in the wide range of studies conducted in diverse disciplines. In operations management, the RO approach has been used in different contexts such as switching between different modes of production or between different products as prices and demand change (Kulatilaka 1998, Triantis and Hodder 1990), expanding manufacturing capacity (Kumar 1995, Karsak and Özogul 2002), and modularizing production systems (Gamba and Fusari 2009). In research and development (R&D) in the pharmaceuticals industry, Cassimon et al. (2004) develop a complex multi-stage option to value investment in new drug discovery. Jensen and Warren (2001) have applied RO in evaluating R&D projects at British Telecommunications. In IS literature, RO has been used in various applications including Integrated Services Digital Networks (ISDN) (Dos Santos 1991), electronic banking (Benaroch and Kauffman 2000), multistage IT investments (Bardhan et al. 2004, Benaroch et al. 2006a), migrating from SAP R/2 to R/3 (Taudes 1998), and risk management (Benaroch 2002, Benaroch et al. 2006b, Benaroch et al. 2007).

Apart from studies performed by academics, RO is catching on in industry itself. Graham and Harvey (2001) found that, in a survey of 392 CFOs, approximately 27% of these CFOs are adopting real options analysis in capital budgeting. RO is being utilized in industries as diverse as bio-technology, manufacturing, and natural resources (Miller and Park 2002). As with any emerging paradigm with the potential for far-reaching ramifications for corporate finance, there will of course be dissenting views and conflicting evidence as to the popularity of the new paradigm. Baker et al. (2015) present a less rosy picture about the take-off of RO. In their study of 215 Canadian firms, they found that only 16.8% were using RO, and that RO actually ranked the last of the nine capital budgeting techniques they were using. In a similar vein, a study conducted by Bain and Co. in 2000 of 451 senior executives across more than 30 industries on their use of management tools, only 9% reported using RO (Teach 2003). Sobering as these statistics are for proponents of RO, it is perhaps more useful to probe the true source of the business world's problem with RO and focus efforts on correcting that problem.

The real problem that appears to be stymieing the embrace of RO by the practitioner world is that RO is too mathematical and complicated to implement (Baker et al. 2015, Teach 2003). Teach states, "The sophisticated mathematics of real options (such as partial differential equations) and the consequent lack of transparency and simplicity are real concerns." Baker et al. echo this sentiment and state, "Managers report that a lack of expertise and knowledge prevents them from using real options." Hence, the real problem to address about RO is devising ways to present the technique in a more transparent and similar fashion to practitioners that eschews gory details of partial differential equations and presents the insights provided by RO in a clear and compelling fashion. Two noted experts in RO, Martha Amram and Nalin Kulatilaka, do precisely that in their book on applying RO to manage strategic investments in an uncertain world (Amram and Kulatilaka 1998).

Following up on Amran and Kulatilaka's (1998) work, several efforts are on-going on presenting RO in a clearer fashion to practitioners. Feinstein and Lander (2002) attempt to make RO conceptually simpler by showing that RO can be recast as a form of NPV analysis by choosing an appropriate value for the discount rate. Ghosh and Troutt (2012) take the approach of open-sourcing the algorithms and the software they built for valuing complex compound options. Open-sourcing the software for evaluating options makes the valuation methodology of RO much less of a black-box, since other RO experts can look at the algorithms and use the associated software to verify if the algorithms for implementing the RO valuation models are indeed correct. This can generate trust among managers who may not have the mathematical background to directly understand the RO valuation models and algorithms but can see what the RO community at-large is saying about the open-source software for evaluating RO models. Apart from the open-sourcing approach for RO software tools, another approach is to develop heuristic frameworks for the application of RO in decision-making. Ghosh et al. (2013) develop a soft operational research (OR) heuristic based on the use of a repertory grid (Eden and Jones 1984) for guiding managerial action on investing in enterprise integration (EI) technology.

Many of the studies on the use of RO logic in the IS field have been done from the perspective of a user or buyer of IT. There is also not much discussion of competitive advantage in these studies. These studies of RO also do not tie in how the investment being made in IT results in competitive advantage in the product and service markets the firms operate in. The focus is mainly on building the quantitative options pricing model (OPM) to value the IT investment opportunity without demonstrating how competitive advantage flows from this investment. To make a case for competitive advantage, one would need to tie this investment to theories of competitive advantage such as Porter's five competitive forces model (Porter 1980, 1985), Barney's resource-based view (RBV) (Barney 1991, 2001), the dynamic capabilities approach (Teece et al. 1997), the core competency theory (Prahalad and Hamel 1990), and ambidexterity theory (O'Reilly III and Tushman 2004). Is the IT investment being made by the firm a unique resource not easily replicable by other firms (Barney 1991, 2001)? Does it renew or enhance a core competency of the firm (Prahalad and Hamel 1990)? Does it serve to create barriers to entry or serve to unbalance competitors thereby entrenching the firm in its market (Porter 1980, 1985)? These questions are generally not answered in RO studies in IS.

We review three key studies in RO in this section to demonstrate that their focus is mainly on building a quantitative OPM for valuing a cash flow stream with managerial flexibility with regard to future investments. There is little or no treatment of achieving competitive advantage in the product and service markets the firm competes in. Bardhan et al. (2004) apply RO to the case of a firm in the utilities industry that is evaluating 31 IT projects to be implemented in a phased fashion over three years where there are sequencing constraints across these projects. Bardhan et al. (2004) develop an OPM that determines the optimal sequencing of these projects given the project interdependencies and the annual budget constraints. Their OPM is a nested model where single-period Black-Scholes (1973) options pricing models corresponding to specific projects are nested within each other to compute the present value of the full, multi-period investment program. There is little discussion in the article of how these IT projects are expected to result in competitive advantage for the firm in the market for energy services that the firm serves. For example, some of these IT projects enable electronic billing and payment. But there is no discussion of what the competitors are doing and whether electronic billing and payment represents an innovation in this market. It could also be that the firm is playing catch-up with its competitors and electronic billing and payment is emerging as a requirement in this market; and the firm in question has to support this to prevent a loss of its customers to competitors. Hence, without a discussion of the competition and competitive advantage, it is not clear if the utilities firm in question is exercising a growth option or a survival option in implementing these IT projects. Some of these IT projects could indeed be for survival purposes, while others may be targeted at growth. Without framing the exercise of real options in the context of the competition makes it very difficult to assess if any competition advantage is accruing to the company from its actions.

Taudes (1998) builds an OPM for analyzing the benefits to a firm of deploying the client-server SAP/R3 version of an enterprise resource planning (ERP) system as compared to the SAP/R2 mainframe-based version of the system. The SAP/R3 deployment has the advantage that it could serve as a platform for value-added services such as electronic data interchange (EDI). Taudes (1998) develops an OPM for this scenario which demonstrates the value of having the flexibility to layer value-added services such as EDI at a later stage. Again, there is no discussion of competitive advantage in this article. The industry in which the firm operates is not even mentioned and it is unclear if the firm’s competitors are using EDI or not. Using EDI may result in some cost-savings for the firm as manual paper-based transactions are moved to an electronic format, but this may not be the source of any sustained competitive advantage as other firms may quickly adopt EDI if they are not already doing so. A reduction of internal inefficiencies is not tantamount to competitive advantage.

Benaroch and Kauffman (2000) develop an OPM for valuing the expansion of Yankee 24, a firm that provides electronic banking services, into point-of-sale (POS) debit services. This study is an RO analysis of whether it would be better for Yankee 24 to immediately enter the market for POS debit services in the New England region or to exercise the defer option and wait a while to enter the market. As it is waiting, it can see if POS debit services took off in other parts of the country, and also actively lobby for changes in Massachusetts regulations to create a more benign environment for POS debit services. The competition is addressed to some extent in this study as it factors in the market signal that Yankee 24’s principal competitor NYCE shows no signs of entering the POS debit services market. So while competition is addressed in this study, it should be noted that competitive advantage is not just about how to get there but also very much about how to stay there. Hence, the all-important aspect of sustained competitive advantage is not addressed in this study.

In this article, we look at how to use RO logic in creating sustained competitive advantage and we do so from the perspective of a vendor of IT rather than a user of IT. This article thus fills an important gap in the use of RO in IS literature. In IS literature, RO has been mainly applied from the standpoint of the user or buyer of IT and, furthermore, little attempt has been made in linking the decision to invest in some key IT to how this creates competitive advantage for the firm. We present in this article a qualitative framework in the form of a repertory grid that can guide IT vendors in leveraging RO logic to strengthen their strategies for achieving competitive advantage. As we argued earlier, the mathematical complexity of RO is proving to be too daunting for many practitioners (Baker et al. 2015, Teach 2003). However, there are clear conceptual benefits to using RO logic in managerial decision-making even if the quantitative OPM is difficult to build. Hence, in this article, we build a qualitative decision-making framework in the form of a repertory grid to guide IT vendors in applying RO logic for enhancing competitive advantage.

There have been efforts in the past to formulate qualitative frameworks incorporating the real options perspective to inform managerial thinking. Fichman who has advocated the use of RO in the IS field (Fichman 2004a) developed a four-perspective framework (Fichman 2004b) on the drivers of option value in IT platform adoption decisions. His framework sheds light on the positive and negative influences on option value in IT platform decisions and is based theories from the areas of strategy (Barney 1991, 2001; Wernerfelt 1984, 1989, 1995), organizational learning (Cohen and Levinthal 1990, Kogut and Zander 1992), managerial fashion and bandwagons (Abrahamson 1996, Abrahamson and Rosenkopf 1997), and technology adaptation (Tyre and Orlikowski 1994, DeSanctis and Poole 1994). Insights that his framework provides include: the option value of a technological innovation increases if it contributes to a firm's absorptive capacity, if the knowledge barriers to its absorption are not too high, if it is susceptible to network externalities, if it cannot be readily replicated by competitors, and if it is adaptable to a given firm's organizational context.

Fichman's (2004b) qualitative framework is at a more abstract level than the repertory grid that we describe in this article. Our repertory grid is more of a normative heuristic that can inform IT vendors on promising avenues to follow as well as pitfalls to avoid as they formulate their competitive strategies. Heuristics essentially allow practitioners to operationalize abstract theories. The AACSB has advocated with some urgency that academic research must become more practitioner relevant (AACSB International, 2008), and this issue has also been noted by researchers in various fields such as Benbasat and Zmud (1999) in IS and Gopinath and Hoffman (1995) in strategy. It is precisely in bridging this gap between abstract academic theory and what practitioners can operationalize that the field of soft operational research or "soft OR" with its focus on graphical techniques such as cognitive maps (Eden 2004) and repertory grids (Eden and Jones 1984) has much to offer.

An exemplar soft OR technique that has successfully bridged theory and practice is the widely used Strengths-Weaknesses-Opportunities-Threats (SWOT) matrix. Kua lists the SWOT matrix as among the six most widely utilized soft OR techniques (Kua 2016). It can be argued that it is the SWOT matrix that has brought the structure-conduct-performance theories of industrial organization (Mason 1949, Bain 1959, Schmalensee 1989, Schmalensee and Willig 1989) within easy reach of the practitioner. Our **C**apability-**U**ncertainty **R**eal **V**endor **O**ptions or CURVO Grid takes the SWOT matrix as its guiding light in developing a repertory grid that distills RO and associated theories of competitive advantage into a heuristic that vendors can use for developing competitive strategy. Ghosh et al. (2013) did something similar but, not surprisingly, their focus was on the user or buyer of IT and not a vendor of IT products and services. Indeed much of the work in the information systems (IS) discipline that has leveraged the RO approach in decision-making has been from the perspective of a buyer and user of IT rather than a vendor of IT. RO logic has not been applied directly from the standpoint of how RO-based decision-making can be used by IT vendors to gain competitive advantage in the IT product and service markets they serve. Hence, this study and the one by Ghosh et al. (2013) have fundamentally different perspectives.

THEORETICAL DEVELOPMENT

Our CURVO Grid is based on the soft OR technique of a repertory grid which seeks to classify a set of elements against a set of dimensions or constructs (Eden and Jones 1984). The elements that are being classified into the repertory grid are chains of real options, or a sequence of linked real options, that a vendor can exercise to improve revenues and enhance its competitive position. For example, a real options chain could be to bundle certain products and services into a package; if the market reaction to the package is favorable, then the package's price could be reduced to garner even more revenue; and this could be followed by enhancing the service and support available on the products in the package.

In an NPV valuation of a program of actions performed over time and the cash flows resulting from these actions, the future actions in the program are fixed *ex ante*. In an RO analysis, the action performed at some future time *t* depends on the state that one finds oneself in at *t*. For example, a reduction in the price of a package to ignite demand depends on whether the package got a favorable market reaction. Hence, the value of an options chain, which some authors refer to as the strategic net present value (SNPV) (Park and Herath 2000) differs from that of a fixed chain of actions because of the managerial flexibility that exists in changing any future action among a set of actions available at a future time. SNPV of an options chain is thus:

$$SNPV_{options\ chain} = NPV_{fixed\ action\ program} + Value\ of\ Managerial\ Flexibility \quad (1)$$

Although Equation (1) looks conceptually simply, the second term, or the value of managerial flexibility, can be notoriously hard to calculate as there can be many future states and many different actions that the firm can take depending on what the future brings. However, this is precisely where a qualitative framework is useful because it allows us to have a discourse on the real options and option chains that are attractive relative to others without actually building an OPM to determine the value of the second term.

Elements of CURVO Grid

The two dimensions of the CURVO Grid are uncertainty and firm capability and the elements being classified into the appropriate cells of the grid are real option chains. An individual real option exercised by the vendor can be any of the following:

- Alter price up/down – the vendor can change the price of the offering up or down. Multiple such actions can be taken over time. To learn about the price elasticity of the product, the vendor could lower the price in a geographically limited pilot, before rolling out the price change to the entire market.
- Introduce new features in existing offering – From introducing high-quality cameras in smartphones to sophisticated cluster analysis functionality in business analytics software, introducing new features is a must for IT vendors. This is a requirement for product differentiation players, which is one of the market strategies that Porter (Porter 1980, 1985) identified as resulting in sustained competitive advantage.
- Introduce new and innovative offering – Harvesting electricity from the air to power communication devices is an example of high-impact innovation (Collins 2018). Innovation can of course be less dramatic than that. There are many innovative apps being developed for smartphones and tablets. The kiwi.com app helps consumers book the cheapest flight by searching 18 billion cheap flight combinations hourly to get the cheapest fare (Kiwi.com 2019).
- Increase research and development (R&D) investment – Developing new and innovative products needs increased investment in R&D. R&D expenditure could be of two types:
    - Pursuit of incremental innovation – Incremental innovation is about making improvements to a firm's existing line of products and services, such as adding new features to the firm's offerings.
    - Pursuit of breakthrough innovation – Breakthrough innovation is about coming up with an entirely new and innovative product. The replacement of analog photography by digital photography which Kodak failed to do is example of breakthrough innovation (O'Reilly and Tushman 2004).
- Enter into technology partnerships (incremental or breakthrough) – Technology partnerships in the IT industry are done quite frequently to acquire necessary technology that the internal research and development (R&D) organization of the firm has not been able to deliver. Again, these technology partnerships could be in support of incremental changes in the firm's existing products or to build entirely new and innovative products.
- Acquire companies to get new technologies (incremental or breakthrough) - Sometimes the technology may be crucial enough for the IT vendor to simply acquire the company that has the technology rather than enter into a technology partnership arrangement to license the technology. Often this path may be followed if the acquiring company is a large company and the target company is much smaller in size. As is the case with technology partnerships, these corporate acquisitions could be in support of incremental changes in the firm's existing products or for building entirely new and innovative products.
- Diversify into adjacent markets with new yet related product – Technology acquisitions can enable an IT vendor to get into a related market. A PC manufacturer acquiring a tablet company would be an example of this.
- Improve the quality of the product – The IT offering could be made more resistant to breakage if it is a hardware product, or more resistant to crashing if it is a software product via rigorous quality assurance (QA) processes In fact, making

smartphones water-resistant which is essentially a quality issue is being seen as a key capability of the smartphones introduced in 2019 (TelcoWorld 2019)

- Step up marketing and advertising – Sometimes stepping up investing in marketing and advertising is the solution for a flagging product. Here, the firm can leverage its knowledge about the impact that previous advertising campaigns have had on sales.
- Open-source the software – Open-sourcing a software product can be used to build a following behind that product. There are many successful open-source products such as Linux and MySQL. The loss of revenue from software licenses can be made up by revenue from selling service and support on the open-sourced software.
- Enhance service and support – Sometimes the product, be it hardware or software, might be great but the service and support is found to be lagging. In such cases, a number of measures can be taken such as offering a variety of service contracts, offering more effective help desk services, investing in customer relationship management (CRM) systems to improve customer satisfaction with service delivery.
- Introduce packages bundling products and services – Create bundles of products and services and price the package attractively. This can help ignite demand for the products and services in the bundle.
- Diversify geographically with existing product – This could involve diversifying geographically within the same country or internationally.
- Do a limited pilot to test market response – Before making a full-scale commitment to sell in a new geographical region, the IT vendor may do a small pilot to test the market and understand differences in consumer preferences between the new region and the ones that it currently sells to.
- Enter into reseller partnerships – Reseller partnerships allow IT vendors to sell their offerings in geographical regions that is not reachable by their own sales force or their online selling channels. This is often the case for diversifying internationally. If the IT vendor does not have a presence in a certain country, then it may enter into a joint venture with a partner in that country to sell their products and services.
- Acquire companies for geographical distribution – A reseller relationship with a partner in a different geographical region, either within the country or abroad, could turn into a corporate acquisition later if the IT vendor determines that that geographical region is crucial to their business.
- Partner with third parties for value-added functionality – Partnering with third-parties is crucial for IT vendors to bring a full solution to their customers. For example, the apps on a smartphone are what brings useful functionality to the users. Yet most of these apps are not built by Google which builds the Android operating system but are built by third-parties.
- Build an eco-system of third-parties – Success in markets for IT offerings often involves building an effective eco-system of various players working collaboratively. For example, in the smartphone market, Google builds the Android operating system, the phones themselves are built by companies such as Motorola, Samsung, and HTC, the apps are built by a variety of third-party players, and the full smartphone system has to then be tested against carriers such as Verizon, Spring, and T-Mobile and their 4G and 5G services. This eco-system does not magically create itself but is something that has to be assiduously nurtured and developed.

- Exit from the market for the offering – Although many of the real options described above strengthen an IT vendor's position in a given market, the vendor may choose to exercise the option of exiting from a given market if it sees that its position in that market is not salvageable. An exit decision could also be triggered if the market is no longer seen as central to the firm's business strategy.
- Defer taking any action – The IT vendor could at any point in time simply defer taking any of the actions described above and choose to wait to gather more information before making any further moves. Depending on the information that arrives in the waiting period, it could resume the option chain it was executing or modify it suitably depending on the information that arrived and then proceed with the modified chain.

The real options defined above from a vendor perspective stand in contrast to the real options that are appropriate from the standpoint of a firm investing in IT as a user of IT (Benaroch 2002, Ghosh et al. 2013) . User real options are:

- Defer – postpone making any investment at this time until more is known about the opportunity
- Stage – Implement one facet of the proposed IT investment. Cash flows generally occur after all facets have been completed.
- Pilot – Implement a small-scale version of the full investment.
- Invest organization-wide – Implement on a large scale, such as investing in an IT enterprise-wide.
- Alter scale – Change the scale of the investment which could include either scaling up or scaling down.
- Alter scope/switch – Change the scope of the investment which could include adding new functionality, changing inputs and outputs, or changing processes for transforming inputs into outputs.
- Strategic growth – Link to a related but new opportunity.

From Options to Option Chains

As we noted earlier, firms don't simply exercise a single option, but they exercise a number of related options over time in an option chain. Exercising a chain of related options over time to increase product sales, build customer satisfaction and loyalty, increase market share, diversify to new markets, and introduce innovative follow-on products is essentially a strategy. As Bowman and Hurry (2003) state, "Strategies are produced by the sequential striking of this options chain." We use this notion of the equivalence between an option chain and a strategy in our CURVO Grid. The grid provides insights into the types of option chains or strategies that are best pursued depending on the state of the firm and the environment. But first we classify different types of option chains available to management.

- Operational Option Chains – These chains are part and parcel of the normal routine of IT vendors such as creating a package bundling in some existing products and services, waiting to see the market reaction to the package, reducing the price of the package if the market reaction is positive to ignite demand, and then enhancing service and support on the package to build customer satisfaction and loyalty. Increasing R&D expenditure for incremental innovation that introduces new features to the firm's existing offerings can also be part of an operational option chain. Management could decide to increase

R&D expenditure in a given product to introduce some innovative features in the next version of the product, launch the new version, gauge market reaction, and if the reaction is positive then step up marketing and advertising investment in the new version of the product.

- Learning Option Chains – Learning option chains are about the pursuit of the next big thing. Every firm has to keep its antenna raised and continue to explore turns in the technology and the market in order not to be blind-sided by them as Kodak was in the paradigm change from analog to digital photography. Learning option chains may involve not just exploring paradigm-shifting technologies but also major new markets, as is the case when a solely US-based business tries to go global. In such a case, a firm could decide to explore certain foreign markets by making a small investment such as a joint venture with a foreign partner to sell its offerings there before jumping in with investing in a foreign operation with its own offices and sales and marketing personnel. Learning option chains are also experimental in that if the prognosis turns out to be not very good, they can be abandoned easily since they don’t represent a major sunk cost. A learning option chain could be initiated by an internal R&D project to build a prototype followed by beta testing of the prototype in a limit market pilot to gauge the market reaction. If the market reaction is negative, the firm may simply exercise the abandon option as the last option in the chain.
- Strategic Growth Option Chains – When the firm decides to make a significant commitment to a new technology, such as a car company in the business of selling traditional cars invests in the manufacture and sales of hybrid cars, then that constitutes exercising a strategic growth option. A major international diversification move for a US-based company would also be considered as exercising a strategic growth option. The casting of a strategic growth option represents the culmination of a learning option chain and the committed pursuit of the growth opportunity. In other words, the experimenting with the new technology in the learning phase has been sufficiently fruitful for management to decide to jump into the new opportunity with full commitment. Investing in the manufacture of the product, and in what volume, is of course one of the real options to be exercised in the strategic growth option chain. Many subsequent options would need to be cast in terms of the investment to be made in the sales, marketing, advertising, and servicing of the new product. In other words, the strategic growth option chain starts when the learning option chain ends.

Dimensions of the CURVO Grid

Uncertainty

The value of an option or option chain depends on the level of uncertainty in the context of the decision. In fact, the more uncertain the environment is, the more is the value of having real options that could be exercised depending on how the future unfolds. There are several facets to the uncertainty facing the vendor that influence the value of the real options held by the vendor. These are:

- Technology – Technological uncertainty is a key factor in formulating market strategies of IT vendors. The pace of technological change can upend the best laid plans of IT vendors. The very architecture of a product may become quickly obsolete under the advent of new technology. This is what happened in the enterprise application integration (EAI) market. There were two camps of vendors in this market. Suite players offered EAI suites, which would tightly integrate many functions into their suite product such as data transformation and business process management (BPM). They found that the market shifted to other EAI vendors who had an architecturally different solution based on an enterprise services bus (ESB) (Fiorano ESB 2009, Progress Software ESB 2009). ESB vendors brought to the market a more flexible architecture where services bus was a platform for layering services such as data transformation and business process management. These value-added services could be added on top of the services bus at a pace that the customer decided upon.

- Market – Market uncertainty arises from many different sources including changes in consumer preferences, merges and acquisitions that change the structure of the market, the entry of new competitors, and the health of the broader economy. A new entrant to the market may come in with a product with new technology that disrupts the existing market structure. A case in point is the entry of Vonage into the telecommunications market with voice over IP (VOIP) phones that was disruptive to established players like Verizon and ATT.
- Standards and Regulations – Changing standards and regulation are also a source of uncertainty for vendors. In fact, the VOIP space and how it is to be regulated has generated controversy and attendant uncertainty. Vendors have been clamoring for minimal regulation whereas the US Federal Communications Commission (FCC) has sometimes taken positions on policies that are at odds with what the VOIP service carriers would like to see (Gross 2003). This had created a state of confusion and uncertainty in this space.
- Firm-Specific – Firm-specific uncertainty and risks include possible changes in management, a lawsuit being filed against the firm, being acquired by some other firm, having to fight a proxy war launched by influential shareholders, and a lack of key resources and funding to support the firm's market strategy.

Capability

The other key dimension in the CURVO Grid for competitive strategizing is capability. Over the last three decades, the theories that have had the most impact on the field of strategy are the core competency theory (Prahalad and Hamel 1990), the resource-based view (RBV) (Barney 1991, 2001) and its extensions such as the dynamic capabilities approach (DCA) (Teece et al. 1997). A firm's long-term competitive advantage in a certain market rests on the unique resources (Barney 1991, 2001) that it possesses that cannot be quickly replicated by its competitors. Teece at al.'s (1997) notion of dynamic capabilities builds on the RBV by drawing a distinction between static resources and what is needed by the firm to succeed in a rapidly-evolving Schumpeterian world of creative destruction (Schumpeter 1934). In fast-changing environments, it is not the static resources themselves but the ability of management to quickly shape these resources and configure a combination of resources to meet the needs of changing markets that results in competitive advantage (Teece et al. 1997). The notions of unique resources and dynamic managerial capabilities also find resonance in the core competency theory of competitive advantage put forth by Prahalad and Hamel (1990) where they exhort companies to focus on what they are best at and divest themselves of all non-critical functions. This view of core competency or "stick to the knitting" was the basis of much of the corporate restructuring that took place in the late 80's and early 90's.

The inward-looking view of competitive advantage which asserts the primacy of internal resources, capabilities, and competencies is at odds with Porter's (Porter 1980, 1985) view of competitive advantage. Porter's view is outwardly focused at the market. Porter's position was that a firm should look at the market landscape; find a white space where there aren't too many competitors but there is an unfulfilled need; enter the market with an offering targeted at the white space; and then entrench itself by erecting barriers to entry for newcomers, building customer and supply intimacy, and keeping competitors off-balance through product differentiation where new and innovative features are constantly added to products. As it turned out, Porter's theory was only one side of the coin and the full theory of competitive advantage also rests on the inward-looking theories of the RBV, DCA, and core competency.

Regardless of the finer distinctions between the terms resource, core competency, and dynamic capability, these terms and their associated theories are all pointing to something valuable that is internal to the firm upon which strategy for building competitive advantage can be based. In our model, we use the term "capability", as encompassing the notions of resource, core competency, and dynamic capability as defined by the RBV, DCA, and core competency schools of thought, and this capability becomes the second dimension in our CURVO Grid shown in Figure 1. The CURVO Gird is a normative heuristic for competitive strategizing that identifies the types of option chains that fit best in certain quadrants of the two-dimensional uncertainty-capability space.

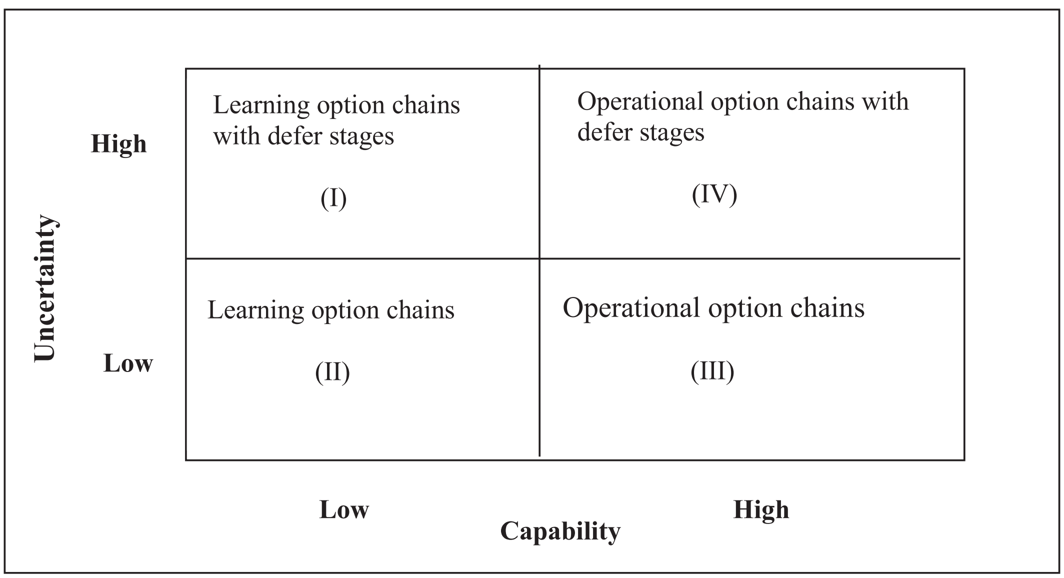

Figure 1: CURVO Repertory Grid

Does Management Always Exercise the Right Options Chain?

Recognizing the equivalence of strategy and option chains, the question in the section title could be put differently as: Does management always pursue the right strategy? Clearly not, otherwise we wouldn't have winners such as Amazon.com and losers such as Borders and Tower Records who were driven out of business by Amazon.com (Evangelista 2015). Misguided strategies abound, such as a firm doing little to explore growth opportunities. In other words, the firm is executing a defer option when it should be aggressively exercising a learning option chain followed by a strategic growth option chain. It is possible that the firm may have become too bogged down in grappling with operational issues in its existing business that it is neglecting growth opportunities. However, this has dire consequences for the survival of the firm in the long-term. The value of the CURVO Grid shown in Figure 1 is in providing management with guidance on the preferred option chains to execute under different conditions of uncertainty and firm capability. Importantly, the grid helps managers recognize when they could be going down the wrong path.

Operational option chains are a string of related actions, or exercises of options, targeted at improving the firm's existing product and service offerings. Since operational option chains are about the firm's existing business and offerings and not about a new market that the company does not know too much about just yet, operational option chains are exercised in Quadrants (III) and (IV) where the capability of the firm is high with respect to the target market. Capability includes unique resources such as technology patents and brand recognition supporting existing offerings; functional competencies such as in precision engineering and high-impact marketing; and dynamic managerial capabilities in perceiving changing market needs correctly and fashioning a response combining internal and external resources; and deploying these resources in a time-phased manner to best meet the changing conditions. Tending to the firm's existing business must be done whether the environmental uncertainty is high or not. Even in uncertain times, when the economy is in doldrums or when consumer preferences are fast changing, looking after the firm's existing business from which it derives its primary revenue must remain as one of the firm's key priorities.

A difference between the operational option chains exercised during times of high uncertainty and those in low uncertainty is that the operational option chain exercised in a highly uncertain environment will be laced with more defer stages (Quadrant III) as compared to the operational chain exercised in case of low environmental uncertainty. In times of high technology, market, or macroeconomic uncertainty it might better to temporarily suspend further action, or exercise the defer option within the option chain, till some information signal arrives that lifts the uncertainty. The signal could be about a technology standard that emerged as the winner in a battle of standards or it could be news that portends a better economy. The operational option chain could be resumed after this defer stage. Defer stages would be less necessary in times of low uncertainty, hence they are not shown in Quadrant (IV).

A firm is a collection of organizations at different levels and of different sizes ranging from ad hoc teams to units to functional organizations to full-scale business divisions. At any point in time, while some organizations, or business divisions, of the firm are tending to the firm's existing business, there must be other organizations that are exploring future growth opportunities. Often these growth opportunities enable the firm to get into a new market through technological innovation. The firm must then be engaged in learning about the new technology through internal R&D efforts and technology partnerships. The learning options chain is about gaining capability in new technologies for new markets that the firm could get into, and it is not about R&D investments to improve the firm's existing product and service offerings. Hence, it is more about discontinuous innovation rather than incremental innovation. The exercise of learning option chains is shown in Quadrants (I) and (II) which are associated with low existing capability. By definition, since the firming is learning about these new technologies and markets, it has a low current capability in this space. Again, just as tending to the existing business has to occur in an up-economy or a down-economy and in fast changing or slowly changing markets, exploring strategic growth opportunities has to be done in some place within the firm regardless of whether environmental uncertainty is high or low.

As in the case of the difference between Quadrants (III) and (IV), learning option chains in times of high uncertainty would be interspersed with more defer stages than in times of low uncertainty. It might be wise to temporarily suspend a learning option chain, or to exercise a defer option, and to wait for some information signal to arrive that lifts the uncertainty about, for example, the winner in a battle of technology standards.

A strategic growth opportunity that involves learning need not necessarily be based on new products and services enabled by discontinuous technological innovation. Entry into a major new market for the firm's existing offerings, such as a domestic firm diversifying internationally could also be viewed as a strategic growth opportunity. Again, a firm's existing capability in a foreign market is low and the firm must therefore learn about this new market via a learning options chain. The chain could begin with a joint venture with a foreign partner followed by a corporate acquisition of the partner.

Exercising Strategic Growth Option Chains

The purpose of learning is for eventually exercising strategic growth options or to execute a growth strategy. In other words, at the end of a learning options chain comes the opportunity to exercise a strategic growth option chain. Given that the CURVO Grid is a normative heuristic, the prescription it provides is that the strategic growth option chain is best executed in Quadrant (III) as shown in Figure 2.

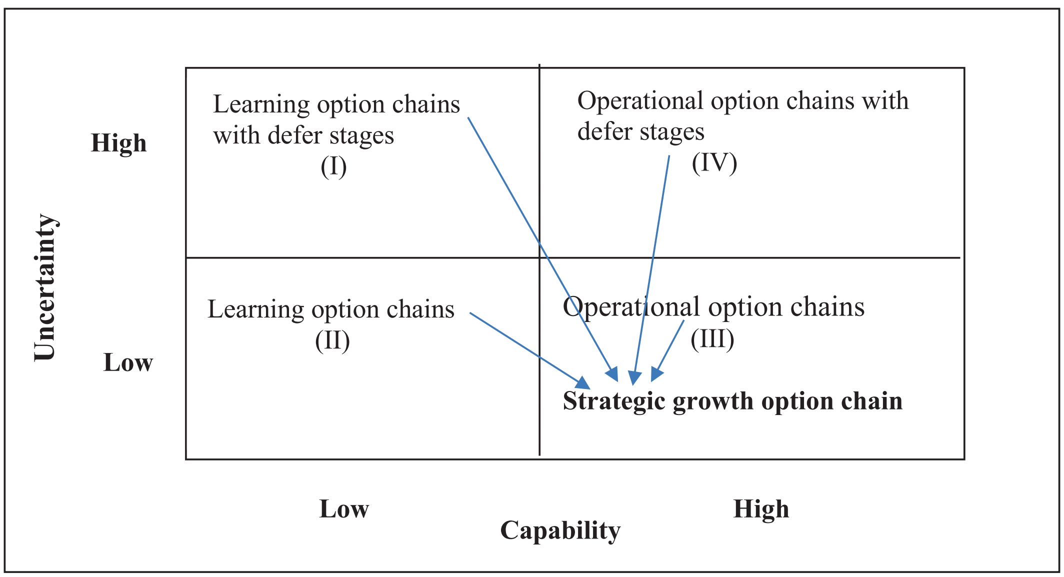

Figure 2: Strategic Growth Option Chain

To begin with, a key difference between exercising a strategic growth option chain versus an operational option chain is that growth options are about making big bets, such as leaping into a new market with innovative products undergirded by a corporate acquisition for new technology, whereas operational options are about making small bets such as enhancing service and support on an existing product. Making a big bet in a time of uncertainty involves a high risk of loss. The high risk of loss can be mitigated by having the growth strategy executed in a more stable environment, which means in Quadrant (III) and not in Quadrant (IV).

Furthermore, the growth strategy must utilize not only the knowledge gained from the learning activities performed in Quadrants (I) and (II) but, very importantly, must leverage the firm's capabilities in its existing business. It is this synergistic fusion of nascent capability in new technologies and markets acquired via the learning option chains with that of the firm's existing competencies that secures the firm's long-term competitive advantage and growth. If the firm's foray into new markets and opportunities was based solely on the learning resulting from the firm's exploration activities, then the firm's position in these new markets would be more open to competitive threat. Exploring new technologies from digital photography to artificial intelligence to business analytics is not the sole preserve of a single firm and many firms are simultaneously pursuing such new technologies. But the difference between a start-up firm introducing products based on new technologies and a firm with an established presence in a related business which is also introducing such products is the reuse of related technologies, possibly patented, and the application of its functional prowess in engineering, manufacturing, and sales and marketing from its existing to the new business. Of course, the watchword here is "related". What may appear to be related in the eyes of the senior management of a company, as the Nokia acquisition was to Steve Ballmer's Microsoft (Ribeiro 2013), may actually turn out to be not so related after all. In fact, a misperception of relatedness may turn out to be a strategic blunder as was demonstrated by the later divestment of Nokia by Microsoft (Warren 2016).

CURVO Grid and Ambidexterity Theory

While all firms have to look beyond their existing business if they are to survive in the future, which means they must simultaneously pursue exploration of future opportunities with exploitation of the current cash cow business, not all firms perform this juggling act successfully. The theory of ambidextrous organizations asserts that there is a particular type of organizational and management structure that allows for the aggressive pursuit and development of the next big opportunity along with the nurturing of the existing cash cow business (O'Reilly III and Tushman 2004). O'Reilly and Tushman (2004) claim that the pursuit of new opportunities must be housed in a separate organization with its own culture, values, structure, and business processes than the organization that tends to the firm's existing business. The exploratory and exploitative arms are by no means divorced from each other and there must be business synergy between the two. The ambidextrous organization has essentially mastered the trick of having both business synergy and organizational separation between the exploratory and exploitative arms of the firm.

O'Reilly and Tushman (2004) state that these two arms of the ambidextrous firm may indeed share resources, expertise, and customers while allowing for different cultures to flourish in these two arms. An example they provide of an ambidextrous firm is USA

Today (O'Reilly and Tushman 2004). USA Today has a traditional newspaper business, an online news service called USAToday.com, and a television operation called USAToday Direct, which are in different organizations with different structures and cultures. USAToday.com has a more entrepreneurial, fast-based, and collaborative culture as compared to that of the newspaper business. However, the pool of print reporters in the traditional newspaper business is the key resource that is being shared across the three organizations. The reporters generate the news stories that are then delivered in the three different media of print, Internet, and television. Hence, USA Today is a firm that is in the business of delivering news and it is essentially sharing "manufacturing" across its three divisions of USA Today, USAToday.com, and USAToday Direct, which are allowed to maintain their own cultures.

Operationalizing the CURVO Grid

To operationalize the CURVO Grid, the firm must first determine its own state in the two-dimensional capability-uncertainty space. The exploitative arm of the firm, by definition, is considered as having high capability because it focuses on the existing cash cow business. The exploitative arm is assumed to have worked with the firm's existing IT offerings for some years and successfully turned the existing business into a cash cow. The exploratory arm of the firm, on the other hand is, by definition, deemed to have low capability since it is just exploring new technologies and markets that the firm has not worked with before. So while the exploratory and exploitative arms of the firm can be located on the CURVO Grid with respect to the capability dimension, an instrument for measuring uncertainty needs to be developed.

<u>Uncertainty Measurement Model</u>

Our uncertainty instrument has items for assessing the economic, technology, market, and firm-specific uncertainties that the firm is facing. There are two versions of this instrument. One version is used by the organizations that are tending to the firm's existing business, or the exploitative arm of the firm, and the other by the organizations that are looking beyond the current business at future growth opportunities. The items in the uncertainty measuring instrument for the exploitative arm of the firm are as follows:

- Economy
    - The economic outlook is uncertain.
    - The economy is in recession or is expected to soon go into recession.
    - It is uncertain when we will see better economic times.
    - The economic uncertainties are causing firms to cut back on investments in IT.
- Market
    - The market outlook for our existing IT offerings is uncertain.
    - Consumer preferences may be shifting away from our IT existing offerings.
    - There are some signs that the market for our existing IT offerings could be shrinking.
    - Customer satisfaction with our existing IT offerings appear to be falling.
    - Our competitors are or will be soon introducing new and innovative IT offerings that could hurt our current market position.
    - There is an increasing threat of new players entering the market for our existing IT offerings with new and innovative offerings.

  - Our competitors are or could soon be introducing new IT offerings that are more attractively priced than our existing offerings.
- Technology
  - New technologies are making or could soon make our existing IT offerings obsolete.
  - Technology paradigms are changing fast in our markets and we could be at risk of falling behind.
  - The outlook is uncertain with regard to technology standards covering our existing IT offerings.
  - Our competitors appear to be stealing a march on us by introducing next generation technologies in their IT offerings.
  - Our competitors' IT offerings have or will soon have new features and functions that are not there in our existing offerings.
- Firm-Specific
  - The financial outlook for our company is uncertain.
  - A funding crunch may result in a reduction in financial support provided to our existing IT offerings.
  - The top management of our company is changing, and it is uncertain if the new management is committed to supporting our existing IT offerings.
  - Employee satisfaction in our firm is falling.
  - We are losing or could soon be losing key talent supporting our existing IT offerings because of employee satisfaction issues.
  - We are finding it difficult to hire the high-caliber talent we need to support our existing IT business.

The instrument for measuring uncertainty to be used by the exploratory arm of the firm has the following menu items.

- Economy
  - The economic outlook is uncertain.
  - The economy is in recession or is expected to soon go into recession.
  - It is uncertain when we will see better economic times.
  - The economic uncertainties are causing firms to cut back on investments in IT.
- Market
  - The market outlook for introducing new IT offerings based on our efforts in exploring new technologies and markets is uncertain.
  - Consumer preferences may already be shifting away from our projected IT offerings based on our efforts in exploring new technologies and markets.
  - There are some signs that the market for our projected IT offerings based on our efforts in exploring new technologies and markets could be shrinking.
  - Customer satisfaction with IT offerings similar to our projected offerings based on our efforts in exploring new technologies and markets appears to be falling.
  - Our competitors could introduce more innovative offerings compared to our projected IT offerings based on our efforts in exploring new technologies and markets

- There is an increasing threat of new players entering the market for our projected IT offerings, based on our efforts in exploring new technologies and markets, with even more innovative offerings.
- Our competitors are or could soon be introducing new IT offerings that are more attractively priced than our projected IT offerings based on our efforts in exploring new technologies and markets.

- Technology
    - New technologies are making or could soon make obsolete our projected IT offerings based on our efforts in exploring new technologies and markets.
    - Technology paradigms are changing fast in the markets for our projected IT offerings, based on our efforts in exploring new technologies markets, and there is a risk of our projected offerings' falling behind.
    - The outlook is uncertain with regard to technology standards covering our projected IT offerings based on our efforts in exploring new technologies and markets.
    - Our competitors may already be stealing a march on us by introducing next generation technologies in their IT offerings that are superior to what will be used in our projected IT offerings based on our efforts in exploring new technologies and markets.
    - Our competitors' IT next generation offerings will have features and functions that will not be there in our projected IT offerings based on our efforts in exploring new technologies and markets.
- Firm-Specific
    - The financial outlook for our company is uncertain.
    - A funding crunch may result in a reduction in financial support provided to our efforts to explore new technologies and markets.
    - The top management of our company is changing, and it is uncertain if the new management is committed to supporting our efforts to explore new technologies and markets.
    - Employee satisfaction in our firm is falling.
    - We are losing or could soon be losing key talent necessary for our efforts to explore new technologies and markets because of employee satisfaction issues.
    - We are finding it difficult to hire the high-caliber talent we need to support our efforts to explore new technologies and markets.

Each item in this instrument is measured on a 5-point Likert scale. Two management teams are formed, one from the exploitative arm of the company and the other from the exploratory arm of the company. Each management team must have both senior technical and business managers in it. For a managerial respondent, an average score is first found for each category of economic, market, technology, and firm-specific uncertainty. Then the average of these category averages taken. This average of category averages is the average level of uncertainty as perceived by that manager. The average levels of uncertainty perceived by the managers in the exploitative arm of the company are averaged to get a firm-level perception of uncertainty facing the firm's existing business. Similarly, this procedure is repeated for the management team assigned to assess the exploratory business to get a firm-level perception of uncertainty facing the exploratory arm of the firm. It is quite possible for the firm-level perception of uncertainty facing the firm's exploratory arm to be different from that facing its exploitative arm. It may well be that the firm's existing business may be in a stable market and is thus facing less uncertainty than its exploratory business. But this does not necessarily have to be true. Stability at one point in time does not mean stability forever, and it is quite possible that the firm's exploitative business could be going through a period of change.

Applying the CURVO Grid

The first step in applying the CURVO Grid is to ascertain how the firm is positioned in the grid. At a minimum the firm must be dual positioned in the grid with some part of the firm positioned in either Quadrant I or Quadrant II and another part positioned in either Quadrant III or IV. In other words, regardless of whether the firm is ambidextrous or not, it must be simultaneously tending to its existing business, and also exploring future growth opportunities as shown in Figure 3. If the firm does not have a position in Quadrant I or II along with a position in Quadrant III or IV, then that is the first indication of a poor strategy. The firm could be too bogged down in grappling with issues in its existing business that it is neglecting exploring future growth opportunities. This does not augur well for the long-term survival of the firm.

Once the firm has determined its positioning in the CURVO Grid, it must then check to see if the options chain that it is executing is the correct one for that cell. The dynamic managerial capability that Teece et al. (1997) propound, where managers can deploy internal and external resources in the right way and at the right time, is recast in this article as exercising the right options chain. An important contribution of options-based thinking in approaching investment decision-making is to consider the defer option (Dixit and Pindyck 1995). In other words, instead of the now-or-never approach of the NPV style of capital management, sometimes it is simply better to wait for more information to arrive to alleviate some of the uncertainty than to take an action now. Exercising the defer option as an alternative to taking some action now applies to the case of a single investment decision being contemplated at time $t = 0$. With regard to an option chain, where many related options are to be exercised in a certain sequential pattern, the equivalent of the defer option is a defer stage. Hence, the exploratory arm of the firm must include defer stages in the learning options chain when uncertainty as indicated by the uncertainty measurement instrument is high. Similarly, the exploitative arm of the firm must include defer stages in the operational option chain when the uncertainty measure is high.

The other key managerial prescription offered by the CURVO Grid is that, while exploring new technologies and markets is a must, learning cannot go on indefinitely. At some point, the learning option chain must be terminated, and then a growth option chain initiated. There are two salient aspects of this conversion. First it is best to convert the learning option chain into a growth option in a time of relative stability. The learning option chain was about making small bets whereas the growth option chain is about making large bets. Hence, the initiation of the growth strategy is best done in a time of relative calm as opposed to that of turmoil and change. Furthermore, the execution of the strategic growth option chain is not done in Quadrant I or II where the capability of the firm with respect to the target markets and technology is low. It is done when the capability is high. One reason for this is that the growth option chain is initiated when the learning option chain has run its course and is terminated. Hence, the firm should have acquired some capability in the target technology and markets through the course of the learning option chain. But, perhaps importantly, there must be synergy and integration between the new opportunity that the firm is getting into and the firm's existing business. The leveraging and reuse of capability from the firm's existing business is an essential part of the growth strategy. The fusion of capability acquired through learning with relevant portions of the firm's capability in its existing business endows the firm with the high capability to execute its growth strategy.

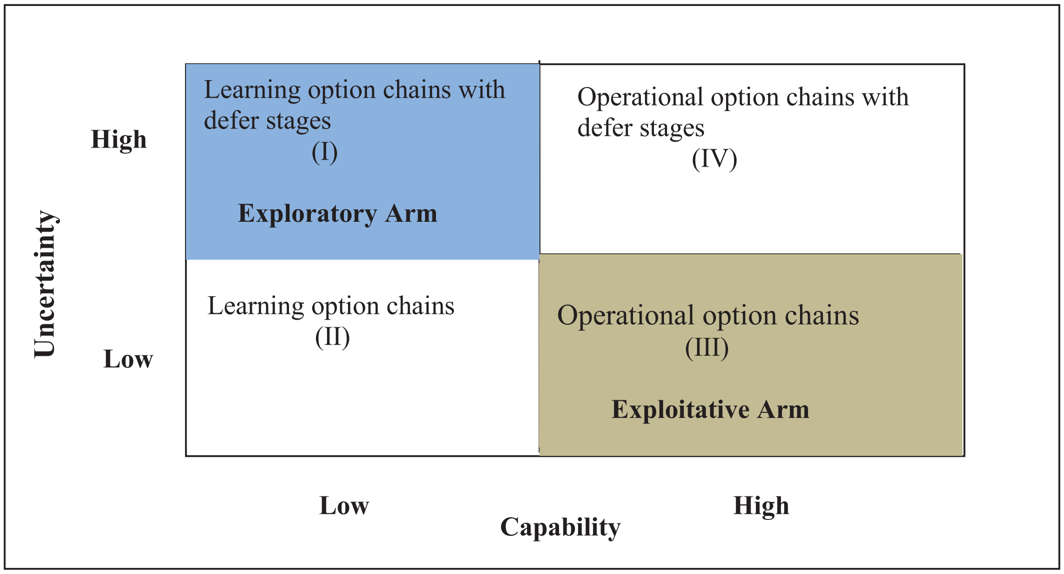

Figure 3 – Multi-Cell Positioning of Firm

CONCLUSION

This paper develops an innovative soft heuristic model, the CURVO Grid, for shaping an IT firm's competitive strategy. The CURVO Grid is informed by all the major theories and perspectives of competitive advantage including Porter's competitive forces model (Porter 1980, 1985), Prahalad and Hamel's core competency theory (Prahalad and Hamel 1990), Barney's resource-based view (Barney 1991, 2001), Teece et al.'s dynamic capabilities approach (Teece et al. 1997), and O'Reilly and Tushman's ambidexterity theory (O'Reilly and Tushman 2004). The article defines strategy in terms of exercising options chains. These include learning option chains exercised by the exploratory arm of the firm; operational option chains exercised by the exploitative arm of the firm; and strategic growth option chains which are triggered upon the culmination of learning option chains. Clearly, not all firms get competitive strategy right. The CURVO Grid provides guidelines in terms of which option chains to execute under what conditions of firm capability and environmental uncertainty.

The CURVO Grid is also a qualitative framework that brings the logic of real options into competitive strategizing without having to work through complex, quantitative options pricing models. As has been noted in RO literature, quantitative OPMs are often inexplicable and hence opaque to high-level managers and strategists (Baker et al. 2015, Teach 2003). Just as the SWOT matrix brought the structure-conduct-performance theories of industrial organization (Mason 1949, Bain 1959, Schmalensee

1989, Schmalensee and Willig 1989) within easy reach of the practitioner, the CURVO Grid does something similar by making RO accessible to practitioners.

ABSTRACT

The mortality rate in the United States due to Cancers is increasing in general but some malignant neoplasm deaths are showing a trend down. This study correlates mortality trends to gender and ethnicity as a way of identifying trends which could be used by policy makers and clinicians to allocate resources appropriately for the treatment of cancers.

KEYWORDS: regression, mortality, ethnicities, sensitivity analysis and health

INTRODUCTION

The United States population is steadily growing, but there is an element that has a major impact on this growth: migration. With the increase of nuclear families for blacks and whites, the overall population is showing signs of decreasing year per year, but there is an ethnicity that is growing continuously and having a smaller death ratio, so we will analyze this part of the population, and we will compare it to the other components to identify possibilities of reducing mortality due to cancers in the US population.

Table 1: USA Population by Race and Gender in 2017

Male		Group	Female	
29.67%	95,842,609	White	98,885,235	30.61%
9.31%	30,058,779	Hispanic	30,094,010	9.32%
6.17%	19,922,595	Black	22,599,391	7.00%
3.78%	12,212,462	Others	13,381,513	4.14%

Interestingly enough, the Hispanic population occupies now the second place on regards to demographics as they represent 18.63% of the total population in the country. The white population is still a strong majority as they constitute 60.28% of the total population. Another interesting fact is that there are more women than men in all ethnicities and races, but the ratio is much larger for black women as they are 6.3% more black women in all the black population, while the ratio for white women is 1.56% and for Hispanics is only 0.06%.

GENDER MORTALITY CAUSED BY CANCER

In this study we are going to focus on mortality caused by all the different types of malignant neoplasms (cancers) in the United States, which along with cardiovascular diseases are the top two causes of death in the world. With the certainty of a R^2 of 98.67% we see the trend of total mortality caused by cancer growing with a slope of 4,358.2 deaths per year.

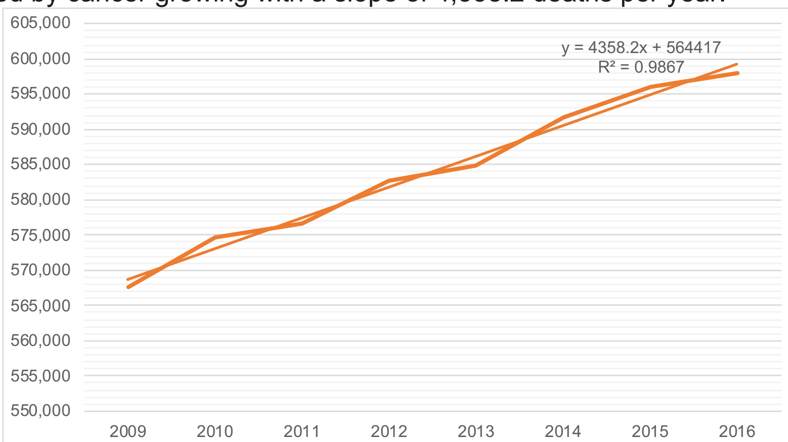

Figure 1. Total Mortality Caused by Malignant Neoplasms in the US

As we separate the mortality chart by the contribution of male's cancers, we see that the total growth of deaths by cancer is highly contributed by males. With a slope of 2,591 and a R^2 of 98.49%, males' deaths represent 59.31% of the yearly increase.

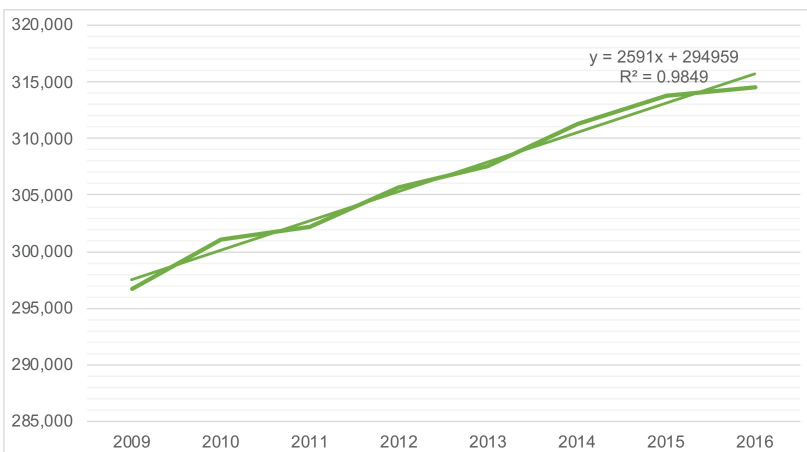

Figure 2. Males Mortality Caused by Malignant Neoplasms in the US

The female contribution to the yearly increase is only 1,767.2 deaths by cancer per year. Considering that women make more than half of the population, we are seeing a constant growth trend, with a much lower slope than men and with an intersect 25,500 already lower. In other words, the number of males' deaths due to cancer will continue increasing the gap with women in the future.

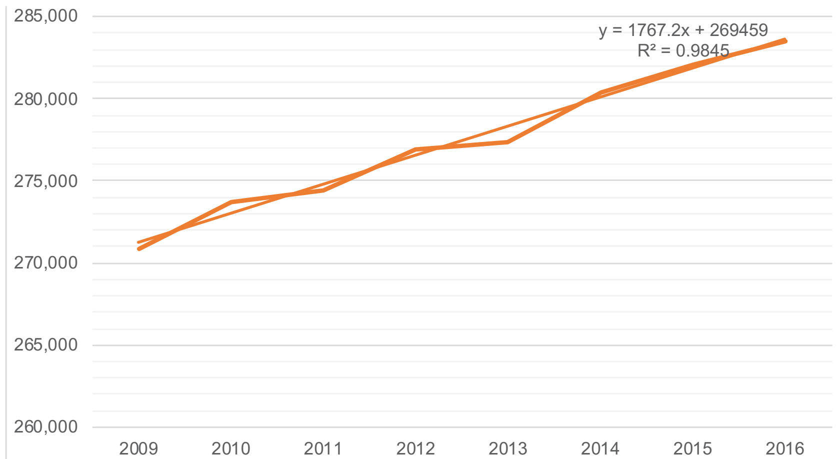

Figure 3: Female Mortality Caused by Malignant Neoplasms in the US

METHODOLOGY

Looking at these charts we can determine that cancer is causing more males' deaths in the Uniterd States, so that gender indeed has an impact on the mortality number and this trend seems to continue, so now we are going to evaluate ethnicity and race to determine if there is also a difference among them. In this project we are going to use linear regression to measure the correlation between two variables that are going to be changing from gender, ethnicity and type of malignant neoplasms; and we will also do sensitivity analyses to identify ailing points.

ETHNICITY/RACE MORTALITY CAUSED BY CANCER

In this study we are going to focus only on three major groups: White, Black and Hispanic where the White and Black groups do not include any Hispanics. The largest group and the first one to analyze is the White Non-Hispanic group. With the certainty of a R^2 of 91.79% we see the trend of White population mortality caused by cancer growing with a slope of 1,395.7 deaths per year.

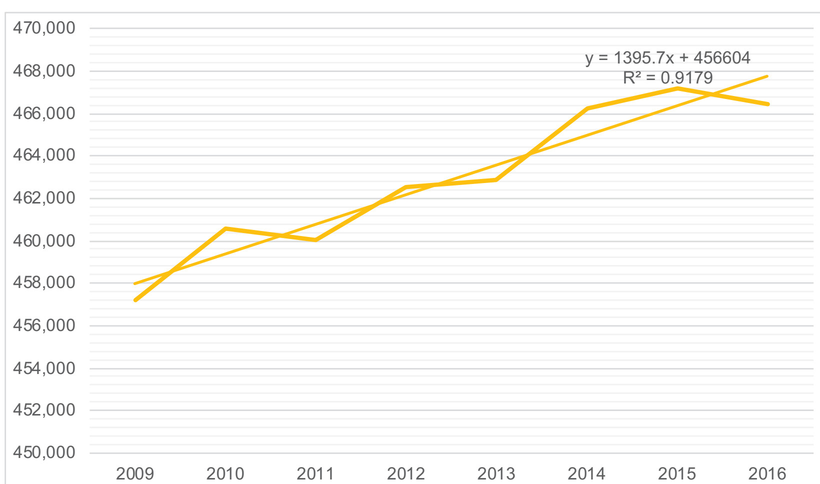

Figure 4. White Population Mortality Caused by Malignant Neoplasms in the US

With a y-intersect of 456,604 deaths, this group is definitively the major contributor of cancer's deaths, but the slope is growing only 1,395.7, that is 33.27% of the total deaths per year. Because the white population represents 60.28% of the total population, the cancer's deaths are only one third, so we can conclude that cancer deaths in the white group is being controlled and the concern about growth of mortality comes from the other groups.

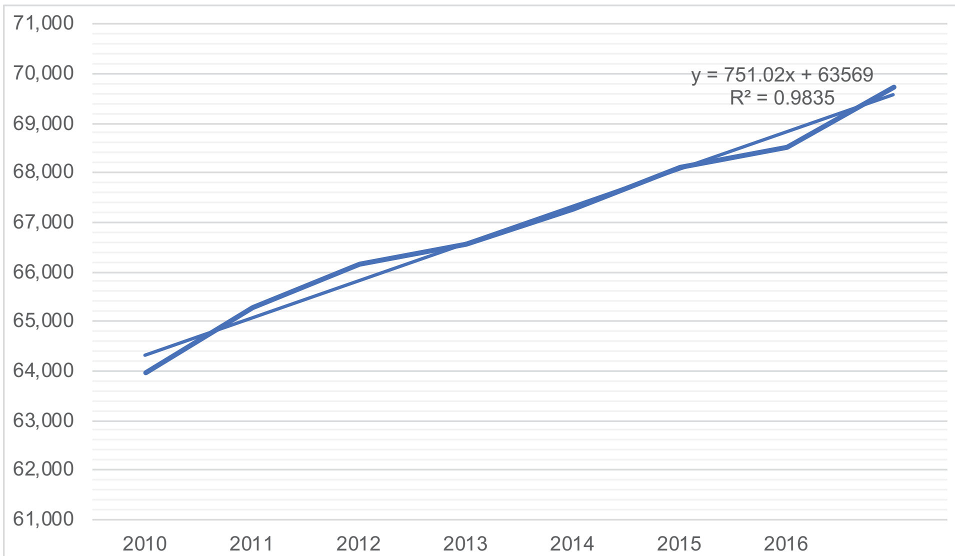

Figure 5. Black Population Mortality Caused by Malignant Neoplasms in the US

The contribution of mortality of the back population is only 751 deaths per year, that is 17.23% while the proportion of the population is 13.17%. The numbers are close, but the ratio of death is higher, so we have to be careful about the different types of cancers as we analyze them.

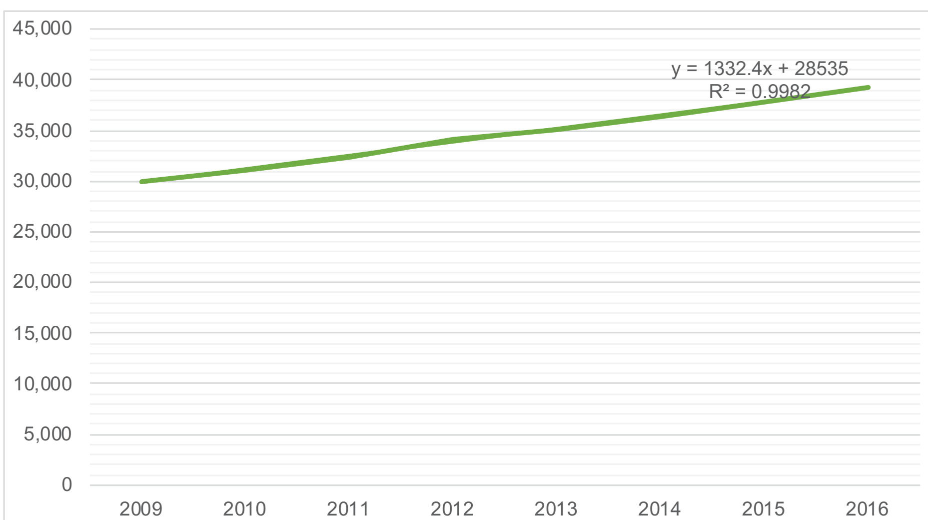

Figure 6: Hispanic Population Mortality Caused by Malignant Neoplasms in the US

We are discovering that 30.57% of the malignant neoplasms deaths every year are Hispanics while the proportion of the population is only 18.63%. In order to determine how critical this growth is, we will probe deeper into the 8 major causes of cancer's mortality and considering the contribution of gender and ethnicity.

Ethnicity	Gender	Xo	Slope	R^2
White	Male	238,870.00	1,183.00	0.9446
White	Female	217,734.00	212.71	0.6055
Black	Male	32,860.00	285.68	0.9835
Black	Female	30,709.00	465.35	0.9654
Hispanic	Male	15,117.00	669.00	0.9986
Hispanic	Female	13,418.00	663.37	0.9934

Table 2. Cancer Mortality lines for Gender and Ethnicity

Table # 2 shows very interesting facts about the cancer mortality. The Xo value for white people is around 7 times higher than the numbers for black people and around 16 times higher than Hispanics, but the yearly number of incidences (slope) for Hispanics and black women is alarming . The only two groups that are showing minimum growth are white women and black men. We will proceed to investigate the different types of cancer provoking death and break doen into these categories to find the possible cause that could drive medical efforts to find a way to reverse the trends.

TYPES OF MALIGNANT NEOPLASMS RESULTING IN DEATHS IN THE USA

The study is based on the available information at the Centers for Disease Control and Prevention (CDC). We are looking at the period between 2009 and until 2016 because these are the tables that have the most complete information.

The slopes show that there has been an important improvement on the treatment of trachea cancers for both genders, as we see decrements on mortality slopes for both. Table # 3 shows that the main contributor for the growth of deaths in males is mostly due to liver, pancreas, prostrate and bladder. On the female side, the major contributors are pancreas and liver. Comparing the contribution of the top ten causes we can quantify 2,329 deaths per year, that is 53% of all cancer related deaths.

Typically, for female's cancers, ovary and breast are the main contributors, but ovary cancer is showing a consistent trend down with a Xo=14,539 and a slope of -45.44. Breast cancer results can be seen in the table 3, and they clearly show that this type of cancer is growing minimally with 105.54 cases per year, but with an intersection of 40,630. Because we are seeing that the main issue on regards to mortality is related to liver, pancreas for both genders and prostate and bladder cancer for males only.

Cancer	Gender	Xo	Slope	R^2
Trachea	Male	89,550.00	(896.48)	0.8704
Trachea	Female	71,105.00	(204.13)	0.339
Colon	Male	26,762.00	126.88	0.7217
Colon	Female	25,332.00	(30.55)	0.1235
Breast	Male	405.75	8.25	0.5633
Breast	Female	40,630.00	105.54	0.7543
Pancreas	Male	17,343.00	564.60	0.9853
Pancreas	Female	17,268.00	423.05	0.9804
Prostrate	Male	27,155.00	315.40	0.435
Prostrate	Female	-	-	0
Liver	Male	12,463.00	704.33	0.9851
Liver	Female	5,977.90	344.81	0.9984
Leukemia	Male	12,961.00	63.00	0.3993
Leukemia	Female	9,687.40	30.66	0.4683
Lymphoma	Male	11,119.00	24.67	0.4162
Lymphoma	Female	9,240.00	(36.88)	0.5812
Bladder	Male	9,801.40	277.99	0.9713
Bladder	Female	4,121.10	73.01	0.9059
Meninges	Male	7,481.00	258.71	0.9391
Meninges	Female	5,950.90	176.36	0.937

Table 3. Cancer Mortality lines for Gender and Ethnicity

Cancer	Ethnicity	Gender	Xo	Slope	R^2
Pancreas	White	Male	14,193.00	335.33	0.9062
Pancreas	Black	Male	1,909.10	57.524	0.8944
Pancreas	Hispanic	Male	1,008.30	46.845	0.8442
Liver	White	Male	8,487.30	391.05	0.8965
Liver	Black	Male	1,848.40	83.507	0.8769
Liver	Hispanic	Male	1,484.60	81.607	0.876
Prostrate	White	Male	20,951.00	105.39	0.1156
Prostrate	Black	Male	4,566.10	33.512	0.1469
Prostrate	Hispanic	Male	1,353.50	69.714	0.9086
Bladder	White	Male	8,752.90	228.71	0.9553
Bladder	Black	Male	562.57	21.179	0.9182
Bladder	Hispanic	Male	325.46	18.536	0.8878

Table 4: Males' Cancer Mortality by Type and Ethnicity

Table # 4 shows that the white male population is the one with the largest Xo because of the high number of incidences. The largest slopes of the selected male cancers are also from the white population, because of the largest proportion of population, but we have to be careful about the Hispanic population death growth which is smaller than the white population, but percentagewise they are higher.

Cancer	Ethnicity	Gender	Xo	Slope	R^2
Pancreas	White	Female	13,883.00	184.15	0.9262
Pancreas	Black	Female	2,157.70	55.536	0.7496
Pancreas	Hispanic	Female	987.07	49.179	0.8466
Liver	White	Female	4,235.30	172.21	0.9172
Liver	Black	Female	767.54	39.298	0.9362
Liver	Hispanic	Female	688.46	51.119	0.8598
Breast	White	Female	81,621.00	-110	0.8484
Breast	Black	Female	5,849.10	51.52	0.732
Breast	Hispanic	Female	2,140.50	100.21	0.9309
Bladder	White	Female	3,483.20	44.571	0.8585
Bladder	Black	Female	420.61	13.463	0.7911
Bladder	Hispanic	Female	151.36	7.8095	0.8857
Ovary	White	Female	12,098.00	-111.4	0.9442
Ovary	Black	Female	1,248.60	10.357	0.3289
Ovary	Hispanic	Female	804.46	26.952	0.8747

Table 5. Female Cancer Mortality by Type and Ethnicity

SENSITIVITY ANALYSIS OF THE CANCERS' MORTALITY

The sensitivity analysis compares the cell versus the summation of the column and then versus the summation of the rows, this way we can determine if the contribution of the events is changing in time. In the particular case of the white males' mortality (table # 6), we can notice that the columns of the liver, meninges and bladder changed from green to red, that is, their contribution in time has been growing. Trachea, bronchus and lung's cancer is showing a positive trend as it changed from red to green.

Year	Trachea, bronchus and lung (C33-34)	Prostate (C61)	Colon, rectm and anus (C18-21)	Pancreas (C25)	Leukemia (C91-95)	Liver and intrahepatic bile ducts (C22)	Bladder (C67)	Non-Hodgkins lymphoma (C81-85)	Meninges, brain & others (C70-72)	Breast (C50)	All Others	Grand Total

Table 6. Sensitivity Analysis for White Males' Mortality by Cancer

Doing the same analysis in the table #7 for the white females, we are finding red lights on the liver, meninges, bladder and pancreas as they change from green to red color code. Breast and colon cancers are showing a slim reduction on the past eight years, so whatever is being done, seems to be working.

Table 8. Sensitivity Analysis for Black Males' Mortality due to Cancers

The next group to analyze are the black males' mortality which is also showing that the meninges, liver and bladder's cancers are the ones showing a continuous increase on proportion in the past years. A success story is the small and consistent reduction of deaths related to trachea, bronchus and lung's cancers.

Because black females' mortality was also raised as an issue, we did the sensitivity analysis and found the liver, bladder and meninges' cancers the major concerns. Breast cancer is showing a very positive reduction for white females, but it is not doing the same for black women. We ought to see what is happening in the treatment for both groups and determine if something can be done to reduce the number of deaths.

Year	Trachea, bronchus and lung (C33-34)	Breast (C50)	Colon, rectm and anus (C18-21)	Pancreas (C25)	Liver and intrahepatic bile ducts (C22)	Leukemia (C91-95)	Non-Hodgkins lymphoma (C81-85)	Bladder (C67)	Meninges, brain & others (C70-72)	All Others	Grand Total	Trachea, bronchus and lung (C33-34)	Breast (C50)	Colon, rectm and anus (C18-21)	Pancreas (C25)	Liver and intrahepatic bile ducts (C22)	Leukemia (C91-95)	Non-Hodgkins lymphoma (C81-85)	Bladder (C67)	Meninges, brain & others (C70-72)	All Others	Grand Total

Table 8. Sensitivity Analysis of Black Females' Mortality due to Cancer

The last group to analyze are the Hispanics. Doing the sensitivity analysis to the cancers' mortality of Hispanic males, we are finding that most of the cancers are showing a trend up in mortality as the green color is noticeable in the first years and the last years are mostly red. The prostrate, meninges and bladder cancers contribution to the total mortality in the past 8 years are the one having larger contributions, so we strongly recommend doing further analysis on these three malignant neoplasms illnesses on the Hispanic males.

Year	Trachea, bronchus and lung (C33-34)	Colon, rectm and anus (C18-21)	Liver and intrahepatic bile ducts (C22)	Prostate (C61)	Pancreas (C25)	Leukemia (C91-95)	Non-Hodgkins lymphoma (C81-85)	Meninges, brain & others (C70-72)	Bladder (C67)	Breast (C50)	All Others	Grand Total	Trachea, bronchus and lung (C33-34)	Colon, rectm and anus (C18-21)	Liver and intrahepatic bile ducts (C22)	Prostate (C61)	Pancreas (C25)	Leukemia (C91-95)	Non-Hodgkins lymphoma (C81-85)	Meninges, brain & others (C70-72)	Bladder (C67)	Breast (C50)	All Others	Grand Total

Table 9. Sensitivity Analysis of Hispanic Males' Mortality due to Cancer

Table # 10 is presenting a very worrying picture because most of the cancers are increasing for this ethnicity in the United States. The Hispanic population is growing rapidly and that might be the reason behind the mortality caused by cancers, but the meninges, bladder and liver malignant neoplasms are areas recommended for further investigation.

Table 10. Sensitivity Analysis of Hispanic Females' Mortality due to Cancer

FINAL MULTIPLE REGRESION ANALYSIS

In order to determine the impact of the different types of cancers that we have analyzed, we conducted a multiple regression analysis to determine which different types of cancers can help us predict the potential number of people due to malignant neoplasms. The elements of gender, ethnicity and year were also included for further analysis.

Model Summary[b]

Model	R	R Square	Adjusted R Square	Std. Error of the Estimate
1	1.000[a]	1.000	1.000	828.74721

a. Predictors: (Constant), Prostate, Breast, Liver, Lymphoma, Bladder, Pancreas, Colon

b. Dependent Variable: Cancer deaths

a. Dependent Variable: Cancer deaths

b. Predictors: (Constant), Prostate, Breast, Liver, Lymphoma, Bladder, Pancreas, Colon

Coefficients[a]

Model		Unstandardized Coefficients B	Unstandardized Coefficients Std. Error	Standardized Coefficients Beta	t	Sig.
1	(Constant)	-838.382	414.823		-2.021	.050
	Colon	5.230	.620	.443	8.431	.000
	Pancreas	7.395	.804	.483	9.194	.000
	Liver	-2.005	.514	-.068	-3.900	.000
	Lymphoma	4.944	.681	.184	7.255	.000
	Bladder	-1.098	.636	-.039	-1.727	.092
	Breast	-.425	.351	-.048	-1.209	.234
	Prostate	.273	.408	.022	.669	.507

a. Dependent Variable: Cancer_deaths

In general, the pancreas and colon cancers are the ones that are mostly driving the number of deaths for all genders and ethnical groups followed by the lymphoma.

CONCLUSION

In this paper, we analyzed the impact of malignant neoplasms in the mortality by genders and ethnicities and we recommend medical research on regards to cancers in the pancreas, liver and bladder. Although these are not the top causes of mortality, they are showing signs of growth that could result on more deaths in the near future. The number of deaths per year of white people is growing but at a slowed rate, while the Hispanics' line is going rapidly upwards. Interestingly the two groups that have a lower growth rate are white women and black men, which could be benchmarked to the other ethnicities in order to reduce the number of deaths.

ABSTRACT

We study the problem of maximizing profits for a distributor who procures perishable products, transports them along the supply chain, and sails them at retail stores. The quality of perishable products deteriorates during the transportation process. Products with different levels of quality are substitutable depending on their prices and the customer's quality sensitivity. The distributor may utilize radio frequency identification (RFID) temperature tags, to track the quality of the products along the supply chain. Based on a quadratic programming problem, we determine the profit-maximizing transportation and pricing policies and evaluate the value of RFID-generated quality information.

KEYWORDS: Technology adoption, Cold chain, RFID, Transportation, Pricing

INTRODUCTION

Perishable goods, from fresh produce to pharmaceutical drugs, must be kept and distributed in a temperature-controlled environment along the entire supply chain. Controlling other factors such as humidity, light, and air pressure may also affect the quality of products delivered to end customers. Failing to transport products in the desired environment increases their quality deterioration rates and yields food (and other perishable products) waste. Food and Agriculture Organization of the United Nations estimates that 40% of the food produced in the world is wasted annually (Gustavsson *et al.*, 2011). Proper refrigeration along the food distribution network in the United States can decrease the food waste by 12% (NRDC, 2012) which significantly reduces its $218 billion annual economic impact. (Mercier *et al.*, 2017)
The series of activities and equipment for producing, storing, and transporting perishable products in a refrigerated environment is referred to as the cold chain. The cold chain maintains the desired low-temperature range for perishable products. However, there is a significant temperature heterogeneity inside each transportation equipment (Raab *et al.*, 2008; Margeirsson *et al.*, 2012) which can considerably affect the quality and the remaining shelf-life of fresh products. Therefore, it is critical to closely monitor the temperature profile of each perishable item during the transportation process and update the distribution policy accordingly. Radio frequency identification (RFID) tags have been widely used in temperature-monitoring systems in cold chains in recent years (Mercier et al. 2017 and references therein). However, the value of the information provided by this technology is not well quantified in the literature. Hence, producers and distributors are reluctant to invest in enhancing their cold chain management systems by implementing RFID temperature tags. RFID generated information can be implemented in inventory system to prioritize selling those pallets with lower qualities.

Also, it can enable retailers to better understand the quality of the products that they receive from suppliers and improve their inventory management and shopper satisfaction. The other area that could take advantage of these new level of information is transportation. In this paper, we are trying to quantify the benefits of implementing RFID and sensor technology in transportation of perishable products and analyze how the profit and waste change after the adoption of RFID and sensor technology from a distributer's point of view.

In this work, we investigate a supply chain in which a distributor procures perishable products, transports them along the supply chain, and sells them at retail stores. The distributor's goal is to maximize its profit by jointly optimizing the transportation (route selection and freshness keeping efforts) and pricing policies. The contributions of this paper are threefold: (1) We develop a mathematical programming model to optimize transportation and pricing policies for a cold chain in which the demand is vertically differentiated at retailers and customers are both price and quality sensitive; (2) We compare the profit of the cold chain with and without RFID implementation to quantify the value of the information provided by this technology; (3) We show that in the absence of strict environmental regulations, a distributor may exploit the RFID technology to increase its profit at the expense of the food waste.

The rest of this paper is organized as follows. First, we briefly review the related literature. Then, we develop our mathematical programming model and using a numerical example, we discuss the benefits and costs of using RFID technology. Finally, we present our concluding remarks in the last section.

LITERATURE REVIEW

There is a large body of literature descriptively studying the benefits of implementing RFID tags in long-haul transportation of perishable products including fresh crops (Delen, Sharda and Hardgrave, 2011), seafood (Abad *et al.*, 2009; Trebar, Lotrič and Fonda, 2015), meat (Narsing, 2005; Raab, Petersen and Kreyenschmidt, 2011), and medicine (Monteleone, Sampaio and Maia, 2017). In particular, Raab et al. (2011) observe that while the continuous control of environmental conditions is critical in the cold chain management, its implementation cost is a major obstacle. To address this issue, . (Badia-Melis *et al.*, 2018) propose the integration of RFID-based technologies with temperature estimation methods to reduce the number of required sensors in cold chain monitoring systems

In the operations management literature, more attention has been paid over the last decade to analytically improving the efficiency of perishable products supply chains. We refer to (He *et al.*, 2018) for a review of the related analytical models.

Tracking the perishable products plays a vital role in the inventory and revenue management. (Gaukler, Ketzenberg and Salin, 2017) show that retailers may benefit from eliminating the risk of selling contaminated products by using RFID tags to determine dynamic expiration dates for perishable products. (Piramuthu and Zhou, 2013) study an inventory management and shelf-space allocation model for fresh produce, where detailed item-level quality information is generated using auto-ID technologies such as RFID with necessary sensors. They assume the demand rate depends on both the display inventory and the freshness of products. (Liu, Tang and Huang, 2008) study an inventory-pricing problem for the supermarkets using the RFID technology to gather accurate information on the quality of perishable items. Their model shows promising benefits for both deterministic and stochastic demand functions. In contrast to these papers which are focused on the inventory and the revenue management, we investigate transportation policies in cold chains.

(Grunow and Piramuthu, 2013) use the RFID-generated item-level information to determine the accurate remaining shelf-life for highly perishable products. They derive conditions under which the RFID implementation in the food supply chain is beneficial for distributors, retailers, or consumers. (Shi, Zhang and Qu, 2010) optimize the distribution strategy when frequent updates of the product quality are available through RFID tags. By sequentially adjusting transportation decisions, the distributor minimizes the cost of meeting the demand while preserving the product quality. Unlike our paper, these studies do not consider the pricing as a lever for the distributor to control the demand for different quality levels of a product.

It is worth to briefly discuss the operations management literature on the transportation and pricing of perishable products without using the updated quality information. (Cai *et al.*, 2010) analyze a supply chain in which a distributor buys fresh products from a manufacturer and distributes them in a target market. They consider different levels of freshness keeping efforts during the transportation which yields different levels of quality at the target market. Assuming the demand depends on both the freshness and the price of products, they propose a model which determines the order quantity, the level of freshness-keeping efforts, and the wholesale (set by the manufacturer) and the retail (set by the distributor) prices. (Cai and Zhou, 2014) consider the problem of supplying a market with a perishable product, using an inexpensive public transportation system which is subject to frequent disruptions. They study both make-to-stock and make-to-order systems and minimize the expected loss by determining the optimal production and delivery schedule. (Ahumada and Villalobos, 2011) present an integrated production-distribution model considering the resource availability, pricing, transportation, and inventory decisions. (Soysal *et al.*, 2018) study an inventory routing problem by considering the perishability of products, demand uncertainty, and logistics cost and fuel consumption. They illustrate the benefit of the horizontal collaboration among suppliers and its sensitivity to the supplier size and the maximum shelf life of products.

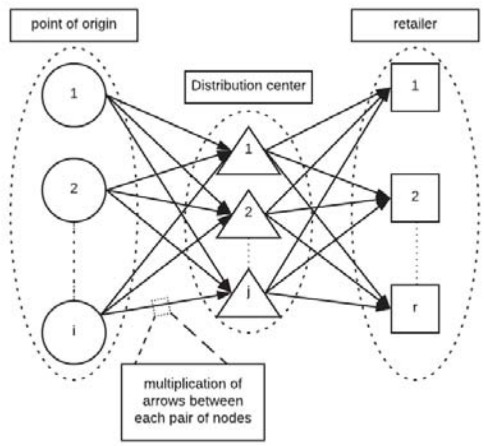
The dynamic pricing of perishable products is frequently discussed in the revenue management literature. (Akçay, Natarajan and Xu, 2010) consider a firm selling horizontally or vertically differentiated substitutable and perishable products. Solving a dynamic pricing problem, they determine the relationship between the optimal prices and inventory for different levels of quality. (Chew *et al.*, 2014) show that how a firm can optimally shift the demand between different quality levels of substitutable and perishable products using dynamic pricing and ordering decisions. (Li, Zhang and Tang, 2014) consider perishable products in a stochastic inventory system and determine the optimal pricing and inventory policies. In a series of papers, (Herbon, 2015, 2016, 2017, 2018) studies dynamic quality-based pricing of perishable products considering price discrimination for homogeneous and heterogeneous customers who are sensitive to the price and freshness of products.

MODEL FORMULATION

We investigate a supply chain in which a distributor procures fresh but perishable products from a set of suppliers, ships them through a set of distribution centers (DCs), and sells them in a set of retail stores after choosing their retail prices. The distributor's goal is to maximize its profit by jointly optimizing transportation and pricing policies.

To determine the optimal transportation policy through the supply chain, we need to consider series of transportation-related decisions including the packaging, route selection, transportation mode and distance, and freshness keeping efforts such as controlling the temperature and humidity. We call each combination of these decisions a transportation option and include all corresponding costs of each transportation option in its transportation cost per unit of the product. Figure 1 presents a schematic view of our cold supply chain network. Note that each arrow may represent a series of transportation options between the corresponding nodes.

Figure 1: Schematic View of the cold supply chain



For the sake of the model simplicity, we consider a single product type which can be categorized into three broad classes based on its quality: High-quality, Acceptable-quality, and Unacceptable-quality. We also assume that all suppliers offer the product with the same initial quality, normalized to be considered as the high-quality. While these assumptions simplify our notation, they will not affect the insights of the model, and the results can be easily extended to include models where suppliers offer different levels of quality of different products.
After the procurement, the distributor chooses among the transportation options to ship the perishable items from the suppliers to DCs. All items going through the same transportation option receive the same level of freshness keeping efforts. However, as discussed in the introduction, they encounter an inevitable variation in the temperature, humidity, and other environmental conditions. Therefore, the deterioration of each specific item during the transportation can be seen as a stochastic process with a rate that depends on the chosen transportation option.
While we assume all items are at the high-quality level at suppliers, by the time they reach DCs, some of them may deteriorate to acceptable-quality level. We separate items at DCs based on their quality levels using the information gathered by RFID tags. Then we choose the transportation options from DCs to retailers according to the quality of the items. One intuitive example of such transportation policy is sending high-quality items with a slower but less expensive option, while expediting the transportation of acceptable-quality products through an expensive transportation mode in order to deliver them to retailers before they deteriorate to the unacceptable-quality level.
The distributor then sets the price for each quality level at each retailer's location. We let the distributor choose different prices at different retail stores, considering the cost of transportation options as well as the retailers' demand and quality preferences. Finally, at each retailer, customers choose among the items at different quality levels and different prices, which we discuss in detail in the next section.

Quality Based Demand Allocation

While we ship the high-quality items through the cold chain, their quality may remain as high (we call it quality level 1) or decrease to an acceptable (quality level 2) or even an unacceptable level. At each retailer location r, products are vertically differentiated based on their quality level. Let α^q denote the desirability of a product with quality level $q \in \{1,2\}$. A customer's utility from purchasing one item at quality level q from the retailer r, is given by

$$\mu_r^q = \theta_r \alpha^q - p_r^q \qquad (1)$$

where θ_r is the quality sensitivity of the retailer r 's customers, and p_r^q is the price of an item with the quality level q at the retailer r. The quality sensitivity factor θ_r is a customer specific attribute. We let customers patronizing different stores have different quality sensitivities, e.g., due to the demographic characteristics of the retailer's location. For the retailer r 's customers, we let θ_r to be uniformly distributed between 0 and τ_r.

We assume the distributor is looking to segment the market such that both quality levels can be sold at the retailers. Hence, the retail prices at each retailer r should follow Lemma 1, which is in line with pricing schemes for vertically differentiated products in (Akçay, Natarajan and Xu, 2010).

Lemma 1 Assume the customer quality sensitivity θ_r is uniformly distributed between 0 and $\tau_r$at the retailer r. To segment the market into both quality levels, the retailer prices for the quality level 1 and 2 should satisfy

$$0 \leq \frac{p_r^2}{\alpha^2} \leq \tau_r \qquad (2)$$

$$0 \leq \frac{p_r^1 - p_r^2}{\alpha^1 - \alpha^2} \leq \tau_r \qquad (3)$$

Proof The price to desirability ratios in (2) are larger than zero by definition and are smaller than τ_r to keep the utility for both quality levels positive. Moreover, if p_r^2/α^2 becomes larger than p_r^1/α^1, all customers will prefer items with quality 1 regardless of their corresponding quality sensitivity θ_r. Similarly, the ratio in (3) is positive as a higher quality and desirability is corresponding to a higher price. Finally, if $p_r^1 - p_r^2$ grows τ_r times larger than $\alpha^1 - \alpha^2$, then the utility of purchasing a quality level 2 item becomes greater than the one for a quality level 1. Thus, all customers prefer items at quality level 2 regardless of their θ_r.

Assuming the total demand at the retailer r is D_r, under the price setting suggested by Lemma 1, it is straightforward to show that the expected demand for the high-quality items is:

$$D_r^1 = \left(1 - \frac{p_r^1 - p_r^2}{\tau_r(\alpha^1 - \alpha^2)}\right) D_r \qquad (4)$$

and for the acceptable quality items is:

$$D_r^2 = \left(\frac{p_r^1 - p_r^2}{\tau_r(\alpha^1 - \alpha^2)} - \frac{p_r^2}{\tau_r \alpha^2}\right) D_r \qquad (5)$$

Note that if the firm decides not to sell a specific quality level at a specific retailer (e.g., due to the excessive cost of delivering high-quality products to a remote retailer), it will have the flexibility to modify the prices to shift the demand of one quality level to another. More specifically, for a given p_r^2, by increasing p_r^1 to a level that makes $(p_r^1 - p_r^2)/(\alpha^1 - \alpha^2) = \tau_r$, the firm can eliminate the demand of high-quality products and increase D_r^2 to $(1 - p_r^2/\tau_r \alpha^2) D_r$. Similarly, if the firm decides to sell only the high-quality products, it is enough to increase p_r^2 to a level that $p_r^2/\alpha^2 = p_r^1/\alpha^1$. At this price, the demand for the quality 2 products shifts to the quality 1 products. Hence D_r^1 increases to $(1 - p_r^1/\tau_r\alpha^2)D_r$.

Model In The Presence Of RFID

In this section, we propose a quadratic optimization problem based on the cold chain network in Figure 1. We present the set of suppliers by S, DCs by D and retailers by R. We assume that there are N_{ij} transportation options between node $i \in \{S, D\}$ and node $j \in \{D, R\}$. We define x_{ijn}^1 and x_{ijn}^2 as the number of items with quality level 1 and 2 to be shipped from node i to node j by transportation option $n \in N_{ij}$, respectively. The corresponding transportation cost is denoted by C_{ijn} per item independent of the item quality, and the procurement cost of one high-quality item at the supplier s is denoted by C_s'. Finally, we let $z_r^1(z_r^2)$ present the number of items with quality 1(2) sold at the retailer r with the selling price $p_r^1(p_r^2)$.
The rate of quality deterioration depends on both the chosen transportation option and the quality of the item. Let λ_{ijn}^1 denote the percentage of high-quality items (quality level 1) that deteriorates to acceptable-quality items during the transportation from nodes i to node j through the transportation option n (we assume the rest of items remain as high-quality). Similarly, let λ_{ijn}^2 denote the percentage of acceptable-quality items (quality level 2) whose quality depreciates to a level that is no longer acceptable by customers and should be discarded when the transportation option n is chosen between nodes i and j. Table 1 summarizes our notation.

Table 1: Summary of Notations	
Indices	
S	Set of suppliers
D	Set of DCs
R	Set of retailers
N_{ij}	Set of transportation options between node i and j
Decision Variables	
z_r^q	Number of quality level $q \in \{1,2\}$ item sold at retailer r
p_r^q	Price of quality level $q \in \{1,2\}$ item at retailer r
x_{ijn}^q	Number of items with quality level $q \in \{1,2\}$ to be shipped between node i and node j by transportation option $n \in N_{ij}$
System Parameters	
α^q	Desirability of a product with quality level $q \in \{1,2\}$
θ_r	Quality sensitivity of a retailer r's customer, uniformly distributed in $[0, \tau_r]$
D_r	Total expected demand at retailer r
C_s'	Procurement cost of one high quality item at supplier s
C_{ijn}	Cost of shipping one item from node i to node j by transportation option n
λ_{ijn}^q	Percentage of quality level $q \in \{1,2\}$ items deteriorates to the next (lower) quality level while getting shipped from node i to node j by transportation option n

Using our notation, we present our profit-maximizing quadratic programming problem in (6-16).

$$\max \pi = \sum_{r\in R}(p_r^1 z_r^1 + p_r^2 z_r^2) - \sum_{s\in S}\sum_{d\in D}\sum_{n\in N_{sd}}\left(C_s^{'} + C_{sdn}\right)x_{sdn}^1 - \sum_{d\in D}\sum_{r\in R}\sum_{n\in N_{dr}} C_{rdn}(x_{drn}^1 + x_{drn}^2) \tag{6}$$

Subject to

$$z_r^1 \leq \sum_{d\in D}\sum_{n\in N_{dr}} x_{drn}^1\left(1-\lambda_{drn}^1\right) \qquad \forall\, r\in R \tag{7}$$

$$z_r^1 \leq \left(1 - \frac{p_r^1 - p_r^2}{\tau_r(\alpha^1-\alpha^2)}\right)D_r \qquad \forall\, r\in R \tag{8}$$

$$z_r^2 \leq \sum_{d\in D}\sum_{n\in N_{dr}} x_{drn}^1\lambda_{drn}^1 + x_{drn}^2\left(1-\lambda_{drn}^2\right) \qquad \forall\, r\in R \tag{9}$$

$$z_r^2 \leq \left(\frac{p_r^1 - p_r^2}{\tau_r(\alpha^1-\alpha^2)} - \frac{p_r^2}{\tau_r\alpha^2}\right)D_r \qquad \forall\, r\in R \tag{10}$$

$$\sum_{s\in S}\sum_{n\in N_{sd}} x_{sdn}^1\left(1-\lambda_{sdn}^1\right) \geq \sum_{r\in R}\sum_{n\in N_{dr}} x_{drn}^1 \qquad \forall\, d\in D \tag{11}$$

$$\sum_{s\in S}\sum_{n\in N_{sd}} x_{sdn}^1\lambda_{sdn}^1 \geq \sum_{r\in R}\sum_{n\in N_{dr}} x_{drn}^2 \qquad \forall\, d\in D \tag{12}$$

$$\frac{p_r^2}{\alpha^2} \leq \frac{p_r^1}{\alpha^1} \qquad \forall\, r\in R \tag{13}$$

$$\frac{p_r^1}{\alpha^1} \leq \tau_r \qquad \forall\, r\in R \tag{14}$$

$$\frac{p_r^1 - p_r^2}{(\alpha^1-\alpha^2)} \leq \tau_r \qquad \forall\, r\in R \tag{15}$$

$$x_{sdn}^1, x_{drn}^1, x_{drn}^2, p_r^1, p_r^2, z_r^1, z_r^2 \geq 0 \qquad \forall\, s,d,r,n \tag{16}$$

The distributor's objective (6) is to maximize the profit of selling different quality levels of products to potential customers by taking into account the procurement cost of high-quality products, the cost of delivering high-quality products from suppliers to DCs, and the cost of delivering high- and acceptable-quality products from DCs to retailers.
Constraints (7) and (8) together guarantee that the sales of quality 1 items at any retailer r are smaller than the minimum of available quality 1 items, and the demand for quality 1, respectively. Similarly, constraints (9) and (10) together guarantee that, at any retailer r, the number of sold quality 2 items is smaller than the minimum of its inventory and demand. Constraints (11) and (12) are DC balancing constraints, limiting the total number of quality 1 and 2 items sent out from each DC to the number of quality 1 and 2 items received at that DC, respectively. Finally, constraints (13)-(15) restrict the candidate prices to the set discussed in Lemma 1 to keep both products appealing to customers, and constraint (16) is the set of non-negativity constraints.
It follows from (11) and (12) that the firm may choose to dispose of some items in DCs, instead of shipping them out. This waste happens despite paying the procurement and transportation cost to DCs. Using RFID tags, the distributor can separate high- and acceptable-quality products and may decide not to ship some of the acceptable-quality items which eventually would not be sold at retailers (either due to the demand or the final quality).

Note that we have not included the RFID adoption cost in our model. Instead, we will compare the optimal profit of this model with the optimal profit of a cold supply chain not enhanced by RFID. Determining the extra profit generated by adopting this technology enables practitioners to choose among different available types of RFID and sensor technologies.

Model in The Absence Of RFID

Without the implementation of the RFID technology, the distributor cannot separate different quality levels at DCs. Therefore, at each supplier, the distributor is essentially choosing the complete route each item goes through to reach the retailers. We define a new decision variable x^1_{sdrnm} which represent the number of high-quality items shipped from the supplier s to DC d thorough the option $n \in N_{sd}$, and then from DC d to the retailer r through the option $m \in N_{dr}$. As all items are fresh at suppliers, there is no item with quality level 2 at the node $s \in S$.
We model the transportation-pricing problem of the distributor as follows:

$$max\,\pi = \sum_{r\in R}(p_r^1 z_r^1 + p_r^2 z_r^2) - \sum_{s\in S}\sum_{d\in D}\sum_{r\in R}\sum_{n\in N_{sd}}\sum_{m\in N_{dr}}\left(C_s' + C_{sdn} + C_{rdm}\right)x^1_{sdrnm} \qquad (17)$$

Subject to

$$z_r^1 \leq \sum_{s\in S}\sum_{d\in D}\sum_{n\in N_{sd}}\sum_{m\in N_{dr}} x^1_{sdrnm}\left(1-\lambda^1_{sdn}\right)\left(1-\lambda^1_{drn}\right) \qquad \forall\, r\in R \qquad (18)$$

$$z_r^1 \leq \left(1 - \frac{p_r^1 - p_r^2}{\tau_r(\alpha^1-\alpha^2)}\right)D_r \qquad \forall\, r\in R \qquad (19)$$

$$z_r^2 \leq \sum_{s\in S}\sum_{d\in D}\sum_{n\in N_{sd}}\sum_{m\in N_{dr}} x^1_{sdrnm}\left(\left(1-\lambda^1_{sdn}\right)\lambda^1_{drn} + \lambda^1_{sdn}\left(1-\lambda^1_{drn}\right)\right) \qquad \forall\, r\in R \qquad (20)$$

$$z_r^2 \leq \left(\frac{p_r^1 - p_r^2}{\tau_r(\alpha^1-\alpha^2)} - \frac{p_r^2}{\tau_r\alpha^2}\right)D_r \qquad \forall\, r\in R \qquad (21)$$

$$\frac{p_r^2}{\alpha^2} \leq \frac{p_r^1}{\alpha^1} \qquad \forall\, r\in R \qquad (22)$$

$$\frac{p_r^1}{\alpha^1} \leq \tau_r \qquad \forall\, r\in R \qquad (23)$$

$$\frac{p_r^1 - p_r^2}{(\alpha^1-\alpha^2)} \leq \tau_r \qquad \forall\, r\in R \qquad (24)$$

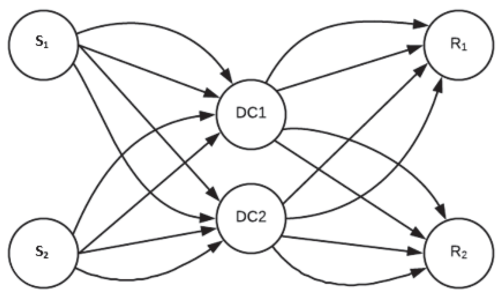
$$x^1_{sdrnm}, p_r^1, p_r^2, z_r^1, z_r^2 \geq 0 \qquad \forall\, s,d,r,n,m \qquad (25)$$

The modeling intuition behind each equation remains similar to the one in (6)-(16) discussed in the proposed model in presence of RFID. However, considering our new transportation decision variables, the objective function and the right-hand side of constraints (18) and (20) are updated. Moreover, the balancing constraints for DCs are implicitly included in the definition of x^1_{sdrnm} variables, and thus omitted.

NUMERICAL STUDY

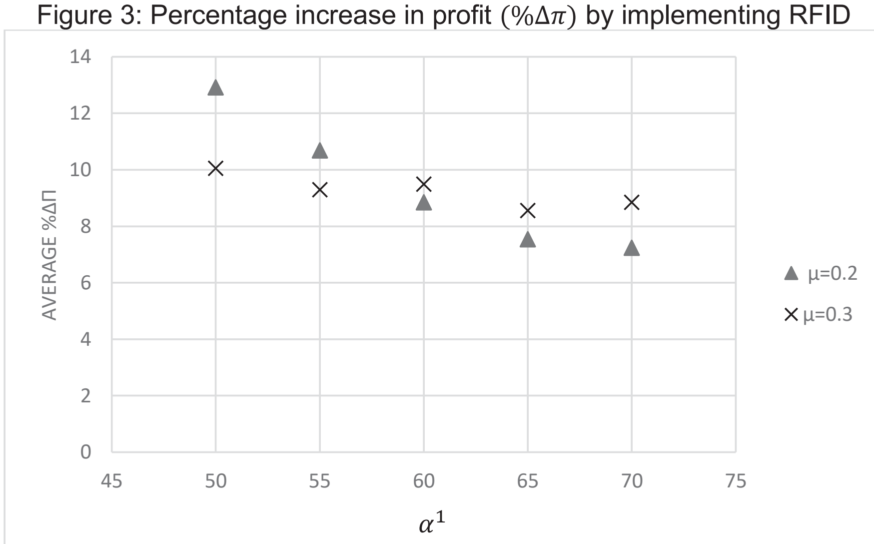
To evaluate the performance of our proposed transportation-pricing model, we use GUROBI software in R platform to find the maximum profit in the presence and absence of RFID tags for a series of numerical examples. We consider a stylized network shown in Figure 2, consists of two suppliers, two DCs and two retailers. We assume the distributor has two transportation options between each pair of nodes. The procurement cost at both suppliers is $20 per item. Intuitively, there is an inverse relation between the transportation cost and deterioration rate of each transportation option: Higher freshness keeping efforts and faster transportation both increase the transportation cost and decrease the deterioration rate. In particular, we assume that the cost of shipping an item through a transportation option equals the inverse of the square root of its deterioration rate for high-quality items. In order to model the faster deterioration of items with lower quality, we assume that the deterioration rate for quality level 2 items is twice as large as the deterioration rate for quality level 1 items for each transportation option. The expected demand at retailer 1 and 2 are assumed to be 1500 and 1000 items, respectively.

Figure 2: supply chain network used in numerical example



We assume that the deterioration rate of high-quality products is normally distributed with mean μ and standard deviation σ. We consider two sets of scenarios with $\mu = 0.2$ and $\mu = 0.3$, with $\sigma = 0.05$ for both sets. In each set, we fix the desirability of items with quality level 2 at $\alpha^2 = 40$ and consider five cases for the desirability of items with quality level 1, $\alpha^1 = \{50,55,60,65,70\}$. For each of our 10 scenarios, we simulate 100 randomly generated replications.
We calculate the percentage change in the profit, denoted by $\%\Delta\pi$, by comparing the maximum profit with and without enhancing the supply chain by RFID-based sensors. This percentage represents the value gained by adopting this technology. For all replications, $\%\Delta\pi$ is positive or close enough to zero, such that the reduction in profit can be explained by approximation and rounding errors.

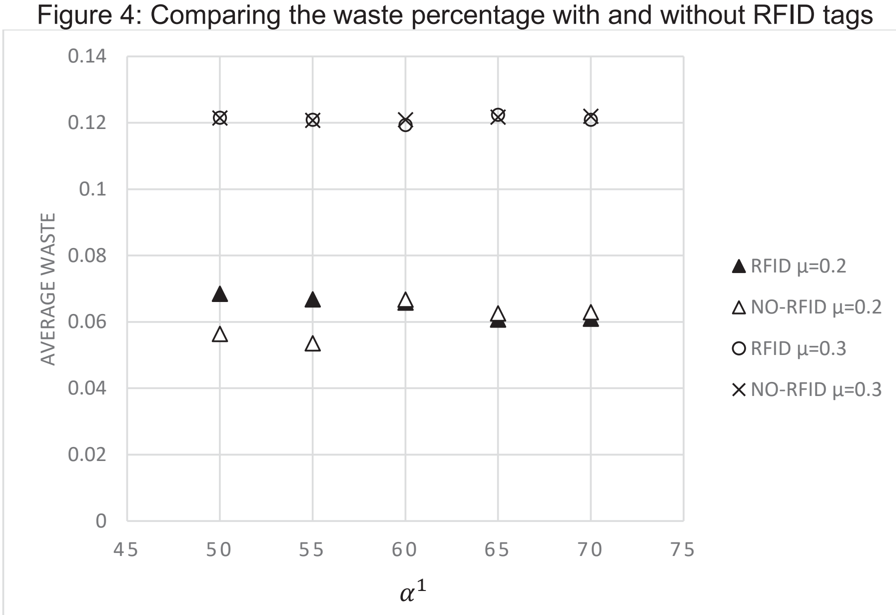
Figure 3: Percentage increase in profit ($\%\Delta\pi$) by implementing RFID



The primary benefit of the updated quality information in our model is to optimally handle items with already reduced quality at DCs. When we use RFID, a transportation option with lower deterioration rate and higher cost may be used for shipping quality level 2 items, if they are valuable enough to cover the extra cost of the expedited transportation. Therefore, we expect a higher value of the RFID implementation when acceptable-quality items are almost as desirable as high-quality items. When the desirability of level 1 increases in comparison to level 2, we observe in Figure 3 that the value of the RFID technology decreases at $\mu = 0.2$. We are not observing the same profit gain when $\mu = 0.3$, as the higher average deterioration rates strike items at quality level 2 harder.

We also compare the percentage of the high-quality items which are wasted, i.e., bought from suppliers but not sold at retailers (discarded at DCs or retailers, or deteriorated to unacceptable quality during the transportation). Figure 4 shows the average percentage of items wasted under different scenarios (with and without RFID tags).

Figure 4: Comparing the waste percentage with and without RFID tags



It is not surprising that a higher average deterioration rate yields a higher percentage of items wasted. However, as it can be seen in Figure 4, the adoption of RFID does not improve the waste level. In contrast, by comparing Figures 3 and 4, we observe that the RFID implementation increases the profit in the cost of tolerating an increase in the food waste. This is the result of our objective function which is focused on increasing the profit. In other words, we cannot merely rely on sensor technologies to decrease the waste. We need some additional constraints or penalties to make sure that the RFID technology does not encourage the distributor to ship more items knowing that it can separate and discard lower quality items later at DCs.

CONCLUDING REMARKS

We study the profit-maximizing transportation and pricing problem for a distributor with price and quality sensitive customers. The distributor decides on the procurement level from the suppliers, transportation policy from suppliers to distribution centers to retailers, and selling prices for different quality levels at different retailers. Comparing the maximum profit in the presence and absence of wireless sensor technologies that can track the products' quality along the supply chain, we derive the value of implementing such a technology.

Our results show that in the absence of strict environmental regulations, enhancing the cold chain by RFID temperature tags provides the distributor with incentives to increase its procurement level, as the temperature abused items can be identified and separately handled later at DCs.

Our study categorizes the perishable products into three groups based on their quality levels: high, acceptable, and unacceptable. It is straightforward to extend our mathematical model to consider multiple quality levels. In this case, the value of implementing RFID tags increases as it will provide more opportunities to customize the pricing and distribution policies. Continuous quality score can also be considered for the products using exponential or Gamma distribution (Yousefi *et al.*, 2019) for the quality.

In this work, we focused on products whose quality are observable for the end customers. If the quality of the product is not observable at retailers (e.g., due to packing the product in a sealed container), then the value of implementing RFID tags will increase. Under this scenario, we cannot differentiate between different quality levels even at the retailers. Thus, we should set a single retail price at each location based on the expected quality of the product and its desirability.

Finally, we can further extend our model by considering the capacity of our transportation options. Adding restrictions on full or less than truckload shipping, or on the total capacity of each option, will broaden the applicability of our model for practical purposes.

ABSTRACT

To ensure business continuity and protect its value, the firm needs to enhance its supply chain resiliency. Based on the organizational information processing theory, we consider the enhancement of supply chain resiliency as an information-based process. In our study, we posit that implementing supply chain risk management practices creates redundancy that enables a reduction of the information processing needs. Whereas, the investment in supply chain integration activities will help the firm increase its information processing capacity. Analysis of data collected from 283 US and French manufacturers, supports our arguments and offers theoretical and managerial insights.

KEYWORDS: Supply chain resilience, Supply chain integration, Supply chain risk management, Organizational Information processing theory.

INTRODUCTION

Understanding and building supply chain resiliency is increasingly becoming a necessity as supply chains are becoming more complex and supply chain disruptions often impact the organizations severely. This has been evident in recent natural disasters. The recent hurricane Maria at Puerto Rico on 20 September 2017, has been recorded as the most powerful storm to hit the Caribbean island in 85 years (Lewin, Roegiers, Tuazon, & Almond, 2017). Puerto Rico is a critical node in the US pharmaceutical industry supply chain as it hosts 13 of top pharmaceutical companies and medical devices manufactures in the US (PharmaBoardroom, 2016). Therefore, disruptive events that strike the region could have a devastating impact on the supply of critical drugs, medical devices but more importantly, the life of patients. Hurricane Maria caused severe damage to the infrastructure of Puerto Rico. The Federal Drug Administration (FDA) issued alarming reports about the potential shortage of 40 critical medication and more than 50 manufacturing companies afflicted by damaged facilities (Kelly, 2017). Thus, understanding the factors contributing to building resiliency will enable organizations to be better prepared to face disruptive events.

The research on supply chain resiliency is at a nascent stage and requires further understanding of its enhancers (Blackhurst, Dunn, & Craighead, 2011). Previous studies (Martin

Christopher & Peck, 2004; Pettit, Croxton, & Fiksel, 2013; Pettit, Fiksel, & Croxton, 2010) have discussed various capabilities that will contribute to build and improve the resiliency of the supply chain based on the main four principles advanced by Christopher & Peck (2004) namely : re-engineering, collaboration, agility and culture of risk management. In their research paper (Scholten, Sharkey, Scott, & Fynes, 2014) designed an integrated framework based on four distinct phases (mitigation, preparedness, immediate response and recovery) wherein each phase is related to a set of capabilities to build supply chain resilience. Although, supply chain resiliency enhancers have been discussed from an information-based perspective, the interplay between the varying degree of uncertainty faced by the company and the capabilities it needs to develop is still unclear. In our paper, we intend to study how companies can deal with uncertainty from an organizational information processing theory (OIPT) to enhance resiliency by either increasing its access to information or by reducing its need for information. We set to contribute to the literature on supply chain resiliency, by studying the mechanisms through which the firm can balance its information needs and information capacity to mitigate disruptive events in a reactive and proactive manner. We empirically test the effects of Supply Chain Integration (SCI) and Supply Chain Risk Management practices (SCRM) on Supply Chain Resiliency (SCRE). Thus, we intend to answer the following research question: To what extent the interplay between SCI and SCRM enhance supply chain resiliency?

In line with extant literature (Sheffi & Rice, 2005; Wieland & Wallenburg, 2012) we conceptualize supply chain resiliency as consisting of two dimensions: Agility “Reactive Approach” and Robustness “Proactive Approach.” Robustness focuses on the ability of the organization to maintain operations in the face of disruptive events (Kitano, 2004), while Agility pertains to the ability of the organization to quickly react to changes by returning to a normal situation (Chowdhury & Quaddus, 2017; Wieland & Wallenburg, 2012). Considering the critical role played by agility and robustness in protecting operational and business performance of the organization (Hendricks & Singhal, 2005b, 2005a), we adopt the view of Brandon-Jones et al. (2014) by considering robustness and agility as performance outcomes.

Past studies have demonstrated the disastrous effect supply chain risks can have on firm performance (Hendricks & Singhal, 2005a). Since supply chain disruptions are a form of risk (Chopra & Sodhi, 2004), firms need to implement supply chain risk management (SCRM) practices to withstand its adverse effects. SCRM practices are the integrated process of identifying, analyzing accepting or mitigating the risks along the supply chain (Blome & Schoenherr, 2011). Previous studies argued that SCRM practices can effectively mitigate supply chain risks through the implementation of tactics and tools which seek to build redundancy in the supply chain, such as slack capacity, dual sourcing (Lavastre, Gunasekaran, & Spalanzani, 2012; Wiengarten, Humphreys, Gimenez, & McIvor, 2016).

Previous studies and meta-analysis demonstrated the benefits of supply chain integration in its external and internal form on the organization’s performance (Ataseven & Nair, 2017; Flynn, Huo, & Zhao, 2010; Schoenherr & Swink, 2012). Research on SCI focused mainly on studying the impact of integrating internally and externally on operational performance (Danese & Bortolotti, 2014; Flynn et al., 2010; Wong, Boon-Itt, & Wong, 2011), business performance (Chang, Ellinger, Kim, & Franke, 2016; Leuschner, Rogers, & Charvet, 2013; Swink, Narasimhan, & Wang, 2007). Although it is fundamental to investigate the impact of SCI on classical forms of firm performance, an organization can derive other benefits from SCI. Thus, by investigating the role of SCI in building supply chain resiliency, we argue that integrating with supply chain partners allow the firm to improve its resiliency and protect its value from disruptive events.

In this paper, we draw on the organizational information processing theory (OIPT) (Galbraith, 1973, 1977) to understand the relationship between supply chain integration, supply chain risk management practices, and supply chain resiliency. According to the OIPT, when facing high levels of uncertainty, organizations need greater levels of information (Galbraith, 1973). Thus, we posit that SCI and SCRM are instrumental in reducing the level of uncertainty to improve the supply chain resiliency. By implementing these supply chain practices, firms can balance their information needs and capacity to enhance their robustness and agility. We build on literature from SCI and supply chain risk management to develop our hypothesis.

We contribute to the literature of supply chain resiliency, by studying supplier and customer integration impact as enhancers of robustness and agility. Based on the OIPT, we view the development of resiliency as an information-based process, where information processing needs and information processing capacity act as levers to reduce the high uncertainty characterizing the identification, processing, and mitigation of disruptive risks. In the following sections, we will review the literature on our main constructs and develop the hypothesis for our research model. Then, we will discuss the methodology and results found after testing our hypotheses. Finally, we will discuss the results and suggest theoretical and managerial implications for our paper.

THEORETICAL FOUNDATIONS

Organizational processing theory (OIPT): a link to resiliency enhancers

According to OIPT, when facing high uncertainty stemming from their business environment, organizations need to deploy the adequate processing needs to improve their organizational performance (Tushman & Nadler, 1978). Therefore, organizations need to collect, transform and interpret the information to reduce uncertainty (Daft & Lengel, 1986). For Galbraith (1974), organizations can manage low uncertainty contexts through a coordination mechanism by utilizing rules, hierarchy, targets, and goals to overcome exceptional situations. However, when the level of uncertainty increases such a “mechanistic approach” is no longer feasible. Galbraith (1974) suggests that organizations can adjust by either decreasing its information processing needs by creating slack or buffers or by increasing its information processing capacity through lateral relations and investing in vertical information systems. For instance, the implementation of some SSCRM practices aims to mitigate disruption risks by positioning safety stock in critical nodes of the supply chain, while firms can create lateral relations through external integration with customers and suppliers.

Disruptive events exert great uncertainty on organizations, thus impeding their ability to develop the adequate measures to withstand disruptions. In addition to this, the occurrence of a disruptive event necessitates collaboration and information exchange with supply chain partners in order to withstand its devastating effects. Organizations seeking supply chain integration will increase their information processing capacity. While implementing SSCRM practices is going to reduce the need for information processing needs of the organization. The joint action of both SCI and SCRM balances the information needs and capacity a firm requires to successfully enhance its resiliency. Thus, OIPT is a suitable theoretical lens to investigate the relationship between SCI, SCRM, and Supply Chain resiliency.

Supply Chain Integration:

Supply chain integration refers to the extent to which a strategic collaboration and the intra- and inter-organization processes are managed between an organization and its partners, to process the flows of products & services, information, funds and decisions effectively and efficiently, to maximize the customer value ultimately (Flynn et al., 2010; Frohlich & Westbrook, 2001). Prior studies differentiated between internal integration and external integration (Flynn et al., 2010; Leuschner et al., 2013; Wong et al., 2011). Internal integration focuses on the in-house processes and aims to synchronize and connect the intra-organizational processes by overcoming the existing functional silos (Kahn & Mentzer, 1996). External integration is oriented towards external partners of the firm namely suppliers and customers. It refers to the extent to which a firm collaborates with external partners through inter-organizational practices to synchronize and streamline processes and improve the supply chain performance (Stank & Keller, 2001). Since we are investigating how the need for information – by increasing the capacity to capture information or reduce the need for it - is crucial to manage disruptive events, we will focus only on external integration as a practice that creates external linkages with supply chain partners in order to collaborate and share information.

Building resiliency in the supply chain requires the collaboration of the organization with its upstream and downstream partners. Based on the OIPT perspective, overcoming exceptional scenarios characterized by high uncertainty such as supply chain disruptions necessitates the investment in information processing needs. To this end, firms can increase their information processing capacity via lateral relations and vertical information systems (Galbraith, 1973). We consider SCI as information exchange relationship involving extensive information gathering, sharing and interpreting. Although high levels of information sharing might lead to detrimental effects on performance (Flynn, Koufteros, & Lu, 2016), it is offset by the instrumental role SCI plays in the development of shared meanings, shared supply chain experiences (Hult, Ketchen, & Slater, 2004) and common understanding (Huber, 1991). As a result, supply chain partners can operate effectively as an integrated network and make sense more easily of greater levels of information. Therefore, we use the OIPT as a lens to argue that organizations need to implement supply chain integration to build resiliency in the supply chain.

Supply Chain Risk Management:

With the extended boundaries of the focal firm and the close inter-organizational relationships, various types of risks may impede supply chain from meeting its customer demand. In our paper, we orient our study specifically to supply chain risks. They can be defined as the probability and impact of different events capable of distorting and causing failures across the organizational levels (operational, tactical and strategic) along with any part of a supply chain (Ho, Zheng, Yildiz, & Talluri, 2015). Supply chain disruption is identified by (Chopra & Sodhi, 2004) as one of the primary sources of Supply chain risks. The occurrence of supply chain risks is associated with uncertainty because of the unexpected nature of risks that may materialize and hinder supply chain activities (Waters, 2007). Based on OIPT framework, we argue that organizations facing a high level of uncertainty will be able to build resiliency by increasing their information processing capacity through lateral relationships such as supply chain integration and by decreasing their information processing needs through the creation of redundancy via the implementation of SCRM practices.

Supply chain risk management is a collaborative approach that involves the external partners (suppliers and customers) in identifying, analyzing and mitigating the risks and uncertainties along the supply chain (Blome & Schoenherr, 2011; Ho et al., 2015; Manuj & Mentzer, 2008). At first, an organization should identify the risks and their drivers, which can hinder the operations of the supply chain. Then, it will analyze the information at its disposal and implement the adequate mitigation processes (Craighead, Blackhurst, Rungtusanatham & Handfield, 2007; Hendricks & Singhal, 2003; Tomlin, 2006). The processes of risk identification aim to scan the environment at an intra-organizational and inter-organizational level for potential risks (Kern, Moser, Hartmann, & Moder, 2012). Being able to precisely and quickly identify the supply chain risk, gives the organization the opportunity to assess its severity and engage the suitable mitigation strategies to limit or avoid its impact on the organizational performance (Blackhurst et al., 2011; Tomlin, 2006; Zsidisin, Ellram, Carter, & Cavinato, 2004). Disruptive events exert high uncertainty on supply chain decisions that requires greater information processing needs. Thus, gathering and interpreting accurate information along the supply chain is critical for the organization to withstand the effects of disruptions. In the hypotheses section, we argue that instead of increasing its information processing capacity, firms can use SCRM practices to create redundancy in the supply chain. This latter will act as an absorber of uncertainty and will allow the firm to demonstrate robustness and agility in case of a disruption.

Supply Chain Resiliency: a proactive and reactive approach

Given the importance of disruption effects on organizational performance, the literature on supply chain resiliency (SCRE) is growing, and multiple definitions of the SCRE are proposed (Ambulkar, Blackhurst, & Grawe, 2015; Bhamra, Dani, & Burnard, 2011; Ponomarov & Holcomb, 2009). For instance, Brandon-Jones et al. (2014) makes a distinction between resilience and robustness and consider them as two distinct concepts. The first is related to the ability of the firm to recover rapidly from a disruption, while the second concept pertains to the ability of the firm to sustain its operations in the face of disruption. Other researchers conceptualize resiliency as a mix of both proactive (robust) and reactive (agile) strategies (Chowdhury & Quaddus, 2017; Hohenstein, Feisel, Hartmann, & Giunipero, 2015; Melnyk, Closs, Griffis, Zobel, & Macdonald, 2014; Wieland & Wallenburg, 2012). In this paper, we adopt this view and consider an organization to be resilient if it is capable of maintaining its operations functioning while adjusting its supply chain rapidly to the new situation to face a disruptive event.

Robustness involves an ex-ante preparation for predictable and unpredictable disruptions. Researchers refer to supply chain robustness as “proactive strategy” (Durach, Wieland, & Machuca, 2015; Klibi, Martel, & Guitouni, 2010; Wieland & Wallenburg, 2012). An organization achieves robustness if it can maintain the continuity of the operations against disruptions (Brandon-Jones et al., 2014). To prepare for disruptive events, firms implement preventive measures across the supply chain in order to be able to operate despite the occurrence of disruption by using safety stock or backup options for instance (Azadegan, Patel, Zangoueinezhad, & Linderman, 2013; Zsidisin & Wagner, 2010). However, developing these “second options” should be done ex-ante via early detection of possible sources of disruptions to enable the organization to withstand disruptive events.

Conversely, to the capability of enduring disruption (robustness), agility is concerned with the reacting capability to disruptive events on an ex-post basis (Husdal, 2010: 14). According to (Wieland & Wallenburg, 2012), supply chain agility refers to the ability of an organization to react rapidly to distortions in the supply chain by readjusting its original configuration. An organization will be identified as agile, if it can respond promptly and recover from disruption with minimal impact (Pettit et al., 2013; Sheffi & Rice, 2005). As supply chain agility is observed after the occurrence of a disruption, the speed at which an organization reacts becomes a critical capability to face disruptions effectively.

HYPOTHESES DEVELOPMENT:

In our research model (*Figure 1*), we look at the direct effects of supply chain integration and supply chain risk management practices on supply chain resiliency in its proactive (robustness) and reactive (agility) form.

Supply Chain Integration Effect on Supply Chain Resiliency:

Facing disruptive events exerts a high level of uncertainty on managers to take the adequate decisions. OIPT suggests to firms in such cases firms to deal with increased uncertainty either by increasing their information processing capacity through lateral relations (SCI), or by creating buffers and slack (Galbraith, 1973). Respectively, engaging in supply chain integration activities with the upstream and downstream partners will allow the firm to leverage its inter-organizational linkages to reduce the uncertainty(Koufteros, 2014; Wong, Wong, & Boon-itt, 2015). The alignment of supply chain processes characterizing SCI will enable the firm to access new valuable information, interpret it and make informed decisions to prepare for and withstand supply chain disruptions.

Based on OIPT, closer integration with customers and suppliers enables the firm to gather, transform and exploit the information collected thanks to its external linkages (Galbraith, 1974; Srinivasan & Swink, 2015). Previous studies have demonstrated that tighter integration with supply chain partners allows the firm to access more accurate and high-quality information (Barratt & Oke, 2007).The development of information sharing among the firm and its suppliers and customers is instrumental in enhancing the supply chain visibility (M. Christopher & Lee, 2004). Armed with an enhanced visibility and established routines of information sharing, the firm can detect possible sources of disruptions in its supply chain and build the adequate measures to face it in a proactive manner. For example, thanks to the sharing of production plans among partners, the firm can detect possible bottlenecks and work with partners to alleviate them to withstand disruptive events, hence demonstrating robustness in face of a disruptive event. Therefore, we suggest the following hypotheses:

H_{1a}: Supplier integration is positively related to robustness

H_{1b}: Customer integration is positively related to robustness

Moving from an arm's length relationship to embedded relationships such as SCI, entails the development of trust and commitment (D. Q. Chen, Preston, & Xia, 2013; Zhang & Huo, 2013). These relational antecedents have been shown to play an essential role in reinforcing of the willingness of the firms to share risks and rewards amongst each other (I. J. Chen & Paulraj, 2004; Mayer, Davis, & Schoorman, 1995; Sambasivan & Yen, 2010). Furthermore, integration with suppliers and customers enable the supply chain partners to develop shared goals, understanding, codified routines, policies and procedures (Rothaermel & Deeds, 2006). Subsequently, by integrating with its suppliers and customers, the firm will be able to share, interpret and act on the available information more quickly since the supply chain partners already have developed routines and procedures to operate their processes. Thus, they will be able to react more quickly to disruptive events since they can process and treat information more quickly than others. Indeed, Liang & Huang (2006) have found that higher levels of external integration allow the firm to improve its agility and responsiveness to market uncertainty. Based on OIPT, closer integration with customer and supplier allow the firm to increase its information processing capacity to gather and exploit data more effectively to improve its agility. As a result, we propose the following hypotheses:

H_{2a}: Supplier integration is positively related to agility

H_{2b}: Customer integration is positively related to agility

Supply chain risk management effect on supply chain resiliency:

From an OIPT perspective, the second lever managers can activate to deal with the uncertainty implied by disruptive events is the creation of redundancy/slack (Galbraith, 1973, 1974). Consistent with this line of reasoning, we suggest that firms can deal with the uncertainty created by supply chain disruptions by implementing SCRM practices. In fact, the different SCRM processes are designed in a way to successfully identify potential sources of risk and apply adequate mitigation measures. To mitigate potential supply chain risks, firms build redundancy in the form of safety stocks, the dual or multiple sourcing, maintaining capacity slack (Lavastre et al., 2012). Implementing these practices enables the firm to lessen the effect the uncertainty by creating “shock absorbers” (Bode, Wagner, Petersen, & Ellram, 2011). However, to effectively mitigate the disruptive risks, the firm needs to identify these risks successfully. Indeed, Kern (2012) empirically demonstrated the positive relationship between risk identification and the success of the subsequent SCRM processes and the quality of the mitigation.

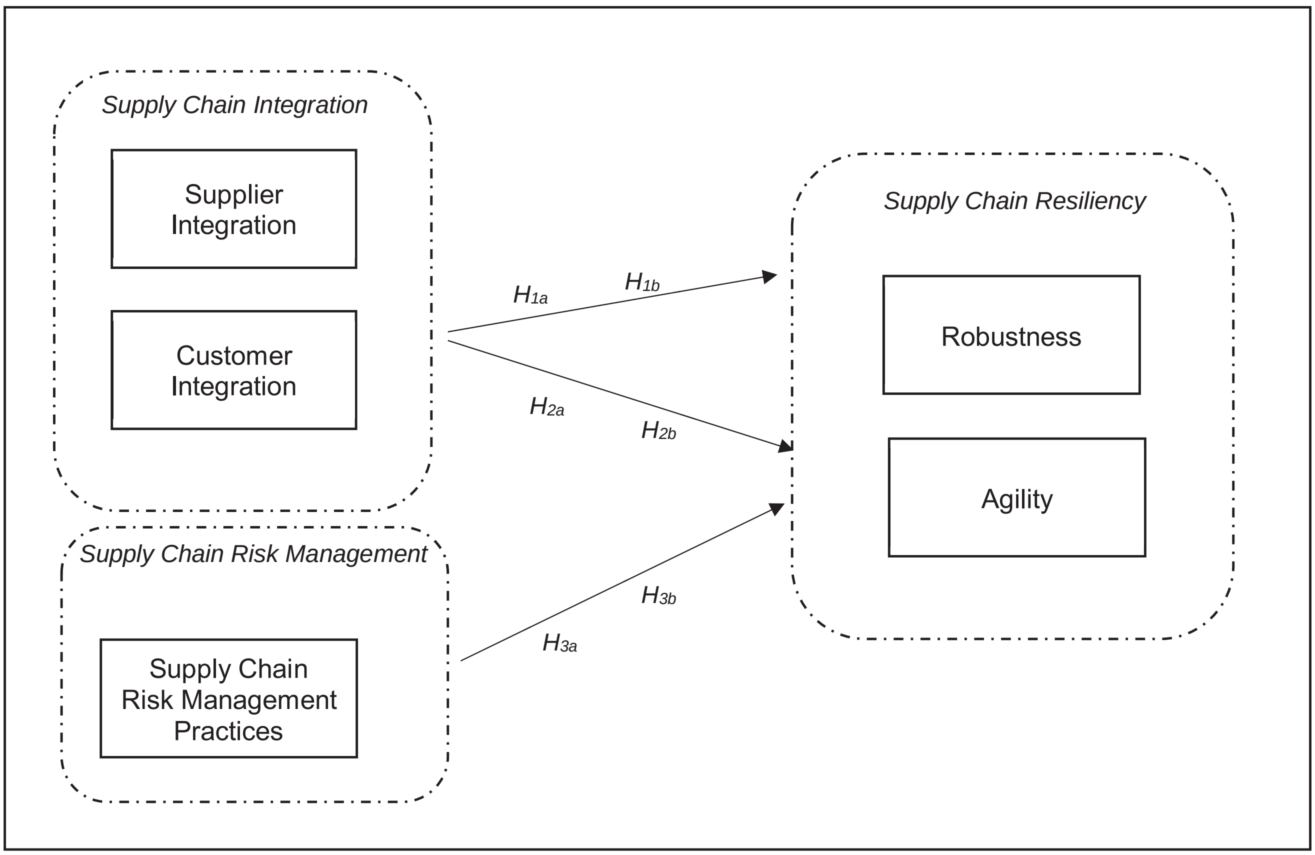
Risk identification is a critical part of the SCRM process (Blome & Schoenherr, 2011; Manuj & Mentzer, 2008). Developing risk identification capabilities will allow the firm to detect possible sources of disruptions and address them in a proactive manner. Risk identification is defined as the ability of the firm to systematically and exhaustively evaluate and recognize potential supply chain related risks (Tummala & Schoenherr, 2011). If this latter is executed correctly, it will allow the firm to effectively create and allocate the slack in its different forms to manage the uncertainty accompanying SC disruptions. As a result, the firm can prepare ex-ante for the disruptive events. For instance, after scanning its environment, the firm detected a vulnerable supplier that might be easily affected by the hazardous event. Based on the assessment of the collected information from, the firm can proceed to ask this supplier to build a safety stock to be able to withstand disruptive events. Thus, implementing SCRM is instrumental in developing robustness in a proactive manner to face SC disruptions. Indeed, practices such as early warning systems and supplier development programs (Azadegan, Kach, Golara, & Mousavi, 2017; Wiengarten et al., 2016) are directly related to developing robustness in response to disruptive events.

Further, the time necessary to react to a disruptive event is a major factor in reducing its impact on the supply chain (Craighead et al., 2007). Risk mitigation techniques (i.e., rethinking and restructuring supply and distribution strategy) (Wiengarten et al., 2016) endow the firm with the ability to promptly redesign and adapt its supply chain in the case of a disruption. Previous studies have stressed the importance of considering the creation of redundancy/slack in the supply chain as a way of mitigating supply chain disruptions (Sarathy, 2006; Sheffi & Rice, 2005). For example, after identifying a distribution-center as weather-sensitive, the firm can build a dual distribution-center that can be utilized in response to disruption. Therefore, by implementing this mitigation technique, the firm will be able to promptly reroute its distribution strategy and recover quickly. From an OIPT perspective, the slack resources used to mitigate the risks absorb the uncertainty created by the disruptive event and allow the firm to recover rapidly from a disruption. Previous studies have demonstrated the relationship between risk mitigation and recovery speed (Blackhurst et al., 2011; Craighead et al., 2007). Based on these arguments, we suggest the following hypotheses:

H_{3a}: Supply chain risk management practices are positively related to robustness

H_{3b}: Supply chain risk management practices are positively related to agility

Figure 1: Research Model



RESEARCH METHODOLOGY:

Data Collection and Sampling:

To empirically test our research model about enhancers of supply chain resiliency, we collected data through an online based survey of 2042 supply chain managers and executives from France and the United States. The questionnaire was developed for a single respondent using the organization level as a unit of analysis. To enhance the generalizability of our results we collected the data from two countries and across various industries. All the measurement instrument used in our questionnaire were adopted from past validated studies. For the French sample, the questionnaire was translated from English to the French language by a professional translator, then resulting version in French was back-translated into English by another bi-lingual researcher. The two versions were compared and checked for discrepancies (Flynn et al., 2010). We submitted the questionnaire to academicians and then to supply chain managers/executives for review. After receiving their comments and reviews, we integrated them to improve the clarity of the questionnaire. Then, we used this latest version to pre-test our questionnaire with 15 supply chain professionals belonging to different industrial sectors. We included the feedback from the supply chain managers to draw the final version questionnaire. Following a key informant approach in our study, we decided to collect data from top managers and executives working in supply chain management activities such as operations, purchasing and supply chain management. These individuals are knowledgeable about their organizations' activities and can readily access sensitive information (Liu, Wei, Ke, Wei, & Hua, 2016; Montabon, Daugherty, & Chen, 2018). Following the key informant approach, we carefully screened the responses and eliminated those whose titles are not reflecting a supply chain related activity or didn't have the required experience inside the company. For the US data, 40% of respondents are supply chain directors and VPs, and 17.8% occupy a Manager or VP position in Supply chain related activities (Materials handling and purchasing). Also, 65.8% are highly experienced professionals in supply chain activities. For the French sample, 58% of the respondents work as Supply Chain Directors and VP's, and 12.7% work in supply chain related activity either as Managers' or VP's. Furthermore, in the US sample, 65.8% of the respondents have at least nine years of experience in the supply chain field. This figure is about 48.5% on the French sample.

To collect data from France, we collaborated with "Association Française pour la Logistique" (ASLOG), the largest association of supply chain management professionals in the country. The organization has more than 1,200 supply chain professionals working across various industrial sectors. The president of the organization signed and sent an email to invite all its members to participate in the study and explaining the objectives of the study and its importance to advance supply chain. Plus, a summary report of the results was promised to the participants to the study. Then, an email that contains the web-link to the questionnaire was sent to the 1200 members of the organization of supply chain management professionals. After two waves of emails and reminders through the social networks of the association, we received 133 usable responses, corresponding to an 11.25% response rate. To collect data in the US, we have commissioned Qualtrics, a third-party online survey administration company to collect data from US supply chain managers and executives. Qualtrics Panels has been employed in previous studies and is identified as a reliable instrument to collect data (Courtright, Gardner, Smith, & McCormick, 2016; Hazen, Bradley, Bell, In, & Byrd, 2017). Qualtrics Panel services sent an email containing the online survey link to a pool of 842 participants. 152 completed questionnaires were recorded corresponding to a response rate of 18.05%.

Measures:

We surveyed the existing literature to identify validated and reliable measures for our study. All measurements scales used in our questionnaire were adopted from existing literature (Malhotra & Grover, 1998).
Supply Chain Integration: We measured supply chain integration in its supplier and customer dimension using scales adopted from (Flynn et al., 2010; Frohlich & Westbrook, 2001). The items used, measured the level of coordination with key suppliers and customers of the flow of information and planning decisions.
Supply chain Robustness: we measured supply chain robustness using a scale adopted from (Brandon-Jones et al., 2014). This scale measures the ability of the firm to keep performing its operations normally in case a disruption occurs. It assesses the extent to which the firm will be able to meet customer demand and achieve the expected level of performance despite the disruption.
Supply chain agility: we measured supply chain agility using a scale adopted from (Wieland & Wallenburg, 2012). It examines the speed at which the firm can modify its operations in case of unexpected changes. It estimates the ability of the firm to rapidly adapt activities such as manufacturing lead-times or delivery reliability to face changes.
Supply chain risk practices: To measure supply chain risk management practices we adopted a scale from (Wiengarten et al., 2016). It evaluates the effort level devoted to implementing programs to identify and mitigate risks, such as vendor monitoring and rating programs and early warning systems and contingency programs (Blome & Schoenherr, 2011; Manuj & Mentzer, 2008).
Control Variables: To enhance the robustness of our results, we included relevant variables as control variables to our research model. We controlled for firm size by measuring the total number of employees, since small-sized companies are less exposed to disruptions (Wagner & Neshat, 2012). Second, the level of SCRM and SCI practices implementation may differ across industrial sectors in terms of exposure to disruptions (Min & Galle, 2001). Thus, we decided to level out the effect of the industry on the results. Third, we included the country as a dummy variable to account for possible differences among the two countries (US and France). Finally, the relationship duration between the firm and its upstream and downstream partners may affect the results since long established firms enjoy more information sharing routines and procedures to improve their performance to withstand disruptive events (Kotabe, Martin, & Domoto, 2003).

Measurement Model:

The analysis of the confirmatory factor analysis 'CFA' results (see Table 1) indicates that the data effectively fit the model: $(\mathcal{X}^2 = \mathbf{401.58}\ (\boldsymbol{df} = \mathbf{178}, \mathcal{X}^2/\boldsymbol{df} = \mathbf{2.256}\ )$; $\boldsymbol{CFI} =\mathbf{.94}$; $\boldsymbol{TLI} = \mathbf{.93}$; $\boldsymbol{RSMEA} =\mathbf{.06})$, thus ensuring strong model fit. Additionally, we assessed the convergent validity of the constructs by analyzing the factors loading, average variance extracted (AVE) and composite reliability (CR). The analysis results show that all factor loadings are greater than 0.5 and significant at ($p < .001$) (Hair, Anderson, Black, & Babin, 2010), thus we can establish high convergence of our measurement instruments. The CR values of all constructs used in our model was found to be greater than 0.7 (Hair et al., 2010), thus ensuring internal consistency and convergent validity. Also, the AVE for each measure was greater than 0.5, hence convergent validity is supported. Furthermore, the AVE results exceeded the squared correlations of the remaining measures (Hair et al., 2010), indicating the support of the discriminant validity. Since all our scales exceed the recommended thresholds for each of the tests, it is safe to say that all our measurements have good reliability, convergent and discriminant validity.

Table 1- Confirmatory Factor Analysis

Construct[a]	Loading
Robustness (α = .89; CR = .90; AVE = .66)	
To what extent do these statements apply to your supply chain should disruptions of operations occur (1= Not at all; 7= To a very great extent):	
ROB1 Operations would be able to continue	,780
ROB2 We would still be able to meet customer demand	,836
ROB3 Performance would not deviate significantly from targets	,829
ROB4 The supply chain would still be able to carry out its regular functions	,820
Agility (α = .85; CR = .86; AVE = .62)	
Please indicate the speed of reaction with which your company can engage in the following activities should changes occur (1= Slow; 7= Fast):	
AGI1 Adapt manufacturing lead-times	,692
AGI2 Adapt level of customer service	,804
AGI3 Adapt delivery reliability	,762
AGI4 Adapt responsiveness to changing market needs	,854
Supply chain risk management practices (α = .89; CR = .89; AVE = .66)	
What level of effort did your company invest in action programs within the previous 3 years (1= None, 7 = High):	
SSCRM1 Rethinking and restructuring supply strategy and the organization and management of supplier portfolio	,811
SSCRM2 Implementing supplier development and vendor rating programs	,820
SSCRM3 Rethinking and restructuring distribution strategy **in order to** change the level of intermediation	,839
SSCRM4 Implementing practices including early warning system, effective contingency programs for possible supply chain disruptions	,785
Supplier Integration (α = .91; CR = .91; AVE = .68)	
Please indicate the extent of integration or information sharing between your organization and your major supplier in the following areas (1 = Not at all; 7 = Extensive):	
SI1 Our major supplier shares their production schedule with us	,840
SI2 Our major supplier shares their production capacity with us	,897
SI3 Our **major** supplier shares available inventory with us	,809
SI4 We share our production plans with our **major** supplier	,804
SI5 We share our inventory levels with our **major** supplier	,735
Customer Integration (α = .84; CR = .84; AVE = .57)	
Please indicate the extent of integration or information sharing between your organization and your major customer in the following areas (1 = Not at all; 7 = Extensive):	
CI1 Our major customer shares Point of Sales (POS) information with us	,756
CI2 Our major customer shares demand forecast with us	,771
CI3 We share our available inventory with our major customer	,686
CI4 We share our production plan with our major customer	,716
The first item in each scale was fixed to a loading of 1.0 in the initial run to set the scale of the construct. Observed CFA fit statistics were: X2(401) = 178.25; TLI = .933; incremental fit index = .944; comparative fit index = .943; root mean square error of approximation = .06	

ANALYSES:

Robustness and agility are two closely related concepts that form the supply chain resiliency concept (Wieland & Wallenburg, 2012, 2013). Thus, error terms in the regression equations may correlate. To overcome this issue, we deem the use of Seemingly Unrelated Regression (SUR) as a suitable method to test the hypotheses of our research model. SUR is adapted to our regression equations because it accounts for the correlations among the error terms (Habermann, Blackhurst, & Metcalf, 2015). Indeed, the SUR equation modeling is suitable to generate robust regression estimates when a set of equations includes identical independent variables (Habermann et al., 2015).

Table 2a: SUR Results for Robustness

Seemingly Unrelated Regression : DV1 Robustness

Model Summary				
R^2	.20		.48	
ΔR^2			.28	

Sample size for all models, N = 283.
[a]Industry type was included as a dummy variable, but for the sake of brevity, it was not included in the table.
Results are presented as coefficients and standard errors in (parentheses).
* *p* < .05,
** *p* < .01,
*** *p* < .000.

To assess multicollinearity, we used traditional OLS regression to estimate the variance inflation factors (VIF) for regression coefficients among our independent variables (Habermann et al., 2015). The VIF values vary from 1.38 to 2.38, indicating that our results are below the recommended cut-offs for multicollinearity problems (Hair, Black, Babin, & Anderson, 2006).

The results of the seemingly unrelated regression are presented in the table 2a and table 2b. The first group of hypotheses proposed a positive direct effect of supplier integration (H1a) and customer integration (H1b) on robustness and a similar positive direct effect between supplier integration (H2a) and customer integration (H2b) on agility. The results of the SUR provided full support for this set of hypotheses H1a, H1b, H2a and H2b, thus demonstrating that SCI positively and significantly enhance supply chain resiliency in its robustness and agility dimension. The second group of hypotheses suggested that SCRM is positively related to robustness (H3a) and agility (H3b). The results indicate that SCRM is positively and significantly related to robustness and agility. Hence both our hypotheses are supported.

Hypotheses 1 proposed a positive relationship between SCI and robustness. The relationship was positive and significant for the supplier integration $(\boldsymbol{\beta = .14},\ \boldsymbol{\rho < .01})$ and customer integration $(\boldsymbol{\beta = .18},\ \boldsymbol{\rho < .00})$, hence providing full support for hypotheses H1a and H1b. Also, our results supported the hypotheses 2, where we suggested that SCI has a positive and significant effect on agility both for supplier integration hypothesis H2a $(\boldsymbol{\beta = .12},\ \boldsymbol{\rho < .05})$ and customer integration Hypothesis H2b $(\boldsymbol{\beta = .18},\ \boldsymbol{\rho < .00})$. Finally, the results confirm the hypotheses H3a and H3b and suggests that SCRM is positively and significantly enhancing robustness H3a $(\boldsymbol{\beta = .33},\ \boldsymbol{\rho < .00})$ and agility $(\boldsymbol{\beta = .26},\ \boldsymbol{\rho < .00})$.

DISCUSSION:

By studying supply chain resiliency from an information-based view, we suggest that firms can enhance their resiliency by balancing their information needs and capacity. As a result, we complement the existing findings enhancers of resiliency (Pettit et al., 2010; Scholten et al., 2014) by nuancing the supply chain practices that company can build on to improve its robustness and agility. Hence, managers can vary the levels of information capacity and information needs according to the set of resources they have in order to enhance the resiliency of their supply chain. Our findings identify supply chain integration and supply chain risk management practices as two important factors that contribute to enhancing the robustness and agility of the firm.
The findings of this study offer a threefold contribution to supply chain management and OIPT literature. First, past studies on SCI focused on investigating its effects on various forms of firm performance such as operational performance (Flynn et al., 2010; Swink et al., 2007), financial performance (Chang et al., 2016; Vickery, Jayaram, Droge, & Calantone, 2003), and business performance (Cao & Zhang, 2011; Flynn et al., 2010). Yet, the study of other types of SCI benefits is still scarce. The results of this paper demonstrate the role SCI plays in enhancing supply chain resiliency in its two dimensions (robustness and agility). We considered SCI as an information exchange relationship that involves repeated interactions between the firm and its supply chain partners to collect and interpret data. In accordance with OIPT principles (Galbraith, 1977), SCI enables the firm to cope with high uncertainty faced to endure and recover from a disruptive event. In fact, SCI acts as a mechanism to increase the information processing capacity of the firm. By closely integrating with suppliers and customers, the firm can enhance its visibility of the supply chain to prepare beforehand for disruptive events. Moreover, SCI allows the firm to leverage the established routines and procedures to quickly make sense out collected information and react quickly to disruptive events.

Second, by considering SCRM practices as a mechanism to reduce the information processing needs of the firm, we clarified how these practices could contribute to supply chain resiliency. Consistent with OIPT principles, we explained that the practices of SCRM allow the firm to build the necessary redundancy in the supply chain to absorb the possible shocks of disruptive events. Thanks to the practices aiming to identify sources of risks, the firm can detect and position more effectively the buffers ex-ante to disruptions. Whilst, mitigation practices will allow the firm to react promptly to disruptions by capitalizing on the created slacks (safety stock, dual sourcing,etc.).

Third, by viewing the enhancement of supply chain resiliency as an information-based process, we deemed suitable to apply the OIPT to explain how the combination of SCI and SCRM practices can allow the firm to cope with the high uncertainty involved in building robustness and agility to deal with SC disruptions. By studying these two factors, we answer the call of researchers to investigate enhancers of supply chain resiliency (Blackhurst et al., 2011). Consistent with OIPT principles, we suggest that managers can cope with the uncertainty implied by disruptive events either by increasing their information processing capacity through SCI or by decreasing their needs for information processing through the implementation of SCRM practices that seeks to build redundancy in the supply chain. Therefore, we contribute to OIPT by offering two mechanisms that can be used to manage or lessen the uncertainty in order to improve supply chain resiliency.

CONCLUSIONS AND LIMITATIONS

Our study extends and clarifies prior research on supply chain resiliency by investigating two mechanisms through the firm can enhance its robustness and agility. Specifically, we study how supply chain integration and supply chain risk management practices enhance the resiliency of the firm to disruptive events. By applying OIPT principles, we identified two mechanisms through which the firm can cope with uncertainty. Our results demonstrate that SCI allows the firm to increase its information processing capacity by leveraging the lateral benefits relations with supplier and customers can confer to the firm. Whilst implementing SCRM practices enable the firm to create the required redundancy to reduce its information processing needs. Combining these two mechanisms allow the firm to enhance robustness and agility thanks to a reduction of the uncertainty created by disruptive events.

The findings of our study offer various practical implications. First, by differentiating between robustness and agility, we aim to help managers understand that each dimension of resiliency requires different capabilities to be enhanced. Second, by investigating SCI and SCRM practices, we offer managers a solution to leverage supply chain practices to enhance their resiliency. Firms can act on the two levers (SCI and SCRM) to increase their information processing capacity or decrease their information processing needs depending on their situations.

Along with the results of this study, you should read it considering its limitations. First, cross-sectional data was used to test the hypotheses of this research paper. As a result, we cannot draw causal relationships between our indigenous and exogenous variables. Thus, future research can attempt to replicate our study to add on its validation or use longitudinal data to analyze the effect of SCI and SCRM practices on agility and robustness over time. Second, we limited our model to two possible enhancers of supply chain resiliency, but other unexplored factors might contribute to supply chain resiliency. We invite future research to explore other factors that may improve robustness and agility.

Email: Javad.Sadeghi@unt.edu; Elisabeth.Struckell@unt.edu; Divesh.Ojha@unt.edu

ABSTRACT

In supply chain management, we examine how to build the capability of managing and avoiding disasters – disaster immunity. Using complex adaptive systems theory, this study supports a novel three dimensional framework of absorptive capacity that includes absorptive infrastructure, complementary knowledge, and human resource management. Our model investigates the influence of two resources – information quality and change management capability – in creating the disaster immunity capability. We used the data collected from 264 US service firms to test our hypothesized model. Our empirical results indicate both information quality and change management capability completely mediate the effect of absorptive capacity on disaster immunity.

KEYWORDS: Absorptive Capacity, Disaster Immunity, Change Management Capability, Information Quality, Complex Adaptive Systems.

INTRODUCTION

It is surprising that given increased focus on prevention at government and corporate levels, the frequency and intensity of natural and manmade disasters and their consequences are increasing in the US, over a fifty-year period. Natural disasters such as hurricanes and earthquakes negatively affect the competitive capabilities of organizations and supply chains by creating disruptions.

A viable approach is developing resilience for managing disasters – disaster immunity capability. In this paper, we build on Ojha (2008) and consider disaster immunity as an organization's ability to manage disasters more effectively than its competitors. Disaster immunity (DI) refers to the organization's ability to avoid, recover, and mitigate negative impact from disasters.

Companies and their supply chain organizations are motivated by the substantial toll and increased frequency of disasters to develop capabilities to mitigate their damaging effects. Prior empirical studies have substantiated the positive relationship between absorptive capacity and organizational resilience to disasters. Absorptive capacity, defined by Cohen and Leventhal (1990) as "an ability to recognize the value of new information, assimilate it, and apply it to commercial ends", is especially useful to organizations in uncertain situations. Natural and manmade disasters are unplanned and epitomize uncertain conditions for impacted organizations. The contribution of this paper is the use of complex adaptive systems theory to empirically support a novel three dimensional framework of absorptive capacity that includes absorptive infrastructure, complementary knowledge, and human resource management. The model presented herein investigates the influence of two mediating resilience enhancing resources - information quality and change management capability – as means to build organizational resilience to disasters – disaster immunity capability. We address gaps surfaced in a review of supply chain recovery literature by (1) increasing the focus on this important organizational phenomenon, (2) providing empirical rigor to the proposed solution and (3) introducing a model that takes into consideration avoidance, recovery, and mitigation. We also contribute by answering calls to increase the awareness of the importance of disaster immunity capability for its humanitarian results beyond efficiency and by broadening the framework of disasters to encompass both natural and manmade disasters, consistent with organizational adoption of risk management focus.

What follows is a theoretical model, literature review, support for hypotheses, our methodology, researching findings, discussion and management implications.

LITERATURE REVIEW

We present a theoretical model, building disaster immunity capability through absorptive capacity and resilience enhancing resources.

Disaster immunity (DI) refers to an organization's ability to avoid disasters, minimize disaster effects, and recover quickly from disasters when compared with competitors.

Learning is a fundamental capability to build supply chain immunity against disasters. Cohen and Levinthal (1990) introduced absorptive capacity as “new perspective on organizational learning” defined as “the ability of a firm to recognize the value of new, external information, assimilate it, and apply it to commercial ends” (p128).

No study was identified to examine the role of absorptive capacity on a firm’s disaster immunity capability, however, the Roberts et al. (2012) review showed a significant body of literature, that considered absorptive capacity as an important enabler to improve firms’ performance.

We support our model with the theory of complex adaptive systems. In the context of this study, when a disaster occurs, external stimuli is introduced to the system – unpredictable in its timing and, at least temporarily uncontrollable. A disaster constitutes a complex organizational phenomenon and the organization entity which includes external interacting partnerships and customers represents a “system”. The firm impacted by the disaster represents the internal mechanism, which consists of agents (organizational business units) that operate under pre-defined rules or schema – organizational routines. The disaster is external to the everyday operating system and is dynamic in nature - constantly changing and non-uniform. In the disaster context, the schema can refer to both the everyday routines of the business as well as special schema that have been devised to prepare for disasters. Coevolution between the system and environment is a result of the feedback loops (learning), which are enhanced by the quality of information exchanged, and other resilience capabilities (change management capability) developed by the system that are inherent in the mutual interactions of the agents. Feedback is motivated by the changes that alter the state of equilibrium in the system and the nature of the organization to restore the equilibrium as quickly as possible and with as little negative impact as possible – disaster immunity capability and orientation.

HYPOTHESES DEVELOPMENT

Absorptive Capacity and Change Management Capability

Change management capability is the ability of a manager to understand how new knowledge should be used, and how to motivate and manage personnel through the change process. Absorptive capacity plays an important role in managing a business unit’s new knowledge. Change management is an ability to continually renew an organization’s direction, structure, and reconfigure capabilities with new knowledge to serve the ever-changing needs of external and internal customers. The importance of change management stems from its ability to help an organization to be competitive in addressing ever-changing customer needs and to survive in a highly competitive market. Feedback loops are an integral part of complex adaptive systems and a mechanism for organizational units to continuously adapt and learn. Torodovo and Durisin (2007) added feedback loops to the model of absorptive capacity. Applying the complex adaptive system model, business units will leverage their past knowledge, using organizational infrastructure, through repetitive interactions. This will give rise to emerging patterns, which will define the ability of the organizations to respond to calamity. We, thus, hypothesize –

H_1: Absorptive capacity is positively related to change management capability.

Change Management Capability and Disaster Immunity

Change management capability positively facilitates supply chain success, and at the same time has been found to mitigate supply chain risks. Applying complex adaptive systems theory, agents (business units) will coevolve naturally, as they strive to achieve the shared goal of survival in turbulent times with minimum possible losses. This shared vision between the business subunits of the organization will directly affect the motivation of the people managing the change, further influencing the firm's resilience to disasters. Thus, we hypothesize –

H_2: Change management capability is positively related to disaster immunity.

Absorptive Capacity and Information Quality

Information quality refers to "accuracy, reliability, relevance, adequacy, ease of access, and timeliness of the information shared across the supply chain" (Lusiantoro, Yates, Mena, & Varga, 2018). For information to be effective, it needs to be accurate (high quality) especially in situations of organizational stress and disruption. Reliance on information is important to decision making and progress. Access to quality information is critical to decision makers in supply chain management. Absorptive capacity can play an important role in identifying, assimilating and employing information – quality information.

The ability to identify the value of new knowledge influences the quality of information. Absorptive capacity motivates firms to renovate their information technology infrastructures that allow them to accurately and quickly process information throughout their supply chain. In their empirical study, Kyoon et al. (2011) showed that absorptive capacity is a critical antecedent to significantly increasing information quality. The quality of exchanging information can be improved by absorptive capacity.

In our research context, mutual interactions of the business subunits, when channeled through robust organizational infrastructure, by people high in intellect and diligence, will result in stronger inter unit connections, which foster effective and efficient communication in challenging times. We, thus, hypothesize that –

H_3: Absorptive capacity is positively related to information quality.

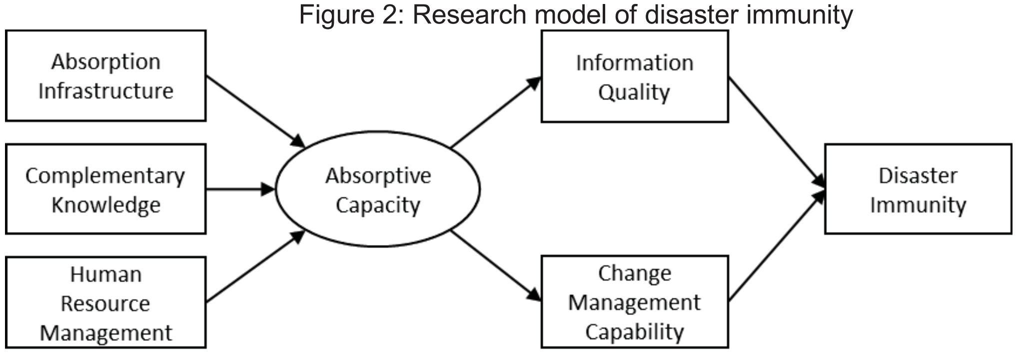
Information Quality and Disaster Immunity

Rich information exchange potentially enhances partnerships and ultimately impacts a firm's performance. Information quality leads to higher decision quality, business performance, and operational performance. Information quality plays an important role in firms to increase supply chain efficacy.

As firms strive to collaborate amongst themselves, the quality of information shared is critical (Işık, Jones, & Sidorova, 2013). Firms seek to establish robust processes to achieve effective inter-unit communication over multiple layers and enhance efficient but secure sharing of dynamic information, with minimum risk and uncertainty. These processes correspond to the coevolution focus of the complex adaptive systems, in which business subunits will collectively build resilience to forces of the external environment, as the patterns, emerging through dynamic interactions, will gravitate towards a coherent unity, after dropping the anti-bonding elements in the inter-unit connections. We, thus, hypothesize that –

H_4: Information quality is positively related to disaster immunity.

Figure 2: Research model of disaster immunity



METHODOLOGY

Analysis

The data was collected using online survey of mid to high level managers from US service industry. To analyze the research model data, we employ structural equation modeling (SEM) as a popular data analysis approach in empirical research. SEM enables us to simultaneously evaluate and estimate relationships in the entire system of variables. To evaluate our structural model, we apply a two-step process (1) evaluate the measurement model and (2) evaluate the structural model (Anderson & Gerbing, 1988). The statistical software utilized to conduct the analysis is IBM SPSS AMOS 25. Moreover, Bootstrapping method verifies the mediation roles of change management capability and information quality in the relationship between absorptive capacity and disaster immunity.

Results

We tested the nomological validity of our hypothesized model using overall fit indices. The structural model has a good overall model (χ^2[df]=719.29 [245], p≤0.000, CFI=.932, RMSEA=.086, RMR= 0.141).

The direct effects were evaluated using the significance of regression coefficients or the hypothesized relationships. The first hypothesis which states that absorptive capacity is positively related to change management capability (β = 0.169 and $p \le 0.001$), is supported. The second hypothesis which states that change management capability is positively related to disaster immunity is also supported (β = 0.283 and $p \le 0.001$). The third hypothesis which states that absorptive capacity change management capability is positively related to disaster immunity information quality is supported (β = 0.167 and $p \le 0.001$). The fourth hypothesis which states that information quality is positively related to disaster immunity is also supported (β = 0.332 and $p \le 0.001$).

Finally, we evaluated the indirect effects or implied mediation in our hypothesized model. We used Bootstrapping procedure in AMOS to test the indirect effect hypotheses. The indirect effect of absorptive capacity on disaster immunity through change management capability and information quality was supported ($\beta = 0.103$, $p = 0.024$).

DISCUSSION

The research supports the theoretical model introduced in the paper. First, the study proposed and research supports a three-dimensional framework of absorptive capacity as appropriate for the disaster immunity context - absorptive infrastructure, complementary knowledge, and human resource management. Second, using complex adaptive systems theory, we empirically demonstrate how business units are able to build disaster immunity capability (avoid, mitigate damages, and increase recovery time) through the absorptive capacity collective as well as through the development of two resilience enhancing mediating resources – (information quality and change management capability).

CONCLUSION

Natural and manmade disaster are increasing in frequency and intensity. Organizations are aware that the damage from disasters reaches well beyond business interruption and can include loss of life and reputation ruin. Given the impact to the value of the enterprise, risk management is a topic that is discussed at the board level of organizations. Proactive organizations are developing capabilities to help them cope with disasters – to avoid them, to mitigate their impact and to recovery more quickly – we call this disaster immunity capability. The research uses complex adaptive systems theory to provide empirical support for how companies can develop disaster immunity capability through the development of absorptive capacity, change management capability and the quality of information exchanged.

ABSTRACT

In this study, we examine multiple relationships among organizational variables and companies' overall green orientation and the resulting effects. How employees perceive cultural practices, quality management maturity, organizational impact of green initiatives, and their companies' overall performance are analyzed. The results are linked to organizations' green orientation embedded in their corporate strategies.

KEYWORDS: Green Movement; Quality Management; Organizational Culture

INTRODUCTION

Organizational efforts to preserve our environment are increasingly being scrutinized. In order to respond to the heightened customer awareness and demands, businesses need to place priority on incorporating green initiatives in corporate strategies in order to thrive among intense global competitions. The green movement is no longer a superficial or short-term focus to alter reputations and increase profit; it has become a vital part in most companies' operations. While "going green" may be costly in the beginning, business leaders realize the long-term benefits should not be ignored. This study explores the relationships between various organizations' green orientation and factors within organizations that can be influenced by the degree of green orientation. Specifically, we focus on the connection between the green movement and sustainability issues, and the linkages between green orientation and organizational culture, quality management maturity, organizational impact, and organizational success.

LITERATURE REVIEW

Companies choose to practice in greener ways because they realize they can contribute to the preservation of our environment, and also increase their profits. Deif (2011) suggested that there are three reasons that justify investing and implementing green manufacturing techniques: efficiency, market share, and government support and regulations. Employing greener manufacturing can save time and money, because the idea is to make the same product using fewer resources or energy. New consumer demands and heightened consumer awareness (Willson, 2011; Ackerman, 1997) combined with increased global competitions pressure manufacturing enterprises to review their strategies in order to secure market shares and sharpen their competitive edges. Pressure from governments to evolve into green manufacturing is also increasing. As regulations change, penalties and tax benefits increase, becoming greener at different manufacturing stages may become a mandate rather an option. Companies worldwide are concerned about the ability to grow and remain profitable, and are pressured by stakeholders to be more eco-efficient (Klebnikoff, 1996).

Total Quality Management (TQM), Sustainability, and Green Initiatives

Total Quality Management (TQM) has its roots in the integrative approach in customer satisfaction and a company's overall success (Chin, Pun, & Hua, 2001). Organizations are constantly facing intense pressure from competitions, and they realize the need to incorporate sustainable development and TQM in order to reach higher level of improvement and ultimate profitability (Hitchcock & Willard, 2002; Jonker, 2000; McAdam & Leonard, 2003). It is a logical continuation of research to expand TQM into a concept that also includes sustainability, long-term survival and growth with the emphasis of globalizing economies (Dervitsiotis, 2001; Wilkinson, Hill, & Gollan, 2001; Zairi, 2002).

Employee attitudes regarding green initiatives may be influenced by their perceptions toward Total Quality Management (TQM) programs implemented in the workplace. Previous research examined employee involvement (Rapp & Eklund, 2002), human resource management and leadership (Daily & Huang, 2001), commitment (Matta, Davis, Mayer, & Conlon, 1996), and personality traits (Ahmad & Schroeder, 2002) all expressed possible connections between perceptions and attitudes. How employees perceive the effectiveness of varying TQM tools employed in the workplace should have significant consequences on employees' attitudes about going green.

Organizational Culture

Employees of the same organization often share similar values and attitudes, and in turn, behave similarly. Therefore, organizational culture often is an invaluable tool to implement company strategies. When green movement inevitably becomes a part of organizational strategy, the culture that binds members of the organization together also impact the level of success on green initiatives. Organizational realize their brand image is on the line if they neglect their part in implementing green initiatives internally. Companies incorporating these initiatives within part of their corporate culture could become the leaders in the green movement and reach higher level of sustainability and profitability (Acharya, Vadher, & Acharya, 2014).

RESEARCH MODEL

In this research, we extend the examination of green movement issues to consider organizational culture, employee perceptions of organizational commitment to the green movement and the relationships which may exist between personal and organizational commitment and the QM Maturity of the organization. Additionally, where there is a higher level of perceived commitment to the green movement and where more mature QM systems are in place, we expect that, in the overall, the organization itself will be seen as "doing better" and the impact of the green movement will be perceived as favorable. Thus, QM and perceptions of the organization's green movement will be seen as having positive impacts upon organizational outcomes. The research model shows the linkages we expect and relates linkages to the corresponding research questions. In our study, we believe that the green movement within the organization should be related to or affected by the organizational culture. Additionally, as organizations become more green-oriented, the organization itself will be seen as "doing better" in general and the impact of the green movement will be more positive. Furthermore, organizations with more desirable organizational culture should be more supportive of the green movement. We also expect that organizational culture is related to the organization's performance in general. Finally, we also believe that as more organizations with more desirable organizational culture, where QM systems are in place, and the organization is "doing better," the employees will perceive the impact of the green movement to be even better.

Research Question 1: Organizational Green Orientation is related to Organizational Culture.

Research Question 2: Organizations which are described by employees as higher in Organizational Green Orientation, will also report more positive feelings about the impact of the green movement.

Research Question 3: Organizations which are described by employees as higher in Organizational Green Orientation will also report more positive feelings about the organization's performance.

Research Question 4: Organizations which are described by employees as higher in Organizational Performance, they will also report more positive feelings about the impact of the green movement.

Research Question 5: Organizations which are described by employees as higher in Organizational Culture, they will also report more positive feelings about the impact of the green movement.

Research Question 6: Organizations which are described by employees as higher in Organizational Culture will also report more positive feelings about the organization's performance.

Research Question 7: Organizations which are described by employees as higher in Organizational Green Orientation will also be described as having higher QM Maturity.

Research Question 8: Organizations which are described by employees as higher in QM Maturity, they will also report more positive feelings about the impact of the green movement.

Research Question 9: Organizations which are described by employees as higher in QM Maturity will also report more positive feelings about the organization's performance.

Research Question 10: Organizations which are described by employees as higher in Organizational Culture will also be described as having higher QM Maturity.

METHODOLOGY

Subjects of the Study

Subjects in the sample were approximately 331 full-time employees from a wide variety of industries in the South. The subjects were roughly 51.7 % male and 48% female with an average age of 41.49. Among these 331 subjects, there are approximately nine categories of industries in our survey instrument. The three largest percentages of the subjects work in retail, health care, and manufacturing industries with 22.1%, 20.8%, and 12.7%, respectively. The results are shown in Table 1.

The results are shown in Table 1.

Table 1 Types of Industry and Annual Revenue of the Organizations

Industry Types		Frequency	Percent
	Manufacturing	42	12.7
	Financial Services	15	4.5
	Retail	73	22.1
	Utilities	9	2.7
	High Technology	7	2.1
	Education	18	5.4
	Health Care	69	20.8
	Government	5	1.5
	Other	92	27.8
	Total	330	99.7
Missing	System	1	.3
Total		331	100.0
Revenue Groups		**Frequency**	**Percent**
	Over $1,000 Million	103	31.1
	$501-$1,000 Million	14	4.2
	$251-$500 Million	13	3.9
	$101-$250 Million	14	4.2
	$51-$100 Million	15	4.5
	$25-$50 Million	21	6.3
	Less than $25 Million	113	34.1
	Total	293	88.5
Missing	Unkmown	37	11.2
	System	1	.3
	Total	38	11.5
Total		331	100.0

Approximately 31.1% of the subjects are employed in a company which has over $1,000 million annual revenue, 4.2% of the subjects are employed in a company which has $501 to $1,000 million annual revenue, 3.9% of the subjects are employed in a company which has $251 to $500 million annual revenue, 4.2% of the subjects are employed in a company which has $101 to $250 million annual revenue, 4.5% of the subjects are employed in a company which has $51 to $100 million, 6.3% of the subjects are employed in a company which has $25 to 50 million annual revenue, and 34.1% of the subjects are employed in a company which has less than $25 million annual revenue. Subjects responded to a survey which asked about their perceptions and experiences about the green movement, quality management, and organizational culture in their own firms. In this study, we will concentrate on the relationships among commitment to the green movement, quality management, organizational performance, and impacts of organizational culture.

Instrument

Organizational Green Orientation

Based on the previous research (Li, Hartman, and Zee, 2009), we measured the Organizational Green Movement by using the survey which provides twenty-one organizational green initiatives question items. The "Green Orientation" variable is a count of the total number of green initiatives implemented in an organization.

Quality Management (QM) Maturity

In this study, QM Maturity refers, in a qualitative sense, to the *degree* of QM implementation in an organization. We suggest, and previous research has shown (Ahire & Golhar, 1996; Flynn, Schroeder, & Sakakibara, 1994; Fok et al., 2000, 2001; Patti, Hartman, & Fok, 2001; Saraph, Benson, & Schroeder, 1989) that it can be measured by examining the perceived use of QM programs. In earlier research (Fok et al., 2000, 2001; Patti et al., 2001), we began the process of developing a measure of QM maturity. The instrument we developed dealt with perceived program *use* and asked respondents whether certain programs were in use in the organization, with a range from "not used" to "high usage."

In this study, the QM maturity instrument was used to gauge QM maturity. We conducted a factor analysis to identify the underlying dimensionality. Two factors emerged from the "Usage" items. The first factor appeared to include all the traditional quality management programs and was termed "Basic TQM Tools." The second factor was termed "Advanced TQM Tools" which includes programs like Six Sigma programs and Black Belt training. 67.39% of the variance was explained by these two factors.

Organizational Culture

Based on previous research (Fok et al., 2000, 2001; Harman, Fok, & Zee, 2009), we measure the Organizational Culture by constructing a series of paired opposite items which asked whether the organization's climate should be described as open vs. closed, soft vs. tough, competitive vs. collaborative, and the like. Table 3 below provides the items and shows the results of our factor analysis. We obtained a two-factor solution in case of the Organizational Culture items and have labeled Factor 1 as “Continuous Improvement Culture” and Factor 2 as “People-Friendly Culture.” 44.529% of the variance was explained by these two factors.

Organizational Performance

We used the Baldridge criteria in the form of a scale which asks respondents to provide perceptions about their organizations along Baldridge lines. The instrument included are items such as “Overall, my company is performing well,” “Overall, morale in my company is high,” “Overall, my company is productive,” and the like. Factor analysis in this study indicated that one factor was present. The results showed that 56.205% of the variance was explained by the factor and we named the factor as “Organizational Success.”

Impact of Green Movement

The instruments included are items such as “Have better relationship with suppliers,” “Have better reputation,” “Provide better working environment,” and “Improve productivity.” Factor analysis produced a single-factor solution and we named it “Impact of Green Movement.” 70.987% of the variance was explained by this factor.

RESULTS

Our first research question examines the relationship between Organizational Green Orientation and Organizational Culture. Table 2 provides the results of our correlation analysis. Both “Continuous Improvement Culture” and “People-Friendly Culture” have significant correlations with “Green Orientation” which implies that as organizations embrace a culture that focuses on quality, team, and being proactive and employee-friendly, they also report higher levels of green orientation.

Research Question 2 is supported by the results in Table 2. The findings support the premise that when organizations develop “green” products/services or use “green” material in the production, show more concern with avoiding negative consequences of not being green, and help their employees at all levels to be more green-oriented, the overall impact of these green initiatives is perceived to be more positive by the employees.

Research Question 3 is supported. The results are shown in Table 2. The relationship between “Green Orientation” and “Organizational Performance/Success” is significant at the .000 level. The relationship is negative which implies that as the organizations show more concern in helping their employees at all levels to be more green-oriented, and pay more attention to safety concerns, the organizational performance is perceived by the employees to be higher.

Research Question 4 is confirmed. The relationship is positive and imply that organizations with higher levels of performance would also be reported to have employees with more positive feelings about the impact of the green movement in their organizations.

Table 2 Pearson's Correlation Matrix – Organizational Green Orientation, Organizational Culture, Organizational Performance, and Impact of Green Movement

Correlations

	Green Orientation	Continuous Improvement Culture	People-Friendly Culture	Organizational Performance	Impact of Green Movement
Green Orientation	—	.127*	-.216**	.414**	.202**
Continuous Improvement Culture	.127*	—	—	.235**	.582**
People-Friendly Culture	-.216**	—	—	-.192**	NS
Organizational Performance	.414**	.235**	-.192**	—	.313**
Impact of Green Movement	.202**	.582**	NS	.313**	—

*. Correlation is significant at the 0.05 level (2-tailed).
**. Correlation is significant at the 0.01 level (2-tailed).
NS = not significant.

Our fifth research question examines the relationship between Organizational Culture and Impact of Green Movement. We found one pair of significant relationship in Table 3. "Continuous Improvement Culture" has a significant and positive correlation with "Impact of Green Movement".

Table 3 Pearson's Correlation Matrix – Organizational Culture, Impact of Green Movement, and Organizational Performance

Correlations

	Continuous Improvement Culture	People-Friendly Culture	Organizational Performance	Impact of Green Movement
Continuous Improvement Culture	—	—	.235**	.582**
People-Friendly Culture	—	—	-.192**	NS
Organizational Performance	.235**	-.192**	—	.313**
Impact of Green Movement	.582**	NS	.313**	—

*. Correlation is significant at the 0.05 level (2-tailed).
**. Correlation is significant at the 0.01 level (2-tailed).
NS = not significant.

Research Question 6 is supported by the results in Table 3. Two pairs of significant relationships are found. "Organizational Performance/Success" has significant correlations with both "Continuous Improvement Culture" and "People-Friendly Culture".

Our seventh research question examines the relationship between Organizational Green Orientation and QM Maturity and Table 4 provides the results. There are two pairs of significant relationships. The factor "Organizational Green Orientation" has significant and positive correlations with both "Use of Basic TQM Tools" and "Use of Advanced TQM Tools". The results confirm that when employees perceive that their organizations are more inclined to develop green products/services and have a green workplace will be reported to have used higher levels of usage of both traditional and advanced TQM tools.

Table 4 Pearson's Correlation Matrix – Organizational Green Orientation, QM Maturity and Impact of Green Movement

Correlations

	Green Orientation	Basic TQM Tools	Advanced TQM Tools	Impact of Green Movement
Green Orientation	—__	.316**	.211**	
Basic TQM Tools	.316**	—	—	.445**
Advanced TQM Tools	.211**	—	—	NS
Impact of Green Movement		.445**	NS	—

*. Correlation is significant at the 0.05 level (2-tailed).
**. Correlation is significant at the 0.01 level (2-tailed).
NS = not significant.

Research Question 8 examines the relationship between QM Maturity and Impact of Green Movement. We found one of significant relationship in Table 4. "Use of Basic TQM Tools" has a significant and positive correlation with "Impact of Green Movement".

Research Question 9 suggests that organizations which are described by employees as higher in QM Maturity will also have employees who report more positive feelings about the organization's performance. Both factors "Use of Basic TQM Tools" and "Use of Advanced TQM Tools" have significant and positive correlations with "Organizational Performance/Success" in Table 5.

Research Question 10 suggests that organizations with higher level of organizational culture would be reported by employees to have higher level of QM Maturity. We found three pairs of significant relationships in Table 5. The relationship between "Continuous Improvement Culture" and "Use of Traditional TQM Tools" is significant at the .000 level which implies that as organizations embrace culture that focuses on quality, team, and being proactive, they also use more traditional TQM tools. “People-Friendly Culture” has significant relationships with “Use of Traditional TQM Tools” and “Use of Advanced TQM Tools”.

Table 5 Pearson’s Correlation Matrix – QM maturity, Organizational Performance, and Organizational Culture (RQ9 and RQ10)

Correlations

	Continuous Improvement Culture	People-Friendly Culture	Basic TQM Tools	Advanced TQM Tools	Organizational Performance
Continuous Improvement Culture	—	—	.331**	NS	.235**
People-Friendly Culture	—	—	-.189**	-.271**	-.192**
Basic TQM Tools	.331**	-.189**	—	—	.378**
Advanced TQM Tools	NS	-.271**	—	—	.181**
Organizational Performance	.235**	-.192**	.378**	.181**	—

**. Correlation is significant at the 0.01 level (2-tailed).
NS = not significant.

DISCUSSION AND CONCLUSIONS

In this research, we find substantial support for relationships among employee perceptions of organizational green orientation and various outcomes include impact of green movement, organizational performance, QM maturity, and organizational culture.

Our results suggest that the more informed employees are about what the company is doing to meet the new societal expectations of eco-friendliness, the more likely they are going to feel positively about various aspects of the organization. Potentially those positive feelings will lead to higher satisfaction and productivity. It is then logical to conclude that more education on the companies' green initiatives should be provided to employees, because the dissemination of these information will be exceedingly helpful in building a strong organizational culture. A strong organizational culture that is supportive of the green movement, and in turn leads to positive organizational outcomes.

S.Mathrani@massey.ac.nz

ABSTRACT

Excessive emissions of greenhouse gases, production of wastes and inefficient utilization of resources have drastic impacts on environmental and operational performance in manufacturing industry. International organization for standardization (ISO) 14001 and lean are used as tools for wastes minimization which have a positive impact on environment. Although ISO 14001 and lean have been largely deployed in the manufacturing sector, little evidence in literature establishes synergies between both strategies in achieving environmental and operational benefits. In this research-in-progress article, an integrated model for ISO 14001 and lean is proposed to evaluate and improve environmental and operational performance in the manufacturing sector.

KEYWORDS: Lean, ISO 14001, integration, environmental performance and manufacturing industry.

INTRODUCTION

The increase in global warming and its effects have been discussed strategically in manufacturing companies since the 1950s. Generation of carbon dioxide, methane, nitrous oxides and ozone in manufacturing operations cause greenhouse gases (GHG) effect and ultimately contribute to global warming phenomena (Abas et al., 2018). Excessive consumption of energy and inefficient utilization of natural resources are considered as potential sources for emissions of GHG in energy-intensive industrial facilities (Roy et al., 2012). Furthermore, the consumption of nitrogen-rich fuels in transportation, fossil fuels in manufacturing processes and emissions of gases from energy-intensive appliances and equipment are also responsible for emissions of GHG (Langematz, 2018). The emissions of GHG are responsible for an increase in surface temperature, depletion of the ozone layer and melting of glaciers in the last few decades (Ding, Zhang, Zhao, Li, & Kang, 2019).

ISO 14001 standard emerges as a prominent internal environmental controlling tool and an appropriate way of expressing the environmental commitment of an organization to its internal and external stakeholders (Wong, Abdullah, Baini, & Tan, 2017). The practical implementation of ISO 14001 facilitates manufacturing operations in preventing wastes generation (air emission and solid wastes), and helps to fulfill the legal and operational compliance requirements through an environmental management system (EMS) (Mariotti, Kadasah, & Abdulghaffar, 2014; Massoud, Fayad, El-Fadel, & Kamleh, 2010). Alternatively, lean manufacturing philosophy has been adopted in manufacturing firms for identification and reduction of the wastes in production processes through an on-going improvement cycle (Verrier, Rose, & Caillaud, 2016). The inefficiencies of raw material utilization and energy consumption are also minimized through process improvement as per the lean perspective (Johansson & Sundin, 2014). The major aim for implementing waste reduction practices in manufacturing industry is to create a healthier environment, increase the profitability of the business, and boost the public image.

Many companies have implemented lean for improving the process flow (Puvanasvaran, Kerk Swee Tian, A.L. Vasu, & Muhamad, 2012). Lean manufacturing practices are uniform in nature, with a comprehensive set of strategies that provide tools and techniques for improving the processes by reduction of wastages (Habidin, Hibadullah, Mohd Fuzi, Salleh, & Md Latip, 2018). On the other hand, ISO 14001 is considered as a strategy for providing rules and roadmap to formulate and adopt an EMS framework in the manufacturing and service facilities (Fisher, 2003). The elements of ISO 14001 provide a clear framework for constructing an environmental program. The environmental objectives, plans and policies with operational procedures are defined through the framework by implementing ISO 14001. However, the current environmental measurement systems still fail in providing the relevant information needed for improvement (Puvanasvaran, Swee Tian, & Vasu, 2014). For instance, the environmental data sources currently used are basically designed for monitoring regulatory compliance only, and not measuring the environmental performance. Although, the measurement of environmental performance is an important parameter for identifying success or failure of an environmental strategy. Lean manufacturing is a strategy that provides value to customer by eliminating wastes (Verrier et al., 2016). The lean strategy includes tools and techniques for waste reduction which could provide additional support to the ISO 14001 EMS processes for enhancing environmental benefits. An integrated system by combining EMS and lean tools could be applied to streamline work processes in reducing wastes (environmental and operational) as well as evaluate performance (Puvanasvaran, Kerk Swee Tian, & Muhamad, 2011). Therefore, the research question for this study is *how can ISO 14001 and lean be integrated to evaluate and improve environmental performance in the manufacturing industry?* This article helps in developing a conceptual model by using different elements of ISO 14001 and lean tools and techniques for an integrated approach towards environmental and operational performance management by sustaining continual improvement through Dr. Deming's plan, do, check and act (PDCA) cycle.

LITERATURE REVIEW

ISO 14001 and Lean Manufacturing

ISO 14001 provides a framework for developing an EMS in an organization. EMS is a framework for monitoring the process for improving the environmental impacts by optimizing resource utilization and reduction of wastes generation in manufacturing facilities (Chattopadhyay, 2001). EMS is an instrumental tool for improving environmental performance and serves as a business strategy. Furthermore, it predicts the present deficiencies in the system for future improvement and management to maintain environmental performance proactively (Qi et al., 2011). The main benefits of an effective implementation of ISO 14001 include improvement in internal processes with reduction in environmental aspects (emissions of GHG and wastes generation) and an increase in production efficiency (Mariotti et al., 2014). One study stated that the World Bank initiated a program to provide technical assistance for implementation of ISO 14001 in 11 energy extensive facilities in Mexico (Wong et al., 2017). The majority of these companies experienced a reduction in wastes generation (solid and air), improvement in resource utilization (raw material and energy consumption) and increase in economic performance.

Since the start of the 1980s, environmental waste management and effective utilization of resources (raw materials and energy consumption) are treated as an integral part of strategy and policy deployment in the manufacturing industry after the introduction of Toyota Production System (TPS) concepts (Campos, de Melo Heizen, Verdinelli, & Cauchick Miguel, 2015). The mass production concept is substituted by lean manufacturing after the successful launch of TPS in the manufacturing industry (Aguado, Alvarez, & Domingo, 2013). The lean philosophy can be defined as: “To do more with less” (Azadeh, Yazdanparast, Zadeh, & Zadeh, 2017, p155). Lean manufacturing provides a favorable business environment for a company by achieving gains in production operations, creating cost-saving opportunities and maintaining customer satisfaction through operational processes (Alves & Alves, 2015). In a study conducted in the European context, it was found that the manufacturing industry consumes around 37% of total primary energy production in Europe. Europe Strategy 2020 aims to reduce 20% of the total energy consumption by implementing lean practices in their industries (May, Barletta, Stahl, & Taisch, 2015). Lean and environmental improvements are proactive tools for reducing heat waste, noise pollution and eliminating environmental impact by focusing on customer satisfaction (Pampanelli, Found, & Bernardes, 2014). The integration of environmental performance and lean is developed into an improvement strategy that achieves environmental and economic benefits simultaneously (Cherrafi, Elfezazi, Garza-Reyes, Benhida, & Mokhlis, 2017). Integration of lean strategy and ISO 14001 will further provide a holistic value-based method to achieve environmental performance in an on-going improvement cycle (Puvanasvaran et al., 2014).

Justification for Selection of ISO 14001 from Entire ISO 14000 Family

ISO 14000 family consists of several standards with their unique process and product-oriented attributes for improving environmental performance in manufacturing processes and service industry (Boudouropoulos & Arvanitoyannis, 1998). The main reasons for selecting ISO 14001 only in this study from the entire ISO 14000 family of standards are: (1) construction of EMS by ISO 14001, (2) high rate of adoption and flexibility of ISO 14001 and (3) low certification cost.

The fundamental standards for constructing an EMS within the ISO 14000 family are – ISO 14001 and ISO 14004 with some additional guidelines. However, only ISO 14001 is used as a base standard for obtaining ISO certification and conducting environmental performance audits because the other standards and guidelines of ISO 14000 family are auxiliary in nature (Fortuński, 2008). The high rate of adoption of ISO 14001 motivates an organization in obtaining ISO 14001 certification. ISO 14001 as an EMS framework has been adopted by more than 32000 international organizations since its launch in 1996 (Ferrón Vílchez, 2017). This certification can be applicable to all types and sizes of organizations since it is a generic standard, is flexible and adjustable to different cultures, geographical and social conditions (Neves, Salgado, & Beijo, 2017). Furthermore, ISO 14001 is a globally accepted international standard which improves the environmental performance of both service industry (e.g., hotel industry and adaptation in university campuses) (Chan & Wong, 2006; Fisher, 2003) and manufacturing sector (e.g., automobile, chemical and food industry) (Azadeh et al., 2017).

From a business perspective, adequate financial support is required for the implementation of the full ISO 14000 series because it is an expensive adoption for small organizations. ISO 14000 adaptation has two types of costs (direct and indirect). The direct cost for adoption of ISO 14000 series involves consultancy expenditures, certification fees and registration audits, and it varies from about \$10,000 (small organization) to \$30,000 (large organization). The indirect cost for implementation of ISO 14000 includes internal training programs, redesign of products and advertisement initiatives for modified environmental-friendly products. It ranges from $100,000 (small organization) to over $600,000 (large organization) (Miles, Munilla, & Russell, 1997) However, the adaption costs for ISO 14001 certification is approximately US$15,000 to US$20,000 in the manufacturing sector (Massoud et al., 2010).

Justification for Integration of ISO 14001 and Lean Strategies

Many different management strategies have been implemented for process improvement in manufacturing in recent decades. For example, (1) lean emphasizes on wastes minimization (Habidin et al., 2018), (2) ISO 14001 pivots on environmental waste minimization (Mariotti et al., 2014), (3) agile targets flexibility and speed (Greer & Hamon, 2011), (4) flexible manufacturing system (FMS) provides flexibility in operations with a minimum time and expenditure for changeover (ElMaraghy, 2005), (5) reconfigurable manufacturing system (RMS) offers flexibility in adjusting its production functionality and capacity by changing its structure as well as its hardware and software components (Koren & Shpitalni, 2010), and (6) dedicated manufacturing line (DML) focuses on manufacturing a single component of a product in high volume over a long period (ElMaraghy, 2005; Koren & Shpitalni, 2010). All above management strategies have a different focus. However, lean and ISO 14001 both focus on waste elimination and improvement of resource efficiency in manufacturing processes (Habidin et al., 2018). Therefore, the integration of ISO 14001 and lean approaches look promising in improving environmental performance because both philosophies have a common focus and some mutual operational objectives.

CONCEPTUAL MODEL OF ISO 14001 AND LEAN IMPLEMENTATION

A model is conceptualized for integration of ISO 14001 and lean strategies as shown in Figure 1. This model has been inspired from a framework by Dalrymple Bay Coal Terminal's EMS program (Dalrymple, 2019) which explains the process of implementing an environmental management plan using the PDCA cycle, however developed through a rigorous review of literature. The suggested structures consist of policies and procedures of ISO 14001 and its measurement tools as well as techniques of lean for improvement of environmental performance in the manufacturing industry. An integrated approach of ISO 14001 and lean implementation is conceptualized for monitoring, measuring and improving environmental performance. The proposed ISO 14001 and lean model is built upon on a continuous improvement process through the PDCA cycle.

The model illustrates that the environmental and waste reduction policies of ISO 14001 and lean implementation are formulated, documented and communicated to relevant stakeholders in the "plan" phase. These policies link with the integrated environmental waste management plan (IEWMP) through a bold arrow which represents the integration relationship (e.g., waste elimination policies of both) and dotted arrow which depicts non-combined impacts of both policies (e.g., legal implications from ISO and operational benefits of lean) in this model.

A clear definition of policy and its effective implementation is at the heart of every management strategy. The environmental policy can be defined as a short written statement which is based on the current status of the environmental performance of an organization by indicating possible future improvements (Uzumeri, Tabor, & Stanwick, 1996).

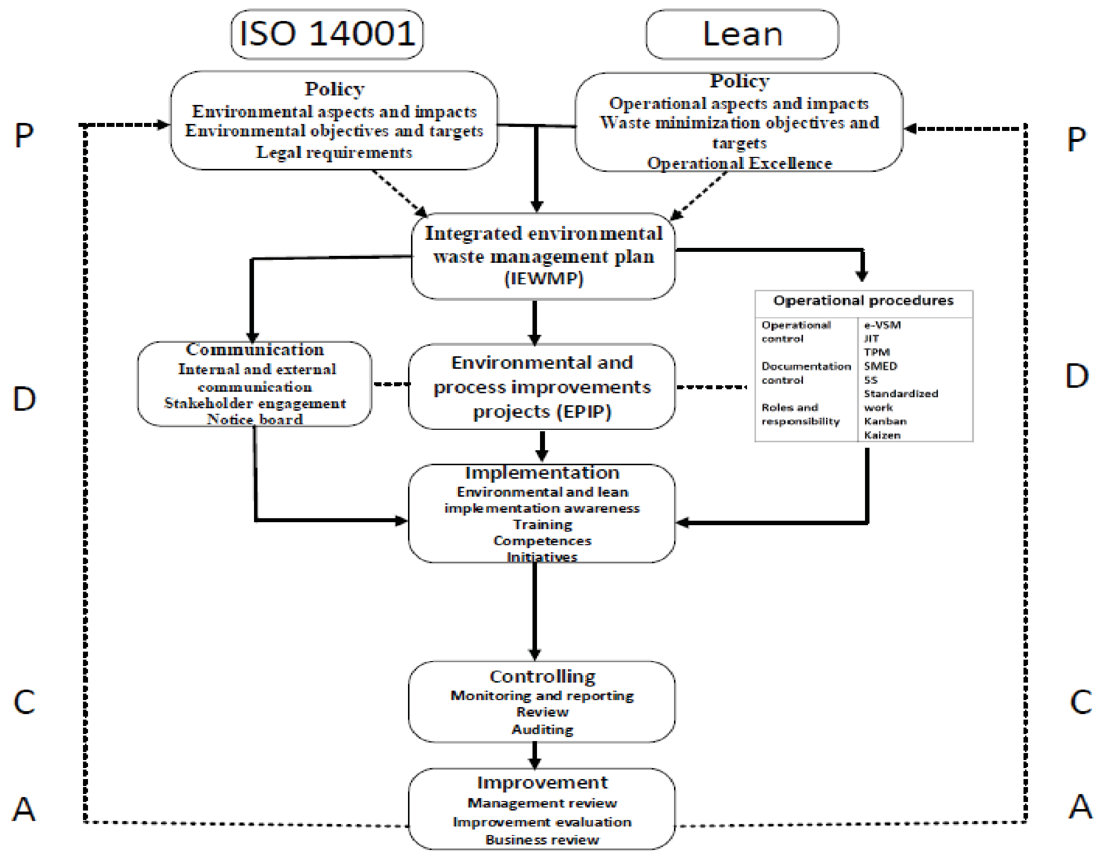

Figure. 1. A conceptual model for integration of ISO 14001 and lean in manufacturing industry

The foundation of the environmental policy lies in the initial environmental performance review of environmental aspects, legal requirements and regulations and the current environmental procedure. The waste minimization program statement includes the environmental objectives and quantifiable targets for EMS. The legal and regulatory requirements are an integral part of EMS policy to reduce or eliminate the potential fines, penalties and strategic constraints for an organization (Arimura, Darnall, Ganguli, & Katayama, 2016). The top management sets the lean and ISO 14001 policies according to the vision of an organization for achieving wastes minimization (Alefari, Salonitis, & Xu, 2017) and environmental performance objectives and targets (Uzumeri et al., 1996) to maintain continual improvements. The operational excellence (financial performance) is considered as an indicator for operational performance in the lean policy. Financial performance improves by reducing operational and environmental costs in the manufacturing sector (Belekoukias, Garza-Reyes, & Kumar, 2014). Once policies for ISO 14001 and lean are documented, it becomes possible to create a clear plan for IEWMP.

The “do” phase of PDCA’s cycle starts from IEWMP until the implementation stage in this conceptual model. The communication, environmental process improvement projects (EPIP) and operational procedures of both strategies start simultaneously indicated through bold arrows. The in-between dotted lines depict their interrelationships.

The communication process consists of internal and external communication, stakeholder engagement and notice board. The communication between the company and its stakeholders (internal and external) provides the fundamentals for the successful execution and maintenance of ISO 14001 (Sohal & Zutshi, 2004) and lean strategy (Worley & Doolen, 2006). An effective communication acts as an information medium for enabling all stakeholders to learn about the changes and exchange of ideas for achieving environmental objectives and targets. The communication medium remains active between an organization and its stakeholders in different implementation stages of EMS (Sohal & Zutshi, 2004). The waste reduction objectives and targets are clearly communicated to employees in different shifts and all stakeholders in producing quality products (Worley & Doolen, 2006). A clear management plan is communicated to all stakeholders (employees, suppliers and contractors) through newsletters, intranet and Internet websites, bulletin boards and trade journals (Savely, Carson, & Delclos, 2007). A continual smooth flow of information can also be managed by putting the relevant details of management initiatives (policy, objectives and targets) on the notice board (Wu & Low, 2012).

The operational procedures are divided into lean tools and techniques as well as process control initiatives (operational control, documentation control, and roles and responsibility). Operational planning and control include critical activities to prevent and minimize environmental accidents, reduce emissions to air and handle hazardous chemicals during operational processes (Foster, 2010). Document control is a mandatory requirement in EMS for documenting the scope of EMS, environmental policy and the core elements of environmental performance by maintaining EMS implementation records, evaluation and future improvement performance recommendations (Uzumeri et al., 1996). The leadership plays a key role in defining roles and responsibilities in an organization for execution of processes in implementing and improving EMS (Chattopadhyay, 2001). The different responsibilities are assigned to the senior, middle and lower workforce with sufficient financial and technical resources for improving the competence of the workforce through training and skill development programs (Muralikrishna & Manickam, 2017).

The lean tools provide solutions for improving environmental performance through implementation of its various methods and techniques. Environmental value stream mapping (e-VSM) is an essential lean tool for mapping consumption of resources (raw materials and energy consumption) as well as waste generation (gaseous emission, hazardous liquid and solid wastes) in manufacturing processing (Garza-Reyes, Kumar, Chaikittisilp, & Tan, 2018). The theme of just in time (JIT) is based on manufacturing the right products at the right time (Belekoukias et al., 2014). Furthermore, JIT helps an organization in managing inventory, decreasing wastes and reducing space utilization by reducing overproduction of goods in the manufacturing sector. Total productive maintenance (TPM) is an approach for maintenance of equipment to avoid breakdown, unnecessary stops and defects in operations. The operational benefits of TPM are controlling oil leakage, reduction of dust formation and emissions of fumes in manufacturing facilities (Belekoukias et al., 2014; Chiarini, 2014). Single-minute exchange of die (SMED) is a methodology practiced for decreasing the time to complete equipment changeovers (Oliveira, Sá, & Fernandes, 2017). Moreover, the reduction of lead time, lower inventory levels and process quality improvement can be achieved by effective implementation of SMED. The workplace is cleaned, organized and maintained through adequate consumption of resources as an effective strategy for waste disposal by sorting, setting in order, shining, standardizing and sustaining (5S) methods (Garza-Reyes et al., 2018). Standardized work is a set of rules and operational procedures to produce a product or execute service. This method is used for eliminating variation and inconsistency in processes by instructing the workforce to follow the defined rules and procedures in the implementation phase (Oliveira et al., 2017). Kanban is a lean tool for reducing idle time. The main philosophy behind kanban is to deliver what is necessary, when necessary. The meaning of kanban from the Japanese is a card or signal (Oliveira et al., 2017). Kaizen / continual improvement is a lean tool for improving programs and processes in a standardized manner. Kaizen is basically a tool for elimination of wastes by following a continual improvement strategy (Belekoukias et al., 2014).

The implementation stage starts on the basis of the outputs from the above three processes. This stage includes environmental and lean implementation awareness, competence development and training which are the integral processes for implementing new ISO and lean projects and their operational procedures. Awareness amongst the workforce is an important initiative to formulate environmental policy by comprehensively defining environmental aspects, impacts and objectives for environmental management (Mariotti et al., 2014). Competence of the workforce to improve environmental performance is judged on the basis of their education, training and experience for developing an environmental policy, implementing EMS and suggestions for improving environmental performance (Massoud et al., 2010). The knowledge creation, skill development and performance management of employees lay down the foundation for proactive lean implementation to achieve financial benefits and employee satisfaction (Bortolotti, Boscari, & Danese, 2015). EMS training helps the employees to understand policy and principles of environmental performance and their potential role in reducing environmental impacts by reducing air emissions, waste generation and effective utilization of raw materials (Jabbour, Jabbour, Govindan, Teixeira, & Freitas, 2013). The involvement of employees in training programs for lean implementation is an essential dimension towards a successful implementation by improving current skills and knowledge of the workforce in turn improving processes (Salonitis & Tsinopoulos, 2016).

The next phase of PDCA's cycle is "control" which is exemplified by a bold arrow indicating a link between implementation and controlling stage in the model. The controlling stage consists of monitoring and reporting on the implemented operational procedures as well as their review and audit. The effective implementation of the waste minimization program helps the organization in measuring and monitoring the environmental objectives and goals (Boudouropoulos & Arvanitoyannis, 2007).

In monitoring and measurement, the indicators of environmental performance constitute according to the organization's environmental policy and targets to achieve environmental objectives. These are achieved by introducing process controls such as calibration of equipment to reduce wastes and emissions, and maintaining ongoing evaluation of environmental performance to fulfill the operations and legal obligations (Muralikrishna & Manickam, 2017). The controlling of the lean initiatives include monitoring the level of success for lean implementation by comparing against the original plans (Mostafa, Dumrak, & Soltan, 2013). Internal audit is used as an evaluation tool to determine the current status of environmental performance against the policy, performance objectives and waste reduction targets in the organization (Foster, 2010).

The improvements are based on the outcomes of the "act" phase. Management review is an assessment initiative to propose future environmental improvements by introducing new performance operational requirements according to the current status of EMS (Muralikrishna & Manickam, 2017). General improvement includes the potential opportunities and actions (corrective, preventive and proactive) to identify the cause of environmental impacts, prevention strategies and elimination of environmental non-conformance during manufacturing processes for implementing EMS effectively (Muralikrishna & Manickam, 2017). Corrective actions are two types: (1) immediate actions which are taken as a follow-up of accidents and (2) revision actions which are made after the management review of EMS (Foster, 2010). The impacts of lean and environmental performance practices have different effects on business (financial and market) performance. The business and environmental performance are interrelated to each other in operational optimization of an organization. The targets are modified for business performance on the basis of lean and EMS implementation (Yang, Hong, & Modi, 2011). The continual improvement in this integrated ISO 14001 and lean model is achieved by the PDCA cycle through effective management of environmental audits, monitoring and measurement of environmental management by proposing improvement (proactive, preventive and corrective) actions.

BENEFITS OF ISO 14001 AND LEAN INTEGRATION

The integration of ISO 14001 and lean as a holistic approach could be utilized in achieving wastes minimization objectives and targets by monitoring, measuring and improving environmental and operational aspects in the manufacturing industry. The sustained integration of ISO 14001 and lean through the PDCA cycle for continual improvement can enable the incremental and on-going development of processes to achieve long-term environmental performance. The integration model will provide an opportunity to an organization to incorporate environmental considerations into the lean tools and techniques for reduction of environmental and operational wastes. A combined approach could be used for identification of environmental and operational deficiencies to provide solutions for mitigating inefficiencies as well as setting roles and responsibilities for all stakeholders. Training programs could be incorporated to create competencies in achieving EMS key performance indicators and implementation of related tools and techniques. These factors could achieve reduction of time and effort in improving the manufacturing processes, leading to an impact on the financial performance of an organization through process improvements such as reduction of environmental costs, scrap and waste generation, and treatment or control of wastes discharge. The integrated ISO 14001 and lean strategies would provide a clear vision for internal (management and employees) and external (suppliers and customers) stakeholders to achieve EMS related organizational goals, competitive advantage and profitability in the manufacturing industry.

CONCLUSION AND FUTURE RESEARCH DIRECTION

This study establishes a relationship between ISO 14001 and lean strategies to develop an integrated approach for evaluating and improving an organization's environmental performance. The various elements of ISO 14001 and lean tools provide the building blocks in the conceptual model for implementing, monitoring and measuring an EMS using the PDCA cycle. Further, the integrated approach of ISO 14001 and lean would help in streamlining the manufacturing processes to achieve long term competitiveness for an organization. This holistic model is generic in nature and could be implemented to any type and size of a manufacturing company for effective utilization of resources (raw materials and energy consumption) and reduction of wastes (solid, liquids and gaseous). In future, this study would be extended by an empirical evaluation of this integrated model through qualitative case studies to examine the impact of ISO 14001 and lean in achieving environmental benefits in the manufacturing industry.
