The 1934-1936 biennial survey on education in the United States report that in the early 1900s, the educational standards in colleges and universities in the US differs greatly. It took about 30 years for the North Central Association of Colleges and Secondary Schools to set up quantitative standards for accreditation of institution of higher education. Overtime, it was noted that accreditation standards put a lot of weight on basic factors, such as endowments or income, infrastructures, faculty education, magnitude of the library, rather than by the extent to which their programs achieve targeted objectives. Hence, in April 1934, after a 3-year study, a new program was adopted proposing that a higher education institution be judged according to the purposes it seeks to serve or based on the total pattern it presents as an institution of higher education (John 1938). Furthermore, the Educational Policies Commission of the National Education Association (NEA) (1935-1968) met to develop a long-term plan, spark new thinking to education, and continuously appraise the teaching profession (Ebben 1982).

Cartter (1966) assessing the quality of graduate education of 29 fields of studies, evaluated (1) the quality of graduate faculty, (2) the effectiveness of the doctoral program, and (3) the probable changes in relative positions of departments in the following 5-10 years. The study polled 4,000 student scholars and department chairs of 106 institutions, used a very comprehensive methodology and was well received by higher education officials; it therefore, lead reputational rankings to become the norm (Cartter 1966). Thereafter, reputational rankings for graduate programs evolved due to tremendous hard work of Kenneth Roose and Charles Andersen from the American Council on Education; however, upon analyzing the second survey of the quality of graduate programs in the United States Johnson (Johnson 1970) argued that rankings are to some degree imperfect.
In 1981, The National Academy of Sciences with the National Research Council published the assessment of research-doctorate programs in the U.S because of rating 2,699 programs at

228 institutions. Fifteen years later, the National Research Council extended the scope by ranking 41 disciplines at 274 institutions resulting in data on 3,634 programs. The 1981-methodology improved when L. Solmon and A. Astin published the ranking of 80-150 departments in 7-fields based on 6-criteria. The 7-fields: biology, business, chemistry, economics, English, History, and sociology. The 6-criteria: overall quality of education, preparation for graduation, preparation for job, faculty commitment, faculty accomplishments, and innovativeness of curriculum.

In 1983, US News published its first edition of ranking college "Rating the Colleges"; followed in 1986 by the US News second edition of ranking college titled " The Best Colleges in America "; then in 1988, the US News third edition titled "America's Best Colleges"; and from 1989 to today US News college rankings have been published every year. On the same note, in 2003, The Shanghai's Jiao Tong University published the rating of institutions based on their research quality. Likewise, in 2004, a British periodical, Times Higher Education Supplement, along with a provider of guides to higher education, Quacquarelli Symonds, countered by producing new rankings based on outsiders' view including employers that recruit graduates and other academics (The Economist, 2010). In 2008, Forbes published its first annual list of "America's Best Colleges".

Since then, some rankings emerged based on such criteria as, the number of links to the university's website from other institutions, the contents of a database of academic articles. Other rankings were created to sell advertisement space and news media; others such as the Shanghai's Jiao Tong University ranking, were intended to acquire more funding for university research. Quacquarelli Symonds created their ranking to give the affiliated countries international status. The *Financial Time* measure were, also motivated by a desire to strengthen and promote the European identity of management education (Wedlin, 2006). The desire to rank high translates in the assumption that a school is only as good as the rankings present it to be. In addition, most schools are willing to bear any high costs if it can improve their ranking. Therefore, the validity and practical relevance of rankings based on outsiders' opinion has raised concerns in academia (Devinney et al., 2008). In addition, DeNisi (2008) and Zemsky (2008) reported that rankings especially those by media outlet do not always signal 'quality' because noise dominates real news; and noise can account for at least half of observed variations in rankings (*Dichev*, 2008). To evaluate the determinants of school quality, it is important to understand the use of college ranking.

The Use of College Ranking

The various stakeholders of universities have a common goal: to promote and insure a quality education for students. The true value of a school must define the number of applicants on the input side as well as the number of employers eager to hire the graduates on the output side. However, the most controversial thing about ranking higher education institutions is that institutions will prioritize to improve their rankings because rankings have a significant influence on admissions, financial resources, and reputation. Some school may try to improve their rankings by redirecting resources toward rankings 'influencing strategies'; therefore, fostering imitation on the measured criteria and reducing uniqueness and heterogeneity (Liberman & Asaba, 2006). Schools may also engage in strategic manipulation to embellish the information given to ranking agencies. These manipulations are achieved by coaching and preparing students, staffs, faculty members and even alumni on the best way to answer questions or by changing the composition of the faculty. In law schools for instance, adjuncts are hired on contracts that end before the audit occurred (Espeland & Sauder, 2007).

With today's trend toward globalization, universities faced the challenge of the global market demand, including the need to broaden the scope and develop mobility for their graduates, in order to be competitive. This challenge is deepening as employers are willingly hiring graduates from foreign schools and the share of foreign students and professors are sharply increasing in the United States and the European Union. There is more than ever a need of a universal way of ranking schools specially in today's global environment, where not only students shop of school internationally, but also employers recruit in the global market. Fletcher (1970) argues that there is a need of a replicable measure that can transcend time and location.

Grewal et al. (2008) found that, over 8 years (1999–2006), ranking positions by the U.S. News for the top 50 National Universities is quite robust as the probability of a university being ranked within 4 points of its current rank is about 90%. Their findings also indicated that increasing expenses on educational resources measures is influence highly ranked institutions in future ranking, while low ranked institutions do well by improving in academic reputation (Grewal, Dearden and Lilien 2008) (Kim, The Functions and Dysfunctions of College Rankings: An Analysis of Institutional Expenditure 2018).

RESEARCH METHODOLOGY AND ANALYSIS OF RANKING PARAMETERS/CRITERIA

Throughout the course of our research, we identified more than a dozen ranking systems. These systems include, but are not limited to, U. S. News ((Dix 2018);), WalletHub.com ((Dix 2018);), Money magazine ((Dix 2018);), Forbes ((Dix 2018);), Kiplinger ((Dix 2018);), Washington Monthly ((Dix 2018);), The Wall Street Journal/Times Higher Education ((Dix 2018);), The Princeton Review ((Dix 2018);), Niche.com ((Dix 2018);), CollegeFactual.com ((Dix 2018);), WalletHub.com ((Dix 2018);), BestColleges.com ((Dix 2018);), CollegeRaptor.com ((Dix 2018);), CollegeAtlas.org ((Dix 2018);). The current study focusses on four of above rankings: U. S. News, The Wall Street Journal/Times Higher Education, Forbes, and the Washington Monthly. The current study analyzes the relationship between universities performances in teaching, research and service and their national rankings. Ranking agency would use different parameters to rank programs, usually based on the signals from the professional world. The question is how much of those signals be based on student performance, faculty resources and performance in research and the university service to the community.

College rankings have drawn significant attention worldwide and has become is a massive business in North America today. More than 100 different guidebooks and rankings are available, and millions of copies are sold each year (Kuh 2011 and references thereafter) (Kuh 2011). As the public's insatiable appetite for comparative information in the form of rankings grows, the U.S. News & World Report (U.S. News), widely viewed as the flagship of college rankings has the enormous yearly consumption of its "US-Best Colleges" ranking, has solidified its market position by expending its ranking business to hospitals among other entities. After three decades and massive criticism on their methodology, the U.S. News & World Report has made significant adjustment in their ranking parameters and associated weights. As commented above, the question has always been about how possible it is to assess the quality of teaching in institutions of higher education. Altbach (2010) argued that, teaching, one of the main functions of any university is largely ignored in all the rankings. He explained that "the quality and impact of teaching is virtually impossible to measure and quantify". To the credit of Critics of college rankings, early ranking flaws lie heavily on the variability in the ranking factors (P. Altbach 2010).

Ranking System (Organization)	Ranking Criteria	Weights
2019-US News & World Report College Rankings (USNWR) • Began – 1983 • Total – 301 • Source – Uses peer and high school counselors' reputation surveys and self-reported data from ranked institutions	**Graduation and retention rates (22%)**	
	Average graduation rate (80%)	17.6%
	Average first-year student retention rate (20%)	4.4%
	Undergraduate academic reputation (20%)	
	Peer assessment survey (75%)	15%
	High school counselors' ratings (25%)	5%
	Student selectivity for admission (10%)	
	Standardized tests (77.5%)	7.75%
	High school class standing (22.5%)	2.25%
	Faculty resources for academic year (20%)	
	Class size (40%)	8%
	% Faculty compensation (35%)	7%
	% Faculty with terminal degree in their field (15%)	3%
	Full time faculty (5%)	1%
	Student/faculty ratio (5%)	1%
	Financial resources/student (10%)	
	Financial resources/student (100%)	10%
	Average alumni giving rate (10%)	
	Average alumni giving rate (100%)	5%
	Graduation rate performance (8%)	
	Graduation rate performance (100%)	8%
	Social mobility (5%)	
	* Pell Grant graduation rate (50%)	2.5%
	* Pell Grant graduation rate vs Other Students (50%)	2.5%

Ranking System (Organization)	Ranking Criteria	Weights
2019-Money Magazine • Began – 1990 • Total – 726 • Source – Takes into account 21 factors partitioned into three groups: educational quality, affordability, and alumni earnings	**Quality of education (1/3 of weighting i.e. 33.33%)**	
	Graduation rate	10%
	Value-added graduation rate	10%
	Peer quality [Academic preparation of students, Yield]	3.33%
	Instructor quality	3.33%
	Financial troubles	5%
	Pell Grant recipient outcomes	1.67%
	Affordability (1/3 of weighting i.e. 33.33%)	
	Net price of a degree	10%
	Educational Debt [Student borrowing, Parent borrowing]	6.67%
	Ability to repay: [Student loan default risk index (SDRI), Value-added SDRI, Federal student loan repayment, Value-added student loan repayment]	10%
	Affordability for low-income students	6.67%
	Outcomes (1/3 of weighting i.e. 33.33%)	
	Graduates' earnings	4.17%
	Earnings adjusted by majors	5%
	College Scorecard 10-year earnings	3.33%
	Value-added earnings	4.17%
	College Scorecard employment outcomes	8.33%
	Job meaning	1.67%
	Socio-economic mobility index	6.67%

Ranking System (Organization)	Ranking Criteria	Weights
World Street Journal (WSJ) and Times Higher Education (THE) • Began – 2004–2009 in collaboration with the Quacarelli Symonds & since 2010 independently • Total – 800 • Source – Uses two reputational surveys for research and teaching (previously used Thomson-Reuters Global Institutional Profiles project data but now plans to do its own data collection and analysis)	**Resources. Does the college have the capacity to effectively deliver teaching? (30%)**	
	amount of money that each institution spends on teaching per student	11%
	ratio of students to faculty members	11%
	number of published scholarly research papers per faculty	8%
	Engagement. Does the college effectively engage with its students? (20%)	
	student's engagement with learning	7%
	student's opportunity to interact with others	6%
	student recommendation	4%
	number of different subjects taught	3%
	Outcomes. Does the college generate good and appropriate outputs? (40%)	
	graduation rates for each institution	11%
	value added by the teaching at a college to both salary	12%
	student's ability to repay debt	7%
	academic reputation of the college	10%
	Environment. Is the college providing a learning environment for all students (diverse student body and faculty)? (10%)	
	proportion of international students on campus	2%
	student diversity – both racial and ethnic diversity	3%
	inclusion of students with lower family earnings	2%
	racial and ethnic diversity of the faculty	3%

Ranking System (Organization)	Ranking Criteria	Weights
Washington Monthly (2018) • Began – 2006 • Total – 316 • Source – Ranks College and universities based upon how well each enhances social mobility, fosters scientific and humanistic research and promotes an ethic of service.	**Research (25%)**	
	institution's research spending	5%
	number of sc. and eng. PhDs awarded by the university	5%
	Number of undergrad. alumni who end up with PhD	5%
	number of faculty receiving prestigious awards	5%
	number of faculty in the National Academies	5%
	Social mobility (50%)	
	*** Graduation rate (16.66%)**

	*** Financial success (100%)**	16.66%
	*** Student loan repayment rate (16.66%)**	
	raw repayment rate	8.33%
	regression-adjusted repayment rate	8.33%
	Ethic of service (25%)	
	military service	5%
	national service (alumni in Peace Corps)	5%
	percentage of FW-S in CSP	5%
	voting engagement	5%
	national service	5%

The variability makes tracking the performance of ranking over time rather impractical. As noted by Kuh (2011), the 1966's College-Rater weight distribution was as follows: high school rank (10%), SAT/ACT scores (2%), number of Rhodes, Wilson, Danforth, and NSF award recipients (5%), student-faculty ratio (4%), proportion of students entering graduate school (9%), library collection (15%), proportion of faculty with doctorates (18%), and faculty salaries (18%). Note that this came 30 years after a program was proposed that an institution of higher education be judged based on the total pattern it presents as an institution of higher education. However, since early 2000s, with the emergence of many ranking systems, the weaknesses in college rankings has seen significant consideration. While some ranking systems focus is concerned with affordability (Forbes, Money Magazine), overall campus and student life (Niche, Washington Monthly), academics (U.S. News & World Report), it worth noting that in the latest editions, the major ranking systems methodologies are comprehensive. Since the 2017 edition, U.S. News followed the Carnegie Classification of Institutions of Higher Education's Basic Classification system to determine schools' placement into the ranking categories. They reported that no schools changed categories between their 2018 rankings and their 2019 edition (Morse, Brooks and Mason 2018).

U.S. News & World Report (2010) based their ranking of Business schools on the calculation of the weighted average of eight indicators: (1) full-time average undergrad GPA, (2) full-time average GMAT score, (3) full-time acceptance rate, (4) average starting salary and bonus, (5) graduates employed at graduation, (6) Employed 3 months after graduation, (7) out-of-state tuition and fees, and (8) total full-time enrollment. The *Financial Time (FT)* ranking is created from 20 attributes that focus on the school and its graduates from different programs. The attributes include among other things, average salary after graduation, value for money and the latest FT ranking. Users can chart the rankings variables and view the location of business schools worldwide via an interactive map (Jacobs, 2009). Thus, the unit of analysis used by FT is open to different interpretations (Devinney et al, 2008).

As the impact of the ranking college grows, so is the critic for the ranking methodology and governmental education policies as well as the number of rankings systems which nowadays has exceeded a dozen in the USA and around the world. The variety of the rankings systems brings lots of confusion to stakeholders and serves as a powerful advertisement tool for well ranked universities or competitiveness measure for others (Brooks 2005). Every ranking agency or system has one or a few focus points of interest and even two of them may have common focus points, the parameters used may differ in type or in weights in the rankings. US News and World Report (Morse, Brooks and Mason 2018) put more weight on the academics which includes outcomes [35%: shared among social mobility (5 percent), graduation and retention (22 percent), and graduation rate performance (8 percent)], faculty resources [20%: class size (8 percent), faculty salary (7 percent), full-time faculty with the highest degree in their fields (3 percent), student-faculty ratio (1 percent) and the proportion of faculty who are full time (1 percent)], Expert Opinion [20%: the peer assessment (15 percent) and the high school counselor assessment (5 percent)], and Student Excellence [10%: standardized tests (7.75 percent) and High school class standing (2.25 percent)].

The means a total of 85% of weight in the 2019's US News and World Report US colleges and universities ranking is attributed to academics related items. It's important to note that although the same items in their 2018 ranking were accounted for 85%, the distribution of weight to these items was different. For instance, the student excellence item in the 2018 ranking was worth 12.5%. Hence, only 15% of ranking weight in the past two editions was attributed to nonacademic, namely Financial Resources (10%) and Alumni Giving (5%). Kiplinger, another ranking agency which debuted in 1998, put more emphasis on best value by contrasting academic quality with cost and financial aid measures. It splits the weights in terms of quality criteria (55%) and cost criteria (45%); the detailed weight distribution is not public (K. Pitsker 2018). This methodology appears to encourage low cost and high retention rate in higher education.

Ranking should reflect success in preparing students for their future job or for further education. Leiter, America's most prominent critic of law school ranking methodology used by the *U.S. News & World Report*, claims that the reputation and the quality of education provided by law schools can be seen by the picks of new graduates by elite employers (*Keller*, 2008). Being ranked by a high-profile organization such as *Business Week, U.S. News & World Report*, or *Financial Time* can signal membership of a somewhat exclusive club, and students and other stakeholders evaluate quality thru rankings (Devinney et al, 2008). Those rankings play a major role in schools decision making as well as its competitive power; therefore, being omitted from the rankings may be as worse as having a poor ranking. Moreover, the ranks of top schools are considerably more stable, while there is a lot of volatility for lower-ranked schools; (Devinney et al., 2008; Dichev, 2008; Morgeson & Nahrgang, 2008). The reason is that at the top the disparity is more substantial and therefore, noticeable; making it difficult to lower level school to break to the top. At the lower level on the other hand, there is a wider distribution of similar schools which can perform better from year to year.

SUMMARY AND CONCLUSION

In a nutshell, rankings matter and have an impact on the universities their surroundings; but some schools not fully disclose information about their school, other may engage in strategic manipulation by not only coaching and preparing students, staffs, faculty members and even alumni how to answer question in order to achieve a higher rank, but also by changing the composition of its faculty. This may be misleading especially to prospective students and recruiters who often rely on those rankings during their selection process. More and more, schools are taking a second look before participating in the ranking contests especially with the refusal to provide information to ranking agencies by Harvard and Wharton few years ago. So what information did these agencies use since both schools always find themselves on the list and among the best? Therefore, do rankings measure quality correctly?

We can agree on the notion that schools that ranked better attract quality students and therefore graduate striving students. Programs that attract very good students have better chances of producing high-quality graduates regardless of the quality of the program (Tracy & Waldfogel, 1997). Therefore, ranking may play more of a matching role for students and schools rather than be a determinant of quality. The question is that could those same schools graduate the caliber of students or if they started with students at a lower competence level. The quality of a program should be measured by the level of knowledge it graduates acquire at the school. Therefore, grouping school based on criteria such as the quality of the entering freshman or the allocation of funds may result in better ranking systems and better valuation of programs. This suggestion bring to an end the current discussion, but it does not put a stop on the research, it rather opens doors to more studies that hopefully be explored soon.

Educational Data Mining and Student Retention in Higher Education

ABSTRACT

The higher education system is dealing with a growing issue: decreasing student retention rates. Student retention could be improved by using a Student Relationship Management model based on data universities are collecting. The focus of such model should be on enriching the "Experience" that students have during their college years.

KEYWORDS: Educational Data Mining, Student Retention, Student Relationship Management

INTRODUCTION

The research field of educational data mining has at its foundation the concept of data mining. In simple theoretical terms, data mining represents one of the steps in the Knowledge Discovery in Databases (KDD) process concerned with the extraction of useful information from raw data. Data mining has been commonly defined as the process of identifying patterns and correlations within large datasets, using intelligent methods such as machine learning, database systems analysis and statistical analysis. As opposed to data analysis, which is concerned with the interpretation of data for descriptive purposes, data mining is focused on knowledge discovery and modelling for obtaining predictive insight. As large batches of data are collected, often times they are rendered useless if not for the discovery and interpretation performed through data mining techniques. By analyzing patterns and relationships in databases, big data is transformed into comprehensible information and predictive outcomes to facilitate the process of decision-making.

In practical terms, the knowledge discovery in databases process (KDD) can be described as interactive as well as iterative, as it consists of several steps that require constant involvement (sometimes repetitive) and active decision-making by the user. Brachman and Anand (1996) and Fayyad et al (1996) were the first to discover and examine the steps in the KDD process. The methods particular to the data mining process, as part of KDD, are used to translate the data into relevant information that is easy to understand. These generally agreed upon methods for performing data mining have been described in research by the same two groups of authors – (Brachman, Ronald J & Anand, Tej., 1996) and (Fayyad, Usama, Piatetsky-Shapiro, Gregory & Smyth, Padhraic., 1996).

Data mining is limitless in terms of its applications and the sectors in which it can be integrated. Figure 1, below, indicates some of the industries where data mining is being applied.

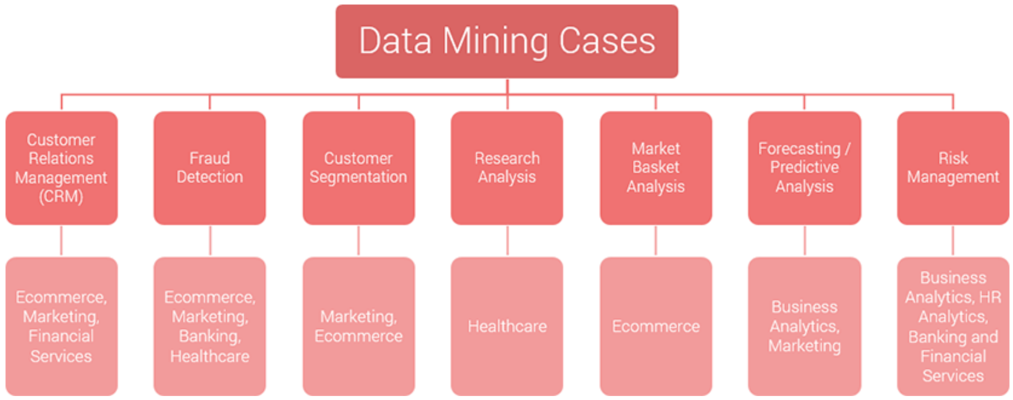

Figure 1. (The App Solutions, 2018)

Some sectors integrate multiple industries listed in the figure above. For example, data mining applications used in customer segmentation, research analysis, forecasting/predictive analysis, business analytics, marketing, etc. are commonly used in the education sector for various purposes.

LITERATURE REVIEW

The Field of Educational Data Mining

The integration of data mining applications, machine learning and statistical analysis, for use in educational settings (e.g., universities), translates into a specific research field: Educational Data Mining (EDM) (Education Encyclopedia).

In the context of educational settings, data mining refers to research, techniques and tools used to develop and improve methods for extracting meaningful information from large repositories of data related to learning activities performed in educational settings. The advances in educational technology, including the explosive increase in computing power and the shift towards computer-based learning environments, have created additional opportunities for analyzing data. Large amounts of data collected from computer-based learning activities are available for analysis and interpretation. Considering the new opportunities, educational data mining has raised continuous interest and in 2009, researchers have established the Journal of Educational Data Mining, as a platform for sharing and disseminating research findings. In 2011, the International Educational Data Mining Society was established, seeking to further grow the field by connecting EDM researchers worldwide (Education Encyclopedia).
These applications require the techniques used in data mining and explained in the first section. The sequence of steps for performing educational data mining is described in the figure below:

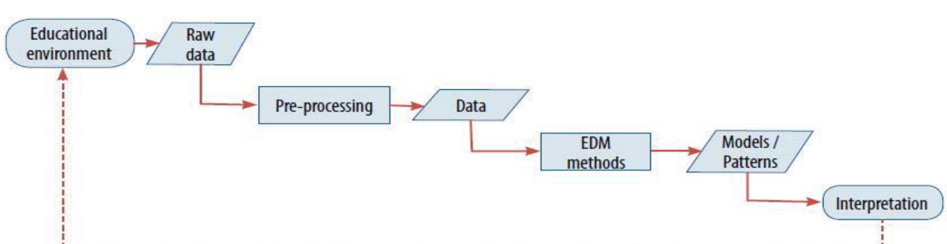

Figure 2. (Universities and Knowledge Society Journal, 2015)

The costs and challenges associated with the implementation of educational data mining are significant. Just storing the data can be costly, but also hiring staff qualified to manage the data systems and ensure the proper and seamless integration is likely to be difficult and add to costs. Also, selecting the data that can be used and useful for mining is a challenging process and requires intensive labor which again, translates into higher costs. Privacy and ethics can also represent challenges in educational data mining, requiring close supervision and attention to these issues from initial strategy to implementation.

In recent years, the impact of educational data mining and its applications has grown exponentially, and the education sector has been completely transformed. As students, teachers, schools and government officials have recognized the effectiveness of EDM and the value of the data collected through its applications, EDM technologies have become more and more prevalent in educational settings. Currently, most higher education institutions rely on EDM to optimize individual learning using educational software, computer-supported assisted learning and computer-adaptive testing resources, pedagogical environments, student success and retention in courses and programs, etc.

Earlier research studies have identified goals and opportunities for improvement of EDM applications in higher education, which are focused mainly on improving different aspects of learning and educational experiences. Such goals focus on the students' learning and behavior based on what students and educators bring to the learning process. These EDM applications consider a broad spectrum of variables related to students learning styles and knowledge along with pedagogical approaches and tactics to improve students' learning (Baker & Yacef, 2009). Improvements have been made in the EDM applications to expand on other students' success analysis than just learning experiences. A research published in 2013 by Romera and Ventura advises more advanced applications to be utilized by EDM. Such applications can be used to detect the overall future academic performance, concerns for academic failure (such as low motivation and poor academic performance), students' social structure match to the academic environment (serves as a predictor of social satisfaction), and curriculum mapping applications (helps matching the curriculum to the learning process). Similar studies suggest that a handful of undergraduate courses should be monitored as predictors for either poor or good performance for undergraduate students, and use the performance on those courses as an early alert to help lower achieving students (Asif at el., 2017).

Student Retention as a Success Index in Higher Education

Student retention in the higher education sector represents the length of time for which a student remains engaged in studies at a particular institution. A series of terms are used to describe specific situations in terms of student retention, such as "retained", "dropout", "transfer", "stopout", and "slowdown" student where each of them represent a group of students who need special consideration and attention in a university setting (Levitz, 2008).

Why do students decide to leave universities before a degree completion? This is a question of interest for higher education institutions and the administrations, but also for students, parents of students, prospective employers, and researchers in the field. From the students' perspective, not completing a degree will translate into less desirable employment opportunities and diminished lifetime earnings, in comparison to college graduates. Parents of students, who in most cases support a substantial amount of costs associated with attending college are put in the position to recognize the investment as a sunk cost if the students do not graduate. Employers are also concerned with student retention as the number of jobs requiring the completion of a higher education degree has been continually increasing, and job requirements are more advanced. Researchers in the field are interested in the concept of student retention, its impacting factors and potential strategies for improvement. Finally, other stakeholders may find value in understanding student retention (Cotter, 2013).

Universities find it increasingly necessary to prioritize efforts to improve student retention and seek effective initiatives and strategies to do so. Every higher education institution has specific conditions and factors determining its retention rate. However, the foundation for developing a strategic plan to be implemented is having a general understanding of what makes students stay enrolled in universities versus dropping out. Every year, universities analyze collected data to generate statistics regarding retention rates. Once they have established the level of retention, administrators look into the factors impacting the results. Then, they transition towards the decision-making process for improving the existing state. This progression requires an initial understanding of the issue (Fishman, Ludgate & Tutak, 2017).

For a university to successfully sustain its mission, student retention represents a fundamental goal. And besides the financial aspect, student retention is a key indicator of organizational success among higher education institutions. According to previous research data, here are some of the main aspects determining the importance of retention rate for institutions of higher education.

To gain insight into why student retention rates are declining is equivalent to understanding why students choose to leave colleges. According to researchers, only 20-30 percent of the students choosing to drop out, do so because of difficulties related to academics. Other factors which influence students to drop out of school are related to the increasing cost of education, finding the right social group to relate to, feeling isolated because of low engagement to different activities, and having unclear goals and expectations about their education (Education Encyclopedia). Among other various factors, these are just the most common challenges for student retention causing decreasing rates. By understanding these factors, universities can develop innovative and efficient programs to help boost retention rates. Statistical research studies show that among higher education institutions in the United States, the highest student retention rates are above 95 percent and the lowest rates may be as low as 10 percent. In the case of elite universities, typical graduation rates may be 85 percent or higher, while for the average level institutions, the rates drop to about 50 percent. The lowest graduation rates reported range between 15 to 25 percent. The students who are most likely to drop out of school are the first-year freshmen. Students in their senior year are the least likely to drop out. Looking at data for an average institution, the attrition rates by students' status are as following: freshman to sophomore year - about 25 percent, sophomore to junior year - about 12 percent, junior to senior year - about 8 percent and only about 4 percent of seniors might leave before their degree completion. For an average institution, about 50 percent of an incoming class of students graduate in 4-5 years (Education Encyclopedia).

While student retention rates may vary because of exceptionally high or low rates for individual institutions, retention is higher at the upper levels of education (masters, doctoral degrees); older institutions with well-established traditions and full-time students who reside on campus (Education Encyclopedia).

Using Educational Data Mining to Increase Student Retention

Data mining in EDM is used extensively to understand what factors are affecting learning and education. A complete review of over 500 research papers published in the last 20 years classified the factors which influence learning in the four main categories: traditional classroom methodologies, technology and media used in learning, educators' actions, and management actions (Rodrigues et al, 2018). A very similar research conducted by Aldowah et al. (2019) on research published between the years 2000 – 2017 identified over 400 studies on the topic of students' learning processes and outcomes. By using different data mining techniques such as clustering, visual data mining, statistics, association rule mining, regression, etc., Aldowah et al (2019) identified the different themes of research in higher education. The majority of the research papers reviewed in this metastudy is focused on students' learning approach, learning materials used by students, collaborative learning used in classes, self-learning, modeling of learning behavior, and retention factors.

Research shows that only 20-30 percent of dropout rates are influenced by difficulties with academics (Education Encyclopedia). The focus of previous research has been mainly on learning and classroom experience. Surprisingly, most of the studies in the last 20 years (over 900 research papers reviewed by Rogrigues et al, 2018 and Aldowa et al. 2019) focus mainly on the classroom teaching and learning styles, technology and learning behavior, but hardly address how students experience their college learning and how they integrate and emerge in the university environment. Not as much research is done on the other reasons why 70-80 percent of dropout rates which are related to: the educational cost, social difficulties, level of engagement and unclear educational expectations (Education Encyclopedia). The latest research is focused more on the “Experience” and “Bonding” that students need with the universities in order to successfully finish their studies.

Chopra and Deranek (2018) suggest that engagement with the local industry partners increases the students' learning and retention during their undergraduate studies. Experiential and active learning teaching style allows students to learn by gaining hands-on experience which is much more valuable for students. Such learning experiences do not only help students retain information and apply critical thinking, but they also help them make the transition to the real world much easier. Students engaged in such active learning activities are more satisfied by the entire learning process. Redirecting the focus of the learning process to the more active learning style, may affect students to continue their education and finish their studies rather than drop out of college.

The keyword for students' success is “Experience”. Students need to experience their education in a way that fits their intentions and backgrounds. A Student Relationship Management (SRM) system can push notifications and allow students to get involved in their education in a way that suits them. A Spanish speaker may want to use the school's portal in Spanish, engineering students can get information about technology labs, a graduate student get different information compared to a freshman. Having an SRM system in place which integrates all information rather than keep them as separate siloes, is very important to keep potential students interested in their education and finish their studies (Britt, 2018).
Social media integration to a Higher Education customer relationship management (CRM) helps with student retention and collaboration. Facebook is found as the most successful social media platform to engage undergraduate students with their academic communications and help with student retention and loyalty. Undergraduate students widely use Facebook versus LinkedIn or Twitter, and it can be used to improve students' experiences while attending college. It can also collect academic concerns shared by students, identify students' negative experiences, and post-academic services feedback (Wali and Andy-Wali, 2018).

Academic advisors have a significant impact of the students' satisfaction in their undergraduate studies. A strong student-advisor relationship can increase the students' perception of fit with the university and their loyalty to their institution. Academic advisors should build a strong interpersonal relationship and trust with the students, which will not only lead to an increase of student retention but also to students staying loyal to the university as alumni (Vianden and Barlow, 2015).

A very interesting program proposed by U-Planner, using data from researchers Ackerman and Schibrowsky, has introduced the concept of a “student relationship management system”, or SRM. Similar to a Customer Relationship Management system, the SRM would be implemented to help institutions build better relationships with their students, increase loyalty to the school and its programs and eventually increase retention rates. Ackerman and Schibrowsky support the SRM idea claiming that “students who perceive a mutual and strong commitment between themselves and the college are more likely to remain enrolled and are more likely to recommend the school to friends” (Ackerman & Schibrowsky, 2008) (U-Planner, 2017).

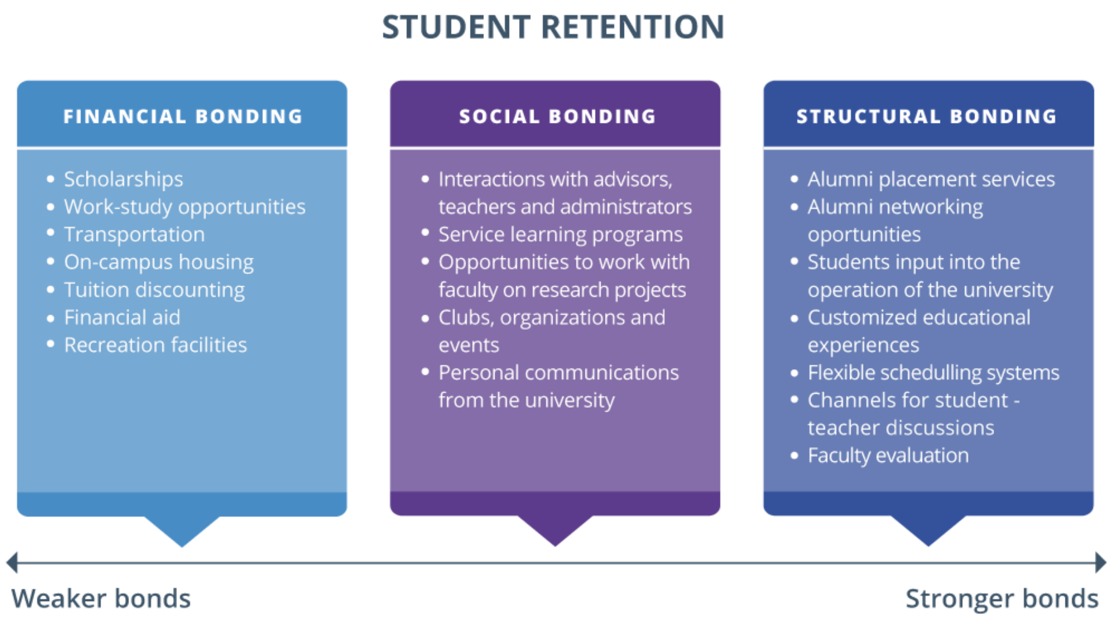

Figure 3. (U-Planner, 2017)

THEORETICAL DEVELOPMENT/MODEL

Student Relationship Management

According to B.J Shaver (2012) and Fontaine (2014), the following table illustrates a comparison between terms used in service marketing literature and their counterpart terms used in enrollment management literature.

Table 1: Glossary of Comparable Terms Used in the Service Marketing Literature and Enrollment Management Literature Service Marketing Terminology Enrollment Management Terminology

Term	Definition	Term	Definition
Customer experience	The period of time from when a customer first receives services from a provider to when he/she stops paying for services	Student experiences	The period of time from when a student matriculates to a university until he/she graduates from or transfers out of the university
Customer expectations	A desire the customer had for his/her service experience prior to the service transaction	Student expectation	A desire the student had for his/her university experience prior to matriculation
Customer changed expectation	A desire the customer had for his/her service experience prior to the service transaction that changed during his/her experience	Student changed expectation	A desire the student had for his/her university experience prior to matriculation that changed during his/her experience
Customer met expectatio	The fulfillment of a desire the customer had for his/her service experience prior to the service transaction	Student met expectations	The fulfillment of a desire the student had for his/her university experience prior to matriculation
Customer satisfaction	The degree to which customers are happy with aspects of their service experience	Student satisfaction	The degree to which students are happy with aspects of their university experience
Customer retention	The customer's act of continuing to patronize a service provider	Student retention	The student's act of remaining enrolled at a university
Customer retention behavior	The customer's act of continuing to patronize a particular service provider or switching to another service provider	Student retention Behavior	The student's act of remaining enrolled or transferring out of a university
Customer life cycle	The period of time beginning when a customer first has contact with a service provider, continuing through his/her customer experience, and lasting as long as he/she remains in contact with the service provider	Student life cycle	The period of time beginning when a student first has contact with a university, continuing through his/her student experience, and lasting as long as he/she remains in contact with the university as an alumnus/alumna
Customer loyalty	A customer's acts of allegiance to a service provider, such as recommending its services to others	Student loyalty	A student's acts of allegiance to one's university, such as applying to graduate school at the university or donating time and/or money to the university
Customer loyalty behavio	A customer's act of encouraging or discouraging others to use his/her provider's services	Student loyalty behavior	A student's act of encouraging or discouraging others to apply to his/her university. Also, a student's act of choosing to apply or not apply to graduate school at his/her university, or choosing to donate or not donate money to the university

Figure 4. (IGI Global)

According to IGI Global dictionary, Student Relationship Management (SRM) is "a specialized CRM concept applied to academic institutions, which involves automating and synchronizing a number of different processes such as academic advising and counseling, in aim to improve the student experience, reduce dropout rates, and improve organizational efficiency" (IGI Global).

In an SRM system, the student takes the role of the customer, as portrayed in how the Customer Relationship Management concept is successfully implemented in the business world. Each student has individual needs in terms of their academic progress and success, and social experience while in a higher education setting. These needs can be better addressed by faculty and administration, through the use of data that is being collected, analyzed and interpreted. An SRM system would represent the central database in which this data is stored and can be accessed to improve decision-making to positively affect students and universities. The concept of the SRM would include everything from the collection of data to the insight provided and the decisions made based on the new information. Higher retention rates could be achieved by touching every aspect of a complete SRM which includes but is not limited to: quality of guidance for selection of major, ability to enroll in desired courses, knowledgeable and approachable advisor, knowledgeable and approachable faculty, safe and secure campus; and much more (Elliot & Shin, 2010).

DISCUSSION AND CONCLUSIONS

The rising interest in the field of Educational Data Mining in the past decade, as well as the constant need for higher retention rates of students in universities, have prompted the discovery of novel opportunities to use big data for the benefit of all stakeholders in higher education. Colleges and universities have been developing and implementing plans to boost student retention, but very few of these initiatives have focused on analyzing the vast amounts of student related data that is already being collected by institutions. Data mining methods can provide an understanding of the causes behind decreasing retention rates. Such an understanding is the basis for building predicting models to prevent attrition and improve students' academic success. All higher education institutions have the opportunity to use already existing resources to develop their own successful retention strategies for the future. Just focus on the data.

The majority of institutions in the United States higher education system are already implementing plans for increasing their retention rate. But it is very often that these plans are not based on the data that is being collected from the students, instructors, alumni, etc. Thus, this valuable data is most likely to remain unused. The plans that are being developed are most times just sporadic initiatives to tackle the issue of retention, but with a vague understanding of the concept and without a project for using data and establishing metrics for tracking and analyzing results. But most universities admit that they are not aware of all the existing data, extra data that could be collected, the proper way to do it, and the way it could be utilized to achieve organizational goals.

Data should be the central pillar in any retention plan implemented at the higher education level. The retention should be focused on planning, implementing and monitoring an SRM where students are advised and mentored on building relationships and creating experiences with the university they are attending. As U-Planner suggests, Structural and Social Bonding help universities to increase student retention. Students need to participate and provide input in the events and structure of their universities. Such participation will increase the bonding and the "fit" with the school they attend. They need to have closer relationships with their advisors, connect with alumni, and participate in events and community activities, which will help them "live" and "experience" the college life in a more beneficial way than just taking classes or partying.

ABSTRACT

This paper investigates whether the independent director's corruption culture influences the corporate innovation and compensation of independent and CEO. Evidence shows that a stronger independent director's corruption culture is decreasing corporate innovation and increasing the compensation of independent director and CEO. However, the poor external corporate governances are weakly supported our results. Such evidence implies that the independent director's corruption culture less likely to monitor activities and imply in inefficient decisions and quality of corporate innovation and compensation policies.

KEYWORDS: Corruption culture, corporate innovation, excess compensation, corporate governance

INTRODUCTION

The general consensus in both the capital market and academic research are that an independent director plays an effective role in corporate governance. Practitioners and researchers suggest that less independent directors, large board members and insider boards, director hold three or more directorship (busy board), a capacity of strengthened by official positions and the connection to other corporate leaders (powerful CEO), CEO who also holds chairman position (duality CEO), and lower institutional ownership are less effective in corporate governance. For example, CEO likely to involved in independent director selection and create more conflicts of interest with replacing more directly independent director into non-directly connected to an insider (gray independent director) that less likely to pressure from monitoring CEO activities (Shivdasani & Yermack, 1999). CEO-director ties potential influence on new director selection with their network connections create less effective of monitoring, and acquisition frequently high-connection firms but destroy the value of shareholders (Fracassi & Tate, 2012). A new member of directors joined into board members after the CEO served (co-opted board) create a friendly in boards and leads a less board monitoring included the sensitivity of CEO turnover-performance, increase sensitivity of pay-performance, and increase investment activities (Coles et al, 2014).

The Sarbanes-Oxley Act of 2002 (SOX) requires a majority of an independent director to increasing their roles in corporate governance. For example, SOX enhanced independent director's workload and effectiveness of monitoring (Coates, 2007; Linck et al, 2009; Bargeron et al, 2010). However, is independent director still independent? We focus on the independent director (namely, independent director's corruption culture). Specifically, we investigate whether the independent director's corruption culture enhances or impedes corporate innovation and compensation of independent director and CEO.

Independent directors have an important role in corporate governance (Adams & Ferreira, 2007; Coles et al, 2008; Hwang & Kim, 2009; Armstrong et al, 2014; Falato et al., 2014; Ishii & Xuan, 2014; Kim et al, 2014; Masulis & Mobbs, 2014; Schmidt, 2015; Masulis & Mobbs, 2016). Independent director with a corruption culture more than the median in the industry (strong corruption culture) tends to be less active on monitoring and indicates that agency problem arise from independent director's corruption culture.

In practical cases, the scandal of *WorldCom* and *Enron* are related to the independent boards. Both cases settlements are required to paid personally (payments by director's pocket) to settle securities class action lawsuits. First, around the years 1997 – 2001 *Enron* was used improper accounting trick to restating their financial statements and inflated stock price by against senior executives and directors and *Enron* is the second-largest bankruptcy in the U.S. at the time with total damage is approximately $25 billion. In 2004, tenth boards agreed to pay $13 million of litigation expenses. Second, around the years 1999 – 2002 *WorldCom* CEO, CFO, and independent directors manipulated a billion dollar virtual transactions and accounting fraud and *WorldCom* is the largest bankruptcy firms in the U.S. at the time. In 2005, twelve boards agreed to pay $24.75 million of a settlement and total settlements over $6 billion for all defendants in securities class action. Beside *WorldCom* and *Enron*, there are eleventh cases of out-of-pocket settlement by independent directors. A consequence of those scandals, the role of the director has been reviewed.

In classical models, firms with the more independent director are obtained more patents and claim more citations (Balsmeier et al, 2017). Independent director increased the monitoring role that reduces agency problem. Generally, firms received more patents from the familiarity with their industry and citation increase will come from the number of patents that firms have it. Thus, innovation efficiency is a way to measures innovation performance. By innovation efficiency, firms may generate the number of patents per dollar of R&D expenditures that allows to compares the output and the input of investment (Hirshleifer et al, 2013). However, the poor corporate governance such as entrenched boards to pursue their own interest rather than shareholders lead less innovation performance (O'Connor & Rafferty, 2012). Further, the independent director may impede their competence and ignore the output of corporate innovation.

In compensation pieces of literature, the independent director and CEO are two parties that have a bargaining advantage to influences their size and structure of the compensation packages (Hermalin & Weisbach, 1998; Ryan & Wiggins, 2004). They also mention that firms with more independent directors are likely to receive more compensation and firms with entrancement CEO and duality are likely to receive cash rather than equity compensation. Furthermore, the compensation of independent director and CEO are positive relationships (Brick et al, 2006).

To test our hypothesis, we measure the independent director's corruption culture as the firm's corruption by using their average level of corruption. For each independent director, we match their surname-ancestry with Corruption Perception Index (CPI) to calculate the average of independent director's corruption culture follow the previous studies (DeBacker et al, 2015; Liu, 2016). We use a sample of 12,332 firm-year observation in the U.S. between 1996–2015, we find that the independent director's corruption culture decreases corporate innovation and increases the compensation of independent director and CEO.

First, our results show that strong independent director's corruption culture is significant to CEO turnover-performance sensitivity. The interaction effect of independent director's corruption culture and *Prior Abnormal Return* indicate that firms with a stronger independent director's corruption culture are associated with a weak in CEO turnover-performance sensitivity. Interestingly, the independent director's corruption culture rather than the percentage of independency board and have more explanatory power for CEO turnover-performance sensitivity. For example, the turnover-performance sensitivity is weaker when the CEO has the bargaining power on board selection (Hermalin & Weisbach, 1998). The classified boards reduce the effectiveness of monitoring in the replacement CEO (Faleye, 2007). More co-opted boards create friendly boards that diminish the CEO turnover-performance sensitivity on poor performance period (Coles et al, 2014).

Second, we argue that weaker monitoring from independent director impact on firm's overinvestment by taking high-risk projects without selection the project's quality and transmitted to poor quality of corporate innovation. Our results are also economically important. For example, the average R&D expenditures in our sample are 0.0396. Thus, firms with a stronger independent director's corruption culture are increases a 64.91% of R&D expenditures per each one-standard-deviation increase in independent director's corruption culture. Furthermore, firms with stronger independent director's corruption culture are decreases a 58.35% number of patents, 49.88% number of citations, and 63.82% innovation efficiency per each one-standard-deviation increase in independent director's corruption culture. For example, co-opted boards are likely to overinvestment in ways they otherwise would not (Coles et al, 2014).

Third, we also find similar results that the independent director's corruption culture increases the compensation of the independent director and CEO. We argue that less monitoring from independent director decreases their efforts and contribution to firms and the bargaining power on decided their own package of compensation, which is preferred to receive cash more than equity compensation. Our results are also economically significant. For example, the average of excess compensation of independent director in the sample is 0.0009. Thus, firms with stronger independent director's corruption culture are increases a 73.68% of excess compensation of independent director per each one-standard-deviation increase in independent director's corruption culture. Further, firms with a stronger independent director's corruption culture are increases 65.23% of cash compensation and decrease 63.70% of equity compensation of the independent director. Also increases 73.86% of CEO excess compensation and decreases 54.78% CEO risk-taking incentives per each one-standard-deviation increase in independent director's corruption culture. For example, both CEO and director have a bargaining power to decide their own compensation package by their own interest (Ryan & Wiggins, 2004). The excess compensation could be director and management is not considered shareholder interests (Brick et al, 2006).

However, the question of whether the independent director's corruption culture influence corporate innovation and compensation of independent director and CEO has been difficult to test due that independent director's corruption culture is likely to be endogenous. To address the endogeneity issues, we use two strategies. Our first strategy is relies on a natural experiment, the Sarbanes-Oxley Act of 2002 (Coles et al, 2014; Balsmeier et al, 2017), which directly affect the independent director's corruption culture but are exogenous to firm's corporate innovation and compensation. Using a difference-in-differences methodology (namely, DiD), we setup DiD isolate the effect of independent director's corruption culture ("Clean" effect). The typical of DiD is use three dummy variables (post-SOX, noncompliant firms, and the interaction term of post-SOX and noncompliant firms) and the main focus is an interaction term of post-SOX and noncompliant firms. This interaction term captures both effects that we want to eliminate (the exogenous shock to the independent director's corruption culture and the direct effect) though of SOX. However, the interaction term between post-SOX, noncompliant firms, and independent director's corruption culture (*IDCC*) does not yield the "Clean" estimate and the clean estimate is the increase of exogenous in independent director's corruption culture that forced noncompliant firms to increase their independent director composition, is given by independent director's corruption culture (*IDCC*), interaction term between noncompliant firms and *IDCC*, and interaction term between post-SOX, noncompliant firms, and *IDCC*. Further, the effect of independent director's corruption culture on corporate innovation and compensation of independent director and CEO are stronger after SOX that indicates the independent director's corruption culture damaging the culture of the firm.

Our second strategy is a propensity-score-matching (PSM) methodology to eliminate the self-selection bias problem. We sorted the level of independent director's corruption culture into quartiles and retain only the top quartile as the firms with highest independent director's corruption culture (treatment) and the bottom quartile as the firms with lowest independent director's corruption culture (control). The PSM methodology confirms that treatment groups are decrease their corporate innovation and increases the compensation of the independent director and CEO than the control groups. Overall, both strategies confirm that the independent director's corruption culture has a negative impact on corporate innovation and positive impact on compensation of independent director and CEO.

We then identify a conditional test through which strong independent director' corruption culture leads to a decrease of corporate innovation and increase the compensation of independent director and CEO. We use DiD in subsample analysis and we expect that the independent director's corruption culture decreases corporate innovation and increases the compensation for independent director and CEO with poor external corporate governance. This is because the independent director's corruption has a substitution effect on other corporate governance mechanisms. For example, the role of institutional holdings is monitoring firm activities and enhance the quality and transparency in corporate governance (Chung & Zhang, 2011; Armstrong et al, 2014). The product market competition allows tight monitoring creditor and effective to reduce inefficiency (Köke & Renneboog, 2005; Tian & Twite, 2011). Both proxies show that poor external corporate governance mechanisms worsen the independent director's corruption culture on corporate innovation and compensation of independent and CEO. However, the poor external corporate governances are weakly supported our evidence.

Furthermore, we conduct two robustness tests to corroborate our main results. (1) We replace the independent director's corruption culture with boards' corruption culture. (2) We control the CEO's corruption culture. Overall, all of our robustness tests support our main expectations.

The main contribution of this paper is to shed light a new set of facts that the independent director's corruption culture is poorer corporate governance. Thus, our paper uncovers the consequence of independent director's corruption culture on corporate innovation and compensation of independent director and CEO (Coles et al, 2014; Kim et al, 2014). Our finding highlight the representation of independent director's corruption culture decreases the effectiveness of their effort and monitoring, thereby the boards likely to approve all project without considering the risks. The consequences are firms spend more R&D expenditures (overinvestment) with lower quality of corporate innovation. Further, the director realizes themselves to avoid the effort to monitoring and less likely to replace cash with equity for their compensation. Either the CEO or the director, their compensation package is positive correlation because it depends on their effort and a certain level of skills (Brick et al, 2006). Firms with higher social ties awards more friendly director that reduce the effectiveness and their true independence of the director (Adams &Ferreira, 2007; Hwang & Kim, 2009; Schmidt, 2015). The director will likely to choose CEO to depend on their familiarity to avoid an effort to themselves (Kumar & Sivaramakrishnan, 2008). Over workload of boards that also hold several directorships in other firms relatively less time to focus on monitoring quality and associated with lower shareholder value (Falato et al, 2014). Lastly, the co-opted boards are more tolerance to the CEO and not all independent director aware with the liability (Coles et al, 2014).

Our paper also contributes to the growing literature on corporate innovation. Several studies have focused on structure of compensation (Holthausen et al, 1995; Cheng, 2004; Lerner & Wulf, 2007; Manso, 2011; Ederer & Manso, 2013; Baranchuk et al, 2014; Chang et al, 2015), corporate governance (O'Connor & Rafferty, 2012; Balsmeier et al, 2017), bank deregulation and competition (Amore et al, 2013; Chava et al, 2013; Cornaggia et al, 2015), analyst coverage (He & Tian, 2013), stock returns (Hirshleifer et al, 2013), bribe payments (Ayyagari et al, 2014), stock liquidity (Fang et al, 2014), economic growth (Kogan et al, 2017), and transparency (Zhong, 2018). Our paper complements these studies by exploring how the independent director's corruption culture influences corporate innovation.

Another contributes to recent studies on the determinants of compensation of independent director and CEO, including board control, activity, and structure (Boyd, 1994; Chhaochharia & Grinstein, 2009; Nguyen, 2014), merger and acquisition (Bliss & Rosen, 2001), CEO's power (Grinstein & Hribar, 2004; Ryan & Wiggins, 2004), corporate risk-taking (Linn & Park, 2005; Coles et al, 2006), CEO optimism and executive overconfidence (Otto, 2014; Humphery-Jenner et al, 2016), liability protection (Aguir et al, 2014), financial accounting quality (Masulis & Mobbs, 2016), excessive compensation (Dah & Frye, 2017), board qualifications (Fedaseyeu et al, 2018). We complement these studies by showing that the independent director's corruption culture influences compensation policy.

LITERATURE REVIEW

Independent Director: Bright Side and Dark Side

A large of empirical studies have examined the influence and the role of director characteristics. For example, the detection and litigation fraud (Beasley, 1996; Brochet & Srinivasan, 2014), the regulation relevance of boards (Wintoki, 2007; Dah et al, 2014). Much of previous studies examine how independent director play their roles in monitoring firms (e.g., Coles et al, 2008; Armstrong et al, 2014; Kim et al, 2014; Masulis & Mobbs, 2016), reduce earnings management (Klein, 2002; Fogel et al, 2014), shareholders wealth (Rosenstein & Wyatt, 1990; Cotter et al, 1997; Nguyen & Nielsen, 2010; Knyazeva et al, 2013). These studies are the bright side of independent director functions.

On the other side, the independent director also may harm board functions. The director may improve the monitoring role, but another agency problem arises because they avoid the effort and relying on CEO (Kumar & Sivaramakrishnan, 2008). The social ties are associated with compensation, the sensitivity of CEO turnover, and poorer acquiring firms performance when board advises surpasses to supervision CEO (Hwang & Kim, 2009; Fracassi & Tate, 2012; Ishii & Xuan, 2014; Schmidt, 2015). CEO with co-option is less monitored by boards and received more compensation and less likely to the turnover on poor performance period (Coles et al, 2014). Over workload for the director is decrease their monitoring quality and hurt the shareholder value (Falato et al, 2014).

Independent Director's Corruption Culture and CEO Turnover-performance Sensitivity

One of the roles of the director is to evaluate CEO turnover-performance. For example, CEO turnover is related to poor firm's performance (Mace, 1971). The classified boards reduce the effectiveness of monitoring in the replacement CEO (Faleye, 2007). Also, turnover-performance sensitivity is weaker when the CEOs have powerful bargaining on board-selection and more co-opted boards (Hermalin & Weisbach, 1998; Coles et al, 2014). Thus, we expect that our first hypothesis as follows:

H1: All else equal, the forced CEO turnover-performance sensitivity decreases with the independent director's corruption culture.

Independent Director's Corruption Culture and Corporate Innovation

Corporate innovation issues become important in recent literature on corporate finance. For example, the majority of independent director is associated with the output quality of corporate innovation (Balsmeier et al, 2017; Lu & Wang, 2018). However, CEO with co-opted boards likely to influence the overinvestment behavior (Coles et al, 2014). Thus, we expect our second hypothesis as follows:

H2a: All else equal, R&D expenditures increases with the independent director's corruption culture.

H2b: All else equal, patent decreases with the independent director's corruption culture.

H2c: All else equal, citation decreases with the independent director's corruption culture.

H2d: All else equal, innovation efficiency decreases with the independent director's corruption culture.

Independent Director's Corruption Culture and Compensation of Independent Director

A large literature addresses the compensation of the board of directors. For example, the key problem of excess compensation is the friendly boards that independent director likely to bargain with managers included CEO, influence management in the pay-setting process, and expected to support rather monitor the CEO activities (Bebchuk et al, 2002). The excess compensation could be a director's culture problem because both director and management are not considered shareholder interests (Brick et al, 2006). The firm with more independent boards are awarded more compensation and both CEO and director have a bargaining power to decided their own compensation package by their own interest (Ryan & Wiggins, 2004). Further, the director of the firm with entrenched CEO and CEO duality is likely to receive cash compensation more than equity compensation. Also, the cash compensation and equity compensation is negatively relationships (Humphery-Jenner et al, 2016). Thus, we expect that our third hypothesis as follows:

H3a: All else equal, excess compensation of independent director is increases with the independent director's corruption culture.

H3b: All else equal, cash compensation increases with the independent director's corruption culture.

H3c: All else equal, equity compensation decreases with the independent director's corruption culture.

Independent Director's Corruption Culture and Compensation of CEO

The CEO's compensation structure is another concern of the board's function. For example, a CEO with friendly boards has a substantial power to influence their own package of compensation when the director's monitoring is weak (Bebchuk & Fried, 2003). The classified boards tend less likely to fire CEOs from poor performance by reducing their compensation to satisfy the shareholders (Faleye, 2007). The classified boards also require higher monitoring costs that hurt the CEO risk-incentives (Ahn & Shresthak, 2013). The excess compensation of director leads to less monitoring and decreases CEO pay-for-performance sensitivity and both excess compensation of independent director and CEO are positively related (Brick et al, 2006; Dah & Frye, 2017). The co-opted boards and CEO pay-for-performance sensitivity cannot be viewed as directly and the CEO requires higher pay when seeking greater risk, thus the co-opted boards apply liberal compensation that is likely to the CEO (Coles et al, 2014). We expect that our fourth hypothesis as follows:

H4a: All else equal, excess compensation of CEO increases with the independent director's corruption culture.

H4b: All else equal, CEO risk-incentives decreases with the independent director's corruption culture.

METHODS

Data and Variables

The main data set we built up in the empirical analysis, we joint availability of data on boards and entrenchment index from the RiskMetrics (IRRC), accounting data from Compustat, stock price data from CRSP, patent and citation data from 2016 edition of PATSTAT with supplement data from Kogan et al. (2017) and the United States Patent and Trademark Office (USPTO) database. Compensation data from ExecuComp, CEO risk-taking incentives (*CEO_Vega*) data from Coles et al. (2006) and Core and Guay (2002). Institutional ownership data is from the Thomson Reuters Institutional (13F) Holdings and Product market competition data is from Hoberg and Phillips (2010, 2016). The final sample consists of 12,332 firm-year observations exclude financial firms (SIC codes 6000–6999) during the period of 1996 – 2015.

Description of Independent Variable

We conduct the main explanatory variable is the independent director's corruption culture, based on the previous research (DeBacker et al, 2015; Liu, 2016). We calculate the average of each independent director's corruption culture index by their surname-ancestry country. Then we matching into the Transparency International release the corruption perception index (CPI) each country per year. In 2015, the CPI ranges from 0.9 (Denmark) to 9.2 (Somalia), where the U.S. index is 2.4.

Following their proxy to measure the corruption, we use more than 139,500 independent director's surname-ancestry to capture corruption behavior. Our data set for surname-ancestry is from Origins Info Ltd. For the surname-ancestry are unmatched, we hand-collect it using sources from ancestry.com.

We focus on the independent director for several reasons. (1) Independent director has an important role in the corporate governance (Armstrong et al, 2014; Masulis & Mobbs, 2014; Faleye et al, 2011; Adams et al, 2010; Nguyen & Nielsen, 2010). (2), The regulations requirement of board structure (Dah et al, 2014; Bargeron et al, 2010). (3) The independent director is also responsible for the corporate decision such as corporate innovation and compensation (Kumar & Sivaramakrishnan, 2008; Balsmeier et al, 2017).

Description of Dependent Variables

To examine whether the independent director's corruption culture can impact on corporate innovation and compensation, we examine four types of corporate innovation and five types of compensation that can be measured in previously studied.

We measure corporate innovation into four dependent variables. (1) *RD* is the total R&D expenditures scaled by total sales and the missing of R&D expenditures is equal to zero (Ciftci & Cready, 2011). (2) The *Patent* is the natural logarithm of one plus the weight-adjusted patent counts. (3) *Citation* is the natural logarithm of one plus the number of citation lag-adjusted citations per patent. We measure the *Patent* and *Citation* following previous studies (Balsmeier et al, 2017). (4) innovation efficiency (*IE*) is the natural logarithm of one plus the number of patents scaled by R&D expenditures (Hirshleifer et al, 2013).

We also measure the independent director and CEO compensation into five dependent variables. (1) excess compensation of independent director (*ID_Compensation*) is the estimated value by the residual from independent director's total compensation regression where the explanatory variables include firm size, ROA, leverage, board size, board independency, director age, female director, director tenure, and year and industry fixed effects (Masulis et al, 2009). (2) *Cash Compensation* is the total cash received by the independent director scaled by total compensation. (3) *Equity Compensation* is the total stock plus options received by independent director scaled by total compensation (Ryan & Wiggins, 2004). (4) excess compensation of CEO (*CEO_Compensation*) is the estimated value by the residual from CEO compensation regression where the explanatory variables include firm size, ROA, leverage, board size, board independency, CEO age, female CEO, CEO tenure, and year and industry fixed effects (Masulis et al, 2009). (5) *CEO Vega* is the natural logarithm of one plus stock return volatility sensitivity change in CEO wealth (Coles et al, 2006).

Control Variables

Following the previous pieces of literature, we control for a vector of firm characteristics, governance characteristics, and independent director characteristics that could disrupt the relation between independent director's corruption culture and firm's corporate innovation and compensation. We compute all variables form firm *i* in year *t-1*. *ROA* is the total net income scaled by total assets. *Leverage* is the current liabilities plus long term debt scaled by total assets. *BHR* is the buy and hold one year return. *Firm Size* is the natural logarithm of total assets. *Dividend* is the total dividend payment scaled by total assets. *E-Index* is a corporate action to boost managerial perceived value rather than to benefit firm financial based on six provisions in RiskMetrics. *HHI* is the size of firms in relation to the same industry and measurement of market concentration. *IO* is the percentage of shares held by institutional ownership. *Board Size* is the natural logarithm of the total number of directors on board. *Board Independency* is the percentage of independent board scaled by board size. *Director Age* is the natural logarithm of the average independent director's age. *Female Director* is a dummy variable that equal to one if the board has a female director and otherwise is zero. *Director Tenure* is the natural logarithm of the average independent director's tenure.

Summary Statistics

In Table 1, we provide the summary statistics of the independent director's corruption culture, corporate innovation, compensation of independent director and CEO, and other control variables. All of the variables are winsorized at 1st and 99th percentiles to minimize the influence of outliers. The average of independent director's corruption culture is 2.5199 with 0.6446 of standard deviation, which is similar to previous research on corruption culture.

In our sample, the average of corporate innovation variables is 3.96% of R&D expenditures, two patents (natural logarithm of 0.7149), two citations (natural logarithm of 0.8325), and 5.27% of innovation efficiency. The average of compensation variables is 0.09% of excess compensation of independent director, 40.22% of cash compensation of independent director, 59.78% of equity compensation of independent director, 0.50% of excess compensation of CEO, and CEO with a risk-taking incentives sensitivity of US$ 19,300 (natural logarithm of 2.9593).

Regarding other variables, the average of book value assets of US$ 0.99 billion, ROA of 5.25%, leverage of 21.91%, buy and hold one-year returns of 12.38%, dividend of 34.47%, nine board members with 74.46% of independent director.

This table reports the summary statistics of all variables. The sample period is from 1996 – 2015 and all of the variables are winsorized at 1st and 99th percentiles to minimize the influence of outliers.

In Table 2, we report the preliminary univariate test. Most of the mean differences show a significant difference at the 1% level. Firms with strong independent director's corruption culture tend to increases R&D expenditures and decreases patents, citations, and innovation efficiency than those with weak independent director's corruption culture. We also find a similar pattern for compensation, which is firms with strong independent director's corruption culture tend to increases compensation of independent director and CEO than those weak independent director's corruption culture.

This table reports the mean difference between firms with strong and weak independent director's corruption culture. Superscripts *, ** and *** denote significance of the *t*-test for the difference in the means between the two subsamples at the 10%, 5%, and 1% levels, respectively.

RESULTS AND DISCUSSION

Independent Director's Corruption Culture and CEO Turnover-performance Sensitivity

To examine the effect of the independent director's corruption culture on CEO turnover-performance sensitivity, we follow the logistic regressions setting of Coles et al. (2014) as follow:

$$\ln\left[\frac{Prob(Forced\ Turnover)}{1-Prob(Forced\ Turnover)}\right]=\alpha_0+\alpha_1 IDCC_{i,t-1}\ X\ Performance_{i,t-1}$$
$$+\alpha_2 Performance_{i,t-1}+\alpha_3 IDCC_{i,t-1}+\boldsymbol{\theta}'\boldsymbol{Z}_{i,t-1}+\gamma_i+\mu_t+\varepsilon_{i,t}, \quad (1)$$

Table 3: *IDCC* and CEO turnover-performance sensitivity

where the proxy for performance is *Prior Abnormal Return*. $IDCC_{t-1}$ represents the independent director's corruption culture index for firm *i* in year *t-1*. $Z_{i,t-1}$ is the vector of the control variables from firm, corporate governance, and independent director factor *i* in year *t-1*. γ_i , μ_t and $\varepsilon_{i,t}$ represent Fama-French 48 industries and year fixed effect and the error of the regression. In all models, the *t*-values are computed on the heteroskedasticity-robust standard errors (White, 1980). Coefficients: ***, **, and * denote significant at 1%, 5%, and 10% levels, respectively.

Table 3 reports the effect of the independent director's corruption culture (*IDCC*) on CEO turnover-performance sensitivity. In models (1) - (4), the focus variable is the interaction term of *IDCC* and *Prior Abnormal Return*. We report the first row is the estimate of coefficient, the second row is z-statistics, and the third row is the marginal effects. The marginal effect represents the probability of *Forced Turnover* percentage change with *Prior Abnormal Return* for an independent director's corruption culture.

Consistent with our first hypothesis that the coefficient on the interaction effect of *IDCC* and *Prior Abnormal Return* (α_1) is positive and significant in models (1) - (4) that indicate that firms with a stronger independent director's corruption culture are associated with a weak in CEO turnover-performance sensitivity. The marginal effects show in row three indicates how the change of the independent director's corruption culture on CEO turnover-performance sensitivity. In model (1), the CEO turnover-performance sensitivity decreases by 0.1226, from -0.3134 to -0.1908 at the mean value when the independent director's corruption culture increases by one standard deviation. Interestingly, the independent director's corruption culture rather than the percentage of independency board and have more explanatory power for CEO turnover-performance sensitivity. For example, turnover-performance sensitivity is weaker when the CEO has the bargaining power on board selection (Hermalin & Weisbach, 1998). The classified boards reduce the effectiveness of monitoring in the replacement CEO (Faleye, 2007). More co-opted boards create friendly boards that diminish the CEO turnover-performance sensitivity on poor performance period (Coles et al, 2014).

Independent Director's Corruption Culture and Corporate Innovation

We first examine whether the independent director's corruption culture impact on corporate innovation. We divided corporate innovation into R&D expenditures (*RD*), the number of patents (*Patent*), the number of citation (*Citation*), and innovation efficiency (*IE*).

Table 4: *IDCC* and corporate innovation

Adj. R^2	0.4660	0.2658	0.2702	0.1817

Table 4 presents the results. The coefficient in the model (1) is significantly positive, implying that R&D expenditures increase with the independent director’s corruption culture. The coefficient of 0.0069 indicates that the independent director’s corruption culture is associated with an increase in R&D expenditures. The average R&D expenditures in our sample are 0.0396. Thus, firms with a stronger independent director’s corruption culture are increases a 64.91% ($e^{0.0069}$ x 0.6446) R&D expenditures per each one-standard-deviation increase in independent director’s corruption culture. The coefficient in the model (2) is significantly negative, implying that the number of patents decrease with the independent director’s corruption culture. The coefficient of -0.0996 indicates that the independent director's corruption culture is associated with a decrease in the number of patents. The average number of patents in our sample is 0.7149. Thus, firms with a stronger independent director's corruption culture are decreases a 58.35% ($e^{(-0.0996)}$ x 0.6446) number of patents per each one-standard-deviation increase in independent director's corruption culture. The coefficient in the model (3) is significantly negative, implying that the number of citations decrease with the independent director's corruption culture. The coefficient of -0.2564 indicates that the independent director's corruption is associated with a decrease in the number of citations. The average number of citations in our sample is 0.8325. Thus, firms with a stronger independent director's corruption culture are decreases a 49.88% ($e^{(-0.2564)}$ x 0.6446) number of citations per each one-standard-deviation increase in independent director's corruption culture. The coefficient in the model (4) is significantly negative, implying that innovation efficiency decrease with the independent director's corruption culture. The coefficient of -0.0100 indicates that the independent director's corruption culture is associated with a decrease in innovation efficiency. The average of innovation efficiency in our sample is 0.0527. Thus, firms with stronger independent board's corruption are decreases a 63.82% ($e^{(-0.0100)}$ x 0.6446) innovation efficiency per each one-standard-deviation increase in independent director's corruption culture.

Therefore, the unfavorable effect of the independent director's corruption culture on corporate innovation is also economically important. The results indicate that firms with strong independent director's corruption culture likely to overinvestment because taking high-risk projects. For example, co-opted boards are likely to overinvestment in ways they otherwise would not (Coles et al, 2014). Also suggesting less monitoring leads and transmitted to decreased efforts, which decreased the number of patenting of inventions, the number of citations, and innovation efficiency.

Independent Director's Corruption Culture and Compensation of Independent Director

We examine whether the independent director's corruption culture can impact on compensation of the independent director. We divided compensation into excess compensation of independent director (*ID_Compensation*), *Cash_Compensation*, and *Equity_Compensation*.

Table 5: *IDCC* and compensation of independent director

Obs.	10,952	11,059	11,059
Adj. R^2	0.4245	0.1312	0.1312

Table 5 presents the results. The coefficient in the model (1) is significantly positive, implying that excess compensation of independent director increase with the independent director's corruption culture. The coefficient of 0.1337 indicates that the independent director's corruption culture is associated with an increase in excess compensation of the independent director. The average of excess compensation of independent director in our sample is 0.0009. Thus, firms with a stronger independent director's corruption culture are increases a 73.68% ($e^{0.1337}$ x 0.6446) excess compensation of independent director per each one-standard-deviation increase in independent director's corruption culture. The coefficient in the model (2) is significantly positive, implying that cash compensation of independent director increase with the independent director's corruption culture. The coefficient of 0.0118 indicates that the independent director's corruption culture is associated with an increase in cash compensation of the independent director. The average cash compensation of independent director in our sample is 0.4022. Thus, firms with a stronger independent board's corruption are increases a 65.23% ($e^{0.0118}$ x 0.6446) cash compensation of independent director per each one-standard-deviation increase in independent director's corruption culture. The coefficient in the model (3) is significantly negative, implying that equity compensation of independent boards decrease with the independent director's corruption culture. The coefficient of -0.0118 indicates that the independent director's corruption culture is associated with a decrease in equity compensation of the independent director. The average of equity compensation of independent director in our sample is 0.5978. Thus, firms with a stronger independent board's corruption are decreases a 63.70% ($e^{(-0.0118)}$ x 0.6446) equity compensation of independent director per each one-standard-deviation increase in independent director's corruption culture.

Therefore, the unfavorable effect of the independent director's corruption culture on the compensation of the independent director is also economically important. The results are suggesting the bargaining power of an independent director, which increased excess compensation of the independent director. Also likely to receive cash rather than equity compensation. For example, both CEO and director have a bargaining power to decide their own compensation package by their own interest (Ryan & Wiggins, 2004). The excess compensation could be director and management is not considered shareholder interests (Brick et al, 2006).

Independent Director's Corruption Culture and Compensation of CEO

We examine whether the independent director's corruption culture can impact on compensation of the CEO. We divided compensation into excess compensation of CEO (*CEO_Compensation*) and CEO risk-taking incentives (*CEO_Vega*).

Table 6: *IDCC* and compensation of CEO

Table 6 presents the results. The coefficient in the model (1) is significantly positively, implying that excess compensation of CEO increase with the independent director's corruption culture. The coefficient of 0.1361 indicates that the independent director's corruption culture is associated with an increase in excess compensation of the CEO. The average of excess compensation of the CEO in our sample is 0.0050. Thus, firms with a stronger independent board's corruption are decreases a 73.86% ($e^{(0.1361)}$ x 0.6446) excess compensation of CEO per each one-standard-deviation increase in independent director's corruption culture. The coefficient in the model (2) is significantly negative, implying that CEO risk-taking incentives decrease with independent director's corruption. The coefficient of -0.1628 indicates that the independent director's corruption culture is associated with a decrease in CEO risk-taking incentives. The average of CEO risk-taking incentives in our sample is 2.9593. Thus, firms with a stronger independent board's corruption are decreases a 54.78% ($e^{(-0.1628)}$ x 0.6446) CEO risk-taking incentives per each one-standard-deviation increase in independent director's corruption culture.

Therefore, the unfavorable effect of the independent director's corruption culture on the compensation of the CEO is also economically important. The results are suggesting the bargaining power of the CEO, which increased excess compensation of the CEO. For example, both CEO and director have a bargaining power to decide their own compensation package by their own interest (Ryan & Wiggins, 2004). Independent director's corruption culture adopting liberal compensation that likely to the CEO, which decreased CEO risk-taking incentives (Coles et al, 2014).

Endogeneity Issues

One of the important concerns in corporate governance literature is endogeneity issues. It is possible that endogeneity issues influence the effect of independent director's corruption culture on corporate innovation and compensation of independent director and CEO. First, if the independent director's corruption culture correlates with an omitted variable, then the estimator is biased and inconsistent. We solve an omitted variable with difference-in-dfferences (DiD). Second, the hire of corrupt independent directors as boards could be a concern for the self-selection bias effect, we following Rosenbaum and Rubin (1983) to solve the self-selection bias with propensity-score-matching (PSM). We use two ways to process to reduce the effect of the independent board's corruption culture on corporate innovation and compensation of independent director and CEO.

<u>Difference-in-Differences (DiD) Methodology</u>

We eliminate the endogeneity of the independent director's corruption culture using a difference-in-differences (DiD) methodology. To eliminate the omitted variable effect of independent director's corruption culture, we turn to a natural experiment to address endogeneity issues. We use SOX as an exogenous shock in DiD methodology. Following by the rules of the Sarbanes-Oxley Act of 2002 (SOX), listed firms are required to increase their independent director percentage on their board more than 50%. We define post-SOX is the period after SOX is applied in NASDAQ and NYSE stock exchanges (2002 – 2015). Pre-SOX noncompliant firms are the firms that increase their independent director proportion after the regulation of SOX and these firms following the regulation to add more new independent directors (Linck et al, 2009).

We allow the possibility of SOX have a direct effect on corporate innovation and compensation of independent director and CEO. This is because SOX is a regulation that likely to affected monitoring firms and provides long-term benefits through several channels. For example, the regulation of SOX increased the role of independent boards for audit, compensation, and monitoring committees.

We setup DiD isolate the effect of independent director's corruption culture ("Clean" effect) (Coles et al, 2014). The typical of DiD is use three dummy variables (namely, *Post-SOX*, *Noncompliant*, and *Post-SOX x Noncompliant*) and the main focus is an interaction term of *Post-SOX x Noncompliant*. This interaction term captures both effects that we want to eliminate (the exogenous shock to the independent director's corruption culture and the direct effect) though of SOX. The DiD model is as follow:

$$Y = \beta_0 + \beta_1 IDCC + \beta_2 Post - SOX\ x\ IDCC + \beta_3 Noncompliant\ x\ IDCC$$
$$+\beta_4 Post - SOX\ x\ Noncompliant\ x\ IDCC + \beta_5 Post - SOX + \beta_6 Noncompliant$$
$$+\boldsymbol{\theta}'\boldsymbol{Z}_{i,t-1} + \nu_k + \mu_t + \varepsilon_{i,t}, \quad (5)$$

Table 7: Difference-in-differences (DiD)

where, *Post-SOX* is a dummy variable that equal to one if the year is 2002 or after and zero otherwise. *Noncompliant* is a dummy variable that equal to one if the firm was not in compliance in 2001 and zero otherwise. *Post-SOX x Noncompliant x IDCC* is typical of DiD methodology but does not yield the "Clean" estimate. *IDCC* represents the independent director's corruption culture index. *Y* represents the dependent variables of corporate innovation and compensation of independent director and CEO.

Panel A of Table 7 present the sensitivity of corporate innovation and compensation of independent director and CEO to independent director's corruption culture in subsamples of (1) compliant with the pre-SOX period, (2) noncompliant with pre-SOX period, (3) compliant with post-SOX period, and (4) noncompliant with post-SOX period. Both coefficients of (1) and (2) are bias thus endogeneity issues. The coefficient of (3) not only bias but reflects the direct effect of SOX. We denote the bias for compliant firms ($Bias^{C}$) and noncompliant firms ($Bias^{NC}$).

The interesting subsample is noncompliant with *Post-SOX* period. This subsample contains the exogenous shock to the independent director's corruption culture. The sensitivity of coefficient (4) is influenced by the combination of the independent director's corruption culture and SOX effects on corporate innovation and compensation of independent director and CEO. The typical of DiD methodology does not report the clean estimate rather than the negative of $Bias^{NC}$. According to Coles et al. (2014), the clean estimate is the increase of exogenous in independent director's corruption culture that forced noncompliant firms to increase their independent director composition, is given by $\beta1 + \beta3 + \beta4$.

Panel B of Table 7 presents the result of a clean estimate for the total impact of independent director's corruption culture on corporate innovation and compensation of independent director and CEO. We compare the results from the base case (Table 4 – 6) and a clean estimate. The *RD* is insignificant and the other of the estimates that increase of exogenous shock in independent director's corruption culture have the same sign and significant in statistically. It supports the argument of Balsmeier et al. (2017) that independent boards are unrelated to the firm's R&D expenditures. But, the independent director spends more effort that increased the monitoring of explorative innovation. However, we find the result that consistent with agency theory. If the independent director's corruption culture is stronger than the role of monitoring will decrease and impact on decreased in innovation. We also support the argument that independent boards are likely to receive cash compensation and less likely to receive equity compensation when the role of monitoring is decreases and leads to ineffective corporate governance (Ryan & Wiggins, 2004). Also the positive relationship between excess compensation of independent director and CEO (Brick et al, 2006).

Overall, we argue that corporate innovation is decreases and compensation of independent director and CEO are increases when the independent director's corruption culture increases after SOX. Therefore, a stronger independent director's corruption culture leads to weakening corporate governance.

A Propensity-Score-Matching (PSM) Methodology

In this subsection, we sorted the level of independent director's corruption culture into quartiles and retain only the top quartile as the firms with highest independent director's corruption culture (treatment) and the bottom quartile as the firms with lowest independent director's corruption culture (control). Matching starts with a probit regression based on the treatment and control firms and uses all control variables. For the robustness results, we use 6 different matching methods: (1) Nearest neighbor (n=2), (2) Mahalanobis, (3) Gaussian Kernel, (4) Epanechnikov Kernel, and (5) Radius (1.0).

Table 8: Propensity-Score-Matching (PSM)

In all models, the *t*-values are computed on the heteroskedasticity-robust standard errors (White, 1980). Coefficients: ***, **, and * denote significant at 1%, 5%, and 10% levels, respectively.

Panel A1 – A4 of Table 8 presents the average corporate innovation of treatment and control groups and the difference in corporate innovation between groups. The differences are to have the same sign and significant. Those results mean that the independent director's corruption culture leads to weakening corporate governance, where less monitoring impact on overinvestment and lower quality of corporate innovation. Panel B1 – B3 and C1 – C2 present the same results. Those results mean that the independent director's corruption culture increases their excess compensation of independent director and CEO.

The Effect of External Corporate Governance Mechanisms

Institutional holdings concern on the composition of the board of directors and quality of corporate governance (Chung and Zhang, 2011). One of the roles of institutional holdings is used the public information disclosure in monitoring firm activities and enhance transparency in corporate governance (Armstrong et al, 2014). The agency problem from an independent director's corruption culture could be the reason why corporate innovation is decreases and compensation of independent director and CEO are increases. Also, that product market competition increases productivity growth, tight monitoring creditor, and also a substitute of block-holder control mechanisms (Köke & Renneboog, 2005). Product market competition is a substitution for internal corporate governance and effective to reduce the managerial inefficiency (Tian & Twite, 2011).

In this section, we explore a conditional test for how increased independent director's corruption culture causes decreased of corporate innovation and increased compensation of independent director and CEO.

In table 9 presents the conditional test of external corporate governance on the independent director’s corruption culture. We find that institutional ownership and product market similarity plays like weaker monitoring that decreases the corporate innovation and increases the compensation of independent director and CEO. Overall, the external corporate governance mechanisms weakly support our evidence.

Robustness Checks

<u>Controlling for CEO’s Corruption Culture and Alternative Measures of Boards’ Corruption Culture</u>

In this subsection, we replace the independent director’s corruption culture with the board of director’s corruption culture and control the CEO’s corruption culture in all models. In table 10, we find the independent director’s corruption culture and board of director’s corruption culture still remains. Further, independent director’s corruption culture leading weakens of corporate governance. Surprisingly, our findings confirm that the independent director’s corruption culture is stronger than the CEO’s corruption culture.

CONCLUSIONS

This study examines the effect of independent director’s corruption culture on corporate innovation and compensation of independent director and CEO. We use 12,332 firm-year observations during the period of 1996 – 2015 and measure the independent director’s corruption culture by determining their surname-ancestry with Corruption Perception Index (CPI).

We first document a strong negative relation between the independent director’s corruption culture and corporate innovation and a strong positive relation on the compensation of independent director and CEO. In addition, we conduct two methodologies to eliminate endogeneity issues, included (1) a difference-in-differences (DiD) with SOX as an exogenous shock, and (2) a propensity-score-matching (PSM) methodology. All of the results support our main expectation. Such evidence indicates (1) that independent director’s corruption culture impact on firm’s overinvestment by taking high risk projects without selection the project’s quality and transmitted to poor quality of corporate innovation, (2) that independent director’s corruption culture likely to less monitoring to applied friendly boards and use bargaining power to set own package of compensation.

We next explore a conditional test of external corporate governance. We find weakly evidence that poor corporate governance plays like weaker monitoring that decreases the corporate innovation and increases the compensation of independent director and CEO.

We continue to perform more robustness tests with (1) an alternative of corruption measurement, and (2) control for CEO corruption. All of the robustness tests are support our main expectation.

APPENDIX

Variable	Definition	Data source
Panel A: Independent variables		
IDCC	The average corruption values for all independent directors by their surname-ancestry country from Transparency International CPI	Risk Metrics
CEO_Corruption	The average corruption values for CEOs by their surname-ancestry country from Transparency International CPI	Risk Metrics
Board_Corruption	The average corruption values for all boards by their surname-ancestry country from Transparency International CPI	Risk Metrics
Panel B: Dependent variables		
Patent	The natural logarithm of the weight-adjusted patent counts	PATSTAT and USPTO
Citation	The natural logarithm of the citation lag-adjusted citations per patent	PATSTAT and USPTO
IE	The natural logarithm of the patents or citations scaled by R&D expenditures	PATSTAT and USPTO
ID_Compensation	The estimated value by the residual from independent director's total compensation regression	ExecuComp
Cash_Compensation	Total cash scaled by total compensation	ExecuComp
Equity_Compensation	Total stock plus options scaled by total compensation	ExecuComp
CEO_Compensation	The estimated value by the residual from CEO compensation regression	ExecuComp
CEO_Vega	The natural logarithm of one plus stock return volatility sensitivity change in CEO wealth	Core & Guay, (2002)
Panel C: Firm characteristics		
ROA	Total net income scaled by total assets	Compustat
Leverage	Current liabilities plus long term debt scaled by total assets	Compustat
BHR	Buy and hold one year return	CRSP
Firm Size	The natural logarithm of total assets	Compustat
Dividend	Total dividend payment scaled by total assets	Compustat
Panel D: Corporate governance		
E-Index	A corporate governance quality based on six provisions following Bebchuk et al. (2009)	Risk Metrics
HHI	The market concentration of an industry	Compustat
IO	The percentage of shares held by institutional ownership	Thomson Reuters 13F
Board Size	The natural of logarithm of total number of directors on board	Risk Metrics

Board Independency	The percentage of independent board scaled by board size	Risk Metrics
Panel E: Independent director		
Director Age	The natural of logarithm of average independent board's age	Risk Metrics
Female Director	Dummy variable equal to one if board has a female director and otherwise is zero	Risk Metrics
Director Tenure	The natural of logarithm of average independent board's tenure	Risk Metrics
Panel F: Product market competition		
Similarity	A text-based analysis of product similarity descriptions	Hoberg and Phillips (2010, 2016)

The Strategic Impact of Human Resource Information Systems and the Moderating Role of Organizational Culture: A Preliminary Empirical Study

Joonghee Lee
Auburn University
Email: jzl0165@auburn.edu

ABSTRACT

Human capital is important, and the strategic role of HRM has been emphasized over recent years. There is limited empirical research regarding the application of Human Resource Information Systems for strategic HRM. This study examines the complementarity among human resource information systems (HRIS) and organizational culture by assessing their impact on the strategic involvement of HR. Our findings suggest that organizational culture positively moderates the relationship between HRIS and strategic involvement of HR. We also find that HRIS contributes to the strategic role of HR.

KEYWORDS: Information systems, Strategic human resource management, Organizational culture.

INTRODUCTION

Demonstrating the value of information technology (IT) is a central issue in the information systems (IS) discipline, and a significant body of research has examined the organizational performance impacts of IT (e.g. Chae et al., 2014; Mithas & Rust, 2016; Mithas et al., 2017; Nevo & Wade, 2010; Wade & Hulland, 2004; Weill, 1992). IT in literature is frequently used as aggregate variables (Devaraj & Kohli, 2003), such as IT investments (Mithas et al., 2012) and IT portfolio (Oh & Pinsonneault, 2007). These variables represent to what extent a firm allocates its budget into IT resources, and different types of IT resource. However, scholars in the IS field have argued that we need to examine the IT-performance link at a disaggregated level, such as at the level of specific information systems (Aral & Weill, 2007; DeSanctis,1986; Mithas et al., 2006). This study investigates the strategic benefits of human resource information system (HRIS). By examining the link between specialized information system within a traditional functional area of an organization and the business value, this study extends our understanding regarding the IT-related value creation at an IT system level.

The human resource (HR) function is ubiquitous and human capital is a critical for organizational performance (Becker & Gerhart, 1996; Liu et al., 2017; Sun et al., 2007). To achieve administrative and strategic benefits, firms have increasingly adopted human resource information systems (HRIS) (Bondarouk et al., 2017) that allow HR activities and processes to occur electronically. While many prior studies suggested positive potential of using technologies to increase the effectiveness of the HR function, researchers increasingly call for more empirical studies regarding consequences of HRIS (Bondarouk et al., 2017). Moreover, a critical trend over recent years in HR management (HRM) is the emphasis on the strategic roles of HRM (SHRM) rather than its administrative role. In other words, HR practitioners are under pressure to be strategic partners and to contribute to a firm's competitive advantage (Paauwe, 2004). HRIS can help HR departments play that strategic role. Literature has broadly suggested two main benefits of HRIS: the improvement of efficiency and reduction of costs associated with HR activities involving day-to-day transactions (e.g. payroll and hiring), and facilitation of a more strategic role for the HR function (Parry, 2011). A large proportion of administrative roles of HRM are now delivered through information technology (IT), which enables HR people to focus more on strategic roles. Thus, we will examine two questions in this study:

(1) *Does HRIS enable HR functions to make more contributions at a strategic level?*
(2) *Under what conditions does HRIS contribute to increase the strategic values of HR?*

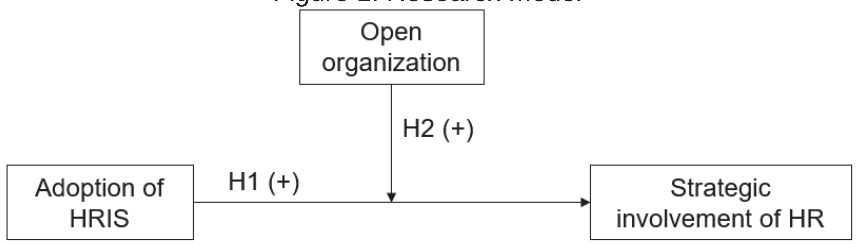
There is a substantial body of research on HRIS with different foci, such as implementation (Lippert & Michael Swiercz, 2005), administrative efficiency (Bondarouk et al., 2009), employee perceptions towards HRIS (Wickramasinghe, 2010), and job satisfaction and turnover intention (Maier et al., 2013). However, little literature exists regarding HRIS. In addition, the link between HRIS and its strategic value is not well established in empirical research. Although scholars have argued the significant relationship between HRIS and its strategic outcomes at a theoretical level (Lippert & Swiercz, 2005; Martin & Reddington, 2010), empirical evidence is inconsistent. Some studies show that HRIS is related to SHRM (Hussain et al., 2007; Marler & Parry, 2016; Parry, 2011), but others did not find evidence showing that HRIS results in direct strategic benefits (Bondarouk & Ruël, 2013; Dery et al., 2013; Parry & Tyson, 2011). Thus, the debate on HRIS and its strategic value is inconclusive (Bondarouk & Ruël, 2013), indicating a need to produce more empirical studies on HRIS and SHRM outcomes (Marler & Fisher, 2013). Moreover, the resource-based view suggests that IT resources may be more effective when they are paired with other resources (Mithas et al., 2011; Melville et al., 2004; Nevo & Wade, 2010; Wade & Hulland, 2004; Bresnahan et al., 2002), in that the organizational influences of IT can be affected by other organizational factors. In addition, the ‘sociotechnical framework’ suggests that technologies should be merged with human dimensions (e.g. organizational culture and leadership) for successful technological performance (Miller & Rice, 1967). In particular, Leidner and Kayworth (2006) suggested that organizational culture is significantly associated with IT value creation. This study investigates the boundary conditions where the link between HRIS and SHRM can vary by including a cultural variable. In particular, open organization, which refers to the culture of trusting and open relationships with minimal bureaucracy, free communications within and across business units, is critical cultural factor linked with IT performance (Powell & Dent-Micallef, 1997; Zuboff, 1998).

This study contributes to the literature in three ways. First, it deepens our understanding of the business value of IT by investigating a specialized information system within a traditional functional area of an organization. Second, it begins to resolve contradictory results in previous research of the relationship between HRIS and SHRM by proposing a moderation model. The inconsistency may be explained by exclusion of other organizational factors or limitation of data sets. Previous studies focused on the direct link between HRIS and SHRM have relied on cross-sectional data from surveys (Bondarouk & Ruël, 2013; Hussain et al., 2007; Parry, 2011) and case studies (Parry & Tyson, 2011; Bondarouk & Ruël, 2009). This study includes organizational factors and use panel data from firms in South Korea. Using longitudinal data and panel models mitigates the problem of endogeneity by reducing omitted variable bias, which results in more precise estimates of coefficients in our model. Third, this study contributes to our understanding of HRIS strategic values by testing the suggested model in a different context, namely South Korean organizations. Previous studies have been conducted in the U.S. and in Europe (e.g. Bondarouk et al., 2009; Bondarouk & Ruël, 2013; Hussain et al., 2007).

RESEARCH MODEL AND HYPOTHESIS

This study investigates the effects of HRIS on the strategic roles of HR functions in organizations – as well as the moderating effect of organizational culture. Specifically, the proposed model is shown in Figure 1.

Figure 1: Research model



The Strategic Benefits of HRIS

Literature in HRM and IS suggests that HRIS reduce administrative burdens of HR staff and allow them to focus on more strategic support for their organizations (Bondarouk & Ruël, 2013; Ngai & Wat, 2006). Specifically, HR departments can automate routine HR tasks and replace 'filing cabinets' by adopting HRIS (Parry et al., 2007), expend more effort on the improvement of HR strategies and policies for the strategic management of employees (Martin et al., 2008; Ruël et al., 2004; Shrivastava & Shaw, 2003) and support strategic decision-making (Bondarouk & Ruël, 2009; Hussain et al., 2007; Parry & Tyson, 2011). Thus, HRIS help transform HR professionals from administrative workers to strategic partners (Bell et al., 2006; Burbach & Dundon, 2005; Haines & Lafleur, 2008; Voermans & Van Veldhoven, 2007). The adoption of HRIS may allow the HR functions to increase its value in strategic levels.

Hypothesis 1: The adoption of HRIS has a positive association with the strategic involvement of HR functions in organizations.

The Moderating Role of Open Organization

According to the resource-based view (RVB), resources are solely responsible for organizational performance (Wade & Hulland, 2004). In particular, IT resources can be more effective for improving organizational performance in conjunction with other firm resources, such as structure, culture, and skills (Chae et al., 2014). Thus, many scholars have viewed the effects of IT as both contingent and complementary (Holland et al., 1992; Kettinger et al., 1994; Kettinger et al., 1995; Powell & Dent-Micallef, 1997). Complementarity refers the effect that one resource in organizations may have on another. Resources may influence performance when combined with another resource (Teece, 1986); the effect of HRIS likely depends on other constructs. Bondarouk and Ruël (2013) suggested HRIS alone is not sufficient to enable HR functions to contribute strategically. In a study of a large federal government organization, they found that HRIS do not automatically result in direct benefits, and so do not necessarily increase the HR functions' capabilities.

In this section, we discuss a boundary condition by which the relationship between HRIS and the strategic role of HR functions are affected. The perspective that firms should merge technology with cultural dimensions is rooted in the 'sociotechnical framework'. This framework suggests that maximized technological performance requires an optimization of social and technological subsystems in an organization (Miller & Rice, 1967). In addition, IS researchers have considered culture to be a critical variable when explaining the effects of IT. Leidner and Kayworth (2006) suggests that organizational culture is related to information systems development, IT adoption, diffusion, use, outcomes, and more. Also, several IS literature suggest that corporate culture may influence the relationship between IT and organizational performance (Melville et al., 2004; Wade & Hulland, 2004; Piccoli & Ives, 2005). An important cultural variable linked with IT performance is openness of the organization (Powell & Dent-Micallef, 1997). The benefits of IT may be negated by structural, relational, and communicational constrictions, such as limited access to information, top-down communication, and autocratic command and control (Zuboff, 1988). A critical benefit of information systems is to increase the accessibility of information. So, firms can increase the value by allowing employees access to information traditionally controlled by upper management, and avoiding traditional hierarchies, and top-down communications (Powell & Dent-Micallf, 1997).

Hypothesis 2: Organizational openness positively moderates the relationship between HRIS and the strategic involvement of HR functions.

METHOD

Sample and Procedure

The data come from the Human Capital Corporate Panel (HCCP) Survey from the Korean Research Institute for Vocational Education and Training (KRIVET, 2015). The survey data of the sample companies are combined with the corporate financial data held by the Korea Investors Service (KIS) using a corresponding firm code (KIS, 2015).

KRIVET has conducted the HCCP survey every two years since 2005; the survey includes a battery of questions regarding HR practices. We focused on the survey data and financial data between 2011 and 2015 for two reasons. First, the HCCP survey sample was changed in 2009. The 9th Korean standard industrial classification was placed into effect on February 1, 2008. Second, to eliminate the effects of the Great Recession, we focused on the data after that time.

For the survey process, KRIVET contacted HR managers at targeted firms, and administered the HCCP survey using on-site interviews. The referent for the survey items was the firm, and HR managers responded to the items. The population for HCCP sample extraction consisted of companies listed in the company overview information of the KIS database with at least 100 employees across six industries: (1) Manufacturing, (2) Finance, banking and insurance, (3) Publishing/video/broadcasting and telecommunications, and information service, (4) Specialist/scientific and technical service (5), education service, and (6) Arts/sports and leisure service. Between 2011 and 2015, companies for the survey sample numbered between 467 and 500.

Variable Operationalization and Descriptive Statistics

Strategic involvement of HR (SHR). This dependent variable consists of responses to four survey questions. The first three questions were asked to HR managers of the firms. The first indicates how much the HR function reflects the company’s mid and long-term strategies with four possible responses between the lowest value of 1 (rarely reflected) and the highest value of 4 (much reflected). The second and third questions indicate whether the firm engages in HR planning each year (1: yes, 0: no), and whether that planning reflects management strategy (1:

yes, 0: no). The fourth question was asked to employees in a firm to indicate how much the HR department contributes to establishing business management strategies (5: from the outset to 0: no contribution). Responses to these items were summed to create a scale from 2 (rarely strategically involved) to 11 (strongly strategically involved).

Table 1. Strategic Involvement of HR and Open Organization Measures

Variables	Items	
Strategic involvement of HR	SHR1	How much the HR function reflects the company's mid and long-term strategies
	SHR2	Whether the firm engages in HR planning each year
	SHR3	Whether the HR planning reflects management strategy
	SHR4	How much the HR department contributes to establishing business management strategies
Open organization	OPENORG1	My company communicates its situation in detail to employees
	OPENORG2	Employees speak freely to their managers
	OPENORG3	My company has good communication between teams
	OPENORG4	Employees trust each other
	OPENORG5	My company has an atmosphere wherein hierarchy is stressed
	OPENORG6	My company communicates thoughts and information top down

HRIS adoption (HRIS). This is a binary variable that is based on the response to a question for HR managers in the firm that indicates whether they use HRIS. Response choices were 0 indicating the use of HRIS, and 1 meaning no use of HRIS.

Open organization (OPENORG). This is a cultural variable in our study, which is conceptualized as a culture of trusting and open relationships with minimal bureaucracy, free communications within and across business units (Powell & Dent-Micallef, 1997). Six items with responses ranging from 1 ("strongly disagree") to 5 ("strongly agree") are used to measure the perception of employees about the openness of their firms. The four items are (1) My company communicates its situation in detail to employees, (2) Employees speak freely to their managers, (3) My company has good communication between teams, (4) Employees trust each other, (5) My company has an atmosphere wherein hierarchy is stressed, and (6) My company communicates thoughts and information top down. The item (5) and (6) are reverse coded.

Controls. The research model in this study controls for firm age (AGE), firm size measured as the number of employees (SIZE1: ≤ 299, SIZE2: ≤ 999, SIZE3: ≤ 1999, SIZE4: ≥ 2000), management systems [fully managed by the owner (OWNER), managed by a management specialist with significant owner intervention (MAS_OWNER1), managed by a management specialist with slight owner intervention (MAS_OWNER2), fully managed by a management specialist], the top priority in the company management [improvement the quality of product/service(QUALITY), cost reduction (COST), new product development], having an organization exclusively responsible for HR (HRDPT), the number of HR employees (HREMP), number of HR managers (HRMG), the number of HR senior managers (HRSMG).

Table 2. Variable Operationalizations

Quantitative variable	Operationalization	Mean	Std. dev
SHR	The sum of ratings on four items (SHR1 – SHR4) in a firm *i* in year *t*	7.475	1.691
OPENORG	The average ratings on six items (OPENORG1 – OPENORG6) in a firm *i* in year *t*	3.369	.355
AGE	A firm *i*'s age	33.914	17.620
HREMP	The number of HR employees in a firm *i* in year *t*	2.841	4.941
HRMG	The number of HR managers in a firm *i* in year *t*	2.566	4.979
HRSMG	The number of HR senior managers in a firm *i* in year *t*	.421	.668
Categorical variable	Operationalization	Proportion	Std. dev
HRIS	1 if a firm *i* adopts and operates HRIS, otherwise, coded as 0 in year *t*	.700	.459
SIZE1	1 if the number of employees in a firm *i* is less than or equal to 299, otherwise, coded as 0 in year *t*	.508	.500
SIZE2	1 if the number of employees in a firm *i* is between 300 and 999, otherwise, coded as 0 in year *t*	.350	.477
SIZE3	1 if the number of employees in a firm *i* is between 1000 and 1999, otherwise, coded as 0 in year *t*	.079	.270
OWNER	1 if a firm *i* is fully managed by the owner, otherwise, coded as 0 in year *t*	.469	.499
MAS_OWNER1	1 if a firm *i* is managed by a management specialist with significant owner intervention, otherwise, coded as 0 in year *t*	.165	.371
MAS_OWNER2	1 if a firm *i* is managed by a management specialist with slight owner intervention in, otherwise, coded as 0 in year *t*	.166	.372
SPECIAL	0 if a firm *i* is fully managed by a management specialist in year *t*, otherwise, coded as 0 in year *t*	.200	.400
QUALITY	1 if a firm *i*'s top priority in the company management is improvement the quality of product/service, otherwise, coded as 0 in year *t*	.523	.500
COST	1 if a firm *i*'s top priority in the company management is cost reduction, otherwise, coded as 0 in year *t*	.296	.457
HRDPT	1 if a firm *i* has an organization exclusively responsible for HR, otherwise, coded as 0 in year *t*	.685	.465

Preliminary analysis

Because of the panel nature of our data set, we specify the following equation for the panel models:

$$Y_{it} = X_{it}\beta + u_i + \varepsilon_{it} \quad (1)$$

where *Y* represents the endogenous variable (i.e. SHR); *X* represents a vector of firm characteristics, such as HRIS, OPORG and other control variables; *β*s are the parameters to be estimated; subscript *i* indicates firms and subscript *t* indicates time; u_i represents unobserved time invariant fixed factors associated with a firm *i*; and *ε* is the error term associated with each observation. Our main independent variable (HRIS) is not a time-constant variable, and the Hausman test rejected the null hypothesis ($X^2(16) = 46.76$, $p < 0.01$)(see Table 3) that the key random effect assumption (i.e., that the unobserved effects is uncorrelated with each explanatory variable) is false so that a fixed effect model is used (Wooldridge, 2013).

Table 3: Hausman Test Results

	Fixed Effects (a)	Random Effects (b)	Difference (a-b)	S.E.
HRIS	-2.540	-1.754	-.786	.356
OPENORG	.375	.780	-.405	.097
HRIS*OPENORG	.812	.568	.244	.103
SIZE1	-.657	-.949	.291	.428
SIZE2	-.706	-.655	-.051	.393
SIZE3	-.358	-.200	-.158	.282
AGE	-.044	-.004	-.040	.022
OWNER	-.080	-.269	.189	.145
MAS_OWNER1	-.206	-.304	.098	.118
MAS_OWNER2	.246	.019	.227	.105
QUALITY	-.044	-.075	.030	.086
COST	-.250	-.276	.026	.088
HRDPT	.724	.974	-.250	.070
HREMP	-.015	-.001	-.015	.009
HRMG	.006	.001	.005	.013
HRSMG	.199	.180	.019	.050
Hausman Test	$X^2(16) = 46.76^{**}$			

RESULTS

A summary of the results of the fixed effects regression models are shown in Table 4. The coefficient of HRIS in model1 is positive and significant, supporting Hypothesis 1. In addition, the interaction term HRIS*OPENORG is positive and significant, supporting Hypothesis 2.

Table 4: Fixed Effects Regressions

Independent Variables	Dependent variable: SHR		
	Model1	Model2	Model3

CONCLUSION AND FUTURE RESARCH

The objective of this study was to analyze and investigate the complementary relationship between HRIS and organizational culture. Based on our preliminary analyses, we find that an open organizational culture positively moderates the impact of HRIS on strategic involvement of HR. We also find that HRIS is positively associated with the strategic involvement of HR. This paper is a preliminary analysis. In the future, we will do robust checks by using different econometric models, such as 2SLS, to handle any endogeneity that might exist in the data.

A Last Mile Delivery Fleet Model with Drones

ABSTRACT

The development and potential adoption of drones as delivery vehicles creates incredible opportunities and unique challenges for last mile delivery. This research presents a last mile delivery fleet model with drones that can be modified and expanded over time as the theoretical morphs into the practical. The model shows the optimal number of drones needed based on demand and how additional batteries can mitigate the total number of drones. The model is presented with a central depot and a delivery radius dependent on the range of the drones.

KEYWORDS: Last mile problem, Drones, UAVs, Supply chain delivery, Logistics

INTRODUCTION

The last mile problem (LMP), which is defined as the optimizing of the last leg of the business-to-consumer delivery service, is of particular concern to supply chain managers who manage road freight transportation. The LMP is considered to be one of the most costly and highest polluting segments of the supply chain and is often the least efficient part of the supply chain due to the high degree of empty running (Gevaers et al., 2011). While costs vary with population density, product type, package size, and package weight, last mile delivery incurs the highest transportation costs in the supply chain (Chopra, 2003). Drones or unmanned aerial vehicles (UAVs) offer a potential resource for companies to reduce both cost and carbon emissions associated with last mile delivery. This paper develops a last mile delivery fleet model with drones delivering one package per trip from a central depot. The model shows the optimal number of drones needed based on demand and how additional batteries can mitigate the total number of drones. The model is presented with a delivery radius dependent on the range of the drones.

As e-commerce continues to grow, a greater burden is placed on last mile delivery. Logistics systems which were traditionally designed to accommodate a single lot delivery of multiple products from one business to another are now under pressure to deliver high volumes of single parcels from a transportation/warehouse hub to multiple individual customers. With the global e-commerce market growing 18% to $2.86 trillion in 2018, solving last mile delivery issues is a major customer service concern for firms (Young, 2019).

In a climate of enhanced awareness of environmentally sustainable business practices, greater pressure is being placed on organizations to advance sustainable logistics within the operation of their supply chains (Abbasi and Nilsson, 2016; Björklund et al., 2016; Golicic et al., 2010). Comprehensive reviews of sustainable logistics have been conducted for various modes of freight transportation including roadways (Demir et al., 2014), railways (Aditjandra et al., 2016), maritime (Davarzani et al., 2015), air (Teoh, and Khoo, 2016), and intermodal (Roso, 2013). The carbon footprint associated with freight transport across all modes is rapidly becoming a key managerial concern and is especially prevalent in road transportation by transport vehicle in North America and Europe. Drones provide a delivery option that can result in a lower overall carbon footprint, but it can depend on the delivery density and the efficiency of the drones and trucks (Goodchild & Toy, 2018).

Determining an optimal drone delivery fleet for dealing with the LMP including the number of vehicles, available delivery hours, delivery range, and total freight capacity is a problem with a solution that varies depending on the customer demand for that delivery cycle. If demand is high, more drones, more delivery time, or more freight capacity may be needed. On a day with less demand, the opposite is true. Demand for last mile delivery is typically not constant and as a result changes to the fleet operating characteristics may change from week to week or even from day to day. In this paper we present a last mile delivery model with drones that can be used for planning and to aid decision makers in managing the operating characteristics of their drone delivery fleet in support of the LMP.

The contributions of this research add to the literature by providing a base model that can be modified and adapted over time as the theory of last mile delivery with drones becomes reality. The model provides a method for calculating the size of the necessary drone fleet based on either deterministic demand or stochastic demand with a set service level.

LITERATURE REVIEW

As a gateway to the general literature on the LMP the reader is referred to the review papers of Ranierie et al. (2018) and Datta (2018). These review papers provide a general overview of the scope of problems (logistical and environmental) associated with last mile delivery in supply chain management and provide a foundation for areas of future research on the LMP.

Research on drones and how they may impact last mile delivery in the coming years has grown steadily as companies like Amazon and Google are investigating drones and how they may be utilized in the future (Gharibi et al, 2016). Perhaps the biggest obstacle holding up the adoption of drones for last mile delivery involves commercial drone regulations. See Jones (2017) for details on these regulations by country.

Goodchild & Toy (2018) compare the CO_2 emissions of a traditional truck vehicle fleet with that of a hypothetical fleet of drones. Their findings suggest that the density of deliveries and the efficiency of the trucks and drones are large factors in determining the overall carbon footprint of the last mile delivery.

Murray & Chu (2015) introduce mathematical programming models aimed at optimal routing and scheduling of drones in conjunction with delivery trucks. They find this type of delivery system can provide faster receipt of customer orders with a reduced environmental impact. Boysen et al (2018) find that a truck fleet can considerably be reduced if drones with decentralized depots support the delivery process. Agatz et al (2018) show that substantial savings are possible when combining drones with trucks in comparison to truck-only delivery.

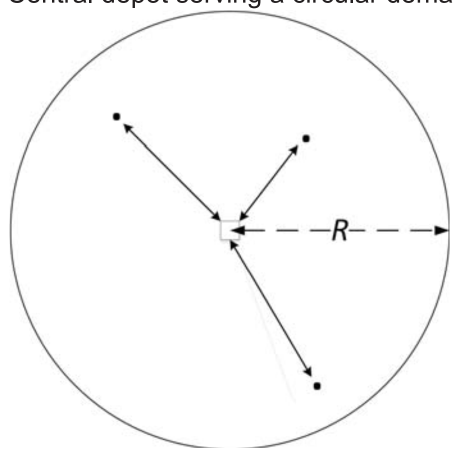
Chiang et al (2019) show that the use of drones can help save fixed logistics costs by reducing the total delivery time and the number of vehicles required. Shifting smaller package delivery from trucks to drones, when adequately deployed, would cut down energy use and CO_2 emissions. To realize the environmental benefits of drone delivery, firms are recommended to carefully plan and control the routing and coordination of the delivery vehicles and drones.

The review of research studies on drones and the LMP identifies that drones have the potential to reduce cost, time, and carbon emissions if applied appropriately to the last mile problem. Much of the research is limited by the knowledge of the current ability of known drones and makes conclusions based on these current technologies. By the time drone flight regulations are in place to allow last mile delivery with drones, the technology may be more advanced and change what was once thought possible. This research develops a base last mile delivery fleet model with drones delivering one package per trip from a central depot. The model is adaptable to future advancements and provides a foundation for further research.

MODEL

The basis for the last mile delivery fleet model with drones is a circular region with a central depot or warehouse. The demand is assumed to be uniformly and randomly distributed throughout the region. Figure 1 shows this general model with drones leaving the depot, making a delivery within the service region, and returning to the depot to either begin a new delivery, have its battery charged, or swap its battery and begin a new delivery.

Figure 1: Central depot serving a circular demand region



The radius, R, of a circular demand region around a central depot depends on the comfortable roundtrip range of the drones loaded with a maximum payload. Since the drone will be empty on the return trip, the range of the drone is determined by the average of the range of a fully loaded drone and an empty drone. In this case the total flight distance or drone range, r_m, is defined as

$$r_m = \frac{r_e + r_f}{2} \tag{1}$$

where

r_e = maximum range of an empty drone

r_f = maximum range of a drone at maximum capacity

The radius of the demand region can be defined as

$$R = \frac{r_m p}{2} \tag{2}$$

where

p = safety factor between 0 and 1 (i.e. 90%)

The expected or average distance from a customer to the depot if demand is uniformly and randomly distributed can be defined mathematically (Brown & Guiffrida, 2014) as

$$\bar{L} = \frac{2}{3}R \tag{3}$$

Thus, the mean roundtrip distance is

$$2\bar{L} = \frac{4}{3}R \tag{4}$$

The average time duration of a delivery can be defined as

$$T_M = \frac{4R}{3V} \quad (5)$$

where

V = average travel velocity of a drone

A drone fleet can be set up either with additional batteries available to swap out or with just one battery per drone. The number of drones needed with battery swapping can be defined as (6). The ceiling brackets indicate the result should always be rounded up. The average setup time includes the time needed to change the battery, load the new parcel, set the delivery location, and launching the drone. Troudi et al (2018) map out the expected activities of how a drone operator manages the parcel delivery process between flights.

$$N_D = \left\lceil \frac{D\left(\frac{4R}{3V} + A\right)}{H} \right\rceil \quad (6)$$

where

D = demand per period

A = average setup time (spent between deliveries) including battery swap

H = operational time per period (i.e. hours per day)

The average number of deliveries made by each drone per period depends on demand and can be defined as

$$D_D = \frac{D}{N_D} \quad (7)$$

The minimum number of batteries depends on a combination of charge time, demand, available time for deliveries, and the number of drones. An important factor in deriving the minimum number of batteries is the average time each drone has between deliveries (average cycle time that includes setup and delivery). This can be defined as

$$T_B = \frac{HN_D}{D} \quad (8)$$

In order to arrive at the minimum number of batteries, we divide the time it takes to charge a battery by (8), multiply that by the number of drones, and add the number of drones. After some term simplification, the minimum number of batteries needed can be defined as

$$B = \left\lceil \frac{C_T D}{H} + N_D \right\rceil \quad (9)$$

where

C_T = charge time for a battery

Charge time is variable depending on how much power is left after the previous trip. This model assumes linear battery usage and charging times. For instance, if 50% of the battery has been used, we assume the charge time is $0.5C_T$. See Dorling et al (2016) for information on the linear energy consumption of drones based on total weight. For simplicity, this model assumes no battery capacity fade over time.

Equation (10) can be reworded as the optimal number of spare batteries, which would assume that the drones would each contain a battery so this would be the number of batteries that are separate from the drones. The optimal number of spare batteries can be defined as

$$B_s = \left\lceil \frac{C_T D}{H} \right\rceil \quad (10)$$

The number of drones needed without additional batteries to swap out changes since a drone will be out of service while charging. The average setup time here includes the time needed to plug the returning drone into its charger, unplug the departing drone, load the new parcel, set the delivery location, and launching the departing drone. The number of drones needed without battery swapping can be defined as

$$N_N = \left\lceil \frac{D\left(\frac{4R}{3V} + A_N + C_T\right)}{H} \right\rceil \quad (11)$$

where

A_N = average setup time (spent between deliveries) without battery swap

NUMERICAL EXAMPLES

In this section, the model is illustrated with a numerical example to demonstrate the differences in the makeup of a fleet of last mile delivery drones with battery swapping and without battery swapping. The following parameter values have been assigned to support the model illustration: r_f = 14.0 miles; r_e = 16.0 miles; p = 90%; D = 120 customers per period; V = 30 miles per hour; A = 0.1 hours; A_N = 0.1 hours; H = 8 hours; C_T = 1 hour.

Based on these parameters, the model was solved for the battery swapping scenario. Table 1 contains the results with battery swapping.

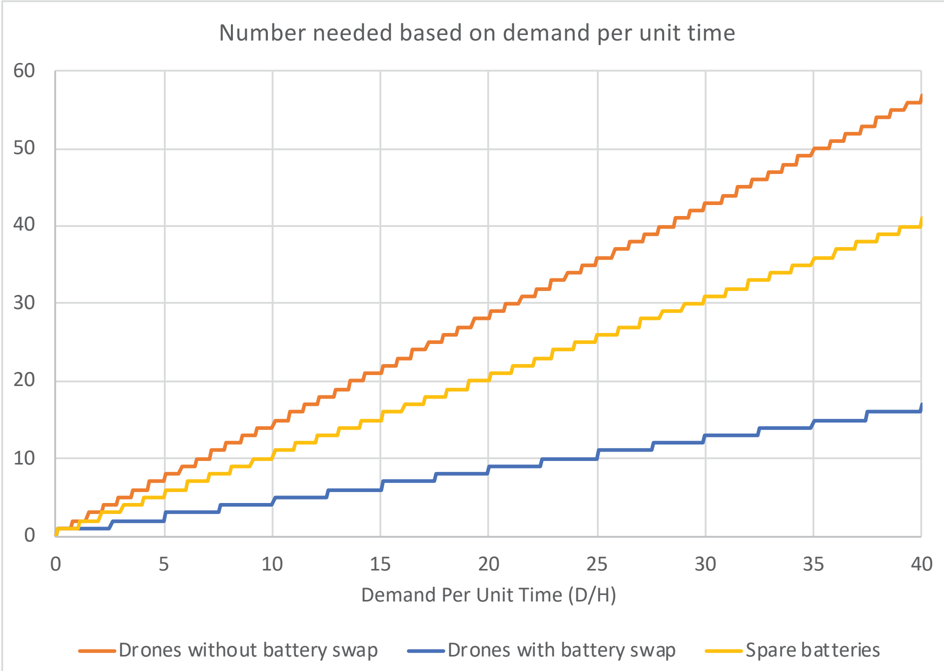
Table 1: Results for deterministic demand example with battery swapping

VARIABLE	RESULT
N_D	6 drones
D_D	20 deliveries per drone per period
T_M	0.3 hours average trip duration
B_s	15 spare batteries needed

Without battery swapping, the number of drones needed would be 21 drones based on these parameters. The only upside to not employing battery swapping is less wear and tear on each drone since each drone would only need to do 5.7 deliveries per period instead of 20 deliveries per period. The additional up-front cost, however, would be substantial. In addition, more storage space would be required for a fleet of 21 drones.

While most of the parameters will remain constant once they are first determined, demand may not. As demand changes, the number of drones needed also changes. The key ratio is D/H or demand per unit time. As the ratio moves, the number of drones and batteries moves at a steady rate. Figure 2 shows how the number of drones and batteries changes as demand per unit time changes.

Figure 2: Drones and batteries needed based on demand per unit time



This information can be used with a demand distribution to determine the optimal number of drones and batteries needed with a desired service level, *s*. This can be illustrated with a new example. Let *f(D)* denote the daily demand function. For this numerical example, *f(D)* is normally distributed ~N(μ,σ). The following parameter values have been added to the previous example's parameters to support the model illustration:
μ = 120; σ = 20; *s* = 99%.

Based on this demand distribution, the last mile delivery fleet would have to be constructed to serve 166.5 customers per period or 20.8 customers per unit time. Table 2 contains the results with this stochastic demand example.

Table 2: Stochastic demand results with battery swapping

VARIABLE	RESULT
N_D	9 drones
B_s	21 spare batteries needed
N_N	30 drones

A fleet of 9 drones with 21 spare batteries (30 total batteries) would be able to serve up to 179 customers based on the parameters. This equates to a service level of 99.84% based on the demand distribution. A fleet of 30 drones without battery swapping would be able to serve up to 171 customers, which equates to a service level of 99.46% based on the demand distribution.

CONCLUSIONS

This paper developed a last mile delivery fleet model with drones delivering from a central depot to find the minimum number of drones needed based on either deterministic or stochastic demand. The model is adaptable to future advancements and provides a foundation for further research. Findings suggest that additional batteries can mitigate the total number of drones and presumably lower the total cost. The model also allows a logistics manager to determine the probability of meeting changing demand with a current fleet of drones.

The contributions of this research add to the literature by providing a base model that can be modified and adapted over time as the theory of last mile delivery with drones becomes reality. The model provides a way to calculate the size of the necessary drone fleet based on either deterministic demand or stochastic demand with a set service level.

The proposed base model has several limitations that can be addresses in the future research. First, it does not take into account that the weight of the package carried by drone will affect its range and battery usage. The model uses the maximum drone capacity to calculate range. Second, the model does not consider the likelihood of no-fly zones and how they would impact flight distance and scheduling within the region . That situation can be addressed in the future.

Future research could also look at ways to extend the delivery range of drones either through more efficient drones or through innovative methods such as distributed landing locations with available batteries and charging facilities. Another extension could be the possibility of a drone making more than one delivery per trip if the cargo capacity and trip duration allowed. This could save time and money and reduce the total travel distance. At this point, there are a myriad of possibilities and applications for drones and last mile delivery and research in this area should explore these possibilities and extend the boundaries as much as possible.

ABSTRACT

Ethical consumers have a dilemma in making a purchase decision: “buy good or buy well.” This study modified the theory of reasoned action to explore driven personal motives of behavioural intention to purchase CSR-related products from customers’ perspectives in the context of ethical consumerism. This is the first study exploring the full mediating effect of price sensitivity on the association between CSR-driven perceptions of personal values and purchase intention. SEM analytical techniques were used to analyze 311 valid questionnaires collected in a Taiwanese dairy food marketplace. Theoretical and practical implications are discussed.

KEYWORDS: Ethical consumption, CSR perception, Price sensitivity, Moral Obligation, Mediating effect, Purchase Intention

INTRODUCTION

Corporate Social Responsibility (CSR) is becoming a global phenomenon and a great concern for society. Firms are using it as one of the profitable investments necessary to maintain a healthy relationship with salient stakeholders and to convey a solid brand image in the public eye. It seems that all sectors of the economy are influenced by the increases in societal expectations and interests in CSR initiatives. Mostly, CSR in the food industry has raised much attention from overseas scholars with many studies from different approaches (Devin & Richards, 2016; Kim, 2017; Maloni & Brown, 2006; Tian, Wang, & Yang, 2011; Wei, Kim, Miao, Behnke, & Almanza, 2018). CSR is highly relevant to the food industry because this sector has a high dependence on natural resources (with multiple effects on the environment) and the food industry is integrated with several societal and ethical concerns including animal welfare, labor’s right protection, food safety, fair-trade and so on.

Consumers are often cautious about food safety and brand credibility based on purchase decision experiences. Health safety becomes much more crucial than ever before because of the suffering of society due to information asymmetry relevant to food quality and whether companies manufactured the food in responsible ways or not. Being fearful of seller’s opportunism, consumers tend to use credence attributes such as CSR initiatives like a safeguard against risks. A recent study pointed out that if firms’ stimulate CSR initiatives, the information asymmetry will reduce (Cui, Jo, & Na, 2018). These CSR activities can affect consumer purchasing behaviors directly since these reflect consumers' perceptions. Researchers have shown that today’s consumers increasingly believe firms engage in CSR campaigns and are eager to pay higher prices for similar quality products perceived as socially responsibility oriented (Becker-Olsen, Cudmore, & Hill, 2006; Carvalho, Sen, de Oliveira Mota, & de Lima, 2010; Creyer, 1997; Mohr, Webb, & Harris, 2001; Rodrigues & Borges, 2015; Sen, Bhattacharya, & Korschun, 2006). Nevertheless, the customer's perception of CSR is diverse and still mostly unexplored. To fill the gap, this study reinvestigated customer's CSR-driven perceptions and its influences on patronage intention toward CSR-related products.

(Cooper-Martin & Holbrook, 1993) defined ethical consumption as "consumption experiences that are affected by the consumer's ethical concerns." Meanwhile, ethical concerns or moral obligations are understood as intrinsic ethical motives that play essential roles in shaping standards of behavior. Several consumption behavior studies found that customers perceived a strong sense of moral obligations when making decisions inherently in relation to ethical issues (Bommer, Gratto, Gravander, & Tuttle, 1987; Shaw & Shiu, 2003). For instance, Shaw carried out a study within the context of fair trade grocery and concluded that the role of moral obligations was imperative in predicting ethical purchase intentions (Shaw & Shiu, 2002). (Arvola et al., 2008) proved a vital link between moral attitudes and patronage intention of organic food. However, a wide variety of literature reviews suggested that the use of consumer's internal ethics, such as moral obligation in the CSR context, had not yet been cultivated.
On the other hand, (De Pelsmacker, Driesen, & Rayp, 2005) found that consumer responses, in some cases, did not align with their positive attitude toward ethical products. A survey (Deng & Jiang, 2011) found that only 12% of respondents would purchase an ethical product among 44% of respondents who made positive responses to cause-marketing practices. Additionally, CSR is not the most critical factor that affects consumers in purchasing decisions because traditional standards, such as price, quality, and brand familiarity are still the dominant criteria in the buying process for consumers (Boulstridge & Carrigan, 2000). A question raised in this research asked if "customers' patronage intention is consistent with their moral values and CSR perceptions under the effect of price sensitivity?". Notably, the role of price sensitivity in the context of social responsibility is still limited and controversial. Therefore, we aimed to explore this research gap.

We investigated the three following primary objectives in this paper. Firstly, we identified significant antecedences of consumers' purchase intentions to CSR-related products in ethical consumption. Secondly, we explored the mediating effect of price sensitivity in the association between purchase intention to CSR-related products and its antecedences. Thirdly, we demonstrated the trade-offs between personal ethical values and price perception in the purchase decision-making process from consumer perspectives. The present study concluded that several significant findings contributed to both theoretical development and managerial practices. It especially recognized the mediating effect of price sensitivity in the context of CSR. We chose milk as an example of experience good since milk also had long been associated with human basic physical needs in daily consumption. That allowed less restriction in data collection. The study followed a quantitative approach structured. We begin reviewing relevant literature of primary constructs and develop hypotheses to test. Next, the research methodology is described and is accompanied by empirical results. Finally, the authors summarize research findings and conclude implications.

LITERATURE REVIEW & HYPOTHESES DEVELOPMENT

Corporate Social Responsibility Initiatives

Corporate social responsibility developed out of the early 1950s and became popular in the 1970s (Carroll, 1999). Nowadays, in the highly competitive market, CSR is a global phenomenon and widely recognized as for strategic importance to a firm. This strategic importance includes deriving consumer-friendly images, reinforcing relationship with significant stakeholders, enhancing competitive advantages, and boosting financial performance to outperform rivals (Becker-Olsen et al., 2006; McGuire, Sundgren, & Schneeweis, 1988; McWilliams, Siegel, & Wright, 2006; Porter & Kramer, 2006; Sen et al., 2006; Shrivastava, 1995; Valentine & Fleischman, 2008). CSR is a broad and complex concept to the extent of what firms should do to keep commitments and respect the community's interests for long-run sustainability. No longer a new concept, CSR has numerous explanations (Perrini, 2006). Nevertheless, many arguments challenged scholars and industrialists as to how CSR should be correctly defined in both the academic and corporate worlds (Dahlsrud, 2008). This probably occurs because CSR's definitions are all biased towards specific interests for distinguished stakeholders (Freeman, Harrison, Wicks, Parmar, & De Colle, 2010).

Every firm operates in a social environment with various stakeholders who have both direct and indirect impacts on its survival. Therefore, the scope of CSR initiatives emphasizes organizational commitments for stakeholders' well-being (Mohr et al., 2001). Indeed, CSR initiatives refer to both ethical and legal obligations that ultimately provide tremendous benefits and diminish the negative influences of firms' actions on the business environment in accordance with moral standards, social requirements, and stakeholder expectations (Berens, Riel, & Bruggen, 2005; Mohr et al., 2001; Pérez, del Mar García de los Salmones, & Rodríguez del Bosque, 2013). In the present research, we adopted the definition of CSR developed by (Dahlsrud, 2008) at one of the primary purposes to examine CSR perceptions concerned by customers who were primarily salient stakeholders of all-size corporates. He drew a relatively general conclusion about the conceptualization of CSR initiatives by systemizing 37 published CSR definitions and viewed CSR as a multi-dimension social construction that encompassed five aspects that included environmental, social, economic, stakeholder, and voluntariness dimensions. It emphasized that there were not many previous studies that examined multiple dimensions of CSR, most concentrated on the role of each dimension of CSR in consumer evaluation (Choi & Ng, 2011)

The theoretical approach in predicting customer response

In recent years, the growth of ethics studies, including CSR, business ethics, and corporate citizenship evoked great insights for academic researchers to produce various theoretical developments from perspectives of both business and customer ethics. A Japanese scholar, Fukukawa, reviewed these studies using two approaches; namely, a normative or descriptive approach to explore customer's responses to relevantly ethical issues in the marketplace (Fukukawa, 2003). In that research, she posited that the normative approach rooted in philosophy, defined ethical conducts of "what a person should do," while the descriptive approach emphasized psychological perspectives as personal values, behavioral psychology, and pro-social psychology referring to "what a person would do." Descriptive approaches can be extremely beneficial in exploring the nature of human beings in ethical contexts, and it develops from applications of cognitive and attitude-behavioral theories such as the Theory of Reasoned Action (TRA) (M. Fishbein & Ajzen, 1975) or the Theory of Planned Behavior (TPB) model as extended from the TRA model (Ajzen, 1991). Ethics scholars applying these descriptive oriented theories investigate underlying personal motives of ethical consumption to predict purchase intention, pre-purchase alternative evaluation, and actual purchase behaviors.

Over the past decade, Ajzen and Fishbein's TRA, one of the most developed theoretical models, has been applied to explore antecedents of consumer intention and behaviors. In the middle and late 1970s, the theory initially introduced by (M. E. Fishbein, 1967) pointed out that both actual behaviors and intentions were the likely outcomes that reflected the information-based processing beliefs and attitudes; an assumption that human actions react under their volitional control. Many researchers attempted to prove the predictive utility of TRA model, among that the findings concluded by (Sheppard, Hartwick, & Warshaw, 1988) seemed to be overwhelming proofs that strongly support the overall reliability of the TRA model. Furthermore, TRA is recognized as an appropriate theoretical approach applied in customer-based research as better than other models (Wilson, Mathews, & Harvey, 1975). In this study, the descriptive approach was adopted, and we modified the TRA model by examining the interrelationship of consumer perception, personal values, and patronage intention toward products made in responsible ways, especially in the food industry. The mediating effects of price sensitivity were also included and examined in this modified framework.

Purchase Intention

Purchase intention is a kind of prior-purchase representing motivations to make a deal with a seller to buy a specific product or service. In other words, purchase intention has a power of foretelling purchasing and consuming process (Ghosh, Dasgupta, & Ghosh, 1990). The concept of consumer purchase intention initially originated from several psychological and behavioral studies. In this study, purchase intention merely was understood as customers' willingness to buy CSR-related products. Besides, a wide range of marketing research proved that purchase intention highly correlated with customer’s beliefs, affective attitudes, and actual purchase. Hence, it quietly makes sense in the present study that we applied TRA to examine customers purchase intention upon the integration of moral obligation (ethical values), CSR-initiatives, and customer’s price sensitivity in the dairy food market. Nevertheless, this work found that the current study was not carried out to measure customer’s purchase behavior explicitly, but concentrated on customer’s purchase intention instead.

Consumer’s CSR-driven perception

Consumers altogether want companies to do good things that are responsible and beneficial to the whole community. Moreover, consumer perceptions of CSR initiatives critically influence involvement and responsiveness to CSR programs (Barone, Miyazaki, & Taylor, 2000; Becker-Olsen et al., 2006). These CSR activities can even directly affect consumer purchasing decisions when these initiatives reflect the CSR beliefs of the consumer. However, in the literature, the customer’s perception of CSR is diverse and still mostly unexplored. To fill the gap, we included this construct into our study to reinvestigate customer’s CSR perception and its influences on ethical consumption toward CSR-related products. Therefore, in this paper, we defined consumer’s CSR-driven perception as the degree to which consumers perceived and believed a firm engaged in its activities interrelated to social causes. Therefore, the construct of CSR-driven beliefs in the current research proposed to consist of two components: CSR expectation (prosocial psychology beliefs) and perceived CSR (cognitive beliefs).

<u>CSR expectation</u>

Research has shown that today’s consumers increasingly believe firms engage in CSR campaigns (Becker-Olsen et al., 2006; Harrison, 2003). Customer expectations can be understood as whatever they desire, want, or hope for what a firm should do, rather than what a firm would do (Zeithaml, Berry, & Parasuraman, 1993). It is likely that customers’ expectations towards CSR initiatives incorporate the way customers compensate the firms (Creyer, 1997;

Nebenzahl, Jaffe, & Kavak, 2001). Therefore, consumer's CSR expectations are indispensable in determining purchasing decisions. Customers bear in mind that meeting the needs of society is a responsibility for firms, and evidence suggests a willingness to buy products perceived as socially responsible is a way to support personal beliefs further (Mohr et al., 2001). Therefore, the definition of CSR expectations in this paper identifies merely some extents that consumer's desire and want every firm to behave ethically in complying with social responsibilities. We proposed the presence of a positive relationship between CSR expectation and purchase intention. Hence, the following hypothesizes was developed.

Hypothesis 1a: Customer's CSR expectations positively impact on their intention to purchase CSR-related product.

Perceived CSR

CSR is portrayed commonly as activities related to society's perception, as far as its obligations towards society (Sen and Bhattacharya, 2001). Previous studies implied that firms that embraced social initiatives could create positive cognitive perceptions; the expectation for customers (Becker-Olsen et al., 2006; Choi & Ng, 2011; Creyer, 1997; Tian et al., 2011). A consumer who has a positive perception of the firm's CSR initiatives tend to have favorable expectations and beliefs that it would not ever act unethically and vice versa (Öberseder, Schlegelmilch, & Murphy, 2013). Several studies provided insights that customer's perceived CSR not only affected their expectation but also influenced their behavioral consequences. Previous research showed a positive relationship between perceived CSR and purchase intention (Carvalho et al., 2010; Grimmer & Bingham, 2013; Tian et al., 2011). Therefore, this study describes the concept of perceived CSR as the extent to which customers acknowledge and recognize that a company supports activities related to social responsibilities. Hence, we developed the second hypothesis to test the impact of customer's perceived CSR on expectation toward CSR and purchase intention.

Hypothesis 2a: Customer's perceived CSR positively impacts on their CSR expectation.
Hypothesis 2b: Customer's perceived CSR positively impacts on their intention to purchase CSR-related products.

Moral obligation

In the literature, the concept of moral obligation is commonly interchanged by either ethical concerns or personal norms. It refers to intrinsic ethical motives driven by each person, reflecting an individual's self-concept about doing what is good/right and what is bad/wrong (S. H. Schwartz, 1977; Shaw, Shiu, & Clarke, 2000). There are two likely basics for moral obligation depending on the morality of the act itself and the goodness of the action consequences (Prichard, 2002). These moral values belong to the personality system and orientate ethical beliefs and attitude that embed into actions (Crowe & Simon, 2000; Fritzsche, 1995). Thus, consumers in the different self-concept of moral obligations have differences in the perception of ethical behaviors.

Several ethical consumption behavior studies found that customers perceived a strong sense of moral norms when making decisions inherently to ethical issues (Bommer et al., 1987; Shaw & Shiu, 2003). Consumers were interested in CSR-related products or responsible firms since they believed they ought to be ethical consumers and "do the right thing." Additionally, moral obligation embraced a significant predictive power of consumer's expectation and patronage behavior (Dickson, 2000; Gorsuch & Ortberg, 1983; Sparks, Shepherd, & Frewer, 1995). Therefore, within the present modified TRA model examining the relationship between CSR initiatives and ethical consumer's patronage intention, studying the impact of moral obligation was imperative, because CSR initiatives were highly embroiled with ethical issues (M. S. Schwartz & Carroll, 2008). Within the context of social responsibility, adapted from prior studies (Arvola et al., 2008; Beck & Ajzen, 1991) the concept of moral obligation in this paper is understood as a consumer's feel of a sense of responsibility to act morally. Thereby, we developed the following hypotheses.

Hypothesis 3a: Moral obligation positively impacts on customer's intention to purchase CSR-related product.
Hypothesis 3b: Moral obligation positively impacts on customer's CSR expectation.

Price Sensitivity and its mediating effects

From perspectives of business-decision makers, pricing is not only one of the most critical strategic management concepts since it affects market demand; generates sources of optimal profits, but it is also a competitive weapon gaining customer's insights. From another perspective, price throughout the past decades is a vital preference most frequently considered by customers in the purchase decision-making process (Kotler & Armstrong, 2010). Different market segmentation (i.e., price-conscious segment) observe various levels of price sensitivity. It is noticeable that economic bargain hunters will consume less as the price increases while those with low price sensitivity will not have a concern as the prices increase. How consumers react according to the perception of price levels or changes can be explained by the term of price sensitivity (Goldsmith & Newell, 1997). Another conclusion about price sensitivity was drawn as the degree of buyers' cognitive reactions when they dealt with the increase in prices of a specific product or service (Monroe, 1973). When purchasing decisions place more on the price attribute, consumers will be sensitive with small pricing fluctuations (Tellis, 1988). In other word, price sensitivity is inconsistent as it can change a consumer's purchase intention (Munnukka, 2008).

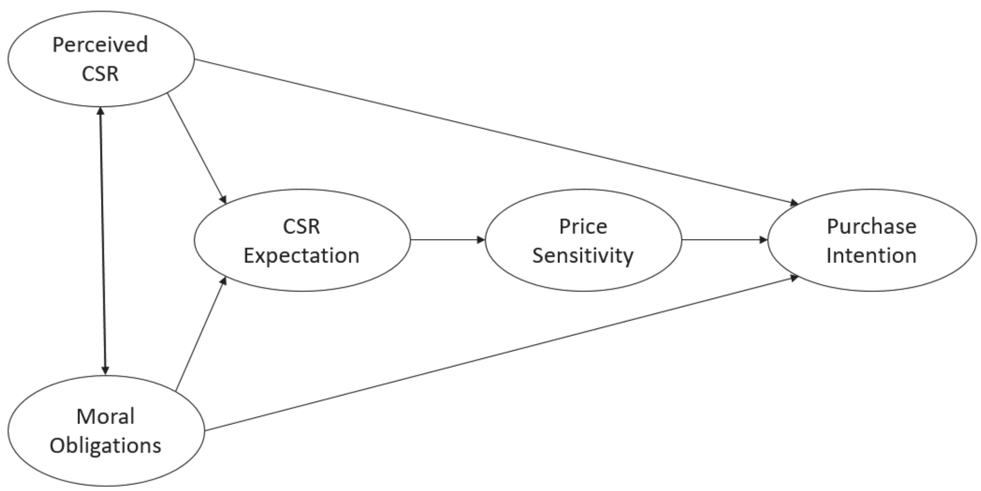
In the literature, evidence demonstrated that consumers were willing to pay higher prices for similar quality products perceived as social responsibility oriented (Becker-Olsen et al., 2006; Creyer, 1997; Öberseder et al., 2013; Rodrigues & Borges, 2015), but only when the products were ethically assured (McGoldrick & Freestone, 2008). For example, the presence of purchase intention when the CSR associated sneaker priced 10% higher was proven by a group of Brazilian scholars. They further confirmed that price fairness mediated the link between CSR perception and purchase intention significantly (Carvalho et al., 2010). As for consumers who are highly sensitive to prices, they might not buy socially responsible foods because they can immediately find cheaper ones at retail stores. Thus, we expect consumers' price sensitivities to vary directly with the extent to which they perceive and desire a company to be socially responsible. Thus, we suppose the likelihood of purchasing a more expensive product from a CSR company will be mediated by the consumer's degree of price consciousness.
Price sensitivity in this paper is defined as price differences that consumers willing (or accept) to pay at a given time. However, many studies investigating customer response to price escalation are still limited. Therefore, we measured the customer's price sensitivity based on a price climb as the same approach developed in previous studies (Gabor & Granger, 1979; Lichtenstein, Bloch, & Black, 1988; Monroe, 1973). We anticipated the well-established association between price sensitivity and purchase intention in the context of social responsibility. Particularly, the mediating effect of price sensitivity was firstly explored in the interrelationship among

consumers' CSR driven perception, moral obligations (ethical values, and patronage intention to CSR-related products in the marketplace. We have not been able to find any published studies that explored the potential mediating role of price sensitivity in the context of ethical consumption. Hence, the following hypotheses were constructed based on the above discussion.

Hypothesis 4: Price sensitivity significantly impacts on purchase intention toward CSR-related products.
Hypothesis 5a: Price sensitivity plays a mediating role in the positive relationship between Perceived CSR and Purchase Intention.
Hypothesis 5b: Price sensitivity plays a mediating role in the positive relationship between Moral Obligation and Purchase Intention.
Hypothesis 5c: Price sensitivity plays a mediating role in the positive relationship between CSR Expectation and Purchase Intention.

CONCEPTUAL MODEL

Figure 1: Research conceptual model



METHODOLOGY

Data collection and characteristics of respondents

This research approached respondents via paper-based surveys. We collected data from consumers shopping in supermarkets and shopping malls in Taiwan. Respondents were initially asked to look through an advertising poster introducing one fictitious dairy-food brand (its information, products, selling price, and its CSR profile). Then they were asked to fill in a questionnaire as a pool of 20 items (which was included detail in Table 3 showing the construct measurements of this study and four items of personal information related to age, gender, education, and monthly disposable income. Participants were asked to scale each item on a seven-point Likert scale (ranging from 1= strongly disagree to 7= strongly disagree). A total of 311 valid samples used for the data analysis process. The sampling process conducted without missing data.

The demographics of the population summarized in Table 1. Respondents were all Taiwanese and slightly more likely to be male (51.4%). Regarding age, the majority of the respondents were younger generations aged 21 to 30 years old (59.5%), followed by 31 to 40 years old (24.7%), over 40 (9.3%), and under 20 years old (5.8%). The statistics for the level of education found most have a Master's degree (45.7%) and 30.5% had a Bachelor's degree. We also surveyed disposable personal income of how much respondents spent per month, and the results showed the most significant percentage (~32%) of respondents had a spending range from over NTD 10,000 to 20,000 per month with the other most common range being from NTD 5,000 to NTD 10,000 (29.6%).

Table 1: Characteristics of Respondents

Demographical variables		Frequency	Percentage
Gender			
1	Male	160	51.4%
2	Female	151	48.6%
Age			
1	Under 20	18	5.8%
2	21-30	187	59.5%
3	31-40	56	24.7%
4	Over 40	29	9.3%
Level of education			
1	High school or below	73	23.5%
2	Bachelor's degree	95	30.5%
3	Master's degree	142	45.7%
4	PhD's degree and above	1	0.3%
Monthly disposable income (NT$)			
1	Below 5,000	29	9.3%
2	5,001 – 10,000	92	29.6%
3	10,001 – 20,000	99	31.8%
4	20,001 – 30,000	34	10.9%
5	30,001 – 40,000	30	9.6%
6	40,001-50,000	18	5.8%
7	Above 50,000	9	2.9%

Measurement of constructs

At the aim of testing the hypotheses, the study used the following five primary constructs: perceived CSR, CSR expectation, moral obligation, price sensitivity, and purchase intention toward CSR-related products. All of the items were tested by other scholars and employed in this study in an existing or slightly modified manner by a 7-point Likert scale (i.e., 1= strongly disagree; 7= strongly agree). *Perceived CSR* was defined as the extent to which customers acknowledged and recognized that a company supported activities related to social responsibilities. It was measured using four scale items adapted from (Brown & Dacin, 1997). *CSR expectation* demonstrated that consumers desired and wanted every firm to behave ethically in complying with social responsibilities. It was evaluated by four scale items originated from (Creyer, 1997). The concept of *Moral obligation* in this paper was understood as a consumer feel of a sense of responsibility to act morally. Three questions were adapted from

(Arvola et al., 2008). The *purchase intention* construct was measured by four questions adapted from (Jamieson & Bass, 1989) and (Carvalho et al., 2010). Merely purchase intention was customer willingness to buy CSR-related products. By identifying *price sensitivity* as price differences that consumers were willing (or accepting) to pay at a given time was an important aspect to study. We measured it by a 5-level pricing climb with price increases $NT 5 higher compared to the fixed price (present market price of sample product) as the same approach developed in previous studies (Gabor & Granger, 1979; Lichtenstein et al., 1988; Monroe, 1973). Participants were asked to answer whether they accepted to pay for sample product at different price levels or not, based on the 7-point Likert scale (i.e., 1= totally not accept; 7= totally accept).

DATA ANALYSIS & RESULTS

Reliability and validity test

A Confirmatory factor analysis (CFA) using AMOS 21 software was adopted to verify the underlying structure of constructs in the proposed hypotheses. Reflective measurement model tests were conducted to evaluate the reliability, convergent validity, and discriminant validity of the latent constructs between perceived CSR, moral obligation, CSR expectation, purchase intention, and price sensitivity.

Reliability of the constructs was estimated by composite reliability (CR) and Cronbach's alpha. All latent constructs achieved acceptable levels of reliability based on Cronbach's alpha that was higher than the recommended .70 level (Hair et al., 2010): perceived CSR (.92), moral obligation (.89), CSR expectation (.73), purchase intention (.88), and price sensitivity (.94) (see Table 3). Similarly, the composite reliability of the latent constructs ranged from .727 to .938 (see Table 2). These findings indicated that all constructs included in the proposed model were reliable.

Convergent validity indicated the extent to which measuring items of a scale that were theoretically related in reality and could be assessed by the standardized factor loading exceeded .400, was significant at .001, *and* the average extracted variances (AVE) were above .50 (Anderson & Gerbing, 1988). In two constructs, namely CSR expectation and moral obligation, to increase the model fit due to the complexity of the whole model, we deleted two items because of their unsatisfied factor loadings. As provided in Table 3, all of the factor loadings that remained in the research model ranged from .60 to .98, and all were statistically significant at p-value <.001 on its underlying construct. The average variance extracted AVE across the constructs mostly exceeded 0.5. The findings suggested these items explained a large portion of the variation and convergent validity was satisfied.

Discriminant validity (divergent validity tested whether constructs that were not supposed to be related were unrelated. The discriminant tests were satisfied if the correction coefficient among latent constructs was lower than the square root of AVE (Chin, 1998). The square root of AVE of the latent constructs ranged from .689 and .894, higher than correlation among latent variables (see Table 2). The findings indicated adequate discriminant validity.

Table 2: Validity, Reliability and Correlation Matrix

	CR	AVE	MSV	MaxR(H)	(1)	(2)	(3)	(4)	(5)
(1)CSR expectation	0.727	**0.745**	0.279	0.758	**0.689**				
(2)Perceived CSR	0.920	**0.742**	0.278	0.937	0.528	**0.862**			
(3)Price Sensitivity	0.938	**0.753**	0.754	0.977	-0.438	-0.429	**0.868**		
(4)Moral Obligation	0.888	**0.799**	0.104	0.981	0.313	0.102	-0.322	**0.894**	
(5)Purchase Intention	0.882	**0.661**	0.752	0.989	0.369	0.393	-0.687	0.288	**0.873**

Table 3: Constructs and Factor Analysis

Construct	Reference	Item	Description	Factor loading	Cronbach's alpha
Perceived CSR	(Brown & Dacin, 1997)	CSR1	Brand X demonstrates that it is concerned with the environment	0.85	**0.92**
		CSR2	Brand X is involved in the community and invests in worthwhile causes	0.85	
		CSR3	Brand X focus on employee benefit and provides an excellent working environment	0.86	
		CSR4	Brand X implements good corporate governance and information transparency	0.89	
Moral Obligation	(Arvola et al., 2008)	MO1	Buying milk from Brand X, I would feel like making a personal responsibility to something better	0.92	**0.89**
		MO2	Buying milk from Brand X, I would feel like the morally right thing	0.87	
		MO3	Buying milk from Brand X, it would not make me feel guilty	delete	
CSR Expectation	(Creyer, 1997)	EXP1	I expect firms have a responsibility not ever to act unethically	0.65	**0.73**
		EXP2	I hope firms have a responsibility to always act with the highest of ethical standards	0.81	
		EXP3	I expect the firms that I buy to act ethically at all times	0.60	
		EXP4	All firms will be unethically sometimes: it is normal	delete	

Purchase Intention	(Jamieson & Bass, 1989)	PI1	Buying a product of brand X will make you feel good about yourself?	0.61	**0.88**
		PI2	Buying a product of brand X will make you feel that you are doing the right thing?	0.65	
		PI3	Does Brand X have a high probability of you purchasing it?	0.98	
		PI4	Are you more willing to buy a product of brand X?	0.94	
Price Sensitivity		P1	I will buy a CSR product if its price at a fixed price	0.91	**0.94**
		P2	I will buy a CSR product if its price at $NT 5 more	0.95	
		P3	I will buy a CSR product if its price at $NT 10 more	0.95	
		P4	I will buy a CSR product if its price at $NT15 more	0.79	
		P5	I will buy a CSR product if its price at $NT 20 more	0.71	

Consequently, the goodness-of-fit result for our final measurement found good improvement in the overall model fit with some most important criteria: Chi-square/d.f. equals to 2.907 smaller than 3, RMSEA= 0.078, CFI = 0.935. The GFI in the model equals to 0.899, which is lower than value 0.90. However, according to (L.-T. Hu & P. M. Bentler, 1995) reported emerging evidence that 0.90 might not always be a reasonable cut-off for all adjunct fit indexes under all modelling circumstances. The choice of a cut-off value lower than 0.90, may be justified: "The rule of thumb to consider models acceptable if a fit index exceeds 0.90 is an inadequate rule" (L. Hu & P. Bentler, 1995, p. 95). We might delete more items to archive the better model fit. Nevertheless, we decided to keep these items to make a broader view of the whole model. However, the most important was that Chi-square/d.f., the CFI and RMSEA provided sufficient and unique information to evaluate the model (Hair, Black, Babin, Anderson, & Tatham, 2010, p. 654).

Testing the proposed research hypotheses

Following the CFA test to attain the best-fitting model, we applied the result in the CFA model to the hypothesized structural equation model. According to (Rowley & Berman, 2000) and (Galbreath & Shum, 2012), the structural equation model(SEM) is much more appropriate than traditional regression analysis in CSR studies. To examine the theoretical model indicated that the t-value of all completely standardized coefficients was statistically significant from 0.001 to 0.05 levels. As can be seen in the below figure (table 4), the results of estimating the basic framework (total effect model) revealed that consumer's perceived CSR, CSR expectation, and moral obligation had a significantly positive relationship with purchase intention of CSR-related products. These results are essential for testing the mediating effect of price sensitivity on the links between purchase intention and its antecedences. The fitness indicators found acceptable model fits with GFI=.946, CFI=.976, and RMSEA=.061.

The hypothesized positive relationship between CSR expectation and purchase intention (**Hypothesis 1a**) was supported (β=.135, t =1.965, $p < .05$). **Hypothesis H2a**, which predicted a positive relationship between perceived CSR and purchase intention was also supported (β= .304, t = 4.542, $p < .001$). Perceived CSR also found a statistically significant positive influence on CSR expectation (β= .488, t = 7.936, p < .001) providing support for **Hypothesis 2b**. As predicted by hypotheses **Hypotheses 3a** and **3b**, moral obligation significantly impacted both purchase intention (β= .217, t =3.717, p < .001) and CSR expectation (β= .258, t =4.352, p < .001).

Table 4: Structural Equation Model Results

Hypotheses		Standardized coefficient	(S.E)	t-value	Model fit measurement
Direct effect model (without mediator)					
H2a	Perceived CSR→ Purchase Intention	.304***	0.145	4.542	Ch-square/df = 2.169; p = .000; GFI=.946; AGFI=.914; NFI=.957; CFI=.976; RMR=.081; RMSEA=.061

Mediating effect model testing

There are plenty of statistical methods to investigate the mediation effects, namely hierarchical regression and SEM approaches. In this study, to examine the mediation effect of price sensitivity, we first adopted the statistical method developed by (Preacher & Hayes, 2004). We used the PROCESS macros version 3.3 for SPSS provided by (Hayes, 2017) to test the significance of indirect effects of perceived CSR; moral obligation; CSR expectation through price sensitivity, on purchase intention. In all analyses, we employed a bias-corrected bootstrap approach with 5000 samples, with a level of 95% confidence interval (CI). The indirect effects of three predictors of purchase intention through price sensitivity can be seen in Table 5 as below.

Table 5: Testing the Significance of Indirect Effects through Price Sensitivity

Independent Variables	**Purchase Intention**			
	Indirect effect	SE	LLCI	ULCI
Perceived CSR	.4404	.0695	.3141	.5872
Moral Obligation	.3349	.0599	.2207	.4573
CSR Expectation	.5467	.0809	.3972	.7108

Note: All items are statistically significant with p < .05, as the lower limit of the confidence interval (LLCI) and upper limit of the confidence interval (ULCI), do not cross zero

Besides, we also applied the SEM method following the procedure of (Baron & Kenny, 1986) and Sobel test (Sobel, 1982) to further confirm the mediation effects of price sensitivity in the interrelationship among variables. We ran three models: (1) direct effect for examining the significant relationship between purchase intention and its antecedences when mediator's effect was not regarded; (2) indirect effect model for testing the considerable association of dependent variable and its predictors with mediator (price sensitivity); and (3) total model for testing both direct and indirect effects.

As shown in Table 4, the z-test for Perceived CSR→ price sensitivity→ purchase intention (β= .253, z-test= 4.381, significant level p< .0001) showed that the mediating effect of price sensitivity on the relationship between perceived CSR and purchase intention toward CSR related product was confirmed in **Hypothesis 5a**. Moral obligation→ price sensitivity→ purchase intention (β= .193, z-test= 3.870, significant level p< .001), which indicated that the mediating role of price sensitivity on the relationship between moral obligation and purchase intention toward CSR related product was significant. Therefore, **Hypothesis 5b** was supported. Furthermore, the z-score for CSR expectation→ price sensitivity→ purchase intention (β= .028, z-test= 2.730, significant level p< .01), which indicated that the mediating effects of price sensitivity on the relationship between CSR expectation and purchase intention toward CSR related product were significant. Therefore, **Hypothesis 5c** was supported.

Additionally, as noted from the total effect model's results; with the intervention caused by price sensitivity, independent variables (perceived CSR, moral obligation and CSR expectation) no longer had significant impacts on purchase intention (all standardized coefficients turn to insignificant with t-value < 1.96). Based on suggestions by (Baron & Kenny, 1986), it was concluded from results that price sensitivity was a complete mediator when it fully mediated the relationship between purchase intention and its antecedences in the model (see figure 2).

Control variables

Regarding the control variables, we included gender, age, level of education, and disposable personal income to examine its effects on purchase intention and price sensitivity. It was shown that none had a significant effect on purchase intention, and these results were similar to previous studies in which the non-linear relationship between consumer demographics and CSR responses was proven (Tian et al., 2011). However, the population age had a significantly negative impact on price sensitivity (β= -.098; t= -2.126, $p < 0.05$).

DISCUSSION & CONCLUSION

As a primary stakeholder, consumer-based responses to CSR initiatives are prudent to provide both the academic world and businesses with contributions from the current study. An enterprise that has a tremendous performance of CSR will build a good corporate image in the minds of consumers to obtain trust and ultimately, consumer willingness to buy the product; thus enhancing the competitiveness of enterprises. Firstly, this study modified the TRA model based on the descriptive approach that concentrated on impacts of CSR-driven perceptions (perceived CSR; CSR expectation) and moral obligations (internal ethics) as personal motives driving consumer patronage intention towards CSR-related products. The effects of CSR initiatives practiced by firms on consumers' purchase intentions was reconfirmed in this paper as the same conclusions were previously found in several studies (Mohr et al., 2001; Öberseder et al., 2013; Rodrigues & Borges, 2015; Tian et al., 2011). Also, it should be emphasized that consumer's perceptions to CSR initiatives were examined comprehensively on multiple dimensions including environmental dimension, social dimension, economic dimension, stakeholder dimension, and voluntariness dimension (Dahlsrud, 2008). Therefore, in business practices, CSR should be more widely implemented as strategic importance to every enterprise for sustainable growth. Consumer social concerns should be integrated into business operations, particularly in the food industry.

Secondly, previous research on corporate social responsibilities tended to ignore the significant role of individuals' intrinsic ethical motives. This study further contributed theoretical implications by identifying the role of consumer's self-concept of moral obligations in predicting consumers' behavioral consequences (i.e., purchase intention). Thus, authors suggest that when developing CSR policies for firms' marketing campaigns, marketing managers should regard CSR initiatives based on studying customer level of moral obligations. Further, consumers can perceive positive perceptions toward firms and simultaneously expect firms to engage in CSR activities, as well as make favorable patronage intention for their products and services.

Finally, yet importantly, this study also contributed to the fast consuming sectors (food industry) background by recognizing the effects of price sensitivity on the linkage between consumers' perceived CSR, CSR expectation, moral obligations, and intentions to buy CSR-related products. We found that price sensitivity fully mediated these associations referring to CSR responses from the perspectives of consumers. In literature, it seems hard to find any published studies that explore the potential mediating role of price sensitivity in the context of ethical consumption. We found that ethical consumers had a dilemma in making a purchase decision. They tend to be price sensitive in the current economic situation, particularly when it came to ethical products; namely, buyers could be ethical up to a certain level of price-consciousness.

Therefore, we expect that evidence of the complete mediation effect of price sensitivity explored in the current paper will contribute crucial references, not only for theoretical studies on consumer-based behavior but also for managerial practices. From perspectives of business-decision makers, pricing is one of the most critical strategic management activities since it affects market demand; generated sources of optimal profits, but also a competitive weapon gaining customers' insights. Meanwhile, price is ultimately a vital preference considered by customers. We also found that consumer's price sensitivity had considerable influence on altering behavioral intention in ethical consumption. They tended to be in an ethical dilemma and had to a trade-off between ethical concerns with price perceptions. Hence, the pricing strategy implemented by firms should be more concerned about customer's segmentation in term of price-consciousness. We believe that favorable pricing strategies and other promotional techniques can make consumers less price-focused and more concerned with core product benefits that align with ethics.

Scheduling Impact on Student Online Learning Performance: A Case Study

San Yun (Nancy) Tsai
California State University, Sacramento
Email: sytsai@csus.edu

ABSTRACT

This research study investigates course schedule scheme impacts on student learning effectiveness in a high enrollment undergraduate computer literacy course over three consecutive semesters. Learning outcome and learning behavior are two elements included to evaluate learning effectiveness. Average course grade (exam) measures learning outcome of each schedule. Passing rate and failing rate evaluate learning behavior of each semester. Descriptive discussion and statistical hypothesis testing reveal that the course schedule does have significant impacts on student learning effectiveness under a teacher-pushed online learning approach.

KEYWORDS: Online learning, Hybrid-blended online learning, Course scheduling, Learning effectiveness

INTRODUCTION

The popularity of daily Internet usage paired with inexpensive information and communication technologies have created a new enhanced virtual environment for a variety of online teaching/learning approaches in the current digital age. Every approach regardless of its format can offer two major benefits to higher education institutions. First, it provides a tool to communicate and educate unlimited number of students without time and location constraints in the universe. Second, it is cost effective by reducing instructional, physical, and overhead expenses. Consequently, almost every higher education institution has embraced these virtual approaches and permanently incorporated them into its existing traditional teacher-pushed classroom learning.

Three major teaching/learning approaches have been adopted at the college level education systems over the past century. These include the traditional teacher-pushed classroom learning, student-pulled online learning and hybrid-blended (teacher-guided) online learning. The traditional teacher-pushed classroom learning can be described as a teacher utilizing the textbook, reading assignment, lecturing, homework exercise and test to guide and evaluate student learning with a specific schedule in a classroom. The student-pulled online learning can be defined as students having total control of their studying pace, when to study, and where to study via an electronic courseware and Internet without any learning push and/or guidance from a teacher. The hybrid-blended (teacher-guided) online learning is a combination of the first two approaches where a teacher adopts some learning rules to direct, stimulate, and influence student online learning process via an electronic courseware and Internet (Eom, Ashill, & Wen, 2006; Smith, 2001).

Without exception, College of Business Administration (CBA) located in northern California has to utilize information and communication technologies for developing various learning effective and cost saving online courses to ease pressures from its funding reduction and limited educational resources. This prompts to move a high enrollment (around 1,400 students per semester) undergraduate computer literacy course (MIS 123) from a teacher-pushed classroom learning to an online student-pulled learning one. Unfortunately, low student learning performance is a major pitfall of this course teaching/learning transformation. It becomes an important and on-going mission for course instructor to renovate MIS 123 teaching strategy and learning approach that will benefit students and facilitate their learning performance.

MIS 123 teaching/learning approach has then been adopted a teacher-guided (hybrid-blended) online learning from student-pulled one (Guay, Morin, Litalien, Valois, & Vallerand, 2015; Klein, Noe, & Wang, 2006; Ratelle, Guay, Vallerand, Larose, & Senecal, 2007; Rienties, Tempelaar, Van den Bossche, Gijselaers & Segers, 2009; Simmering, Posey, & Piccoli, 2009; Wyss, Lee, Domina, & MacGillivray, 2014).

This empirical study investigates impacts of different schedule schemes on MIS 123 student learning performance including learning outcome and learning behavior in three consecutive semesters. Average course grade measures student learning outcome of a specific learning schedule. Passing rate and failing rate measure student learning behavior for each learning schedule. Descriptive discussion and statistical hypothesis testing reveal that course schedule does have a significant impact on student learning performance under the teacher-pushed online teaching/learning approach.

COMPUTER LITERACY COURSE

MIS 123 is open to every student enrolled in the university. It is a prerequisite requirement for every undergraduate student before declaring a concentration of CBA. Major objective of this course is providing students with knowledge, skill and ability to apply microcomputer technology in other courses and their professional career. Only one instructor is responsible for establishing course material, managing course activity, and directing student learning process.

The course is separated into three one unit, credit/no credit sub courses: MIS 1 Word Processing, MIS 2 Spreadsheets, and MIS 3 Presentation Graphics. The upper enrollment limit is 500 students for each sub course in a semester. A student survey has identified several sub course characteristics. MIS 1 and MIS 3 are the two easier sub courses and the most useful in taking other courses. MIS 2 is the hardest one and most useful in professional career.

No classroom meeting is scheduled for MIS 123. A detailed course syllabus is posted on Canvas sub course web site for students to obtain a set of step by step “how to” information. That includes (1) logging on course web site; (2) getting courseware technical support for any hardware and software issue; (3) learning and mastering lessons; (4) taking exams; (5) obtaining lesson and exam schedule; (6) viewing performance records; (7) finding course grade; and (8) communicating with instructor. Students receives an email with a copy of course syllabus before the first day of a sub course. In addition, a posted announcement will be given to students via an email too.

There are two approaches for students to solve any learning problem during a semester. First, students can have a face to face discussion with instructor during 3 weekly office hours or by a special appointment. Second, students can seek a solution from instructor via two email systems including CBA and Canvas without time and place restrictions. Most students (99%) prefers second approach to acquire supports and helps.

Each sub course adopts different portion of a courseware developed and supported by a reputable publisher. Both MIS 1 and MIS 3 have 8 lessons. There are 12 lessons included in MIS 2. Sub course materials are posted on Canvas sub course web site 24x7 that provides students with unlimited access during a semester. Courseware offers four lesson learning methods to students that includes e-text (reading), audio PowerPoint presentation (listening), videos (watching), and simulation training (practicing with learning aids). Each lesson comes with an exam that students must complete it for earning sub course credit. Students can pick any learning method that fits into his/her learning preference to master lessons. MIS 123 students have total control of their learning process in terms of when, where, how fast and how long to take lessons and exams within a sub course schedule. The instructor does not provide any learning guidance to students except information as stated in sub course syllabus. Therefore, it is a student-pulled online learning approach.

Unfortunately, most MIS 123 students lack self-motivation and high-discipline required to complete online lessons and submit exams on time for each sub course. This fact produces a poor performance record with low passing rate and high failing rate for every sub course. One major responsibility of instructor is to renovate each sub course for improving student learning effectiveness. It is a necessary and urgent task for instructor to incorporate some educational motivation strategies and/or implement an appropriate schedule scheme for the renovation. Consequently, this active instructor involvement in student online learning has advanced MIS 123 teaching/learning approach from a student-pulled to a teacher-guided one.

STUDY

MIS 123 implemented three different course schedule schemes (1, 2 and 3) to define allowable learning period for students over three consecutive semesters. Students took same courseware lessons and exams for acquiring knowledge and skill of a sub course in every semester. Each scheme had its own lesson studying schedule and exam submitting schedule. Students had unlimited attempts to complete and submit an exam at any time before specified deadline. The courseware will record the highest score for that exam. Students had another chance to make up and submit any missing exam during the reopen period that was last three days before the end of a sub course. The intention of second chance was to eliminate any make up request and to increase learning effectiveness. The passing course grade was 70 or higher of average exam score. These exam rules were clearly stated in sub course syllabus. Weekly Canvas announcement with an email to students served as a reminder to inform them about coming exam(s) due date. Differences among these three schedule schemes were the number of sub courses offered, offering period of each sub course, and length of offering period as described in followings.

Schedule scheme 1 allowed students to take three sub courses (MIS 1, MIS 2, and MIS 3) simultaneously from week 1 to week 15 of first semester. Students were required to submit a MIS 1 exam and a MIS 3 exam every 13 day, and submit a MIS 2 exam every 9 days. Students had the most studying time to complete two or three exams of three sub courses each week during the entire semester.

Schedule scheme 2 allowed students to take two sub courses simultaneously during the second semester. MIS 1 was scheduled from week 1 to week 8; MIS 2 was scheduled from week 3 to week 14; and MIS 3 was scheduled from week 9 to week 16 (including final exam week). MIS 2 offering time overlapped with MIS 1 or MIS 3. Students required to submit 2 exams (MIS 1 and MIS 2, or MIS 2 and MIS 3) between week 3 and week 14. Students had either a week to master one lesson and submit one exam of one sub course, or one lesson and one exam each of two sub courses.

Schedule scheme 3 allowed students to take one sub course every 5 weeks of the third semester. MIS 1 was offered during the first five weeks between week 1 and week 5. MIS 2 took the middle five weeks from week 6 and week 10. MIS 3 had the last five weeks between week 11 and week 15. Students had to submit a MIS 1 exam or MIS 3 exam every 5 days and submit a MIS 2 exam every 3 days. Students had the least studying time, but could concentrate on only one sub course material within its offering period.

The average course grade (exam), number of students receiving "credit" (passing), and number of students receiving "no credit" (failing) were gathered for every schedule scheme of each sub course. These data were the basis to measure a specific schedule scheme impact on student learning effectiveness.

ASSESSMENT OF STUDENT LEARNING PERFORMANCE

Student learning effectiveness can be evaluated by student learning outcome and student learning behavior. The average course grade measures student learning outcome. A two tails hypothesis testing with 99% (2.58 Z value) and 95% (1.96 Z value) confidence levels evaluates student learning outcome change between a pair of two schedule schemes for every sub course. The number of students receiving "credit" and "no credit" describes and assesses student learning behavior change among three schedule schemes of each sub course.

MIS 1 Word Processing: Easy Subject and Useful Skill for Other Courses

Tables 1 presents statistical summary of MIS 1 learning performance. Schedule scheme 3 has the highest average course grade with the least standard deviation. Students can achieve 17 to 7 points more of average course grade and 6 to 8 points less of standard deviation as comparing with schedule schemes 2 and 1. These results show that students will improve learning performance when there is only one sub course material to study with the shortest learning period of 5 weeks long. Schedule scheme 2 produces the worst learning performance. Its average course grade is 10 to 17 points less than other two schedule schemes 1 and 3. Students cannot handle to master a lesson and submit an exam each of two sub courses within a week. On the other hand, students can do better to comprehend a lesson and submit an exam each for three sub course if the learning period is longer than a week such as one and half or two weeks defined in schedule scheme 1.

Table 1: MIS 1 Learning Performance

Schedule Scheme	Enrollment	No. of Credit	No. of No Credit	Average Course Grade	Standard Deviation
Schedule 1	426	353	73	84.97	23.22
Schedule 2	476	433	43	74.99	20.93
Schedule 3	470	426	44	91.64	15.00

Hypothesis 1: There is no statistical significant difference of MIS 1 learning outcome as

measured by average course grade between a pair of two schedule schemes.

Hypothesis testing result: Reject no difference hypothesis at both 99% and 95% confidence levels for every pair of two sub courses as illustrated in Table 2.

Hypothesis testing finding: Schedule scheme 3 with offering one sub course every 5 weeks is the most suitable schedule for students to achieve the highest learning outcome. Schedule scheme 1 with offering three sub courses concurrently during the entire semester is significantly a better one than schedule scheme 2 with offering two sub courses every week within a semester for obtaining a higher learning outcome. There is a positive relationship trend between learning outcome, number of sub courses, and allowable study time in MIS 1.

Table 2: MIS 1 Z Value of Learning Outcome	
Schedule Scheme Pair	Z - Value
Schedule 1 vs 2	6.75
Schedule 1 vs 3	5.05
Schedule 2 vs 3	14.08

Learning behavior discussion: Table 3 presents the passing rate and failing rate of three schedule schemes. It is interesting to note that schedule scheme 2 with the lowest learning outcome produces the same passing rate (91%) and failing rate (9%) as schedule scheme 3 with the highest learning outcome. Schedule scheme 1 is not a suitable strategy for improving learning behavior since it generates the least passing rate (83%) and the highest failing rate (17%) as comparing with other two schedule schemes 2 and 3. Schedule scheme 3 is the most suitable scheduling strategy for MIS 1 students due to it can generate the highest learning effective impacts on learning performance as measured by learning outcome and learning behavior.

Table 3: MIS 1 Passing Rate and Failing Rate		
Schedule Scheme	Passing Rate	Failing Rate
Schedule 1	83%	17%
Schedule 2	91%	9%
Schedule 3	91%	9%

MIS 2 Spreadsheets: Tough Subject and Useful Skill for Professional Work Place

Tables 4 presents statistical summary of MIS 2 learning performance. Schedule scheme 3 has the highest average course grade with the least standard deviation. Students can achieve 8 or 7 points more of average course grade and 6 to 5 points less of standard deviation as comparing with schedule schemes 1 and 2. Students can do well if they only need to study one sub course material with a shortest 5 weeks learning period. There exists a 1 point difference in average course grade and its standard deviation between schedule schemes 1 and 2. Learning outcome does not change that much if students have to master a lesson each and submit an exam each of two or three sub courses in one or two weeks.

Table 4: MIS 2 Learning Performance

Schedule Scheme	Enrollment	No. of Credit	No. of No Credit	Average Point	Standard Deviation
Schedule 1	469	330	139	77.40	27.60
Schedule 2	483	342	141	78.27	26.49
Schedule 3	496	408	88	85.36	21.08

Hypothesis 2: There is no statistical significant difference of MIS 2 learning outcome as measured by average course grade between a pair of schedule schemes.

Hypothesis testing result: Accept no difference hypothesis at both 99% and 95% confidence levels for the pair of schedule schemes 1 and 2. Reject the no difference hypothesis at both 99% and 95% confidence levels for the pair of schedule schemes 1 and 3, and for the pair of schedule schemes 2 and 3 as illustrated in Table 5.

Table 5: MIS 2 Z Value of Learning Outcome

Schedule Scheme Pair	Z - Value
Schedule 1 vs 2	0.50
Schedule 1 vs 3	5.01
Schedule 2 vs 3	4.63

Hypothesis testing finding: Schedule scheme 3 with only offering MIS 2 from week 6 to week 10 is the most suitable schedule strategy to produce the highest learning outcome. Schedule schemes 1 and 2 with offering three or two sub courses concurrently during the semester result a no difference impact on learning outcome.

Learning behavior discussion: Schedule schemes 1 and 2 have achieved a very close two passing rates (70% or 71%) and two failing rates (30% or 29%) as illustrated in Table 6. These two schedule schemes have a same effect on MIS 2 learning behavior. On the other hand, the schedule scheme 3 yields 12% to 11% higher passing rate and the 11% to 12% lower failing rate as comparing with schedule schemes 1 and 2. Therefore, schedule scheme 3 not only achieves the highest learning outcome as measured by average course grade (85.36), but also generates a better learning behavior as measured by passing rate (82%) and failing rate (18%). Schedule scheme 3 is a suitable scheduling strategy to result the most positive learning effectiveness impacts on MIS 2.

Table 6: MIS 2 Passing Rate and Failing Rate		
Schedule Scheme	Passing Rate	Failing Rate
Schedule 1	70%	30%
Schedule 2	71%	29%
Schedule 3	82%	18%

MIS 3 Presentation Graphics: Easy Subject and Useful Skill for Other Courses

Tables 7 presents statistical summary of MIS 3 learning performance. Schedule scheme 3 has the highest average course grade with the least standard deviation. Students can achieve 1 to 3 points more of average course grade and 1 to 3 points less of standard deviation as comparing with schedule schemes 1 and 2. Students can put their entire studying effort in one sub course and perform well on exams with a short 5 weeks learning period. Schedule scheme 2 produces the lowest learning outcome with a 2 to 3 points less average course grade and standard deviation than other two schedule schemes 1 and 3. In general, students achieve very similar average course grade and standard deviation with every schedule scheme.

Table 7: MIS 3 Learning Performance					
Schedule Scheme	Enrollment	No. of Credit	No. of No Credit	Average Point	Standard Deviation
Schedule 1	456	363	93	87.58	19.51
Schedule 2	459	346	113	85.11	21.29
Schedule 3	498	406	92	88.55	18.73

Hypothesis 3: There is no statistical significant difference of MIS 3 learning outcome as measured by the average course grade between a pair of schedule schemes.

Table 8: MIS 3 Z Value of Learning Outcome	
Schedule Scheme Pair	Z - Value
Schedule 1 vs 2	1.81
Schedule 1 vs 3	0.78
Schedule 2 vs 3	2.64

Hypothesis testing result: Accept no difference hypothesis at both 99% and 95% confidence levels for the pair of schedule schemes 1 and 2, and for the pair of schedule schemes 1 and 3. Reject no difference hypothesis at both 99% and 95% confidence levels for the pair of schedule schemes 2 and 3 as illustrated in Table 8.

Hypothesis testing finding: Schedule scheme 3 is slightly a better strategy as comparing with scheme 2. There is no difference impact on learning outcome either between schedule schemes 1 and 3 or between schedule schemes 1 and 2. There is no superior scheduling strategy to have a significant impact on MIS 3 learning outcome.

Learning behavior discussion: Passing rate and failing rate of each schedule scheme are shown in Table 9. Schedule scheme 1 is a litter better strategy than schedule scheme 2 since it has achieved 5% higher passing rate and 5% less failing rate than schedule scheme 2. However, schedule scheme 3 achieves a 2% to 7 % higher passing rate and a 2% to 7% lower failing rate as comparing with schedule schemes 1 and 2. Therefore, schedule scheme 3 is an appropriate scheduling strategy to improve MIS 3 learning effectiveness since it has the highest average course grade (88.55), the highest passing rate (82%), and the lowest failing rate (18%).

Table 9: MIS 3 Passing Rate and Failing Rate

Schedule Scheme	Passing Rate	Failing Rate
Schedule 1	80%	20%
Schedule 2	75%	25%
Schedule 3	82%	18%

CONCLUSION

Student online learning performance as measured by learning outcome (average course grade) and learning behavior (passing rate and failing rate) have sufficient statistical evidences to support that the schedule scheme 3 is the most effective and promising scheduling strategy under the teacher-pushed online learning approach. It outperforms other two schedule schemes in every sub course regardless the course material difficulty, lengthy, and usefulness. Its superior result can be contributed to several factors. It only requires students to focus on one sub course material without joggling their studying time between two or three course materials within every 5 weeks. It allows students to complete each lesson of only one sub course by following a clearly defined and short learning period. Its exam submission deadline guides and regulates their studying time and effort (evenly pacing the studying within the five weeks). The reopening exam at the last three days gives students second chance that increases passing rate and reduces the failing rate.

The current teacher-guided online learning approach via guidance, encouragement, motivation and optimal schedule scheme does positively receive a better student online learning performance. However, this computer literacy course needs other educational motivation strategies to further improve passing and failing rates, especially for MIS 2 Spreadsheets (the hardest materials) and MIS 3 Graphic Presentation (limited studying time at the end of a semester). Based on this empirical study finding and instructional experience, two strategies might enhance learning effectiveness of all sub courses. These includes granting students more studying time for a subject and changing grade system. Restructure MIS 123 by splitting MIS 123 into two courses that can give students more studying time for a subject. Combine two easier subjects (MIS 1 Word Processing and MIS 3 Presentation Graphics) in one course where each subject offers longer studying time (7 and half weeks as comparing current 5 weeks for a subject). Create another independent course for MIS 2 Spreadsheets that allows students to have 15 weeks studying time to comprehend and master a difficult subject. Make the grade system of these two new courses to a regular letter grades (A, B, C, D and F) instead of credit/no Credit grade.

ABSTRACT
The results of the current investigation lead to concludes that the IFRS-8's management approach is useful to internal and external decision makers especially that it explains its relationship with real earnings practices. For example, the management approach of IFRS-8 enhanced the perceptions of the managers about reliable segmental information.

KEYWORDS: Segmental Reporting, IFRS-8, Earnings Management, UK

1. INTRODUCTION
International Financial Reporting Standards (IFRS) have played an important role in the development of Earnings Management practices since their inception (Jeanjean and Stolowy, 2008). While Earnings Management (EM) is simply a practice whereby a company produces results in such a manner as to ensure that it looks as if it is performing better than it actually is (Jeanjean and Stolowy, 2008). In essence, Healy and Wahlen (1999) have argued that the company aims to portray a more positive outlook, thus securing the faith of its shareholders, future investment and cash flows. Hence, the IFRS was set up to meet the requirements of accounting standards, of which Earnings Management is one of the target areas. Accordingly, accounting standards have continuously been amended since the inception of IFRS in April, 2001, which has given rise to interpretations in different countries that depend on their own specific governance and other criteria. It is this interpretation issue that this study aims to address. The main objective of the current study is to assess this development from an interpretive angle, and with specific attention to the UK's Non-Financial FTSE-100 companies. Mostly, banks and financial institutions are excluded from earnings management research, as their characteristics are fundamentally different to other industrial companies (Peasnell et al., 2000).
The adoption of segmental reporting standards Internationally (IFRS 8) and in the USA (SFAS 131) offers new paradigms for a company's financial position and performance. This is called the management approach (Van Tendeloo, and Vanstraelen, 2005). A management approach is a key characteristic of IFRS 8 (Crawford et al., 2012). It underlines the strategy relating to the reporting of segmental information (André et al., 2016) and outlines the reporting choices that might be made by the Chief Operating Decision Maker (CODM). In this approach, the CODM is given a significant role in determining the segmental information that is to be disclosed for a particular financial year under IFRS 8 (Mardini et al., 2012).
A number of arguments have surfaced, and these have concentrated on justifying the effect of the segmental reporting requirements on earning management. The first argument that is of concern is clearing the air in regard to the relationship between the new segmental reporting standard and earnings (smoothing) management. Capkun et al., (2012) attributed the provision

of flexibility in the selection of accounting treatments to addressing earnings smoothing. The second arguments provide that the increase in disclosure in relation to the operating segments' items in the financial reports following the adoption of IFRS 8 in 2009, which may improve earning management for Jordanian listed companies (Mardini et al., 2012), as well as the UK's FTSE-100 companies (Mardini and Ammar, 2018). Moreover, According to Ettredge et al., (2005), the increase in available information relating to more reporting with regard to the segments' items (SFAS 131) strengthens the association between returns and future earnings. The adoption of the new IFRS standards as a mandatory requirement in the European zone is a matter of concern in relation to what the effects of better financial reporting turns are (Capkun et al., 2008). More specifically, the IFRS 8 standard is emphasised, since it encompasses the scope of reporting on operating segments that, in turn, influences the financial performance of the companies. The adoption of IFRS 8 articulates more specificity and exclusivity with regard to the earnings management of the reportable and operating segments (Jeanjean, and Stolowy, 2008; Zéghal et al., 2011). According to Mardini et al., (2012), the principle focus of IFRS is to enhance the understanding of a company's position and performance in relation to internal reports that are reviewed by the chief decision makers.

The arguments above have promoted a platform from which we can present a study based on the interpretation of accounting standards through paying attentions to IFRS 8 from the perspectives of UK listed companies that are subject to a thorough evaluation of Earnings Management. There are many advantages to the promotion and implementation of accounting standards worldwide. IFRS hopes to ensure all companies will use only one format, which increases transparency whilst promoting accountability. If economies aim to develop and grow, whilst being supported by good governance, one simple accounting standard should ensure that they do not become a group. This therefore overrates their company earnings and thus reduces the cash flow in the long run – a practice that has contributes to distrust amongst shareholders and also to the reduction of economic growth. IFRS promotes hopes of gaining the trust of investors, since they rely on companies reporting the correct information, particularly information relating to future earnings, and hence returns on investment. In terms of Earnings Management, over-valued financial reporting has a significant effect on subsequent operating performance. Some of the Earnings Management practices are associated with future operating performances. This reporting practice may have an effect on the subsequent years' return on assets, which are usually contrary to the stakeholders' expectations, and this then has an impact on future earnings and cash flows. The motivation of this study is thus threefold: (i) The study will evaluate the extent to which IFRS 8 has contributed to changes in Earnings Management practices in the UK non-financial FTSE-100 listed companies. All financial firms, including banks, insurance companies, and other financial institutions, have been excluded from the initial sample utilised in earnings management research, as the environments of their financial reporting are different from those of other industrial companies, and their accrual processes differ fundamentally where the expectation models of normal accrual activity are not able to capture (Peasnell et al., 2000). This can be evaluated in two time periods before the post-implementation review of IFRS 8 (2013), and after the review (2014-2016);(ii) the results will enable us to assess whether the practices have played a role in the country's economic performances or prosperity, particularly in light of the fact that poor practices are harmful to these causes; (iii) the importance is underpinned by inspecting and assessing whether performance differences played a part in Earnings Management, both before and after the post-implementation review of IFRS 8. Assessments can be made on comparisons drawn in order to provide results that will answer the question as to whether or not the differences that exist are in terms of the implementation of the amended standard, or if IFRS 8 is simply open to interpretation that depends on the governance of that country.

These motivations demonstrate a need for further research that explores earning management and segmental reporting under IFRS 8 in a different context. The implications of this have the potential to contribute to existing literature and also to assist policy makers and practitioners. The premise of this paper takes a more comprehensive approach that aims to address the aforementioned research gaps. What is missing in the literature, and the problem that is being addressed by this research, are the post-implementation review of IFRS 8 intercepts earnings management practices. Instead of replicating what is available in the existing literature, the current study may expand the present understandng of the IFRS 8 post-implementation review's impact on earning managements within an international context. This research also deals with some of the contradictory evidence by examining this aspect in relation to the FTSE-100. Importantly, this paper contributes to society through offering clarifications that advance the understandings of academics, policy makers, and practitioners about why different contexts that are implemented through IFRS 8 show different implications. In other words, prior studies on earnings management that have a segmental reporting perspective tend to focus on US companies. Hence, investigating this issue in relation to UK FTSE-100 firms may yield different results.

The structure of the current paper is as follows: Section 2 offers a literature review, theoretical framework and the hypothesis development, while Section 3 illustrate the methodology. Section 4 outlines the results and discusses the findings. Finally, Section 5 concludes the paper and identifies some research opportunities for future investigation.

2. LITERATURE REVIEW, THEORETICAL FRAMEWORK AND HYPOTHESIS DEVELOPMENT

2.1 Literature Review

A massive amount of research on the benefit of IFRS is being conducted. According to studies carried out by Gassen and Sellhorn (2006), Barth et al., (2008), and Hung and Subramanyam, (2007), there was much improvement in the quality of earning after the voluntary adoption of the IFRS standards . However, there exists a concern over the predicted improvements that were reported on the quality of the financial reports after the adaptation of the IFRS may lack sustainability (Street et al., 2000, 1999).The IFRS standards have a provision for the utilisation of private information and the execution of judgment. The resultant effect is that managers are granted a substantial amount of discretion. Research shows that the discretion is a double-edged sword (Watts and Zimmerman, 1986). Discretion promotes an inexpensive method of reporting regulation, and it allows corporate insiders to assimilate the financial reports with the aim of reflecting on the economic reality as well as producing the information that lies within a given organisation. On the other hand, the discretion can be put to use optimistically. For instance, reporting discretion might be utilised by corporate managers to safeguard certain economic performances that are obfuscated, whether targets or earnings, and to avoid the violation of the set agreements (Leuz, 2010). It is evident that the insiders have the upper hand on the information over the outsiders, and this makes it difficult to curb such behaviour. The degree to which the discretion is applied pivots on the national legal institutions (Ball et al., 2003) and on specific organisational traits (incentives on reporting and operating characteristics) (Burgstahler et al., 2006; Christensen et al., 2015). This means that accounting standards are in constant interaction with a variety of contextual factors, such as the law, commercial codes, and the social norms that exist in various contexts and in different ways (Fearnley and Sunder, 2012).

The current work examining the issues relating to the voluntary adoption of the IFRS makes it difficult to carry out an extrapolation, especially in cases where the adoption of the IFRS has been mandatory. In cases where organisations are coerced to employ and adopt the IFRS, there exist different compliance incentives which make it easy for opportunists to manipulate financial reports due to the existence of massive flexibility (Soderstrom and Sun, 2007). The various ways through which the institutional factors influence the quality of financial reporting after forcing the adoption of IFRS remain an open and interesting question. Following a discussion on the merits of implementing IFRS from a global perspective, Ball (2006) argues that one fundamental advantage is information that is of high quality, which will be instrumental in promoting informed decision

making among investors. According to Barth et al. (2008), Cai et al. (2008), Gassen and Sellhorn (2006), and Hung and Subramanyam (2007), pieces of evidence have been discovered that offer support for this among the adopters of the IFRS globally. However, research conducted by Jeanjean and Stolowy (2008), Van Tendeloo and Vanstraelen (2005) and Goncharov (2005), demonstrates that the application of the IFRS has no particular impact on quality, and, most specifically, on the management of earnings. An explanation of the mixed findings can be partially explained via the country's influence on specific factors such as the adoption of one accounting standard that will be applicable around the world. Nevertheless, this may not lead to an improvement in homogeneity in the financial reporting for various companies and countries, due to different factors, such as the countries' legal systems, incentives for financial reporting, and political systems that may affect the quality of accounting (Soderstrom and Sun, 2007). It is evident that high quality accounting standards are necessary for the achievement of financial, economic systems that are cost effective (Ball, 2001). Country specific factors, such as the separation of financial reporting for the interests of the public, taxation, the existence of a legal system that is independent, the corporate governance and ownership structures, and a strong accounting profession, play a part in the creation of a public disclosure environment that is efficient (Ball, 2001). La Porta et al. (2000) put forward excellent work that leads to the popularisation of the conception of how country specific factors have made an impact on corporate governance. In particular, the strength of protecting investors which, in most cases, is usually based on the legal structure and the origin of a given country, and that is explained within the various practices of corporate governance. Financial reporting is a mechanism of corporate governance and any existing differences on the protection of investors may result in different accounting practices across different nations, even when they all apply the same accounting standards. Leuz et al. (2003), investigated the various ways through which the levels of earning management differed in the different countries. He discovered that countries that had strong protection for investors had lower levels of earnings management. Nobes (2011) suggests that countries that have congruent legal backgrounds, or those that have a shared history, can display similar accounting practices. After he classified into two groups the accounting practices of fourteen states in 1983, he discovered that these groupings remained in the post-IFRS era. These findings suggested that country specific factors tend to influence the various practices in accounting in ways that the harmonisation of international accounting may find difficult to overcome. In essence; the alignment of *de jure* accounting may not result to the harmonization of *de facto* accounting.
Generally, these studies have argued that useful segmental disclosure increases the liquidity of the market, reduces the information gap between management and investors, and lowers the capital costs per firm. Specifically, for the current study's objectives, a number of prior studies (e.g., Botosan and Stanford, 2005; Ettredge et al., 2005; Herrmann and Thomas, 2000; Johnston, 2001) have investigated the economic consequences of segmental reporting, and they have found that segmental disclosure enhances the market value of a firm and its returns. They also found that segmental reporting enhanced the ability of the firm to forecast and assess the likely persistence of future earnings. With data for 172 companies, Behn et al. (2002) examined whether the segmental information disclosed did help the users of financial statements to understand the risks and growth prospects of their investee companies. They found that in excess of 50% of their sample companies provided accurate segmental information; hence, they concluded that segmental reporting enhanced the ability of analysts to forecast a company's future earnings. Ettredge et al. (2005) documented that the segmental information disclosed increased the usefulness of financial statement disclosures for forecasting information, and it enhanced the predictive ability in relation to business segment earnings[1].

[1] They used the Future Earnings Response Coefficient (FERC) methodology to assess this argument; the FERC was obtained by regressing current year share returns, against the next year's corporate annual earnings plus the control variables (which include earnings growth, earnings persistence, and the information environment).

2.2. Theoretical Framework

The request for corporate information can be raised by information asymmetry between managers (agents) and investors (principals), which has serious importance for the well-organised allocation of existing resources, and thus for the running of a competent capital market. Firms deliver information in numerous forms, such as financial reports, and this is mandatory and must be audited. Firms also provide information through voluntary channels, such as press releases and the company's website. Furthermore, financial intermediaries, such as financial analysts and experts, also offer information about firms. Nevertheless, considerable managerial discretion is allowed in relation to how the companies, in generating financial reports, apply accounting standards. Firms with different characteristics take on different accounting policies. (Watts and Zimmerman, 1986; Jensen and Meckling, 1976) IFRS 8 puts in place disclosure requirements for the firms. The standard application and the disclosure of mandatory and voluntary segmental items depend on the firms' disclosure policy. The benefits and costs perceived by managers are connected with segment disclosure and these affect their segment disclosure interpretation of the standard. The current study adopts three theoretical perspectives, namely, agency, proprietary and regulation and enforcement theory. The current sub-section provides an overview of these theories, while the hypothesis development section demonstrate the linkages between the current study's objectives, the literature review, and the theoretical framework of the current study, in order to develop a hypothesis.

Agency theory

Agency theory, first detailed in Jensen and Meckling (1976) and explained in greater detail in Eisenhardt (1989), is the theoretical framework most often used to explain why managers might be interested in engaging in earnings management. In many modern corporations, the shareholders of the firm are the owners (the principals) and appoint managers as agents to act on their behalf. However, modern corporations are increasingly complex and, because shareholdings tend to be diffuse, it can be difficult for shareholders to carefully monitor managers. In particular, when managers are being rewarded for a firm's performance, they may have incentives for choosing the accounting measures or for choosing to record transactions in such a way that they maximise their own compensation (Healy, 1985). Apart from managing earnings for their own selfish purposes, managers in modern corporations could also be pressurised to earnings manage because of demanding shareholder expectations. Koller et al (2010, p. 43) describe an "expectations treadmill", in which shareholders demand that the managers of their companies constantly improve performance above expectations. When these demands are met, the expectations increase again, which puts additional pressure on managers. The continually ratcheting pressure on managers thus creates the potential for managers to consider earnings management to be an alternative way to meet shareholder expectations.

Proprietary Theory

Disclosure is put out to help to reduce information asymmetry. Common theories (e.g., agency, signalling, capital need and political cost) are used in this era, and they recommend that firms are motivated to disclose more financial information as requirements under accounting standards. However, financial information disclosure to outside parties may also include proprietary information that could be likewise taken and used by the company's competitors, by opposed shareholders and employees, or by tax authorities, with a negative effect on the disclosing firm. Accordingly, when the firm decides the volume of information to be disclosed, firms face a compromise between the benefits of disclosing information to capital markets and the drawbacks of revealing proprietary information. (Hayes and Lundholm, 1996; Leuz, 2004). The managers' motivation, to avoid possible negative effects and retain competitive advantage, touches the disclosure of segmental information provided by firms. Prior studies on segmental disclosure have revealed that the segment disclosure's quantity or quality is limited by the proprietary cost that is associated with the disclosure of more detailed information to the market (Leuz, 2004). The association between the competition level and the quantity or quality of the segment information disclosed by the firms in the market, seems to be positive. Consequently, the more competitive firms working in a market are, the more there is a propensity to disclose segmental information, as the higher competition level shrinks the competitive damage that is associated with segmental information. (Birt et al., 2006; Pisano and Landriana, 2012).

Regulation and Enforcement
Accounting is subjective, as it must fulfil the needs of several regulations, like the International Accounting Standards, the UK Companies Act of 2006, and those of the London Stock Exchange. The regulatory requirements will have no quality in relation to financial reporting if the firms do not fulfil the requirements of these regulations (Gaffikin, 2005). Prior studies' connotation is that the mechanism of enforcing and monitoring IFRS requirements, like an effective internal control system and the need for an independent auditor, are significant workings of accounting standards implementation. The other studies' results have also shown that compliance with IFRS demands the disclosure of more proprietary information.

2.3 Hypothesis Development

Prior studies propose that many factors could affect earnings management through financial reporting requirements. The results of these prior researches and the theory that is presented briefly in Section 2.2 are considered to develop the following hypotheses as an alternative means through which to answer the research questions raised by the association between earnings management (real earnings management) and the following variables.

Insert Table 1

Glaum and Street (2003)'s paper argues that a company with a higher growth rate has higher future funding requirements. In respect of agency theory, it has been found that there is a positive association between non-disclosures of geographical earnings and foreign sales growth (Hope and Thomas, 2008). Hope and Thomas (Ibid.) concluded their study by indicating that managers have a propensity to reduce the shareholder's abilities by reducing the disclosure quality, in order to observe their international operations' expansion. In addition, it can be argued that this occurs because for proprietary reasons too. The managers might attempt to shrink their competitors' ability, in different geographical locations, in order to monitor their business activities.

H_3: The growth rate is positively associated with real earnings management under the post-implementation review of IFRS 8.

Large firms are more likely to produce information with less cost, and to have the capability and resources to produce information adequately (Cooke, 1989; Ali et al., 2004). Nevertheless, agency, proprietorship and competition-like entry barriers similarly can encourage companies to disclose more (Jensen and Meckling, 1976; Watts and Zimmerman, 1978 and 1990; Dye, 1986; Hayes and Lundholm, 1996; Nagarajan and Sridhar, 1996) when conforming to accounting standards and regulations. In alignment with regulation and enforcement theory, it has been argued that the financial reporting regulators might be blamed for any possible future crisis. Further, proprietary theory has argued that the detailed disclosure in relation to segmental information might harm smaller firms more than the bigger ones (Katselas et al., 2011; Bens et al., 2009). Prior studies have used total assets as a proxy for size (Prather-Kinsey and Meek, 2004; Al-Ulis, 2006; Al-Jabri, 2008; Bova and Pereira, 2012; Fekete et al., 2008; Al- Shammari et al., 2008; De Vicente Lama et al., 2011; Pisano and Landriana, 2012), other studies have used total sales (Hodgdon et al., 2009; Fekete et al., 2008).Market capitalisation has also been used in previous studies (Al-Jabri, 2008). Furthermore, Crawford et al's (2012) study found differences between the segmental information disclosure of the FTSE 100 and of the FTSE 250 firms.

H_4: The size is negatively associated with real earnings management under the post-implementation review of IFRS 8.

As a proxy for the financial risk of a company, gearing can be used. With a higher gearing, the more unpleasant the debt covenant restraint is for the firm, therefore the higher the likelihood is that the firm will abuse the debt covenant. Where companies are experiencing difficult financial times, administrators are more motivated to violate Earnings Management. Callao and Jarne (2010), Vander et al. (2003) and Jelinek (2007) have proved that higher gearing gives rise to more prominent degrees of Earnings Management.

H_5: The gearing is negatively associated with real earnings management under the post-implementation review of IFRS 8.

Watts and Zimmermann (1986)'s paper has indicated that companies with higher profitability have a greater propensity to disclose financial information in detail in their annual reports in order to act as a good agent (Agency theory). Profitability is a common factor in compliance studies. Prior research has discovered negative associations between Earnings Management and ROA (Young, 1999; Dechow et al, 1995; Duke and Hunt, 1990).

H_6: The profitability is negatively associated with real earnings management under the post-implementation review of IFRS 8.

Liquidity is the ability of a company to meet its short-term financial liabilities and it is one of the vital factors when financial statements' users assess a company. The argument here is that the better liquidity a company has, the greater the incentive to engage in earnings management practices. Firms with a higher liquidity ratio are thus more likely to present more disclosure and to have a greater propensity to manage earnings.

H_7: The liquidity is positively associated with real earnings management under the post-implementation review of IFRS 8.

Regarding agency and regulation theories, companies that are internationally visible have varied stakeholder groups (working under different tax authorities and stock exchange markets' regulators, more overseas suppliers and customers, financiers, personnel, etc.). One can argue that a company with more international visibility has a greater disclosure quality so as to meet the information requirements of its stakeholders, and thus it has the propensity to engage in earnings management practices. Previous studies have suggested that there is a significant association between listing status and International Accounting Standards requirements. They have found that companies have more compliance when they are listed on more stock exchange markets (El-Gazzar et al., 1999; and Prather-Kinsey and Meek; 2004). Here, the argument may be that the international visibility of a company affects the quality of its disclosure.

H_8: The international visibility is positively associated with real earnings management under the post-implementation review of IFRS 8.

Previous studies (e.g., Hayes and Lundholm, 1996; Harris, 1998; Botosan and Stanford, 2005; Birt et al., 2006; Pisano and Landriana, 2012) have indicated that the competitive harm may decrease under a higher level of competition that is associated with segmental information disclosure. Firms therefore have more incentive to disclose segmental information when they operate in industries that are more competitive. This is aligned with Proprietary theory "In fact, the release of additional information could benefit the firm by reducing information asymmetries between management and shareholders." (Birt, et al., 2006, p236). The proxy for industry competition is the Herfindahl-Hirschamn Index (HHI), because it takes into consideration the company's relative size and the companies' distribution in a market. HHI indicates that a higher index means a higher concentration in a market and lower competition in the market. While Capital intensity proxies the barriers to entry in a market and is a negative proxy for market competition (Givoly et al., 1999; and Wang et al., 2011). This paper used each industry sector along with the HHI and the capital intensity of the companies to measure the market competition.

H_9: The capital intensity is negatively associated with real earnings management under the post-implementation review of IFRS 8.

H_{10}: The market concentration is positively associated with real earnings management under the post-implementation review of IFRS 8.

3. METHODOLOGY

3.1 Sample

To address the questions being tackled in the current investigation, the initial sample included all of the FTSE-100 firms. However, the current research includes some sampling criteria for the purposes of its analysis. First, the firm must provide segmental information in its annual report. Specifically, some FTSE-100 companies may only sell/produce one product, or may provide only one service and operate locally. As a result, they may not disclose any segmental information in their annual reports. Second, all financial firms, including banks, insurance companies, and other financial institutions, have been excluded from the initial sample in earnings management research, because the environments of their financial reporting are different from those of other industrial companies, and their accrual processes differ fundamentally which means that the expectation models of normal accrual activity are not able to capture them (Peasnell et al., 2000). Table 2 indicates that this has led to the exclusion of 15 companies which did not have any segmental reporting. It has thus resulted in 85 companies, which were FTSE 100 companies with segmental reports. Additionally, the sample taken for this particular study also concentrated on eliminating banks along with financial companies, which did not have any available data (29 companies). The final sample taken in order to conduct this study was comprised of 56 companies. These companies were selected on the basis of the firm's years from 2012 to 2016. Hence, the companies included in this study were included in the FTSE-100 for 2012-2016, based on which it can be stated that some of the factors affected the earnings management with respect to financial reporting.

<u>**Insert Table 2**</u>

3.2 Model

The independent variables are the adoption of IFRS 8[2], the size of the firm (Market Capitalism). For the control variables, we chose gearing, growth, return on assets and loss, and market

[2] For the purposes of the current study, the checklist collects data on the number of segments published and of segmental items for the operating segments that were reported, based on the IFRS 8 requirements. It also captures any voluntary disclosures that were provided over and above the IFRS 8's requirements. The checklist includes 18 mandatory segmental items and 5 voluntary items, if viewed by the CODM as needing to be reported. Companies were not penalised for non-disclosure of items, which did not apply to their circumstances; the relevance of each

competition. In this model, gearing is used as an indicator to replace 'debt covenant restraints tightness'. The control variables are revenue growth and the Return on Assets (ROA), and these variables are included to account for differences in performance. Skinner and Sloan (2002) stipulate that the growing companies are more attracted to the activities of Earnings Management because part of their incentive is not to disappoint their shareholders. Their companies are expected to show signs of growth year after year, and therefore their company directors would like to make market commentators aware of their performances and thus the earnings report may be over inflated.

Past studies discover negative relationships between Earnings Management and ROA (Young, 1999; Dechow et al, 1995; Duke and Hunt, 1990). With a higher gearing, the more unpleasant the debt covenant restraint is for the firm, the higher the likelihood there is for the firm to abuse the debt covenant. Where companies are experiencing difficult financial times, administrators are more motivated to violate Earnings Management. Callao and Jarne (2010), Vander et al. (2003) and Jelinek (2007) have proved that higher gearing gives rise to more prominent degrees of Earnings Management. Loss is incorporated into the control variables and Francis and Yu (2009) find that organisations reporting a loss the previous year are more averse to Earnings Management than those firms that report good profits. Finally, it is clarified that organisations with good profits are more motivated to take part in Earnings Management in order to keep their shareholders content. In this model, we will add dummies, which are 'industry' and 'year', to control for the effects of industry and the year. Whilst this methodology, being a popular adoption in the literature, will allow us to assess the companies cross-sectionally and to assess the differences in both time periods and in looking for evidence of their interpretation of IFRS 8 rules, it does not necessarily assist in measuring the interpretation of the standard. Compared to accruals management, real earnings management has not been extensively examined in the literature. The models described in this section are those of Roychowdhury (2006), and Cohen and Zarowin (2010). According to Cohen and Zarowin (2010), we start by estimating "normal" levels of CFO as a linear function of revenues and changes in revenues. Using the following panel regression for each industry and year, we have the following model:

$$\frac{CFO_{it}}{Assets_{i,t-1}} = \frac{k_{1t}}{Assets_{i,t-1}} + \frac{k_2 Sales_{it}}{Asset_{i,t-1}} + \frac{k_3 \Delta Sales_{it}}{Assets_{i,t-1}} + \varepsilon_{it}$$

The figures provided for this model are the "normal" CFO levels, and the abnormal CFOs are thus simply the actual CFO – normal CFO. Cohen and Zarowin (2010) also explained that production costs and discretionary expenses can be manipulated to manage earnings. The following models relate to production costs and discretionary expenses to sales respectively:

$$\frac{Prod_{it}}{Assets_{i,t-1}} = \frac{k_{1t}}{Assets_{i,t-1}} + \frac{k_2 Sales_{it}}{Assets_{i,t-1}} + \frac{k_3 \Delta Sales_{it}}{Assets_{i,t-1}} + \frac{k_4 \Delta Sales_{it-1}}{Assets_{i,t-1}} + \varepsilon_{it}$$

$$\frac{DiscExp_{it}}{Assets_{i,t-1}} = \frac{k_{1t}}{Assets_{i,t-1}} + \frac{k_2 Sales_{i,t-1}}{Assets_{i,t-1}} + \varepsilon_{it}$$

absent item was investigated, and the item was then classified as a "non-disclosure", or as being "non-applicable". In other words, the IFRS 8 mandatory items may not be applicable to all companies; the applicability of the items included in the checklist was based on the company and its operations. For instance, not all companies have joint ventures or associate companies, so the segmental item for 'profit from associates and joint ventures', which is required by IFRS 8 (if reviewed by the CODM), may also not be relevant. (See Appendix 1 for details).

Finally, the various real earnings management variables are combined into a single comprehensive measure that is used to summarise the extent to which real earnings management has been undertaken. The procedure for doing this is described with the following equations:

$$R_{CFO} = \frac{CFO_{it}}{Assets_{i,t-1}} * (-1)$$
$$R_{DISC} = \frac{DiscExp_{it}}{Assets_{i,t-1}} * (-1)$$
$$R_{PROD} = \frac{Prod_{it}}{Assets_{i,t-1}}$$
$$R_{PROXY} = R_{CFO} + R_{DISC} + R_{PROD}$$

Based on the hypothesis given in Section 2.3 and the description of the methodology, above, the following regression model has been built:

$$Y_j = \beta_0 + \beta_1 X_1 + \beta_2 X_2 + \beta_3 X_3 + \beta_4 X_4 + \beta_5 X_5 + \beta_6 X_6 + \beta_7 X_7 + \beta_8 X_8 + \beta_9 X_9 + \beta_{10} X_{10} + \varepsilon$$

Where

$Y_j=$	Each sample company's earnings management proxies
$X_1=$	Number of reported segments
$X_2=$	Percentage of disclosed items mandatory, voluntary and total (IFRS8)
$X_3=$	Growth
$X_4=$	Size
$X_5=$	Gearing
$X_6=$	Profitability
$X_7=$	Liquidity
$X_8=$	International visibility
$X_9=$	Capital intensity
$X_{10}=$	Market concentration
$\varepsilon_j=$	error

Insert Table 3

Based on Table 3, above, it can be stated that the independent variables included a number of reported segments along with the percentage of disclosed items, growth, gearing, size, profitability, liquidity, capital intensity, market concentration, and international visibility. However, based on the study findings of Street et al. (2000), a significant concern related to predicted improvements can be observed. These were reported based on the overall quality of the financial reports, following the implementation of IFRS, and this was due to the lack of sustainability.

3.3 Checking outliers, multicollinearity

Insert Table 4

4. RESULTS AND DISCUSSION

This section presents the results of the analyses of all the data collected during the course of this study. The empirical results are then presented, beginning with the analysis of the relationship between earnings management, as estimated by the real earnings model. The results of the analysis showed that the post-implementation of IFRS 8 did lead to significant changes in earnings management behaviour, as measured on the earnings management model. The data for this study were collected manually from financial statements and from the OSIRIS database for the period (2012-2016). Then, the obtained data was transformed into Excel sheet form along with company characteristics (e.g., growth, market cap, ROA, etc.) and the disclosure of IFRS 8.

Insert Table 5

Table 5, above, focuses on highlighting the correlation among the number of items, % mandatory items, % voluntary items, % total items, growth, marketing capitalism, gearing, ROA, liquidity, international visibility, capital intensity, and the market concentration. In this context, it can be stated that the relationships between the variables have been observed to be both positive and negative. For instance, it has been observed that the relationship between the number of segments and the R-proxy is calculated to be -0.1781, which is negative. This indicates that if the value of one variable increases, the value for the other variable decreases. On the other hand, a positive relationship was noted between % voluntary items and R-proxy. This indicates the fact that the hike in the value of one variable leads to a simultaneous increase in the value of another variable. In this context, Goncharov (2005) has stated that the implementation of the IFRS practice has no effects on the management of the earnings of a company. In addition, it will degrade the quality of financial reporting.

Insert Table 6

Table 6, above, focuses on highlighting the regression of real earnings management against the three segments' models. In other words, it illustrates the results so as to answer the main research question of the paper, which is to investigate an association between earnings management and segmental reporting. The adjusted-R^2 of the mandatory segment has been calculated as 56.80%. The same is found for the voluntary segment model, and the results of the total segment model are recorded to be 54.65% and 56.53%, respectively[3]. Hence, this has helped in comparing the overall explanatory power that is related to the three models that comprise the various predictors. In this case, the predictors have included the number of reported segments, the percentage of disclosed segmental items, growth, market capitalism, gearing, liquidity, ROA, market intensity, international visibility, and market concentration. In this particular context, as presented in Table 6, most of the null hypotheses are being rejected for those in which an alternative hypothesis can be used. For example, with respect to the mandatory segments model hypothesis, which are being rejected at 0.01 significance level, this includes ROA (-0.03) and market intensity (-0.07). On the other hand, the null hypothesis, which is rejected at 0.05 significance level includes the market relating to the voluntary segment model, which is market concentration (0.01). The reason for accepting a null hypothesis is that it can help in claiming a level of significance of $P<0.05$ (Filho et al., 2013). Hence, in this context, it has been evident that standards relating to the accounting needs for high quality are used in order to maintain an accurate level of significance. This is because it will help to achieve and maintain economic and financial systems (Ball, 2001).

[3] Moreover, the value helps in predicting the adjusted-$R^{2,}$ which is often perceived to be an upgraded version of $R^{2.}$ In this context, the adjusted-R^2 is observed to increase if it helps in improving all the predictors that are related to the respective models mentioned above. On the other hand, the R^2 value decreases when the predictor is observed to have a negative impact on the three models. This can thus help in assessing the development of a firm from the various interpretative angles.

The results of regression analysis with respect to the three models of the segmental reporting have represented slight variations in the obtained F-values. Contextually, the F-value of the mandatory segment model was calculated to be 13.75%, which was relatively more in comparison to the other two models. The F-value of the voluntary was again observed to be 12.69%, while the data recorded for the total segments model was 13.61%. The F value in the regression refers to the test outcomes, where a null hypothesis implies that the regression coefficients are zero. Since the F-values of all of the models are high, it does not support the null hypothesis. An alternative hypothesis is more compatible in this context. This is because the null hypothesis refers to the variances in the errors, which are often found to be equivalent to one another (Breusch & Pagan, 1979). Hence, in this regard, the disclosure of this information helps to decrease information asymmetry. However, it is essential to disclose the company's segmental information, since it has become mandatory under IFRS 8. However, the quantity of the information being disclosed in the capital markets depends on the company, which has its own advantages, as well as its disadvantages (Hayes and Lundholm, 1996; Leuz, 2004). Following proprietary theory, the disclosure of the information can help in significantly reducing its asymmetry. Hence, it has been evident that agency, along with capital need, signalling, and the political cost theories, assist in recommending that the companies reveal information with respect to their financial conduct in a stated period. This also includes complying with all the mandatory segmental disclosures needed for the information on the basis of the IFRS 8 management approach. Additionally, it is also essential to maintain the amount of information that will be shared in the markets (Hayes and Lundholm, 1996; Leuz, 2004). From an overall perspective it can thus be stated that this will significantly help in understanding and interpreting the accounting standards that the companies need to follow in order to assess their development from the interpretive angles.

The increasing and positive value of the adjusted-R^2 is good for the performance of the company. In order to maintain the adjusted R^2 value, the managers thus need to become involved in enhancing the overall earnings management. According to Jensen and Meckling (1976), this can also help to manage earnings better. It was further evident that the managers are pressurised to manage earnings due to the shareholders' demands. The adjusted-R^2 can help the managers of the company to assess the predictors relating to the model so as to enhance organisational performance. In this particular context, it has thus been observed that using the adjusted-R^2 has helped in comparing the overall suitability of fit relating to the regression model. This has been compared by taking into consideration the different types of independent variables, as in Table 6, above. Contextually, the agency theory offered by Jensen and Meckling (1976) was significantly detailed in the theoretical framework presented by the Eisenhardt (1989). This particular framework has significantly focused on the reasons for which the managers may be interested in becoming involved in the management of the company's earnings. In respect of the modern corporations, it has therefore been observed that the shareholders of the company are the owners, and it is they who appoint managers to act on their behalf. Additionally, the managers are rewarded if they perform well for the company. It will thus be essential for the companies, as well as for the managers, to act according to the accounting standards or measures in order to select the recorded transactions, and this can assist in maximising the overall compensation (Healey, 1985).

The results of regression analysis with respect to the three models of the segmental reporting show that the number of reported segments is associated negatively with real earnings management. This indicates that managers engage in fewer real earnings management practices when the reported number of segments is increasing. This result is aligned with regulation theory, since the greater the segmental number that is disclosed the more this makes the stakeholders more likely to be aware of setting internal control procedures and policies in order to stop managers from being engaged in real earnings management practices. Further, the results show a positive association between real earnings management and the parentage of the reported segment items under the mandatory and total disclosure models. However, the empirical results show that the voluntary disclosure of segmental items has insignificant effects on real earnings activities. For instance, Emmanuel (2012) found that UK firms that voluntarily adopted IFRS tended to have a more significant positive change in equity and earnings than firms that adopted IFRS on a non-voluntary basis. The firms in this study's samples that adopted IFRS were thus likely to have been a self-selected sample that may have adopted it because of a higher level of financial sophistication. This, in turn, could mean that the firms in the sample that adopted IFRS had more knowledge about the ways in which earnings management could be performed. This effect may have led to the positive relationship between IFRS adoption and earnings management measured on their real earnings model.

Under ruining the regression of the three above models, growth and market concentration show a significant positive association with real earnings management. While a negative association has resulted in market capitalism, ROA and capital intensity. Additionally, this has further assisted in comparing the different variables of the mandatory segments model, the voluntary segments model, and the total segments model. This includes growth, market capitalism, ROA, gearing, liquidity, market intensity, and market concentration. However, there are several factors which affect the overall requirements of the earnings management and financial reporting of the company. In summary, these results indicate that segment-related disclosures are of interest, and real earnings managers are using them when they are making investment decisions. Accordingly, it is relevant for the segmental information disclosed by UK FTSE-100 firms to rely on earnings management and this may explain the variations in earning management practices.

5. CONCLUSIONS, LIMITATIONS AND FUTURE RESEARCH

The results of the current investigation lead to concludes that the IFRS 8's management approach is useful to internal and external decision makers especially that it explains its relation with real earnings practices. For example, the current paper results suggest that the management approach of IFRS 8 enhanced the perceptions of the managers about the reliable segmental information with further insights to publish such information to the shareholders. The current paper results also suggest that the segmental earnings effect on the extent of segment reports, rather than by equity of the firm. The implication of these findings for regulators is thus that allowing firms to disclose voluntary segmental information in accounting standards will not necessarily lead to improved earnings quality on their own: it is likely that companies will opt to report using which ever accounting standard allows them to report the "best" earnings. DeAngelo et al (1996) have suggested that the managers of public firms have strong incentives to avoid losses in reporting earnings; it is therefore likely that the incentive to avoid losses in this case would trump any desire to use a more stringent financial reporting standard.

The current study has some limitations. Our sample size was reduced, due to a lack of segmental information for several of the UK FTSE-100 firms, and thus many firms had to be excluded for data availability reasons. The effect of industry as a control variable was not included when the models were run, yet the industry effect has been run in measuring real earnings management.

[4] On the basis of the Table 4 presented above, it focuses on depicting the overall validity test relating to the real earnings management. The mean VIF relating to mandatory segments model has been calculated to be the1.60, which indicates for voluntary segment model, it was 1.64, and the total segments model has been calculated to be 1.62. Since, the VIFS for all the models are exceeding the value 0.1, it can be stated the collinearity can cause problems (Ramsey, 1969). On the contrary, Breusch-Pagan test three models were recorded to be 0.63, 0.18, and 0.25 respectively. It can thus be depicted that the values of Breusch-Pagan test related are not equal to one another. However, the Breusch-Pagan tests indicate that the null hypothesis associated with different variances of the errors is observed to be equivalent to one another. Furthermore, probability was obtained for the mandatory segments model was calculated to be 0.43. The same for voluntary segments model was 0.67 and for total segments model was recorded to be 0.62 correspondingly. This indicates that the White test has an advantage in reducing biases using the Breusch-Pagan test, which occur when errors are abnormally distributed (White, 1980).

ABSTRACT

This article relates earnings quality with earnings management to determine if good or poor earnings quality is an indicator for financial or accounting irregularities by considering the persistence of earnings, cash flows and accruals between companies with high or low earnings quality. A sample of 61 companies accused by the Securities and Exchange Commission of accounting irregularities and 61 control companies were used. The data analysis showed that accused companies have poorer quality than control ones; similarly, control companies presented less discretionary accruals and better return on assets than accused ones.

KEYWORDS: Earnings Management, Quality, Persistence, Fraud, Manipulation.

INTRODUCTION

Financial reporting shenanigans tend to be mostly associated with accrual-based earnings. Further, an important red flag is when cash flow does not move in the same direction as revenue, accounts receivable, and net income (Deo & Cathy, 2016), affecting the quality of earnings and signaling possible earnings management. Earnings management is an umbrella for managers' discretion that affects the reported accounting earnings or their interpretation. It starts with production and investments decisions, the choice of accounting treatment, the size of accruals, and decisions that affect the interpretation of reported earnings. Healy & Wahlen (1999) stated that "e*arnings management occurs when managers use judgment in financial reporting and in structuring transactions to alter financial reports to either mislead some stakeholders about the underlying economic performance of the company or to influence contractual outcomes that depend on reported accounting numbers"* (p. 368).

There are several other earnings management definitions, but most of them are difficult to operationalize directly using attributes of reported accounting numbers since they center on management intention which is unobservable (Dechow & Skinner, 2000). Although not to be confused with illegal activities to manipulate financial reports that do not reflect or show the economic reality of the company, this practice has been used for many years. Financial reporting requires managers to estimate future benefits and obligations such as allowance for doubtful accounts, and deferred revenues. These estimates allow managers to choose from different accounting procedures giving them the option to influence financial results. The problem arises when managers ignore those rules to show a more successful organization to influence shareholders' decisions. Researchers had been trying to predict earnings management for a long time. Since it is not possible to observe directly, researchers have been using several models to predict whether companies are involved in this practice.

LITERATURE REVIEW

The external pressure from shareholders, financial analysts and credit rating agencies take its toll on managers who struggle to make the financial results forecasted and try to achieve their goals through aggressive accounting procedures to give the illusion of financial strength, for example, the Enron case where executives engaged in deceitful practices to inflate earnings and increase stocks prices to profit themselves, this is consistent with the 2007 subprime crisis and the 2008 collapses of Bear Sterns and Lehman Brothers. During the 1960s and throughout the 1970s, the earnings management literature was focused mainly on capital markets, starting with the Mechanical Hypothesis that postulates a mechanical relationship between stock prices and accounting earnings. This hypothesis predicts that stock price is associated with accounting information changes and concluded that the market is systematically misled by accounting procedures. Kaplan and Roll (1972) stated that when the mechanical hypothesis is prevalent, investors and practitioners believe that their stock prices are inflated as reported earnings are inflated by corporate managers.

Healy (1985) tested for earnings management by comparing the mean of total accruals, scaled by lagged total assets, across the earnings management partitioning variable. Healy's study differs from most other earnings management studies predicting that systematic earnings management occurs in every period. DeAngelo (1986) used the last period's total accruals as the measure of non-discretionary accruals to investigate the accounting decisions made by managers who proposed a management buyout. Jones (1991) proposed a model that relaxes the assumption that nondiscretionary accruals are constant. Her model tried to control for changes in a firm's economic situations on nondiscretionary accruals. Dechow, Sloan and Sweeney (1995) developed the Modified Jones Model by adjusting for the changes in receivables in the event period.

Since the 1990s, earnings management have shifted back to capital markets incentives. Dechow & Skinner (2000) pointed out three reasons for this shift. One of the reasons is the market efficiency concept prevailing among early accounting researchers. Also, Capital Markets are usually available to a much wider spectrum of users of financial statements, making earnings management more likely to be effective as the cumulative effects of information asymmetry between investors and managers are significant. In addition, since the 1990's the stock market valuation based on accounting benchmarks substantially increased, making stock prices highly sensitive to accounting measures such as earnings. Earnings are the net benefits of a firm's operations according to the SFAC No. 2, the primary determinants of earnings quality are relevance and reliability, and these two dimensions make accounting information useful for decision making (FASB 1980).

Earnings Quality

Earnings quality is one of the most popular topics in the accounting literature. The subject is also of great interest to practitioners in the investing community such as analysts (both buy and sell side), hedge funds, and institutional investors (Khan, Peddireddy, & Rajgopal, 2019). Recent research has changed the focus to earnings quality and quality of accruals and the relation between earnings management and earnings quality. Earnings quality focuses on the extent to which the reported net income deviates from the actual, true earnings of the company

(Warshavsky, 2012). Most researchers agree that highly managed earnings have low quality. Dechow, Ge and Schrand (2010) provided a broad and very detailed review of earnings quality research by reviewing over 300 studies trying to define earnings quality broadly to help with decision making. Schipper and Vincent (2003) defined earnings quality as the extent which reported earnings faithfully represent Hicksian income, where representational faithfulness means "correspondence or agreement between a measure or description and the phenomenon that it purports to represent" (FASB Concepts Statement No. 2 para. 63). Dechow and Schrand (2004) argued that a high-quality earnings number is one that accurately reflects the company's current operating performance, is a good indicator of future operating performance, and is a useful summary measure for assessing firm value. Nakashima & Ziebart (2016) used accrual quality, discretionary accruals, and the accuracy of cash flows predictions as surrogates for earnings quality and found mixed results between tone at the top and those variables. They defined tone at the top as the ethical atmosphere created in the workplace by the organization's leadership and stated that the CEO sets the tone at the top, and it affects integrity, ethics, and other factors underlying a positive control environment.

The quality of earnings is of interest to those who use financial reports for contracting purposes and investments decisions (Schipper & Vincent, 2003). Decisions based on low-quality earnings will induce unintended wealth transfers, and from the investment side, low-quality earnings might provide a defective resource allocation signal (Schipper & Vincent, 2003). Earnings quality can vary among companies as a function of accruals, even in the absence of intentional earnings manipulation (Dechow & Schrand, 2004). One role of accruals is to shift or adjust the recognition of cash flows over time so that the adjusted numbers (earnings) better measure firm performance. Since accruals require assumptions and estimates of future cash flows, Dechow and Dichev (2002) argue that the quality of accruals and earnings is decreasing in the magnitude of estimation error in accruals. If net income is high, but cash flow from operations is low, then there is a need to scrutinize the quality of the net income with particular attention to the type of industry and the life cycle of the firm (Deo & Cathy, 2016). Nakashima & Ziebart (2016) argued that if the internal control system is good, segregation of duties will be the norm, and earnings management would be controlled, leading to an improvement in earnings quality. Accrual analysis is comprehensive- measuring both the effect of accounting method choices and operating, financing, and investments decisions insofar as they affect accruals, but there is a drawback; accruals models generate low-power tests of earnings management even for fairly high levels of manipulation as high as 5% of total assets (Jiambalvo, 1996).

For the estimation of unexpected accruals, some studies start with total accruals, measured as the difference between reported net income and cash from operations. Total accruals are regressed on variables that are proxies for normal accruals to allow for typical working capital needs, and gross fixed assets to allow for normal depreciation; unexpected accruals are thus the unexplained or residual components of total accruals (Healy & Wahlen, 1999). These unexpected or discretionary accruals are used by managers to manage earnings. A simple approach to measuring earnings quality as the inverse of estimates and judgments embedded in accruals is based on changes in total accruals. As long as some portion of accruals is both non-manipulated and approximately constant over time, changes in total accruals measure managerial manipulations and provide an inverse measure of earnings quality (Schipper & Vincent, 2003). Earnings quality can be improved when accruals smooth out value-irrelevant changes in cash flows, but earnings quality is reduced when accruals are used to hide value-relevant changes in cash flows (Dechow & Schrand, 2004). Less reliable accruals or earnings quality lead to lower earnings persistence.

Earnings Persistence

Earnings volatility or earnings persistence is the continuity and durability of the current earnings and denotes how constant or unstable earnings are. A company with fluctuating earnings may be seen as a risky investment, especially when cash is needed for capital investments because future cash flows can be uncertain. Earnings are, on average, more persistence that cash flows, but the cash flow component of earnings is more persistence than accruals (Dechow & Schrand, 2004). Sloan (1996) evaluated whether cash flow from operations and accruals had different implications for the persistence of future earnings and showed that the extent to which current earnings performance persists into the future is shown to depend on the relative magnitudes of the cash and accrual components of current earnings.

Dichev & Tang (2008) investigated the link between earnings volatility and earnings predictability and found that the consideration of earnings volatility brings substantial improvement in the prediction of both short-term and long-term earnings. Artikis & Papanastasopoulos (2016) examined the persistence, pricing, and economic significance of the cash component of earnings in the United Kingdom listed firms from 1981 to 2013. The results from the persistence tests indicated that there were systematic differences in the persistence among the cash subcomponents of earnings and that the cash component of earnings cannot be treated as a homogeneous unit. Richardson, Sloan, Soliman & Tuna (2005), linked accrual reliability to earnings persistence by constructing a model showing that less reliable accruals led to lower earnings persistence, also confirmed that less reliable accruals lead to lower earnings persistence and that investors do not fully anticipate the lower earnings persistence, leading to significant security mispricing. Dechow, Larson & Resutek (2019) stated that empirical regularity that accruals persist into future earnings at a lower rate than cash flows is frequently interpreted as evidence of low accrual quality. They predicted that accrual heterogeneity significantly impacts this empirical regularity and showed that their consistency measure captures unique aspects of reporting quality and that reporting consistency can induce both higher or lower earnings persistence depending on the measurement rules attributable to the underlying accrual.

RESEARCH STATEMENTS DEVELOPMENT

To detect earnings management or financial manipulation, we used a modified version of the Dechow and Dichev (2002) accrual quality model that classifies the quality of accruals and earnings in low and high quality, utilizing changes in working capital as a measure of accruals and cash flow from operations as a proxy for cash flow related to accruals. The residuals from the regression reflect the accruals that are not related to cash flow realizations, and their standard deviation is a firm-level measure of accrual and earnings quality. Our aim is to verify the following statement:

$S_{1:}$ firms with low-quality (high-quality) accruals are more likely to engage (not engage) in earnings management.

Dechow & Dichev (2002) used the standard deviation of the residuals from their regression as a firm-specific measure of accrual quality, where a higher standard deviation signifies lower quality. Therefore, we expect net income and CFO measures to be much closer together for firms with good earnings quality. CFOs feel that most earnings misrepresentation occurs in an attempt to influence stock price and to avoid adverse compensation and career consequences for senior executives (Dichev, Graham, Harvey, & Rajgopal, 2013).They also pointed out that the two most common red flags to potential misrepresentation are: persistent deviations between earnings and the underlying cash flows and deviations from industry and other peer experience. In this research, the first statement attempts to verify that firms with these characteristics have a higher probability of earnings management.

Most practitioners and academics agree that cash flows are more reliable than earnings, and unlike earnings that contain accruals, cash flows are not estimated, and for a company to manipulate it, it must incur real costs. Earnings are, on average, more persistence than cash flows, but the cash flow component of earnings is more persistence than accruals (Dechow & Schrand, 2004). Sloan (1996) stated that the extent to which current earnings performance persists into the future is shown to depend on the relative magnitudes of the cash and accrual components of current earnings. Kubota & Takehara (2019) investigated the time-series properties of accounting earnings and their components and proposed a new measure of earnings persistence in accordance with the vector autoregressive (VAR) model- linking earnings and stock returns. As a preliminary analysis, they estimated the first-order autocorrelations and test the stationary of five variables: earnings, cash flow from operations, total accruals, current accruals, and non-current accruals. They argued that earnings and noncurrent accruals have a more persistent time-series than cash flows and current accruals. Following the literature on earnings persistence, this research also verifies the following statements:

S_2: There is a difference (no difference) in the persistence of cash flow (earnings) between companies with high or low earnings quality.

RESEARCH METHODOLOGY

Research methodology utilized in earnings management and fraud detection varies depending on the question been asked or the hypothesis the researcher is trying to develop. For the manipulation of earnings, managers have a variety of choices to increase or decrease earnings. In the 1970s and early 1980s, many studies found that managers can exercise discretion through the choice of accounting methods or policies (Sun & Rath, 2010). Executives or managers can use specific accounting policies to manipulate earnings (Juma'h, 2014, 2019). Researchers have tried to detect earnings management by dividing accruals into two components: discretionary and non-discretionary. Discretionary accruals are the ones that managers can choose within the flexibility of accounting or from Generally Accepted Accounting Principles (GAAP) to adjust the firm's cash flows. Non-discretionary accruals result from normal business operations. Since discretionary accruals are the management choices to make accounting adjustments, they are of our interest because of the opportunity they represent to manipulate earnings. Also, those discretionary accruals can determine the quality of earnings of the company. Earnings management literature agreed that a higher number of accruals denotes the poor quality of earnings and the financial press suggest that a company has an earnings-quality problem if earnings contain unusual items or lack transparency, even if reported earnings and the related disclosures are in accordance with GAAP (Dechow & Schrand, 2004).

The main research question is how the quality of earnings reported by a firm can point out or signal earnings management or financial statements fraud. Good earnings quality will give the investor a sure ground to analyze companies and make an investment in a well-informed environment. The key objective of this research is to examine the relation between earnings quality and earnings management and how these variables, among others, affect the financial reporting of firms; or similarly if firms with low-quality accruals are more prone to engage in earnings management or financial reporting irregularities. To obtain an earnings quality measure, we used a regression method based on past, present, and future cash flows from operations.

Past researches (Sloan, 1996, Dechow & Schrand, 2004, Richardson *et al.* 2005) showed that the accrual component of earnings is less persistent than the cash flow component of earnings and attributes this difference to the greater subjectivity of accruals. Earnings volatility or earnings persistence is the continuity and durability of the current earnings and denotes how constant or unstable earnings are. A company with fluctuating earnings may be seen as a risky investment, especially when cash is needed for capital investments because future cash flows can be uncertain. Richardson *et al.* (2005) suggested that the recognition of less reliable accrual estimates introduces measurement error that reduces earnings persistence and leads to significant security mispricing, allowing for less verifiable and less reliable estimates into accounting numbers that can compromise their usefulness.

Research design

We use multiple linear regression with dummy variables to estimate the nondiscretionary component of accruals. The nondiscretionary component reflects the business condition that naturally creates and destroy accruals, while discretionary accruals identify management choices. The purpose of separate discretionary accruals from total accruals is to determine the number of accruals that are due to management's choices; this is a better proxy for earnings quality.

The equation to obtain total accruals is derived by using:

$$TA_{i,t} = \Delta CA_{i,t} - \Delta CL_{i,t} - \Delta CASH_{i,t} + \Delta STDebt_{i,t} - DEPN_{i,t} / (A_{t-1})$$

Where,

$TA_{i,t}$ = Total accruals

$\Delta CA_{i,t}$ = change in current assets in year t

$\Delta CL_{i,t}$ =change in current liabilities in year t.

$\Delta CASH_{i,t}$ = change in cash and cash equivalent in year t.

$\Delta STDebt_{i,t}$ = change in short-term debt in year t.

$\Delta DEPN_{i,t}$ = depreciation and amortization expense in year t.

A = Total assets.

This equation reflects a balance sheet approach used in prior researches by Healy (1985), Jones (1991) and Dechow *et al*. (1995). After estimating total accruals, the Jones Model is used to estimate non-discretionary accruals. Non-discretionary accruals are the residuals of the following regression:

$$TA_{i\,t} / A_{i\,t-1} = \alpha_{I\,t} (1/A_{i\,t}) + \beta_1 (\Delta REV_{i\,t} /1/A_{i\,t}) + \beta_2 (PPE_{i\,t} /1/A_{i\,t}) + e_t$$

Where,

$TA_{i\,t}$ = total accruals for a company i in year t

ΔREV = revenues in year t minus revenues in year t-1

$PPE_{i\,t}$ = gross property plant and equipment in year t

$A_{i\,t-1}$ = total assets in year t-1

e_t = error term in year t.

Accruals require estimation from the management; these estimates allow management the ability to choose different accounting procedures giving them the option to influence financial results presenting an economic picture different from the real performance. Also, these estimations, either intentional or unintentional, reduces the ability of earnings to reflect future cash flows (Dechow & Schrand, 2004). Earnings or cash flows are judged to be of higher quality when they are: more persistent and less volatile, more strongly associated with future cash flow realizations and more strongly associated with contemporaneous stock performance or market value (Dechow & Schrand, 2004, Dechow, Larson & Resutek, 2019).

Similar to Dechow & Dichev (2002), to obtain a practical measure of working capital accruals quality, a firm-level time-series regression is used: $\Delta WC = \beta_0 + \beta_1 (CFO_{t-1}) + \beta_2 (CFO_t) + \beta_3 (CFO_{t+1}) + e_t$; where ΔWC is the change in working capital and CFO is cash from operations. The model was modified to include seven years, five years before the fraud was discovered (CFO_{t-5}, CFO_{t-4}, CFO_{t-3}, CFO_{t-2}, CFO_{t-1}) and one year after (CFO_{t+1}) to capture long-term accruals. The residuals from this regression reflect the accruals that are unrelated to cash flow realizations (Dechow & Dichev, 2002). The standard deviation of these residuals is a firm-level measure of accrual quality, where higher standard deviation denotes lower quality.

To measure the persistence of earnings and cash flow from operations, this research follows Dechow & Schrand's (2004) regression of the future value of the variable on its current value: $X_{t+1} = \alpha_t + \beta(X_t) + e_t$. The closer β is to 1, the more persistent the variable X_t is. The following regressions models estimate the persistence of earnings and cash flows respectively: $Earnings_{t+1} = \alpha + \beta(Earnings_t) + e_t$; $CFO_{t+1} = \alpha + \beta(CFO_t) + e_t$; where β is the persistence parameter.

Sample

The sample's financial data was obtained from Compustat and consist of 61 firms accused by the Securities and Exchange Commission (SEC) of fraudulent financial reporting in Accounting and Auditing Enforcement Releases (AAER) issued during a ten-year period between January 2007 and December 2016. The sample is limited to firms with complete data for assets, earnings, cash flow from operations, changes in account receivable, and change in inventory. Excluded from the sample are Financial firms (SIC codes 6000-6999) and firms without complete data. Of the total sample of 303 firms, 51 financial firms were excluded because of the regulation of such firms along with 104 CPA's firms and individuals accused in the sample period, 5 releases involving the same firm and 82 firms with no or incomplete data. A group of non-accused firms (control firms) was used to determine differences in accruals and earnings quality. The control firms are of the same size and industries as the accused firms. That results in a final sample of 122 firms. See Table 1.

Table 1
Companies accused by the Securities and Exchange Commission from 2007-2016, Excluded Firms and Final Sample for Research

Accounting and Auditing Enforcement Releases between 2007 and 2016	303
Financial Firms	(51)
Auditing and other accusations not related to research	(104)
Releases involving the same firm	(5)
Companies with no or incomplete data	(82)
Total accused companies by SEC included in the Sample	61
Selected companies (competitors) for comparison	61
Final sample	122

The Appendix shows descriptive statistics and correlation for accused firms from 2007 to 2016.

RESULTS

According to our sample, the industry with the highest total of accusations is Business Services (SIC code 73) with 10 accusations; Electronic equipment except computers (SIC code 36) with 6 accusations follow by Food and Kindred Products (SIC code 20) with 5. Based upon information included in the AAERs we classify the methods used to deceptively reporting the financial statement information and the SEC definition of the alleged violation; the two most common techniques used to deceive investors were overstated earnings (64%) and the presentation of False Financial Statements (18%).

The most common techniques used to deceive investors (overstated earnings and false financial statements) take over six years to be detected. However, for 7 firms in the sample, the time between fraud year and accusation year was more than 10 years; for 17 firms, the time was between 7 and 9 years and for 37 firms, the time was 6 years or less.

Considering the Auditor's Opinion on the Financial Statements, all accused companies received an Unqualified Opinion, and 18 firms received an Adverse Opinion on internal control due to a material weakness. Two firms showed doubts about their ability to continue as a going concern, and two did not receive an opinion on internal control. This is consistent with the argument that the main objective of an audit is to issue a statement or an opinion as regards the quality or integrity of the company's reported financial information and not to detect fraud.

As shown in Table 2, the mean for total accruals of accused firms is -0.07 compared with a -0.066 for control firms. That result could be expected since a high percentage of these companies were accused of overstated earnings.

Table 2: *Descriptive Statistics Total Accruals Modified Jones Model (Accused companies)*

Mean	-0.070
Std Error	0.021
Median	-0.051
Std Deviation	0.162
Control companies	
Mean	-0.066
Std Error	0.018
Median	-0.044
Std Deviation	0.145

Descriptive statistics for the variables used in the Jones Model to determine non-discretionary accruals are shown in Table 3. Total accruals are lower for control firms (-0.088) compared with the accused firm's (0.001). The results were expected since a high percentage of the accused firms were accused of overstating revenues. Also, the data showed that changes in revenues for the accused firms are greater than the control sample. The discretionary accruals are higher for accused firms compare to the control sample. This result can be expected since discretionary accruals often provide managers the opportunities to manipulate earnings. Also, can be interpreted as the control companies having better earnings quality than the accused companies, since more accruals indicate more estimation and errors of estimation, and therefore lower quality of accruals (Dechow & Dichev, 2002). Correlations for both sub-samples are shown in Table 4.

Table 3: *Descriptive statistics of Jones Model Variables for Accused and Control Firms*

Table 4: *Pearson Correlation for Variables of Accused and Control Firms for Jones Model*

Control Firms

Variables	TA/Ai t-1	1/Ai t-1	∆REV/Ai t-1	PPE t/Ai t-1
TA/Ai t-1	1			
1/Ai t-1	-0.986	1		
∆REV/Ai t-1	0.346	-0.344	1	
PPE t/Ai t-1	0.093	-0.038	-0.071	1

Correlations (Accused firms)

Variables	TA/Ai t-1	1/Ai t-1	∆REV/Ai t-1	PPE/Ai t-1
TA/Ai t-1	1			
1/Ai t-1	0.506	1		
∆REV/Ai t-1	0.001	0.028	1	
PPE/Ai t-1	-0.065	-0.027	0.977	1

∆REV= changes in revenues, PPE = property, plant and equipment, Ai = total assets.

Notice the negative relation between total accruals and Gross PPE for the accused sample. A negative relation means that as one variable increases, the other decreases. In this case as total accruals increases, gross property, plant and equipment decreases. The decreasing account is most likely be the account of net property, plant and equipment since the adjusting entry increases an expense account (depreciation expense) and a contra-asset account (accumulated depreciation) decreasing the book value or the net property, plant and equipment. The positive correlation between total accruals and gross PPE for the control firms resembles the normal operations of a business. Another atypical correlation arises between ∆REV and total accruals for the accused firms. The 0.001 coefficient shows almost no relation between variables. But keep in mind that among the accused sample, there is a high percentage of overstated-earnings accusations, so this coefficient at least should show a medium to high correlation. Also, there is a high correlation between PPE and ∆REV for the accused sample giving the impression of a high fixed-assets turnover ratio. This ratio is used by analysts to measure operating performance, specifically measures a company's ability to generate net sales from fixed-asset investments.

For model developing, residuals from a firm-level time-series regression are obtained to determine the quality of the earnings, where the standard deviation of these residuals is a measure of accrual quality where higher standard deviation denotes the lower or poor quality of earnings. Descriptive statistics and correlations for our sample of accused firms are provided in Tables 5 and 6.

Table 5: *Descriptive Statistics Accused Companies (Pool)*

	∆WC	Earn	Prof	Accruals	CFO t_{-1}	CFO t_0	CFO $_{t+1}$	TA $_t$
Mean	0.021	0.047	-0.043	-0.068	0.060	0.056	0.018	6,136
Median	0.027	0.101	0.031	-0.034	0.070	0.066	0.060	1,101
Std Deviation	0.115	0.411	0.567	0.259	0.249	0.294	0.393	13,675

All variables scaled by average total assets

An examination of the descriptive statistics shows that the results are in line with previous research with comparable variables (e.g., Barth et al. 2001, Dechow & Dichev, 2002). Earnings are less than $CFO_{t,}$ suggesting that accruals are mostly negatives. Accruals are negative mainly because of depreciation.

Table 6: *Correlations Accused Companies (Pool)*

	∆WC	Earn	Prof	Accruals	TA $_t$	CFO $_{t-1}$	CFO $_t$	CFO $_{t+1}$
∆WC	1							
Earn	0.705	1						
Prof	0.567	0.952	1					
Accruals	0.566	0.811	0.93	1				
TAt	-0.043	0.055	0.076	0.06	1			
CFO $_{t-1}$	0.439	0.884	0.856	0.665	0.003	1		
CFO $_t$	0.452	0.922	0.877	0.658	0.055	0.956	1	
CFO $_{t+1}$	0.449	0.926	0.916	0.734	0.067	0.912	0.957	1

All variables scaled by average total assets

There is a positive relation between Earnings (Earn) and Cash flow from Operations ($CFO_{t\,0}$) (0.92), between Earnings and ∆WC (0.71) and between Accruals and ∆WC (0.57). Tables 7 and 8 show descriptive statistics and correlations for a sample of control companies. As with the accused companies' sample, earnings are lower than CFO and accruals are negatives. ∆WC is negatively correlated with CFO_{t+1} and $CFO_{t,}$ and CFO_t is positively correlated with CFO_{t+1}. These results agree with previous researches.

Table 7: *Descriptive statistics (Control Firms)*

	CFO_t	$∆WC_t$	$Earn_t$	$Prof_t$	$Accruals_t$	$TA_{t\ (in\ million)}$
Mean	-0.061	-0.199	-0.162	-0.018	-0.031	3,995
Median	0.099	0.014	0.098	0.044	-0.054	587
Std Deviation	0.842	1.605	1.624	0.223	0.364	9,391

All variables scaled by average total assets

Correlations are in line with Dechow & Dichev (2002), CFO is negatively correlated to ∆WC and accruals and positively correlated to CFO_{t+1}, CFO_{t-1} and $Earn_{t+1.}$ Accruals are positively correlated with Profits and ∆WC as expected and negatively correlated with CFO_t, CFO_{t-1}, and CFO_{t+1}. Also, accruals are negatively correlated with earnings $_t$ and earnings $_{t+1}$ suggesting income-decreasing accruals such as depreciation.

Table 8: *Pearson correlations of control companies*

	∆WC	Accruals	CFO	CFO $_{t-1}$	CFO $_{t+1}$	Earn	Earn $_{t+1}$	Prof
∆WC	1.000							
Accruals	0.051	1.000

CFO $_{t-1}$	-0.018	-0.029	0.002	1.000				
CFO $_{t-1}$	-0.002	-0.703	0.034	0.070	1.000			
Earn	0.971	-0.154	-0.026	-0.001	0.224	1.000		
Earn $_{t+1}$	-0.083	-0.694	0.048	0.074	0.984	0.141	1.000	
Prof	-0.053	0.106	0.019	0.055	0.439	0.019	0.430	1.000

All variables scaled by average total assets

To obtain the residuals needed to measure the quality of earnings of accused firms the following regression was run:

$$\Delta WC = b_0 + b_1 *CFO_{t-5} + b_2 * CFO_{t-4} + b_3*CFO_{t-3} + b_4 * CFO_{t-2} + b_5 * CFO_{t-1} + b_6 * CFO_{t\,0} + b_7 * CFO_{t+1} + e_t$$

Where $CFO_{t-5,}$ CFO_{t-4}, CFO_{t-3}, CFO_{t-2}, and CFO_{t-1} are cash flows from operations before the companies engaged in fraud. $CFO_{t\,0}$ is the fraud year while CFO_{t+1} is cash flow from operations the year after the fraud was perpetrated. Accruals are negatively related to current cash flows and positive related to past and future cash flows (Dechow & Dichev, 2002), results showed a different sign in the current cash flow ($CFO_{t\,0}$) coefficient (0.051), that may be explained by our sample of accused firms. Results on CFO_{t-1} and CFO_{t+1} are in line with past research.

The standard deviation of the residuals was 0.089 for our sample of accused firms. We compared the results of the accused sample with a sample of 65 companies that have not been accused. The standard deviation of the residuals was .058 showing that control firms have better earnings quality than accused firms. To validate the results of the earnings quality coefficient of our model and evaluate its consistency we compared our results with another widely used model, Francis *et al*. (2005), which utilized the Dechow & Dichev approach augmented with two regressors, the results showed a slightly higher coefficient (0.092) for the Francis *et al.* (2005) model compared to our model (0.089), showing the validity of our outcomes and the strength of the results with respect to a different definition of earnings quality. The main objective of this research was to demonstrate if firms with low-quality earnings are more prone to engage in earnings management or financial reporting irregularities. According to our regression results, a measure of less than 0.058 was to be considered a good quality measure, anything above that would be medium to poor quality. Twenty-six percent of the accused firms showed poor quality, while sixty-four percent exhibited good quality and ten percent medium quality. Just eight percent of the control firms showed poor quality, while eighty-seven percent presented good earnings quality, and five percent medium quality.

Persistence of earnings is measured as the persistence of profitability (i.e., ROA) since the metric used for measuring earnings persistence is earnings deflated by some measure of assets such as average total assets. Table 9 shows descriptive statistics for Return on Assets for our sample of accused companies and control companies.

Table 9: *Descriptive statistics for Return on Assets of Control and Accused Firms*

Descriptive Statistics (Control Firms)	Total Assets	ROA
Mean	4,012	0.005
Median	587	0.046
Std Deviation	9,388	0.202

Descriptive Statistics (Accused Firms)	Total Assets	ROA
Mean	6,136	-0.036
Median	1,101	0.032
Std Deviation	13,675	0.530

The return on assets of the control companies is higher than the return on assets of accused sample. The returns are as high as 0.40 on our control sample compared to a high of 0.155 on the accused sample. This means that in general, control companies are more effective in converting the money they invest in net income.

Table 10 provides results for future earnings on current earnings and Cash Flow from Operations and Accruals for our sample of accused companies. We can interpret these results as follows: for each dollar a company earns, $0.36 cents will persist into next year earnings. For each dollar of CFO, only 1.5 cents will persist into next year's earnings. For each dollar that represents accruals $-0.001 persist into the following year. The negative sign in accruals could be because a very high percentage of the accused companies manipulated earnings. These results show that earnings backed by cash flows are more persistent that earnings that represent accruals. This is consistent with Dechow and Schrand (2004).

Table 10: *Regressions results of Future earnings on current earnings and CFO and accruals (Pool Accused Companies)*

	Earnings $_t$		Accruals and Cash Flows	
Variable	Coefficient	t-statistics	Coefficient	t-statistics
Intercept	-0.014	-0.79	-0.059	-2.537
Earnings	0.359	24.134		
Accruals			-0.001	-2.149
CFO			0.015	2.981

Source: Adapted from Dechow and Schrand (2004). All variables scaled by average total assets.

As shown in table 11, for the pool control companies, $0.59 will persist into next year earnings for every dollar the company earns, representing a 64% increase over the accused companies. Also, for each dollar that represents accruals $0.32 persist into the following year. Consistent with Sloan (1996), Dechow & Dichev (2002), and Dechow & Schrand (2004), results show that earnings performance attributable to the accrual component of earnings exhibits lower persistence than earnings attributable to Cash Flows from Operations.

Table 12 shows the analysis of future earnings and future cash flows from operations on current earnings and current cash flows from operations from our pool sample of accused companies;

the firms were grouped into four quartiles. The first quartile contains firms with high negative accruals and fourth quartile groups companies with high positive accruals. Earnings are less persistence than CFO in the first, third, and fourth quartiles, while in the second quartile earnings are more persistence that CFO. In line with Sloan, (1996), Dechow & Dichev, (2002), and Francis et al. (2005), persistence of earnings is reduced with larger accruals of either sign, which is the case in 1^{st} and 4^{th} quartiles.

Table 11: *Regressions of Future earnings on Current Earnings and CFO and Accruals (Pool Control Companies n=165)*

	Earnings $_t$ Only		Accruals and Cash Flows	
Variable	Coefficient	t-statistics	Coefficient	t-statistics
Intercept	-0.103	-1.278	-0.176	-2.724
Earnings	0.594	13.895		
Accruals t			0.324	5.995
CFO t			2.202	12.801

All variables scaled by average total assets

Table 12*: Persistence of accused companies by quartiles*

	1st quartile	2nd quartile	3rd quartile	4th quartile
Earnings	0.627	1.07	0.635	0.612
Accruals	-0.00072	0.672	-0.569	-0.002
CFO	1.01	0.001	0.668	1.11

The test for the persistence of earnings and cash flow from the data revealed that Cash Flow from Operations is more persistence that earnings in both control and accused companies. These results may be perceived inconsistent with past researches that alleged that earnings are more persistence that cash flows, on average, but large accruals significantly reduce the persistence of earnings. Results show that there is a difference between the persistence of earnings of accused companies and the persistence of control companies, overturning our statement that there is no difference in the persistence of earnings between companies with high or low earnings quality. Cash Flows from Operations of control companies shows a higher coefficient than the accused firms. This result validates our statement that there is a difference in the persistence of cash flows between companies with high or low earnings quality.

CONCLUSIONS

The accounting discipline has changed in the practical and theoretical backgrounds at the beginning of the twenty-first century. The resulting environment raises a host of questions that are of concern to academics, regulators, and practitioners, including the way companies manage earnings in order to present financial health that differs from reality. Managers try to achieve their goals through aggressive accounting procedures to demonstrate the company's financial strength. The external pressures from shareholders, financial analysts, and credit rating agencies influence managers to incur in deceitful practices to inflate earnings and increase ~~stocks~~ prices sometimes for their benefit. The data showed that the years 2007 and 2009-2010, the pre-and post-years of the Credit Crisis present the highest percentage of accusations announcements.

Total accruals were calculated for 61 accused firms and 61 non-accused or control firms. To determine which companies are more prone to earnings management or financial statements fraud, we used the Jones Model (1991) to determine non-discretionary accruals. Control firms showed a higher coefficient for non-discretionary accruals (0.004) compare to a (-0.049) for accused firms; the non-discretionary component reflects the business condition that naturally creates and destroy accruals. We can infer from these results that a high percentage of the accruals created by the control firms were due to their normal operations.

The residuals from the regression reflect the accruals that are not related to cash flows from operations, and the standard deviation of those residuals is a firm-level measure of accrual or earnings quality. A higher standard deviation represents lower quality, and a lower standard deviation denotes higher quality. The residuals from the regression reflect the accruals that are not related to cash flows from operations, and the standard deviation of those residuals is a firm-level measure of accrual or earnings quality. A higher standard deviation represents lower quality, and a lower standard deviation denotes higher quality. The standard deviation of the residuals for our sample of accused firms was 0.089, while for the control firms was 0.058 showing that control firms have better earnings quality than accused firms.

Accused firms showed higher discretionary accruals than control firms; this is consistent with the sample characteristic that 68% of the firms were accused of overstating earnings or assets. Earnings management literature agreed that a higher number of accruals denotes the poor quality of earnings, so we expected accused companies to have a poor quality of earnings while expecting a high percentage of the control companies or non-accused firms to have good earnings quality. The latter was the case when eighty-seven percent of non-accused firms showed good earnings quality, while twenty-six percent of the accused firms showed poor quality.

Our results for future earnings on current earnings and Cash Flow from Operations and Accruals for our sample of accused companies showed that for each dollar a company earns, 0.36 cents would persist into next year earnings. For each dollar of CFO, 1.5 cents will persist into next year's earnings. For each dollar that represents accruals $-0.0001 persist into the following year. The negative sign in accruals could be because a very high percentage of the accused companies manipulated earnings. For future earnings on current earnings and Cash Flow from Operations and Accruals for the sample that for control companies $0.59 will persist into next year earnings for every dollar, the company earns, representing a 64% increase over the accused companies. Also, for each dollar that represents accruals $0.32 persist into the following year. Our findings are consistent with Sloan (1996), Dechow & Dichev (2002), and Dechow & Schrand (2004), and show that earnings performance attributable to the accrual component of earnings exhibits lower persistence than earnings attributable to Cash Flows from Operations.

The difference between the persistence of earnings of accused companies and the persistence of control companies overturns our statement that there is no difference in the persistence of earnings between companies with high or low earnings quality. Cash Flows from Operations shows different coefficients for both samples. The coefficient for control or non-accused firms is higher (1.33) than the coefficient for our accused sample (1.03) validating our statement that there is a difference in the persistence of cash flows between companies with high or low earnings quality.

As general findings, our research showed that the industry with the highest total of accusations was Business Services (SIC code 73) with 16% of the accusations. This finding agrees with prior similar research (i.e., Dechow *et al*. 1996). Also, 64% of the accused companies overstated earnings, being this violation, the most common technique used to deceive investors, taking an average of 6.78 years for the company to be accused. This result also agrees with the *Fraudulent Financial Reporting 1998-2007,* where 61% of the firms (n=347) were accused of some type of improper revenue recognition. Our results indicate that nor the firms (SIC 73) or the technique used to deceive investors (improper revenue recognition) have not changed much in the past 22 years; we can consider this a new finding in the literature.

An important and unexpected finding was the high percentage (100%) of Unqualified Opinions on Financial Statements for the sample of accused firms. We expect at least some opinions to be qualified, or even a disclaimer. One reason to issue a qualify opinion could be that the company did not present its financial records in accordance with GAAP, which was the case in some of these firms. Only nineteen percent (19%) of the accused firms received an Adverse Opinion on internal control due to a material weakness. This should have raised red flags on those companies. The Sarbanes-Oxley Act requires all financial reports to include an Internal Controls Report that shows that a company's financial data are accurate (within 5% variance) and adequate controls are in place to safeguard financial data. Results also show that out of 61 firms accused, 80% of the companies kept operating, 12% were either sold or privatized, and 8% merged.

This study corroborates prior empirical studies and updates the earnings management, earnings quality, and earnings persistence literature. Consistent with previous research (Sloan,1996), Dechow & Dichev (2002), and Dechow & Schrand (2004), our results validate that earnings performance attributable to the accrual component of earnings exhibits lower persistence than earnings attributable to Cash Flows from Operations. Similarly, our findings show that in general, control or non-accused companies are more effective in converting the money they invest in net income than accused firms or firms with low earnings quality, or in other words, control firms have a better Return on Assets percentage than accused firms. Nonetheless, earnings are more persistence for control firms than for accused firms.

Our results also showed firms that have not been accused of any wrongdoing showed a higher coefficient for non-discretionary accruals compare to the accused firms, meaning that a high percentage of the accruals created by the control firms were due to their normal operations. But accused firms have higher discretionary accruals than our control firms signaling some type of manipulation or lower earnings quality.

Finally, a numerical scale is suggested for expressing the earnings quality measure of firms. This scale can be used as a guide to determine good or poor earnings quality in any public firm that a user can be interested in and could serve as a complement to the SEC's Accounting Quality Model to eradicate potential fraud or simply identify aggressive uses of the discretion allowed under GAAP. We used the standard deviation of control firms (0.058) to develop an earnings quality scale. If a data distribution is normal then about 68 percent of the data values are within one standard deviation of the mean (mathematically, $\mu \pm \sigma$, where μ is the arithmetic mean), about 95 percent are within two standard deviations ($\mu \pm 2\sigma$), and about 99.7 percent lie within three standard deviations ($\mu \pm 3\sigma$) because 95 percent is the most commonly used interval we can argue that a good earnings quality can be any measurement below 0.058 based on our results. A measurement of 0.074 or higher can be view as a poor earnings quality.

LIMITATIONS

Our model for earnings quality is based on Dechow & Dichev (2002); the model was modified to include seven years instead of the original three years. As with the original model, the independent variables are measured with error, implying that the regression coefficients are likely to be biased toward 0, and the R^2 will be reduced. Also, the bias is more severe for b_1 and b_3 as compared to b_2 (Dechow & Dichev, 2002). The final sample size might be a limitation too, from an original 303 accused firms, 61 had the required data. However, the results were comparable with prior research.

One constraint common in prior works on persistence models is the assumption that the coefficient on accruals and cash flows is equal in the absence of accrual measurement error (Richardson et al., 2005). That same constraint is present in our persistence model also.

FUTURE RESEARCH

In this research, the focus was on earnings quality, earnings, and cash flow persistence as an indicator of earnings management or accounting fraud. A partially functioning model was developed based on earnings quality but might need to be developed further to increase its precision and accuracy. Also, some non-financial variables such as personality, optimism, aggressiveness, and other related traits can be an interesting addition to the model, since tone at the top sometimes dictates the organizational culture, and we need to understand what drives these executives to report misleading information.

APPENDIX

List of variables and descriptive statistics for sample data
The following table shows variables, descriptive statistics, and correlation for our sample of accused firms from 2007 to 2016. Where CFO is cash flow from operations, IBEI is income before extraordinary items, A/R is account receivables, CPLTD is current portion of long-term debt, TA is total assets, PP&E is property, plant, and equipment, TL is total liabilities, Dep&Amor is depreciation and amortization, DIV is dividends, COGS is the cost of goods sold, and GPM is gross profit margin.

Summary of Variables and Descriptive Statistics

VARIABLES	MEAN	MEDIAN	STD DEV	MINIMUM	MAXIMUM
CFO	1,045.32	73.71	5,142.06	-663.20	48,601.00

ABSTRACT

Today, political campaigns rely heavily on analytics to target potential voters. The algorithms used, as well as bias that may be introduced in the process, may skew the results and cost an election, as seen in the Clinton campaign. Additionally, Social Media plays a huge role in political races, as does fake news. More alarming is the new trend for Social Media sites to censor anyone or anything which can also make or break a campaign. In this paper we research events that affected the 2016 Presidential election and present issues that may have an effect on future elections.

KEYWORDS Big Data, Bias, Analytics, Fake News, Social Media

INTRODUCTION

In Data Sciences and Computing in general, bias can be introduced in a variety of ways. Conscious or subconscious prejudice, bias, can be found in the data collection phase, analysis phase, and insight phase. Bias can also be found in the outcome phase, assessment phase and improvement phase. Analysts must be aware of bias and cautious to prevent it in all phases of their analysis. Analytics and ethics are not necessarily enemies but can be if not properly treated. For example, releasing data gained through analytics, whether it is technically correct or not, could result in a company's loss of their reputation, create competitive weakness, or possibly result in legal sanctions (Noyes, 2015). Big data and analytics extend well beyond organizational benefits and Gartner (Noyes, 2015) predicts that by 2020, big data analytics will cause half of all business violation ethics. The use and or misuse of data also holds true in political analytics.

Today, companies world-wide use big data in many meaningful ways, and recently, so has our political system. In fact, during the 2008 and 2012 elections, the Obama campaign relied heavily on analytics to outperform their Republican counterparts. Going into the 2016 elections, both sides had come to realize that there had been a major shift in how people communicated, moving away from landline phones and going more for mobile phones and Social Media. As a result, it came as no surprise that both the Democratic and Republican campaigns would follow what Obama had done and use analytics in a big way for the 2016 election (Enderle, 2016). With so much data, what went wrong for the Clinton campaign and what went right for the Trump campaign?

LITERATURE REVIEW

Introducing Bias

The Book “Shattered” shares a perspective on why Clinton lost the 2016 election. Highlights include Clinton’s campaign manager, Robby Mook, who put a lot of faith into a self-developed, super analytic system called Ada. Mook felt that Ada was the campaigns “secret weapon." As for Mook’s algorithm, when approached, Mook’s team said, “we’re the smartest guys around here so let us do our thing” (Jacknis, 2017). The Ada algorithm played a role in just about every strategic decision made by the campaign, including where and when to send the candidate, her staff, and where to place TV ads. Interestingly, Ada was able to run about 400,000 simulations a day, providing a detailed picture of which battleground states would be the tipping point. (Wagner, 2016). Sometimes too-much is too much. Because it’s humanly impossible to sift through 400,000 simulations every day, staff had to rely on Ada to produce summary results of these simulations.

One of the things that Ada missed was the states of Michigan and Wisconsin. The Clinton campaign had paid little attention to these states, assuming they were in the bag, and it wasn’t until just a week before the election that staff realized they had a problem. It appears that Ada had been programmed to underestimate the power of rural voters. The campaign then tried a last-minute ad campaign and a tour of these states with Clinton and the Obama’s, but it was simply too late. (Wagner, 2016)

Was there bias? According to Aurerbauch (2017), Ada was developed by dozens of researchers who were led by Clinton’s director of analytics, Elan Kriegel, in close consultation with campaign manager Robby Mook. Inputs to Ada included polls and surveys as well as the campaigns data from field workers and it’s possible that bias could have been introduced at these points.

The UPB Phenomena

At the beginning of the 21st century, accounting scandals, among other events, led to the collapse of billion-dollar companies. These scandals only confirmed that unethical acts were being conducted, often flourishing within organizations. Research into unethical behavior within organizations has found assorted reasons as to why employees might engage in unethical acts, for example, personal gain, the gain of the organization, or even to cause harm against the organization. (Umphress, 2010). These acts fall under the title of unethical pro-organizational behavior. UPB includes acts of commission (e.g., “cooking” numbers to boost analyst projections and stock values) and omission (e.g., withholding information about the hazards of a pharmaceutical product) that are typically considered unethical.

UPB is predominantly considered pro-organizational behavior which is neither specified in formal job descriptions nor ordered by superiors, yet, is carried out to benefit or help the organization. Many theorists believe that the more an individual identifies with their organization, the more likely they are to disregard their personal moral standards and engage in acts that favor the organization. Further research has found that the stronger the employees’ organizational identification, the more influence it will have on productive work behavior, such as increased extra-role behaviors, and job performance. Umphress et al., believe that individuals who identify strongly with their organization may be more likely to engage in UPB. (Umphress, 2010).

As a public example, we have recently noted journalists who have been found to be lying or “bending” the truth. In 2015, NBC Nightly News anchor, Brian Williams, was caught lying about riding in a helicopter that was shot down in Iraq in 2003. NBC suspended him for six months without pay and the Peabody Award-winning newsman, became the top story himself. In 2015, Fox News Channel star, Bill O'Reilly, was caught lying about experiencing war involving Argentina and England in 1982. In 2011, MSNBC's Rachel Maddow, was caught lying when she accused Rush Limbaugh of racism. She was later forced to apologize to Limbaugh on the air. Be it public figures, or an analyst within an organization, people tend to get caught up in the moment, the organization, personal gain, or a number of reasons that might fall under UPB. Imagine then, how an analyst could add an extra day of revenue to the monthly or quarterly reports for a company. Depending on their position within the company, unethical behavior may be committed (Umphress, 2010).

What does the UPB phenomenon have to do with political analytics? Probably more than we know! In fact, Aurerbach (2017) determined that Clinton analysts did have bias, and programmed that into Ada, assuming that Michigan, Wisconsin and Pennsylvania were a "lock". As Aurerbauch (2017) points out, "If a piece of code crashes, it's broken, but at least you know it's broken. The most dangerous kind of code—as I learned too many times in my years as a software engineer at Google and Microsoft—is the kind that breaks but appears to keep working. The worst part is that you have only yourself to blame" Aurerbauch (2017). In essence this was Ada's failure……..it went wrong early and no one caught it.

Passive Bias

Enderle (2016) found another type of bias was introduced, passive bias. As the campaigns matured prior to the November elections, things heated up and Clinton began a very negative campaign against Trump, one that would see her call his followers "deplorables". This caused many folks on both sides to either not respond to surveys or not respond truthfully. As a result, this introduced massive pro-Clinton bias, a bias that Ada could not account for. Enderle went on to state that "As an analyst, a big part of the job is identifying and mitigating bias otherwise you are driving the people who pay you to make bad decisions and, given the outcome, that would seem to be the case here" (Enderle, 2016).

If that were not enough, even more bias was introduced by complacency. Because Ada was reporting great numbers to the Clinton campaign, Mrs. Clinton reportedly became complacent and started laying back while Trump who didn't believe any of the numbers pushed even harder. As Enderle (2016) pointed out, when people don't challenge the results they like, it almost always leads to bad results…….this certainly proved out in Clinton's case. In fact, Enderle pointed out the three rules of analytics. First, assure your data source. You must have a strong sampling methodology to obtain accurate results. Secondly, it is a must to identify and eliminate any and all bias; any bias will invalidate the results. Finally, decision makers must challenge the analysis, especially if the analysis is telling you what you want to hear.

Even more bias was introduced via polarization. Smith (2017) found that as campaigns target their supporters with data, there is less effort put forth to persuade these same supporters, causing polarization. Polarization happens because the data puts these potential voters into predetermined buckets which reflects the public's ideology and voting preferences. As Smith (2017) points out, this can be dangerous and may lead to self-induced bias.

The Use of Facebook

While the Trump campaign relied on voter data owned by the Republican party, they also engaged the services of Cambridge Analytica, using their models to help make decisions on advertising and how to better reach donors (Kirchaessner, 2017). Because the Clinton campaign was using a highly sophisticated analytical approach, Trump's campaign knew they needed to combat that with their own analytics. One of the things that helped Cambridge Analytica turn the tide was in their ability to acquire data on people who had voted early, data that it collected from local counties and states. This data was then linked to individual Facebook accounts and then analyzed to determine the political advertisements that they had been subjected to (Kirchaessner, 2017). In his book "Outnumbered" David Sumpter, a professor of applied mathematics at the University of Uppsala in Sweden, analyzed the Cambridge Analytica's models and found they were using a regression "that takes the data we already have about a person and uses them to predict something we don't know about him or her." (Rathi, 2018) However, as Rathi (2018) points out, it is quite difficult to predict a person's personality from their Facebook page using this regression model. Rathi went on to state that a better method is to use Facebooks advertising platform which enables developers to build audiences similar to a manually selected audience.

Although Trumps campaign was investigated for using Cambridge Analytica and their use of Facebook, the Clinton campaign also gathered tons of information from Facebook users by creating and distributing an app that asked users to pair their Facebook friends and families with the smartphone contacts. In this way the Clinton campaign could reach friends of friends (Jacknis, 2017)

The Analytical Focus on Social Media

It used to be that elections would almost certainly be decided by about 20 percent of voters who fell somewhere in the "ideological middle", but that logic has now disappeared as a result of big data analytics. And because of this, Todd (2017) believes that Big Data is hurting American politics, not because it's wrong or that it can't be used for good, it's the cries of "fake news" and "unskew" that are accurate.

Prior to the 1900's, local, national and world news came to us primarily by way of newspapers. In the early 1900's, radio introduced a new medium by which people obtain news. These mediums had editorial boards that scrutinized articles written by trained professionals. These professionals often went through years of college preparatory courses and internships prior to attaining a job in the world of news. Television appeared in the 1950's, and the footsteps of radio were followed when it came to news integrity. When the Internet arrived in the late 90's, so did Blogs, Facebook, Twitter, YouTube, and a host of other Social Media sites. With Social Media, came reporter "wanna-bees", with little or no training in the world of news reporting, and frequently, with little, if any, reporting ethics, presenting information that is often hard to substantiate.

Fake News

It's not known which came first, poor reporting on the Internet, or, poor reporting on the major cable networks such as CNN, MSNBC, FOX, BBC. As witnessed prior to the 2016 presidential election, everyone appears to be scrambling to be the first to report news, be it accurate or not. As a result, we regularly see, companies such as The New York Times and CNN retracting stories upon realizing the stories are incorrect. How much damage is done when a wrong (Fake News) story goes out? Researchers at MIT researched this question, and recently concluded a five-year study on "Fake News on Twitter" (Meyer, 2018).

The study found that a false story reaches 1,500 people six times quicker, on average than a true story does. They also found that false stories outperform the truth on every subject including business, terrorism and war, science and technology, and entertainment, determining that fake news on politics routinely outperform the other categories. Ultimately the researchers found that between 2006 and 2016, about 126,000 tweets had been retweeted more than 4.5 million times. Some of these were linked to "fake" stories hosted on other websites while others started rumors themselves, either in the text of a tweet or in an attached image. For example, a rumor was tweeted in February of 2016, reportedly by a recently deceased elder cousin of Donald Trump, and opposing the presidential bid, stated in his obituary, "As a proud bearer of the Trump name, I implore you all, please don't let that walking mucus bag become president". However, Snopes could not find evidence of the story and rejected it as false. Nonetheless, roughly 38,000 Twitter users re-tweeted the story. It's not known how many might have shared this in the form of an email or other medium (Meyer, 2018)

In a 2017 study of Higher Education Students, Chandra, Surjandy and Ernawaty found that higher education students can become emotional and be misguided by fake news. Alarmingly they can disseminate this fake news faster because of Social Media and instant messaging applications. Because Social Media and instant messaging are used by almost everyone who has a smartphone, to interact and communicate with just about anyone, they can quickly disseminate information, motivations, and promotions, good or bad. Through their research, it was determined that a large proportion of their sample population of Higher Education students actually modify the news and made it look legitimate by including a reliable source! (Yakob, C., Surjandy, Ernawaty, 2017).

Misinformation and Disinformation

False information comes in two forms: misinformation and disinformation. Disinformation is false information that is purposely spread to deceive. Misinformation is simply incorrect information, for example, "I was misinformed about when to meet you for lunch, however I know it was not deliberate." One study, as reported by Kshetri (2017) found that roughly 62% of US adults get their news from Social Media sites, and of those 40%, from Facebook. Kshetri (2017) also determined that in the final three months of the 2016 US presidential campaign, the top performing fake election news stories on Facebook attracted more views than the top stories from major news outlets such as the New York Times, Washington Post, Huffington Post, or NBC News. During that time 8.7 million shares, reactions, and comments were generated on Facebook as compared to just over 7.3 million from 19 major news websites. As we all know now, Russia was involved.

Russia, however, was not the only country spreading fake news. We have recently learned that other fake news creators were known to be operating from countries such as the Republic of Georgia and Macedonia. For example, during the one-year period before the 2016 US presidential election, residents of the Macedonian town of Veles (population 45,000) launched more than 140 US political websites. Most of the domain names looked American, such as WorldPoliticus.com,TrumpVision365.com,USConservativeToday.com,DonaldTrumpNews.com, and USA DailyPolitics.com Kshetri (2017).

The China Syndrome

Realizing that Social Media can sway stock markets and has the potential to overthrow governments, the Chinese central government has placed bans on many Social Media URLs. It is common knowledge that Facebook, Google, YouTube and Twitter are banned, in fact, over 8,000 sites are banned in China (Greatfire.org). Studies (Kuang, 2018) suggest that all media content harmful to the legitimate ruling of the communist state is censored. To protect its rule, the Chinese Communist Party (CCP) has identified a few priorities including the sustaining of economic growth, nationalism, social stability, and rational legal authority and electoral legitimacy. This is also what sustains the current political regime. Therefore, the news most likely to be censored is news that the propaganda authorities believe will have a negative effect on the legitimate rule of the Communist Party state. Further, Chinese law mandates that all Chinese news media must contribute to the enhancement of party ruling (Kuang, 2018).

China, however, is not the only country to ban Social Media sites. Figure 1 is a good representation of the major sites banned by numerous countries around the world (Yasaklanan and Ağlar, 2018). North Korea is not shown as everything is blocked. Until recently, Cuba was very much like North Korea, although presently more and more sites are being allowed by the Cuban government. However, all the Internet access is controlled by the Cuban government and opposition sites are blocked (San Pedro, 2016).

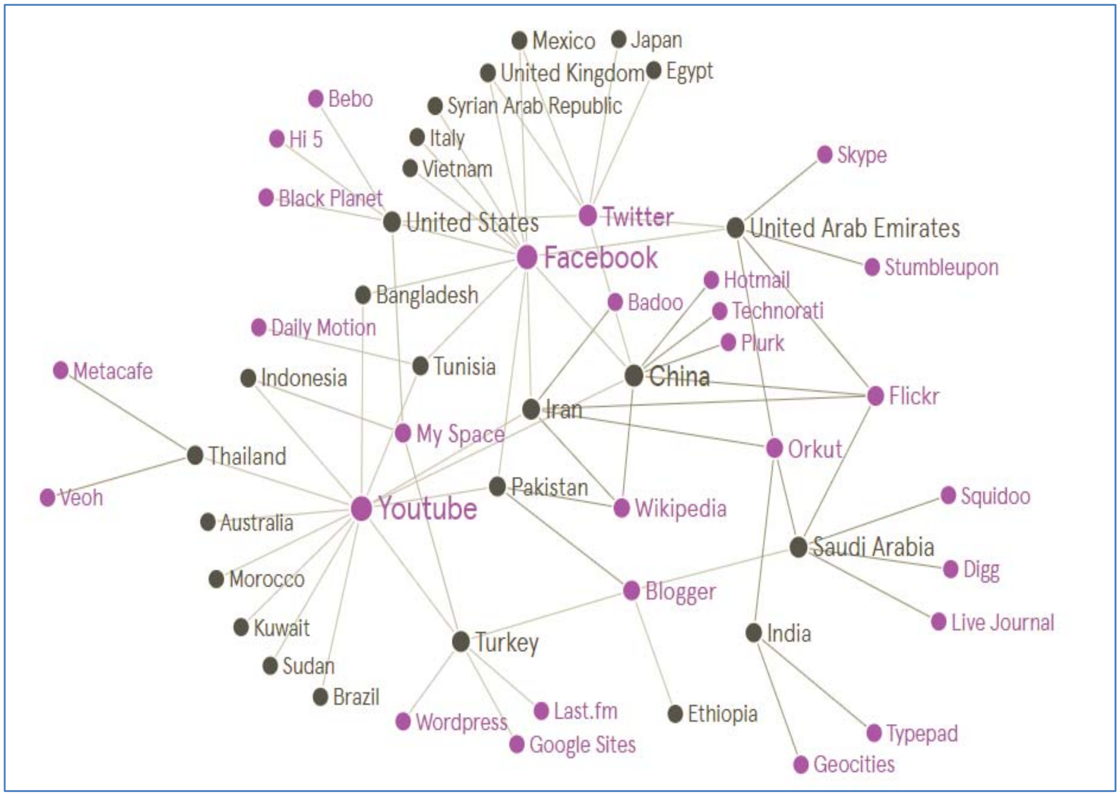

Figure 1 (Yasaklanan, 2018) a high-level view of countries that block various websites

The Push to Curtail Social Media

As we have seen, some governments simply ban Social Media sites while others such as the U.S. are either trying to pass laws to ban certain content or have asked the leaders of these organizations to do their own censoring. After the 2016 election, attention was given to the false, inflammatory and misleading information being presented on Facebook, Twitter, Google and other online services who now find themselves in a position of how to appropriately operate on a global platform (Lima, 2019). In a recent and certainly controversial move, Facebook banned the accounts of far-right extremists Alex Jones, Milo Yiannopoulos and Louis Farrakhan. To most, this seems like the right thing to do, however it begs the question, where do you draw the line. For example, when questioned by Congress, Zuckerberg stated that he that “he'd allow posts denying the Holocaust as long as the people behind them sincerely believed what they were saying” (Lima, 2019).

In a Senate hearing during April 2019, Republicans accused Facebook, Google and Twitter that they censor conservative user’s content online. They went on to threaten regulation of these and other online services. In the hearing, Senator Ted Cruz stated "Not only does big tech have the power to silence voices with which they disagree, but big tech likewise has the power to collate a person's feed so they only receive the news that comports with their own political agenda" (Romm, 2019). During this hearing it became clear that Republicans believe that Facebook, Google and Twitter are biased against the party. Political parties or not, "Every time Facebook makes the choice to remove content, a single company is exercising an unchecked power to silence individuals and remove them from what has become an indispensable platform for the speech of billions” (Lima, 2019). This should put fear into a lot of people because it is possible that just a few Social Media companies have the power to define elections in the United States.

CONCLUSION

As demonstrated in this paper, data analytics is often swayed by bias. Managers of data and analytics need to be aware of this and ensure that the findings they present are accurate and without bias. It remains to be seen if the UPB phenomenon will continue to grow, or if those in charge of data will come to realize the ethical and moral values of accurate reporting. It also remains to be seen if college students, news organizations and others will continue to spin “fake news” across Social Media sites, or if they too will come to realize the ultimate ramifications of putting out un-validated stories.

This paper presented the UPB phenomenon, pointing out that it is quite easy to fabricate data, be it for personal reasons, or to benefit a company or a political campaign. Data can be analyzed and presented in a way that may be incorrect and more importantly, analysts need to be aware of personal bias, or biases that may come from above. Finally, it was determined that Social Media and “Fake News” are presenting and will continue to present dangers to our society, especially through our young, college-level students. This danger was seen not only in the use of Social Media, but also television, radio, print and cable news. As pointed out, Fake New travels at a rate six times faster than real news, yet Fake News is often more believed and therefore opinions formed with no real basis.

With the 2020 Presidential elections closing in, it remains to be seen as to what effect analytics will again have on the election. Will campaigns be able to data mine Facebook users accounts as they did in the 2016 elections? Will they find other ways, legal or not to get to the data that they’re looking for? Will they be better able to target market those swing voters? Most importantly, will Social Media sites introduce bias or cutoff certain messages in an effort to sway the election?

ABSTRACT

This study investigates how individual borrowers in the online peer-to-peer (P2P) platform can improve the chance of success for their loans. Specifically, this study examines the relationships between the length and emotions in loan descriptions and loan success. Emotions in the descriptions were extracted using one of the text mining approaches—sentiment analysis. The results reveal valuable new information in the P2P lending context such that, in the absence of market interest rates, borrowers can improve the chance of funding success by incorporating specific emotions in their loan descriptions.

KEYWORDS: P2P Lending, Sentiment Analysis, Emotions, Microfinancing

INTRODUCTION

Ledgerwood (2000) defines microfinance as “the provision of financial services to poor or low-income clients, including consumers and the self-employed.” A 2018 study showed that at the end of 2017 there were more than 900 microfinance institutions (MFIs) providing loans to more than 139 million borrowers (Convergences, 2018). Over the past decade, the provision of loans to microentrepreneurs in this sector has increased due to rapid adoption of the online channel in various parts of the world and the proliferation of peer-to-peer (P2P) applications. In P2P microfinance lending, the lending platform is used to provide microfinance services that match lenders with borrowers without the use of an official financial institution as an intermediary (Investopedia, 2018).

One of the main reasons for the growth of P2P lending is increasing adoption of the Internet, which has provided new opportunities for microentrepreneurs in developing countries to raise funds. While the Internet has provided a new dimension to the establishment of the relationship between P2P borrowers and lenders, questions regarding the motivation for individual lenders to fund loan projects has not been fully addressed. In general, P2P platforms do not pay interest to lenders; therefore, in the absence of the interest, there are several other uncertainties and risks associated with a decision of a lender to fund some loan projects and not others (Zohir & Matin, 2004). Specifically, without interest payments, P2P lending platforms rely on lenders’ trust in the borrowers to promptly repay the loans (van Bastelaer & Leathers, 2006). Consequently, there are increased concerns in P2P lending regarding trustworthiness of borrowers since it is difficult for a lender to ensure whether the borrower intends to repay the loan.

The major objective of this study is to explore characteristics of P2P loans, especially emotions in loan project descriptions, that make them more appealing to lenders. The results of this study contribute to the literature on P2P lending platforms by increasing our understanding of the distortions that can arise from information asymmetries and can provide practical guidance to platform providers and microentrepreneurs seeking to understand ways to improve P2P lending success.

LITERATURE REVIEW AND HYPOTHESES

Loan Descriptions

In the P2P lending context, previous studies have reported that among the various features of loans, loan description appears to be the top feature that influences the loan's success. According to Heller and Badding (2012), loan description was found to be the most important factor that determines the funding success measured by funding time. Therefore, we further investigate components of loan description in influencing the loan success.

Past studies have provided interesting evidence that, in addition to the content of the message, the length of the message can be rationally perceived as an indicator of the quality of the information since it is relevant to completeness of the message (Ferrari, Bouffard, & Rainville, 1998; Ransbotham & Kane, 2011). Such effects can be explained by the elaboration likelihood model (ELM) used by Petty and Cacioppo (1986) who examine the underlying mechanisms or influencing routes individuals rely on when making a decision or evaluation. ELM posits that the two routes (central and peripheral) of influence can cause individuals' attitude changes. These two routes differ in the amount of thoughtful information processing or "elaboration" demanded of the individuals. The central route requires higher cognitive effort in the evaluation, for example, an individual can critically think about the informational message by scrutinizing relative merits prior to forming an informed judgement. In the P2P lending context, an influence route may refer to the evaluation of a loan's features to determine the risk, such as loan purpose, amount, and the borrower's personal information.

On the other hand, the peripheral route requires lower cognitive effort to process information than the central route since it involves examining simple cues. It has been reported that when a high level of cognitive processing is demanded to evaluate a message such that it overloads an individual's working memory, he or she may use the peripheral route (length of text) as a primary route in forming the judgement (Petty & Cacioppo, 1986).

Previous studies have provided evidence of such peripheral route features of textual information on user's evaluation. For example, Korfiatis et al. (2012) reported that text's stylistic elements such as readability and length positively influenced helpfulness of online reviews. In a recent study in microfinance in the European countries, Dorfleitner et al. (2016) confirmed that soft information in loan descriptions especially description length can mitigate information asymmetry between lenders and borrowers and thus can be used as a predictive factor for loan default probability. Consequently, we utilize the insights of previous literature to further investigate how description length drives P2P funding success. Thus, we propose that lenders in the P2P lending may perceive longer loan descriptions as more complete and trustworthy because they provide more information of the loans, which subsequently influences funding success.

H1: The length of loan description is positively correlated with funding success.

Emotions in Loan Descriptions

In this study, we aim to investigate how affect-related factors (especially emotion) in loan descriptions influence funding success. Specific to textual information, previous studies have suggested that emotion can shape readers' attitudes and judgment of credibility of messages (e.g., Chaiken & Maheswaran, 1994). In addition, research in the marketing domain has provided evidence that product description is a crucial factor for sellers to convince and persuade customers of their legitimacy and trustworthiness. For example, MacInnis et al. (1991) found that product description can be considered as a stimulus that provides executional cues to borrowers' emotional responses and behaviors.

Consistent with previous studies, the persuasive message in P2P loan description can evoke emotional states of potential lenders, such as joy, liking, and fear, which can further influence the lender's evaluation of the borrower (Larrimore, Jiang, Larrimore, Markowitz, & Gorski, 2011). This effect can be explained by the concept of "affect-as-information" (Schwarz, 1986) which posits that emotions generated from a loan description are carried over to the lender's evaluation of the borrower's credibility (Hwang & Kim, 2007; Kim & Tadisina, 2010). In the online commerce literature, emotion has been widely studied and its important has been consistently shown as an effective component that drives overall impression of users which subsequently influence several key factors in online commerce success, such as trust (Hwang & Kim, 2007), satisfaction (Hsu, Chang, & Chen, 2012), and evaluations and responses (Éthier, Hadaya, Talbot, & Cadieux, 2006). In this study, we investigate a set of basic emotions such as anger, fear, joy, disgust, and sadness, which are thought to serve distinct functions in individuals' motivation and behavior (Ekman, 1992; Frijda, 1986). In the online P2P lending context, associations between an emotion and lenders' responses should be stronger if the emotion elicits physiological changes that are to a higher degree compatible with the lenders' lending interests and preferences, which consequently influence funding success. For example, a loan with sadness as the main emotion in the description may be more probable than joy to activate a lender's lending behavior. Therefore, we propose the following hypothesis.

H2: Emotions in loan description are associated with funding success.

METHODOLOGY

Data Collection

We conducted this investigation based on an open public access data source retrieved from the P2P lending website www.kiva.org. Kiva is a non-profit organization which provides microfinancing services to people from more than 83 countries (www.kiva.org/about). Kiva's lending model is based on a typical crowdfunding model which any individual can fund a particular loan by contributing to a loan individually or as a part of a lending group. Typical microloans are in increments of $25.

Data Preparation Procedure

Our original dataset was comprised of P2P loans that were collected between November 2011 and December 2016. However, most of the loans were fully funded by field partners and the funds were disbursed within 24 hours after the loans had been listed. Those field partners were local financial intermediaries that sought to general profits from P2P lending by collecting interests or fees. Therefore, those loans were excluded from the analysis since they did not represent the actual P2P lending interactions between individual borrowers and lenders as discussed in this study aiming at assessing the factors influencing funding success in the context of philanthropic giving. As a result, the dataset included 815 loans (240 from Kenya and 575 from the U.S.) that were funded solely by lenders and the funds were directly transferred from the lender's account to the borrower's account without going through an intermediary.

Sentiment Analysis

In this study, sentiment analysis was selected to perform emotion tagging. According to Pang and Lee (2008), sentiment analysis refers to the use of data mining techniques to identify and extract subjective information in source material. Sentiment analysis addresses the polarity of texts—positive, negative, or neutral—at different levels and for various aspects, including emotions, which are investigated in this study.

A proprietary sentiment analysis tool, IBM Watson Natural Language Understanding (NLU) was used to analyze emotions in Kiva loan descriptions. Watson NLU is available on the IBM cloud computing PaaS (Platform-as-a-Service). Watson NLU provides a set of services to build applications for natural language processing (NLP) and emotion recognition. For our study, the detectable emotions include the five basic emotions (anger, disgust, fear, joy, and sadness) suggested by Ekman (1992). A programming script was created in Python to pass the loan descriptions to Watson NLU, which subsequently extracted emotions and emotion score values associated with the descriptions. The emotion score values ranged from 0.0 to 1.0 and represented the prominence of the emotions conveyed in a loan description. A higher value represented more prominent emotion found in a loan description and if a score was above 0.5, the corresponding emotion was considered as the major emotion in the description. In addition to the emotion score values, Watson NLU also evaluated sentiment (positive, negative, or neutral) and provided sentiment score values to be used in our analysis to indicate the significance of sentiment in loan descriptions.

ANALYSIS AND RESULTS

Emotion in Microfinancing Loan Descriptions

The results from the emotion analysis reveal that joy and sadness appear to be the highest and second-highest emotions found in loan descriptions. We then determined the major emotions conveyed in loan descriptions based on two criteria—(1) an emotion that appears to have the highest frequency and (2) the emotion must have a documented emotion score above 0.5 (IBM Watson, 2018).

Dependent and Independent Variables

The dependent variable is loan's success determined by the length of time (in days) a loan takes to be fully funded. A set of independent variables as proposed in the hypotheses was examined. These variables include length, loan repayment term, sentiment score, five emotion scores, and a dummy variable assessing whether the major emotion found in a lender's lending description matches the major emotion of the loan description the lender funded.

Analysis and Hypothesis Testing

A series of multiple regression analyses was carried out to examine the influence of loan features including emotions on the dependent variable, loan's success. Overall, the results suggest that the length of loan descriptions, sentiment score, anger score, and disgust score appear to be statistically significant predictors of the funding at the 0.05 level.

Regarding the hypothesis testing, the results indicate that longer loan descriptions are significantly associated with funding success in the overall dataset (H1, $p < 0.05$). As for the emotion in the loan description (H2), the hypothesis is supported such that Anger and Disgust are found to negatively influence funding success ($p < 0.05$). The results are presented in Table 1.

Table 1: Regression Results for the Relationships between Loan's Success and the Independent Variables

Independent Variable	***β***	**Sig. ($p < 0.05$)**
Length	0.011	Yes
Repayment Term	0.055	No
Sentiment	7.276	Yes
Anger	-20.380	Yes
Disgust	-11.115	Yes
Fear	2.648	No
Joy	13.325	No
Sadness	11.214	No

DISCUSSION AND CONCLUSION

Overall, our results confirm the relationship between loan description and funding success reported in existing studies. For various features in P2P lending, borrowers have struggled to determine which strategies work best in improving the chance of finding success. This study investigates how P2P borrowers can improve the chance of funding success by manipulating their descriptions. The results provide some insights into the linguistic features of successful strategies based on trust-related factors that can be applied to the online persuasion context. Specifically, in accordance with the trust building strategies, the results indicate that increasing word count or incorporating appropriate emotions in loan descriptions can improve funding success.

Regarding research implications, our research indicates that while there are several strategies borrowers can implement to increase the likelihood of P2P loan success, borrowers can reduce uncertainty and establish trust by providing more information to lenders. This can be achieved by simply adding more details to the loan descriptions which can help lenders better understand how the funds are to be spent and repaid. This strategy not only increases the length of the descriptions but also is effective in providing more concrete information to lenders to understand what they can expect after funding the loans.

The findings of this study also suggest a number of avenues for future research. First, a controlled empirical test of how emotions influence funding success in the P2P lending context would shed further light on the actual value of incorporating emotions in loan descriptions. Second, it might be interesting to investigate whether emotional loan description is more preferred over a rational detailed informative loan description. Third, it is important to explore how interactions between borrowers and lenders occur in the online P2P lending environment. Therefore, as the P2P lending market expands, future research may consider investigating matching features of loan projects and characteristics of lenders who are interested in funding the loans.

Overall, the factors related to funding success in the microfinance area have been studied too little by scholars and applied too little by practitioners. This paper articulates the importance of trust-related loan description features on funding success. In the current research, we provide empirical evidence that loan project description is an important factor in online P2P lending by adding to the literature emphasizing emotions extracted from the descriptions. The results provide practical solutions that can be effectively implemented and a theoretical foundation for future research on the success of the growing field of P2P lending.

ABSTRACT

This research study focuses on performing granular sentiment detection, using a recurrent neural network approach, over a dataset of online reviews for Slack, an American cloud-based set of proprietary team collaboration tools and services. A client interface was built, attaching sentiment scores to opinion units, keywords and performance indicators, and generating interactive visualizations of the same. An encoder-decoder model with Attention was also implemented, to generate an abstractive customer feedback summary for the client, as a premise for future product development.

KEYWORDS: Information Science, Data Mining, RNN, Sentiment Analysis, and Summarization

INTRODUCTION

Online platforms, such as Capterra, are increasingly being used as a source of information and opinions about a plethora of issues, concepts and products. Such a user review corpus is a rich data source, as it provides information to both the company's prospective customers and marketing teams about the user sentiment with respect to the product or service considered. People's choices are also dependent to some degree on how others view and evaluate the world.

E-commerce platforms provide companies with a structured data set for analysis. In the real world, tracking data is not as easily obtainable, with the primary sources of intelligence being user feedback and the financial data of firms. The purpose of this research study is to perform effective sentiment detection of user feedback, using an encoder-decoder RNN(recurrent neural network) approach with Attention to process a dataset of online service and product reviews for the Slack software. A user interface was then built to implement a report generation engine for the clients' to present a priority view of areas to be addressed to increase customer satisfaction and maximize product performance and recommendation likelihood.

The first step towards training a classifier with machine learning is feature extraction, which is an approach that transforms each text into a numerical representation in the form of a vector. This is done using one shot encoding in RNN. Then, the RNN algorithm is fed with training data that consists of pairs of feature sets to produce a classification model. To learn new tasks, new tags can be created.

Key phrases can provide highly condensed and valuable information that allows users to quickly acquire the main ideas. The task of automatically extracting them is achieved using an RNN encoder-decoder model to combine key words and context information. It has two hidden layers to discriminate keywords and classify key phrases, and these two sub-objectives are combined into a final objective function.

Automatic summarization is the process of shortening a text document with software so as to create a summary with the major points of the original document. Technologies that can make a coherent summary consider variables such as length, writing style and syntax. There are two general approaches to automatic summarization: extraction and abstraction. Extractive methods work by selecting a subset of existing words, phrases, or sentences in the original text to form the summary. In contrast, abstractive methods build an internal semantic representation and then use natural language generation techniques to create a summary that is closer to what a human might express. Such a summary might include verbal innovations. Attention is used in the RNN model to generate an abstracted summary.

LITERATURE REVIEW

Ghosh & Sanyal (2018) investigated the inability of the widely used feature selection methods (IG, Chi Square, Gini Index) individually as well as their combined approach on four machine learning classification algorithms. The proposed methods were evaluated on three standard datasets viz. IMDb movie review, electronics product review dataset, and kitchen product review dataset. Initially, the feature subsets were selected from three different feature selection methods. Thereafter, the statistical methods of UNION, INTERSECTION and revised UNION method were applied to merge these different feature subsets to obtain all top ranked (including common selected) features. Finally, the classifiers of SMO(sequential minimal optimization), MNB(multinomial naïve bayes), RF(random forest), and LR (logistic regression) were trained with this feature vector for classification of the review data set. The performance of the algorithm was measured by evaluation methods such as precision, recall, F-measure and ROC(receiver operating characteristic) curve. Experimental results showed that the combined method achieved best accuracy of 92.31 with the classifier SMO.

Liu (2010) described a threefold approach to sentiment analysis. The first one, classical approaches, used techniques that predated the statistical revolution, i.e. before natural language processing researchers embraced techniques that speech engineers had already been using successfully. The second, empirical and statistical approaches, covered state-of-the-art data-driven models. The third one, application oriented approaches, catered to the needs of NLP(natural language processing) practitioners and language-engineering professionals in academia as well as in industry. No efficient method to tackle opinion spam was identified. The usage of SVM(support vector machine) was proposed, though the results produced were not directly human understandable. A pure machine learning reliance hence served to limit the cognitive ability of a system.

Santos & Gatti (2014) implemented character-to-sentence mapping in a convolutional neural network. Two convolutional layers were used to extract relevant word/sentence features. The datasets used were SSTb Movie Review, and Tweets (STS). Word and character level embeddings and sentence level scoring interfaces were implemented using CNN(convolutional neural network) to extract wider feature selection. Feed forward neural networks were found to be as effective as RNTN(recursive neural tensor network) usage. A binary accuracy of 85.7% and a fine-grained accuracy of 48.3% were achieved. Their study did not consider the impact of an unsupervised pretraining step using texts from the domain.

Severyn & Moschitti (2015) described a deep learning system for the sentiment analysis of tweets. They developed a model for initializing the parameter weights of the convolutional neural network, which is crucial for training train in an accurate model while avoiding the need to inject any additional features. An unsupervised neural language model, trained initial word embeddings, and these were further tuned by a deep learning model on a distant supervised corpus. The pre-trained parameters of the network were then used to initialize the model. The deep learning model was trained on the supervised training data made available by the official system evaluation campaign on Twitter Sentiment Analysis organized by Semeval-2015. A comparison between the results of this approach and the systems participating in the challenge on the official test sets, suggested that this model could be ranked in the first two positions in both the phrase-level subtask A (among 11 teams) and on the message-level subtask B (among 40 teams).

Habernat, I., Ptacek, T. & Steinberger, J. (2014) examined N gram and POS(part of speech) related features, with emoticons selected using MI(mutual information), Chi, RS(relief based selection). Classifiers used include SVM, on a Czech Social media data set, the IMDb Movie set, and the Amazon Product set. Lemmatizing was done with the PDT toolkit using Java framework with a 10-fold cross validation. Bigram feature had the highest performance, outperforming the baseline in three class classifications with an F-Measure of 0.69. In their study, many negative posts had happy emoticons (misleading features) which couldn't be handled. Hidden irony was also not identified in negative posts.

Pang, B., Lee, L. & Vaithyanathan, S. (2002) used NB, SVM, Maximum Entropy in a bag of features framework on the IMDb Movie Review dataset. The bag of unigram features achieved roughly 90% accuracy. Feature presence was found to be more effective than feature frequency (SVM). Overall accuracy was 77.4-82.9%. The model, however, was not able to achieve accuracy on topic based categorization. It was also not able to classify mixed reviews. Thwarted expectations and rhetorical devices were also not identified.

Extraction

Zhang, Q., Wang, Y., Gong, Y. & Huang, X. (2016), in their study, considered key phrases as capable of providing highly condensed and valuable information that allowed users to quickly acquire the main ideas. They examined the issue of automatically extracting key phrases from tweets. Due to the length limitations of Twitter-like sites, the performances of existing methods usually drop sharply. To overcome this, they sued a novel deep RNN model to combine key words and context information to address this problem. Their experimental results indicated that the RNN method performed significantly better than previous methods.

In their study, Zhang et. al. (2016) extracted explicit product features and opinions by phrase level SA(sentiment analysis) to generate recommendations and dis-recommendations according to specific product features to the user's interests. Intuitional feature level explanations were also generated. However there was no comparison group assigned, with other explanations for the dis-recommendation engine. Cart items were recorded as user purchase behavior approximation, as security prevented the tracking of user purchases, which introduced a significant margin of error. Their study's focus was only on persuasiveness, not on other utilities like transparency, user trust, effectiveness, suitability, etc. which might also factor into SA.

Churn

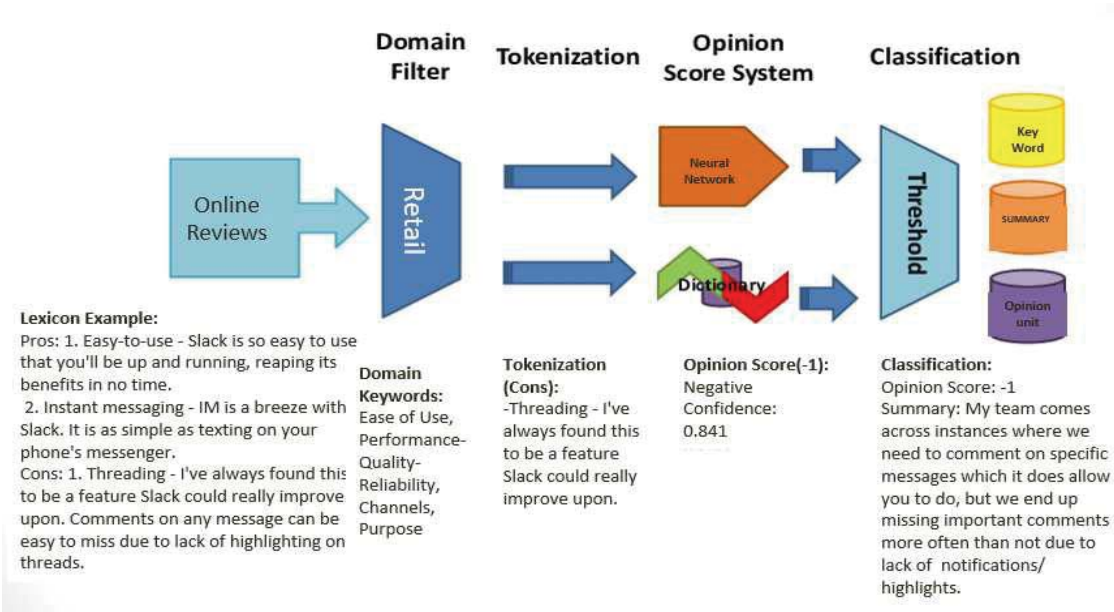
McKnight (2011) presented a reference implementation of a customer churn analysis project that was built by using the Azure Machine Learning Studio. Businesses in the consumer market and in all enterprise sectors have to deal with churn. Sometimes churn is excessive and influences policy decisions.

His study suggests that the common factor is that businesses need to minimize these special customer retention efforts. A natural methodology to use would be to score every customer with the probability of churn and address the top N ones. The top customers might be the most profitable ones. For example, in more complex scenarios, a profit function is employed during the selection of candidates for a special dispensation. However, these considerations are only a part of the complete strategy for dealing with churn. Businesses also must consider risk (and associated risk tolerance), the level and cost of the intervention, and plausible customer segmentation.

His study's findings suggest that the implementation in Azure Machine Learning Studio lags behind SAS in accuracy by about 10-15% (Area Under Curve or AUC). However, the most important metric in churn is the misclassification rate: that is, of the top N churners as predicted by the classifier, which of them did not churn, and yet received special treatment. This was found to be identified with highest accuracy by the model implemented.

MODEL

Figure 1: System Architecture



The system architecture given in Figure 1 explains the overall flow of the model in this research study. The customer reviews are scraped from the feedback site. These are then fed into models for data cleaning and splitting as per categories - pros, cons and sub-ratings. Then, tokenization is done and a keyword/opinion unit lexicon is generated from the training set, along with sentiment weighting at a word level, using an RNN. The test data is then passed through the network, and an encoder-decoder RNN model with Attention is used to abstract summaries and generate an average user feedback report to the client.

The client is provided with a series of tree-maps, a facility to construct pie review, word and letter level sentiment charts, along with an overall review summary. The client's analyst may generate and view the above, as well as additionally view all the extracted raw review sets and reweight the neural network according to the service provided by the client to its customers, in order to dynamically generate summary reports of reviews to the client in real time.

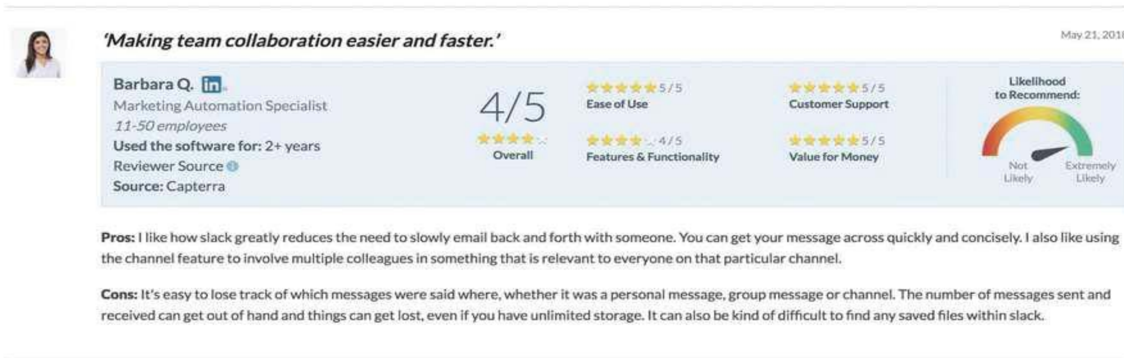
MODULES

The various modules that form part of this research study's methodology are: Data collection, Data cleaning, Lexicon construction and weighting, Scoring, Sentiment Threshold Computation, Summary Generation and Client Interface.

Data Collection

The first step was to collect all of the reviews of Slack that people have left on Capterra. On Capterra, reviews were parceled into chunks including the reviewer's overall rating of the product, the text of their review, and sub-ratings (the ratings of certain aspects of the product, e.g. Customer Support, Ease of Use, and Value for Money). The reviews were then saved in .csv files for future analysis.

Figure 2 : Slack Review on Capterra



Data Cleaning

The following were implemented in the data cleaning module using modified Rattle package functions:

- Getting Rid of Extra Spaces
- Selecting and Treating All Blank Cells(NA)
- Converting Numbers Stored as Text into Numbers
- Removing/Merging Duplicates
- Highlighting Errors
- Changing Text to Proper Case
- Deleting all Formatting

Lexicon Construction

Aspect classifier and extractor lexicon was built to help detect the content of the texts in the reviews (e.g. pricing, UX, customer support, performance, integrations, etc.). A set of tags was defined, that accounted for most of the topics or aspects included in the Slack reviews. By tagging the text data, the RNN algorithm were written so that for a particular input (reviews), a particular output (tags) is expected. The more data were tagged, the better was the model's working. Since most reviews include more than one sentiment, splitting longer texts into smaller bits helped detect different sentiments which were then later aggregated. The reviews were first submitted to the aspect classifier and extractor module, and then the opinion units and keywords obtained were fed as input to the next RNN layer.

Scoring

The text was transformed into a numerical representation, i.e. a vector. Each component of the vector represents the frequency of a word or expression in the predefined dictionary. Some samples were tagged as positive, negative, or neutral. These were used as a basis to classify the aggregate of lexicon scores, considering the context of their usage by first world level and then sentence level weighting, (feature extraction and weighting) to compute a review sentiment score.

Sentiment Threshold Computation

The algorithm used to implement the sentiment threshold computation was an RNN Encoder Decoder Model, with Attention considered, over the set of polarized keywords and opinion units generated in the scoring module. Scores were generated on a scale from -1 to 1, with Laplace smoothing used to weigh review scores as +1 (Positive), -1 (Negative) and 0 (Neutral).

Summary Generation

There were two main types of summarizing text in NLP:

- **Extraction-based summarization:** Involved pulling key phrases from the source document and combining them to make a summary. The extraction was made according to the defined metric without making any changes to the texts.
- **Abstraction-based summarization:** Entailed paraphrasing and shortening parts of the source document. When abstraction was applied for text summarization in deep learning problems, it overcame the grammar inconsistencies of the extractive method.

The merited key phrases were extracted across the review corpus, using the aspect classifier and extractor. A binary classifier was used to make the text summarization, by identifying and organizing pros and cons. Some of the features used include:

- Length of the key phrase
- Frequency of the key phrase
- The most recurring word in the key phrase Number of characters in the key phrase
- Lexicon weighting of the key phrase

Client Interface

The client was provided with a series of tree-maps, color coded according to review sentiments which can be viewed selectively using keywords and opinion unit search. A facility to construct pie charts to discover keywords pertaining to sentiment categories was also provided, along with category wise scoring of reviews. Word and letter level charts were displayed, along with an extracted summary generation for one per ten opinion units. An overall review summary was generated using an abstraction of the previously extracted summaries.

Hardware Description

Developing Kit			
Software	**Processor**	**Ram**	**Disk Space**
R Studio -Rattle -Monkey Learn Api -Rfutilities -Testthat	Intel Computer With A 2.6 Ghz Processor Or Higher	64mb	Minimum 20 Gb
Google Chrome -Selector Gadget	Intel Pentium 4 Processor Or Higher	128mb	Minimum 100mb
Database			
MS Office -Excel	Intel Pentium Processor At 2ghz Or Faster	2gb Ram Recommended	Minimum 4gb
Interface			
Tableau	Intel Pentium 4 Processor Or Higher	Minimum 512gb Physical Memory; 2gb Recommended	Minimum 1.5gb

Table 1: Hardware and Software Specifications

Scoring

The algorithm used to implement scoring was an RNN Encoder Decoder Model, with Attention taken into account, over the set of polarized keywords and opinion units generated in the scoring module. Scores were generated on a scale from -1 to 1, with Laplace smoothing used to weigh review scores as +1 (Positive), -1 (Negative) and 0 (Neutral).

Attention

A problem with the encoder-decoder architecture is that performance is poor on long input or output sequences. This is due to the fixed-sized internal representation used by the encoder. Attention is an extension to the architecture that addresses this limitation. It works by first providing a richer context from the encoder to the decoder and a learning mechanism where the decoder can learn where to pay Attention in the richer encoding when predicting each time step in the output sequence.

To model sentiment behavior, we used Feature Functions, that has multiple input values, such as:

- a sentence s
- the position i of a word in the sentence
- the label li of the current word
- the label li−1 of the previous word

Next, we assigned each feature function fj a weight λj . Given a sentence s, score a labelling l of s by adding up the weighted features over all words in the sentence:

$$score(l|s) = \sum_{j=1}^{m} \sum_{i=1}^{n} \lambda_j f_j(s, i, l_i, l_{i-1})$$

We transformed these scores into probabilities p(l|s) between 0 and 1 by exponentiating and normalizing:

$$p(l|s) = \frac{exp[score(l|s)]}{\sum_{l'} exp[score(l'|s)]} = \frac{exp[\sum_{j=1}^{m} \sum_{i=1}^{n} \lambda_j f_j(s,i,l_i,l_{i-1})]}{\sum_{l'} exp[\sum_{j=1}^{m} \sum_{i=1}^{n} \lambda_j f_j(s,i,l'_i,l'_{i-1})]}$$

The merited key phrases were extracted across the review corpus, using the aspect classifier and extractor. A binary classifier was used to make the text summarization, by identifying and organizing pros and cons. Some of the features used include length of the key phrase, frequency of the key phrase, the most recurring word in the key phrase, number of characters in the key phrase, and lexicon weighting of the key phrase.

To obtain the above accurately with respect to user ratings, we obtained a summary of the mean sentiment (based off numerical representation of sentiment as -1, 0,1) for opinion units that were classified into each aspect. We split these mean sentiment ratings into three equal parts and assigned those parts valences that describe the mean sentiment for that aspect. We found the tertiles of the mean sentiments by dividing them in three groups as they relate to each other. Then, we used these tertiles as the bounds for assigning valences.

We colored the bars of the bar-plots generated with those valences as arranged by different variables while retaining the measure of sentiment per category. We weighted the aspect-sentiment by the number of times it occurred in an opinion unit. This gave us a better idea of the sentiment in the context of how often it's mentioned. We considered this important because if an aspect has very low sentiment, but it's almost never mentioned, it may be less critical to focus on improving than an only mildly badly rated category with a lot of mentions. We used this to rank the order of abstraction when generating the summary.

The client was provided with a series of tree-maps, color coded according to review sentiments, which can be viewed selectively using keywords and opinion unit search. A facility to construct pie charts to discover keywords pertaining to sentiment categories was also provided, along with category wise scoring of reviews. Word and letter level charts were displayed, along with an extracted summary generation for one per ten opinion units. An overall review summary was generated using an abstraction of the previously extracted summaries.

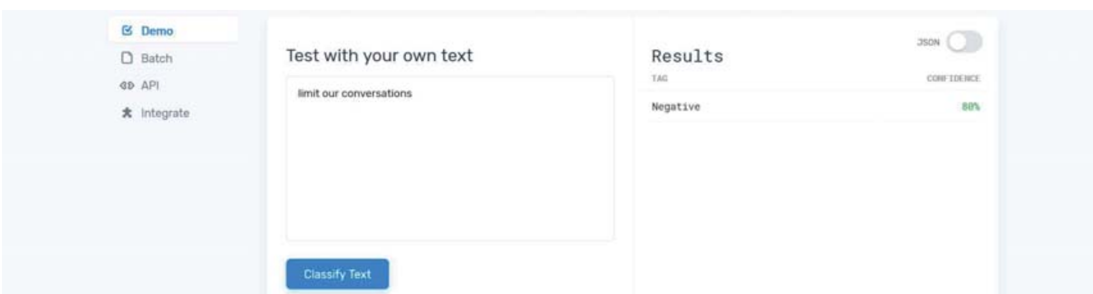

Figure 13 : Summary Abstraction Performance

CONCLUSION

This research study focused on performing more granular sentiment detection, using a recurrent neural network approach, over a dataset of online reviews for Slack, an American cloud-based set of proprietary team collaboration tools and services. A client interface was built, attaching sentiment scores to opinion units, keywords and performance indicators, and generating interactive visualizations of the same. An encoder-decoder model with Attention was also implemented, to generate an abstractive customer feedback summary for the client, as a premise for future product development.

Various test cases on both, real-life and synthetic data, were conducted to and the findings suggest that our approach outperformed traditional methods in sentiment analysis on data and delivered more or less the same performance on sparse data. Hence, our findings suggest that the system we proposed in our research study helps in the efficient handling of report generation based on sentiment analysis.

Future Enhancement

The scope of this research study can be further extended by:

- Developing a generalized keyword and scoring set, to apply across different products/services.
- Implementing sarcasm detection and increased handling of emojis in reviews.
- Integrating an automatic review mining and analysis module instead of periodic manual addition to and processing of the data set.

ABSTRACT

This study investigates how cloud computing is perceived by Thai college students and which factors can influence their willingness to accept cloud computing as part of their course curriculum. The study findings should help increasing the chance for the success of the integration of cloud computing into the program.

KEYWORDS: Cloud Computing, Technology Acceptance Model (TAM), Perceived Usefulness, Perceived Ease of Use, Perceived Security, Perceived Speed, Perceived Cost, Thailand

INTRODUCTION

Cloud computing has attracted considerable attention because their services offer numerous benefits (Ya-Ching, 2019). The popularity of the usage is derived by its ability to provide faster on-demand infrastructure, self-service, and independent ability to contribute to and access resources. It is increasingly growing in convenience as a ubiquitous network that requires little interaction between the cloud service provider and the user (Changchit & Chuchuen, 2018). This flexibility and independence can help to save the consumer time, and stress by making the process simple and allowing the account design to be based entirely on individual needs.

In the past few years the concept of "cloud computing" has emerged as a viable and promising solution to the challenges associated with shrinking IT budgets and escalating IT needs. Cloud computing has become increasingly popular among users and businesses around the world. Education is also a driving force for the continuous improvement of cloud computing. Students can gain a lot from this technology as it serves as a convenient mobile storage space (Singh & Veralakshmi, 2012). Cloud computing can bring an increased number of benefits to an educational setting (Behrend et al., 2011). It is not only the cost effectiveness, but also the thirst for technology that college students have today, which allows learning and adopting these new technologies easier for them.

Cloud computing is now considered one of the commonly deployed services due to its relative advantages for organizations, firms, and enterprises (Almubarak, 2017). This technology provides a number of benefits to an educational setting (Behrend et al., 2011). The technology allows students to have their own mobile storage space (Singh & Veralakshmi, 2012). Some of the benefits that students can derive from cloud computing, in an educational setting, include using it for completing assignments, online classes, group projects, creating and editing papers and presentations; as well as for work or entertainment (Changchit, 2015).

With the many benefits generated by the cloud computing model, it is interesting to investigate students' perceptions of this technology. This is key since the success of integrating a course into a curriculum depends a lot on students' attitudes toward such a topic. The purpose of this study is to examine the factors that encourage or discourage students to accept cloud computing as part of their course curriculum.

LITERATURE REVIEW

The high demand for more advanced and efficient technology has contributed in the creation of new advancements in technology such as cloud computing. The popularization of cloud computing by companies like Amazon®, Google®, and Apple® ensure that the usage of the cloud as a storage medium for music, movies, and other media content files, will be ubiquitous in the next 10 years. Cloud computing is a promising prospect for educational institutions, especially during times of budget constraints. Research in cloud computing adoption in educational settings has focused part of its efforts to understand the drivers and constraints that students and schools perceive in the adoption of this computing model. With today's technology, students' learning is no longer confined to the classroom. The educational environment could be improved to allow students to access learning resources anywhere and anytime (Wu, 2013).

One study examined the factors leading to adopting cloud computing as a virtual computing lab for a class (Behrend et al., 2011). The authors in this study found that students' ease of use perception would positively affect intentions for future use, but not for actual use. Students who complete their work faster and in a more practical manner were more likely to recognize cloud computing as an effective service, and use it more if there is no "effort to learn". This study also found that students with anxiety about new technologies had a negative effect on perceived usefulness. Another study also suggested that in order to deal with technology anxiety, it is important for universities to plan hands-on training to help students become more familiar with these new technologies (Blue & Tirotta, 2011).

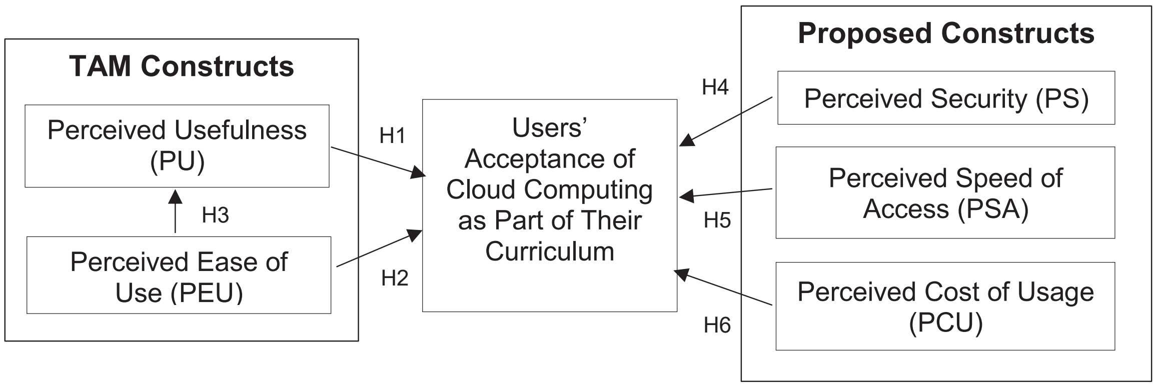
In Thailand, since the year 2011, the use of cloud computing services has negatively impacted the hard disk manufacturing industry as it is considered a hard disk substitution. Cloud computing services in Thailand are in the early adopter stage, with the market projected to grow exponentially in the next 4-5 years (Leesa-Nguansuk, 2018).

With many benefits promised by the use of cloud computing, it is not surprising that the demand for graduates with exposure to Cloud Computing is on the rise (Chen et al., 2012). However, despite the potential for positive change, there are still other factors to consider before cloud computing can be accepted entirely by academic groups. Before integrating such topics into the curriculum, it is crucial to understand which factors can encourage or discourage students from accepting it as a part of their course curriculum. The findings in this study should help programs to focus on the factors that encourage students to like the topic as well as finding ways to minimize the effect of discouraging factors, thus increasing the chance for the success of the integration of cloud computing into the program.

THEORETICAL DEVELOPMENT/MODEL

The Technology Acceptance Model (TAM) developed by Davis in 1986 and was proposed to address the question why users accept or reject information technology. The model was derived from the Theory of Reasoned Action, developed by Fishbein and Ajzen (1975). TAM was a big hit for modeling user acceptance of information systems (Bagozzi, 2007; Davis et al., 1989). This study has modified TAM to include three additional factors: (1) Perceived Security (PS), (2) Perceived Speed of Access (PSA), and (3) Perceived Cost of Usage (PCU). The proposed research model is shown in Figure 1 below.

Figure 1 Research Model



Perceived Usefulness of Cloud Computing (PU)

Perceived usefulness is defined as the prospective users' subjective probability that using a specific application system will increase his or her job performance within an organizational context (Davis et al., 1989). This factor has a significant effect on usage intention (Davis et al., 1989; Venkatesh & Davis, 2000). A prior study also reported that this construct positively influence subjects' intention to adopt cloud computing (Changchit & Chuchuen, 2018). Based on the foregoing, we propose the following hypothesis:

H1: Perceived usefulness (PU) positively affects subjects' acceptance of cloud computing as part of their curriculum.

Perceived Ease of Use of Cloud Computing (PEU)

Perceived ease of use is defined as the degree to which the prospective user expects the target system to be free of effort (Davis et al., 1989). This factor plays a crucial role in understanding individual responses to information technology (Chau & Hu, 2001). Research over the past decade provides evidence of the significant effect perceived ease of use has had on usage intention (Venkatesh & Davis, 2000). We, thus hypothesize that:

H2: Perceived ease of use (PEU) positively affects subjects' acceptance to have cloud computing as part of their curriculum.

In addition, perceived ease of use has been shown to have an impact on perceived usefulness. Davis (1986, p. 26) states "a system which is easier to use will result in increased job performance (i.e., greater usefulness) for the user." We, therefore, posit that:

H3: Perceived ease of use (PEU) positively affects perceived usefulness (PU).

Perceived Security of Cloud Computing (PS)

Security awareness is an important issue for all individuals who are dealing with sensitive data in everyday life (Changchit, 2008). Flavián and Guinalíu, (2006) presented their view of perceived security as a subjective probability with which consumers believe that their personal information (private and monetary) will not be viewed, stored, and manipulated during transit and storage by inappropriate parties in a manner that is inconsistent with their expectations. There is a high likelihood that subjects should be more willing to learn about cloud computing if they find this technology to be secure. We, therefore, posit that:

H4: Perceived security (PS) positively affects subjects' acceptance of cloud computing as part of their curriculum.

Perceived Speed of Access of Cloud Computing (PSA)

The speed of using applications over the Internet can be a factor that has prevented cloud computing from being a viable option for outsourcing IT operations. Users may be unaware that the use of applications via the Internet still allows them to retrieve the data at the same speed as when the data is stored on their personal computers. For cloud computing to be widely accepted, it is crucial that the services must allow users to access data at a reasonable speed. Users' perception on the speed of access should influence their intention to use cloud computing service. Hence, we posit that:

H5: Perceived speed of access (PSA) positively affects subjects' acceptance of cloud computing as part of their curriculum.

Perceived Cost of Usage of Cloud Computing (PCU)

A survey conducted by ComputerWorld magazine (Wood, 2011) of IT professionals revealed that while "saves money" ranked first on the list of cloud computing key benefits, "costs more" ranked third on the list of drawbacks suggesting that the issue of cost in outsourcing information technology resources is a complex issue. In many public and private sector industries, including education, federal and state government, and telecommunications, cloud computing systems are being pilot-tested and implemented to save IT costs and improve performance (Behrend et al., 2011). Based on the foregoing, we hypothesize that:

H6: Perceived cost of usage (PCU) positively affects subjects' acceptance of cloud computing as part of their curriculum.

METHODOLOGY

The questionnaire designed for this study adapted the instrument and scales developed for the TAM with additional constructs added as described in the proposed research model.). The questions used to measure the additional constructs were adapted from prior studies (Pikkarainen et al., 2004; Venkatesh & Davis, 2000, Vijayasarathy, 2004; Wong & Hsu, 2008). (Pikkarainen et al., 2004; Venkatesh & Davis, 2000, Vijayasarathy, 2004; Wong & Hsu, 2008; Venkatesh et al., 2003).

The questionnaire consists of thirty-seven (37) questions. Thirty questions with the five point Likert scale were designed to measure subjects' perceptions on cloud computing and whether they believe it should be integrated into their curriculum. The remaining seven questions were asked to gather some demographic data on the subjects. To validate the clarity of these questions, three professors and three researchers were asked to read through the survey questions. Revisions to the survey were made based on the feedback received.

The surveys were administered to students at a Northern University in Thailand. These students are certainly part of the target group for companies providing cloud computing services. Five hundred and forty-eight (548) subjects participated in this study. All 548 surveys were returned completed so all 548 of the surveys were used in this study. The participants' demographics are shown in Table 1 below.

Table 1: Subjects' demographics (n=548)

	No.	%		No.	%
Gender			**Level of Education**		
Male	110	20.07	Above bachelor degree	26	4.74
Female	438	79.93	Bachelor degree	474	86.50
No answer	0	0.00	Below bachelor degree	33	6.02
			No answer	15	2.74
Age			**Monthly Income (in Thai Baht)**		
15 - 24	460	83.94	Below 15,000	178	32.48
25 - 34	46	8.39	15,000 - 30,000	95	17.34
35 - 44	10	1.82	30,001 - 50,000	22	4.01
above 44	32	5.84	Above 50,000	10	1.82
No answer	0	0.00	No answer	243	44.34
Use Cloud Computing Before			**Employment Status**		
Yes	350	63.87	Un-employed	414	75.55
No	164	29.93	Part-Time	36	6.57
No answer	34	6.20	Full-Time	98	17.88

DATA ANALYSIS AND DISCUSSION

The data analysis for this study was conducted using SPSS 25.0 and AMOS 24.0 statistical software. A reliability test was conducted to examine the internal consistency of the research instrument. The test confirmed the reliability with Cronbach's alpha coefficient of 0.975. In addition, since multicollinearity can have harmful effects (Cenfetelli and Bassellier 2009), multicollinearity was assessed for all of the indicators in the research model. The results revealed that the multicollinearity is not an issue with this data set.

Confirmatory factor analysis with varimax rotation was also conducted to examine the construct validity and to verify the groupings of the survey items adopted from previous studies. The results of the factor analysis confirm that the thirty survey items distributed themselves into six factors (see Table 2). The survey items which recorded a value below the suggested reliability level of 0.5 (Hair et al. 2009) were removed from the data analysis.

Table 2: Factor analysis

Constructs	Component					
	1	2	3	4	5	6
PU1	.259	.283	.271	.243	.215	**.743**
PU2	.258	.261	.286	.236	.202	**.756**

Structural Equation Model (SEM) and Hypothesis Testing

Properties of the causal paths including standardized path coefficients are presented in Figure 2. The results of hypothesis testing are shown in Table 3.

Figure 2 Structural equation model path analysis

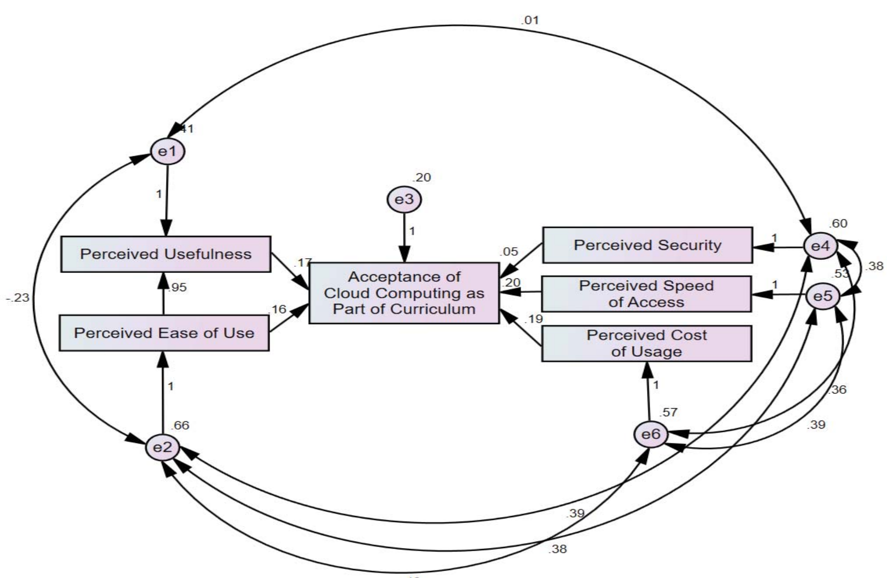

Table 3: Hypothesis testing and results

H#	Hypothesis Testing			Standardized estimate (β)	Critical Ratio	p-value
1	Perceived Usefulness	→	Acceptance of Cloud Computing as Part of Curriculum	0.169	0.039	***
2	Perceived Ease of Use	→	Acceptance of Cloud Computing as Part of Curriculum	0.157	4.453	***
3	Perceived Ease of Use	→	Perceived usefulness	0.948	19.455	***
4	Perceived Security	→	Acceptance of Cloud Computing as Part of Curriculum	0.054	1.467	0.142
5	Perceived Speed of Access	→	Acceptance of Cloud Computing as Part of Curriculum	0.203	4.735	***
6	Perceived Cost of Usage	→	Acceptance of Cloud Computing as Part of Curriculum	0.190	4.702	***

*** indicates significance level < 0.001

Hypothesis 1 examined the relationship between perceived usefulness and subjects' acceptance of cloud computing as part of their curriculum revealed a p-value of 0.000 making it significant at the <.001 level of significance. Thus, the data demonstrates support for H1. The presence of perceived usefulness is positively related to subjects' willingness to accept cloud computing as part of their curriculum. This finding indicates that the higher level of usefulness they perceived in using cloud computing, the more likely they are willing to learn more about this technology.

Regarding Hypothesis 2, the results also show that there is a positive relationship between subjects' perceived ease of use and their willingness to accept cloud computing as part of their curriculum, with the p-value of 0.000 making it significant at the < .001 level of significance. Thus, the data demonstrates support for H2. The result reveals that subjects tend to accept cloud computing as part of their core curriculum if they perceive that the technology of cloud computing is not difficult to use.

Hypothesis H3 examined the relationship between perceived ease of use and perceived usefulness revealed a p-value of 0.000 making it significant at the < .001 level of significance. Thus, the data demonstrates support for H3. This is in line with the connection discovered by Davis et al. (1989), which indicates that the perceived ease of use can positively influence subjects' perceived usefulness.

Hypothesis H4 examined the relationship between perceived security and subjects' acceptance of cloud computing as part of their curriculum revealed a p-value of 0.142 indicating that there is no support for the relationship between these two constructs. This finding is quite interesting. This may be because Thai students usually do not store the confidential data in the cloud storage and thus security is not viewed as an important factor to them. In other words, regardless of whether they believe in the security of cloud computing technology, their belief will not affect their willingness to learn this technology.

Regarding hypothesis H5, the results shows a positive relationship between the constructs perceived speed of usage and subjects' willingness to accept cloud computing as part of their curriculum with p-value of 0.000. It is pretty obvious that the speed of access should be considered a crucial feature of cloud computing. Subjects who view cloud computing as having a good speed of access are more likely to want to learn about this technology and thus willing to accept it as part of their core curriculum.

Hypothesis H6, examined the relationship between perceived cost of usage and subjects' acceptance of cloud computing as part of their curriculum revealed a p-value of 0.000 making it significant at the < .001 level of significance. Thus, the data demonstrates support for H6. This finding indicates that subjects who perceive the cost of the cloud computing as low are willing to learn more about the cloud computing technology and are likely to accept it as part of their core curriculum.

CONCLUSION

The results in this study reveal that four out of the five factors play an important role in encouraging Thai students to accept cloud computing as part of their core curriculum. These factors are perceived usefulness, perceived ease of use, perceive speed of access, and perceived cost of usage. The results reveal that if students perceive cloud computing as a technology that will be beneficial to them, they will be generally open to using it as well as learning it as part of their curriculum. In addition, the students today grew up surrounded by several technologies, they thus will be more likely to accept cloud computing if their "perceived ease of use" is high, which means that less effort is required to learn how to use it.

The result in this study also reveals that the speed of access and the cost of using cloud storage are also crucial factors that can influence Thai students' acceptance of cloud computing as part of their curriculum. Students prefer technology that allows them to get the thing they want in a timely manner. In addition, it does not matter how great a service a new technology can render, it will be useless if students cannot afford the cost of using it. Students will be more likely to accept cloud computing technology if they perceive that it does not cost them much to use the technology.

Interestingly, this study does not find a relationship between students' willingness to learn cloud computing and their perception about its security. This finding may be unique to Thai students as most of them do not store sensitive data in the cloud storage. So, regardless of whether the cloud storage is secure, it does not impact their willingness to learn about this technology.

There is an inherent limitation in this paper. The sample in this research was limited to subjects in one university. Although there was an attempt to gather the data from a variety of courses in the university, future research should be conducted at multiple universities. Further research should also consider expanding demographics to include users in various countries. In addition, a future study conducted could investigate in more details which feature of cloud computing help increase students' effectiveness and efficiency in the classroom.

ABSTRACT

In the past few years, supply chain management has been an important business function creating competitive advantage. Companies worldwide have strived to develop and improve their supply chain networks. Incorporating information technology and Decision Support Systems in Supply Chain Management operations has help companies achieve the desired competitive advantage.

KEYWORDS: supply chain management, decision support systems, information technology tools, Walmart, Amazon, competitive advantage

INTRODUCTION

Companies such as Amazon and Walmart are the leaders on the current competitive online marketplace. It would be beneficial to understand how those companies were able to reach and sustain the competitive advantage. It would be interesting to know if Decision Support Systems (DSS) tools play in a role in supply chain management (SCM) functionality and secure competitive advantage to those companies online.

In 2017, an American research firm specialized in Information System (IS) related insight to IT and business leaders in functional areas like Supply chain, IT, and Marketing, ranked both Walmart and Amazon in the Gartner Top 25. Amazon on the one hand, reaching Masters Status for being in the top five, seven times in the past ten years; Walmart on the other hand secured the 18th place. As information technology became an integral part of businesses focused on communicating and interacting with customers, businesses are able to react dynamically and respond rapidly to both, internal and external changes (Hershman, 2004). As it is common knowledge that companies like Amazon and Walmart are the leaders in today business world, it is difficult to determine to what extend their domination can be attributed to utilization of DSS throughout their SCM strategies. The current paper analyzed the impact of DSS on the SCM of both Amazon and Walmart.

COMPANY OVERVIEW – 2016 YEAR END

The choice of Amazon and Walmart derives from the fact that one company started as a brick-and-mortar storefront (Walmart) and the other as fully an online company (Amazon). Today, both companies are present online and essentially fighting for the same customers. Let us first give a brief summary of each company.

Company	**Industry**	# of EE's	Revenue	Profit Margin
Walmart Stores Inc.	Discount, Variety Stores	2,300,000K	487.51B	2.79%
Amazon.com Inc.	Online Shopping	341,400K	150.12B	1.28

Amazon.com Inc.

Amazon is a Fortune 500 online company established in Seattle, Washington. The company is known for being one of the first large company to sell goods over the Internet. Founded in 1984, Amazon Inc. started out as an online bookstore and added other unique items like DVDs, music, video games, electronics, and apparel. The Company also offers services, such as database options, publishing opportunities, digital content subscriptions, and advertising. It functions through three divisions: North America, International, and Amazon Web Services (AWS).

Amazon has become what one may identify as an online mall where third parties sell goods of virtually any kind. Amazon.com provides customers with the most variety of packaged products online in the marketplace. The company's strategy of continuous improvement has encouraged its leaders to explore different business opportunities, which resulted in the creation of separate business franchises. Amazon can be credited for popularizing online shopping in the world today. The company is very customer-centric. Amazon believes that the company's success depends greatly on customers' satisfaction. According to Schneider (2017), "Not putting the customer first, will certainly lead to total failure".
Business intelligence (BI) is at the core of Amazon success and business strategy. Thanks to BI technology, Amazon can personalize product recommendations and market products, uses BI software tools to make successful logistical business decisions. In-depth data analysis is what enables Amazon's massive supply chain to run smoothly. "From optimizing shipping routes to allocating inventory among warehouses, data and BI tools influence practically every step of Amazon's supply process", reports CCS Technology , an IT Service company (CCS Technology Group , 2018).

Walmart Stores Inc.

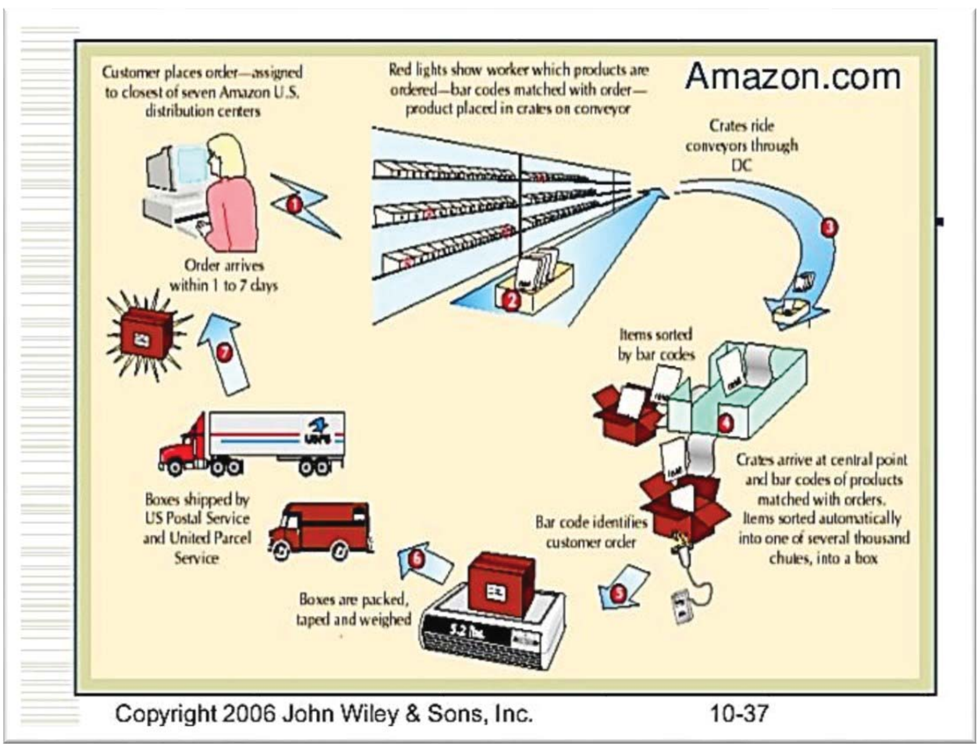
Walmart began as a discount store in Rogers, Arkansas, selling products for less. It rapidly grew in the second half of the century into the largest retail company in the world. Each week, over 260 million customers visit the more than 11,000 stores around the world. The company has approximately 2.3 million employees worldwide and is the number one employer in the US workforce. Wal-Mart sales a wide variety of products in their stores as well as online. From grocery and entertainment to sporting goods and apparel, Wal-Mart carries a good mix of products preferred by customers for its low prices. For many customers, Wal-Mart is a one-stop-shop for basic goods and services such as grocery products, health and beauty, household goods, pharmacy, electronics, cellular service, entertainment, small appliances and many other necessary items.

With a revenue of $485.9 billion in 2016, Walmart generates the most revenue than any other company in the world. With supermarkets built at a rapid pace in urban areas around the world, Walmart was projected to gross over $500 billion dollars in sales. One of the company's key goals since 1962 is to help customers save money so they can live better worldwide. They use their size to provide access to high-quality goods at everyday low price.

SUPPLY CHAIN MANAGEMENT STRATEGIES

SCM - Amazon

Amazon's SCM system is very simple: a customer places an order and the order is received at the warehouse. Their SMC network uses barcode technology to match the orders with the merchandises in the warehouse. Then, Amazon uses conveyors to ship the merchandise to the central point where goods are sorted, customer matched, weighted, and packaged before shipping via USPS, FedEx, or UPS. The illustration below by John Wiley and Sons, Inc. provides visualization for Amazon's SCM process model.



Amazon wants to take advantage of every opportunity that can add business value to the company using the latest technological to stay ahead of competitors. In spite of technology, Amazon remains true to the company's focus, which is "The Consumer-Centric Approach". Over the years, Amazon has invested in minimizing delivery time to improve customers' satisfaction. The goal was to reduce most transactions to same-day delivery and ultimately achieving even less than one-hour-delivery for some products. Same-day delivery and less than one-hour shipping is not realistic for traditional shipping lines like UPS and FedEx to handle. For this reason, Amazon decided to insource some of their distribution by investing in their own fleet of distribution trucks to satisfy same-day deliveries. Today, Amazon in-house delivery service has grown so much that that e-commerce giant relationship with delivery/shipping service providers is in jeopardy. In June of 2019, FedEx decided to cut ties with Amazon. In addition, the US Postal Service (USPS) reported a volume decline in package shipments during its fiscal third quarter, citing "intense competition" from "certain major customers" that have formed in-house last-mile delivery services, which according to USPS's CFO Joe Corbett, is the carrier's first quarterly volume decline for packages in nine years.

According to Burnson (2016), Amazon has over 100 warehouses or fulfillment centers in the United States alone. These warehouses are strategically positioned outside major metropolitan areas to reach customers as quickly as possible. Therefore, reducing the delivery time from 2-days to Same-day for certain products. In addition, in the warehouses/fulfillment centers, Amazon has invested in robotics and automation by acquiring Kiva Systems in 2012, in order to achieve quality and efficiencies in the supply chain (Burnson, 2016). In the fulfillment centers worldwide, Amazon has more than 30,000 robots operating to pick, pack, and sort products with no human intervention. This robots help streamline Amazon's SCM process by cutting costs, improving efficiency and speed and therefore increasing customer satisfaction. Using robotics also reduce manual work for hazardous tasks, improving Amazon's working conditions therefore keeping employees safer.

Amazon has also been working on delivering products to customers by air via Drones called "Prime Air". These drones are intended for delivery within 30 minutes, with does not come as a surprise, given Amazon obsession with customers satisfaction with speedy delivery. However, Prime Air development has faced regulation obstacles in the United States (Burnson, 2016); but in other countries like India, Prime Air has a better chance to launch and thrive globally. Amazon has also been using artificial intelligence (AI) to make it easier for customers to buy what they like based on its recommendation engine.

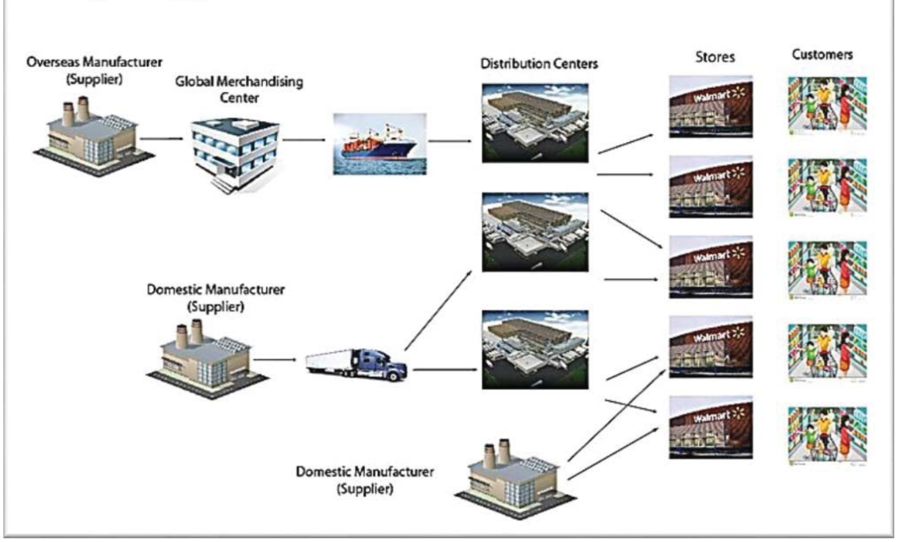
Amazon has innovated its user interface screens to streamline shopping and better serve customers from an overall user experience perspective. They have added the "Dash Button" which enables customers to order products with a click of a button. With just one-click, Amazon made shopping easy and quick. This feature allows Amazon to collect data at real-time and to provide insight to when the demand for a product rises or drops. Therefore, adjust the supply of each product accordingly to inventory levels. This strategy also led Amazon to developing predictive analytics technology. Creating a predictive shopping and purchasing system allows Amazon to deliver goods that customers will likely buy; since Amazon knows what customers are likely to buy. This technological strategy has revolutionized Amazon's supply chain and a brief list of innovative SCM strategies that Amazon incorporates throughout their business operations is presented in the table below.

Innovative Business Strategies: Amazon.com Inc.			
Company	**SCM Strategy**	**Business Impact**	**IS System Involvement**
Amazon	Predictive Shopping and Purchasing	Delivering goods that customers that will likely buy even before they order them.	Yes
Amazon	Army of 30,000 robots	Automated warehouse solutions: Picking, Packing and Sorting Shipments.	Yes
Amazon	Amazon Delivery - Reduce deliver time	Own fleet of delivery vehicles to fulfill same-day deliveries for customers.	Yes
Amazon	Drone Delivery system	Customers who live within 10 miles of a fulfillment center will be able to receive their packages via drones within 30 minutes or less.	Yes
Amazon	Dash Button	Streamlined Shopping: Allows users to simply press a button to order household goods.	Yes

SCM - Walmart

Walmart is listed in Gartner's top 25 companies as having one of the best supply chains in the world. Walmart's SCM strategy including but not limited to product cost reduction, inventory storage cost reduction, and highly competitive pricing. This strategy has enabled Walmart to maintain a sustainable top position against competitors for many decades. A key to Walmart success resides in its focus and investments in innovative technology, especially decision support systems to improve all its business functions including supply chain. Technology is the foundation of Walmart's supply chain strategy.

Figure 2: Supply chain model of Wal-Mart



Inventory storage cost can be so expensive, so incorporating an innovative system to cut inventory storage costs is a tremendous game changer in the retail industry, which proves why Walmart is very profitable because of its successful SCM.

Innovative Business Strategies: Wal-Mart Stores Inc.			
Company	SCM Strategy	Business Impact	IS System Involvement
Wal-Mart	Strategic Vendor Partnerships	Provide potential long-term and high volume purchases in exchange for the lowest possible prices.	Yes
Wal-Mart	Cross Docking	Strategy to replenish inventory efficiently	Yes
Wal-Mart	Predict Inventory Levels	Ability to proactive determine inventory levels to replenish inventory efficiently	Yes
Wal-Mart	RFID Technology	Ability to track pallets of merchandise moving along the supply chain.	Yes
Wal-Mart	Data Harmonization and Data learning	Integrating data from many different sources which will drive new business insights, decreased costs, and improved data accuracy. Also creating algorithms to provide continuous improvement in the supply chain.	Yes

One major SCM business driver for Walmart is the strategic vendor partnership (SVP) system. In this system, Wal-Mart commits with vendors/Suppliers to create strategic sourcing opportunities for products at the lowest possible prices. This can only be achieved by Walmart guaranteeing suppliers a long-term and high capacity purchase in exchange for the lowest price points on the market. In turn Walmart can offer its customers very competitive prices. This SCM partnership also restraints Wal-Mart to streamline purchasing by working with only select suppliers.

Walmart is also a leader in innovative logistic practices. Using the “Cross Docking” tactic, Walmart is able to strategically replenish inventory by direct handover of products directly from sending trucks to receiving trucks therefore, bypassing storage costs. Another cost cutting strategy is Walmart’s cross docking also known as, “centerpiece” strategy, which is an inventory tactic to replenish inventory efficiently (Lu, 2014). This strategy cuts costs, reduces transportation time, and keeps balanced inventory levels.

Walmart also uses radio frequency identification (RFID) technology like no other company in the world. RFID is no only a DSS tool, but it is another innovative technology with the ability to scan numerical codes from a distance to track merchandise. Walmart operates RFID technology to track pallets of merchandise moving across the entire supply chain network. Walmart also mandates that their suppliers/vendors use RFID tagging to control what products are sent through their distribution channels. This innovative SCM tactic improves overall efficiency by tracking products, sorting merchandises, reducing driving, and managing delivery time. Below is an illustration of Walmart’s SCM network.

Walmart is also a forerunner in utilizing big data to drive business insight within its functional areas. With billions of data transactions between Walmart’s distribution centers, stores, suppliers and customers, the company has the capability to collect a vast amount of data on their customer needs a well as the marketplace. This allows Walmart to gain unique knowledge and business insight on the market conditions giving them a competitive edge over their competitors. Walmart integrates data from various sources including suppliers, customers, prices, shipping and many other valuable segments. In order to collect data from all these sources, Walmart has to invest in advance information systems that interface with various data sources to collect and process large amounts of data. Walmart SCM strategy uses data analytics to learn about the entire supply Chain environment. Data analytics help drive additional business insight and make better decision in the marketplace.

SCM Commonalities between the Two Companies

Amazon and Walmart are leaders in the marketplace and have been able to maintain their competitive advantage for decades. Both companies' strengths seem to reside in their SCM strategies. On the one hand, Amazon uses DSS tools to create strategic vendor partnerships; on the other hand, Walmart tracks inventories for competitive advantage using RFID technology. A summary common innovative DSS tools and SCM strategies used by Amazon and Walmart, to improve their supply chain, is in the table below.

Common Innovative SCM Strategies		
Common SCM Strategies	Business Impact	IS System Involvement
Strategic Vendor Partnerships	Provide potential long-term and high volume purchases in exchange for the lowest possible prices.	Yes
Predict Inventory Levels	Ability to proactive determine inventory levels to replenish inventory efficiently	Yes
RFID Technology	Ability to track pallets of merchandise moving along the supply chain.	Yes
Data Harmonization and Data learning	Integrating data from many different sources which will drive new business insights, decreased costs, and improved data accuracy. Also creating algorithms to provide continuous improvement in the supply chain.	Yes

FOCUS GROUP - DSS TOOLS AND SCM ANALYSIS

It is clear that Decision Support Systems tools play an important role in Supply Chain Management of both Amazon and Walmart. On the one hand, the companies could not operate efficiently without automation such as managing supplier transactions and order entries from customers; on the other hand, it would be almost impossible those companies to deliver such amount of products/goods without the information systems to streamline their supply chain management strategy. The Supply chain management systems of both companies therefore gives them gives them more efficiencies in their operations and enable them to expand, grow and become more profitable and competitive. Other innovative DSS and SCM tools that can be used gain competitive advantage are best practices and presented in table below.

The competition between Amazon and Walmart is only going to widen for many reasons. Amazon investment in groceries and gourmet food might have caught many by surprise as did their in-house delivery service. But, just like auto makers, as Walmart.com has become amazon Inc. fiercest competitor, it makes sense that the e-commerce giant brings the competition to where it can hear Walmart hard. The introduction of free shipping by Walmart.com, a service Amazon Inc. offers mainly for its prime members, is one way to gain competitive advantage over Amazon. Since Walmart Labs was originally created to build and test new technology for Walmart.com; they had evolved and focus on getting Walmart.com to a place of operational efficiency: rebuilding the search engine, focusing on social / local / mobile (SoLoMo) and building a new platform.

Participants List Innovative DSS Tools	Amazon and Wal-Mart Current Compatible DSS/SCM Tools	Company
Predictive Inventory	Predictive Inventory Levels	Both
ERP Systems	Strategic Vendor Partnerships	Both
Freights Service Management	Amazon Delivery – Reduce deliver time	Both
Lean Cost Management System	Slash Inventory, Cross Docking, Strategic Vendor Partnerships	Both
Order Management – Predictive Behavior Analysis	Dash Button	Amazon
Automated Warehouse System	Army of 30,000 Robots	Amazon
Inventory Tracking System	RFID Technology, Predict Inventory Levels	Both

One great advantage Walmart has is that it is first and foremost a retail company that recognizes technology as the critical enabler, behind the company's associates, in helping achieve success. Walmart Labs is comprised of: (i) Customer Technology that focuses on customer's shopping experience; (ii) Merchant Technology overseeing our online and in store search (pricing, catalog, content, inventory, replenishment, and fulfillment technology) to provide optimal online shopping experience; (iii) Supply Chain Technology ensuring that customers receive their orders as fast as they want and where they want in a predictable way; (iv) Global Cloud and (v) Global Data Analytics team warrants that Walmart's decisions are data-driven, smarter, faster, and highly-automated. This strategy has enabled Walmart eCommerce and store technology teams to increase operating efficiencies while decreasing enterprise expenses.

As both companies compete at the eCommerce rink, Walmart's tremendous and lengthy successful experience in retail stores is something Amazon is still learning. Amazon name as a store is not as a household name as Walmart is. A 3-year old child knows that his/her toy will be found in a Walmart store or a Target store. Walmart platform also enable customers to shop online and pick up in a nearby Walmart retail store, which Amazon does not possess. While picking a product ordered online, customers are likely to shop in-store. While both companies use similar DSS tools, Walmart competes locally against stores like Publix, Kroger, Targets, Best Buy, to name a few. Its platform is two-fold: traditional mortar and brick store and online.

CONCLUSION

It is evident that leaders like Amazon and Walmart use Decision Support Systems (DSS) tools to improve their in supply chain management to gain and maintain competitive advantage. These companies constantly use DSS tools to manage their daily operations. Both companies have similar innovative SCM strategies, which earned them a spot on the Gartner's Top 25.

ABSTRACT

Precision medicine is a high-cost complex medical procedure that provides targeted treatments according to the individual characteristics of each patient. We present a preliminary cost-benefit dynamic model to assess learning curve effects in cost reduction through interaction with a centralized database repository. We also develop a simulation model to study the dynamics of the precision medicine approach and discuss insights derived from this model.

KEYWORDS: Health Care, Bioinformatics and Biological Data modeling, Cost Benefit Analysis, Knowledge Acquisition, Database Design for Big Data and Analytics Applications, Simulation

INTRODUCTION

Precision medicine is the use of personalized data to provide, integrate, and interpret information about an individual's health and better manage it (Snyder, 2016). Individual data are compiled from sources such as sequencing of the DNA (genome), measuring of biomolecules in the body, sensors to continuously monitor physiology and activity, and studying the microbial community that resides in the body. The cost of sequencing genomes has decreased dramatically in recent years and has had a large impact on personal genomics. In particular, one area of highest impact is cancer, which will strike 40% of people in their lifetime (Snyder, 2016). Traditionally, when a patient is diagnosed with cancer, he/she will be treated by a general procedure targeting the symptoms of the disease. Since the body cannot afford too many trials, only a limited number of treatments can be applied to the patient. The treatment and the drugs used by the physicians must be proven to be effective and be legally approved and registered. For many cancer patients, treatments that were proven effective in the past do not work well. This is because, genetically every person is different, even for the same pathogenesis a drug or a general treatment cannot be effective for all the patients. Further, even if the drug or treatment has proven to be effective for the given pathogenesis in the past, the treatment can still be ineffective because of the dosage or the combination of adjuvants that does not fit well the individual characteristics of the patient. Thus, the effectiveness of traditional methods depends heavily on the similarity between the personal characteristics of the tested group during the general treatment development and approval phase.

On the other hand, precision medicine provides an alternative to treating patients. It classifies individuals into subpopulations whose members (and their tumors) are genetically similar, and probably can be treated by the same therapies (Timmerman, 2013). Precision medicine for the treatment of cancer is based on the context of a patient's genetic content (Lu et al., 2014) or other molecular or cellular analysis. It usually consists of a series of activities including gene sequencing, pathogenesis identification, disease database matching, customized medicine development experiments, database updating, and so on. Development of a personalized treatment requires the use of intelligent-platform experiment-based techniques involving the use of patient's cell cultures for multiple screening runs of different depth (i.e., dosage, toxicity, functional test, molecular targets, etc.) and outcome analysis guided by machine-automation and machine learning to improve the efficiency (Tang-Schomer, 2017). Therefore, personalized treatments are more expensive than general traditional treatments and cost-benefit analysis is a major concern.

A less expensive approach is using a proven successful treatment of a similar case that matches the patient's characteristics. This experience-based approach relies in the use of a data repository of historical treatments generated as a by-product of previous experiment-based findings. One main factor to decide whether a patient should use a newly experiment-based personalized treatment as described before or an experience-based database treatment is the size of the data repository. As more experiment-based personalized treatments are performed and more data points are added to the database, finding a match between a current patient and a previously treated patient becomes more likely. Thus, as the database grows the number of experiment-based personalized treatments, and hence, the overall cost of the precision medicine approach is expected to decrease.

In this paper, we propose a tentative abstract model of the decision process of a patient, and his/her supporting healthcare providers, who is undergoing a precision medicine treatment and must decide whether to use a (more expensive) experiment-based treatment or a (less expensive) experience-based database treatment. In the model, the main driver of the decision is a cost-benefit analysis of the patient's situation that incorporates the expected cost and the likelihood of success of the treatments. This leads to finding an economic breakeven point to decide whether to match the patient's profile to an existing case, or to develop a new personalized treatment via experimentation. By considering information gathered from patients who choose to develop an experiment-driven personalized treatment into a database, we also hope to understand how information technology dynamics (as a learning process) affect the overall cost of this precision medicine approach. To do so, we develop a simulation model to study the evolution dynamics of the database and the overall cost of the precision medicine treatments as the number of patients grows through time. We then apply our simulation model to different scenarios, where we consider the likelihood of success in finding a matching treatment and, if there is a match, the likelihood of success of the treatment. Finally, based on our numerical analysis from the simulation, we provide insights about the learning process associated with precision medicine and some implications to public policy.

LITERATURE REVIEW

In recent years, precision medicine (PM) has become a popular term in the new medical treatment development frontier. Although people have widely discussed the advantages of the PM approach in the literature, adopting its prevention and treatment strategies in real medical practice is still at a very early stage (NRC, 2011). Until now, the medical industry has applied precision medicine to treat limited genetic related illnesses, especially some types of cancer such as lung cancer (Jamal-Hanjani et al., 2014) and metastatic breast cancer (Arnedos et al., 2015). The public recognizes the success of precision medicine, but big challenges are still hindering precision medicine from incorporating into our existing medical system. One challenge is whether people are able to afford the huge cost of precision medicine, because personalized treatments are always more expensive. Whether it is worthwhile to apply precision medicine treatments instead of traditional medicine treatments really depends on how people value the utility of the treatment based on his or her own condition. Finding a general measurement for the value of precision medicine is of great importance (Grosse et al., 2008). On the other hand, to target a disease caused by a certain defective gene(s) needs sophisticated decision algorithms, because a gene segment could be the source of several diseases (Jameson et al., 2015). Thus, whether we can extend precision medicine into the medical system in the future depends on whether we can make precision medicine affordable by enlarging biological databases, which entails identifying problematic genes and genetically classifying patients efficiently (Collins and Varmus, 2015).

Generally, there are two major aspects to consider when valuing the economic benefit of applying medical procedures: health outcomes and treatment cost. Correspondingly, in the literature researchers have used cost-effectiveness analysis (CEA) and cost-benefit analysis (CBA) focusing on different aspects of the procedures (Grosse et al., 2008). Typically, CEA focuses on the cost per unit of "natural" health outcomes, such as the cost of a 1% increase in the five-year survival rate. CEA is suitable for a single target disease since it compares only one aspect of the outcomes at a time. One type of CEA is based on a very popular measure called the *quality-adjusted life year index*, which maps the life duration and quality into a comparable number (Klarman and Rosenthal, 1968). However, since it is very hard to define the state of "quality" of life, the method cannot be widely applied and is under debate (Prieto, 2003; Mortimer and Segal, 2008; Dolan, 2008). Another popular CEA is the *incremental cost-effectiveness ratio* (ICER), which is the ratio of incremental costs to incremental outcomes and it captures how an additional input affects the health outcomes. A patient can decide whether to undergo further treatment based on an ICER value. It is also controversial since it may limit the availability of treatments to patients because of healthcare rationing. In contrast, CBA is more comprehensive and can be applied in a wider range of contexts. It considers more than only the health outcomes, but also many non-health outcomes. The idea is to map all the benefits and losses into monetary units, and then to calculate the net benefit. One method for the mapping is to estimate the indirect value of regain/loss of health, such as future value of economic production when with and without health. A second approach of CBA is more customer-driven and is favored by most economists; it is called *willingness-to-pay* (WTP), which is the minimum amount of money that a person is willing to pay for the benefit from a treatment. The implementation of WTP is very helpful for decision makers to have criteria for choosing a plan or not. However, WTP depends on a subjective contingent perceived valuation of each person (Donaldson et al., 2002; Gafni, 1990; O'Brien and Viramontes, 1994; Jarrett and Mugford, 2006). All CBA results are expressed in monetary units, which makes it a good indicator for decision makers to compare different treatment scenarios (Krupnick, 2004), while CEA compares direct results, making it easy for healthcare system to see the outcomes (Oliver et al., 2002; Grosse et al., 2007).

When it comes to precision medicine, traditional CEA and CBA approaches as discussed above need to be revised and re-defined in some cases because of the personalized nature of the procedure. In particular, to the best of our knowledge, there have been very few attempts to do so. For instance, Grosse et al. (2008) introduce preliminary extensions of CEA and CBA for genetic testing; their paper also contains references to prior attempts of economic evaluations of genetic testing. Unfortunately, those approaches mostly focus on static information and do not consider the evolving nature of precision medicine and reducing costs from learning curves. In our research, we propose an original combination of the CEA and CBA approaches. To do so, we consider the monetary value of the precision medicine experiment and experience-based procedures (as in a CBA approach), as well as the likelihood of success of the procedures, to compute an economic break-even point (or indifference point) between procedures. From this, we derive a formula that compares the cost ratio of the procedures to the probability of success to determine (as in a CEA approach) which procedure to perform for each patient. Our approach also considers the learning dynamics as reflected by an increasing database of successfully treated patients using personalized procedures.

GENOME AS INFORMATION

Like many researchers (e.g., Calude and Paun, 2000), our approach to the structure of the genome is targeted to our goal of a cost-benefit analysis of a precision medicine procedure. Hence, we ignore a lot of the biochemical information not necessary for our analysis and instead, we present our models using a simplified version of the DNA. A DNA molecule is a polymer that serves as the instruction manual to guide the development process from a single cell to a complex individual. It is made up of four constituent parts (nucleotide bases). These bases are adenine (A), cytosine (C), guanine (G), and thymine (T), and they are paired as A - T and C - G. A human DNA molecule contains about six billion base pairs into 46 chromosomes. Hence, it can be seen as a finite string variable consisting of about six billion characters, each character taking values in {AT, TA, CG, GC}. In particular, assignment of values to this variable constitutes an individual's genome. Genomes differ by “variants”; a variant is a DNA sequence change. Approximately 3.8-4 million variants (one in every 1,200 bases) are single letter or base changes (called single nucleotide variant: SNV). There are 50,000-850,000 small insertions and deletions of 1-100 bases ("indels"). There are thousands of large insertions, deletions, inversions, and other types of chromosome rearrangements (some several hundred kilobases, 1 kilobase = 1,000 bases) and are called structural variants (Hartl, 2000; Snyder 2016).

The human genome sequence is a composite of several individuals yielding what is called the “reference” genome. The reference genome in its more finished form was completed in 2003 and it was prepared using DNA pooled from several individuals (thus it does not represent a single individual’s genome) (Snyder 2016). It consists of approximately 3 billion base pairs, and includes each of the 22 chromosomes plus the X and Y sex chromosomes. State of the art technology allows sequencing an individual’s genome in a few days. Variants are mapped when comparing millions of short sequenced fragments (100-150 bases in length) of an individual to the reference genomes. By comparing to known fragments, it can be deduced whether there is deletion, insertion, or inversion in the sequenced regions (Snyder 2016).

In bioinformatics, it is customary to quantify DNA similarity across individuals by modeling DNA as strings of characters and using an “edit” or Levenshtein distance to compute the similarity between strings (Gusfield, 1997). Concretely, we denote by V the set of all the different DNA molecules (strings) in the human population. For each v in V, we denote by $l(v)$ the length of v, that is, the number of characters in v. Hence, $v=(v_1,v_2,\ldots,v_{l(v)})$ is a string such that each character v_i is in {AT, TA, CG, GC}. The Levenshtein distance between two strings is the minimum number of single-character edits (insertions, deletions or substitutions) required to change one string into the other (Gusfield, 1997).

A key notion in our approach is that every genome can be matched to a number in the [0, 1] interval. Concretely, if we (arbitrarily) map the values AT, TA, CG, and GC to 0, 1, 2, and 3, respectively via a function (say) h, we can then create a map ϕ:V -> [0,1], that assigns to each string v in V a unique number of the form:

$$\phi(v) := \sum_{i=1}^{l(v)} h(v_i) 4^{-i}. \tag{1}$$

in the interval [0, 1]. Notice that ϕ is a bijection between V and $\phi(V)$; we call $\phi(V)$ the set of *numerical* genomes. This way, if there is a finite subset of E of V consisting of the genomic information of a group of patients, each individual genome in E can be represented as a point in the interval [0, 1]. Furthermore, if T denotes a set of personalized treatments that have been successful in treating the patients in E, then a genomic-treatment database D based on the individuals in E can be modeled as Cartesian product $D := \phi(E) \times T$, where for every pair (v, r), with v in E and r in T, we have ($\phi(v)$, r) in D.

The Levenshtein distance induces a distance in the set of numerical genomes $\phi(V)$, namely,

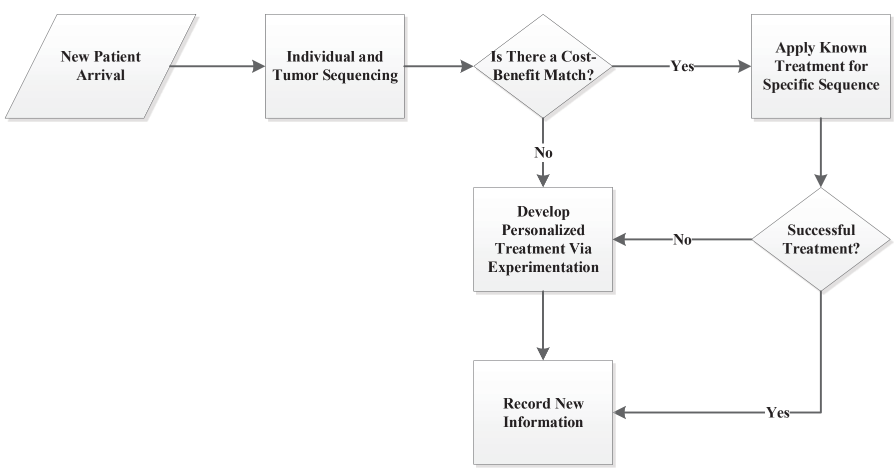
$$dist(x, y) := dist_L(\phi^{-1}(x), \phi^{-1}(y)), \tag{2}$$

for x, y in $\phi(V)$, where $dist_L$ is the Levenshtein distance. Therefore, we can determine the closeness between two individuals in a genomic database, or between one individual not in the database and one in the database, by using this induced distance.

COST-BENEFIT MODEL

We model the process of a patient's decision through a workflow as illustrated in Figure 1.

Figure 1: Precision medicine treatment workflow.



In this model, we assume that patients have been already diagnosed with a cancer (cancerous tumor) and they can be successfully treated if we are able to find an adequate (personalized) treatment. To start the process, the patient’s genomes, as well as the tumor’s, are sequenced for each new arrival. Next, the treatment database is searched for possible genome matches. The matching database string can be an exact or partial match based on the induced Levenshtein distance *dist* from (2). If there is a close enough database match, then the patient will decide whether to use this matching case based on a cost-benefit analysis that incorporates the likelihood of the success of the matching treatment. If the there is no database match or there is one but is not cost effective, then a personalized treatment will be developed from scratch via experimentation. If the database treatment is not successful, then the experiment-based approach will also be used. If the patient is treated using a matching experience-based case and this treatment is successful, or if the patient is treated by an experiment-based treatment, then the patient's genomic data and the details of his/her treatment are recorded into the database for future use.

Concretely, we denote by C_e the expected cost of developing an experimental treatment from scratch, whereas we denote by C_d the cost of applying a known-treatment from a matching database case, where we assume $C_e > C_d$. A patient chooses an experiment-based or experience-based treatment based on a cost-benefit analysis as follows. Let D_t denote the current genomic-treatment database at the time of arrival of the patient number t. From the discussion in the previous section, D_t consists of a finite number of pairs (x, r), where x in [0, 1] is a numerical representation of the genome of a previously treated patient and r denotes that patient's treatment. We denote by $X_1, X_2, \ldots, X_t, \ldots$ the numerical genomic values of patients in order of arrival to the system. We assume that the X_t are independent and identical distributed random variables in the interval [0, 1], and denote by f their corresponding common probability density function.

Given $\delta \geq 0$, we define the probability of a δ–matching of patient as the probability that there is at least one individual in database D_t whose induced Levenshtein distance is less than or equal than δ. Formally, let $B(x, \delta)$ be the subset of [0, 1] consisting of y such that $dist(x, y) \leq \delta$. For a given database D_t, define (abusing notation) the set of points in [0, 1] within δ distance from at least one element in D_t as

$$I_t(\delta) := \left(\bigcup_{y \in D_t} B(y, \delta) \right) \bigcap [0,1]. \tag{3}$$

Then, for x in [0, 1], the δ–matching probability is defined as

$$\pi_t(x, \delta) := \int_{I_t(\delta)} f(z)dz. \tag{4}$$

We denote the probability of a successful database treatment by p. Therefore, from a cost-benefit analysis point of view, a patient should first select an experience-based (database) treatment whenever we have

$$C_e \geq C_d + \left(1 - p\pi_t(x, \delta)\right) C_e, \tag{5}$$

given that $X_t = x$. In other words, from inequality (5), it follows that the experience-based treatment should be first selected when the ratio of the costs is below the probability of success of the database treatment:

$$\frac{C_d}{C_e} \leq p\pi_t(x,\delta). \tag{6}$$

Notice that the δ–matching probability is an increasing function of the size of the database because the more points added to it, the greater the integral region $I_t(\delta)$. Since the cost ratio on the left-hand side of (6) is less than 1, we conclude that, as long as new patients are added to the database, there will be a breakeven point (indifference point), where equality is attained in (6). After that point in time, it will be more cost-effective to perform all treatments using the database approach.

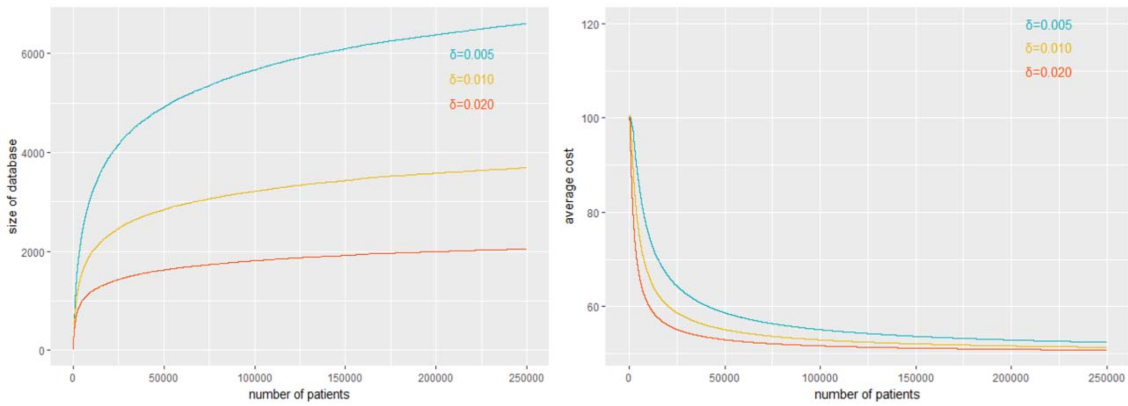
SIMULATION MODEL

We use a Monte-Carlo simulation model to study the dynamics of our proposed approach. In the simulation, for each scenario under consideration we generate a sample of 250,000 patients to go through the workflow from Figure 1. To simulate the matching process, in our experiments we assume that the density *f* (as described in the previous section) corresponds to the density of a uniform distribution. At each iteration of the algorithm, we randomly generate a point in the interval [0, 1] to represent the location of the new patient on the database.
The closeness of a match is determined by a proxy for the induced Levenshtein distance; namely, we use a simple absolute deviation difference between the randomly generated point corresponding to the new patient and the already existing points corresponding to existing database entries. In particular, a database point is considered a close match if the absolute difference between the new point and the database point is less than or equal to predefined value of δ. This is without loss of generality because if there are *k* tumor-causing variants and they are ordered such they represent the first *k* characters of the patient's genome string, then by choosing $\delta = 10^{-k}$ the two matching strings would agree in their first *k* characters (bases). Moreover, if an exact match is required, then we can always set $\delta = 0$ in the simulation.

NUMERICAL RESULTS

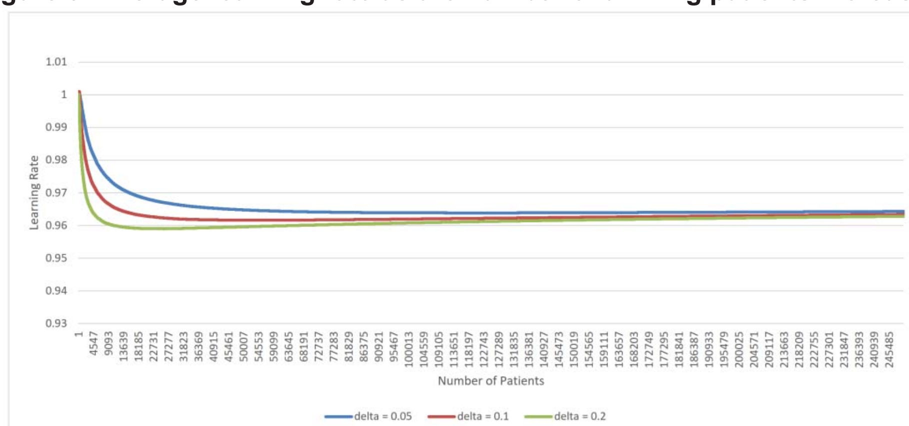
Using our simulation model as described in the previous section, we ran several scenarios. In particular, we considered three values of δ (i.e., 0.005, 0.10, and 0.20) to run our simulations. Figure 2 shows two graphs, the graph on the left corresponds to the growth of the database as the number of patients increases, whereas the graph on the right corresponds to the decrease in average cost per patient as the number of patients increases. The average cost per patient at time *t* is computed as the total accumulated cost up to time *t* divided by the number of arriving patients up to time *t*.

Figure 2: Evolution of the average database size and the average cost per patient as the number of arriving patients increases.



We can readily see that when δ is doubled, the size of database is almost halved. In addition, as δ increases, the average cost per patient decreases.

Figure 3: Average learning rate as the number of arriving patients increases.



With respect to learning curve effects, our results show an exponential the decrease of the average cost per patient at a constant speed exponent (see Figure 3). Moreover, the learning rate increases with δ. In our experiments we also tried other probability distributions (e.g., normal distribution) and found see that learning curve is not significant affected by how gene sequences are distributed, and it is more affected by the cost ratio between database and experimental treatments. When the ratio is low, the learning curve has a faster decrease speed rate.

DISCUSSION AND CONCLUSIONS

We have developed an original economic model of the precision medicine process that incorporates both cost-benefit and cost-effectiveness analysis. Our results show that as long as new patients continue being added to the genomic-treatment database, eventually the database will reach a size that will (1) provide a matching treatment for most patients and (2) the expected cost for patients will be more affordable than the cost from developing a personalized treatment from scratch (inequality (5)). Further, the convergence to this state of the database is exponentially fast in the number of treated patients.

Our formulation provides a decision criterion (inequality (6)) that is statistically computable in practice and it is useful for patients to decide the best approach when undergoing a precision medicine treatment. From a public policy point of view, a comprehensive database does not need a high amount of records, so that for the society benefit it makes sense to implement a subsidy policy for less wealthy patients with the objective of boosting the database growth.

ABSTRACT

The use of Information and communication technologies (IT) has allowed the development of a digital version of public administration through the implementation of electronic government (e-government). This paper aims to analyze the web pages of Mexican government Ministries in order to evaluate the level of performance based on three main characteristics: accessibility, usability and service and contents. The results will allow to propose some improvements in those key elements related to a better performance of Mexican electronic government.

KEYWORDS: Information and communication technologies, Electronic government, Mexico, Accessibility, Usability, Service and contents.

INTRODUCTION

The technological development influences governments to look for new ways of innovation transforming it in order to face new challenges or social environment and new complex situations for public administration. In the same sense, the intensive use of information systems and telecommunication networks has caused society to develop more and new demands on information (Gascó, Rodríguez & Mármol, 2014).

In the last decades the information and communication technologies diffusion changed people's way of life as well as government's performance. As a response, governments have to introduce new policies to improve services through a digital version of public administration, known as electronic administration in Europe, while in Latin America is called electronic government (Ruíz, Morales y Gómez & Contreras, 2014).

The main reason for emerging e-government and the transformation of the relationships among citizens and public institutions is to focus on technological innovation for offering government services (Pérez, et al, 2015). As a result, IT use improve all the papers to make, and allow a quickly, efficient, effective and secure way of access to public information (Aguilera, 2008).

In Mexico, e-government presents different advance levels, citizens can access some online information and services, for example the payment of taxes, downloading the format for driving licenses and passports, to search for a job or to make a medical appointment (Gil-Garcia, Mariscal & Ramirez, 2008). Nevertheless, most of the procedures and services in federal Ministries are not online.

LITERATURE REVIEW

The CINVESTAV (2004) and OECD (2011) define electronic government as the use of Internet and IT to reach a better management of government through transparency and public access to information, reinforces the basic association between public sector and citizens.

In the last years, the development process of electronic government has changed, and it continues changing from evolve non-sequential stages to an overlap and connected building blocks (ONU, 2016).

In this sense, there are several proposals, which establish key requirement elements to develop an e-government. For example, CINVESTAV (2004) points some actions that governments have to implement: working places based on knowledge; change of management; IT infrastructure update which imply an independent but networked, flexible and robust infrastructure; the possibility to do financial transactions, and to provide electronic services, hot spots, sites, and getaways of the state. ONU (2012) defines some evolve stages for e-government implementation: emerge presence, extended presence, interactive presence, transactional presence and total integration. Yu-Che and Gant (2011) include some characteristics for e-government development: incorporate information and services on line, government agencies interoperability, and relationship between governance and citizen for decision-making. Criado and Gil Garcia (2013) suggest some areas to consider in order to create a strategy focus for e-government: e-government national agenda, sites to provide electronic public services, interoperability initiatives, social networks and public administration networks, and open government and transparency.

In México the reason for electronic government is to make easier and to increase the relationship between the State and citizens through IT use, being Internet the key communication tool. Since 1995 the different federal governments have worked in the development of a technological infrastructure for communicate with people, increasing the offer of better services and procedures on line, as well as designing a legal framework for IT use (Luna, Gil-Garcia & Sandoval, 2015). The Mexican electronic government strategy is reflected in the legal and institutional structure built by several projects (Gil-Garcia, Mariscal & Ramirez, 2008). The central axis to manage electronic government for the last government (2012-2018), was the National Digital Strategy (EDN, 2013).

In particular, according to Welp (2008) who analyzed the electronic government web pages of 18 Latin American Countries the Mexican electronic government was considered as “no-functional”, Mexico was ranked 11^{th} compared to other countries in the region. Regarding the countries’ development electronic government functionality, The Global Information Technology Report 2016. Innovating in a digital economy of the World Economic Forum (2016), presents the results of an evaluation conducted in 139 countries. According to such report, Mexico was ranked 76^{th} scoring 4.0 out of 7 (Islas, 2016).

This paper aims to analyze the web sites of Mexican Federal Ministries that offer IT procedures and services, and to review three main characteristics in order to evaluate if the corrections of them would drive to a general improvement of Mexican electronic government: accessibility level, usability level and contents and services. The research uses a quantitative approach through the analysis and evaluation of 21 web sites of Mexican Federal Ministries, including the President’s office, the Attorney General Office and the Legal Advice Office of the Federal Executive (See Appendix 1.).

Based on the previous objective the research question was established as: ¿The improvements of Ministries' web site in terms of accessibility level, usability level, contents and services would increase the low level of Mexican electronic government functionality?

METHODS

A content and qualitative analysis of the Ministries' web sites was conducted. We decided to study the federal Ministries' web sites because they are the governmental main offices in charge of the national public administration. Therefore they represent the first channel for citizen to access procedures and services provided by government. Currently, the Mexican public administration comprises 18 Ministries, the President's Office, the Attorney General Office (PGJ) and the Legal Advice of the Federal Executive (CJEF). A questionnaire was used to analysis each Ministries' web sites. It was designed including 50 questions organized by three subjects: accessibility level, usability level and contents and services.

The following research variables were defined: three independent variables were created: accessibility level, usability level and contents and services. The dependent variable was defined as the level of government site performance; it is the result of the sum of all the independent variables. Based on the dependence variable and establishing a percentage range, the performance level of web sites was defined.

The first independent variable, accessibility level, refers to a set of technologies, rules and design for making easier the use of web sites. The technical basis for developing an accessible web site is to allow the access for information without limits for any reason deficiencies, disabilities, or technology used (CTIC, 2017; DISCAPNET, 2017). For example: hearing problems, sight, movements; problems for reading or cognitive comprehension; inability to use the keyword or the mouse, a small screen, or a slow connection.

We used the rules established by DISCAPNET (2017) on measurable parameters: noticeable, feasible, understandable and robust for accessibility level. The previous characteristics are technical features often included in the web sites that are not easily observed. In order to determine the presence of the previous characteristics we reviewed each one of them at the web sites under study by using two free web analyzers. The first one is part of the TAW Project (2018) and the second one is WAVE (2018), which was developed and offer as a free community service for WevAIM. Those two webs analyzers automatically review the technical features associated with the accessibility level and produce a report of the web site indicating the presence or the absence of diverse accessible characteristics. We considered two values: 1 and 0 to indicate the presence or absence of each characteristic. The total amount of all items produces the score for this first variable; the 30% of the total weighting was assigned.

The second independent variable, level of usability, is utilized to determine the IT products easiness of use. According to Ortiz (2012), this word is used very often among software and hardware products to explain if the use of this technology makes a better and easier experience for user's satisfaction. Following Guia Digital (2017), usability includes several characteristics including corporation identity, web site utility, browsing, visibility of system's status, integrity and compliance with the standards, attention to errors, esthetic and design, help with errors and feedback. This variable was measured using the TAW analyzer, as well as a manual revision of WAVE analyzer results, on the presence or absence of items related to this variable. The characteristics of the level of usability had to values, 1 (presence of the characteristic) and 0 (absence of the characteristic). The total amount of those items produces the score for this second variable; the 30% of weighting was assigned.

The last variable, contents and services, refers to the main activities and procedures provided by the institution to the citizens. It includes for example a guide of procedures, which provides key information for people needing to attend to the Ministry, or information about activities on line (Guia Digital, 2017). We assessed the web sites contents and services that include (CTIC, 2017; DISCAPNET, 2017; Guía Digital, 2017): functional activities to make in the web site; list of applications for mobile devices; links to social networks (YouTube, Facebook, Twitter). Finally to evaluate this variable, we reviewed the presence or absence of the characteristics included in the questionnaire, values of 1 and 0 were used. We also tested the functioning of the government procedures and services offered by the web site. The total amount of general characteristics that produces the score was obtained as well. The weighting of this variable was assigned to be 40% of the total.

Data collected from the web sites was coded and processed using JMP software. In every web site the presence or absence of the previous variables were counted assigning 100% if all the items of each independent variables were included; the percentage of weighting for each variable was assigned according with their characteristics to obtain a final score. This total amount represents the value of the dependent variable as the level of government site performance. The level of government site performance was classified in three categories: non-functional (0-35%), average functional (36%-70%) and functional (71%-100%).

RESULTS

Once the web sites of the Ministries was analyzed, the evaluation of the characteristics of accessibility, usability and contents and services was conducted for obtaining the value of the dependent variable and to establish the level of function of e-government (See Table 1).

Table 1. Federal Ministries Web Sites' level for e-government performance

Ministry	Accessibility level	Usability level	Contents and Services	Total	E-Government level*
President's Office	17.1%	18.9%	21.5%	57.6%	AF
Government Ministry (SEGOB)	16.3%	18.9%	33.8%	69.0%	AF
Ministry of Foreign Affairs (SRE)	18.0%	20.0%	30.8%	68.8%	AF
Ministry of National Defense (SEDENA)	18.0%	20.0%	33.8%	71.8%	F
Admiralty (SEMAR)	18.0%	20.0%	30.8%	68.8%	AF
Treasury (SHCP)	18.0%	18.9%	30.8%	67.7%	AF
Ministry of Social Development (SEDESOL)	18.0%	18.9%	30.8%	67.7%	AF
Ministry of Environment and Natural Resources (SEMARNAT)	18.0%	20.0%	30.8%	68.8%	AF
Ministry of Energy (SENER)	18.0%	18.9%	30.8%	67.7%	AF
Ministry of Economy (SE)	18.0%	20.0%	30.8%	67.9%	AF
Ministry of Public	18.0%	20.0%	33.8%	71.0%	F

Education (SEP)					
Ministry of Agriculture, Livestock, Rural Development, Fishing and Food (SAGARPA)	18.0%	20.0%	33.8%	71.0%	F
Ministry of Communications and Transport (SCT)	18.0%	18.9%	33.8%	69.9%	AF
Ministry of the Public Service (SFP)	18.0%	18.9%	30.8%	66.8%	AF
Ministry of Health (SALUD)	18.0%	18.9%	36.9%	73.0%	F
Ministry of Labor and Social Security (STPS)	18.0%	20.0%	33.8%	71.0%	F
Ministry of Agrarian, Territorial, and Urban Development (SEDATU)	18.0%	18.9%	33.8%	69.9%	AF
Ministry of Tourism (SECTUR)	18.0%	18.9%	30.8%	66.8%	AF
Ministry of Culture (CULTURA)	18.0%	20.0%	36.9%	74.1%	F
Attorney General Office (PGJ)	18.0%	18.9%	30.8%	66.8%	AF
Legal Advice of the Federal Executive (CJEF)	18.0%	18.9%	27.7%	63.7%	AF
*E-Government level: NF: non-functional; AF: average functionality; F: functional.					

Basically, all web sites present the same result for the first independent variable (18%), with the exception of two: the President's Office (17%) and SEGOB (16.3%). The principal reason explaining this result is because web sites are located in the same digital platform following the same web accessibility presenting only few differences among them. The President´s office (2018) and SEGOB (2018) web sites present problems in the links to some documents and downloads, several paths are not accessible to find information or links (PRESIDENCIA 2018; SEGOB, 2018).

The following common characteristics included in web sites were found: consistent browsing, headers everywhere, the possibility to use keyword for browsing, multiple paths to find information, Spanish language as standard, color used for highlights elements, text resizing and images resizing. However, sites do not have hearing description, neither the characteristic of robustness related to compatibility of software and assist devices. As a result, web sites allow a proper interaction with the content and the user can work with them, however, people having special requirements different from sight have problems to work with the platform.

In the same way of the first variable, the result of the level of usability has a similar perform in all Ministries, with the exception of one item, the area for frequent questions. This feature is totally different in all web sites, some of them include a special area for questions, other web sites have a division according to a set of topics, and another does not have any section for questions. The characteristics included in all web sites are: corporative identity, visual hierarchy by sections, procedure catalogs and special information about them, institutions activities, an available searcher, and the Ministries contact details. Although the web site sends an error message, the web site does not send instructions how to resolve or avoid it. There is not a page or section related to the page structure of page functioning; there is not either information about the author or contact of the web site. When the page has an error, it is not possible to go back to the previous page. Even though web sites are useful providing information, there is not attention at errors; this is a key element for digital platforms when users are interacting with them and try to solve some problems. There is not option neither to provide feedback in those characteristics that need to be improved by the people in charge of the web sites.

Results for the last independent variable present a variety of differences among the web sites. Each Ministry has specific procedures and activities, and each of them has a particular offer in their web site. Based on the National Digital Strategy (2013) Ministries have to offer educational activities using IT, such as, courses, training, and on line education. There are also several applications for mobile devices in each institution, but only 7 Ministries offer one application in their web site.

The results on the assessment of the e-government level for the Mexican Ministries indicate that 15 web sites present average functionality scoring from 57.6% to 69.9%, while the remaining 7 Ministries' web sites scores from 71% to 74.1%, meaning web sites are functional.

DISCUSSION AND CONCLUSIONS

According to the research results, the Mexican e-government is using IT to establish relationships with different internal and external agents, generating a change in the way information is given and governmental services are provide, as well as how the interaction between citizens and government institutions is taking place.

However, a characteristic mentioned by various authors (Yu-Che & Gant, 2011; Criado & Gil-Garcia 2013; ONU 2012) relates to how the procedure to develop an electronic government is not always consecutive; the procedure is described in stages, phases or strategies. In that sense, Yu-Che and Gant (2011) posit three stages of electronic government, two of them were confirmed in this research: to add information and services on line, a stage that we found in the contents of all Ministries' web sites. And the second, government agencies' interoperability (Yu-Che & Gant, 2011), as the Federal government decided to centralize its offer in one electronic address for all Ministries: www.Gob.mx, which allows citizens to have access to all services and procedures offered by the Federal government. The third element mentioned by Yu-Che and Gant (2011) refers to governance and citizen for decision-making, situation that was not assessed in this research but probably in a future some improvements in Mexican e-government could be included.

According to strategies for e-government development mentioned by CINVESTAV (2011), the web site Gob.mx follows the strategy related to IT infrastructure updating, which imply the independence on IT use, interconnection and converge. In this sense each Ministry has its own web site to share information and multimedia content, but there is also a specific space named "Unique-window" for procedures and services. This single-window is the result of all procedures and services reviewed to date having a standard digital version; the idea is to continue adding more procedures and services in the following years to save time and to improve the numbers on web sites users'. However the strategy linked to having a flexible and robust IT infrastructure (CINVESTAV, 2011), should to be improved, because based on the research results there are some features on accessibility and usability that need to be developed in order to make all Ministries' web sites functional. Additionally, another important characteristic that Mexican e-government does not include but should be incorporated is the possibility to make financial transactions (CINVESTAV, 2011). The problem was the need of a legal framework allowing the equivalence between a digital with a handwritten signatures. The only web site that accepts this issue is the Tributary Administration Service (SAT for its acronym in Spanish), a decentralized office of the Treasury which main objective is to apply the tax and customs legislation. The SAT's web site is one of the first developed within e-government having advanced and secures procedures and services compared to the rest of the Ministries' web sites. Nevertheless it is currently included as part of the web site Gob.mx, the site was not included in this research because it is an independent platform.

Based on the evolution framework proposed by UN, e-government initiative is classified by its level of maturity considering five evolutionary levels (Gastón & Naser, 2011). Research results let us confirm that Mexican e-government is in the transition process between interactive presence and transactional presence (third and fourth stages each in order). This process shows the presence of several Ministries in the web that offer interactive services and information, as well as complete and secure transactions. While in the majority of web sites there are few digital procedures, it is possible to send and receive official documents such as detail information, registration receipt, pre-registration for a program or service through the web site and by electronic mail; there are also complete and secure on line procedures that include payment of taxes for example.

For 2012, Latin-American countries presented similar process about e-government development. Defined by Criado and Gil-Garcia (2013), the development characteristics include national agendas for e-government that in Mexico has been created by the Digital National Strategy (2013). The second characteristic is the development of web site to provide electronic services, the authors also establish that the web site should offer information and digital procedures as well, considering the idea that the utility of a transactional site is online are the procedures, its statistics and its functionality. In the case of Mexican Ministries', web sites include information about the institution, their projects, results and newsletters, but the main objective is not their on line procedures. The third characteristic relates to interoperability, the possibility of sharing information between public departments and projects developed together (Criado & Gil-Garcia, 2013), we found in the web site of SNIIV a project developed by SEDATU and the National Housing Commission. The following characteristic is the use of social networks (Criado & Gil-Garcia, 2013); all the Ministries' web sites have an official account for popular social networks such as Facebook, Twitter, YouTube and Instagram; in some cases the institutions also use them as a diffusion tool. The last characteristic proposed by Criado and Gil-Garcia (2013) is about an open and transparent government, which implies a way to open and to present their accountability through digital media; we found some information in some web sites of Mexican e-government, but this is a task that has to be improved.

Research results related to e-government phases or classification confirm that Mexican electronic government has a superior average level for transactional phase, because of the result of the majority of Ministries (MF) and only 4 out of 22 had a functional level. Therefore the research hypothesis "The level of Mexican electronic performance is low because of the Ministries web sites' development, which has lacks in characteristics such as accessibility level, usability level and contents and services" was rejected.

However, some of the characteristics associated to accessibility level and usability level can be improved in order to increase the general level of Mexican e-government functionality. As it was mentioned before it is important to review the "error an suggestions" section in order to make the web sites more user friendly and easy to use. Another feature to improve is to make the web sites browsing easier, adding the option to return to previews o next pages or jump directly to a specific section without the need to return each time to the original path. The web sites have to include less frequent tools, for example the audio-description and assistance tools adaption that will make the site Gob.mx a real accessible virtual platform and inclusive for a major number of citizens.

Nowadays due to smartphone and tablet's diffusion, it is important the design and implementation of applications for them. The development of these new technological tools represents a key challenge to increase communication, access to information and services and improve the relationship between citizen and government. This is a much needed further step for e-government web sites.

In the same sense, Mexican e-government should work focused on the inclusion of all the characteristics of the transactional phase, to start with the addition of a major number of digital procedures, even though their information could be completed, the idea is to give citizens the option to complete all procedures on line. Increasing on line procedures will increase also the number of web site's visitors and the utility of the platform.

Finally, another suggestion is the inclusion of characteristics for citizens' participation by e-government use. Through this tool, citizens can be involved in decision making processes, become activities and public resources transparent and establish and better channel of communication for an efficient and effective government.

In order to extend the broad and diversity of studies related to Mexican e-government it would be very useful to conduct research in diverse Federal government institutions, as well as in State and local departments.

Electric Vehicles: Are they an Alternative to Weaken the Fossil Fuels' Industry Power?

ABSTRACT

The increasing cost of gasoline in the world has been pushing auto makers to the alternative of making electric vehicles, some of them hybrids and others fully electrical. This study tries to identify the factors that might be having a major impact on the sales of electric vehicles in the United States, as well as our prognosis for the near future.

KEYWORDS: Regression, electric, alternative fuels, plug-in vehicles

INTRODUCTION

In a research project, we asked some academics about their Smart Grids' impressions and we found out that for most of them the Electric Vehicle is hardly considered as part of the Smart Grid general concept; they see it as a necessary investment when the time is right. Consumers seem to be expecting the prices to drop, and to see how the charging of the vehicle into their homes will have an impact on their monthly electricity bills. Because there are so few vehicles at this time, their impact on the consumption of electricity is not noticeable yet (Heuer et al., 2011). Khattak et al. (2012) consider that the electric vehicle could hold the largest potential within the smart grid to deliver carbon savings, so the implementation process needs to be included into the SGD projects. One major area of research is the future problem of millions of electric vehicles charging batteries at the same time and connected to the general grid, this phenomenon is called V2G (vehicle to grid connection).

An aspect that is being explored more nowadays is the role of the electric vehicle as a consumer of energy, but also as a mobile energy source (Couillet et al., 2012). This flexibility of the electric vehicles reinforces the modern concept of "prosumers," wherein the consumer also becomes a producer of energy and sells the excess to the utility company for a just price. In the past years, there has been some confusion and fear about electric vehicles catching fire after an accident, even hours after the incident, so the National Fire Protection Association (NFPA) is issuing warnings and recommendations for vehicle owners (Lekach, 2019).

IMPLEMENTATION PROGRESS

It is important to differentiate between three types of vehicles that are grouped under this category: Hybrid Vehicles Plug-In Hybrid Electric Vehicle (PHEV) and Plug-In Electric Vehicle (PEV). PHEV is a vehicle that can operate with either electricity or an alternative energy source. PEV uses only electricity to operate and is plugged-in to recharge the battery in order to be prepared for further use. PEVs sales in the US began in 2010, while hybrids have been in the market since 1999.

There are several factors that have been influencing the erratic behavior of the PHEV growth, as there was a frankly increasing period from 1999 to 2007, but then the trend reversed to decrease until 2011—when it reaches bottom and begin growing again. Form 2011 grew to 2013 and the declined back, but the gains have been larger than the losses. We are going to analyze some of the factors that may be the major contributors for this behavior.

Hypotheses

Based on our consumers' experience, we expect that electric vehicle growth is strongly influenced by the price of gas or oil in general, government incentives, the cost of the vehicle itself, availability of charging stations, wattage of the battery, and miles to run under a normal battery charge.

To evaluate these factors, we develop the following hypotheses:

H1. EV sales are influenced by the price of gasoline

H2. EV sales are influenced by the governmental incentives to consumers

H3. EV sales are influenced by the cost of the vehicle

H4. EV sales are influenced by the availability of charging stations in the area

H5. EV sales are influenced by the wattage of the battery in the vehicle

H6. PHEV sales are influenced by the number of miles run in a single battery charge

Deployment of Electric Vehicles in the US

The number of vehicles sold in the US is shown in Figure 1. The chart shows hybrids, PEV and PHEV together, although we are going to focus on PEV and PHEV for the analysis, as there is a longer period of time available to come up with conclusions. Figure 2 shows the average price of gasoline in the US. Although there are some statistics per region, we are using the national average to compare with national sales of Electric and hybrid vehicles.

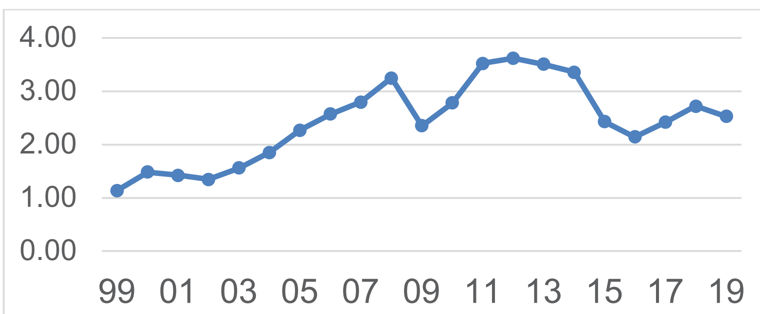

Figure 2: Average Gasoline Prices (Source: eia.gov)

Conducting a linear regression analysis for number of hybrid and electric vehicles sold in the US, and the average price of gasoline in the year, we find that a R2 of .585 and the significance is under 1%. With these results we can support hypothesis H1 regarding the cost of gasoline correlating to the number of hybrid and electric units sold in the US.

The government has been giving tax credits to consumers who buy PHEVs in order to promote their diffusion. Checking the analysis done by David Diamond (2009), he discovers a weak relationship between government incentives and PHEVs adoptions. For our research, we looked for federal tax credits per manufacturer and calculated the average for all vehicles, then, based on the number of sold units, we tried to find non-linear regressions, but the best one was the exponential distribution with an R^2 of 0.356 and significance of 12%. Based on these results, we do not support the hypotheses H2, as we agree with Diamond that the federal government incentives do not have a relationship with the number of PHEVs sold. Some companies do not for federal tax credits per manufacturer and calculated the average for all vehicles, then, based on the number of sold units, we tried to find non-linear regressions, but the best one was the

exponential distribution with an R^2 of 0.356 and significance of 12%. Based on these results, we do not support the hypotheses H2, as we agree with Diamond that the federal government incentives do not have a relationship with the number of PHEVs sold. Some companies do not show tax credit incentives as shown on Table 2, so they were not used for the comparison. The price of the PHEVs varies based on the vehicle's features, so companies like General Motors are pushing low price PHEVs through Saturn, and big trucks such as the Silverado, Yukon and Tahoe with higher prices. Porsche is selling sport luxury cars that can be as costly as the Panamera with a manufacturer suggested retail price (MSRP) of almost 100,000 dollars.

In 2007, PHEV's prices dropped in order to overcome the fall of sales, but the average price still went down for the first time, and in 2011 the number of sold vehicles was reduced, while the average cost of sold PHEVs went up considerably. Figure 3 shows the breakdown of PHEVs by manufacturer and year. In Figure 4 we can also see how, following 2011, the average prices balanced down with a positive more realistic trend upward.

Figure 3: PEV and PHEV vehicles breakdown by brand

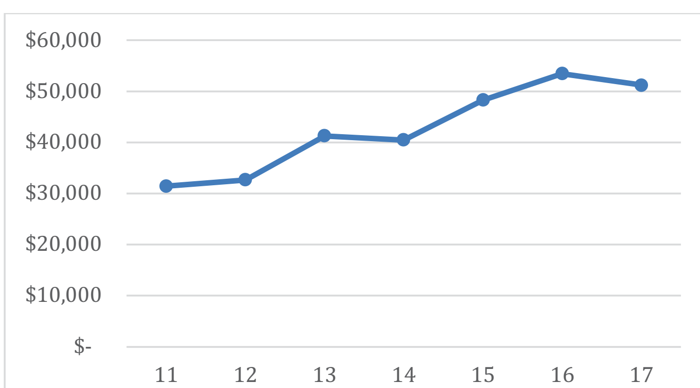

Figure 4: Number of PHEVs sold versus average price

The number of hybrid vehicles sold in the US in the period from 1999 through 2017 presents a positive trend, as compared to the average price of all sold PHEVs. Because the amount of expensive hybrid vehicles is small, the averages do not grow that much on a yearly basis, although there are very expensive PEVs that are sold in smaller amounts. Doing a linear regression analysis between these two variables we are finding a favorable relationship.

With the R^2 of 0.847, we are seeing a significant relationship between the average price of the PHEV and the sales. If the demand and offer of PHEVs in the market react as expected, the higher the prices would imply the lower the sales, but as in the gasoline vehicles the prices mostly increase on a yearly basis, seeing increases on PHEVs may have the same impact. Based on the above shown results, we can support hypothesis H3, stating that the price of PHEV's has an impact on their sales.

Table 3: Regression results for PHEV average price vs yearly sales

Model Summary[b]

Model	R	R Square	Adjusted R Square	Std. Error of the Estimate
1	.920[a]	.847	.816	25792.82974

a. Predictors: (Constant), Avg_Price
b. Dependent Variable: PHEV_Sales

	Avg_Price	6.373	1.213	.920	5.255	.003

To discover the relationship between available PHEVs to the number of charging stations, we have to research the number of outlets and stations as well as the number of registered vehicles per state—in order to determine if one has an impact on the other. The more vehicles, the more charging stations, but if the number of charging stations is limited, sales of EVs may be affected negatively.

Two noteworthy states from Table 3 are California, which has 19,687 outlets for electrical charging stations for over 500k of electric vehicles. That is, there are 25.73 vehicles per charging station, which is the highest in the United States. On the other side of the spectrum, Missouri es the state with less electric vehicles per outlet or charging station with 3.88, which is telling us that there are almost 4 vehicles per outlet.

The amount of stations and the number of registered vehicles make sense in most cases, so doing a regression analysis we find a linear relation with a R2 of 0.992 and significance below 1%. With these results we can support hypothesis H4, that there is a regression between the number of loading stations and the number of EVs. As the number of EVs increases, the number of charging stations will have to grow accordingly otherwise, it can become a reason for the PHEV and PEV deployment.

Table 3: Registered PHEVs vs. charging stations per state

St	Outlets	EV Stock	EV Stock/ Outlet
CA	19,687	506,608	25.73
TX	3,109	34,239	11.01
FL	3,010	40,548	13.47
NY	2,828	46,397	16.41
WA	2,383	41,459	17.40

IL	1,255	22,475	17.91
AR	1,223	18,129	14.82
MI	1,112	18,434	16.58
TN	1,054	6,684	6.34

To analyze the battery size and wattage before relating these elements to sales, we need to go by model and company. We can see in Figure 4 the distribution of PEVs separated by their manufacturing company. This breakdown is compared to the average battery size by company in order to test the relationship among sales and battery size.

	2011	2012	2013	2014	2015	2016	2017
Others	76	873	2,603	2,561	2,041	726	2,288
Kia				250	1,015	1,728	2,157
Smart	310	139	923	2,594	1,387	657	543
Chevrolet			560	1,145	2,629	3,614	23,320

Tesla		2,171	19,000	16,750	26,408	49,800	49,970

Figure 4: Plug-in Electric vehicles breakdown in the U.S.

Table 4: PEV Vehicles Sales in 2017, Battery Size and Miles Run in One Charge

PE Vehicle	Sales in 2017	Battery Size KWh	Distance in one charge (Miles)
Tesla 3	1,770	75.0	310
Tesla S 60	26,500	60.0	170
BMW i3 (2019)	4,141	42.0	115
Nissan Leaf	11,230	30.0	100
Fiat 500e	3,336	24.0	85
Mercedes B	744	28.0	85
GM Spark	23	21.0	75
Ford Focus	1,817	23.0	75
Smart for Two	543	17.6	68
Mitsubishi MiEV	6	16.0	55
Chevrolet Volt	20,349	16.0	40
Cadillac ELR	17	16.5	35
Ford C-Max	8,140	7.6	21
Ford Fusion	9,632	7.6	21
Porsche Panamera SE	1,574	9.4	20
Toyota Prius Plug In	20,936	4.4	15

Based on the statistical analysis of the regressions conducted in this project, we are finding half of the hypothesis that can be supported, as they nicely correlate the variable of sales with the cost of gas, the cost of the vehicles and the availability of charging stations.

Table 5: Hypotheses Results

Hypotheses	Results	Comments
H1. EV sales are influenced by the price of gasoline	Supported	R^2 of 0.585 with significance under 1% for the linear regression
H2. EV sales are influenced by the governmental incentives to consumers	Not Supported	R^2 of 0.356 with significance above 12% for the exponential regression
H3. EV sales are influenced by the cost of the vehicle	Supported	R^2 of 0.847 with significance under 1% for the linear regression
H4. EV sales are influenced by the availability of charging stations in the area	Supported	R^2 of 0.920 with significance under 3% for the linear regression
H5. EV sales are influenced by the wattage of the battery in the vehicle	Not supported	R^2 of 0.006 for a non-significant linear regression
H6. PHEV sales are influenced by the number of miles run in a single battery charge	Not Supported	R^2 of 0.001 for a non-significant linear regression

CONCLUSIONS

There is an important diffusion of electric vehicles in the US, as the manufacturers and the state and federal governments are addressing some of the major concerns. One of the major concerns about electric vehicles has been the battery durability and reliability. This issue has been addressed as more plug-in electric cars are being sold now with larger batteries, but there is still the concern about the cost of the replacement battery and what is going to be done with the old one. As new and more efficient batteries are being developed, the cost of the PEVs is going down and new lower price versions are appearing.

We are finding that with the ever-increasing cost of gas, the trends of hybrid and plug-in vehicles are going up, but until the cost of gas becomes prohibitive, the larger proportion of vehicles is not going to be electric. Government incentives are not having the expected major effect, although some publications mention that consumers have been taking all the credits and incentives from the governmental programs. A proposed action for the government is to increase taxes on gas, and that will definitively have a major impact on the diffusion of electric cars.

More charging stations are being installed throughout the country, with a growth of 30% since 2013 (DoE, 2014). There are expectations that the growth will become exponential to satisfy the large demand of electric vehicles; but the battery sizes and miles run with a single battery charge do not seem to have a big impact on sales, probably because batteries are still evolving.

Teaching Tips: Cultivating Essential Soft Skills in an Undergraduate Business Analytics

Benyawarath Nithithanatchinnapat
University of North Carolina at Charlotte
Email: bnithith@uncc.edu

ABSTRACT

The presentation illustrates how soft skills can be developed in an undergraduate business analytics course. An activity design guideline and one activity were developed. The activity was used once with satisfactory results, and the next step is to develop a complete set of exercises with assessment tools.

KEYWORDS: Business Analytics, Soft Skills, Data Exploring

INTRODUCTION

Employers are looking for new college graduates who possess essential soft skills (Chamorro-Premuzic & Frankiewicz, 2019; Dishman, 2016; Dutton, 2012). However, based on the review of the undergraduate business analytics course outlines and syllabus that are available online, the activity or topic that help students cultivate essential soft skills seem to be missing. Of course, the focus of an undergraduate business analytics course should be quantitative and qualitative methods, but making sure that students can also develop important soft skills employers look for help students become more competitive in the job market (Chamorro-Premuzic & Frankiewicz, 2019). Soft skills that students in the analytics field should possess are, for instance, critical thinking, problem-solving, curiosity, opportunity finding, and storytelling (McPherson, 2016).

Measuring, assessing, and cultivating soft skills in undergraduate students and new hires are essential in the academic realm as well. In the scholarly literature, there are two streams of research about soft skills, one is skills assessment, and another is about cultivating them. To the analytics field, there is still a need for more teaching tips, cases, and approaches in soft skills development since this field is new. Thus, this study aims to offer a guideline in designing activities that business analytics instructors can use to help students develop their essential soft skills. This study is built on a framework presented in Dubey and Gunasekaran (2015) and in Blaszczynski and Green (2012) and Green and Blaszczynski (2012).

In addition to the soft skill issue, the author also found that the ability to make sense of a large volume of data is critical in today's digital age (Kerner, 2019; Mela & Moorman, 2018). So, to fill the gap and to help new graduates become more competitive in the job market, the author developed an activity for an undergraduate Introduction to Business Analytics course in a public AACSB accredited institution. Students must learn critical thinking, opportunity finding, and storytelling in a real-world context. Using this activity, the author shows how students can analyze historical unintegrated data, come up with interesting questions and storytelling plan, and more importantly, students had fun doing the exercises and saw the importance of developing essential soft skills. Most students said that this exercise was much more challenging than learning how to use software and how to write basic SQL. However, a soft skill development activity or a teaching case that is ready to be used in an undergraduate business analytics course is still missing, to the best of the author's knowledge.

This study is to be continued. In the next phase, the author will develop an assessment method (Beard, Schwieger, & Surendran, 2008) such as having peer-evaluation as well as instructor-evaluation and having pre- and post-exercise questionnaires, as well as a complete set of exercises for this course. The rest of the paper is organized as follows. The next section is a review of the literature. Following that is the design and the detail of the exercise and ending with the instructors' guideline and conclusion.

LITERATURE REVIEW

Cultivating soft skills in current employees and students are of interest to both scholars (Beard et al., 2008; Ellis, Kisling, & Hackworth, 2014; Gibb, 2014; Hagmann, Almekinders, Bukenya, Guevara, & Halemichael, 2003; Henry & Venkatraman, 2015; Liberatore & Luo, 2013; Petter & Randolph, 2009; Wats & Wats, 2009) and practitioners (Briggs, 2015; White, 2014). Soft skills are essential in most, if not all, professions, such as in economics (Suciu & Lacatus, 2014), software development (Ahmed, Capretz, Bouktif, & Campbell, 2015), and dental education (Gonzalez, Kasim, & Naimie, 2013).

In academic literature, one stream of "soft skills" studies focuses on the assessment part (Abbas, Abdul Kadir, & Ghani Azmie, 2013; Gibb, 2014), another on cultivating them (Blaszczynski & Green, 2012; Hagmann et al., 2003; Wats & Wats, 2009), and some studies offer both (Beard et al., 2008). After the review of the literature about "soft skills" development and assessment in scholarly business and management journals, the gap is found, which is the lack of soft skills development activities that are suited for analytics classes, such as undergraduate business analytics. This study is built on three previous work, one is Dubey and Gunasekaran (2015), which offered an education and training framework for a successful career in big data and business analytics. The data was collected from ten heads of business analytics for companies situated in Mumbai and the Pune region of Maharashtra, India. Since India has many major IT hubs, the author believes that the finding applies to other countries as well. Another two are Blaszczynski and Green (2012) and Green and Blaszczynski (2012), which offered effective strategies and activities for developing soft skills. They offered soft skills-building activities, such as pyramid building activity, a role-play, a reflection journal, a listening activity, a "What's on a Penny?" activity, a line-dancing activity, and a story-in-the-bag activity. Adding on to this list is the new data exploring activity, which directly relate to data analytics and is easy to implement.

GUIDELINE IN DESIGNING ACTIVITIES

Table 1 shows a list of soft skills from Dubey and Gunasekaran (2015) and McPherson (2016). To get a holistic picture, the author used both lists and came up with plausible things that the instructors can do and have students do in a business analytics class.

Table 1: Soft Skills and Activities for Analytics Class		
Soft Skills Important for Analytics Graduates	**Activity Designing Plausible Things to Do**	
	Have students do	**What the Instructors can do to facilitate**
Ability to learn and Curiosity	Learn new tools that have not been covered in detail in class	Make sure the instructions are not detailed step-by-step, and instead generate curiosity
Ability to focus on key issues	Solve a given business problem	Sit with students, one group at a time, and ask them how they are doing and whether they are clear on what problem they are solving
Communication, Listening Skills, and Storytelling	Communicate with other group members Briefly summarize the plan to the instructor Prepare a written submission Make sure the selected business problems and design of the presentation is coherent	Listen to students' plan Give feedback to students Guide students to the understanding of the importance of storytelling with data
Critical Thinking	Propose rational recommendation based on scientific data	Ask students back what they think, if they ask whether their business questions sound good
Leadership ability	Determine the project manager	Ask students how they are doing, whether there is an informal team leader, have students try to determine one
Opportunity Finding	Explore Big Data and determine interesting questions or business problems that are likely to improve business performance if answered	Give students unintegrated data and ask students to make sense of it
Patience	Brainstorm with team members	Remind students that the right solution may need a few rounds of discussion
Positive attitude and Passion	Learn from others to build their confidence Answer themselves why analytics is essential and what can they benefit from the exercise	Encourage students that they can come up with interesting business problems by recalling all the relevant subject they have learned such as economics, finance, and marketing
Problem Solving	Solve a given business problem, come up with the right approach for solving a problem	Guide students through the steps of solving a problem if needed

Table 1: Soft Skills and Activities for Analytics Class		
Soft Skills Important for Analytics Graduates	**Activity Designing Plausible Things to Do**	
	Have students do	**What the Instructors can do to facilitate**
	Select the appropriate variables and determine the right methods after the business problems are defined	Advise students on how to find necessary resources
Team skills	Work in a small group setting	Have students team up in a group of three to four, and help them find a group if needed

The author has considered both the principle of business analytics, business problem and opportunity, and the current needs in the job market in designing this soft skill development activity. Based on the recent survey showing that up to 73% of company data goes unused (Barrett, 2018), the storytelling and opportunity finding skills are selected as the focus of the activity. To help students develop these two skills, the author asked the students to explore and try to make sense of the data provided. The author put to together publicly available data sources and shortlist to three sources. Following are some publicly available data sources:

International / government organizations:

- UN Data http://data.un.org/
- OECD https://data.oecd.org/
- US Census https://www.census.gov/
- US Public Data Visualization https://datausa.io/
- US Bureau of Economic Analysis https://www.bea.gov/
- World Economic Forum Reports http://reports.weforum.org/

Businesses:

- Tableau's Global Superstore https://community.tableau.com/docs/DOC-1236
- Wells Fargo's Campus Analytics Challenge https://www.mindsumo.com/contests/building-better
- Amazon Web Services public datasets http://aws.amazon.com/datasets

Three datasets were selected. For problem one, students use Tableau's Global Superstore and World Economic Forum's Global Competitive Index (i.e., unintegrated datasets); for another problem, the dataset used is Wells Fargo's. The author explained the objective of this exercise and asked the students to explore the data (e.g., variables, entities-relationship), list potential interesting questions that could add to a value of a company, list of the potential values added, and draft the outline of the presentation with dummy data.

This exercise is designed for students to work together in a group setting for one hour in class and about one to two hours outside of class time. This is a group assignment, and all students receive the same grade based on the following rubric. The students upload a Word file(s) to Canvas as a group submission and are also able to submit images of their presentation design.

- Questions and selected variables are appropriate
- Questions and potential value-added make sense
    - based on an instructor's experience and opinion
    - based on students' justification
- Questions and the output designs are appropriate

While students were working in class, the author walked around and talked to each group, and gave any advice where appropriate. Most groups could not complete this exercise in an hour, so they had to work outside of class for one to two hours on average.

INSTRUCTORS' GUIDE

Before having students do the above exercise, the instructors should have already taught the following: an overview of business analytics, data analytics tools in the market, data management, hands-on problem in combining data from multiple sources (with a business problem and analytics-ready datasets given), this could be exercise #1. After showing the hands-on problem, ask students how difficult it seems. Most students will say that it is challenging because it is their first time exposed to a selected software package, whether it is RStudio, SAS Enterprise Miner, or Tableau Prep.

Before having students start the exercise above, tell them that in the real world of Big Data, they might be asked to make senses of data and come up with interesting questions that would add value to a company if answered. In exercise #1, the business problem and precise requirement of the output file are provided, the students prepared the output file based given conditions. Exercise #2 is intended to be a soft skill development exercise assessing their storytelling and opportunity finding skills. Present the following form to them so they can self-assess their soft skills without the instructor mentioning the name of the skills.

	Specify how did you do in completing the exercise 1. I came up with one immediately. 2. I needed some time to come up with one. 3. I came up with one but not sure if it is good. 4. I had no idea, so I did not offer any to the group.
Figuring out an interesting business problem	
Figuring out the variables needed in the analyses	
Finding opportunities – potential improvement in business performance	
Designing a persuasive presentation	

DISCUSSION AND CONCLUSIONS

Lastly, soft skills development should be part of all exercises used in class and each focus on different skills. The exercise above does not cover all the skills listed in Table 1, but for certain covers at least opportunity finding, critical thinking, storytelling, and teamwork. Not all soft skills are equally important. To determine which ones are more critical to analytics, the author considered the principle of the analytics and the demand in the analytics market. In the next phase of this study, the author plans to develop a complete set of exercises or activities for an undergraduate business analytics course. With that, an assessment of both hard skills and soft skills for each exercise will also be developed and tested.

ACKNOWLEDGEMENT

Thank you, the reviewers, for the comments on how to improve the paper.

Analyzing the Profit-linked Multifactor Productivity Measurement Models

Mohan Rao
Texas A&M University-Corpus Christi
Email: mohan.rao@tamucc.edu

ABSTRACT

This paper analyzes the results from two different profit-linked multifactor productivity measurement models. Theoretical analysis was made in a 1989 *Management Science* article. Now the analysis is based on a real-world case from micro-irrigation industry. The APC (American Productivity Center) model was introduced by the American Productivity and Quality Center, and the PPP (Profitability = Productivity + Price Recovery) model was introduced by David Miller in a *Harvard Business Review* article in 1984.

KEYWORDS: performance evaluation; performance measurement; productivity; multi-factor productivity; chained-dollar; chain-type index; micro irrigation

INTRODUCTION

The desire to accurately determine firm performance led to the creation of several performance measurement systems. Among two of the most widely used approaches include American Productivity Center's total factor model (APC) and Ethyl Corporation's (PPP) model in which Profitability = Productivity + Price Recovery (Singh, Motwani, and Kumar, 2000). These two models link productivity performance to profitability by considering the issue of price adjustment.

In this paper, we introduce a revised comparison between APC and PPP its consequences and, ultimately, to gain a greater insight into the strengths and weaknesses of each model. This method builds on Miller and Rao (1989) by utilizing actual operational data. Its starting point is the actualization of performance, productivity, and price data and the application of deflation based on each model's requirements. To demonstrate how the analysis can be applied to produce insights on a company's performance measurement, we apply operational data from Finolex an Indian micro-irrigation firm.

This article contributes to two key areas. First, this study compares two models that on the surface appear to be similar, but because deflation is applied differently, it can provide management strikingly different assessments of the company's performance measurements. Hence, we fill a gap in the prior research that is scant on comparing similar models, especially the APC and PPP versions. Second, we complement our model comparison by analyzing actual organizational data from Finolex. The content of irrigation is essential to the world, as less than 1% of the Earth's water is available for irrigation (Whitmee et al., 2015). Therefore, it is vital for a manager to optimize the irrigation system to maximize output to assist farmers, households, etc.

The outline of the paper is straightforward. We start with a literature review outlining the APC and PPP model differences. This review is followed by detailed steps of the application of each model. We proceed with a comparison between the APC and PPP models and provide some managerial applications. The conclusions and limitations are presented at the end.

LITERATURE REVIEW

APC and PPP models correlate the relationship between productivity and profitability and have been previously used to measure profitability, productivity, and price recovery performance (Rao et al., 2018; Rao 2015). The application of both models extends into multiple contexts. For instance, researchers applied APC to a pharmaceutical production facility (Phusavat and Photaranon, 2006), wastewater plant (Rao and Phusavat, 2015), and micro-irrigation (Rao et al., 2018). Similarly, PPP has been applied to a wastewater treatment plant (Rao 2015) and the airline industry (Oum and Yu, 1998). The American Productivity and Quality Center developed APC in 1977, while Miller (1984) created the PPP model.

The APC model jointly measures the relationship and impact of productivity and price recovery with operational results and profitability (Phusavat and Photaranon, 2006), while PPP mainly focuses on a production unit with tangible outputs and inputs (Rao, 2013). Both models originate from similar accounting data and present the appropriate productivity, and price recovery impact in a dollar context rather than ratios or indexes. Moreover, the models utilize data from specific base periods to compare performance to future periods. The only difference between the models is how deflating techniques are applied (Rao, 2015). Essentially, the PPP model utilizes an aggregate deflation method and controls dollar values during its analysis. Conversely, the APC model contrasts period to period deflation to arrive at unit-less ratios (Singh, Motwani, and Kumar, 2000).

The PPP model's deflating methodology has its roots in chain-type annual-weighted index. Chain-type indexes strive to address one of the most fundamental obstacles in measuring output and prices of choosing the comparison base period (Landefeld and Parker 1997). To address this issue, the Bureau of Economic Analysis (BEA) introduced the Fisher index which uses the weights of the first period along with the Paasche index that uses the weights of the second period (Parker and Tripplet, 1996).

With this in mind, Miller (1986) conceptualized profitability = productivity + price recovery to address some of APC's shortfalls, including the deflating methodology. As Singh, Motwani, and Kumar (2000) indicate "the PPP approach provides a more suitable tool for examining productivity changes over a trend of at least three or more periods. On the other hand, since the APC approach utilizes only the base period prices, its price weights are independent and separable and more suitable for a two-period comparison" (p. 235).

Prior research is scant in comparing APC and PPP in a real operational setting. It appears Rao and Miller (1989) are the first to attempt such a comparison between the two models. Their findings, based on fictional data, discovered when multiple items are evaluated in multiple time periods, the results differ for each model. More specifically, their research found a nearly 10% deviance between the two models. However, for the past three decades, the comparison between APC and PPP is non-existent. A point, this article serves to resolve. We utilize the micro-irrigation industry in our article, as it has served as a suitable source for data for similar studies (Rao et al, 2018).

Micro-Irrigation Industry

The need to maximize the earth’s water supply is of utmost importance as municipalities and companies examine the best options to maximize water usage for the earth’s 10 billion inhabitant. A number that is expected to grow by 2 billion in the next 50 years (Brinegar and

Ward, 2009). Since much of the world food production depends on irrigation (Howell, 2001) and the need to increase food production to support the growing world population, improving the technical and economic performance of irrigation is critical to long term success (Brinegar and Ward, 2009). Therefore, many countries have started to focus on maximizing water conservation efforts to maximize water usage. A major challenge that many entities face is how to better irrigation water. For instance, the earth's surface consists of 71% water, while only 1% of those water sources is used for irrigation, drinking, and household demands (Rao, et al., 2018). To alleviate this problem, many different tactics have been applied. For instance, in the United States, drip irrigation has been applied to provide for crops, at the same time reduce water usage (Fereres and Soriano, 2006).

Since India is the most populous country in the world, it has taken great steps to maximize micro-irrigation. Hence, India has in excess of 150 drip and sprinkler irrigation companies, with an annual turnover of ~$750 million and growing at 25% annually. The market is dominated by 15 companies that have over 70% of the market share. With three companies controlling nearly 56% of the overall market – Jain Irrigation Systems, Ltd. 36%, Netafilm Irrigation Lrd. 14%, and Finolex Plasson Industries Pvt. Ltd. 5.5%. Our data focus centers around Finolex operational data. To better understand Finolex, it is important to know some of its key operational factors.

Measurement Models

We focus on comparing the two measurement models of APC and PPP. As explained earlier, both are similar yet different. Both models require at least two periods with data from revenue generating organizations. The data needs to include both outputs and inputs, with at least two of the following: quantities, prices, and values (revenues and expenses). The model demands fit our data perfectly as we secured two years-8 quarters of Finolex's operational data.

COMPARING THE MODELS

Conceptually it is understood the models differ on in the application of its deflating techniques. However, it is important to mathematically understand the differences between the two models. With this mind, the following section takes a closer look at both models, including the applicable equations.

APC and PPP Computations

The APC model considers many variables, but at its core, it calculates the profitability contribution by subtracting each input value change from the total output change ration and multiplying the resulting number the inputs value in the first period (Miller and Rao, 1989). To be more specific, APC model computation steps are:.

Step 1 Enter quantities and prices
Step 2 Calculate costs and values
Step 3 Calculate deflated values
Step 4 Calculate change ratios for quantities, price, and values
Step 5 Calculate performance indexes
Step 6 Calculate performance contribution for productivity, price recovery, and profitability

The PPP approach differentiates from the APC approach because its actual gross profit realized in a period is compared with the gross profit that would have been realized had the company's profit margins remained consistent. The PPP model computational steps are:

Step 1 Costs and revenues
Step 2 Implied and composite deflator for each input for all periods
Step 3 Input and output profit margins and deflated profit margins
Step 4 Profitability, productivity, and price recovery indices
Step 5 Productivity, price recovery, and profitability contributions

The implied deflator is the main difference between the two model. The implied deflator (ID_t) is the ratio of the total current period value to the value in previous period prices (deflated value).

$$ID_t = \frac{\prod_{i=2}^{t}\left(Q_{Xi}P_{X(i-1)} + Q_{Yi}P_{Y(i-1)}\right)}{\prod_{i=2}^{t-1}\left(Q_{X(i-1)}P_{X(i-1)} + Q_{Y(i-1)}P_{Y(i-1)}\right)}$$

Hence the applicable equations, are as follow.

Profitability	$= S_t\,(\text{Margin}_t - \text{Margin}_B)$
	$= S_t\,[((S_t - C_t)/S_t) - ((S_B - C_B)/S_B)]$
	$= (S_t C_B - S_B C_t)/S_B$
where Margin_B	= Base period gross profit margin
Margin_t	= Period t gross profit margin.
Productivity	$= S_{tD}\,(\text{Margin}_{tD} - \text{Margin}_B)$
	$= S_{tD}[((S_{tD}-C_{tD})/S_{tD}) - ((S_B-C)/S_B)]$
	$= (S_{tD}C_B - S_B C_{tD})/S_B$
where Margin_B	= Base period gross profit margin
Margin_{tD}	= Deflated gross profit margin in period t.
Price recovery	$= \text{Sales}_{tPR}\,(\text{Margin}_{tPR} - \text{Margin}_B)$

APC VS. PPP PERFORMANCE RESULTS

It is important to contrast the two models to highlight the key differences between the two perspectives. Our approach in this endeavor will visually compare both models. The following illustrations will focus on paralleling the overall performance, material, cost by category, employee, sales distribution, supplies, and sales/deflated sales.

Overall Performance

Figures 1 and 2 illustrate the overall performance calculated by each model. On the surface a manager would compare the two items and determine the profitability is similar under both models. The challenge for any manager is to take the information a step further to understand what is truly driving results. According to the APC model, after starting to decline after period four, price recovery bottomed out in period six, rising significantly periods seen and eight. In contrast, the dip after the fourth period in the PPP model is by far more drastic, dipping into the negative, before becoming positive in period eight. Similarly, both models differ on the evaluation of productivity. Where, PPP has a more drastic improvement after period six, than the APC model. It is obvious the deflating values have a more severe influence on the PPP model's evaluation of productivity and price recovery.

Figure 1 – APC Overall Performance

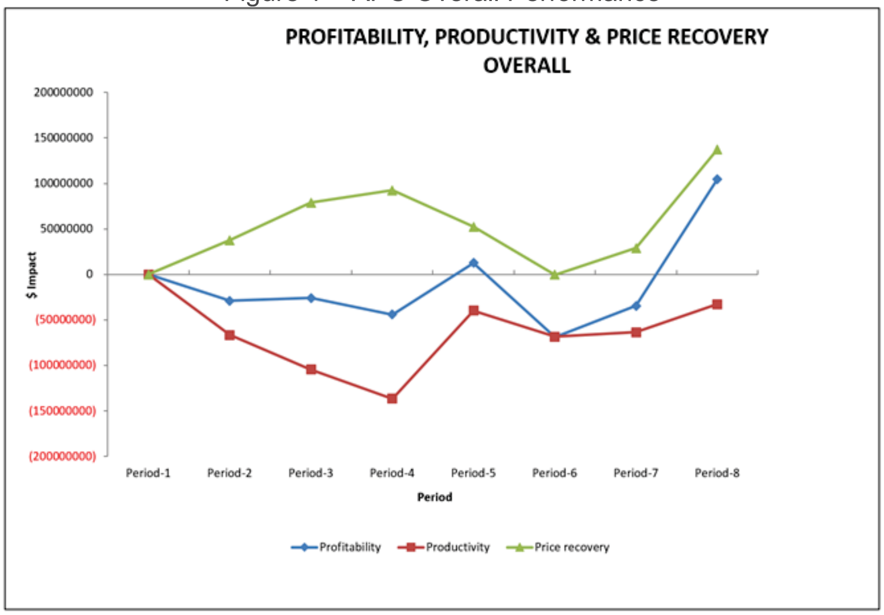

Figure 2 – PPP Overall Performance

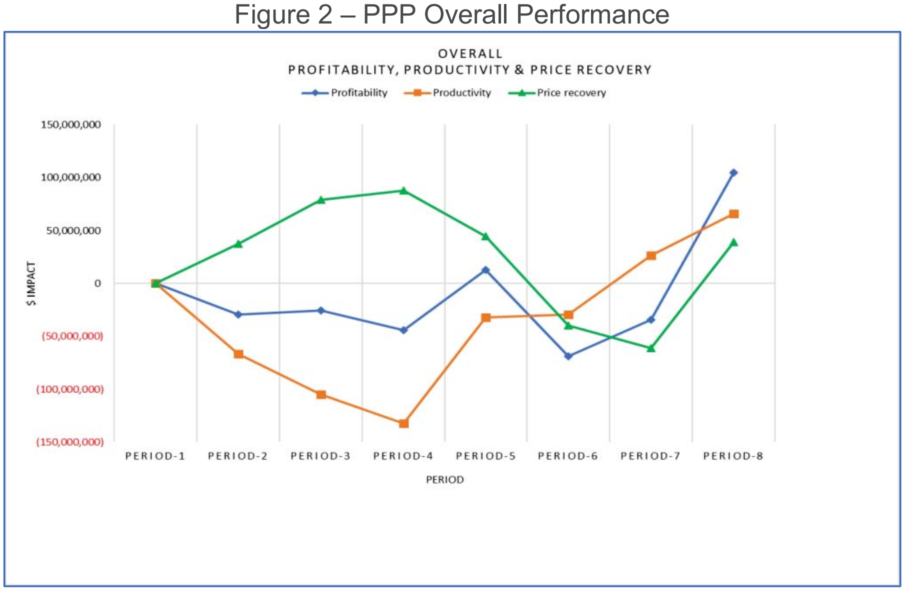

In summary, there are differences and similarities between the models. We are not making a statement that one model is superior to the other, but merely indicating that different models will generate different results, even if the models have the same data. In this instance, the deflating approach utilized by the PPP model, offers different results when more periods are part of the calculation.

A few more differences to consider include the fact APC uses mainly ratios, while PPP uses mainly dollar amounts and profit margins. Moreover, the APC method is generally used for 2-period data. On the other hand, the PPP method is mostly used for 3 or more periods. The results of our study clearly demonstrate the influence of differences listed above.

SUMMARY AND CONCLUSIONS

Overall, most of the results differ from the APC to the PPP models. It is critical to recognize the difference in deflating techniques. As we mentioned earlier, it does not mean one model is better and the other model is worse. This study merely points out the differences between the models. In addition, both models can be easily created from available accounting data. As our study demonstrates with Finolex’s data, basic accounting data itemized by expense category provides the necessary basis to use either of the models.

Along with benefits of charts and graphs, each model provides the benefits of being able to drill down by category. For instance, we recognized the significant influence materials has on Finolex’s profitability. However, in order to truly comprehend business expense drivers, we were able to utilize both models to drill further by analyzing the effects of polyethylene and other traded items.

In summary our research compares two similar yet different measurement models that extend prior research by Miller and Rao (1989). The context of this study is water conservation. With the expected global population growth trends and the potential impact of climate change, micro irrigation could play a key role in water conservation and irrigation strategies.

DECISION SCIENCES INSTITUTE
The Complementarity between Human Resource Information Systems and Strategic Human Resource Practices: A Preliminary Empirical Study

Joonghee Lee
Auburn University
jzl0165@auburn.edu

ABSTRACT

The past decade witnessed two tends in HR field: emphasis of strategic role of HR and increase of use information technology (IT). This study examines the complementarity between human resource information systems (HRIS) and HR practices. Our findings suggest that HRIS positively moderate the relationship between HR practices and productivity.

KEYWORDS: Human resource information systems, Strategic human resource management,

INTRODUCTION

All specialized department in a corporation desires to demonstrate the value of what they do for the rest of organization. Human resource (HR) department is no exception. Although the human resource (HR) function is ubiquitous and human capital is considered a critical for organizational performance (Becker & Gerhart, 1996; Liu et al., 2017; Sun et al., 2007), human resource (HR) practitioners and researchers have been attempting to prove that HR practices make a contribution to the organization (Wright et al., 2005). In response to these pressures, a critical trend in HR management (HRM) has been seen over the past years. That is the emphasis on the strategic roles of HRM (SHRM) rather than its administrative role. In other words, HR practitioners are under pressure to be strategic partners and to contribute to a firm performance (Collins & Clark, 2003; Paauwe, 2004; Shin & Konrad, 2017). In addition, the past decade has witnessed a surge in the adaptation of e-HRM technology to achieve administrative and strategic benefits (Bondarouk et al., 2017; Marler & Parry, 2016). These are obvious HRM trends in the past. So previous research studied the impacts of HR practices and human resource information systems (HRIS) on economic efficiencies, but relatively fewer studies have focused on the complementarity between HRIS and SHRM. This study propose that these two phenomena are related and that the performance benefits of HR practices depend on HRIS.

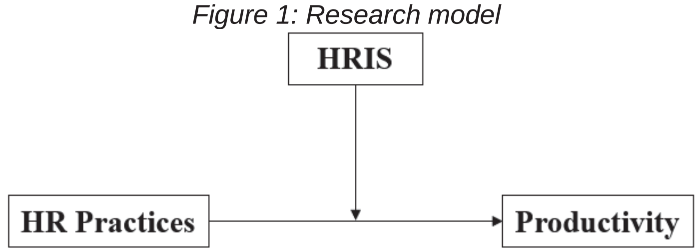
This study contributes to the literature in three ways. First, it deepens our understanding of the economic value of HR practices in an organization by proposing a holistic mode. In addition, this study contributes to our understanding of HRIS strategic values by testing the suggested model. There is a substantial body of research on HRIS with different foci, such as implementation (Lippert & Michael Swiercz, 2005), administrative efficiency (Bondarouk et al., 2009), employee perceptions towards HRIS (Wickramasinghe, 2010), and job satisfaction and turnover intention (Maier et al., 2013). However, little literature exists regarding HRIS's economic value. Third, it deepens our understanding the business value of IT by investigating a specialized information system within a traditional functional area of an organization. Demonstrating the value of information technology (IT) is a central issue in the information systems (IS) discipline, and a significant body of research has examined the organizational performance impacts of IT (e.g. Chae et al., 2014; Mithas & Rust, 2016; Mithas et al., 2017). IT in literature is frequently used as aggregate variables, such as IT investments (Mithas et al., 2012) and IT portfolio (Oh & Pinsonneault, 2007). However, scholars in the IS field have argued that we need to examine the

IT-performance link at a disaggregated level, such as at the level of specific information systems (Aral & Weill, 2007; DeSanctis, 1986; Mithas et al., 2006). By examining the link between specialized information system within a traditional functional area of an organization and the business value, this study extends our understanding regarding the IT-related value creation at an IT system level.

RESEARCH MODEL AND HYPOTHESIS

This study investigates the effects of HRIS on the relationship between strategic HR practices and firm performance. Specifically, the proposed model is shown in Figure 1.

Figure 1: Research model



HR practices and Productivity

The resource-based view (RBV) of the firm suggests that organizations can increase firm performance by using valuable and inimitable internal resources. Human capital is a potential source of competitive advantage (Barney, 1991). In this perspective, firms can enhance organizational performance by investing in people that constitute the organization-specific resource results in higher organizational performance. In addition, the behavioral perspective suggests that HR practices increase employee engagement in productive behavior (Shin & Konrad, 2019).

These theoretical explanations of the effect of HR practices on performance are empirically supported by previous research. For example, MacDuffie (1995) found that “bundles” of HR practices were related to productivity. Delery and Doty (1996) found significant relationships between HR practices and accounting profits. Youndt et al. (1996) found that combinations of HR practices were related to operational performance indicators. Also, many previous studies proved the positive relationship specific HR practice and firm performance, such as employee training (Delaney & Huselid, 1996; Kalleberg & Moody, 1994) and performance-based payment (Lazear, 2000; Way, 2002). More recent studies by Shin and Konrad (2019), and Wright et al. (2005) also showed the positive relationships between HR practice and firm performance.

Productivity is a commonly used measure of firm performance in the strategic human resource management field (Combs et al., 2006). HR practices increases productivity by enhancing employee knowledge, skills, and ability (Lawler, 1986). Also, the RBV and previous studies provide the theoretical and empirical base for predicting a positive effect of HR practices on firm productivity.

Hypothesis 1: HR practices is positively associated with productivity.

The Moderating Role of HRIS

According to the resource-based view (RVB), resources are not solely responsible for organizational performance (Wade & Hulland, 2004). In other words, the effects of organizational resources are viewed as both contingent and complementary. Complementarity refers the effect that one resource in organizations may have on another. Resources may influence performance when combined with another resource (Teece, 1986). In particular, IT resources can be more effective for improving organizational performance in conjunction with other firm resources, such as structure, culture, and skills (Chae et al., 2014). In particular, previous literature showed the complementary between a specific technology and a set of organizational practices (Aral et al., 2012; Black & Lynch, 2001; Bresnahan et al., 2002). For instance, Aral et al. (2012) found that the human capital management software adoption, HR analytics practices, and performance pay together act as a complementary system.

HRIS can help HR departments play that strategic role. Literature has broadly suggested two main benefits of HRIS: the improvement of efficiency and reduction of costs associated with HR activities involving day-to-day transactions (e.g. payroll and selection), and facilitation of a more strategic role for the HR function (Parry, 2011). A large proportion of administrative roles of HRM are now delivered through information technology (IT), which enables HR people to focus more on strategic roles. Literature in HRM and IS suggests that HRIS reduce administrative burdens of HR staff and allow them to focus on more strategic support for their organizations (Bondarouk & Ruël, 2013; Nagi & Wat, 2006). Specifically, HR departments can automate routine HR tasks and replace 'filing cabinets' by adopting HRIS (Parry et al., 2007), expend more effort on the improvement of HR strategies and policies for the strategic management of employees (Martin et al., 2008; Ruël et al., 2004; Shrivastava & Shaw, 2004) and support strategic decision-making (Bondarouk & Ruël, 2009; Hussain et al., 2007; Parry & Tyson, 2011). Thus, HRIS help transform HR professionals from administrative workers to strategic partners (Bell et al., 2006; Burbach & Dundon, 2005; Haines & Lafleur, 2008; Voermans & Van Veldhoven, 2007). The adoption of HRIS may allow the HR functions to increase its value in strategic levels.

Thus, I hypothesize that the effects of HR practices are more leveraged when they are implemented with HRIS.

Hypothesis 2: The HRIS positively moderate the relationship between HR practices and productivity.

METHOD

Sample and Procedure

The data come from the Human Capital Corporate Panel (HCCP) Survey from the Korean Research Institute for Vocational Education and Training (KRIVET, 2015). The survey data of the sample companies are combined with the corporate financial data held by the Korea Investors Service (KIS) using a corresponding firm code (KIS, 2015).

KRIVET has conducted the HCCP survey every two years since 2005; the survey includes a battery of questions regarding HR practices. We focused on the survey data and financial data in 2011 – 2015 for these reasons. First, the HCCP survey sample was changed in 2009. The

9th Korean standard industrial classification was placed into effect on February 1, 2008. Second, to eliminate the effects of the Great Recession, I focused on the data after that time.

For the survey process, KRIVET contacted HR managers at targeted firms, and they administered the HCCP survey using on-site interviews. The referent for the survey items was the firm, and HR managers responded to the items. The population for HCCP sample extraction consisted of companies listed in the company overview information of the KIS database with at least 100 employees across six industries: (1) Manufacturing, (2) Finance, banking and insurance, (3) Publishing/video/broadcasting and telecommunications, and information service, (4) Specialist/scientific and technical service (5), education service, and (6) Arts/sports and leisure service. In 2009 – 2015, companies for the survey sample numbered between 467 and 500.

Variable Operationalization and Descriptive Statistics

Table 2 provides the operationalization and the descriptive statistics for the variables in our study.

Strategic HR practices (SHRP). Theoretically, strategic HR practices are those that are related to overall organization performance. Prior research (Delery & Doty, 1996; Shin & Konrad, 2014) suggested practices that are considered strategic HR practices. These are internal career opportunities, training, compensation, employment security, employee involvement, and work design. Using HCCP data, SHRP is measured with four sets of practices in the area of internal career opportunities, training, compensation, and employment security (see Table 1). I use additive indices of HR practices following previous studies (Shin & Konrad, 2014; Wright et al., 2005). Each practice is coded as a binary variable based the response to a question for HR managers in the firm. This indicates whether they implement each HR practice (1 = yes, 0 = no). Adoption of practices is obtained by calculating the mean across the specific practices.

The first practices, Internal career opportunities, indicate the extent to which organizations can use internal labor markets to hire. The training measure refers to the formal training programs or policies given to employees for helping them develop their knowledge and skills. The HR practices in the compensation category focus on results-oriented compensation system that ties pay to individual and organizational performance. The fourth practice is the degree to which employees are given employment security.

HRIS adoption (HRIS). This is a binary variable that is based on the response to a question for HR managers in the firm that indicates whether they use HRIS. Response choices were 0 indicating the use of HRIS, and 1 meaning no use of HRIS.

Productivity. This variable is commonly used as a measure of financial performance in the SHRM field (Comb et al., 2006; Huselid, 1995). Consistent with prior research (Konrad & Mangel, 2000), I use a standard measure of productivity calculated as the logarithm of the gross operating revenue per employee.

Table 1: Strategic HR Practices

HR practice	Items
Internal career opportunities	- Does your company operate the internal job posting system? - Does your company develop core talents internally? - Does your company implement career development planning? - Does your company implement succession planning? - Does your company operate the job circulation?
Training	- Does your company provide orientation for new employees? - Does your company provide collective internal training? - Does your company provide a domestic training program? - Does your company provide an abroad training program? - Does your company operate the training leave system (provision of vacations and financial support for personal competence development)? - Does your company provide mentoring (or coaching)? - Does your company provide on the job training? - Does your company provide financial support for studying a domestic college program? - Does your company provide financial support for studying a domestic graduate school program? - Does your company provide financial support for studying an overseas graduate school program?
Incentive compensation	- Does your compensation system include the individual incentive? - Does your compensation system include the team incentive? - Does your compensation system include the division incentive? - Does your compensation system include the corporate incentive? - Does your compensation system include the profit sharing? - Does your compensation system include the stock option? - Does your compensation system include employee stock ownership plan?
Employment security	- Over the last 2 years, did your company ever adjust employment by lay-off, resignation advice, voluntary retirement, transfer to affiliate/partner, corporate division, and others?

Controls. The research model in this study controls for firm age (AGE), firm size measured as the logarithm of the number of employees (SIZE), management systems [fully managed by the owner (OWNER), managed by a management specialist with significant owner intervention (MAS_OWNER1), managed by a management specialist with slight owner intervention (MAS_OWNER2), fully managed by a management specialist (SPECIAL)], the top priority in the company management [improvement the quality of product/service(QUALITY), cost reduction (COST), new product development (DEV)], having an organization exclusively responsible for HR (HRDPT), number of HR employees (HREMP), number of HR managers (HRMG), the number of HR senior managers (HRSMG).

Table 2. Variable Description

Quantitative variable	Operationalization	Mean	Std. dev
SHRP	The average ratings on the items in Table 1 in a firm *i* in year *t*	8.079	1.038
Productivity	The logarithm of the gross operating revenue per employee in a firm *i* in year *t*	9.965	1.242
AGE	A firm *i*'s age in year *t*	33.914	17.620
SIZE	the logarithm of the number of employees in a firm *i* in year *t*	5.792	1.092
HREMP	The number of HR employees in a firm *i* in year *t*	2.841	4.941
HRMG	The number of HR managers in a firm *i* in year *t*	2.566	4.979
HRSMG	The number of HR senior managers in a firm *i* in year *t*	.421	.668
Categorical variable	Operationalization	Proportion	Std. dev
HRIS	1 if a firm *i* adopts and operates HRIS in year *t*	.700	.459
OWNER	1 if a firm *i* is fully managed by the owner, otherwise, coded as 0 in year *t*	.469	.499
MAS_OWNER1	1 if a firm *i* is managed by a management specialist with significant owner intervention, otherwise, coded as 0 in year *t*	.165	.371
MAS_OWNER2	1 if a firm *i* is managed by a management specialist with slight owner intervention, otherwise, coded as 0 in year *t*	.166	.372
QUALITY	1 if a firm *i*'s top priority in the company management is improvement the quality of product/service, otherwise, coded as 0 in year *t*	.523	.500
COST	1 if a firm *i*'s top priority in the company management is cost reduction, otherwise, coded as 0 in year *t*	.296	.457
HRDPT	1 if a firm *i* has an organization exclusively responsible for HR in year *t*	.685	.465

Preliminary analysis

Because of the panel nature of our data set, we specify the following equation for the panel models:

$$Y_{it} = X_{it}\beta + u_i + \varepsilon_{it} \quad (1)$$

where *Y* represents the endogenous variable (i.e. Productivity); *X* represents a vector of firm characteristics, such as HRIS, SIZE and other control variables; *β*s are the parameters to be estimated; subscript *i* indicates firms and subscript *t* indicates time; u_i represents unobserved time invariant fixed factors associated with a firm *i*; and *ε* is the error term associated with each observation. Our main independent variable (HR practices) is not a time-constant variable, and Hausman test rejected the null ($X^2(14) = 39.04$, $p < 0.01$) which is taken to mean that the key random effect assumption, the unobserved effect is uncorrelated with each explanatory variable, is false so that a fixed effect model is used (Wooldridge 2013).

RESULTS

A summary of the results of the fixed effects regression models are shown in Table 2. Model 1 includes the variable composite HR practices only. The coefficient of SHRP is not significant. The interaction term SHRP*HRIS in model 3 is positive and significant, supporting hypothesis 2.

Table 3: Fixed Effects Results

Independent Variables	Dependent variable: Productivity		
	Model1	Model2	Model3
SHRP	-.044 (.041)	-.045 (.041)	-.156* (.076)

CONCLUSION AND FUTURE RESEARCH

The objective of this study was to analyze and investigate the complementary relationship between HRIS and strategic HR practices. Based on our preliminary analyses, we find that HRIS positively moderates the impact of HR practices on productivity. It is a preliminary analysis. In the future, we will do alternative analysis by using different econometric models, such as 2SLS, to handle any endogeneity that might exist in the data and present more detailed findings and implications for future research.

ABSTRACT

We first differentiate between clinical transfer and non-clinical transfer based on their varied coordination properties, and develop a practical method to separate the two transfer types using patient-level discharge data. We evaluate the impacts of the two transfer types on care outcomes (measured by readmission, mortality, and LOS). Our analysis yields two major findings. First, clinical transfers are more routinized and are associated with better care outcomes than non-clinical transfers. Second, transfer destination choices matter differently for the two transfer types. Specifically, for non-clinical transfers, destinations within the same multihospital system are associated with better care outcomes than those out of the system, whereas for clinical transfers, destinations out of the system are associated with better care outcomes than those in the system. The robustness of the models are checked using propensity score matching techniques. The results shed light on the nature of the two different transfer types, and provide practical destination choice strategies to practitioners.

KEYWORDS: hospital operations management; interhospital transfer types; destination choice strategy

INTRODUCTION

Interhospital transfer (IHT) of patients occurs commonly between hospitals (Iwashyna, 2012) when patients' needs exceed the resources available at the current hospital. The increasing specialization of a single hospital, especially in urban areas, combined with the demand for sophisticated medical treatments, generates a great need for IHT. Although IHT represents an effort of hospitals to provide better care through inter-provider collaboration, it often increases risks to patients and leads to the development of clinical complications (Barry & Ralston, 1994). In order to develop strategies to better manage IHT, it is important to identify different IHT types and understand the individual operations nature of each type.

Because the reasons underlying IHT are largely unknown, most literature focuses on disease and site-specific studies so that a typical transfer type can be identified. In this paper, we specify an IHT from a sending hospital to a receiving hospital as *clinical transfer* if the sending hospital (also referred to as the "sender") does not offer the specialty or higher levels of care needed for

the patient while the receiving hospital (also referred to as the “receiver”) does, otherwise as *non-clinical transfer*. Our definition of clinical transfer depends on a hospital’s clinical service scope, which is a long term strategic plan and forms the basis of the lower-level operational and tactical decisions (Ivanov, 2010). Services that are outside of the scope but are required for patients will need to be “outsourced”, i.e., those patients need to be transferred to another hospital for further care. In contrast, a non-clinical transfer occurs due to the ad hoc status of operational factors. One major cause of non-clinical transfers is the unavailability of medical staff or beds due to ED crowding (Morley, Unwin, Peterson, Stankovich, & Kinsman, 2018).
The two IHT types have fundamentally different decisions models. As a result of a hospital’s service scope strategy, clinical transfer decisions are dictated by the strategic-level service scope decision, and the decisions tend to be repeated from case to case. Non-clinical transfer decisions, on the contrary, need ad hoc tactical evaluation of the operational factors, causing decision inconsistency because of stochastic operational situations. In the literature, there is no known analysis of the different intrinsic natures between the two IHT types, or methodology to operationalize the differentiation of them. Our study fills the gap.
We develop our hypotheses using Organizational Information Processing Theory (OIPT) (Galbraith, 1974) and empirically test it with the 2014 Florida community hospitals’ emergency department and inpatient discharge data, which are made available by the Healthcare Cost and Utilization Project (HCUP), and the 2014 American Hospital Association (AHA) annual survey data. We find that non-clinical transfers are associated with worse care outcomes as measured by 30-day hospital readmission, in-hospital mortality, and LOS, than clinical transfers. Distinct from previous disease- and site-specific studies about IHT, to the best of our knowledge, our paper is the first to estimate the varying effects of the two IHT types on care outcomes.
Hospitals in the US have a strong tendency to transfer patients within the same hospital system (Lu & Lu, 2018; Bosk, Veinot, & Iwashyna, 2011). Hospitals may have more effective communication for transfer arrangement with hospitals within the same system than with those outside the system. Hospitals in the same system are less likely to reject the transfer requests from within the system and more likely to have implemented transfer protocols among them. Therefore, choosing the IHT destinations inside the same system may improve care efficiency. However, without knowing the specific IHT types, it is hard to tell if this practice is the optimal choice, as the routinization of clinical transfers may offset the communication convenience of in-system coordination. Is it better for a patient to be transferred out of the system or within the system? Will the answer be the same for the two IHT types? We investigate the effect of system-based destination choices under the scope of coordination mechanisms, and find that the optimal choices diverge. For non-clinical transfers, in-system destinations offer higher care efficiency (measured by LOS) with the same care quality (measured by readmission and mortality), while for clinical transfers, out-of-system destinations offer the same care efficiency with higher care quality. This finding extends the findings of Lu and Lu (2018), and offers more general destination choice strategies for hospitals to use for different IHT types, considering both care quality and care efficiency.

LITERATURE REVIEW

IHT is an understudied area where little is known about the process of information transfer and its association with patient outcomes (Herrigel, Carroll, Fanning, Steinberg, Parikh, & Usher, 2016). Our research contributes to the empirical healthcare operations literature on categorizing IHT types and comparing their effects on the care performance.

Impacts of IHT

Inter-organizational communication of IHT is challenging. Once a patient has been identified to need transfer, the medical staff of the sending hospital needs to request and negotiate with the candidate receiving hospitals (Bosk et al., 2011). The negotiation can be an intense process (Iwashyna, 2012), as the sending physician needs to explain why the patient needs to be transferred and provide transfer timing and method to the referred physician (Dunn, Gwinnutt, & Gray, 2007). The negotiation is a time consuming process (Bosk et al., 2011). Identifying a hospital that accepts the patient may take multiple phone calls and multiple rounds of negotiation (Rosenberg, Hofer, Strachan, Watts, & Hayward, 2003).
Because of the above challenges, IHT can impact patient care performance, which are commonly measured by readmission, mortality and LOS. Table 1 summarizes findings of several recent papers on the relationship between IHT and care performance. Most studies generally find that transfers has unfavorable impacts on care performance. However, several studies find neutral or even favorable impacts. This difference is likely due to the scope of these studies. Most the findings are based on a single hospital setting or a single disease. Furthermore, most studies do not differentiate between transfer types. Without understanding the nature of each IHT type, it is hard to discern their varied effects on care performance or act on specific cases to minimize the potential negative consequences. Our study uses a state-wide discharge data that covers all hospitals in the region and all conditions, and we differentiate between the two IHT types.

IHT Types

Several studies have taken various approaches to categorize IHT types. Duke and Green (2001) categorize transfers for specialty care or higher level of care as Category A transfer and those due to a hospital's temporary unavailability of beds as Category B transfer. Gray et al. (2003) split transfers into transfers for specialty care and transfers for non-clinical reasons. Stolte et al. (2006) differentiate transfers due to capacity from those for specialty services. While these categorization concepts make sense, they do not identify the fundamental difference in the nature of the decisions in various IHT types.

We differentiate between two IHT types. The first type is transfers for clinical reasons, e.g., for specialty care or higher level of care. The transfer decision in this type originates from a hospital's services scope, which is a strategic level decision (Butler, Leong, & Everett, 1996; Li, Benton, & Leong, 2002). The second type is transfers for non-clinical reasons, e.g., bed unavailability, patient preference, etc. The transfer decision in this type is made after tactically evaluating several operational factors such as a hospital's capacity resource and the patient's hospital preference. We categorize the first type as clinical transfer, and the second type as non-clinical transfer.

In many cases, it is technically difficult to separate the data based on the transfer type definitions. Our study develops a methodology to identify different transfer types based on the definition above.

IHT Destination Choices

Our study also contributes to the optimal destination choices in IHT. According to the Future of Emergency Care report released by the Institute of Medicine, "regionalization is an active process by which patients are appropriately matched to appropriate resources" (Carr & Martinez, 2010). For care regionalization to succeed, it is critical to choose the best destinations for IHT.

Literature on IHT destination hospital choice suggests that hospitals generally choose destinations based on same-system relationship (Lu & Lu, 2018). Transfers within the same system can have several advantages, e.g., it is easier to implement transfer protocols within the same multihospital system. Hospitals within the same system typically have a better relationship since they have shared goals, shared knowledge and better communication platform (Gittell, Fairfield, Bierbaum, Head, Jackson, Kelly, Laskin, Lipson, Siliski, & Thornhill, 2000). Although preferred by hospitals, transferring within the same system also can have drawbacks. Iwashyna

(2012) suggests that transfers based on relationship tend to overlook service quality and neglect patients' clinical interests. Lu and Lu (2018) find that relationship-based (within the same system) patient transfers led to worse clinical outcomes than distance-based and quality-based transfers.
We view system-based IHT destination choice as a tool that a hospital may use to coordinate the complex transfer procedures. Inter-organizational tasks such as IHT require multi-functional teams and departments to provide a wide variety of services. These teams and departments may have different task specializations and work priorities (Tucker, Nembhard, & Edmondson, 2007), which may clash. The good relationship between hospitals within a system may minimize the conflicts.

HYPOTHESIS DEVELOPMENT

Clinical transfers and non-clinical transfers originate from different levels of decisions and thus possess fundamentally different operations characteristics. Clinical transfers originate from a hospital's limited service scope. In this case, hospital decision makers can accurately predict that patients out of service scope will be transferred, and preplan for that situation. The relative stability of the service scope and the preplanning nature of clinical transfers lead to the repetition of transfer practice: whenever a patient requires some services out of scope, they must be transferred, unless the patient refuses further treatment. They also promote the sending hospital to establish long-term relationships with the receiving hospitals, e.g., tertiary hospitals and medical centers that offer specialty care or higher levels of care. In practice, sending hospitals tend to establish IHT protocols and agreements with the capable receiving hospitals to govern the long-term relationships. Practice repetition and interhospital protocols nurture the decision and process routinization in clinical transfers. Non-clinical transfers, in contrast, do not nurture routinization due to the ad hoc nature of the decisions. First, whether a patient is transferred depends on the operational situations at a specific time for a specific patient. For example, the decision to transfer a patient due to bed unavailability may be a slow process as bed occupation level is time dependent and stochastic. The patient may just need to wait for a short while before beds become available. Second, patients' choices vary. For example, between two patients who need to be admitted when no bed is available, one patient may prefer to wait while the other may prefer to be transferred. Third, hospitals view patients as sources of revenue (Veinot et al., 2012), and generally are reluctant to transfer patients and their revenues out (Kahn, Asch, Iwashyna, Rubenfeld, Angus, & Asch. 2008). In non-clinical transfers, hospitals typically have the option of retaining the patient instead of transferring. Hospitals need to weigh the benefits and costs of retaining versus transferring. Therefore, nonclinical transfers are less routinized than clinical transfers, and we advance our following hypothesis.

Hypothesis 1. Clinical transfers are more routinized than non-clinical transfers.

As a process becomes more complex, the amount of information to be processed increases, and if not managed well, will affect a firm's performance. Organizational information processing theory (Galbraith, 1974) prescribes several coordination mechanisms to organizations to increase their information processing capabilities. Formal mechanisms include departmentalization of organizational units, centralization of decision making through the formal hierarchy, procedure standardization, strategic planning, and output control such as financial performance goal. Informal mechanisms include lateral (cross-unit or cross-organizational) relations, informal communication through personal relationships, and socialization through culture-building (Martinez & Jarillo, 1989).

Clinical transfers are coordinated with both formal and informal coordination mechanisms. Formal mechanisms for clinical transfers include strategic planning and procedure standardization. A hospital usually preplans for scenarios where it is incapable of caring, because it knows what patients can be cared and what cannot. The plan is typically strategic as it does not change in the short term. Furthermore, clinical transfers are usually routinized, therefore, they usually have standard procedures. Informal mechanisms such as cross-organizational relations and personal relationships are also prevalent in clinical transfers. Furthermore, personal relationships, if exist between the sending physician and the receiving physician, may dominate the referral decision (Forrest, Nutting, Starfield, & Von Schrader, 2002). In non-clinical transfers, formal mechanisms are weak and informal coordination mechanism is largely missing. Due to decision inconsistency, non-clinical transfers are less likely to have sender-receiver transfer protocols. Lack of routinization prevent the transfer process to follow standard procedures. The ad-hoc nature of the transfer decisions makes the sender-receiver relationship temporary, suppressing long-term personal relationships between the referring and referred physicians.

Having both formal and informal coordination mechanisms, clinical transfers may be better coordinated than non-clinical transfers, which essentially have no informal coordination mechanism. Better coordination reduces communication breakdowns, care delays, and medical errors, improving patient care quality and care efficiency. Therefore, we hypothesize the following.

Hypothesis 2A. Clinical transfers have better care quality (lower readmission and lower mortality) than non-clinical transfers.

Hypothesis 2B. Clinical transfers have better care efficiency (shorter LOS) than non-clinical transfers.

In cases where a sender and a receiver belong to the same hospital system, the sender has the option to choose destinations based on its system membership. If the sender choose to transfer within the system, formal coordination mechanisms such as centralization of decision making and output control by financial performance goal may affect the IHT coordination.

In practice, a physician' primary concern about IHT is the fractured and contentious process of negotiating with the candidate destination hospital (Iwashyna & Courey 2011; Iwashyna, 2012). The concern is especially valid for non-clinical transfers because in such cases the sender is also capable of treating the patient, and the receiver needs to be convinced that the patient indeed needs to be transferred (Bosk et al., 2011). The negotiation would be much simpler if the receiver belongs to the same hospital system, since hospitals within the same system are less likely to reject a transfer request. Therefore, for cases of same-system transfers, same-system convenience implicitly carried out the mechanism of centralization of decision making. Further, a hospital system may explicitly centralize transfer navigation system, transfer case management and administrative procedures such as transmission of IHT paperwork.

Moreover, hospitals within the same system typically share some common financial interests (Veinot et al., 2012). Upon choosing a same-system hospital as the destination, the sender retains the revenue from the care within the system (Bosk et al., 2011).

The two system-induced coordination mechanisms discussed above may have varied effects on the two IHT types, as clinical transfers already have other strong formal and informal mechanisms, and non-clinical transfers only have other weak mechanisms. For clinical transfers, the coordination mechanisms of strategic planning and procedure standardization are likely to dominate the system-induced coordination mechanism. This is especially true for clinical transfers due to regionalization of care, where the regionalization protocols instead of system memberships direct where to transfer. For example, a Level 1 trauma center has the

responsibility to accept patients from lower level providers and the transfers are governed by established protocols, regardless of the hospitals' system.
For non-clinical transfers, the system-induced coordination mechanisms weighs more since the existing coordination mechanisms are weak. Therefore, we argue that non-clinical transfers benefit more from same-system relationship than clinical transfers.

Hypothesis 3A. Non-clinical transfers within the system have better care quality (lower readmission and lower mortality) than those outside of the system.

Hypothesis 3B. Non-clinical transfers within the system have better care efficiency (shorter LOS) than those outside of the system.

Hypothesis 3C. Clinical transfers within the system have better care quality (lower readmission and lower mortality) than those outside of the system, but the difference is smaller than for non-clinical transfers.

Hypothesis 3D. Clinical transfers within the system have better care efficiency (shorter LOS) than those outside of the system, but the difference is smaller than for non-clinical transfers.

METHOD

To test our hypotheses, we obtain patient level visit data that has patients' demographics, visit information, diagnosis and treatment service details, as well as hospital level data that has hospital characteristics. Next, we develop a method to differentiate the IHT types based on the definition. Lastly, we compare the differentiated IHT and test the hypotheses.

Data

We use the Healthcare Cost and Utilization Project (HCUP) 2014 Florida State Emergency Department Databases (FL-SEDD) and the State Inpatient Databases (FL-SID) obtained from the Agency for Healthcare Research and Quality (AHRQ) for the patient level variables, service details and visit information, and use the 2014 American Hospital Association (AHA) annual survey data, as well as the readmission data from the Centers for Medicare & Medicaid Services (CMS) website (https://www.cms.gov) for the hospital level variables. There are 2,381,173 inpatient discharge observations from FL-SID, and 6,887,904 ED discharge observations from FL-SEDD. The two datasets include 299 common hospitals, 217 of which also appear in the AHA and readmission data.

Transfer Definition and Scope

Similar to Lu and Lu (2018) in a study of IHT of heart attack patients, we restrict our analysis to cases where patients are transferred from one hospital's ED to another hospital's inpatient department with emergent admissions (an example of a non-emergent admission is an elective admission). The restriction is due to two considerations. First, compared with transfers out of inpatient, transfers out of the ED are more time sensitive, and more critical to the patients and need quicker decisions. Second, emergent transfers happen within a short period of time, during which little unobserved endogenous factors may affect the LOS. For example, in emergent transfers, patients and families have less influence on the transfer decisions. Our study focuses on emergent transfers that need some procedures (one or more procedures) at the receiving hospitals since these cases involves higher risks to the patients and need more clinical resources than cases where no procedures are performed.

Out of the 2,381,173 inpatient records, 755,867 observations are emergent admissions needing procedures, and 12,016 of them are identified as transfers. At the hospital-level, 208 out of 237 hospitals have sending records and 236 out of 237 hospitals have receiving records.

Differentiating IHT Types

The HCUP data includes complete service codes that a hospital has performed on each patient. DX codes represent diagnosed conditions and PR codes represent performed procedures. Based on the codes, we deduct whether a transfer is a clinical transfer or not. If the receiver has performed any DXs or PRs that the sender never performed during the full year, we consider that the sender transferred the patient due to clinical reasons. Otherwise, the transfer is made due to non-clinical reasons. The data generates 9,716 non-clinical transfers and 9,854 clinical transfers. Following the above differentiation process, we process the data and obtain the differentiation result summarized in Table 2. We use the dichotomous variable CLN_TRANS to indicate IHT types.

Table 2 Transfer Type Classification Result

CLN_TRANS	Frequency	Percent
0 (Non-clinical transfer)	4,434	36.90
1 (Clinical transfer)	7,582	63.10

Table 3 (see Appendix) lists the most frequent principle diagnosis codes in IHT. The 23 diagnosis codes in the list account for 60% of all transfers. For each of the frequent diagnosis codes, the table shows the frequency of transferring inside the system (in-system) versus outside the system (out-of-system), as well as the frequency of clinical transfers versus non-clinical transfers. Note that the percentages of in-system and out-of-system transfers do not sum to 1 ‘because there are cases where the sender does not belong to any hospital system. Table 4 (see Appendix) shows frequencies of age group, patient insurance type, hospital ownership type, teaching status, and bed size, for each group of destination choice, as well as for each IHT type.

Variables

Transfer routinization is a construct that reflects the repetition and stability of the process. We operationalize routinization in IHT by measuring a sender’s repetition of destination relationships across quarters of the year (DEST_OVERLAP). For example, a high routinization case is when the sender keeps sending a certain types of patients (as measured by MDC, Major Diagnostic Category) to the same receiving hospital from one quarter to another. On the contrary, a lower routinization case is when the sender does not use the same receiving hospitals across the two consecutive quarters.

We measure care quality by 30-day hospital-wise readmission and in-hospital mortality. A readmission occurrence is identified if a patient is admitted to any hospital within 30 days of discharge from the previous hospital. We measure care efficiency by LOS. Considering that patient LOS at EDs is normally within one day, we consider hourly length of stay (HLOS) as the dependent variable. An initial check of the data shows that HLOS follows an approximate exponential distribution. The log transformation of HLOS (LNHLOS) approximates a normal

distribution. Therefore, we use LNHLOS as the dependent variable in our model. Table 5 and 6 (see Appendix) summarize the statistics of the dependent variables.
We control for a variety of patient-level and hospital-level variables. Table 7 summarizes the control variables. Total charge is controlled for as it indicates the amount and complexity of the care delivered to the patient. Geographic distance is controlled because transferring a patient over a long distance increases risks for the patient, especially for critically ill patients (Duke & Green, 2001; Bosk et al., 2011). Furthermore, in our analysis of destination choice (H3a - H3d), we also require that the destinations be within 75 miles of geographic distance, in order to minimize the sample selection bias.

Table 7 List of Control Variables

Variable Type	Variable Name
Patient demographics	Female (1 is female, 0 is male)
	Age
	Race
Conditions and care	Principle diagnosed conditions
	Number of diagnoses,
	Number of chronic conditions
	Number of comorbidities
	Number of procedures
	Number of current procedural terminology
Visit information	Log of total charge
	Primary payer/insurance
Hospital variables	number of beds
	ownership type
	teaching status
	hospital referral regions code
	hospital-wide readmission rate
Other variables	geographic distance

Econometric Models

We use the following linear model to model the relationship between transfer type and routinization.

$$DEST\_OVERLAP = \beta_0 + \beta_1 \times TransferType + \beta_2 \times HospitalVariables \quad (1)$$

We use generalized linear models for the hypothesized relationships between transfer related variables and care performance. The following shows a general structure of the models.

$$Care\_Outcomes = \beta_0 + \beta_1 \times TransferRelatedVariables + \beta_2 \times PatientDemographics + \beta_3 \times ConditionsAndCare + \beta_4 \times VisitInformation + \beta_5 \times HospitalVariables + \beta_6 \times OtherVariables \quad (2)$$

Readmission and mortality performance is only evaluated for the receiver's section of a transfer case since the sender has transferred out the patient to the receiver, thus does not have any readmission and mortality directly tied to it. LOS performance is evaluated for both the sender and the receiver.

RESULTS

The result for transfer routinization is shown in Table 8. The odds ratio of 1.416 for the IHT type factor means that clinical transfers have 41.6% higher chance of choosing the same receiving hospitals for transfer destinations from quarter to quarter than non-clinical transfers. The difference is statistically significant. Therefore, H1 is supported. For clinical transfers, the senders tend to have a stable set of receiving hospitals. Non-clinical transfers, however, have a changing set of destination hospitals from time to time. To the receiver, a non-clinical transfer relationship with the sender is temporary because the sender may not make the same transfer decision for the next patient.

Table 8 Destination Quarterly Overlap

Factors	Odds Ratio	95% Wald Interval	
		Lower	Upper
IHT Type: Clinical vs Non-clinical	1.416	1.264	1.586
N	7,086		

Control variables: Hospital variables.

Table 9 shows the result of the effect of transfer types on readmission and mortality. From the table, clinical transfers 16.4% smaller chance of incurring readmissions than non-clinical transfers. However, the difference's significant level is at the borderline. The table also shows that clinical transfers have 21.3% lower chance of mortality than non-clinical transfers, and the difference is statistically significant. The result suggests that overall, clinical transfers have better care quality than non-clinical transfers, supporting H2a.

Table 9 IHT Type on Readmission and Mortality

Factors	Readmission			Mortality		
	Odds Ratio	95% Wald Interval		Odds Ratio	95% Wald Interval	
		Lower	Upper		Lower	Upper
Clinical vs Non-clinical	0.836	0.675	1.037	0.787	0.632	0.980
N		11,000			11,619	

Control variables: Patient demographics, Conditions and care, Visit information, Hospital variables.

Column 1 and 3 of Table 10 correspond to the results of the linear regression for the sender's LOS and the receiver's LOS. As the table shows, clinical transfers are negatively associated with LOS for both the sending and the receiving hospitals, supporting Hypothesis 2b. On average, transferred patients for clinical reasons stay 5.2% (0.35 hour, or 21 minutes) shorter in EDs than patients transferred for non-clinical reasons. Even though the saved time is not much, considering that the average ED stay of nonclinical transferred patients is only about 5 hours and process efficiency is critical to emergent patients, the saved 21 minutes LOS has practical significance. At the receiving hospital, clinical transfers incurs 3.5% (about 3.35 hours) less LOS than non-clinical transfers, whose average LOS is 136 hours. That is an approximate saving of 3.4 hours.

Table 10 IHT Type and Destination Choice on LOS

	Ln (Sender's HLOS)		Ln (Receiver's HLOS)	
	1	2	3	4
Clinical transfer	−0.052 (0.013)	−0.057 (0.022)***	−0.035 (0.012)***	−0.055 (0.018)***
Clinical * in-system transfer		−0.039 (0.022)*		−0.001 (0.018)
Non-clinical * in-system transfer		−0.057 (0.023)**		−0.016 (0.020)
N	9,320	7,352	8,866	6,967
$R2$	0.236	0.234	0.725	0.735

Control variables: Patient demographics, Conditions and care, Visit information, Hospital variables.

*p <0.1, **p <0.05, ***p <0.01, ****p <0.001 (Standard errors in parentheses)

The results for H3a and H3c are shown in Table 11 - 12. For either clinical or non-clinical transfers, choosing in-system does not affect patients' readmission probability. Table 12 shows the results for mortality. While choosing in-system has no effect on mortality probability for non-clinical transfers, it does have a positive effect for clinical-transfers. Overall, the results imply that non-clinical transfers' care quality does not benefit from nor is it hurt by choosing in-system destinations, while clinical transfers' care quality (mortality) suffer by choosing in-system destinations. Therefore, neither H3a nor H3c is supported.
The results for H3a and H3c may be explained by an alternative view. While we argue that transferring within the same system may help improving care quality, it may also reduce the probability of a patient getting the best care quality. In Florida, on average, a multihospital system has 4 to 5 hospitals, while outside of the system there are over 200 hospitals. Even considering a certain driving distance (e.g., 75 miles), there are still many times more hospitals outside of the system than inside of it. Therefore, the chance that the best quality hospital exists inside the system is much lower versus outside of the system. Furthermore, clinical transfers may suffers more from choosing in-system destinations since the receiver's clinical competence is more of a concern for a clinical transfer, than for a non-clinical transfer. This view is consistent with that of Lu and Lu (2018), who suggest that transfers out of system have higher chance of landing better clinical quality than those in the same system.

Table 11 Destination Choice on Readmission for Each IHT Type

Factors	Readmission (Non-clinical)			Readmission (Clinical)		
	Odds Ratio	95% Wald Interval		Odds Ratio	95% Wald Interval	
		Lower	Upper		Lower	Upper
In-system vs out-of-system	0.876	0.533	1.440	0.925	0.581	1.473
N		3,038			3,929	

Control variables: Patient demographics, Conditions and care, Visit information, Hospital variables.

Table 12 Destination Choice on Mortality for Each IHT Type

Factors	Mortality (Non-clinical)			Mortality (Clinical)		
	Odds Ratio	95% Wald Interval		Odds Ratio	95% Wald Interval	
		Lower	Upper		Lower	Upper
In-system vs out-of-system	1.263	0.723	2.209	1.627	1.022	2.591
N		3,196			4,131	

Control variables: Patient demographics, Conditions and care, Visit information, Hospital variables.

Column 2 and 4 of Table 10 shows the results for H3a and H3d. As Column 2 shows, for the sender: choosing in-system destinations saves about 5.7% (about 18 minutes) for non-clinical transfers (significant at $p < 0.05$), while it saves only 3.9% for clinical transfers (significant at $p < 0.10$). For the receiver, choosing in-system destinations does not affect LOS for either non-clinical or clinical transfers. Considering both the sender and the receiver, the result supports H3b and H3d.
The results for H3a to H3d unveils an interesting situation for a hospital's transfer destination choice strategy. Considering both care quality and care efficiency, in-system is a better destination for non-clinical transfers since it is associated with better care efficiency while maintains the same care quality. Out-of-system is a better destination for clinical transfers, since it is associated with better mortality and similar care efficiency. The results imply that non-clinical transfers may benefit from the coordination mechanisms of same-system relationships without missing the possibly better quality of out-of-system hospitals. On the contrary, clinical transfers may miss the higher chance of better quality possibly existing in out-of-system hospitals while not benefiting much from the ease of internal coordination, because preplanning and routinization have already helped cultivate the formal and informal coordination mechanisms that are independent of system coordination mechanisms, as discussed in the Hypothesis Development section.

Robustness Check

To check the robustness of the results, we focus on addressing endogeneity issue, which is a common concern for studies using observational data. In our study, the issue is addressed both in concept and with propensity score matching techniques. Concept wise, endogeneity is less of a concern in our study for three reasons. First, the HCUP and AHA are regarded by many researchers as among the best quality and most reliable archival data sources for healthcare operations research, and measurement errors in the data are not much concerned. Second, simultaneous causality between IHT type and is of little concern as well. Clinical transfers are decided by a sending hospital's service scope. The receiver's care performance is unlikely to reversely affect clinical transfer decisions. The receiver's care performance may reversely affect nonclinical transfer decisions. However, such effects can only make our conclusion stronger because positive receiver's performance attracts more non-clinical transfers and therefore, the observed readmission, mortality and LOS measures for non-clinical transfers are overestimated. Correcting the overestimation only strengthens our conclusion that clinical transfers have better care quality and care efficiency than non-clinical transfers. Third, our model controls for both patient and hospital level variables. The chance of missing non-ignorable variables is small.

Next, we discuss the process and results of using propensity score matching techniques to address two possible endogeneity issues.

The Varied Effect of IHT Types

Patients who are directly admitted could have been transferred for non-clinical reasons (Note that the case is not valid for clinical transfers). We use one to one matching method to identify the direct admissions that are equally probable to be non-clinically transferred. Based on a 1% propensity score radius, we obtain 3,377 pairs, and compare the matched direct admissions with both clinical and non-clinical transfers. The result shows that non-clinical transfers have 22.1% more LOS than direct admissions ($p < 0.001$), while clinical transfers do not have significant different LOS than direct admissions. The result for readmission and mortality is not significant, possibly due to limited pairs matched. Overall, the result supports our previous findings that clinical transfers have better care performance than non-clinical transfers. It further shows that non-clinical transfer's care efficiency is worse than direct admissions while clinical transfer's efficiency is similar to direct admissions. This finding would not have been possible without differentiating the two IHT types. Existing literature's contradictory findings about the effect of IHT on LOS (e.g., Nathens et al. (2003) and Hill et al. (2011)) could have been due to mixing the two IHT types.

The Effect of System-based Destination Choices

Choosing in-system versus out-of-system a transfer destination may be an endogenous decision: the care performance associated with an in-system destination choice may be affected by the transfer case itself instead of the destination choice. To solve the issue, we use a one-to-one propensity score matching method to match the transfers within the same system with those outside of the system. Based on 1% propensity score radius, we obtain 446 pairs for the clinical transfer group, and 314 pairs for the non-clinical transfer group. The result for readmission and mortality is not significant, probably due to the limited pairs matched. The result for LOS, though, is consistent with our original findings. As Table 13 shows, for non-clinical transfers, in-system destinations are better as it saves 16.8% of the sender's LOS, and 22.7% of the receiver's LOS. For clinical transfers, the benefit of in-system destinations is not statistically significant.

Table 13 IHT Type's Destination Choice on LOS

	LNHLOS (Non-clinical)		LNHLOS (Clinical)	
	Sender	**Receiver**	**Sender**	**Receiver**
In-system transfer	−0.168 (0.071)**	−0.227 (0.104)**	−0.038 (0.062)	−0.041 (0.088)
Propensity Matched Pairs	314	314	446	446

*p <0.1, **p <0.05, ***p <0.01, ****p <0.001 (Standard errors in parentheses)

DISCUSSION AND CONCLUSIONS

EDs are getting more crowded due to the increasing level of diagnostic and treatment intensity (e.g., more clinical tests) for many maladies and the use of advanced medical technology (e.g., advanced imaging, particularly CT scanning) (Pitts, Pines, Handrigan, & Kellerman, 2012). Between 1997 and 2007, the increase in total annual ED visits almost doubled compared to what would be expected from population growth (Tang, Stein, Hsia, Maselli, & Gonzales, 2010). Transferring patients to another hospital may not only provide timely care for patients with time-sensitive conditions, but also helps alleviate hospital congestion (Iwashyna, Christie, Kahn, & Asch, 2009a; Russell et al., 2015). Moreover, hospital nursing resources in the US are in short demand (Rosseter, 2014). Transferring patients to hospitals where they can be cared for more efficiently may save overall nursing resources.

Contributions

IHT management is associated with challenging communication and information sharing that frequently breaks down, causing adverse clinical outcomes and wasting care resources. Understanding the characteristics and the impact of IHT on care efficiency may help hospitals make better transfer decisions. Our study investigates this subject using data from all of the hospitals within the state of Florida and considering all patient conditions. This is in stark contrast to existing studies that use a single hospital setting or consider a single disease. Our study makes two main contributions.

First, our study delineates the fundamentally different characteristics between clinical and nonclinical transfers, use OIPT to analyze the different coordination mechanisms adopted in each IHT type, and technically differentiates the two IHT types using empirical data. We show that clinical transfers are more routinized than non-clinical transfers. Very few studies have conceptually differentiated between the two IHT types, and none have technically separated them. Our empirical approach rigorously differentiates between clinical transfers and non-clinical transfer and the method can be used by future studies.

Second, we demonstrate the varied impacts of the two IHT types on care quality and care efficiency. Specifically, non-clinical transfers are associated with worse care quality and care efficiency than clinical transfers. Further, compared with direct admissions, non-clinical transfers have clearly worse care efficiency, while clinical transfers have not much different care efficiency. The varied impacts imply that coordination mechanisms (which are abundant in clinical transfers but lack in non-clinical transfers) are critical to meeting information processing demand in IHT.

Transferring within the same healthcare system has been shown to overlook care quality for certain diseases when IHT types are not differentiated (Lu & Lu, 2018). Our findings complement this view. We find Pareto sets of destination choices for the two IHT types. When both care quality and care efficiency are considered, in-system destinations are better for non-clinical transfers and our-of-system destinations are better for clinical transfers.

Managerial Implications

Hospital staffs generally view IHT as a burden because of the process complexity and the additional coordination work involved (Bosk et al., 2011). In many situations, the feeling of burdensomeness originates from the lack of understanding of the characteristics and impacts of IHT, as well as evidence-based destination choice guidelines. Our research provides new specific suggestions to IHT operations. Knowing that non-clinical transfers are less routinized, lack coordination, and incur worse care quality and care efficiency than clinical transfers, hospitals management may implement more coordination mechanisms, e.g., standardized processes, strategic planning, and long-term stable partnership with receivers, to improve the care performance. Hospitals can even consider reducing the volume of non-clinical transfers though better planning and resource allocation.

Hospitals prefer to transfer within healthcare systems for the convenience of communication and coordination as well as for the system's financial interest. This practice may be improved.

Knowing the transfer-type-specific impacts of system-based destination choices, hospitals may form different transfer destination guidelines for the two IHT types. For non-clinical transfers, hospitals may keep their current same-system preference for the communication and coordination advantage. For clinical transfers, hospitals may choose out-of-system destinations for better care quality.

Limitations and Future Research Directions

We take an evidence-based approach to differentiate IHT types, i.e., the classification completely base on the historical diagnosis and procedure records in discharge data. While this approach is objective, in some scenarios, it may not completely reflect the actual transfer situations. Moreover, our study is in the setting of Florida and the results may not hold in states that have drastically different healthcare policies than that of Florida. Future research may verify our results in settings of other states.

Our IHT type classification method may be used by future IHT-related researches. For example, studies predicting patient transfers may consider that in some cases (clinical transfers) hospitals don't have the option not to transfer while in other cases (non-clinical transfers) have that option. Studies of care regionalization may need to filter non-clinical transfers when examining the effect of regionalization on care quality or care efficiency.

Most of the extant studies of the IHT destination choice problem focus on the sending hospitals' decision, however, a transfer arrangement is a result of negotiation between the sending and the receiving hospitals. The receiving hospital faces the problem of how to prioritize bed assignment between different IHT types as well as between IHT and direct admissions. Furthermore, with the implementation of the readmission penalty by CMS, hospitals probably don't want to expose themselves to penalty risks and need to make decisions of considering the different odds of readmission between clinical and non-clinical transfers.

Information sharing and task coordination is the key to IHT management. Hospitals' adoption of electronic health records (EHR) systems and their interoperability affects IHT management (Bosk et al., 2011; Usher, Sahni, Herrigel, Simon, Melton, Joseph, & Olson, 2018). Future research may explore the effect of hospitals' use of EHR on the coordination mechanisms existing in different transfer types.

APPENDIX - TABLES

Table 3 Most Frequent Principle Diagnosis Codes

Code	Description	Count	In-system	Out-of-system	Clinical	Non-clinical
109	Acute cerebrovascular disease	994	43.46%	38.03%	58.35%	41.65%
100	Acute myocardial infarction	931	54.99%	25.24%	84.43%	15.57%

Flexible Staffing of Retail Sales and E-Fulfillment Associates to Maximize Profits

ABSTRACT

Some brick-and-mortar stores utilize existing sales associates to fill online orders during slow periods, while others rely on dedicated staff for each operation. We formulate a profit-maximizing mathematical program to evaluate alternative staffing strategies for retailers with in-store fulfillment operations. In experiments simulating different customer traffic patterns, traffic variability, and forecast accuracy, we measure expected profits, the flows of flexible staff between sales and fulfillment, and the sensitivity of those metrics to different market and employee characteristics. We find that fulfillment operations with as few as one cross-trained employee are more profitable than those with dedicated sales and fulfillment staff.

KEYWORDS: Retailing, Workforce staffing, Shift scheduling, Mathematical programming

INTRODUCTION

By Q2, 2017, online purchases represented about 8.9% of all U.S. retail sales and were increasing at an annual rate of 16.2%; much faster than overall retail sales growth rate of 4.1% (US Dept Commerce, 2017). Recognizing opportunities for growth, nearly half of the traditional retailers responding to a recent survey were planning or had already implemented an omni-channel distribution strategy (Forrester Research, 2014). An event study by Xia & Zhang (2010) found that publicly-traded retailers with an omni-channel presence experienced improved sales, expenses, and ROI. Besides the top-line benefits from increased geographic reach, assortment, and 24-7 availability, omni-channel strategies reduce costs and improve ROA through increased buying power with suppliers, lower transaction costs, and smaller inventories. To achieve these synergies, however, the marketing and operational strategies for in-store and online channels must be carefully integrated (Bendoly, Blocher et al., 2007; Zhang, Farris et al., 2010).

Order fulfillment remains one of the most costly processes for online retail enterprises (de Koster, 2002). The key elements of an online order fulfillment strategy include inventory location (centralized, decentralized, or drop-shipped directly from the manufacturer or wholesaler), warehouse organization (integrated or segregated picking locations for store replenishment and online orders), physical distribution (allocation of on-line orders to fulfillment sites, picking and packing, delivery destinations, transportation modes, and pick-up or delivery scheduling), and merchandise returns. Because the relevant information is easily digitized, some or all parts of the online order fulfillment process can be readily outsourced to third-party vendors (Perdikaki, Peng & Heim, 2015). However, many prominent U.S. omni-channel merchants (Best Buy, Dick's Sporting Goods, Lowe's, Nordstrom's, and Wal-Mart, among others) fulfill online orders from their own stores – for two important reasons (Rueter, 2014; Sheldon et al., 2014). First, a retail store is often closer to the buyer than any distribution center, so a ship from store strategy may reduce shipping time and shipping costs. Second, the real-time inventory visibility needed to support a ship from store strategy enables virtual pooling of retail demand across all store locations and the online channel (Mahar, Bretthauer & Venkataramanan, 2009), reducing chain-wide markdowns and stockouts due to forecast errors.

Countering these benefits, retailers pursuing in-store order fulfillment strategies must invest in staff training and provide enough space, equipment, packaging and staff time to support fast error-free picking and packing (Cunnane, 2015). Some ship from store retailers rely on their sales associates to fill online orders during slow periods (Fowler & Dodes, 2010; Reuter, 2014). However, diverting associates from the selling floor can imperil in-store sales (Fisher, Krishnan & Netessine, 2009; Ryan, 2014) and may adversely affect productivity through changeover losses whenever workers transition between sales and fulfillment tasks (Nembhard, 2014). To avoid such losses, other stores employ dedicated associates to pick and pack online orders (Partridge, 2013). However, the work rules governing employee schedules and the inherent variability of online order volume make it difficult to achieve a perfect match between the quantity of scheduled labor and the amount of labor needed to fill online orders, resulting in costly under- or over-staffing (Mani, Kesavan & Swaminathan, 2015).

While Quan (2004) and Lang (2010) summarized many of the issues related to retail labor staffing and scheduling, few analytical models have been developed for such decisions (Van den Bergh et al., 2013). Traditionally, retail staffing and scheduling decisions begin with demand planning (Netessine, Fisher & Krishnan, 2010), or forecasts of hourly (or more frequent) store sales. Those forecasts are then translated to the labor requirements for each planning interval, for up to a few weeks into the future, that drive workforce scheduling decisions. However, existing retail staffing and scheduling models may be ill-suited for retail operations with in-store fulfillment because they do not allow for the transfer of cross-trained workers between sales and e-fulfillment areas and fail to recognize heterogeneous task priorities.

To more accurately evaluate staffing alternatives for in store fulfillment operations, we propose a contribution-oriented workforce staffing and scheduling model for retail operations that allows for two demand streams – in-store customers and online orders. The sales floor and e-fulfillment areas each have their own skill requirements, and in-store customers have a higher priority because sales may be lost if an insufficient number of sales associates are available when the customers are present. Our model allows modest levels of cross-training and more fully exploits task-switching flexibility and the priority differences between store traffic and online orders than extant retail staffing and scheduling models. To demonstrate the benefits that flexible staffing can provide to retailers with instore fulfillment operations, we applied it in a full-factorial numerical experiment designed to compare the performance of alternate staffing strategies under uncertain in-store traffic.

The remainder of our paper is organized as follows. In the next section, we review the relevant literature. Then, we present our mathematical programming models and solution methods. Starting with a two-stage stochastic program for a single-period, we propose and evaluate a heuristic solution strategy based on expected traffic. We then extend that deterministic approach to a multi-period version of the problem. After that, we describe a numerical experiment based on that model and its results. In the final section, we summarize our findings, point out the limitations of our study, and suggest directions for future research.

LITERATURE REVIEW

Labor-related expenses such as hiring, training, and wage costs account for 10 – 20% of a retailer's costs, typically the largest expense after cost of goods sold (Nettesine et al., 2010).

Thus, a retailer's profitability is significantly affected by the quality of its staffing decisions. For this literature review, we first classify and review retail staffing strategies and the timetabling decisions needed to ensure sufficient capacity for in-store fulfillment of online orders. Then, we take a closer look at the sales response functions incorporated into current contribution-oriented workforce staffing and scheduling models for retail workers.

Retail Workforce Staffing and Scheduling Decisions

Fulfillment operations tend to be labor intensive, and handling costs tend to be the largest single expense for most fulfillment operations. Largely due to space and equipment limitations, in-store fulfillment operations may have higher labor requirements and labor costs per order than centralized fulfillment (Bendoly et al., 2007; Bretthauer et al., 2010). It is also likely that those costs will vary with the types of employees charged with order fulfillment. For example, some retailers like Saks staff their in-store fulfillment operation with dedicated specialists who focus on picking and packing online orders (Partridge, 2013), while other omni-channel retailers ask their sales associates to fill online orders during slow periods on the floor (Fowler & Dodes, 2010; Rueter, 2014). The latter approach combines online and in-store workload, offering the potential for productivity gains through reduced idle times (Schultz, et al., 2003). However, those gains may be offset by the cycle of learning, forgetting, and relearning following an assignment change. For example, Shultz et al. (2003) found that even short-term interruptions due to task switching adversely affects the productivity of cross-trained operators. Nembhard (2014) provides an excellent summary of the research pertaining to the productivity of cross-trained workers.

Staffing decisions for instore fulfillment operations can impact both labor expenses and sales. Although store labor budgets and staffing levels for traditional retailers are often based on monthly sales forecasts (Fisher et al., 2009), empirical studies (Lam, Vandenbosch & Pearce, 1998; Fisher et al., 2006; and Perdikaki, Kesavan & Swaminathan, 2012) find that sales vary with store traffic and staffing levels. Improving the match between store capacity and customer traffic can boost store profitability by 3% or more (Netessine et al., 2010; Chapados et al., 2011). However, retail stores usually operate beyond the normal 8 AM – 5 PM work day and often experience significant hour-to-hour and day-to-day variability in store traffic. In addition, certain times of the year are much busier than others. Due to restrictions on work hours, meal breaks and rest periods, state and federal statutes, and local custom, it can be difficult to match scheduled labor with forecasted demand. Furthermore, work schedules for full- and part-time retail employees are often developed well in advance of the realization of actual demand, so aligning capacity with actual demand may require real-time adjustments in employee work hours and/or task assignments.

Although the literature related to workforce staffing and scheduling is extensive (Van den Bergh, et al. 2013; De Breucker et al., 2015), few existing models are applicable to the retail setting assumed for this research (Mou et al., 2018). Among its distinguishing features, this setting includes multiple demand streams with different skill requirements and priorities, serviced by a mix of specialized and cross-trained employees, where workforce management decisions influence both income and expenses. The key workforce management decisions in such an environment include staffing decisions (S), training decisions (X), scheduling decisions (shift (SS), day-off (DO), or tour (TS) scheduling), and flexible worker assignment (A) decisions (Abernathy et al., 1973). In Table 1 we summarize the key decisions, the primary components of the objective function, and some of the key constraints for a selection of workforce staffing and scheduling models applicable to the assumed operating environment. All the models in Table 1 integrate two or more of these key decisions and can accommodate multiple demand streams, each with its own skill requirements. In the discussion below, we focus on the key similarities and differences between the models' objectives and constraints.

Most of the models in Table 1 track wage costs, but only the recent model by Cuevas et al. (2016), which views labor costs as sunk in the short run, addresses the diminishing impact of additional staff on revenue. Easton (2011) and Henao et al. (2015) incorporate quasi-fixed costs such as benefit and training costs that vary with headcount rather than hours worked. Cuevas et al. (2016) also model task switching costs as linear functions of the duration of the assigned task, incurred whenever a flexible employee is transferred from one task assignment to another. Other models (e.g., Brusco & Johns, 1998; Campbell, 2011; Easton, 2011**)** approximate this loss with reduced productivity when flexible workers are assigned outside their home area. However, Berman & Larson (2004) suggest switching costs in retail services arise from a brief period of non-productive "re-orientation time" by the transferred worker and vary with the number of transfers.

While all of the above models assume multiple demand streams with different skill requirements, where cross-trained employees can service more than one type of demand, none of them appear to recognize priority differences among the different demand streams Billionnet (1999), Campbell (2011), Henao et al. (2015) and Cuevas et al. (2016) confine cross-trained workers to the same task assignment for their entire shift, potentially limiting the value of cross-training. Loucks & Jacobs (1991), Brusco & Johns1998), Billionnet (1999), Cai & Li (2000), Bard (2004), and Easton (2011) require solutions that meet or exceed the staffing goals for each task in each period, and do not allow shortages. In contrast, Campbell (2011) and Henao et al. (2015) both allow under-staffed solutions, while Restrepo et al. (2017) consider target staffing levels as goals and penalize solutions (biased in favor of overstaffing) that deviate in either direction from staffing targets for each task and period. Campbell (2011) imposes a quadratic penalty on any shortage, while Henao et al. (2015) and Restrepo et al. (2017) rely on linear penalties. Loucks & Jacobs (1991) penalize surplus staff, while Cai & Li (2000) propose a secondary objective that encourages its even distribution. Cuevas et al. (2016) do not specify minimum staffing levels but impose upper bounds on the number of workers assigned to a task in each period.

Cross-training flexibility has been shown to mitigate supply – demand mismatches arising from forecast errors, unplanned absences, and employee turnover (Easton, 2011). When cross-trained sales associates also pick and pack online orders, the in-store and online demand streams are effectively pooled, reducing relative demand variability. This should allow retailers to achieve better store performance than a system staffed by the same number of specialists. However, any of the multiskill models in Table 1 assume deterministic demand, a shortcoming previously noted in the extensive review by De Breucker et al. (2015). Campbell (2011) and Restrepo et al (2017) address uncertainty through two-stage stochastic programs, establishing time-tabling decisions for employees in stage 1, postponing recourse decisions such as task and rest-break assignments in stage 2 after actual demand is revealed.

Finally, well-known service quality instruments like SERVQUAL (Parasuraman et al., 1988) have long assigned a prominent role to "responsiveness" in the assessment of customer satisfaction. By prioritizing in-store customers over online order fulfillment, increased service levels may result in increased sales and revenue. While events such as the arrival of a customer at the store may require a near-immediate response, order fulfillment tasks are often interruptible as well as postponable (Berman & Larson, 2004). An online order could remain queued without ill effect provided it is processed some time before the latest outbound parcel pickup of the day. However, none of the models in Table 1 acknowledge priority differences among the multiple demand streams. The distinct temporal priorities for each demand stream, as well as the flexibility to divert online orders to other fulfillment centers when necessary, could also temper the effects of positively correlated demand streams on cross-training performance.

Thus, these limitations may cause existing retail staffing and scheduling models to undervalue the benefits of cross-training flexibility.

Table 1: Key decision variables, objective function components, and constraints for selected integrated staffing, scheduling and allocation models for multi-skill workforce

Multi-skill Workforce Mgt Model	Decis-ions	Objective Function Terms					Constraints

Sales response functions

Queueing theory suggests that decreasing the number of sales associates on the floor will increase waiting time and the likelihood that impatient customers in the store will leave without buying. Grewal, Baker et al. (2003) confirmed the importance of perceived waiting, finding that once in the store, customer purchase intentions are influenced by their expectations about waiting. More store employees visible on the sales floor tends to produce favorable wait expectations, while increased customer density on the sales floor results in more negative expectations. Fisher & Raman (2010) explained that retail staffing levels influence store sales in two ways: directly through the level of sales assistance available to shoppers, and indirectly through execution of store operational activities such as stocking shelves, tagging merchandise, and maintaining the overall store ambience. Netessine et al. (2010) found the practice of matching sales associates to store traffic rather than sales forecasts resulted in larger mean purchases. Perdikaki et al. (2012) confirmed that retail store sales tend to increase with store traffic, but at a decreasing rate that is moderated by sales associate staffing levels.

Lam et al. (1998) were among the first to propose a two-input sales response function conditioned on store traffic (λ) and the sales associate staffing level (W_h) during time h, where:

$$S_{Wh} = \alpha\, [\lambda_h^{\beta}]\, [e^{-\Upsilon/Wh}]. \tag{1}$$

In their model, S_{Wh} represents sales in period h conditioned on store traffic and staffing levels. Parameter α represents the "sales potential," or mean purchase amount for customers who make a purchase. The bracketed expression following α is the number of shoppers in the store who are "buyers." Reasoning that sales should increase with traffic at a decreasing rate, Lam et al. (1998) confined traffic elasticity β to the interval $0 < \beta < 1$. The parameter Υ in the bracketed expression on the right is usually defined as the responsive-ness of sales to labor. With $\Upsilon > 0$ and staffing level $W_h \geq 1$, the expression $\exp(-\Upsilon/W_h)$ can be interpreted as the fraction of "patient" store traffic willing to remain in the store and complete their purchases, which decreases in Υ at a rate moderated by W_h.

In their empirical study, Mani et al. (2015) found that the fitted values for traffic elasticity β for an apparel retailer tended to be higher during weekdays (when the ratio of traffic to staffing is lower) and lower on the weekends (when the ratio of traffic to staffing is larger). Asserting that traffic elasticity β should depend on both traffic and staffing levels, Chuang et al. (2016) proposed alternate ways to model and estimate sales response functions. However, both measuring and predicting store traffic remain challenging (Chapados et al., 2014; Song, 2015), particularly at the resolutions required for operational decisions such as staffing and scheduling. Complicating factors include nested seasonality and the impact of traffic drivers such as pricing, promotion, product mix, competitive actions, and political, economic, meteorological and cultural events.

MODELS, SOLUTIONS, AND BOUNDS

Our literature review suggests that omni-channel retailers planning instore fulfillment operations may find existing retail staffing and scheduling models inadequate, for the following reasons:

- Most contribution-oriented retail staffing and scheduling models tend to ignore differences in the skills needed to respond to different requirements, and they ignore priority differences between in-store traffic and postponable, interruptible online orders.
- Despite a well-established relationship between store traffic, staffing levels and store sales, most cost-oriented retail workforce management models ignore the diminishing marginal revenue produced by additional staff and, in some cases, assess penalties if scheduled staffing exceeds exogenous targets.

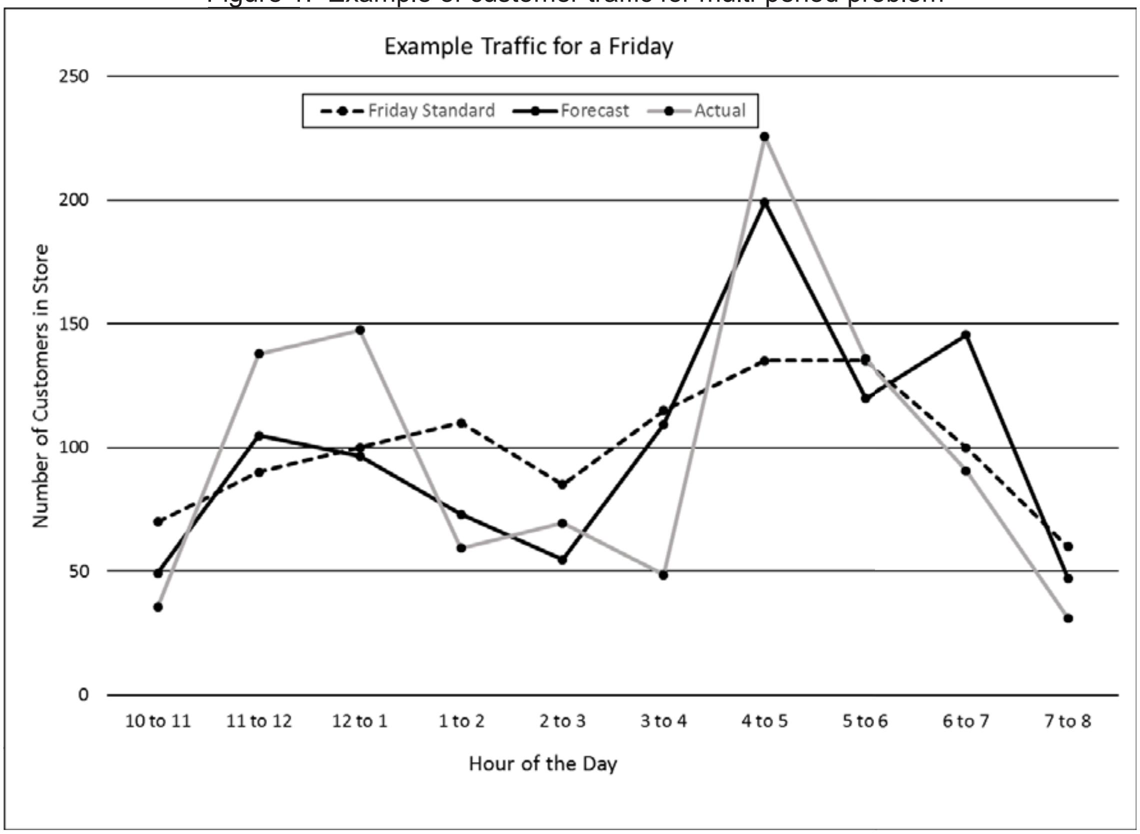
This study begins to address these limitations by developing models for use in investigating alternative staffing strategies (dedicated versus multi-skilled workers) for retailers with in-store customers and online orders.

Overview of models and solution methods

We assume the retailer services two distinct demand streams: assisting in-store customers and fulfilling online orders. An example of in-store customer traffic for the multi-period decision problem appears in Figure 1. Hourly store traffic varies by time of day, day of the week, and season. The three hourly traffic curves shown in Figure 1 represent mean, forecasted, and actual traffic for a Friday. When actual traffic is less than forecasted, we assume that any on-duty sales associate can be temporarily assigned to help fulfill online orders and contribute to fulfillment capacity, albeit less proficiently than a fulfillment specialist. We also assume there are a limited number of in-store fulfillment associates trained to assist on the sales floor. At any hour, store managers can review current actual traffic and decide whether sales associates can profitably be assigned to fulfillment tasks, or whether any cross-trained fulfillment associates can be profitably diverted to the sales floor.

The complexities of the stochastic, multi-period environment shown in Figure 1 make it difficult to obtain optimal solutions to problems of realistic size, even for versions that do not allow for cross-utilization. For purposes of evaluating the value of cross-utilization, which is the main focus of our study, we develop heuristic solution procedures based on deterministic versions of the multi-period problems. To demonstrate the effectiveness of the heuristics, we compare their performance against optimal solutions based on single-period versions of the stochastic problems, obtained using Monte Carlo methods.

Figure 1: Example of customer traffic for multi-period problem



We begin by presenting two single-period stochastic staffing models. The first is similar to the single-period contribution-oriented staffing model for sales associates described in Lam et al. (1998) and Henao et al. (2016). The second model has two stages: stage 1 staffing, which must be completed long before actual traffic is known; and stage 2 recourse, which allows flexible sales and fulfillment staff to be reassigned at the beginning of a period based on realized customer traffic. We use the two-stage single-period stochastic model to define upper bounds and demonstrate the performance of a heuristic solution approach based on a deterministic version of the problem, which is then extended to a multi-period environment.

Contribution-oriented stochastic program for single-period staffing.

In seeking to maximize profit contributions for a single period, equation (1) can be used within an objective function. W, the number of workers, is an integer decision variable, for which we set lower and upper limits of L and M, respectively. At the time when staffing is performed, customer traffic is a random variable, $\boldsymbol{\lambda}$, with mean $\hat{\lambda}$. A single-period model based on Lam et al. (1998) can be stated as follows:

$$\underset{W}{\text{Maximize}} \{g \ \alpha\boldsymbol{\lambda}^{\beta}e^{-\Upsilon/W} - \ cW\} \tag{2}$$

$$\text{Subject to:} \quad L \leq W \leq M \text{ and integer,} \tag{3}$$

where g is the gross profit margin (e.g., 51% as in Lam et al., 1998) and c is the periodic wage rate for the sales associates. Definitions for the sales response function parameters α, λ, β, and γ were introduced previously following equation (1).

Lam et al. (1998) present optimality conditions derived from mean forecasted store traffic and forecast error variance. For our study, we adopt a heuristic approach by solving a deterministic version of the problem that substitutes $\hat{\lambda}$ for $\boldsymbol{\lambda}$:

$$\underset{W}{\text{Maximize}} \{g \ \alpha\hat{\lambda}^{\beta}e^{-\Upsilon/W} - \ cW\} \tag{2'}$$

$$\text{Subject to:} \quad L \leq W \leq M \text{ and integer} \tag{3}$$

For the single-period deterministic version of the problem, an optimal solution W* is easily obtained through enumeration. As a heuristic solution strategy, substituting the unbiased estimator $\hat{\lambda}$ for the random variable $\boldsymbol{\lambda}$ is both computationally efficient and practical, especially when forecast error variance cannot be reliably estimated. Furthermore, as Chapados et al. (2014) noted, the contribution function for profit-oriented retail scheduling decisions tends to be fairly flat near its maxima. Using Monte Carlo simulations with 100 replications of actual customer traffic for each of 60 different hourly customer traffic distribution parameter/sales model parameter combinations (described in section 4), the optimal solutions to the model given by (2') - (3) resulted in staffing levels with the highest profits for 52 of the 60 cases. For the 8 cases where heuristic solutions resulted in lower profits based on the Monte Carlo sampling, the average difference in profits was 0.12%, and the maximum difference was 0.29%. This supports the use of the deterministic approach based on mean forecasted customer traffic $\hat{\lambda}$ for generating solutions to single period problems that do not allow for cross-utilization. The next section builds on this result to model situations where reallocation of flexible workers is permitted at the beginning of the period based on actual customer traffic.

Stochastic program with recourse for staffing and scheduling for a single period.

Extending the single-period staffing model for sales associates in (2) – (3), we next consider a two-stage, single-period model with multi-skilled sales associates and a limited number of cross-trained fulfillment staff. Using forecasted traffic, the Stage 1 model determines the ideal staffing level for sales associates, each of whom is also trained to perform fulfillment tasks when necessary. The Stage 2 recourse model allows appropriately-trained workers to shift between the sales floor and the warehouse in response to differences between predicted and actual customer traffic. A summary of model parameters and decision variables is shown in Table 2.

Table 2: Model parameters and decision variables

Model Parameters:	
L, M	lower, upper bounds for number of sales associates on duty. Sales associates are indexed k = 1, …, M.
$\boldsymbol{\lambda}$, $\hat{\lambda}$, λ	random, mean forecasted, or actual customer traffic during the hour.
c	sales associate hourly wage rate.
b	fulfillment associate hourly wage rate, where $b \leq c$.
g	gross profit margin (e.g., 51% as in Lam et al., 1998).
P_f	relative proficiency of workers transferred *from* sales to fulfillment operation.
P_t	relative proficiency of workers transferred *to* sales from fulfillment operation.
U	maximum number of workers that can be moved to the sales floor each hour.
Stage 1 decision variable:	
W	number of sales associates scheduled in advanced for the hour.
Stage 2 recourse variables:	
T	number of fulfillment associates moving to sales floor at the beginning of the hour.
F	number of sales associates moving from sales floor at the beginning of the hour.

Single-Period Stage 1 Model: Contribution-oriented sales associate staffing

$$\underset{W}{\text{Maximize}} \ \{E_{\boldsymbol{\lambda}}\,[Q(W,\boldsymbol{\lambda})] - cW\} \tag{4}$$

$$\text{Subject to:} \quad L \leq W \leq M \text{ and integer} \tag{3}$$

Note that $E_{\boldsymbol{\lambda}}[\,]$ denotes the mathematical expectation with respect to the random variable $\boldsymbol{\lambda}$.

Single-Period Stage 2 Model: Cross-utilization recourse after actual customer traffic is known

$$Q(W,\lambda) = \underset{F,T}{\text{Maximize}} \ \{g\,\alpha\,\lambda^{\beta}\,e^{-\Upsilon/(W+P_tT-F)} + P_f\,F\,b - T\,b\} \tag{5}$$

$$\text{Subject to:} \quad T \leq U \tag{6}$$

$$F \leq (W - L) \tag{7}$$

$$F, T \in \{\text{non-negative integers}\} \tag{8}$$

The problem shown above is a two-stage stochastic program with integer decision variables (see Birge & Louveaux, 2011). The solution to the stage 1 model establishes the staffing levels for retail sales associates (W) for the period, which constrain the subsequent stage 2 assignment decisions (T and F, the recourse variables) that are made at the beginning of the period. At that time, sensors reveal actual store traffic, λ, and management decides how to best deploy their on-duty multi-skilled staff.

When T fulfillment associates with sales proficiency P_t are reassigned to the sales floor to assist the W sales associates already on duty, we expect a proportionate increase in sales. However, we assume that the capacity diverted from the in-store fulfillment operation must be replaced, possibly through assistance from sales associates at other times of the day, or by either increasing local fulfillment staffing levels at cost Tb or diverting some local fulfillment load to another fulfillment center in the chain. Similarly, when F sales associates are temporarily reassigned to fulfillment duties, store sales will decrease. However, the shift also reduces labor expenses in the warehouse by P_fFb, where P_f is the average relative proficiency of sales associates assigned to fulfillment duties.

Constraint (6) limits the number of cross-trained fulfillment associates that can be deployed to the sales floor (T) to the number trained for such work (U). Constraint (7) ensures that at least L sales associates will remain on the sales floor at all times. Due to the restricted range of values for integer variables T and F, stage 2 optimal solutions can be obtained through simple enumeration. The objective function ensures that at most one of T and F will be non-zero, because with both P_t and P_f both < 1, it would never be profitable to transfer workers both to and from the sales floor in the same period.

To optimally solve stage 1 of the stochastic programming problem, we require additional information about the distribution of λ. Barring that, however, we can still obtain an upper bound for its solution. For upper bounds, we define the following:

Z_{PI} -- the optimal stage 1 profit with perfect store traffic information.

Z_{ub} -- an upper bound corresponding to the optimal profit when stage 2 is solved with:

1) no constraint on U; 2) the wage premium (c-b) charged only for worker-hours used for transfers to the sales floor; and 3) $P_f = P_t = 1.0$.

For the single-period problem, $Z_{ub} = Z_{PI}$. However, because work rules such as such as the minimum or maximum shift length tie the periods together, this may not be the case for multi-period problems.

To establish a heuristic solution, the following stage 1 problem based on mean forecasted customer traffic ($\hat{\lambda}$) can be solved:

$$\underset{W}{\text{Maximize}} \{g\ \alpha\hat{\lambda}^{\beta}e^{-\Upsilon/W} - cW\} \tag{2'}$$

$$\text{Subject to:} \qquad L \leq W \leq M \text{ and integer} \tag{3}$$

This formulation is the same deterministic model presented in section 3.2. Let W* be the optimal solution for (2') – (3), easily obtained through enumeration. Once actual traffic λ, is known, the following represents the profit that would be realized if no cross-utilization were used:

$$\text{Profit without cross-utilization} = Z_{w/o} = \{g\ \alpha\lambda^{\beta}e^{-\Upsilon/W*} - cW^*\} \tag{9}$$

With W* as a starting point, the stage 2 problem can be solved to obtain the following:

$$\text{Profit with cross-utilization} = Z_{xu} = Z_2{*} - cW^* - U(c-b), \tag{10}$$

where $Z_2{*} = Q(W^*, \lambda)$ and sales associate wages cW^* and wage premiums (c-b), if any, paid to the U cross trained fulfillment workers on duty (which are paid regardless of where they are assigned to work).

<u>Performance measures:</u>

Let **\$xu** be the mean value for (Z_{xu} - $Z_{w/o}$), representing the average value of cross-training flexibility under uncertain demand, and **%xu** be the percentage (**\$xu**/$Z_{w/o}$). Let **\$pi (%pi)** represent the mean (percentage) difference between Z_{PI} and $Z_{w/o}$, a measure that captures the impact of demand uncertainty without cross-training flexibility. Finally, define **\$ub** (**%ub**) as the mean (percentage) difference between Z_{ub} and $Z_{w/o}$, a measure of the potential improvement in profits attainable with completely accurate forecasts, complete scheduling flexibility, unconstrained redeployment of cross-trained staff, and flexible workers with task proficiencies comparable to dedicated workers. In our computational study, we also report the mean flows from and to the sales floor (consequence variables **Fxu**, **Txu** from the stage 2 cross-utilization solution) and compare them to **Fub and Tub**. Although these performance measures have been defined based on the single-period models and solutions, they also apply for multi-period cases, which are described next.

Deterministic staffing and scheduling models for multiple periods.

The multi-period stage 1 problem builds on (2') by including constraints for allowable schedule patterns such as the minimum and maximum allowable shifts, allowable start times, etc. We add the index h, representing one of the H periods in the planning horizon, to model parameters and variables $\hat{\lambda}$, λ, W, T, and F (defined in Table 2). Table 3 defines additional notation used with the multi-period model.

Table 3: Parameters and decision variables for multi-period formulation

Additional Model Parameters:	
H	number of hours in planning horizon. Hours are indexed h = 1,…H.
N	number of different shift patterns. Shift patterns are indexed j = 1,…,N.
a_{hj}	1 if hour h is a work period for shift pattern j, 0 otherwise; ∀ h, j.
$\hat{s}_{hk}$, s_{hk}	mean forecasted marginal sales, actual marginal sales (based on eq. 1) produced during hour h by k^{th} sales associate based on forecasted, actual traffic; ∀ h, k.
C_j	wage cost per sales associate assigned to shift pattern j.
Additional Stage 1 Decision Variables:	
X_j	number (integer) of sales associates who work shift pattern j, j=1,…,N.
Y_{hk}	binary variable for k^{th} on-duty sales associate in hour h, equal to 1 if $\sum_{j=1}^{N} a_{hj}X_j \geq k$, 0 otherwise.

<u>Multi-Period Stage 1 Model: Deterministic contribution-oriented sales associate staffing</u>

$$\underset{\forall X,Y}{\text{Maximize}} \quad Z_1 = g\sum_{h=1}^{H}\sum_{k=1}^{M} Y_{hk}\hat{s}_{hk} - \sum_{j=1}^{N} C_jX_j \tag{11}$$

Subject to:

Relate sales associates on duty during period h (W_h) to number assigned to shift pattern j (X_j):

$$\sum_{j=1}^{N} a_{hj}X_j - W_h = 0; \; h=1, \ldots, H \tag{12}$$

Fix minimum and maximum staffing level for sales floor during operating hours:

$$L \leq W_h \leq M; \quad h=1, \ldots, H \tag{13}$$

Count on-duty sales associates to compute revenue for each hour:

$$W_h - \sum_{k=1}^{M} Y_{hk} \geq 0; \; h=1, \ldots, H \tag{14}$$

$$Y_{hk} - Y_{h,k-1} \leq 0; \; h=1, \ldots, H \text{ and } k=1, \ldots, M. \tag{15}$$

Other constraints: $X_j \geq 0$ and integer $\forall$ j; $Y_{hk} \in \{0,1)$ $\forall$ h,k (16)

Period h Stage 2 Model: Cross-utilization recourse after actual customer traffic is known in hr. h:

$$\underset{F_h, T_h}{\text{Maximize}} \; Z_{2h} = \left[g\left[\sum_{k=1}^{W_h-F_h} s_{hk} + P_t \sum_{k=W_h+1}^{W_h+T_h} s_{hk}\right] + P_f F_h b - T_h b\right] \quad (17)$$

Subject to:

$$T_h \leq U \quad (18)$$

$$F_h \leq (W_h - L) \quad (19)$$

$$F_h, T_h \in \{\text{non-negative integers}\} \quad (20)$$

For the multi-period stage 1 problems in this paper's computational study (see section 4), shift patterns (a_{hj}) are defined based on four-hour shifts, which is consistent with Lam et al. (1998), Mani et al. (2015), and Quan (2004). With multi-hour shifts in the formulation, the stage 1 multi-period problem is more complex than the deterministic single-period problem given by (2') - (3) and requires integer programming solution methods. For moderate problem instances, such as the stage 1 problems modeled in our computational study (7 general integer and 400 binary integer variables), optimal solutions for the stage 1 model given by (11)- (16) can be readily obtained with commercial optimization software such as the IBM ILOG CPLEX (2017).

The hourly stage 2 recourse problems are always feasible, and optimal solutions (Z_{2h}*) can be obtained through simple enumeration over the restricted range of values for integer recourse variables T_h and F_h (the objective function ensures that at most one will be non-zero). The hourly problems are independent of each other because the number of sales associates scheduled for period h (W_h) is fixed when stage 1 is solved – in practice, this corresponds to shift schedules for sales associates that are established in advance based on forecasted customer traffic.

For multi-period problems, the following apply:

$$\text{Profit with cross-utilization} = Z_{xu} = \sum_{h=1}^{H}[Z_{2h}^* - cW_h - U(c-b)] \quad (21)$$

$$\text{Profit without cross-utilization} = Z_{w/o} = g\sum_{h=1}^{H}(\alpha \lambda_h^{\beta} e^{-\Upsilon/W_h}) - \sum_{j=1}^{N} C_j X_j \quad (22)$$

Also, with multi-hour shifts, the following relationship between bounds and heuristic solutions apply:

$$Z_{ub} \geq Z_{PI} \geq Z_{w/o} \quad (23)$$

Where:

Z_{PI} -- the optimal stage 1 profit with perfect store traffic information; and

Z_{ub} -- an upper bound corresponding to the optimal profit when stage 2 is solved with: 1) no constraint on U; 2) the wage premium (c-b) charged only for worker-hours used for transfers to the sales floor; and 3) $P_f = P_t = 1.0$.

Performance measures for multi-period problems are the same as those defined earlier for the single-period problem. These performance measures are summarized in Table 5, presented in the next section.

NUMERICAL EXPERIMENTS

To evaluate the benefits of flexible workers, we simulated the operation of a hypothetical omni-channel retailer that operates for seven days/week, 10 hours per day. Assuming part-time sales associates who work 4-hour shifts/day, we established bounds on profitability and measured changes in profitability and the flows of flexible workers between the sales floor and the fulfillment operation when a few fulfillment associates are trained to assist on the sales floor.

In the US, mean hourly wages for retail employees and for warehousing & storage workers are nearly the same (BLS, 2015), so we fixed the wages for both sales and fulfillment associates at $12/hr. After Schultz et al. (2003), we assumed that cross-trained associates are less proficient than dedicated employees when working outside their primary area. In our main numerical experiment, we fixed P_f and P_t at 80%, and limited the number of cross-trained fulfillment associates to U = 1. However, the value of flexibility depends on both the number and the relative proficiency of cross-trained associates, so we performed additional sensitivity analysis with values of P_f and P_t ranging from 0.70 to 1.0 and for $1 \leq U \leq 3$.

To facilitate replication, we adopted the sales response model S (eq. 1) and gross profit margin (51%) from Lam et al. (1998). Due to the heterogeneity of the different retail enterprises they examined, Lam et al. (1998), Kabak et al. (2008), and Mani et al. (2015) found quite different values for the sales response model coefficients used in their studies. Viewing the staffing level W_h as endogenous, we used their fitted values to establish ranges for the experimental sales response model coefficients α (average purchase amount), Υ (related to customer patience), and β (traffic elasticity) used in our study. For our main numerical experiment, we fixed the sales response model coefficients at their medium values. To isolate the influence of these parameters on results, however, we also performed additional sensitivity analysis with these parameters at their low, medium, and high values. Those values are shown in Table 4.

Table 4: Experimental parameters for store traffic and sales response function

Finally, we combined store traffic data from Mani et al. (2015), Lam et al. (1999), and other publicly available retail traffic studies to create the average store traffic patterns $\bar{\lambda}_h$ shown in Table 4. We assumed that weekday (Mon – Thr) traffic averaged 600 customers per day, while on weekends (Fri-Sun), mean traffic per day increased to 1,000. Because the benefits of flexibility tend to increase with increasing variability (Iravani et al., 2011, among others) we simulated traffic forecasts $\hat{\lambda}_h$ for each period by sampling from the normal distribution $N(\bar{\lambda}_h, CV\bar{\lambda}_h)$. Consistent with Thompson (1992) and Mani et al. (2015), we used three different CV levels (CV = 0.2, 0.4, or 0.6) to generate the forecasts. The sample values were then normalized to ensure that the average daily demand for the test problems corresponded to the assumed values (e.g., weekdays = 600/day; weekends = 1000/day), with negative hourly traffic forecasts truncated to zero. Actual hourly traffic values λ_h were simulated by adding a random forecast error term ε_h to the forecast (e.g., actual hourly traffic $\lambda_h = \hat{\lambda}_h + \varepsilon_h$). The error terms were generated by sampling from a normal distribution with mean 0 and a standard deviation corresponding to one of the three levels of forecast accuracy: % mean absolute deviation (%MAD) = 12%, 24%, or 36%. The 12% and 24% values are similar those reported in Mani et al. (2015), and the 36% level represents higher forecast errors.

Main Experiment Results

Our main numerical experiment examined the impact of store traffic on performance: specifically, the mean hourly traffic for each day, the coefficient of variation of forecasted traffic, and forecast error. Fixing the sales response parameters (α, Υ, and β) at their medium values (see Table 4), with $P_f = P_t = 0.8$ and U = 1, we used a full factorial design with three levels each for store traffic (Mon-Thr, Friday, and Sa-Su), CV, and %MAD factors, with five replications for each of the 27 experimental cells. For each test problem, we solved with and without cross-utilization to obtain the four objective measures described in the previous section ($Z_{w/o}$, Z_{xu}, Z_{ub}, and Z_{PI}). From them, we computed ten absolute and relative measures to help establish the value of cross-training flexibility. Table 5 shows the overall mean values and standard errors for those measures.

Compared with dedicated sales and fulfillment associates, cross-utilization helped increase expected daily profits by an average of **$xu** = $ 39.51 (**%xu** = 1.81%). In contrast, perfect information about customer traffic lifted daily profits for dedicated staffing strategies by only **$pi** = $18.11 (**%pi** = 0.96%) -- roughly half that achieved with flexible workers -- supporting previous experimental findings that cross- training flexibility may be more valuable than perfect information (Campbell, 2011). The upper bound results of $95.88 (4.16%), when compared against $**xu** and %**xu**, provide an indication of the losses associated with the 80% worker efficiencies and limitation on U assumed for the cross-utilization solutions. These losses are evaluated more closely in the sensitivity analysis presented in a later section.

Table 5: Results summary, main numerical experiment

Performance Measure	**Grand Mean**	**Standard Error**
$ profit increase with cross-utilization (**$xu)** = ($Z_{xu}$ - $Z_{w/o}$)	$39.51	$4.66
$ profit increase with perfect information (**$pi)** = ($Z_{PI}$ - $Z_{w/o}$)	$18.11	$2.16
Upper bound for $ profit increase (**$ub) = (**$Z_{ub}$ - $Z_{w/o}$)	$95.88	$7.92
% profit increase w/cross-utilization (**%xu) =** [(Z_{xu} - $Z_{w/o}$)/ $Z_{w/o}$]*100	1.81%	0.24%
% profit increase w/perfect information (**%pi)** = [(Z_{PI} - $Z_{w/o}$)/ $Z_{w/o}$]*100	0.96%	0.17%
Upper bound on % profit increase (**%ub)** = [(Z_{ub} - $Z_{w/o}$)/ $Z_{w/o}$]*100	4.16%	0.35%
Mean workers/hour from sales floor F_h | P_f = 0.8 (**F_{xu}**)	0.86	0.07
Mean workers/hour to sales floor T_h | P_t = 0.8 (**T_{xu}**)	0.19	0.01
Mean u. bound, workers/hr from sales floor F_h | P_f=1.0, U = ∞ (**F_{ub}**)	1.43	0.08
Mean u. bound, workers/hr to sales floor T_h | P_t=1.0, U = ∞ (**T_{ub}**)	1.09	0.05

Table 5 also summarizes the mean number of flexible workers moving from and to the sales floor. For solutions with cross-utilization and 80% proficiency, $\mathbf{F_{xu}}$ and $\mathbf{T_{xu}}$ averaged 0.86 and 0.19, respectively. For Z_{ub}, the upper bound solutions, cross-trained worker proficiencies equal their dedicated colleagues (i.e., $P_f = P_t = 1$) and U is relaxed to permit unrestricted movement to the sales floor. The upper bound solution values $\mathbf{F_{ub}}$ = 1.43 and $\mathbf{T_{ub}}$ = 1.09 suggest that with increased cross-training and proficiency, movement to the sales floor is likely to increase at a faster rate than movement from the sales floor.

Table 6: ANOVA results for the main numerical experiment

(Shading indicates F-statistics with better than 0.05 significance. Effect size (η^2) indicates the proportion of variance in the dependent variable explained by the independent variable.)

While the overall results presented in Table 5 provide a general indication of performance for the main numerical experiment, Table 6 summarizes the Analysis of Variance (ANOVA) results. The main experimental factors (traffic differences by day of week, forecasted traffic CV and MAD forecast error) exhibit a statistically significant relationship with almost all of the financial and flexible worker flow measures. The effect sizes (η^2), which reflect the number of cell replicates involved in their calculations, are consistent with the main and interaction effects. With one exception, however, interaction effects appear insignificant. Based on the ANOVA results, our discussion of the results will focus on the main effects of the experimental factors.

Effects of Daily Traffic Pattern (Day)

Table 7 presents the cell means for the 10 performance measures for each level of each of the three traffic factors we examined. The upper left portion of Table 7 shows the mean and percentage increase in profits for 80% cross-utilization (**$xu, %xu**), perfect information (**$pi, %pi**) and upper bounds (**$ub, %ub**) under each of the three daily traffic patterns. The 80% cross-utilization solutions and upper-bound solutions both exhibit larger absolute profit increases relative to solutions without cross-utilization on weekends (and especially Fridays). The solutions with perfect information, which do not benefit from cross-utilization, have much smaller improvements with all three traffic patterns. While mean percentage increases on weekends appear smaller, the differences are not statistically significant (see Table 6).

The lower left portion of Table 7 summarizes the mean number of workers moving from and to the sales floor each hour for the 80% cross-utilization ($\mathbf{F_{xu}}$, $\mathbf{T_{xu}}$) and the upper-bound ($\mathbf{F_{ub}}$, $\mathbf{T_{ub}}$) solutions. Average flow from the sales floor exceeds the mean flow to the sales floor, with the largest flows occurring on Fridays and the weekend. With increased proficiency and no restrictions on flows to the sales floor, the mean number of fulfillment associates assisting with sales ($\mathbf{T_{ub}}$) soared above $\mathbf{T_{xu}}$ by more than six-fold on Fridays and weekends. To justify such an increase, actual customer traffic would have to significantly exceed the forecasted level in some periods. Considered together, the daily traffic pattern results suggest that the value of cross-training flexibility tends to increase with store traffic.

Table 7: Performance measures by treatment levels of experimental factors

	Daily Traffic Pattern			Coeff. of Dem. Var.			Forecast Error Mag		
Perf. Measure	M-Th	Fri.	Sat.-Sun	0.2	0.4	0.6	12%	24%	36%
$xu	$19.90	$54.75	$43.89	$19.12	$32.67	$66.75	$20.46	$41.33	$56.75
$pi	$12.62	$26.63	$15.06	$17.07	$18.60	$18.64	$3.48	$14.16	$36.68
$ub	$47.24	$125.67	$114.72	$60.68	$80.65	$146.30	$58.36	$102.98	$126.29
%xu	2.10%	1.98%	1.35%	0.86%	1.65%	2.91%	0.87%	1.71%	2.84%
%pi	1.43%	0.96%	0.49%	0.80%	0.97%	1.10%	0.15%	0.69%	2.03%
%ub	4.64%	4.31%	3.52%	2.59%	3.71%	6.17%	2.47%	4.22%	5.78%
F_{xu}	0.41	1.10	1.07	0.56	0.76	1.26	0.56	0.95	1.07
T_{xu}	0.16	0.20	0.22	0.16	0.17	0.24	0.16	0.20	0.23
F_{ub}	0.70	1.81	1.77	1.14	1.34	1.81	1.13	1.53	1.63
T_{ub}	0.60	1.31	1.37	1.01	0.97	1.30	0.90	1.16	1.22

Effects of Traffic Variability (CV)

The middle three columns of Table 7 display mean values for the 10 performance measures with respect to the variability of the mean hourly arrival rates (CV). For 80% cross-utilization and upper bound solutions, the absolute and percentage profit difference measures increase at an increasing rate in CV. The effect is most pronounced for the upper-bound results. In contrast, the solutions with perfect information, which do not benefit from cross-utilization, appear relatively insensitive to CV. This observation, which is supported by the ANOVA results reported in Table 6, suggests that improvements may be due to cross-utilization flexibility. The lower half of the middle three columns of Table 7 shows average hourly flows of flexible workers to and from the sales floor for the 80% cross-utilization and upper bound solutions. In general, the flows from the sales floor increase with CV for both solutions. On the other hand, CV appears to have much less of an influence on flows to the sales floor.

Effects of Forecast Error Magnitude (%MAD)

The final three columns of Table 7 show the effects for forecast error magnitude %MAD on the absolute and percentage increases. The effects on the solutions with cross-utilization are similar to those induced by traffic variability, with larger forecast errors creating more profitable opportunities for flexible workers. The bottom half of the last three columns in Table 7 show the effects of forecast errors on the flow of flexible workers to and from the sales floor. The strength of the effect is as expected, with increased flows at higher levels of forecast error.

Sensitivity analysis

In our main numerical experiment, we focused on the influence of traffic and cross-training on profitability. Other potentially important environmental characteristics were held fixed, such as the assumed parameters for the sales response function (α, β, and Υ), the proficiency of cross-trained workers (P_f and P_t), and the number of cross-trained fulfillment associates allowed to assist on the sales floor (U). We now examine the sensitivity of the main experimental results to changes in those previously fixed environmental parameters.

Sensitivity to Sales Model Parameters

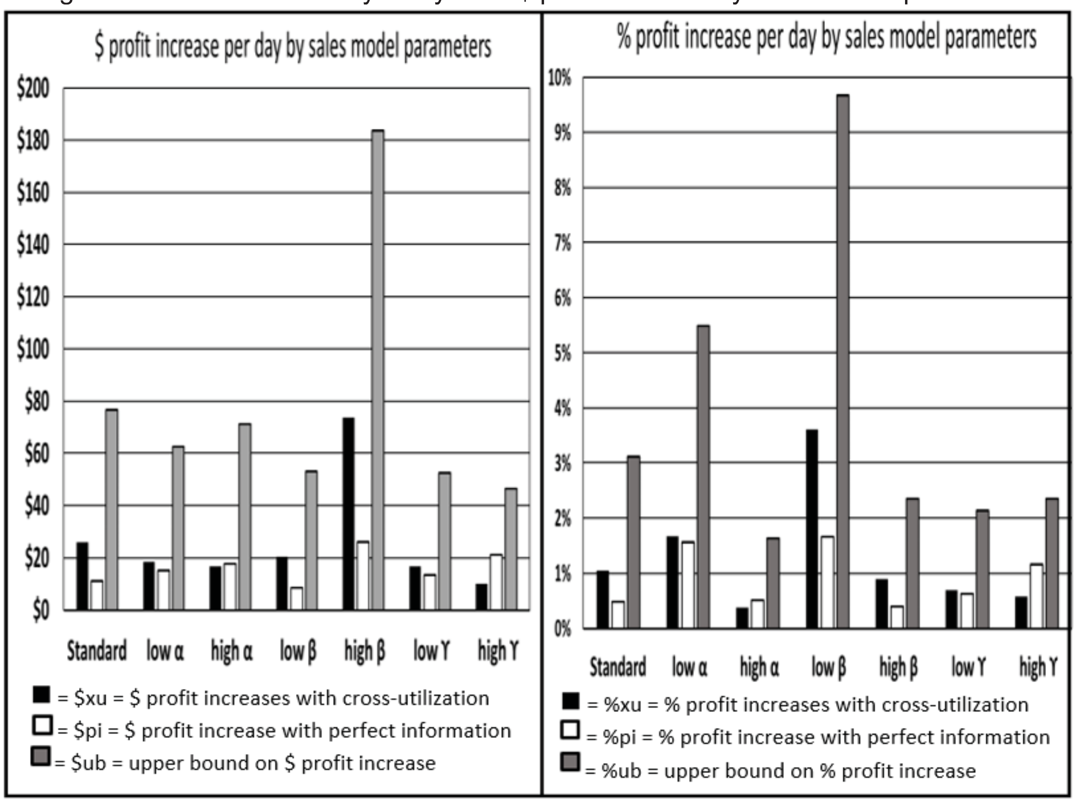
We first consider sensitivity to the assumed parameter values for the sales response function (eq. 1). Guided by the parameter values reported in Lam et al. (1998) and Mani et al. (2015), we established low, medium and high values for sales response function parameters α, β, and Υ. To assess the sensitivity of our results to changes in those parameters, we developed a compact experimental design to estimate the $ and % profit changes as the sales response parameters are varied from their low to medium to high settings while the other parameters remained fixed at their medium values (see Table 4).

With traffic variability CV = 0.4 and uncertainty %MAD = 24% (same as main numerical experiment) we first fixed one of the three sales response parameters at its "low" level and the other two parameters at their medium settings (as used with the main numerical experiment). Reusing the 5 replicates for each of the 3 daily traffic patterns generated for the main numerical experiment, we solved the problems with the new sales response parameters and obtained $Z_{w/o}$, Z_{xu}, Z_{PI} and Z_{ub} for all 15 problem instances. We then reset the test parameter to its high value and solved the problem sets again. Repeating this process for the second and third sales response model parameters, we solved a total of 90 additional problems to assess profit sensitivity to the three sales response parameters.

Figures 2A and 2B summarize differences between profit metrics **$xu/%xu**, **$pi/%pi**, and $**ub/%ub** as each of the sales response model parameters are varied. For comparative purposes, we also display the mean values from the main numerical experiment, hereafter referred to as the "standard" case. In both absolute and percentage terms, parameter β (traffic elasticity) appears to have a much greater influence on profit than either α or Υ. In Fig. 2A, increasing β from low to high more than triples all three absolute profit differences. As β approaches 1.0, customers become less sensitive to congestion and the proportion of buyers among the arrivals increases. With more willing buyers among the arriving customers, it is easier to justify increased staffing levels. However, **$pi** benefits the least from increasing β.

Even with accurate forecasts, scheduling constraints make it difficult to efficiently match staffing levels to demand with dedicated sales associates, especially at higher CVs. For the staffing options that allow cross-utilization, flexible workers can be shifted to and from the sales floor for short periods of time to achieve a better match between capacity and demands during busy periods. Those same workers can be deployed to assist with fulfillment during low traffic periods, reducing labor costs for the fulfillment operation. With the ability to perfectly match highly proficient staff to demand, **$ub** shows the largest absolute gains from increasing β. In percentage terms, however, profit improvement decreases with increasing β, as seen in Fig. 2B. Total profits are very sensitive to β, averaging \$629 at low β, \$2463 at standard β, and \$7216 at high β. These differences in total profit are much wider than the percentage difference in dollar profit increases seen in Fig. 2A, resulting in the reversal of the impact direction for β when going from a dollar basis to a percentage.

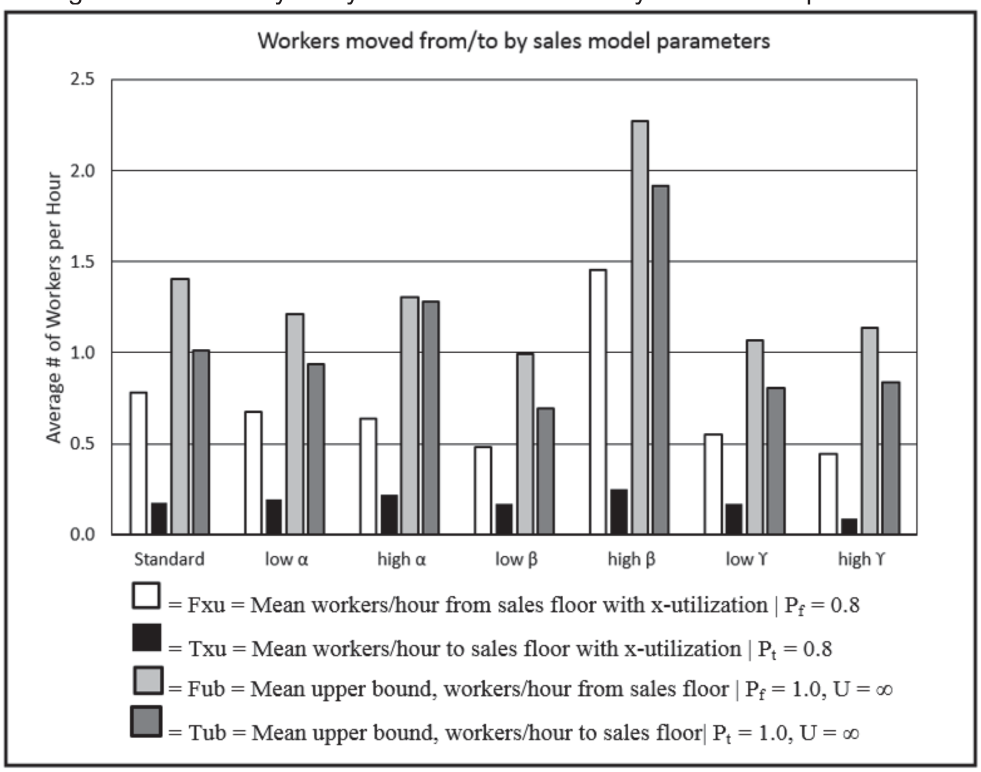
Figures 2A & 2B: Sensitivity analysis of $ profit increase by sales model parameters



With respect to sales potential α, the differences **$xu**, **$pi** and **$ub** in Figure 2A are surprisingly small as α is varied across its range. As α increases, the revenue per transaction increases while traffic remains the same. The increased margin supports a larger sales staff, which in turn captures more of the potential revenue. However, as more of the arriving customers receive prompt assistance, there are fewer opportunities to generate additional sales and it becomes more difficult to profitably add sales staff. The profit differences **$xu**, **$pi** and **$ub** are relatively unchanged as α increases, even though profits for the dedicated staffing strategy $Z_{w/o}$ steadily increase from \$1,256 when α is at its low setting to \$4136 at high α. This suggests that most of the benefits of cross-training, forecast accuracy, and scheduling flexibility are already present with α at its low setting. Thus, the percentage increases from those strategies, as shown in **%xu**, **%pi** and **%ub,** diminish as $Z_{w/o}$ increases with α. Finally, profit differences are less sensitive to sales response parameter Υ, which governs the sales responsiveness to store labor. For a given staffing level, the fraction of arrivals willing to wait for service decreases in Υ. As Υ increases, more staff are needed to meet customer wait time expectations, increasing labor costs and driving profits downward.

Figure 3 summarizes how the flow of cross-trained workers between sales and fulfillment operations varies with the sales model parameters. Here again, β appears to have the largest impact and Υ the smallest. Compared with the standard case, increasing β drives larger flows of flexible workers in both directions. When flows to the sales floor are limited to U=1, mean flows from the sales floor (**F_{xu}**) greatly exceed flows to the sales floor (**T_{xu}**). For the unconstrained upper bound solutions, with $P_t = P_f = 1.0$ and U unlimited, cross-utilization in both directions (**F_{ub}** and **T_{ub}**) increases with increasing β and notably, **T_{ub}** >> **T_{xu}**. The large differences**,** particularly at high values of β, hint at opportunities to improve profitability through investments in training and process improvements.

Figure 3: Sensitivity analysis of workers moved by sales model parameters



<u>Sensitivity to Cross-Utilization Efficiencies and Constraints</u>

To develop additional insights about the environmental conditions driving cross-utilization T_h and F_h, we examine how performance changes as the values of U, P_f, and P_t are varied while all other parameters remain at their medium levels. The magnitude of the changes in performance is based on the difference between the experimental treatment solution and the corresponding mean values for the standard problem set (i.e., CV = 0.4, %MAD = 24%, with the values of α, β and ϒ at their medium settings, for each of the three daily traffic patterns and 5 replications per cell.). To isolate the effects of P_f from P_t, we varied one while maintaining the other at 80%. Parameter U influences the flow of workers to the sales floor, and is therefore varied in conjunction with P_t. Figure 4A shows changes in **$xu** and **%xu**, relative to the standard solutions, as the proficiency of workers moved from sales (P_f) is varied from 70% to 100% in 5% increments. The steady increase in relative profitability in P_f is due solely to the increasingly efficient fulfillment assistance from sales associates. However, at P_f = 100%, the cross-utilization solutions must conform to U = 1 and P_t = 0.8. Therefore, the profit increase for cross-utilization solutions remains below the level of the upper bound solutions, where we assume P_f = P_t = 100% and U is unconstrained.

Figure 4B depicts the average number of sales associates/hour who assist with fulfillment operations over the range of P_f and largely explains the profit increases shown in Figure 4A. The flows from the sales floor are proportional to the profit increases, rising steadily from P_f = 75% to 100%. At P_f = 100%, the average number of workers moving from the sales floor for the cross-utilization solutions matches the flow of workers from the sales floor for the upper bound solutions.

Figures 4A & 4B: Sensitivity analysis of profit increases and number of workers moved from sales floor by proficiency of workers moved from sales (P_f)

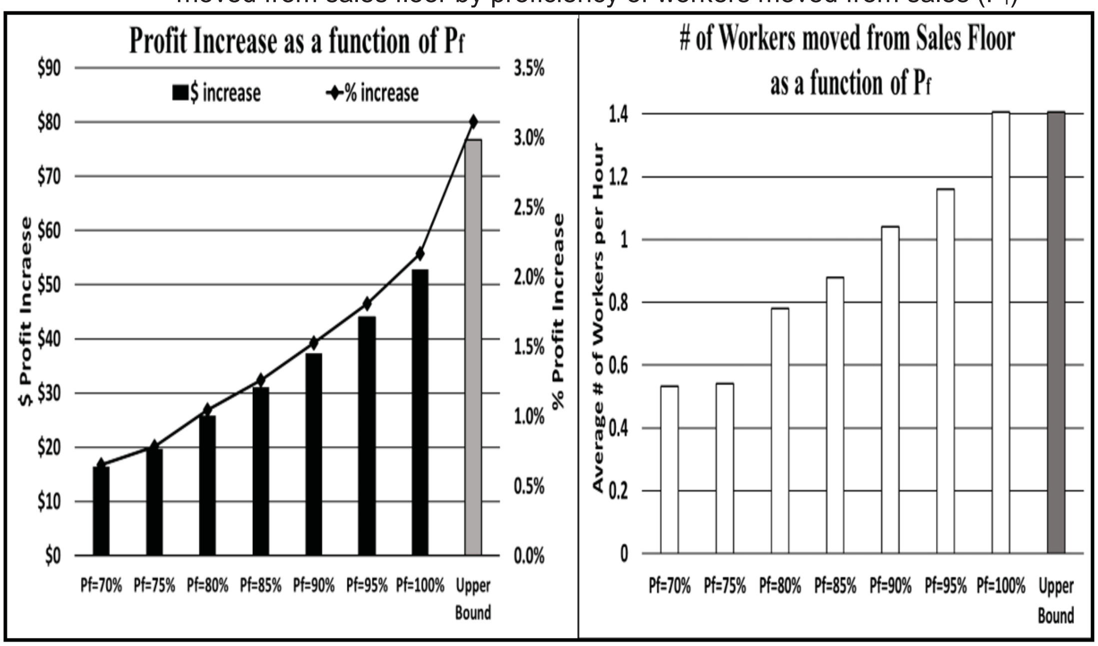


Figure 5A shows the effects on **$xu** and **%xu** as the proficiency of workers moved to sales (P_t) varies between 70% and 100% at 10% intervals, and the upper bound on number of workers moved to sales (U) varies from 1 to 3 for each value of P_t (P_f remains fixed at 80%). In general, profits increase steadily in P_t, and for a given level of P_t, exhibit diminishing returns to scale in U. Although decreasing returns to scale for U have been reported in several previous studies, including Henao et al. (2015), our results also show a strong interaction between P_t and U, with the effects of U more pronounced at higher levels of P_t.

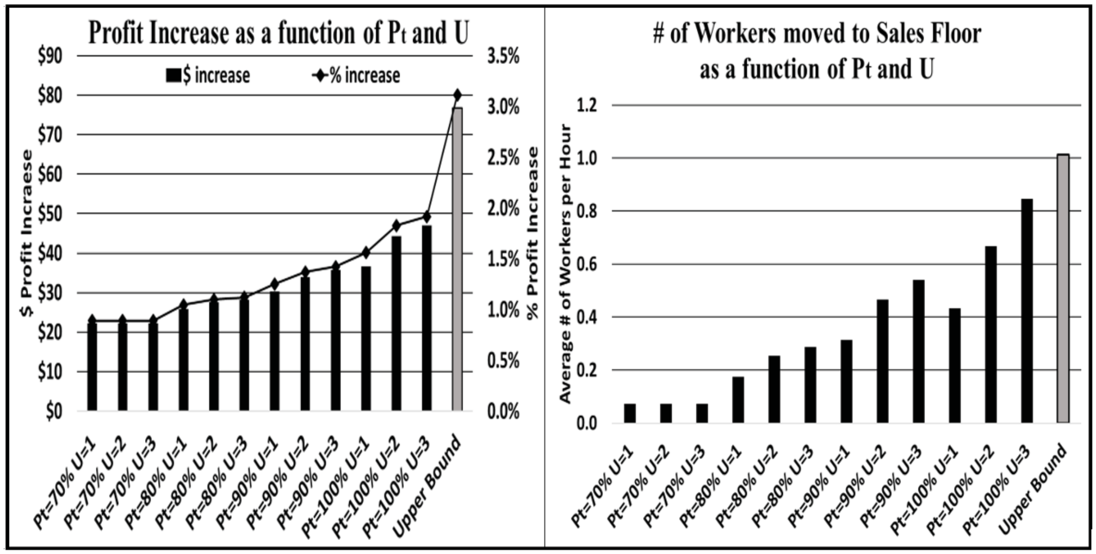
Figure 5B displays the mean number of workers moving to the sales floor per hour over the same range for P_t and U. As with Figure 5A, we see a strong interaction between P_t and U, with

U exerting a larger influence at higher levels of P_t. The number of workers moved to the sales floor when U is constrained never quite equals the number of workers moving to the sales floor for the upper bound solutions. Flows to the sales floor increase in U, but even with P_t = 100%, U = 3 remains a binding constraint on the flow of cross-trained fulfillment workers to the sales floor.

Figure 5A & 5B: Sensitivity of profit increase and # of workers moved to sales floor by proficiency of workers moved to sales (P_t) and upper bound on # of workers moved (U)



SUMMARY AND CONCLUSIONS

In this study, we explored the impact of cross-trained flexible staff on store-level profitability for the large and rapidly growing cadre of omni-channel retailers that fulfill online orders from their stores. Our framework contributes to the workforce staffing and scheduling literature by proposing a model with the following features: a profit-oriented objective, employees with multiple skills, two types of tasks with different priorities and uncertain arrivals, and task-switching flexibility. We apply the model in a computational study to ascertain and compare the benefits of specialized and partially cross-trained fulfillment workers for daily customer traffic patterns, hour-by-hour traffic variability, and forecast error magnitude. We measure the benefits of cross-training in terms of actual and potential profit increases and the flows of cross-trained workers between fulfillment and the sales floor, as well as the sensitivity of our results to the assumed values for key model parameters. Compared with dedicated staffing options, the results of our study suggest that:

- The additional profit attributable to cross-trained staff increase with traffic variability (CV) and forecast error magnitude (MAD); approaching 3.0% when both experimental factors were at their highest settings.
- Cross-training flexibility helps mitigate forecast errors, exceeding the profitability of systems staffed by specialists even when the specialist system benefits from 100% accurate demand forecasts.
- Consistent with earlier cross-training studies (e.g. Nembhard, 2014), we find decreasing marginal improvements with increased cross-training. However, even a single cross-trained fulfillment worker boosts average daily profits significantly (in our case, by 1.81%),

suggesting that both low- and high-volume in-store fulfillment operations are likely to benefit from flexible fulfillment staff.

- Increasing the proficiency of cross-trained sales associates who assist with fulfillment (P_f) has a strong positive influence on profits. Increasing the proficiency of fulfillment workers who assist on the sales floor (P_t) has a similar effect, with greater impact when also accompanied by an increase in the number of cross-trained fulfillment workers U.

Because sales model and store traffic parameters were adapted from recent empirical studies, this study should provide useful insights for many retailers. However, the retail landscape is very diverse, and our ability to generalize our results to that larger domain is not assured. For example, parameters used in this study that might not apply in some retail settings include those related to employee skills, their training costs and proficiencies, their mobility, their wage rates, scheduling constraints, the availability of real-time traffic information, or some other implicit or explicit exogenous factors.

Besides considering a wider range of problem parameters, this research could also be extended in other ways. A straightforward and practical extension is to develop a timetabling model, based on this framework, for both full- and part-time employees with a planning horizon of a week or more. Along with this, other practical scheduling issues such as meal and rest breaks or unplanned absences could possibly be considered. Another useful extension would be to address retail environments with more than two types of cross-trained workers. Other possibilities for extending this research relate to modeling and solution methods. While deterministic heuristics for the inherently stochastic problem were shown to work well for the single period problem without cross-utilization, the two-stage problem may benefit from other stochastic programming solution methods, such as the L-shaped algorithm used for a two-stage integrated staffing and scheduling model by Kim and Mehrotra (2015).

Considering the dramatic impact that e-commerce continues to have on the retail landscape, flexibility is likely to remain an important element for future research and practice. Furthermore, while our study focused on omni-channel retailers with in-store fulfillment, other services involving both direct customer contact and interruptible back-office tasks (e.g., retail banks, auto repair, public safety, health care, government services) may benefit from a similar analysis.

What's in a Name – Identity, Community, Controversy, Responsibility, Reputation - Cases A & B

John Davies
Victoria Business School, Victoria University of Wellington, New Zealand
john.davies@vuw.ac.nz

ABSTRACT

A set of inter-related cases, set in the context of a murderous terror attack on a religious group provides a platform for examination of matters as diverse as the conduct of international and national politics, the governance of social media and the identity and accountability of sporting organisations.
The cases provide opportunity to examine the responsibilities and accountabilities associated with functional management and governance, especially as they relate to crisis and media management, the management of stakeholder relationships, identity / brand management, on the one hand, then gun law reform and social media regulation, on the other hand.

KEYWORDS: Stakeholder Management, Brand Identity & Equity, Crisis Management, Governance, Ethical behaviour, Sport Culture,

CASE OVERVIEW

Inter-related Cases A, B & C

A set of inter-related case narratives provides a platform for a multi-level and multi-perspective analysis of how a white-supremacist terror attack on a religious group has impacted a country, a city and its community organisations.
The cases are set in the context of a murderous terror attack, a hate crime, and a spectrum of stakeholder reactions at local, national and international levels. The context also includes a perceived need for various community organisations to support and care for victims and their families, to foster diversity and inclusivity in the community, and address the concerns of others who see their very identity, for example, the Crusaders professional franchise sports team, as being insensitive, divisive and disrespectful.
Each case narrative provides opportunity to conduct a formal stakeholder analysis to document and understand the consequential impact of the attack on a broader set of stakeholders than just those subject to attack. They also provides opportunity to understand how responses to the attack both reflect and reshape the dynamics of stakeholder relationships, which have sparked both global action and impacted community organisations in unforeseen ways.
In particular, each narrative also provides opportunity to identify how dormant stakeholders or prior non-stakeholders may emerge post-event with significant attributes of power/influence, legitimacy and urgency that, in turn, require other stakeholder organisations to reflect on their identity, purpose, responsibilities especially in terms of how others perceive them.
The inter-related Cases A and B highlight the nature and impact of the changing stakeholder landscape that may emanate from unforeseen external events – in this case, an act of terror. Case A looks at community responses and the management of political relationships in the international domain to curtail the spread hate speech, the live-streaming of murderous activity etc. As such, it may explore the issue of social-media regulation taking place at national government level or via global, multi-country forums. Case B requires attention be given to the nature of stakeholder relationships and dynamics, and how they may impinge on the functional

management of brand identity and brand names at the organisational level.
In addition, both case narratives A and B provide a context for examining changing societal attitudes to religion, hate speech, extremist groups, minorities etc, specifically but not exclusively Muslims, on the one hand, and the management of terror attack risk, crisis and media management, on the other hand.
A further Case C, not addressed here, examines how the terrorist's choice to live-stream, via Facebook, his shooting/killing of innocent people at a place of worship, has had many unintended consequences for a spectrum of current and erstwhile stakeholders. They have also led to the emergence of new stakeholders and groups coalescing around issues of social media and internet regulation, and of the power and responsibilities social media companies like Facebook and Facebook-owned social media companies.

Here, we use Case B to direct emphasis to whether the community's most prominent and successful sporting organisation, the Crusaders, should respond to pressure to decide to change its name and rebrand. Its name and its identity has particular sensitivity given the connotations with mediaeval religious wars between followers of different faith, one being the dominant faith in the community, and the other being the faith that was subject to attack. Case B may be separated into Case B1 and B2.
Case B1 can explore the need for the Crusaders to develop an awareness of, and then act appropriately on matters relating how to its formal name and its brand identity as the Crusaders may be perceived as disrespectful and insensitive to ethnic minority and religious minority groups.
Case B2 can be used more broadly to explore issues of ethical behaviour and moral responsibility relating to individuals, to matters of management and governance at the Crusaders, and of national body governance. It foreshadows discussion of how such behaviour may be perceived by a spectrum of stakeholders with different stakes and interests, and then how stakeholder legitimacy intersects with influence and an ability to command urgency, and to influence the nature and timeliness of action taken by critical actors.
Case B2, may also be used to explore specific issues of locus of responsibility for branding decisions that relate both to the franchisee organisation, the Crusaders, and to the franchisor, the national governing body of the sport, the New Zealand Rugby Union (NZRU).
As such, Cases B1 and B2 not only foreshadow and encompass increasing calls for accountability in relation to the managerial and governance practices of professional sports organisations and their governing bodies. They also surface societal disquiet with the culture of sports organisations.

Here, the case narratives are set out in sequence, but each is organised similarly with respect to the flow of time. As such, although each case can be explored separately, they can also be explored in alternation with case information released in chunks, and then discussed as events lapse over time. For the latter, sample students discussion prompts are interspersed throughout the narrative, in illustration of how issues may be explored. Both modes provide an effective basis for class exercise.

CASE A1 - POLITICAL AND COMMUNITY RESPONSES

Week 1, Day1 -The Terror Attack

On **Friday afternoon, 15 March 2019**, at 1.15pm, a lone gunman brandishing a variety of semi-automatic weapons, entered the Masjid Al Noor Mosque in Deans Avenue, Christchurch, and then the nearby Linwood mosque. The gunman, later identified as a white-supremacist

Australian, who had been living in the provincial city of Dunedin proceeded to fire his weapons in a deliberate manner, killing fifty-one and injuring scores of Muslims in prayer.
The attack which was live-streamed on Facebook by the gunman, took place over a seventeen-minute period before he was captured by police (MFAT, 2019). The gunman had also posted a 'manifesto' online, and emailed a copy to media in New Zealand.

1 Stakeholder Analysis
1a Provide a list of **generic** stakeholders linked to the Terror Attack and state how they may have been impacted by the actions of the key players listed above.
1b Then for those generic stakeholder, identify a set of specific stakeholders, and the impact on those stakeholders relating to their roles, responsibilities and identities
2 Crisis Management
2a Use Bundy, Pfarrer et al's framework to explore what actions would be expected of government giving consideration to practical, humanitarian, media-information, political and legislative matters.

Responses to the Terror Attack

Week 1, Day1 - The Immediate Organised Response

The police responded to emergency calls **immediately**, dispatching anti-terror squads to the area, and capturing the terrorist as he fled from the Linwood mosque. Para-medics raced to the mosques to treat the wounded victims, and prepare the wounded for delivery to local hospitals who were ready having been alerted by two Muslims who had witnessed the shooting. (RNZ, 2019x).
Christchurch had faced a similar kind of terror, albeit of a natural kind in the 2011 earthquake that resulted in 167 deaths. That unfortunate experience meant that the response of the police, the military, the para-medics, hospitals, social services, the schools and community groups etc, was immediate, practiced and effective.
The visible response from the police, with extra officers on the ground outside mosques and elsewhere in the city, and helicopters flying overhead, blockades etc, was reassuring in the event that a second attack was a possibility. The invisible response from the police in meeting with, and briefing victims' families and Muslim groups, was also meant to provide reassurance to a group that felt under-attack, isolated yet exposed (Stuff, 2019a), and also to make them aware of the legal procedures and time frames required to identify and release the bodies for religious burial purposes. Overall, the response from other community groups and organisations almost seemed practised.
Within hours, a crisis centre was set up at Hagley Community College to assess the needs of victims and their families and to ensure that co-ordinated support could be provided urgently to those in need. The support provided by the existing *All Right? Campaign* was also immediate and reflective of a prior Christchurch response to the effects of the deadly 2011 Christchurch earthquake (all Right, 2019).
The *Campaign* organisation had been launched in 2013, as a Healthy Christchurch initiative led by the Canterbury District Health Board and the Mental Health Foundation of New Zealand, 'to improve Cantabrians' mental health and wellbeing as they recover and rebuild from the earthquakes' (CreativeNZ, 2019).
The *Campaign's* success and effectiveness in dealing with post-traumatic stress is evident in continuing support from the Ministry of Health and relationships with the Ministry of Social Development and other organisations including the Red Cross, Special Kids, Involved Parents (SKIP), the Christchurch City Council and the Waimakariri District Council (All Right, 2019). Similarly, the Ministry of Education trauma team was immediately mobilised on the Friday afternoon, to work alongside the team of mental health and support workers still embedded

within schools as part of the Ministry of Education Mana Ake Programme following the earthquake (Ardern, 2019b).

Week 1, Day1 - Outpourings of Grief, Empathy and Support

The response from the community on learning of the terror attack was of course, initial shock, but a heartfelt and instantaneous outpouring of grief, empathy and support for the Muslim victims, their families, and the Muslin community in general.
The response manifested as a wall of floral tributes, messages, candle-lit vigils at mosques in Christchurch and throughout New Zealand, and fund-raising events and campaigns that raised more than $10m in less than a week through fund-raising sites set up by the NZ Council of Victim Support Groups. Sporting events and theatrical productions were also cancelled, and remembrance services were organised.
Other symbols of support included the wearing of headscarves, and meaningful slogans like "They are us!" resonated with local Muslims who had been living in fear, and who had feelings of increasing isolation. Bariz Shah (2019), President of the University of Canterbury's Muslim Student Association, offered a view that after many years of feeling that he did not belong, the actions and words of Cantabrians and New Zealanders in general, and the Prime Minister, Jacinda Ardern, in particular, had provided him with a different sense of belonging.

Week 1, Day1 - The Response from the Prime Minister and Government

The Immediate Response to Reassure the Muslim Community
In the hours following the attack, Prime Minister, Jacinda Arden condemned the gunman's hate-filled atrocity, and said

> 'We should not be perpetuating, sharing, giving any oxygen to this act of violence and the message that sat behind it' – a message aimed at both individuals and social media platforms (Ardern, 2019aa; Cooke, 2019).

She had already acted to contact the latter, and had received assurances that social media platforms were working to remove the footage. She indicated that she was calling for a ban on the spread of messages of hate.
A Prime Ministerial statement (2019a) on the **Saturday morning** was designed to reassure the Muslim community that they would be supported in their grief and protected from harm and from extremism. On the same day, she met with Christchurch Muslim leaders at the Canterbury Refugee Resettlement and Resources Centre in the company of Deputy Prime Minister Winston Peters, and Leader of the Opposition National party, Simon Bridges.
She indicated her awareness of possible roots of the terror attack, and said that the police and the intelligence community were focused on extremism of every kind, and that security agencies would be assessing whether there had been any activity on social media that should have prompted a response. She said that the offender had obtained a gun licence and weapons whilst living in NZ:

> "While work is being done as to the chain of events that led to both the holding of this gun licence, and the possession of these weapons, I can tell you one thing right now.
> Our gun laws will change.
> There have been attempts to change our laws in 2005, 2012 and after an inquiry in 2017.
> Now is the time for change**."**

She also said that:

> "Police are aware of distressing material relating to this event being online and are reminding people it is an offence to distribute objectionable material."

It later transpired that these comments were not empty rhetoric, or devoid of meaning! Neither was the image of the Prime Minister wearing a hijab devoid of meaning! 'It's a photo which has gone around the world. She looks forward, her brow raised with concern and hands clasped. She's not speaking and doesn't show any sign that she is about to launch into a political speech. Jacinda Ardern is simply listening' (McConnell, 2019).

2 The Impact of the Prime Minister's and Government's Statements and Actions Politics and Brfanding

Consider the statements made, and actions taken by the Prime Minister, Jacinder Arden, and the Labour/Greens/NZ First collation government, and whether their statements:

(i) Would have led to reputational gain as individuals or politicians.
(ii) created beneficial brand equity at a political level

3 Brand Management - Evaluating Actions by the Crusaders organisation

Students may be introduced to issues of Branding, Brand Equity, Brand Management at this stage – that relate to politicians and political parties.

(i) Students should engage in preliminary discussion of whether the Prime Minister has enhanced an identity around decisiveness, compassion etc –that constitutes a political brand identity, or constitute a brand in itself.

Week 1, Day4 - A Call to Immediate Arms Reform

On **Monday, 18 March 2019**, in its first meeting following the attack, Cabinet made 'in-principle decisions' around the reform of gun laws, hoping to finalise details of gun-law reforms at its next meeting (Arden, 2019c). Cabinet also decided that there would be an inquiry to look at the specific circumstances leading up to the Christchurch attack. Ardern referred to the terror attack in Christchurch on Friday as 'the worst act of terrorism on our shores', and that 'the time to act is now'

Week 1, Day 7 – A Promise for Gun Law Reform

On **Thursday, 21 March**, the government announced how it would proceed with gun law reform placing a ban on all military style semi-automatics (MSSA) and assault rifles in New Zealand (Ardern, 2019e; Mann, 2019), stating that:

> 'On 15 March our history changed forever. Now, our laws will too. We are announcing action today on behalf of all New Zealanders to strengthen our gun laws and make our country a safer place. All semi-automatic weapons used during the terrorist attack on Friday 15 March will be banned - the Government will take immediate action today to restrict the potential stock-piling of these guns.'

Week 2, Day 1 – Hate Speech

On **22 March 2019**, when addressing Organisation of Islamic Cooperation Emergency Meeting on the Christchurch Terror Attack, Deputy Prime Minister Winston Peters referred to the innocent people who were killed as they practiced their religion, and said:

> 'In a country that practices religious tolerance, an attack on one of us, observing their beliefs, is an attack on all of us. … Whenever and wherever a terrorist strikes, the aim is to provoke fear and panic. In New Zealand, it has failed. It failed because our thoughts are not the terrorist's thoughts, and his extremist ways are not our ways. And to be clear, in New Zealand hate speech is not tolerated.'

Week 4, Day 6 – Gun Law Reform - Arms Amendment Bill

On **10 April 2019**, the Arms Amendment Bill was passed into legislation following its third reading in Parliament. Work had also begun on the Arms Amendment No. 2 Bill, which would address issues about 'a gun register, the licensing regime, the system of Police vetting, and the 'fit and proper person' test, storage requirements and penalties', amongst other matters (Nash, 2019).

Week 1, Day 4 – Commemoration and Respect - PM Jacinda Arden: They are us

On that same **Monday following the attack**, Ardern (2019c) also said that the government's Department of Internal Affairs (DIA) would be working in conjunction with the Muslim community, iwi, local government, and the mayor of Christchurch, police, and other agencies so that New Zealanders would have 'the ability to commemorate as one the lives lost at Deans Avenue and Linwood mosques'. One such opportunity to reflect took place one week after the attack on Friday, 22 March when the nation stopped for the *Muslim Call to Prayer* at 1.30pm (Ardern, 2019d), at Hagley Park, opposite the Al Noor Mosque, a time when the nation stopped to mourn. A National Remembrance Service took place just one week later.
At that service, Ardern said:

"**We will remember the tears of our nation**, and the new resolve we have formed,"
Over the past two weeks **we have heard** the stories of those impacted by this terrorist attack.
They were **stories of bravery**.
They were stories of those
… who were born here, grew up here, or who had made New Zealand their home.
… who had sought refuge, or sought a better life for themselves or their families.
These stories, they now form part of our collective memories.
They will remain with us forever.
They are us.
But with that memory comes a responsibility.
A responsibility to be the place that we wish to be.
A place that is diverse, that is welcoming, that is kind and compassionate. Those values represent the very best of us.
But even the ugliest of viruses can exist in places they are not welcome.
Racism exists, but it is not welcome here.
An assault on the freedom of any one of us who practices their faith or religion, is not welcome here.
Violence, and extremism in all its forms, is not welcome here.
And over the last two weeks we have shown that, you have shown that, in your actions.
And we also ask that the condemnation of violence and terrorism turns now to a collective response.
The world has been stuck in a vicious cycle of extremism breeding extremism … and it must end."
We cannot confront these issues alone, none of us can.
But the answer to them lies in a simple concept that is not bound by domestic borders, that isn't based on ethnicity, power base or even forms of governance.
The answer lies in our humanity.' (Heard, 2019)

The Christchurch Call - Reforming Social Media to Counter Terrorism

The NZ Government expressed a view that the terrorist attack had 'made clear once again the harms that can be caused by terrorist and violent extremist content online, a threat that continues to evolve.' There was concern that the attack, having been livestreamed, had not only gone viral at the time, but continued to remain available on social media despite the measures taken by social media providers to remove it. Indeed, Prime Minister Ardern regarded the March 15 attack as shocking in its use of social media as a tool in the act of terror. She sought to address the matter through what became known as *The Christchurch Call* to eliminate terrorist and violent extremist content online (MFAT, 2019).
Ardern's vision, however, related to a global rather than a local response. Ardern found a willing political ally in French President Emmanuel Macron in bringing together political leaders and leaders from the social media and internet world to develop the *Call* as an action plan and to agree to implementing the call.

Week 9, Day 6 – The Christchurch Call, Paris Summit

On 15 May, two months to the day after the Christchurch terror attack, the *Call* brought leaders from ten countries and Facebook, Google, Instagram etc to Paris, where a commitment \was made to a set of collective actions:

- developing tools to prevent the upload of terrorist and violent extremist content;
- countering the roots of violent extremism;
- increasing transparency around the removal and detection of content, and
- reviewing how companies' algorithms direct users to violent extremist content.

Ardern said that implementing the Call was owed to 'those affected by the attacks in Christchurch, and other attacks in cities and towns around the world where terrorism and violent extremism have struck, to undertake this work' (Beehive, 2019).

Set alongside the Christchurch Call as a practical global response aimed at limiting the spread of offensive extremist views and the roots of violent extremism, Case A now provides opportunity to other matters deemed to be offensive in the context of the terror attack, and what a practical response to those matters might be.

The offense relates to the name, imagery and identity of the southern hemisphere's most successful professional sports team, the Canterbury Crusaders. Some had regarded the Crusaders name as being inappropriate at the time the franchise rugby team was formed in 1996, because of its connotations to the mediaeval geo-religious wars between the Christian Crusaders and the Muslim-faith based Saracens.

Whilst it had been previously claimed that the name was offensive to Muslims in general, and to the community at large, because of such connotations, the poignancy of the terror attack on the Muslin community had refocused attention on the Crusaders name.

THE CANTERBURY CRUSADERS - CASE B

The Canterbury Crusaders and SupeRugby

The Canterbury Crusaders are a professional rugby union organisation playing in the SANZAR sanctioned southern hemisphere SupeRugby competition. They were formed in 1996, as one of five regional franchise teams initially licensed by the New Zealand Rugby Football Union (NZRFU, now NZRU) governing body to compete in the original *Super 12* international interprovincial competition, involving the leading southern hemisphere rugby playing countries – South Africa, Australia and New Zealand (SANZAR). They have been the most successful team in the 25 years of the competition. In turn, the SuperRugby competition is widely regarded as the toughest competition in world rugby, and the Crusaders are recognised as one of the elite teams in global professional sport.

They are revered for creating an organisational culture that breeds success, winning nine of the thirteen championship finals they contested between 1996 and 2018; and for a development programme that has fostered character and community-mindedness amongst players. The organisation and its players are regarded as role models not just within its extended Crusaders community, but also globally.

The Crusaders region, encompassing the Canterbury, Nelson, Marlborough, Buller and West Coast provinces, also took great pride in their achievements and how the Crusaders conducted themselves on and off-the-field and in their support of local communities. They were widely thought of as exemplars of what could be achieved with shared values relating to excellence, vision and a strong team culture.

They are a pride of the community, whose successes have served to lift the spirits of people in Christchurch since the deadly earthquakes of 2011 devastated large regions of the city, and led to the death of more of than 150 people.
The advent of professional rugby in 1996 positioned the SupeRugby competition at a level above what was then the amateur National Provincial Championship (NPC) involving NZ's elite representative provincial teams. At that time, NPC team names simply reflected the names of their provinces, although most teams had nicknames and/or mascots.
However, multi-million dollar media-rights and sponsorship deals not only enabled an era of professionalization and professionalism in the conduct of rugby as a sport, but also in fostering commercialism and commercialisation in the conduct of all dimensions of the business of rugby.
Much consideration was given to the creation of franchise teams that had exclusive geographical territories and then names, logos and iconography that were readily identifiable with the franchise region, preserve existing traditions, and which reflected or had connotations with geographical, cultural or other demographic characteristics.
It was also considered important that names were readily identifiable in overseas rugby playing markets in order to attract spectators to matches and viewers. As a consequence, the initial franchise team names were double-barrelled place and nick names: namely Wellington Hurricanes, Waikato Chiefs, Otago Highlanders, Canterbury Crusaders and the Auckland Blues. The place names were those of the elite provinces well-known in international markets. The Highlanders name reflected the origin of the early Scottish settlers; the Chiefs name and associated iconography reflected the region's pervasive Maori heritage and culture; the Hurricanes name reflected Wellington's windy nature. By contrast, the Crusaders name, apart from its alliterative qualities, was said to be a 'nod' to the English heritage of Christchurch and Canterbury, albeit drawing on images of mediaeval England that afforded a link to 'the pageantry of knights and horsemen', and the iconography, later used in marketing, of shields, banners, flags and swords.
At the time, all five franchises were owned by the NZRU but licensed to a lead or host province in each region to organise on behalf of, and in harness with the other provinces in the region. The ownership model meant that the NZRU had the final decision in operating a centralised player drafts, player payment system, and names. Coincidentally, the NZRU CEO in 2019 had been the CEO of the Canterbury Rugby Football Union and the Crusaders in 1996 (TVNZ, 2019).

Immediate Reactions to the Terror Attack

Week 1, Day1 - The Impact on Sports Events

Rugby – New Zealand's national sport is rugby union, and the Canterbury Crusaders are the country's most successful professional rugby franchise. **On the day of the attack**, the Crusaders were in Dunedin, preparing to play the Otago Highlanders the following day. Both teams and the New Zealand Rugby Union (NZRU) agreed that it was inappropriate for the match to be played. It was cancelled out for respect for the Muslim community with the Crusaders team returning to Christchurch to provide support to their families, the victims and the community (Egan, 2019).

Other Sports - **Within hours of the attack**, the mainstream media were reporting the views of New Zealand CEO, David White, as saying that New Zealand sports hosting would change forever with the mosque shootings (Egan, 2015). White had immediately been in contact with his Bangladesh counterpart, Nizamuddin Chowdhury, and the decision to cancel the series of Test matches between NZ and Bangladesh, was quickly made, with "no other consideration" being given to alternatives.

The Bangladesh cricket team had been in Christchurch to play an international test match against the NZ Black Caps starting on the following day. They were on their way to the Masjid Al Noor Mosque for afternoon prayers when the Terror Attack happened. They fled from the area unharmed, and following the cancellation of the Test match, they flew home the next day.
White offered a view that the attack would "change the entire fabric of international sports hosting" and that the idea of even New Zealand being a 'safe haven' had disappeared. He suggested that there was a renewed need for an in-depth examination of security matters.
White also said that a decision had also been made to cancel the two remaining fixtures between the New Zealand women's development team and the Australia under-19 women's team scheduled for same weekend at nearby Lincoln's Bert Sutcliffe Oval.

THE CALL FOR THE CRUSADERS' NAME CHANGE

Week 1, Day1, Friday – Pressure bubbling in Social Media

Almost immediately after people became aware of the Attack, the web became active with calls for the Crusaders to change their name! It was suggested that not only did the Crusaders' name and other imagery have inappropriate connotations to violent religious wars between Christian and Muslim nations, but that, at a time, when Muslims in Christchurch had been harmed, the name would serve as a continual reminder of disrespect, on the one hand, and threat, on the other hand. As such, it was claimed the name was inappropriate.

1 Initial Response of the Crusaders What action should the Crusaders organisation have taken on first learning of the social media commentary?
2 Stakeholder Analysis In parallel, students should undertake a preliminary **stakeholder analysis**, identifying generic and specific stakeholders, their roles, stakes or interests, and their **attributes**. Such **stakeholder attributes** would include: their **power** or **influence** to impact others; their ability to act with **urgency** or **timeliness** and/or to effect urgent or immediate response from other; and the **legitimacy (**social, legal or otherwise **acceptance** of their views or actions. The Stakeholder Analysis should seek to identify **stakeholder dynamics** in terms of the emergence of 'new' stakeholders, or stakeholders whose attributes, say power or legitimacy have changed because of the Terror Attack
3- Crises and Crisis Management Students should briefly reflect on what they understand to be a crisis, and how crisis management situations can be distinguished from other management situations. In this case, students should become aware of how stakeholders associated with the Terror Attack, and whose interests/views have gained in legitimacy, may also have become and gained influence as Crusaders stakeholders, with an ability to 'coerce' a response – effecting a crisis in the Crusaders organisation

Week 1, Day 3, Sunday – The Crusaders' Response to the Call for a Name Change

A media statement from the Crusaders CEO, Colin Mansbridge, **on the Sunday following the attack**, expressed shock at the tragedy, stated that:

> 'Like all New Zealanders, the Crusaders team and organisation are deeply shocked by this tragedy and our thoughts are with the victims and their families. This is bigger than rugby and we're absolutely heartbroken for our wider community, which is where our thoughts are … the team and the wider organisation are united with our community in standing against such abhorrent acts … in Christchurch, and in standing in support of our Muslim community.'

The statement acknowledged and understood the concerns that have been raised about the Crusaders name, but that it was "a reflection of the crusading spirit of this community (and Canterbury rugby), and certainly not a religious statement.' (Crusaders, 2019a)

> 'What we stand for is the opposite of what happened in Christchurch yesterday (Friday); our crusade is one for peace, unity, inclusiveness and community spirit.
> In terms of the Crusaders name, we understand the concerns that have been raised. For us, the Crusaders name is a reflection of the crusading spirit of this community.
> In our view, this is a conversation that we should have and we are taking on board all of the feedback that we are receiving, however, we also believe that the time for that is not right now.'

Earlier on the same Sunday, Mansbridge had told TVNZ (2019), before issuing the statement, that the club would have a discussion about what to do next.

> 'There's a lot of emotion going around in terms of conversation at the moment. We've heard it, we've heard the feedback, and we do want to have a conversation about it.'
> 'At an appropriate time, we will thoroughly consider the issues that have been raised and our response to that," the Crusaders said in a statement. "That will include conversations with a range of people, including our Muslim community.'

Mansbridge said it was important to note that "things are still fairly raw".

> "I would say we are in a state of shock. We will acknowledge the feedback that we have had. It is appropriate. (But) rugby, in the context of what has happened, it is pretty hard to … elevate this conversation right at the moment.'

4 Crisis Management - Evaluating Actions by the Crusaders organisation

Consider the actions taken by the CEO, Mansbridge:

(i) on hearing of the Terror Attack
(ii) in explaining the Crusaders' concerns, values, and action plan on the Sunday following the Attack and the social media storm.

… and how they may reflect a crisis management plan to deal with such situations?

Consider the statements made, and actions taken after the Terror Attack, during the first week, Week 1, by the Prime Minister, Jacinder Arden, and the Labour/Greens/NZ First collation government.

Consider whether their statements of compassion and commitments to reform gun law, and their consequent legislative actions:

(iii) have created additional pressure for the Crusaders to act in terms of a possible name change or
(iv) have given direction to the Crusaders' decision-making

Week 1, Day 3, Sunday – Response to the Crusaders' Initial Statement

<u>The local/global media reaction to Mansbridge's statements and sentiments</u>

News that the Crusaders were contemplating a name change resonated throughout the sports world, and was reported in all major newspapers globally, reflecting not just interest in how NZ was handling the terror attack, but also the stature of, and interest in the Crusaders (TVNZ, 2019a; Stuff, 2019a)

Senior sports reporter, Tony Smith (2019) said that 'Mansbridge deserves credit for the sympathetic tone of his statement about the name issue. The very fact that the organisation is open to considering changing the name of the most successful team in professional rugby history speaks volumes for its leadership.'

He believed, like others, that the key issue, as Mansbridge highlighted, is how the Muslim community feel.

> "Would they be uncomfortable, after last Friday's tragedy, at their city's premier sporting team continuing to bear a name associated with wars waged against Muslims in the Middle East in the 11th to 13th centuries?

He suggested that the feelings of the Muslim community 'matters more than a moniker, adopted as much for marketing reasons and alliterative properties, as geographical location', and that no one doubted 'Mansbridge's sentiments.'
A view was offered that whilst no Crusaders player or coach, in his memory, had made a direct link about their rugby journey to the holy crusades, that 'perception, however, is important, and that there was a need to know what the Crusaders name means to Christchurch's growing Muslim community? He also reflected on an oft-stated view that 'was acceptable to the general populace in the mid-1990s may not be now, given New Zealand's more diverse demographics.' No-one can deny the mosque murders have changed the socio-political landscape forever.'

5 Crisis Management - Evaluating Actions by the Crusaders organisation
As in 4 above, does the extensive global interest in the Crusaders' potential name change and the initial response for their empathetic concerns about the Muslim community, reinforce the pressure for the Crusaders get things right – for the Muslim community, the Christchurch community and the rugby community stakeholders.

Week 3, Day 5 – The Crusaders' Commitment to Considering a Name Change

Nearly three weeks later, on 3 April, following extensive discussions with Crusaders' stakeholders, and with the governing body, the New Zealand Rugby Union (NZRU), Mansbridge explained the nature of their commitment (NZH, 2019; TVNZ, 2019b).

> 'This is an event that rocked our community and brought some important issues to the fore. One of the contentious issues that has been brought up in the aftermath of the Christchurch attacks is the name of our rugby team – the Crusaders.
> "Because of our desire to be the best we can be and to support our community, we are treating the question around the appropriateness of our brand extremely seriously.
> We are committed to undertaking a thorough process, taking into account all relevant opinions and, most importantly, we are committed to doing the right thing.'

Mansbridge said:

> 'Our challenge is that the name Crusader has come to mean something quite different to many of the team's supporters. This team is proud of the positive contribution it makes to the community. In recent times, the Crusaders region has been through a number of tragic and trying events and the team has played an important role in helping galvanise the community and raise spirits following significant events. Through these events, the Crusaders name has become more reflective of a positive Crusade."

New Zealand Rugby Chief Executive Steve Tew offered a view that:

> 'In the wake of the Christchurch attacks, it is apparent that the symbolism the club has used, combined with the 'Crusaders' name, is offensive to some in the community due to its association with the religious Crusades between Christians and Muslims.
> "One thing that has become very clear in the last two weeks is that there are divided opinions on the best way forward for the brand. We understand and appreciate the passionate feedback that we are receiving on both sides of the conversation, and at this stage we are committed to keeping an open mind until the independent research has been done."

Tew then outlined actions that had been decided, including engagement of the consulting organisation Research First, to seek feedback and provide recommendations on the Crusaders team name and brand name, specifically whether to retain the name but changing the branding and associated imagery; or undertaking a complete rebranding of name and imagery:

> 'Maintaining the status quo in terms of the Crusaders name along with the current imagery of knights on horseback is, in our view, no longer tenable because of the association with the religious Crusades that has now been drawn.
> That is therefore not one of the options that we will be considering.'

Tew said that any changes will be introduced in time for next season, 2020, and that the team would drop the horses and related entertainment for the rest of the current season.

6 Brand Management - Evaluating Actions by the Crusaders' organisation
Students may be introduced to issues of Branding, Brand Equity, Brand Management at this stage.
(ii) Students should engage in preliminary discussion of whether the Crusaders name is an element of brand identity, or constitute the brand itself.
Students would need to consider what, if any issues
(iii) may relate to and conflate the essential identity of the Crusaders organisation with the Crusaders brand and brand image/identity; and
(iv) may also impact brand equity;
They should also have preliminary discussions about whether existing elements of brand equity have been damaged by the negative connotations that have resurfaced with the Terror Attack.

When the first year of Super Rugby kicked off in 1996, the Crusaders title was chosen for the side representing the provincial unions from the top half of the South Island and the brand was built on a stylised version of medieval England, in a nod to the English heritage of Christchurch. The club's marketing over the past 23 years has incorporated the pageantry of knights and horsemen, and included symbols such as swords and banners.

Week 3, Day 7 – Response to the Crusaders' Commitment to Consider a Name Change

<u>The local and global media reaction to Mansbridge's statements and sentiments</u>

Following the joint Crusaders/NZR announcement that they would contemplate a change to the name and branding, there was an unfolding of media commentary. As much as people were polarised about whether to execute change or not (Dickens, 2019; Garner, 2019; Norquay,2019; Stuff, 2019c), there were also different views about whether and how any change would affect the Crusaders (Cully, 2019; Heard, 2019; Newstalk ZB, 2019; NZH, 2019; Troughton, 2019). Nevertheless, the Crusaders organisation were praised by the Prime Minister for contemplating change (Whyte, 2019).
Religious scholar, Troughton (2019) was unequivocal in stating that it was 'scarcely conceivable the name and brand will survive careful scrutiny and reflection. Ideally, the consultation should extend to input from other religious communities, including Christians.' His view was that 'the contemporary resonances of the Crusades remain steeped in images of violence and domination that are deeply disturbing and problematic.' However, whilst on the one hand, the Christian military expeditions at the time of the first millennium had sought to reclaim the Holy Land and other territories held by Muslim nations, on the other hand, Christian groups in NZ and the USA had often embarked on crusades for social improvement or social purity, or crusades for the 'battle of souls'. However, even such 'crusader' type branding has been subject to change – often to 'mission'-led brands.
Troughton has offered clear opinion that:

> 'while many supporters will use the Crusaders name with little thought to its origins and implications, it remains an anachronism and source of discomfort to many New Zealanders – Muslim, Christian, secular and others. If the Crusaders franchise and New Zealand Rugby chose, as they might, to consult with the Christian community, they are unlikely to find great enthusiasm for retaining the current name. Indeed, New Zealand Christians will probably be grateful to see it go.'

Senior sports reporter, Kevin Norquay (2019) supported change for similar reasons, attempting to put such change in the context of it not being of the great challenge that others perceive.

> 'There are many historically tarnished names no one sensible would consider naming a sports team after - the Jihadists for example, that being one Muslim equivalent of Crusaders.

> Adding Crusaders to that list would not be the end of the world, in fact it might help start a brave new one.'

By contrast, political commentator, Garner (2019), didn't perceive 'war and blood' in the Crusader imagery, he sees talent, playing by the rules, values, ethics … and winners. He sees 'a DNA and a record that refines the word Crusaders in our country.' Radio journalist, Andrew Dickens (2019), offered a similar view of the need for change, portraying the furore over the Crusader name as another example 'that virtue signalling and political correctness is alive and well in this country.'

7 Brand Management - Evaluating Responses to the Crusaders' Action Plan
Students should consider the range and credibility of the diverse opinions that have surfaced about a potential name change and rebranding, and how such commentary could feed into analysis of the name change/branding decisions

Week 4, Day 5 – Stakeholder Views – A Petition and Survey Responses

Public opinion seemed a little less divided as evidenced by a petition and a survey. The petition to retain the Crusaders name had accumulated 25,000 supporters by 9 April.(One News, 2019a). Then on 20 April, initial findings from a survey (conducted by One News Colmar Brunton) indicated that a majority (75%) of New Zealanders favoured retention of the Crusaders' name, with 14% opposed. The survey indicated that who were more likely to favour the Crusaders keeping their name included those living in Otago and Southland at the south of NZ's South Island, right-leaning National Party supporters and people aged 18-29.

8 Brand Management - Evaluating Actions by the Crusaders organisation
Students should be confronted with the challenge of balancing the weight of public opinion, in raw percentages, against the views of those who have a voice in the media, and those who have well-articulated views relating to the ethical, political, religious and marketing nuances. Students should identify the ethical, political, religious and marketing dimensions.

Renaming and Rebranding Experiences

In considering the matter of a name change, the Crusaders' dilemma may be set alongside a spectrum of similar dilemmas relating to name change that have been faced by other sporting and education-related organisations. They include some cases where name change and rebranding were considered to be worthwhile, and some cases, where no deliberate attempt had ever been made to create an official nickname.

Indeed, calls for name changes to official and unofficial mascots, logos, buildings and teams have become common place (SDUT, 2016), Students across the United States have been pressuring their colleges to update mascots, mottos and building names that they say are insensitive, and which demean, denigrate, impugn or alienate minorities or ethnic groups (AP, 2015; Gambino, 2014; Hoft, 2015).

For example, Susquehanna University dropped its nickname, the Crusaders, due to concern over potential offensiveness and negative connotations, and to ensure sure the campus remained 'welcoming and inclusive'. SU President L. Jay Lemons said that it was a Philadelphia sportswriter, not the college itself, that dubbed the athletic teams the "Little Crusaders" in 1924. The name stuck as "medieval iconogrophy" such as the Maltese cross came to accompany the nickname.

In the 1980's, Susquehanna formally dropped the Knight mascot and Maltese cross adopted as the "Crusader flag," to distance themselves from 'the medieval Crusaders iconography that had been present in an earlier time'. However, in the late 1990's, the image of the Crusader morphed 'strangely' into the form of a caped tiger, which then remained the mascot until 2014 when students began the discussion over the name and mascot again.

Similarly, following 'one or two' complaints, from its Muslim and Jewish membership, the Middlesex County Cricket team changed its name from the Middlesex Crusaders to the Middlesex Panthers (Cramb, 2009; Coc et al., 2016)). The President, at the time, said that the nickname was introduced because 'we wanted more kids to pick up a cricket bat, that's why it was devised. We were on a crusade to get children into cricket.

Some organisations, for example, the Washington Redskins have refused to bow to external pressure to change their name, including pressure to change on ethical grounds (Mintz, 2013). For example, the Oneida Indian Nation in upstate New York even launched an advertising campaign to urge the team to change its name, stating 'we do not deserve to be called redskins. We deserve to be treated as what we are — Americans." However, A Washington Post poll in 2016, found that nine out of 10 Native Americans were not offended by the Washington Redskins name, reflecting a similar survey in 2004. Washington's owner, Dan Snyder, has claimed the poll backs his stance resist change to the team's name"

> "The Washington Redskins team, our fans and community have always believed our name represents honor, respect and pride, … polling shows Native Americans agree. We are gratified by this overwhelming support from the Native American community, and the team will proudly carry the Redskins name."

Examples relating to education and sport include:

Sport	Organisation	Nicknames	Potential Name Change	Decision to Change
All Sports	Susquehanna University	Crusaders	Squirrels & River Hawks	Yes
	Alvernia University	Crusaders		
	University of North Dakota	Fighting Siouxa	Fighting Hawks	Yes
	Amherst College	Lord Jeff(rey Amherst)		Yes
Cricket	Middlesex Crusaders			
Basketball	Washington Bullets	Bullets	Washington Wizards	Yes
AFL	Houston Colt 45s	Colt 45s	Houston Astros	Yes
	Washington Redskins	Redskins		No
Baseball	Tampa Bay Devil Rays	Devil Rays	Tampa Bay Rays	Yes
	Atlanta Braves	Braves		No
	Cleveland Indians	Chief Wahoo mascot/logo		Yes

Week 9, Day 6 – The *Christchurch Call* Paris Summit

On 15 May, two months to the day after the Christchurch terror attack, the Christchurch *Call* brought leaders from ten countries and Facebook, Google, Instagram etc to Paris, where a commitment \was made to a set of collective actions:

- developing tools to prevent the upload of terrorist and violent extremist content;
- countering the roots of violent extremism;
- increasing transparency around the removal and detection of content, and
- reviewing how companies' algorithms direct users to violent extremist content.

9 Crusaders' Decision Making

Students should consider whether the success of the global initiative, described as the *Christchurch Call*,
(i) has created additional pressure for the Crusaders to act in terms of a possible name change or
(ii) has given direction to the Crusaders' decision-making.

10 Brand Management - Advice to Crusaders about a Potential Name Change and Branding

(i) Students should set out the pros and cons for name retention or name change as they impact brand identity, brand equity, and the Crusaders name as an element of equity and identity
(ii) Students can then provide advice to the Crusaders' CEO and the NZR, in relation to issues of brand identity, brand equity, and the Crusaders name as an element of equity and identity

Week 17, Day 2 – NZ Gun Buyback Scheme - Arms Amendment No. 1

On **13 July 2019**, the government gun buyback scheme began with the voluntary surrender of banned guns. Within one month, 10k guns had been surrendered with owners obtaining agreed compensation (Small, 2019).

Week 18, Day 6 – Gun Law Reform - Arms Amendment No. 2 Bill – Second Tranche

On **22 July 2019**, the government announced a second tranche of gun law reform to include the creation of a firearms register and more stringent licencing requirements (Fitzgerald et al, 2019).

SAMPLE OF CASE B QUESTIONS AND DISCUSSION POINTS - Managerial Issues and Tasks

General:

11a - Chronology of Events, Decisions and Dilemmas
Students should familiarise themselves with the both case narratives by creating a chronology of events, including the decisions made/dilemmas confronted by the major actors and stakeholders.

11b - Stakeholder Analysis
In parallel, students should undertake a stakeholder analysis, identifying generic and specific stakeholders, their roles, stakes or interests, and their attributes.
Such stakeholder attributes would include: their power or influence to impact others; their ability to act with urgency or timeliness and/or to effect urgent or immediate response from other; and the legitimacy (social, legal or otherwise acceptance of their views or actions.
The Stakeholder Analysis should clearly identify stakeholder dynamics in terms of the emergence of 'new' stakeholders, or stakeholders whose attributes, say power or legitimacy have changed over the time of the Affair.

11c - Crises and Crisis Management
Students should reflect on what they understand to be a crisis, and how crisis management situations can be distinguished from other management situations. In this case, students should become aware of how those stakeholders whose interests/views have gained in legitimacy, may also have gained influence, and an ability to 'coerce' a response – effecting a crisis in the primary case organisation.

Specific:

12 Crisis Management - Evaluating Actions by the Crusaders organisation
12a Consider the actions taken by the CEO:
(i) on hearing of the Terror Attack
(ii) as events unfolded over days and weeks.
1 and how they may reflect a considered crisis management plan to deal with such situations?
12b Given that considerable media coverage had been given to the actions of the Prime Minister and the Government, would it be reasonable for CEO to assume that a crisis/media storm surrounding the action on a name change had been averted? Say why.

13 Governance, Multiple Jurisdictions, Justice and Fairness, and Locus of Responsibility
Offer some brief comment on where the locus of responsibility should lie in the name change? – the Crusaders, NZR, *World Rugby*? That is, offer reasoned comment on whom should take responsibility for a name that has negative connotations for the religious minority subject to the terror attack, and for many others in the wider community..

14 Brand Management
What advice could you give the Crusaders' CEO and the NZRU, in relation to issues of brand identity, brand equity, and the Crusaders name as an element of equity and identity.
Establish the pros and concerns for name retention or name change.

15 Applicability to other Managerial or Professional Situations
a What are the implications, the ethics, crisis and brand management lessons, for those involved in management and governance?
b Can the situation be seen as presenting opportunities for the key people to accept responsibility for leadership, values and ethics; to be honest, to behave appropriately, to act with compassion and to convey integrity?
c Consider whether and why an inappropriate name, inappropriate to ethic or indigenous minorities minorities - may more or less acceptable in some contexts than in others.
d Provide a Summary of Implications for Management and Governance

16 On reflection, why did the Crusaders name attract initial media attention?
In particular, comment on how and why evolving interest from different stakeholder groups kept the spotlight on the Crusaders and the New Zealand Rugby Union.

17 Should the Crusaders organisation, its CEO and senior management; have been pressured following the terror attack, because of decisions made a quarter of a century earlier?

DECISION SCIENCES INSTITUTE
Impact of paradoxical thinking and individual perceptions on entrepreneurial intention

ABSTRACT

Individual perceptions on internal resources and external environmental factors have garnered significant research interest recently as potential antecedents of individuals' entrepreneurial intentions. Prior studies also have emphasized the needs to investigate how individuals' diverse capabilities play their roles in an individual's decision-making to start one's own business. In this study, I investigate the role of an individual's paradoxical thinking capability in terms of its moderating effect on the relationship between individual perceptions, i.e., perceived individual capability, perceived opportunity, social perception of entrepreneurship, and perceived fear of failure, and subsequent entrepreneurial intentions. Analyses of survey responses of 10,000 individuals in South Korea reveal that paradoxical thinking positively moderates the effects of perceived capability, perceived opportunity, and fear of failure on entrepreneurial intention. On the other hand, paradoxical thinking negatively moderates the relationship between social perception of entrepreneurship and entrepreneurial intention. These findings suggest that while paradoxical thinking positively affects individuals' perceived feasibility, it simultaneously decreases individuals' perceived desirability because paradoxical thinking expands individuals' options to choose from, which, as a result, would decrease the desirability of an option of starting one's own business.

KEYWORDS: entrepreneurial intention, paradoxical thinking, individual perception

INTRODUCTION

Entrepreneurial activities have been gathering universal interests from various stakeholders that range from aspiring entrepreneurs in an individual level to governments in a societal level. These interests peak especially when economies are in bad situations such as financial crises, largely due to the distinguished impact of entrepreneurship: entrepreneurial activities are one of rare phenomena where micro-level activities have macro-level impacts on society as a whole (Davidsson, 2004). Understanding how and why these micro-level activities happen, even under the harsh environment of high failure rates, is important for both individuals who try to create new organizations and society as a whole which would benefit from those individuals who successfully initiate entrepreneurial processes to deliver their new ideas.

One observable indicator that has been found to be a single best predictor of behavior is an individual's intention (Kim & Hunter, 1993). Since the actual behavior is either rare or difficult to observe (Ajzen, 1991), prior studies have observed an individual's entrepreneurial intentions to understand the possible sources of one's decision to start a business. Prior studies have investigated entrepreneurial decision-making processes and organizational emergence from various perspectives, such as psychological, cognitive, behavioral, and strategic standpoints. However, our understanding of the possible origins of these micro-level activities is hardly complete, mostly because individual decision-makings and subsequent organizational emergence involve a series of perception-driven decisions (Bird, 1988; Gartner, 1985; Katz &

Gartner, 1988; Shapero & Sokol, 1982). Individuals' social and situational perceptions, in conjunction with their individual characteristics, lead to one's decision to start a new business. Naturally, prior studies have discussed individual perceptions of entrepreneurs in terms of risk perceptions (e.g., Gartner & Liao, 2012; Simon, Houghton, & Aquino, 2000), perceived opportunities (e.g., Krueger, 1993), or perceived environmental uncertainties (e.g., Milliken, 1987).

In this study, individual perceptions and their subsequent effects on their entrepreneurial intentions are investigated in terms of individual capability of thinking in a paradoxical way. Specifically, I focus on the individuals' paradoxical thinking capability that handles both perseverance and strategic flexibility with equal dexterity, and study the impact of this paradoxical thinking capability on the relationship between individual perceptions and their subsequent entrepreneurial intentions.

LITERATURE REVIEW

Intentionality is defined as 'a state of mind directing a person's attention toward a specific object or a path in order to achieve something' (Bird, 1988, p. 442). This rather broad definition of intentionality has been applied to and understood in the context of an entrepreneur who pursues entrepreneurial ideas. Entrepreneurial intention is an individual desire to become an entrepreneur (Jenkins & Johnson, 1997), more specifically defined as a self-acknowledged conviction about the likelihood of starting one's own business at some point in the future (Crant, 1996; Thompson, 2009). Prior studies that have focused on entrepreneurial intention have identified a wide range of possible antecedents: personality traits such as proactiveness (Crant, 1996; Zhao, Seibert, & Lumpkin, 2010), behavioral traits such as propensity to act (Krueger, Reilly, & Carsrud, 2000), individual predispositions such as proclivity for improvisation (Hmieleski & Corbett, 2006) or self-efficacy (Boyd & Vozikis, 1994; Piperopoulos & Dimov, 2015; Zhao, Seibert, & Hills, 2005), individual exposure to entrepreneurship (Bae, Qian, Miao, & Fiet, 2014; Krueger, 1993), or general individual factors such as gender or culture (Shinnar, Giacomin, & Janssen, 2012), to name a few.

According to the review article on entrepreneurial decision-making by Shepherd, Williams, and Patzelt (2015), perception-based variables have garnered more research interests recently mostly because of the subjective nature of individual perceptions, intentions, and subsequent actions as a form of decision-making. More specifically, a common theme that underlie the identified antecedents of entrepreneurial intention is how an individual perceives oneself as well as the surroundings of oneself. Endogenously, individuals perceive their resources (Kor, Mahoney, & Michael, 2007), capabilities (Gatewood, Shaver, & Gartner, 1995), identity (Fauchart & Gruber, 2011), personal motivations (Birley & Westhead, 1994), and potential goals. Simultaneously, individuals perceive exogenous factors such as environmental opportunities and threats (Krueger, 2003), social norms , and the level of uncertainties (Townsend & Hart, 2008). Constant interactions between perceptions of endogenous and exogenous factors are processed to form an individual's overall perceptions. Inherent heterogeneity in individuals' self-perceptions and environmental perceptions, consequently, drives the variance in the level of entrepreneurial intentions.

Prior studies in entrepreneurial intention have identified two critical dimensions of individual perceptions which impact one's entrepreneurial intention: perceived desirability and feasibility of a potential opportunity (Fitzsimmons & Douglas, 2011; Krueger et al., 2000). Perceived desirability is the degree to which an individual is attracted to an idea of the recognized opportunity. Perceived feasibility is the degree to which an individual feels capable of oneself to pursue the opportunity. These two specific types of perception have been empirically shown to have positive impacts on one's intention to start a business (Krueger et al., 2000). Prior studies have proposed various ways to conceptualize and measure the perceived feasibility and desirability constructs: a single-item measure such as 'how feasible or desirable' an entrepreneurial opportunity is (Krueger et al., 2000); self-efficacy as a perceived feasibility measure and perceived attractiveness of certain hypothetical career profiles as a perceived desirability measure (Fitzsimmons & Douglas, 2011); or more specifically, an entrepreneur's attitude toward risks as a proxy to measure one's perceived desirability (McMullen & Shepherd, 2006). Although both endogenous and exogenous factors which have been identified as possible antecedents of entrepreneurial intention as summarized above, empirical studies has not been incorporating both endogenous and exogenous factors so far. Therefore, in this study, both endogenous and exogenous factors are investigated to further understand the perceived feasibility and desirability.

Endogenously individuals perceive their ability to accomplish their intentions, and, at the same time, exogenously, they perceive entrepreneurial opportunities in their surroundings. Following the definition of the perceived feasibility, i.e., the degree to which an individual feels capable of oneself to pursue the opportunity, I focus on the perceived individual capability to pursue entrepreneurial opportunities as the endogenous factor, and the perceived availability of entrepreneurial opportunities as the exogenous factor of the perceived feasibility. Models and theories that explain the entrepreneurial intention model, such as Ajzen's (1991) theory of planned behavior or Shapero and Sokol's (1982) entrepreneurial event model, argue the positive impact of the perceived feasibility and subsequent entrepreneurial intention. Subsequent studies that have empirically tested the models show the supporting evidence of the positive relationship between the perceived feasibility and entrepreneurial intention (e.g., Krueger & Carsrud, 1993; Kautonen, van Gelderen, & Fink, 2015). Hence I hypothesize the positive relationships between the perceived capability as well as the perceived availability of entrepreneurial opportunity and the entrepreneurial intention.

Hypothesis 1. An individual's perceived capability to pursue entrepreneurial opportunities has a positive influence on his or her entrepreneurial intention.

Hypothesis 2. An individual's perceived availability of entrepreneurial opportunities has a positive influence on his or her entrepreneurial intention.

Following the definition of the perceived desirability, i.e., the degree to which an individual is attracted to an idea of the recognized opportunity, I focus on an individual's fear of failure as the endogenous factor, and the social perception of entrepreneurship in general as the exogenous factor of the perceived desirability. Fear of failure is the perceived possibility of experiencing failure and its consequences (Arenius & Minniti, 2005), which should be distinguished from a general risk aversion (Wyrwich, Stuetzer, & Sternberg, 2016). Fear of failure is a context-specific process which is affected by an individual's personal assessment and understanding of one's possibility and consequences of accomplishing his or her aspiration. Since each individual holds heterogeneous level of fear towards the possibility of failure, how individuals perceive their own fear of failure contributes to their intentions towards pursuing an entrepreneurial opportunity. However, an individual's endogenous fear of failure is not the only factor that affects one's assessment of desirability of the opportunity. Social perception of entrepreneurship in general, such as how the society where an individual belongs to views entrepreneurs and entrepreneurial processes, also affect an individual's aspiration to pursuing one's recognized entrepreneurial opportunity. Prior studies on social norms have found that social norms indeed affect an individual's entrepreneurial intention (e.g., Krueger & Carsrud, 1993; Kautonen, Tornikoski, & Kibler, 2011). Hence, I hypothesize that an individual's fear of failure negatively affects the entrepreneurial intention, whereas the positive social perception of entrepreneurship in general positively affects the entrepreneurial intention.

Hypothesis 3. An individual's fear of failure has a negative influence on one's entrepreneurial intention.

Hypothesis 4. An individual's social perception of entrepreneurship in general has a positive influence on one's entrepreneurial intention.

These hypothesized relationships between individual perceptions and entrepreneurial intentions are likely to be contingent upon individual characteristics. Prior studies that have focused on the entrepreneurial intention trace back to a few "epicenter" studies (e.g., Ajzen, 1991; Shapero & Sokol, 1982), one of which is Bird's (1988) intentionality model. The intentionality model conceptualizes a wide range of both individual and environmental attributes, e.g., personal history, personality, social and political contexts, that are potential antecedents to intentionality. While the intentionality model is fundamentally a behavioral model, Bird (1988) identified two distinctively different types of cognitive processes: (1) a rational, analytical, and cause-effect thinking process, and (2) an intuitive, holistic, and contextual thinking process. Although individual and environmental attributes have been investigated extensively so far (e.g., Boyd & Vozikis, 1994; Crant, 1996; Mueller & Thomas, 2001), two competing cognitive processes have been relatively under-investigated, mostly due to the inherent difficulties with measuring and collecting an individual's cognitive processes.

Bird (1988) argues that two competing cognitive processes, i.e., the analytical thinking which searches and processes information in a systematic and comprehensive way, and the intuitive thinking which searches and processes information in a heuristic and satisficing way, are equally critical for entrepreneurial intention. Moving away from the conventional conceptualization of "either/or" model, Bird's (1988) intentionality model implicitly assumes the presence of paradoxical thinking. Paradoxical thinking is an individual's ability to juxtapose and integrate contradictions, such as actively processing opposite ideas or concepts simultaneously (Rothenberg, 1979). Paradoxes, which are defined as "contradictory yet interrelated elements that exist simultaneously and persist over time" (Smith & Lewis, 2011, p. 382), are prevalent in our everyday decision-makings: we try to be efficient, yet flexible at the same time; we aspire to have "big picture" visions, yet be detail-oriented at the same time. Embracing and effectively handling, not avoiding or eliminating, paradoxes is a common task for individuals in the field of creativity (Rothenberg, 1979) or innovation (Martin, 2007), where a creative resolution is not only generated by processing opposing ideas but also superior to each idea (Ingram, Lewis, Barton, & Gartner, 2016). Logically challenges of paradoxes become more significant for individuals who aspire to be entrepreneurs, as their decision-makings need to accommodate and embrace competing yet interrelated concerns.

Departure from the formal "either/or" logic to adopt "both/and" one enables individuals to acknowledge the paradoxical nature of entrepreneurial ideas which require entrepreneurs to be efficient with limited resources, yet, at the same time, flexible under the high level of uncertainties they constantly face throughout their entrepreneurial journeys. More specifically, resource constraints require entrepreneurs to be efficient and effective in combining existing resources to create new resource bundles (Baker & Nelson, 2005). Concurrently, high level of uncertainty imposes a critical challenge to entrepreneurs: they need to be adaptive to environmental contingencies, and moreover, proactive with exploiting the recognized contingencies in a beneficial way (Sarasvathy, 2001). As a result, entrepreneurs are required to handle seemingly intractable paradoxes of systematically executing tactical movements efficiently while flexibly accommodating to future possibilities. These types of paradoxical tensions demand paradoxical thinking because an individual capability to process contradictory problems and generate superior solutions is more likely to show superior performance. Individuals who are capable of conducting paradoxical thinking, therefore, are expected to handle the paradoxical nature of pursuing entrepreneurial ideas in a superior way. Paradoxical thinking enables individuals to better process contradictory aspects of entrepreneurial ideas, and consequently, assists individuals to realize their entrepreneurial intention through perceived feasibility of their ideas. In other words, the individual capability of paradoxical thinking is likely to facilitate the process of transforming perceived opportunities and individual capability into individuals' intentions to pursue their ideas.

Hypothesis 5a. Paradoxical thinking positively moderates the relationship between the perceived individual capability and entrepreneurial intention.

Hypothesis 5b. Paradoxical thinking positively moderates the relationship between the perceived opportunities and entrepreneurial intention.

Individuals who are adept at paradoxical thinking, on the other hand, should be able to generate greater number of potentially desirable options to choose from, which may make an option of starting one's own business less desirable.

Hypothesis 5c. Paradoxical thinking negatively moderates the relationship between the social perception of entrepreneurship and entrepreneurial intention.

Hypothesis 5d. Paradoxical thinking negatively moderates the relationship between the fear of failure and entrepreneurial intention.

METHODS

In this study, I analyzed the nation-wide, individual-level Entrepreneurship Survey of South Korea 2017. The Korean Entrepreneurship Foundation conducts an annual survey to measure entrepreneurial aspects of general public in South Korea, by collecting survey responses from 10,000 South Korean individuals between August and October, 2017. Demographic profile and entrepreneurship-related experiences of survey respondents are summarized in Table 1.

Table 1. Survey Respondents

Gender	Male	5,055
	Female	4,945
Age	13-19	1,401
	20-29	1,651
	30-39	1,754
	40-49	1,836
	50-59	1,824
	60-69	1,534
Entrepreneurial experience	Yes	1,127
	No	8,873
Entrepreneurial education	Yes	4,672
	No	5,328

The dependent variable of entrepreneurial intention is measured by a survey item, "I have a plan to start my own business within three years." The perceived individual capability is measured by a survey item, "I have relevant knowledge and capability to start my own business." The perceived opportunity is measured by a survey item, "I believe abundant opportunities are available for me to start my own business." The social perception of entrepreneurship is measured by three survey items: (1) "Entrepreneurs are respected and well regarded," (2) "Becoming an entrepreneur is considered a good career choice," and (3) "Stories of successful entrepreneurs are readily available in media." Individual fear of failure is measured by a survey item, "Fear of failure makes me hesitant to start my own business."

Following the prior studies that create a multiplicative measure to capture a construct which contains two contradictory aspects, such as organizational ambidexterity measure (Gibson & Birkinshaw, 2004; Jansen, Simsek, & Cao, 2012; Kauppila & Tempelaar, 2016), I have created a multiplicative measure by multiplying two survey items, which measure (1) an individual's mindset to persevere through challenges without compromising, and (2) an individual's mindset to pivot, or adapt, flexibly according to environmental contingencies. This multiplicative interaction between individual perseverance and pivot adequately capture an individual's "both/and" thinking of planning and changing. Perseverance is measured by a survey item, "I am inclined stick to my original plan and achieve my goal regardless of challenges." Pivot is measured by a survey item, "I am inclined to change my plan and try new paths when I face challenges."

All variables are measured by a single survey item except the social perception of entrepreneurship, as they are theoretically simple and concrete constructs. Although single-item measures are commonly considered to show lower content validity, sensitivity, and reliability (McIver & Carmines, 1981), this methodological issue is prominent with complex and multidimensional constructs. When the construct is relatively simple and concrete, single-item scales have been argued to be appropriate measures (Freed, 2013; Grapentine, 2001). Accordingly, prior studies empirically show that single-item scales that measure theoretically simple constructs show identical performance with multi-item scales (Bergkvist & Rossiter, 2007; McKenzie & Marks, 1999) or even superior performance than multi-item scales (Bush et al., 2010).

In order to control for individual characteristics and entrepreneurial experiences, six control variables are added: age, current income, personal experience in entrepreneurship, personal experience in entrepreneurial education, family members' experience in entrepreneurship, and one's perceived creativity.

RESULT

Table 2. Means, standard deviations, and correlations among variables (N=10,000)

	Mean	S.D.	1	2	3	4	5	6	7	8	9	10

**** p<.001 ** p<.01 * p<.05*

Table 2 displays means, standard deviations, and correlations among all variables. Table 3 shows the results of the hierarchical regression analysis. As the first step of the hierarchical regression analysis, Model 1 contains controls. Model 2 includes the main effects of individual perception, i.e., perceived capability, perceived opportunity, social perception of entrepreneurship, and fear of failure, and paradoxical thinking. Model 3 includes the interactions between individual perceptions and paradoxical thinking.

The analysis result of Model 2 show that the hypotheses regarding the direct effects of individual perception on entrepreneurial intention are supported. The change in R2 from Model

1 to Model 2 for the main-effect model indicates a significant increase in R2 above and beyond the control variables. The analysis result of Model 3 show that the interaction effects between individual perception and paradoxical thinking are indeed statistically significant as hypothesized. Figure 1 shows the interaction effects between individual perception and paradoxical thinking on entrepreneurial intention.

Table 3. Hypothesis testing using hierarchical regression analysis

DISCUSION

In this study, I investigate the role of an individual's paradoxical thinking capability in terms of its moderating effect on the relationship between individual perceptions, i.e., perceived individual capability, perceived opportunity, social perception of entrepreneurship, and perceived fear of failure, and subsequent entrepreneurial intentions. Analyses of survey responses of 10,000 individuals in South Korea reveal that paradoxical thinking positively moderates the effects of perceived capability, perceived opportunity, and fear of failure on entrepreneurial intention. On the other hand, paradoxical thinking negatively moderates the relationship between social perception of entrepreneurship and entrepreneurial intention. These findings suggest that while paradoxical thinking positively affects individuals' perceived feasibility, it simultaneously decreases individuals' perceived desirability because paradoxical thinking expands individuals' options to choose from, which, as a result, would decrease the desirability of an option of starting one's own business.

Email: jhong@scsu.edu

ABSTRACT

This paper proposes a new procedure of integrating data envelopment analysis (DEA), multiple criteria data envelopment analysis (MCDEA), multiple objective programming (MOP), and the cross-efficiency (CE) method to evaluate and rank the decision-making units (DMUs). Through a case study of designing the humanitarian supply chain network (HTSCN) system, we demonstrate that the integrated method performs well in terms of designing HTSCN system effectively and efficiently.

KEYWORDS: Multiple Criteria Data Envelopment Analysis, Cross Efficiency Evaluation, Multiple Objective Programming, Humanitarian Supply Chain Network

INTRODUCTION

Data envelopment analysis (DEA) is one of the methodologies that have been widely used to evaluate the relative efficiency of a set of peer organizations called decision-making units (DMUs) that use multiple inputs to produce multiple outputs. The DMUs in DEA to be assessed should be relatively homogeneous. As the whole technique is based on a comparison of each DMU with all the remaining ones, a considerable large set of DMUs is necessary for the assessment to be meaningful (Meza & Jeong, 2013; Ramanathan, 2006). DEA eventually determines which of the DMUs make efficient use of their inputs and produce most outputs and which do not. DEA produces a single, comprehensive measure of performance for each DMU. The best ratio among all the DMUs would identify the most efficient DMU, and every other DMU would be rated by comparing its ratio to the best one. However, a weakness of the DEA-based assessment is that a considerable number of DMUs out of the set of DMUs to be rated are classified as efficient so that it may suffer from a lack of discrimination particularly.

To improve the discriminating power of DEA methods, Li and Reeves (1999) propose a multiple criteria DEA (MCDEA) model under the framework of multiple objective linear programming (MOLP). The MCDEA model involves a broader definition of relative efficiency that the classical one introduced by Charnes et al. (1978). In other words, several different efficiency measures are defined under the same constraints. Each measure serves as a criterion to be optimized. They (1999) claim that efficiency criteria that are more restrictive than the classical one will yield fewer efficient DMUs and will allow less flexibility for input/output weight distribution. But, they (1999) do not explain how to rank DMUs but merely show which DMUs are more efficient than other DMUs by solving the MCDEA sequentially with one objective out of three objective functions. For example, a DMU, which is consistently efficient regardless of the objective function, is considered to be most efficient. Then, if several DMUs turn out to be consistently efficient after evaluated by MCDEA, the question of how to rank them in terms of efficiency remains.

DEA allows each DMU to be evaluated with its most favorable weights due to its nature of the self-evaluation. Thus, to maximize the self-efficiency, the DEA model may even ignore unfavorable inputs/outputs. That is the inherent deficiency stemming from the self-efficiency. To remedy this deficiency, the cross-efficiency (CE) evaluation method is suggested by Sexton et al. (1986) as a DEA extension to rank DMUs with the main idea of using DEA to do the peer evaluation, rather than DEA's pure self-evaluation. Due to its enhanced discriminating power, the CE evaluation has found a significant number of applications in the DEA literature (Wang and Chin, 2010).

To remedy the weaknesses/deficiencies of DEA and MCDEA, this paper proposes a new procedure of integrating MCDEA with CE evaluation method for a humanitarian supply chain network (HTSCN) design problem in a pre-disaster scenario. The HTSCN design problem consists of finding the optimal emergency response facility (ERF) locations and allocation scheme of humanitarian supplies through ERFs, where all ERFs are under the risk of disruptions. For a case study, we use Hong and Jeong's (2018) HTSCN design problem to demonstrate the applicability of the proposed procedure. This paper demonstrates that the innovative integrated procedure can be applied for various supply chain network design problems with multiple performance measures.

MULTIPLE CRITERIA DEA MODEL

Charnes et al. (1978) establish a CRS (Constant Returns to Scale) m-DEA model to find an efficiency score for DMU_k, which is formulated as the following LP problem:

$$Max\, h_k = \sum_{r=1}^{s} u_r y_{rk}\,, \tag{1}$$

subject to

$$\sum_{i=1}^{m} v_i x_{ik} = 1, \tag{2}$$

$$\sum_{r=1}^{s} u_r y_{rj} - \sum_{i=1}^{m} v_i x_{ij} \le 0, \forall j, \tag{3}$$

$$u_r, v_i \ \ge 0, r = 1 \dots, s; i = 1 \dots, m$$

where
Ω = number of DMUs being compared in the DEA analysis
h_k = efficiency rating of the DMU_k being evaluated by DEA
y_{rj} = amount of output r generated by DMU_j , *j= 1, 2, …, k, …* Ω
x_{ij} = amount of input i used by DMU_j
i = number of inputs used by the DMUs
r = number of outputs generated by the DMUs
u_r = coefficient or weight assigned by DEA to output r
v_i = coefficient or weight assigned by DEA to input i

Li and Reeves (1999) propose the following MCDEA model using the LP model in (1)-(3):

$$Max\ h_k = \sum_{r=1}^{s} u_r y_{rk}, \tag{4}$$

$$Min\ M_k, \tag{5}$$

$$Min\ D_k = \sum_j d_j \tag{6}$$

subject to

$$\sum_{i=1}^{m} v_i x_{ik} = 1, \tag{7}$$

$$\sum_{r=1}^{s} u_r y_{rj} - \sum_{i=1}^{m} v_i x_{ij} + d_j \leq 0, \qquad \forall j, \tag{8}$$

$$M_k - d_j \geq 0, \forall j\ , \tag{9}$$

$$u_r, v_i \ \geq 0, r = 1 \ldots, s; i = 1 \ldots, m; \text{ and } d_j \geq 0, j = 1,\ 2,\ \ldots,\ k,\ \ldots,\ \Omega.$$

Note that the three performance measures for each DMU would be classified as one output, h_k, to be maximized and two inputs, M_k and D_k, to be minimized. Thus, this paper proposes a multiple objective programming (MOP) model to MCDEA to combine these three performance measures into one objective. Solving the MCDEA model by MOP for a given set of weight set assigned to each performance measure would yield one DMU with two inputs, M_k and D_k, and one output, h_k. Thus, regardless of the number of performance measures for a supply chain system, solving the MCDEA by MOP will yield DMUs with two inputs and one output, so that the cross-efficiency DEA method can be applied effectively to rank the multiple efficient DMUs.

We propose the following procedure of integrating method with DEA, MCDEA, MOP, and CE method:

(i) Apply DEA to identify efficient DMUs.
(ii) For those efficient DMUs identified by applying DEA, apply MCDEA model and solve it by MOP with various sets of weights assigned one output and two inputs
(iii) Apply CE DEA method to rank those efficient DMUs.

HUMANITARIAN SUPPLY CHAIN NETWORK

Humanitarian supply chain (HSC) plays a critical role in providing disaster relief items such as first aids, drinking water, food, and daily commodities to alleviate the suffering of people. In 2017, the U.S. experienced a historic year of weather and climate disasters. In total, the U.S. was impacted by 16 separate billion-dollar disaster events including three tropical cyclones, eight severe storms, two inland floods, a crop freeze, drought, and wildfire. During 2018, the U.S. experienced a very active year of weather and climate disasters (see Figure 1). In total, the U.S.

was impacted by 14 separate billion-dollar disaster events: two tropical cyclones, eight severe storms, two winter storms, drought, and wildfires. The past three years (2016-2018) have been historic, with the annual average number of billion-dollar disasters being more than double the long-term average. The number and cost of disasters are increasing over time due to a combination of increased exposure, vulnerability, and the fact the climate change is increasing the frequency of some types of extremes that lead to billion-dollar disasters (https://www.climate.gov/news-features/blogs/beyond-data/2018s-billion-dollar-disasters-context). In early 2019, a wild March headlined by abnormal warmth in the US's coldest state and a destructive and costly "bomb cyclone" in the central US. By a landslide, Alaska posted its warmest March on record, and the powerhouse storm in the central US became the second billion-dollar weather disaster of 2019.

In this respect, the HTSCN design has become an important strategic decision due to the major damage inflicted by several natural disaster events. The weather-related emergencies have brought issues of emergency relief planning again. Indeed, after emergencies, it is critical through emergency response facilities (ERFs) to distribute humanitarian aid to the affected areas efficiently and effectively for saving human lives and alleviating suffering, and for a rapid recovery. Van Wassenhove (2006) emphasize that since the disaster relief is 80% logistics, it would follow that the only way to achieve this is through slick, efficient and effective logistics operations and more precisely, supply chain management. Logistics planning in emergencies involves the quick and efficient distribution of emergency supplies from the emergency response facilities to the affected areas via supply chains. The ERFs considered in this paper are three distinctive ones. They are (i) Central Warehouses (CWHs) or Distribution Warehouses (DWHs), where emergency relief commodities are stored, (ii) intermediate response facilities termed Relief Distribution Center (RDC) or Commodity Distribution Point (CDP), where people can more effectively gain access to relief goods, and (iii) neighborhood sites (NBSs) in need of humanitarian items. The distribution framework of HTSC is depicted in Figure 2 (see Hong and Jeong, 2019).

The HTSC design problem is an inherently strategic and long term in nature. The primary objective of the strategic level is to strengthen emergency preparedness as well as to select the most cost/distance-effective location of CWHs and CDPs among a set of candidate locations, to establish the distribution of emergency supplies throughout the HTSC, and to assign NBSs to CDPs and CDPs to CWHs. Determining such locations/allocations is a critical area in the design of an effective HTSC. However, traditional cost-based facility location models implicitly assume that located facilities will always be in service or be available and do not consider an associated risk of disruption. All facilities are susceptible to disruptions due to natural disasters, accidents, breakdowns, weather, or strikes. Effects of disruptions could be aggravated as a result of a lack of flexibility and interdependency in the HTSC.

CASE STUDY AND OBSERVATIONS

This paper applies the proposed procedure using a case study considered by Hong and Jeong (2019). Using major disaster declaration records in South Carolina (SC), they (2019) consider forty-six counties are clustered based on proximity and populations into twenty counties. Then, they choose one city from each clustered county based on a centroid approach and assume that all population within the clustered county exists in that city. The distance between these cities is considered to be the distance between counties. The database also provides a list of counties where a major disaster was declared. They assumed that when a major disaster is declared, the emergency facility in that county is disrupted and shut down. Based on the historical record and the assumption, the risk probability for each neighborhood (a county or a clustered county) is calculated in Table 1. The potential five locations for CWHs were selected based upon population, the proportion of area that each location would potentially cover, and the proximity to Interstate Highways in SC.

20	Greenville†	Greenville/Laurens	521	0.125

†potential locations for CWH

They consider four goals as major performance measures. The first goal is to minimize the total logistics cost (*TLC*). The second goal is to minimize the maximum coverage distance (MCD), which attempts to minimize the longest delivery distance between ERFs. The third goal is to maximize the expected amount of satisfied demands (*ESD*), whereas the fourth goal is to maximize the covered demands in case of emergency (*CDE*). The goal programming model for the case problem is solved for various values of the weight, $\boldsymbol{\alpha}=\{\alpha_1, \alpha_2, \alpha_3, \alpha_4\}$, where each weight assigned to each goal changes between 0 and 1 with an increment of 0.1.

There are 286 configurations for each model arising out of the combinations of the setting of $\boldsymbol{\alpha}$ under the condition $\alpha_1 + \alpha_2 + \alpha_3 + \alpha_4 = 1$. After 286 runs, we reduce 286 configurations into 71 consolidated configurations, based upon the values of the four-performance metrics. Each of the 71 configurations is considered as a DMU, which represents the optimal locations of ERFs and their supply chain schemes. First, the DEA model is applied to find efficient DMUs with a perfect efficiency score (ES) of 1.000 and 27 DMUs are found to be efficient. Second, the efficient 27 DMUs are solved using MCDEA by MOP model. As expected, we see several efficient DMUs but there is no way to rank them. Thus, the CE method is applied to find the most efficient DMU, and DMU #81 is identified as No. 1 efficient one. Figure 3 depicts the network scheme of DMU #81. As shown in Figure 3, the most efficient HTSCN, DMU #81, finds {Greenville, Charleston} for the CWH locations and {Anderson, Lexington, Spartanburg} for CDPs covered by the CWH {Greenville}, and finds {Walterboro, Conway} for CDPs covered by the CWH {Charleston}. DMU #81 generates ($327,393, 107, 2854, 2827) as the four-performance metrics.

SUMMARY AND CONCLUSIONS

Several problems have appeared as DEA has been applied to a wide variety of evaluation areas. DEA evaluates DMUs in terms of self-evaluation, which allows each DMU to rate its efficiency score with the most favorable weights to itself. Consequently, the problems related to weak discriminating power have arisen as the applications of DEA advance, since multiple DMUs frequently turn out to be efficient. Lack of discrimination power is the major weakness for DEA. To remedy this weakness and increase the discrimination power, the cross-efficiency (CE) evaluation methods and the multiple criteria DEA (MCDEA) model have emerged. But there is no explicit procedure of ranking the efficient DMUs by either of them.

This paper proposes an innovative procedure of ranking efficient DMUs by integrating these three methods, remedying the inherent weaknesses of three DEA methods. In the first step, DEA is applied to obtain efficient DMUs. In the second step, a MOP model is applied for each efficient DMUs found in the first step to solve the MCDEA model for various values of the weights assigned to the three criteria. In the third step, for each solved MCDEA model, the CE DEA methods are applied to obtain the cross-efficiency score (CESs) for each efficient DMUs and each solved MCDEA model. Fourthly, we rank the efficient DMUs based on the CESs obtained in the third step.

To demonstrate the proposed procedure, this paper uses HTSCN design problem, whose goal is to relieve and minimize the effects of a disaster. To design more balanced HTSCN schemes, a GP model is applied to generate various HTSCN schemes. Then, the proposed procedure to evaluate many HTSCN schemes is implemented. Through the case study, we can rank the efficient HTSCN schemes and identify the most efficient scheme. This paper demonstrates the applicability of the new proposed approach and shows that the proposed approach would be used as an important tool for designing various supply chain network systems efficiently.

ABSTRACT

In this study, a survey on Hurricane Harvey is designed to analyze the preparedness of Houston for a Natural Disaster. The project implements a survey research methodology where the data is gathered by asking questions to individuals. The questionnaire consisted of eleven close-ended questions, and the responses were recorded through online forms and face-to-face interviews. The study illustrates the significance of disaster management, previous approaches used in the field of disaster management, and analyzes the survey responses using graphical and tabular representation. The results of the study help understand the challenges and opportunities in disaster preparedness.

KEYWORDS: Hurricane Harvey; Natural Disaster; Survey research; Disaster management; Preparedness

INTRODUCTION

Hurricanes are the most destructive kind of natural disasters and have devastating impacts on the environment. Hurricanes are large, strengthening tropical storms that can pack wind speeds of over 157 mph and unleash more than 2.4 trillion gallons of rain a day (Nunez, 2014). When Hurricanes make a landfall, they carry heavy rain, strong winds and heavy waves that damage the environment and result in loss of lives.

Hurricane Harvey was a category four storm that made landfall in Texas on August 25th, 2017 (National Weather Service, 2017). Harvey made landfall three times in six days, affecting several residents of Houston (Amadeo, 2017). It incurred a loss of $125 billion in damages due to the catastrophic rainfall-triggered flooding (Amadeo, 2017). Houston received more than 50 inches of rainfall, leaving one third of Houston completely flooded (National Weather Service, 2017).

Natural disasters occur with minimum amount of warning and are difficult to prevent, but the risks involved in any disaster can be avoided by being prepared. Lack of preparedness before disaster leads to loss of life and property, and this study enhances the importance of being prepared before any disaster to avoid risks. This paper discusses the importance of efficient use of the resources and how to take measures to serve the affected community, based on the survey result analysis of Hurricane Harvey on the population of Houston. The government, emergency management agencies and the volunteers play a major role in disaster management to ensure adequate help to the affected population. Disaster management involves four phases: mitigation, preparedness, response and recovery, and, in this study, we analyze and discuss these three phases. The goal of this paper is to address the key issues in analyzing the preparedness of Houston to deal with a natural disaster, based on the Hurricane Harvey survey results.

This study applies survey research methodology, which benefits in understanding the preparedness of the government, communities and various organizations in Houston for any natural disaster. The study proposes solutions to reduce risk of damages and loss of lives due to natural disasters and discusses how to be prepared and efficiently to use resources during a disaster. The survey questions also aim to provide analysis on the significance of volunteering and on how various social media platforms can be used to assure help to the affected community, laying emphasis on digital volunteering. We believe that this paper provides a base to various other researches in the field of disaster management and an analysis on Hurricane Harvey.

LITERATURE REVIEW

In recent years, there have been several studies in the field of disaster management and how to efficiently deal with disasters; these studies provide a basis of understanding to our research. Each study differs in specifications. They provide analogies on disaster management and act as resources for our project.

The first study, "*Six in ten Americans are ready to deal with a natural disaster*" by Jeffery M. Jones, is a survey paper that provides guidelines to our research (Jones, 2007). This paper implements the survey research methodology to record the response to Hurricane Katrina. Telephone mode of survey is used in this paper to record responses, which are depicted graphically. In comparison, one key similarity is that our study utilizes survey research methodology, as well, and the key difference in our study is that we implement more than one mode of survey.

Like Harvey, Hurricane Katrina also had a huge impact on the population of New Orleans, and it is significant to understand the effects of another hurricane before analyzing Hurricane Harvey. The study conducted by Narayan Sastry discusses the effects of Hurricane Katrina by collecting data from the residents of New Orleans (Sastry, 2009). The paper lays emphasis on a pilot study, which is a collection of data on the after-effects, and the data is collected through a questionnaire. In comparison, the similarity is that our paper also implements a questionnaire for analysis of Hurricane Harvey.

Hurricane Andrew caused severe damage to the population of Florida, as the authors Stanley K. Smith and Christopher McCarthy discuss in their paper, which implements a telephone survey research methodology by random digit dialing (Smith & McCarty, 1996). The results discuss the damage caused, insurance settlements of the residents, evacuation of the residents, return status and living arrangements of the residents. This study inspires us as an implemented survey research methodology to understand the effects of Hurricane Harvey.

Fuqing et al. discuss the evacuation decisions taken by the residents of Texas Gulf Coast prior to Hurricane Rita (Fuging et al, 2007). They implement a face-to-face survey methodology to analyze the societal impacts of Rita. The survey results discuss the evacuation decision prior Hurricane Rita as well as the influence of Hurricane Katrina for the decision to evacuate. In comparison, our project implements the face-to-face survey methodology to analyze the preparedness of Houston and the effects of Hurricane Harvey.

Disaster preparedness plays a significant role in the disaster management cycle, and one of the objectives of our survey is to understand the preparedness of Houston for a natural disaster. Burke et al. provide insights on the preparedness of the vulnerable populations that are susceptible to the effects of natural disasters (Burke et al. 2012). Survey research methodology is implemented in their paper to assess the risks involved, and the survey results depicted Hurricanes as the top concern for the residents of North Carolina. Transportation and language were found to be of major concern for the vulnerable population, and the paper suggests that the emergency alerts, news, disaster threats and other information regarding the disaster should be provided in the population's native language. In comparison, the paper implements a survey research methodology to analyze the preparedness of the vulnerable population of North Carolina and provides great insights on the language barrier issue when dealing with the preparedness of a natural disaster (Burke et al. 2012). The study conducted by Anthony A. Peguero also enhances the barriers of disaster preparedness and the significance of Hurricane mitigation for the citizens to preserve safety (Peguero, 2006). The survey in this study is conducted through random digit dialing in Florida. The survey results discuss the various sources for information related to hurricanes, and the result and discusses the problems faced by the Latino community in Florida. In comparison, the survey research methodology gives an understanding and analysis on mitigation and preparedness for a Hurricane.

Surveys are designed to illuminate a specific problem through focused data analysis, and, in our project, we implement the survey research methodology to collect information from individuals, focusing on the problem of dealing with natural disasters. The study conducted by Kelley et al. (2003) provides a checklist of good practice in the conduct and reporting of survey research. The paper also discusses the processes of data collection, data analysis and reporting. This study provides a guide to our study and assists in understanding the implementation of research methodology.

It is significant that the effects of natural disaster on surveys are understood and analyzed before conducting the survey. Harter et al. (2006) illustrate an overview of the effects of disasters on surveys and their direct human causes. They discuss the effects of disaster such as injuries, death, refugees, loss of cooperation, inaccessibility and failure of necessary technology, that have an impact on the survey components and these components alter the survey response rates and eligibility rates. The study provides an understanding of the sensitivity of conducting the survey and the measures to be taken for an on-going survey, providing an understanding on survey research methodology.

Whittaker et al. (2015) insight on informal volunteerism of citizens and lays emphasis on growth of digital volunteerism in emergency and disaster management. This study provides a base to our project as our survey questions aim at understanding the role of informal volunteerism and awareness of digital volunteering during a disaster. The growing platform of digital volunteering is significant to reach out to the affected community, and, in our project, one of the survey questions aims at understanding the awareness of digital volunteering and its importance. Park & Johnston (2017) discuss the conceptual framework of digital volunteer networks in response to disasters and crises, as well as the challenges of digital volunteer networks for crisis response. This study helps our project explore the aspects of digital volunteering in preparedness for a natural disaster.

However, the information processed through digital volunteering platforms should be structured accordingly, and the data collected should be distributed to all the volunteers. It is important to consider all the aspects of data collected online, and the study conducted Starbird (2011) enhances the use of crowdsourcing for various information processing tasks during disasters and mass emergencies. This study provides a basis for our project on understanding data collection for digital volunteerism.

Social media platforms such as Facebook and Twitter can be used to help the affected community, as they cater to the response stage of disaster management. Li & Goodchild (2012) discuss the benefits and challenges of using social media in emergency management. The study provides an understanding on issues related to data access, data quality, information synthesis, privacy and equity. In comparison, our survey includes questions related to use of social media during a disaster.

Various-level government collaboration is significant in implementing the life cycle of disaster management, and, in the study, we also discuss the importance of collaboration of government with citizens as first responders. Lord (2003) discusses the framework of integrated emergency management, which allows various levels of government to work together to mitigate, respond and recover from disasters. In comparison, our questionnaire analyzes the role of government in response to a disaster. One such organization, Federal Emergency Management Agency (FEMA), took an initiative to create awareness for preparedness for earthquakes in the central United States. The paper, '2011 FEMA Central States Disaster and Earthquake Preparedness Survey Report' by FEMA, provides an analysis on earthquake preparedness in central United States (FEMA, 2011). The survey conducted in this paper evaluates the effectiveness of the Earthquake outreach activities and provides recommendations for increasing preparedness. The survey targeted the households in eight different states through telephone mode of interview, for which random digit dialing was implemented. The results of the survey indicate that the Earthquake Outreach program was effective and that outreach initiatives prepare communities to avoid risks. In comparison, the survey report in this study provides insights to our project for analysis of the results and our project uses two modes of survey, whereas, in this survey, report telephone mode of survey is implemented.

SURVEY RESEARCH METHODOLOGY

This methodology is a systematic process of gathering information by asking questions to individuals. The methodology was implemented to our project considering the following process:

Designing Survey

Here, goals are defined, target population is considered, and the timeline of the survey is defined. In this phase of methodology, we defined the objective of our project, and the objective of the survey was designed to understand the preparedness of communities and government during a natural disaster, the usage of social platforms during a disaster, the awareness of digital volunteering, and lastly, the collaboration of government and citizens as first responders during a disaster. The residents of Houston were considered as target population for our survey in order to understand the effects of Harvey and their preparedness for a natural disaster. Considering the timeline, the survey was completed within the timeline of 1-2 months.

Developing Questions

In this step of the process, closed-ended questions are developed, which includes response alternatives to all of the questions. The survey consisted of eleven closed-ended questions and one open-ended question to record the comments or suggestions of the respondents. The appendix of this paper consists of the survey form. Most of the questions in this survey were developed as close-ended question to avoid time consumption and to make the questionnaire effortless for the respondents.

Testing and Training

In this phase, the questions are reviewed, tested and revised multiple times. To ensure the validity of our survey questions, the sample survey form was distributed to a few students to obtain feedback. The feedback was obtained from these sample responses to make the required changes to the survey, and the final revised edition of the survey form was distributed to the communities in Houston.

Collecting Data

In this step, the survey is conducted using various modes such as telephone, email, online and interviews, and the response rate is recorded. In the project, two modes of data collection was implemented: online survey responses and face-to-face interview responses. Online survey responses were recorded using Google Forms, and face-to-face responses were collected by targeting the affected areas of Houston. The total number of responses collected is 120; 73.34% responses were recorded through google forms and 26.67% of the responses were recorded through face-to-face responses.

RESULTS

The survey responses were obtained through Online forms and Face-to-Face interviews, and a total of 120 responses were obtained. 73.34% of responses were recorded through Google Forms, and 26.67% of the responses were recorded through face-to-face responses.

Table 1: Number of responses obtained

Total responses	**120**
Online	88
F2F (face-to-face)	32

The following tables depict the results obtained for each question.

1. **Did you have the following minimum disaster supplies on-hand before Hurricane Harvey?**

Table 2: Response concerning minimum disaster supplies

	Online	**F2F**	**Total**	**%**
Sufficient supply of Food and Water	77	17	94	78.3%
Supply of personal care items and hygiene products	60	14	74	61.7%
A first aid kit	44	14	58	48.3%
Supply of Medicine	48	13	61	50.8%

Flashlight	51	18	69	57.5%
Local maps	16	13	29	24.2%
Cell phone with backup battery	46	11	57	47.5%
None of the above	7	4	11	9.2%

2. Prior to Hurricane Harvey, did your emergency evacuation plan include the following?

Table 3: Response concerning evacuation plan

	Online	**F2F**	**Total**	**%**
Evacuation Route	21	9	30	25.0%
Fuel in the vehicle tank	41	20	61	50.8%
First aid kit	30	12	42	35.0%
Emergency contact list	32	13	45	37.5%
I did not have any emergency evacuation plans	47	9	56	46.7%

3. **If needed, were you able to reach 911 at the earliest?**

Table 4: Response concerning 911

	Online	**F2F**	**Total**	**%**
Yes	20	14	34	28.33%
No	6	12	18	15.00%
I did not need to call 911	62	6	68	56.67%
			120	100.00%

4. **If needed, did you post a request for help on social media?**

Table 5: Response concerning social media

	Online	F2F	Total	%
Yes	13	12	25	20.83%
No	13	15	28	23.33%
I did not need help	62	5	67	55.83%
			120	100.00%

5. **Do you think Police departments, fire departments and rescue squads assured help and support as first-responders to the people of Houston?**

Table 6: Response concerning first responders

	Online	F2F	Total	%
Yes	79	22	101	84.17%
No	9	10	19	15.83%
				100.00%

6. **Do you think the Emergency Management Agencies should use social media as a platform to assure help for the people of Houston during a disaster?**

Table 7: Response concerning Emergency Management Agencies

	Online	F2F	Total	%
Yes	81	25	106	88.33%
No	7	7	14	11.67%
			120	100.00%

7. **Did you offer any kind of help during Hurricane Harvey as a volunteer?**

Table 8:Response on total initiatives as volunteer

	Online	F2F	Total	%
Yes	35	14	49	40.83%
No	53	18	71	59.17%
			120	100.00%

8. **Do you think enough citizens took initiative as volunteers for search and rescue operations during Hurricane Harvey?**

Table 9: Responses for citizens as volunteers

	Online	F2F	Total	%
Yes	73	18	91	75.83%
No	15	14	29	24.17%
			120	100.00%

9. **Would you trust help from anyone apart from friends or family during the disaster?**

Table 10: Response concerning trusting of help during a disaster

Yes	79	20	99	82.50%
No	9	12	21	17.50%
			120	100.00%

ANALYSIS AND DISCUSSION

The graphical representation of the result is provided for a better understanding and analysis of the data.

Mode of Survey: The data was collected using two modes of survey: online surveys and face-to-face interviews. The number of responses obtained for the online survey was greater than face-to-face interview responses as depicted in Figure 1, with a total 120 responses, 73.34% responses were obtained from online surveys, and 26.67% of the responses were obtained by conducting face-to- face interviews. Face-to-face interviews were very challenging, as it was comparatively difficult to obtain responses. The following are the disadvantages:

- The respondents were self-conscious about the responses
- Refusals due to time constraints

- Refusals due to language barriers
- Sensitivity of the topic and lack of interest in the survey, leading to refusals.

The responses obtained from online surveys were higher in number and had several advantages such as:

- Easier and faster due to the availability of the software that support online survey forms; our project implemented Google Forms to conduct online surveys
- Responses were obtained from various distant locations in Houston
- Automated data collection through Google Forms which reduced waste of time and efforts
- Facilitated the respondents to participate at their convenience (Wright, 2005).

In conclusion, to overcome the challenges of conducting face-to-face interviews, one should provide a comprehensive introduction and adequate information regarding the survey to gain the trust of the respondents. Rewards, expressing appreciation and sense of confidentiality should be provided to the respondents to increase the response rate through face-to-face interviews. [28]

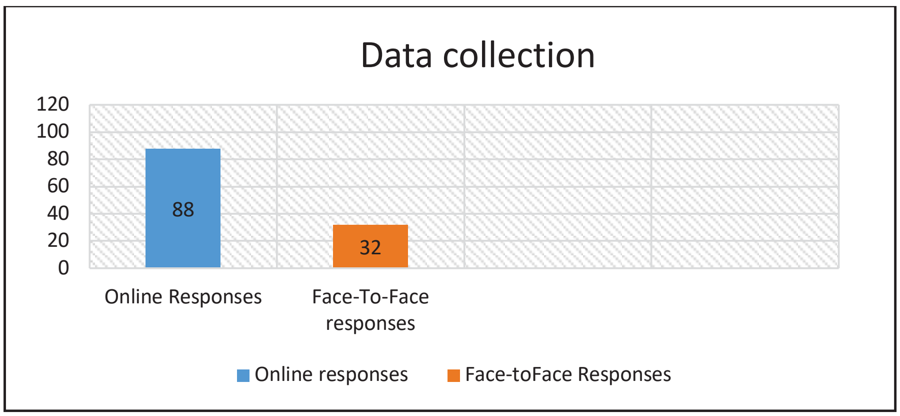

Figure 1: The collection of survey responses

Disaster Preparedness: The first question of the survey provides insight into the number of people that possessed the disaster supplies prior Hurricane Harvey. The objective of the project is to understand the preparedness of the people of Houston. Figure 2 depicts the number of people who had the minimum supplies before Hurricane Harvey.

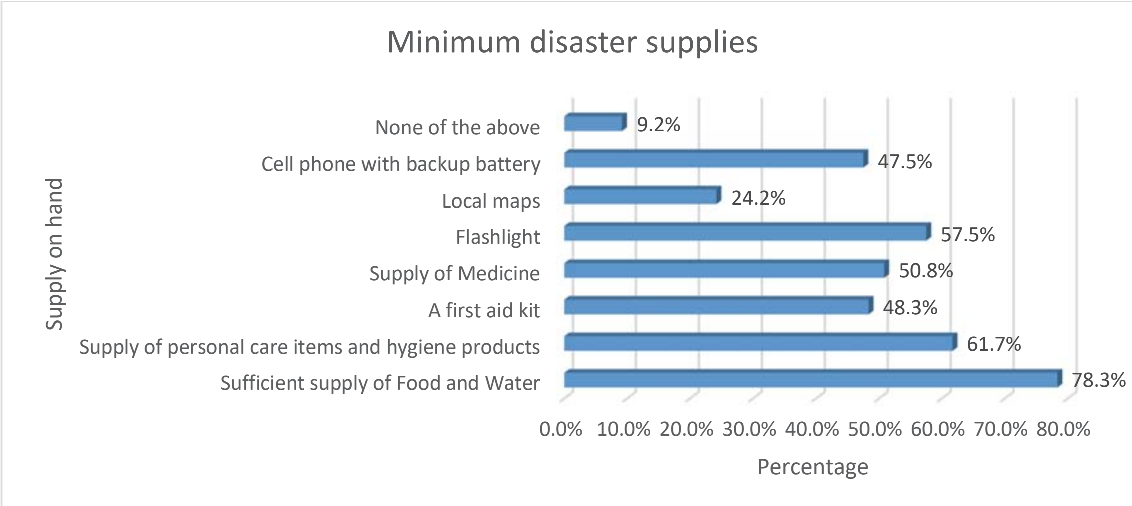

Figure 2:Minimum disaster supplies

Analyzing Figure 2, 9.2% of the respondents did not have any of the minimum supplies, and most of the respondents did not possess all the supplies listed in the question. Therefore, it is essential to create awareness regarding the minimum disaster supplies prior to any disaster among the communities, as disasters cause a lot of damage and can have long-last effects. Likewise, the second question also concerns disaster preparedness. Figure 3 depicts the number of respondents with an evacuation plan prior to Hurricane Harvey. Having an evacuation plan plays a major role in the preparedness phase of disaster management to avoid risks and damages, and 46.7% of the respondents did not have any emergency evacuation plan

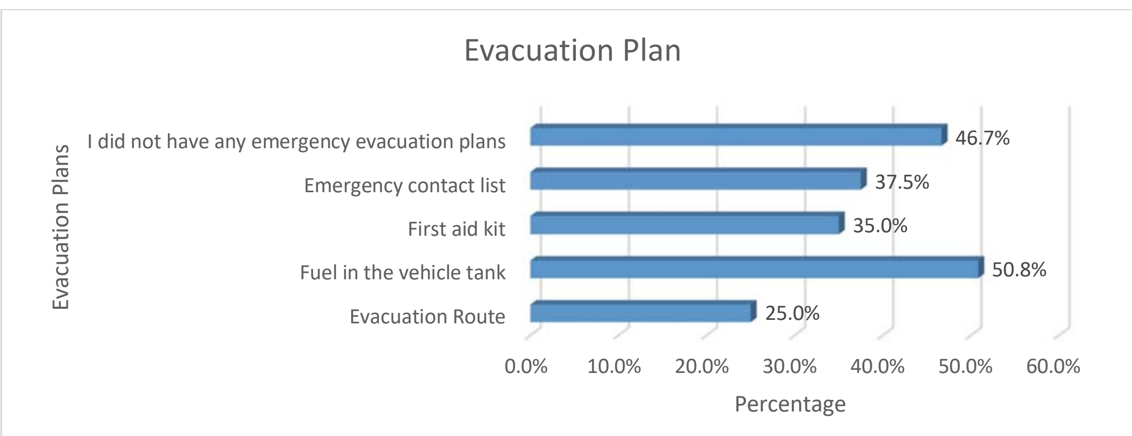

Figure 3: Responses concerning Evacuation Plan

Based on the survey result, we analyze that most of the respondents did not possess disaster supplies or an evacuation plan. However, it is important to create awareness about preparedness, and the following are proposed solutions for creating awareness: (Smith, 2008)

- The Emergency Management Agencies should conduct informational meetings and workshops at various localities of Houston to create awareness regarding the significance of planning and preparing prior any disaster.
- Local media should take initiative to inform and create awareness among the citizens regarding minimum disaster supplies and how to create an evacuation plan.
- Initiative should be taken to promote emergency preparedness at various levels of schools and colleges.
- Announcements should be made over television channels, radio stations and on various disaster management websites.
- With evolving technology, there is a drastic increase in the number of people that rely on social media platforms like Facebook, Twitter etc. for information and the use of social media platform to create awareness will prove successful. Therefore, social media should be better utilized by federal and state government agencies.
- Awareness booths should be set up at fairs and events; brochures containing the list of disaster supplies and evacuation plan should be distributed to the residents.

Emergency Number: The emergency number, 911, received around 80,000 calls in a 24-hour period during Hurricane Harvey (Kelly, 2017). Most people were unable to get through the lines as they were put on hold, and, based on our survey result in Figure 5, we observe that 15% of the respondents were unable to reach 911. It is important that every individual of the affected community is assured help, which is why it is necessary to create awareness about digital volunteering platforms and the use of social media platforms such as Facebook and Twitter to respond and ensure help during a disaster. The emergency number system should be advanced and updated to attend more number of calls and should provide a platform to process text messages from people to assure help to a greater number of people.

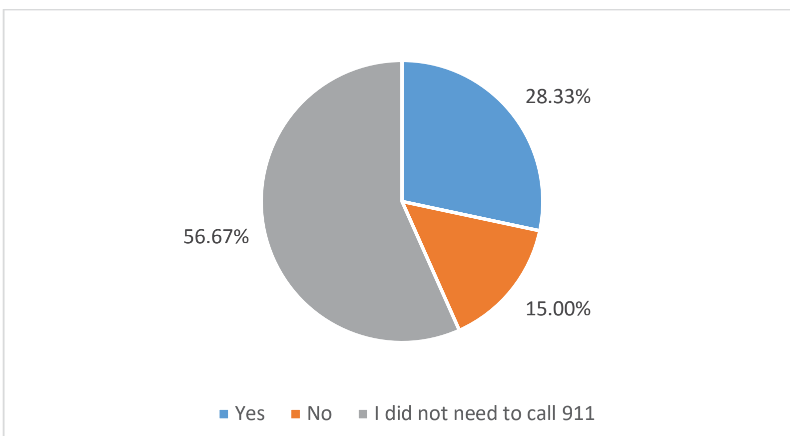

Figure 4: Response concerning 911

Social media in disaster management: With evolving technological innovations, social media plays a significant role in updating and keeping people informed. Use of social media platform in the field of disaster management can benefit a huge population and enhance the response phase. Based on the survey result, Figure 6 represents that 55.83% of the respondents used social media to post requests for help during Hurricane Harvey. Social media platforms such as Facebook and Twitter served as an alternative to 911 during Hurricane Harvey. The social media platform should be used by government organizations, Emergency Management Agencies and various other non-profit organizations to collect data and provide help to the affected community.

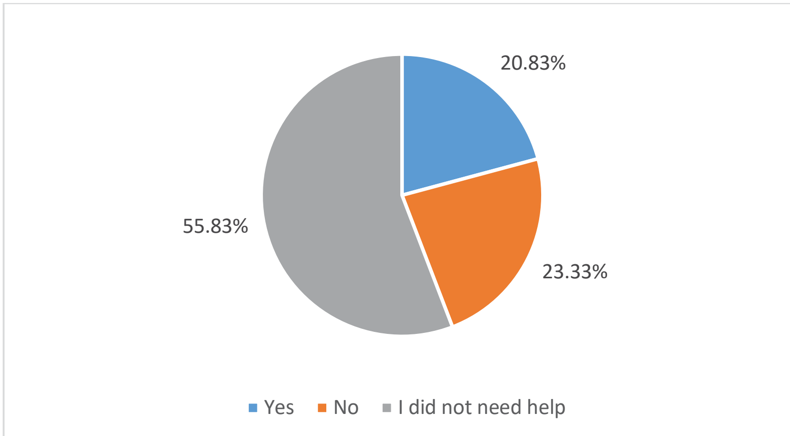

Figure 5: Response concerning social media

First-Responders: First-responders play a major role in disaster management, as they address the response phase. Considering the survey results, Figure 6 depicts that 84.17% of the responses show that the fire departments, police departments and rescue squad assured help and support to the people of Houston during Hurricane Harvey. The first-responders should be offered adequate training and guidelines to rescue and offer help during any disaster.

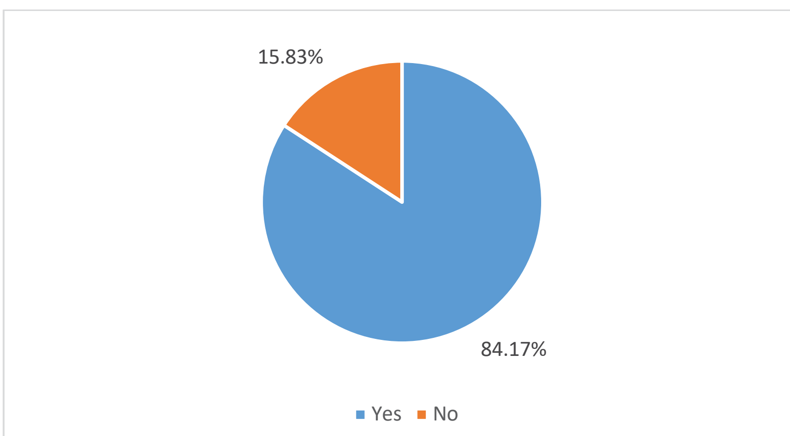

Figure 6: Response concerning first-responders

Emergency Management agencies: Federal Emergency Management Agency (FEMA), American Red Cross, the Federal Government of the United States and various other agencies played a significant role in reaching out to the affected communities during Hurricane Harvey. The Coast Guard deployed 2,060 personnel, 50 aircrafts and 75 boats to rescue 11,022 people and 1,384 pets. FEMA assigned 28 Urban Research and Rescue teams to assist local agencies, and there were various organizations that aided and supported the affected community during Hurricane Harvey (FEMA, 2017). Based on the survey results, Figure 8 represents that 88.33%

of responses suggest that the Emergency Management Agencies should also use social media platforms to provide more assistance and support to the communities of Houston. Social media platforms like Facebook and Twitter are being used by almost everyone today, and using these platforms to reach out to people will benefit the agencies.

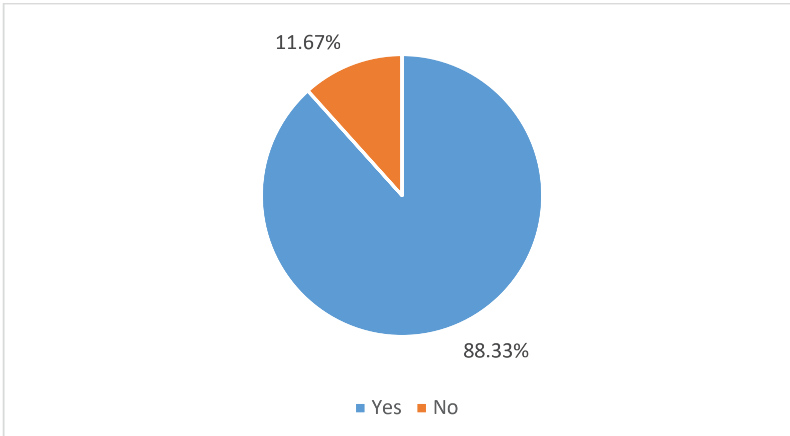

Figure 7: Response concerning Emergency Management Agencies

Informal Volunteerism: Citizen participation plays a vital role in disaster management, and the disaster relief and response phases rely largely on the citizens. In the survey, when asked if citizens participated as volunteers, the response depicted in Figure 8 illustrates that 59.17% of the respondents did not participate. It is essential to create awareness among the citizens regarding the importance of volunteerism and the evolving concept of digital volunteering.

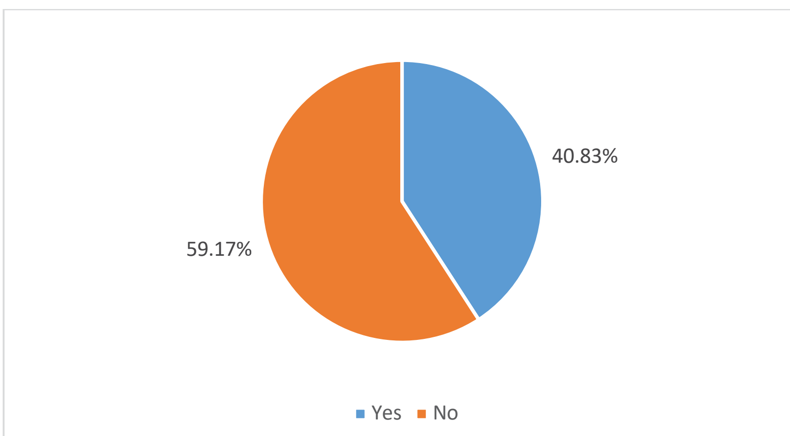

Figure 8: Responses on total no of initiatives as volunteer

The respondents were also asked if they thought enough citizens took initiative as volunteers during Hurricane Harvey, and Figure 9 illustrates that 75.83% of the respondents chose ‘YES’. The result illustrates that 24.17% thought that not many initiatives were taken for volunteerism, which is why it is important to create awareness regarding volunteerism, It is also significant that volunteers engage in their roles

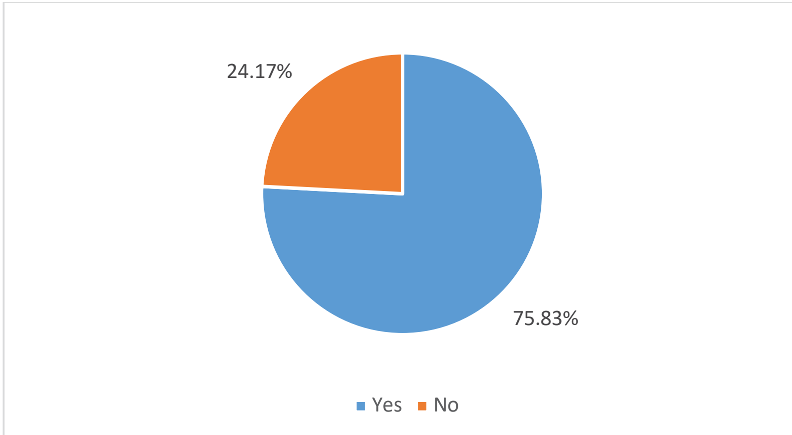

Figure 9: Responses for citizens as volunteers

Referring to Figure 10, 17.50% of the responses illustrated that help is not trusted from people other than family and friends, and 82.50% of the respondents' trust help from others. It is essential that the volunteers are trained to make sure that they gain trust of the citizens. The following are to be considered to create awareness and engage volunteers in their roles (CNCS, 2019):

- Create awareness among the citizens using various social media platforms, through T.V. and radio announcements, workshops and informational meetings at various locations in Houston.
- Define the roles and responsibilities of every volunteer and provide adequate training.
- Assign tasks to volunteers and provide them with necessary tools

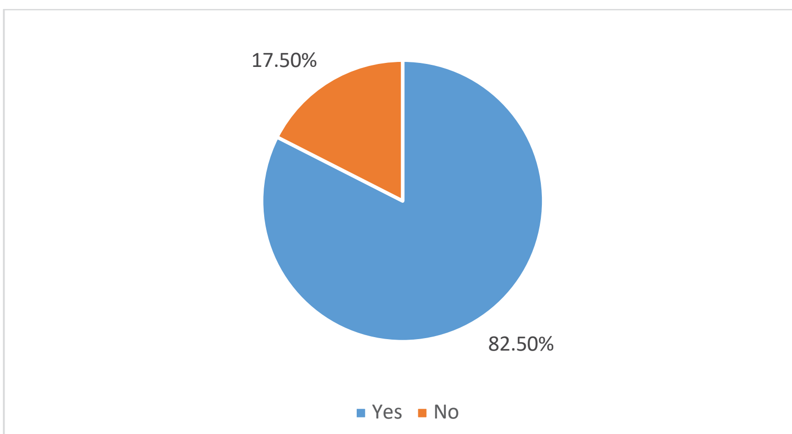

Figure 10: Responses to trusting help from volunteers

Digital Volunteering: With improving technological innovations, volunteering has been revolutionized, as it is more accessible and flexible. The digital volunteer networks allow citizens to contribute to disaster management, as digital volunteering utilizes social media and web-based mapping software to record and share emergency-related information that allows volunteers to respond to the affected communities. Figure 12 illustrates the awareness of digital volunteering among the citizens; 67.50% of the respondents are unaware of digital volunteering. It is important that citizens are aware of digital volunteering. With the help of digital platforms, every individual can contribute even from distant localities and can contribute at their convenience. ‘Crowdsourcerecue.com’ played a vital role in responding to the people of Houston during Hurricane Harvey. The platform connected over 12,000 professionals and volunteer rescuers with 35,000 people using its mapping and dispatching technology (https://crowdsourcerescue.com/). The platforms such as CodeCorps, All for Good, Volunteer-Match, American Red Cross and various other websites provide volunteer opportunities.

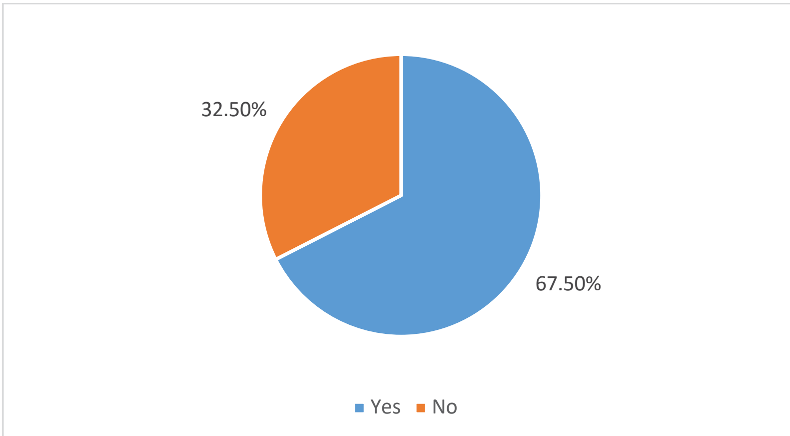

Figure 11: Response concerning awareness of digital volunteering

Collaboration of Government Organization: Government organizations should collaborate with citizens as first responders to create awareness and provide better support during any emergency. Figure 12 illustrates that 82.5% of the respondents expect government organizations to collaborate with the citizens as first-responders. Government organizations and volunteers play a significant role in disaster relief and response.

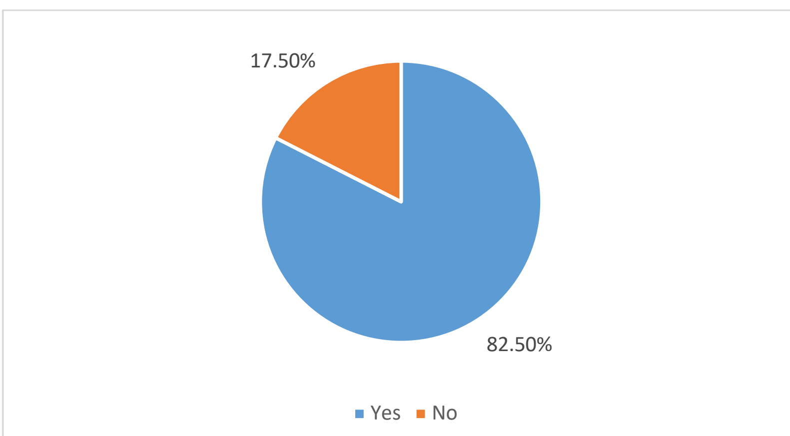

Figure 12: Collaboration

CONCLUSIONS

The objective of the study ‘Preparedness for Natural Disasters in Houston: A Survey on Hurricane Harvey’ is to understand the risks and damages associated with Hurricane Harvey and to propose effective solutions by analyzing the survey responses. The survey implemented online and face-to-face survey methodologies to understand the impact of Hurricane Harvey. The survey responses provided an insight into the preparedness of citizens, government organizations and first-responders for a natural disaster. It also provided an understanding of the awareness of digital volunteering and the role of social media in disaster management among the residents of Houston. Overall, the study provides solutions to reduce risks and damages caused by any natural disaster, information on how to effectively use resources, and suggestions on how to create awareness for disaster preparedness and digital volunteering.

APPENDIX

A Survey on Hurricane Harvey

<u>Instructions</u>:
☐ - Choose multiple options.
O - Choose only one options.

1. Did you have the following minimum disaster supplies on-hand before Hurricane Harvey?
   - ☐ Sufficient supply of Food and Water
   - ☐ Supply of personal care items and hygiene products
   - ☐ A first aid kit
   - ☐ Supply of Medicine
   - ☐ Flashlight
   - ☐ Local maps
   - ☐ Cell phone with backup battery
   - ☐ None of the above

2. Prior to Hurricane Harvey, Did your emergency evacuation plan include the following?
   - ☐ Evacuation Route
   - ☐ Fuel in the vehicle tank
   - ☐ First aid kit
   - ☐ Emergency contact list
   - ☐ I did not have any emergency evacuation plans

3. If needed, were you able to reach 911 at the earliest?
   - o Yes
   - o No
   - o I did not need to call 911

4. If needed, did you post a request for help on social media?
   - o Yes
   - o No
   - o I did not need help

5. Do you think Police departments, fire departments and rescue squad assured help and support as first-responder to the people of Houston?
   - o Yes
   - o No

6. Do you think the Emergency Management Agencies should use social media as a platform to assure help for the people of Houston during a

disaster?
- o Yes
- o No

7. Did you offer any kind of help during Hurricane Harvey as a volunteer?
- o Yes
- o No

8. Do you think enough citizens took initiative as volunteers for search and rescue operations during Hurricane Harvey?
- o Yes
- o No

9. Would you trust help from anyone apart from friends or family during the disaster?
- o Yes
- o No

10. Are you aware of digital volunteering?
- o Yes
- o No

11. Do you expect the government organizations to collaborate with citizens as first-responders during the disaster response?
- o Yes
- o No

ABSTRACT

The study aims to understand the crowdfunding behavior of donors for supporting development of disaster affected areas from both technological and governance viewpoint in an Indian context. The results offer counter intuitive arguments to explain why and how facilitating conditions and recruitment network are insignificant in explaining crowdfunding behavior.

KEYWORDS: Crowdfunding; Civic Voluntary Model; Financial Donors; and Natural Disaster

INTRODUCTION

There has been a transcendental shift in the area of Humanitarian Supply Chain (HSC) and Disaster Relief Operations (DRO). The field has gradually gained attention by transdisciplinary researchers in the recent past. Statistical data related to disasters reveal two important trends: firstly, the rate of casualty deaths caused because of natural disaster has come down significantly and secondly, the rate of economic losses resulting due to catastrophes have gone up significantly(https://www.emdat.be/). Data from EM-DAT reports that between 1998 and 2017, countries with maximum likelihood probability of facing disaster reported $2.9 trillion in direct economic losses of which 77% of it was a resultant of climatic change. Out of the total losses recorded, one third of it has been reported by United States followed by China, Japan, India and Puerto Rico(UNISDR, 2018). Looking at the economies of United States, China and Japan, it can be figured out that they qualify these countries to lie in the developed nations while countries like India still struggle in position itself in the developing nations category. A two decade report published by UNISDR on disaster relief operations report India to be the only lower middle income country featuring in the top 10 countries affected highly by disaster(UNISDR, 2018). This makes India an interesting case and a geographic area of research by humanitarian researchers are moreover social scientists working in the area of financial and economic ecosystems linked with disaster.

India has a history of disasters with earthquake, floods and droughts being the most common ones and with the highest degree of disaster. Around 58% of the Indian landmass is prone to moderate to high intensity of earthquake of which 110 districts (just over one seventh of the total districts in India) fall in Zone 5 resembling the highest risk zone in the glossary of earthquake. Looking at the water based disasters, the figures are much more gruesome. The erosion data of Indian coastline shows that in the past 26 years (1990-2016) , one third of the coast has eroded.

Disaster although has not been a direct reason for it but climate change is, which resulted in 1.35 million people displaced from these affected areas in 2017, which indeed is an alarming rate. The displacement of people increases the population density of other places thus making them vulnerable to disaster in the long run(NDMA, 2019).

Complexity begins with multiple causes of disaster. The recent Kerala floods disaster is a fine example of the same. Extreme rainfall, rush of dam water and landslides each brought unique challenges to affected areas. Just weeks after the floods, parts of the state were facing a dry spell with groundwater levels falling. Thus, damage that look similar need to be addressed differently which makes every disaster an unique case in itself. Disasters are said to cost the global economy USD 520 billion dollars every year (Crunch, 2018). Considering that no economic loss data is available for nearly 87% of disasters in low-income countries (UNISDR), the actual figures may be much higher. The economic losses that do hit the headlines are often in terms of insured claims or large-scale infrastructural damage. These are clearly rising. However, what about the cost to those under the radar? Informal and uninsured losses don’t get captured or compensated. The massive floods across India in 2017, for example, were estimated by Munich Re to have cost the country USD 2.5 billion, yet insured losses were negligible(Kron, 2018). While economic and financial losses are inevitable, its recovery remains a constant challenge for the households and the society at large. India alone suffered a staggering economic loss of $79.5 billion due to climate related disasters in the past two decades (UNISDR, 2018). The recent Kerala floods in 2018 itself caused $4.25 billion economic loss which excludes the direct damage and business interruption costs(Aon catastrophic report, 2018). A careful assessment of monetary supply chain has been missing from the literature which would help in achieving financial stability to the affected people post natural disasters.

Systematic reviews and development of theoretical, conceptual and practical models related to humanitarian supply chain have been umpteen in number in academic literature(Banomyong et al., 2016). Studies have also used theoretical lens and cases study based analysis to understand various aspects of humanitarian supply chain (Dubey and Gunasekaran, 2016). However, there is a dearth of literature which explores the enablers of financial supply chain for relief victims in order to achieve financial normalcy. The stakeholders contributing towards financial normalcy includes government agencies, non-government organizations, banks, insurance firms, CSR activity done by companies and crowdfunding by agencies and individuals. There has been umpteen research done on understanding the role of government, NGO, banks and insurance firms regarding their contribution towards financial relief for the victims, while individual contribution made by the countrymen still needs attention(Burkart et al., 2016; Kunz and Gold, 2016). This also calls for addressing the topic of crowdfunding in the context of DRO and moreover the willingness of people to participate in it. The individual contribution made by countrymen are usually voluntary donations made through various channels like direct transfers to affected people (which is made when the affected people are related to the affected masses), indirect transfers made to the government routed through either from their firms which they work, payments made to the government on the disaster relief portals, donation made to relief agencies like red cross, etc. While some portion of these payments are made due to voluntary contributions, a large part of it is also involuntary as they are triggered by external agencies like NGO’s, state or central government, companies etc. (Bukart et al., 2016; Kabra and Ramesh, 2015). The existence of multiple players in the financial ecosystem contributing towards economic development sprouts issues related to coordination, abrupt pattern of flow of funds, disintegrated approach towards handling the demand and supply of monetary relief, unstructured disbursement of funds, unregulated and unplanned expenditure etc.

Studies confirm that there are multiple models and framework which are developed and adopted for disaster relief operations and humanitarian logistics (Habib et al., 2016), but the financial supply chain remains uncertain in general. While it is uncertain, the objectives of it is well defined when compared to disaster relief operations and humanitarian logistics which work on multi layered and multi actor approach. The problem becomes more relevant and important in an Indian context as it belongs to lower middle income bracket which doubles the impact on the affected audience. As government plays as an aggregator and facilitator for financial donations made through multiple agencies, its role in the financial supply chain becomes important. Both NGO and government has been instrumental in making their significant contribution in disaster planning and disaster relief, however the role of citizens has off late being less discussed in the contributing towards disaster relief operations. Literature confirms that citizens contribute both in cash and kind from remote locations and offer support to the disaster affected citizens by offering physical help as well. Furthermore, studies have also confirmed that it calls for multiple theories to explain this complex nature of human beings (Zolotov et al., 2018; Dwivedi et al., 2017).

While behaviour of an individual is a result of its reaction of stimuli and vice versa, it is important to reconsider looking at behavioural studies from multiple lens. The present study aims to understand the behaviour of citizens towards helping victims of a natural disaster by making financial contribution. Therefore, behaviour in the present study would not be an outcome of only pre constructed models in IS literature. Rather, it would an outcome of constructs borrowed from governance literature as well. While payments can be made directly or indirectly to the government to ensure economic development, the present study only limits to direct transfers made to the government by citizens and more importantly voluntarily.

The study therefore proposes to borrow constructs from both governance and IS literature which would help in explaining the voluntary behaviour. The study proposes to use unified theory of adoption and use of technology (UTAUT) from the information technology literature and civic voluntarism model (CVM) from political participation domain. UTAUT proposed by Venkatesh et al. (2003) explain the behavioural intention by integrating multiple theories from information systems (IS) literature and thus is considered better than the earlier theories like theory of planned behaviour, theory of reasoned action , diffusion of innovation theory, technology acceptance model etc. The present study aims to understand only the intentions and not the actual behaviour as in an Indian context e-governance for financial achieving financial resilience has not been implemented. The primary objective of using CVM is to identify and measure the effect of socio economic factors for civic engagement of citizens for achieving financial resilience for disaster affected people. The contribution of this study is to use political ideology as a construct in the model whose effect would be measured in the behaviour of the citizens.

The remaining paper is structured as follows. Section 2 discusses the theoretical underpinning and discusses how the proposed gap could be addressed using lens of Civic Voluntarism Model. Section 3 details the research design section and discusses a systematic approach for data collection. Section 4 reports the results and findings of the proposed hypothesis. Section 5 discusses key findings in the context of the research problem and how results of hypothesis testing have been used to extend the body of knowledge in explaining financial resilience of victims of natural disaster. Section 6 offers conclusion with theoretical and practical implications along with guidelines for future scope of research.

BACKGROUND OF RESEARCH

There is a steep rise in the requirements of funding for humanitarian and disaster relief operations in comparison to charity (Besiou et al., 2018). Most of the disaster relief operations performed involve essence of crowdfunding to sustain its activities. Crowdfunding is identified as “a collective effort by people who network and pool their money together, usually via the Internet, in order to invest in and support efforts initiated by other people or organizations” (Ordanini et al., 2011: 444).

Over the years, there has been a transition from physical channels of crowdfunding to internet based crowdfunding. Belleflamme et al. (2015) classified crowdfunding into four categories: lending based crowdfunding, equity based crowdfunding, donation based crowdfunding and reward based crowdfunding. Most of the crowdfunding processes have a defined financial goal which they intend to achieve in a stipulated time period. Donation based crowdfunding is the only category of crowdfunding which involves investments without any tangible or intangible returns. Donations made towards DRO is one of such sub type of donation based crowdfunding.
In a recent report published by Centre of Disaster Philanthropy (2018) discussed some of the key factors which resulted in a donation towards disaster relief operations by US citizens in 2017 and 2018. Some of the key factors were: intensity of disaster, media coverage of the disaster, connections of the donors with the disaster hit geographical area, relationship with the affected masses, reputation and efficiency of the recipient of the crowdfunded agency, frequency of disaster etc. Payment method also plays an important role in understanding the behaviour of donation. Study from the report also reveals that a total of 61% of the total households in US made a contribution towards disaster relief operations of which more than half of the donations were made either by cash or cheque. Other forms of donations also included donations made by organization website, direct wire transfers and crowdsourcing platforms.
Humanitarian supply chain differs from commercial supply chain in a lot of ways. One of the key differentiator is the degree of uncertainty involved in the process. In an uncertain environment, it becomes more important to discuss the degree of uncertainty in financial donations as it contributes towards the well-being of the affected masses. Burkart et al. (2018) highlighted that role of funding and its importance in a humanitarian context primarily due to shortfall of collected funds from global agencies. Most of the crowdfunding agencies use multiple strategies to enhance the amount of donations either by focusing on frequency of donations or by capturing larger masses. Studies also confirm that majority of the donations made towards crowdfunding are involuntary in nature while a handful of them are voluntary. While studies have not shown similar trends across different categories of crowdfunding (Belleflamme et al., 2015), it becomes important to understand the nature of voluntariness as a control variable towards behaviour of donors. Donation based crowdfunding unlike the remaining three types is a like a non-returnable boomerang and thus transparency also plays a vital role in the process of donation. Studied related to transparency in humanitarian operations are mostly linked to its accountability (Villa et al., 2017; Starr and Van Wassenhove, 2014; Haavisto and Goentzel, 2015; Beamon and Balcik, 2008). Mejia et al. (2019) studied the effect of operational transparency and conventional transparency on likelihood of receiving donations by private donors.

UNDERPINNING THEORIES

Citizen participation in democracy has a long history and scholars have theorized the phenomenon of citizen participation from different theoretical viewpoints (Kim et al., 2006). It is interesting that scholars have addressed key issues of citizen participation in democracy and politics but have missed some of the key aspects of continuous participation and lifelong participation. Unlike learning where the engagement is longer and systematic, citizen intervention is not that frequent and regular. This partially explains why some individuals sometimes participate while other are reluctant in participating in governance issues of the country (Pattie et al., 2003; Uthaman and Ramankutty, 2017). Some frequently used theories in the space of civic culture include the famous theory of polyarchal democracy, rational actor theory, civic voluntarisms model etc (Oni et al., 2017). While most of these theories discussed civic participation in the offline democracy, extensions of these were also tested for e-governance with technology often used as mediators or moderators or both in multiple studies. The current form of governance has majorly drifted towards the e-governance and thus it is important to not only check the effect of technology in these theories, it is also important to use multiple layers of theories drawn from different disciplines to understand the phenomenon of citizen behaviour (Khan and Krishnana, 2017; Ryzhov et al., 2015). Behavioural researchers have also claimed that behaviour is an outcome of a systematic thought process which is often driven by perception, experience, societal influence and other social traits (Blackburn, 2014). The changing nature of technology and evolving e-governance has although made the youth more inclined towards it but the technology has not engaged the older generation relatively. The launch of online portals for managing and governing services has a lower rate of adoption by older people as proposed by Xavier and Oliveria(2016) and one of the prime reason stated is their weak rate of communication with the government through online channels. Naher and Krimmer (2005) in their early research proposed Social Media Politics model which discussed a continuous cycle of political communication between media and different political and democratic actors. Studies also confirm that while certain hypothesis related to citizen engagement holds true in the developed nations, they fail in the developing nations (Uzoka, 2008; Jain and Suri, 2017). Recent proposition made by Kolmann and Kayser (2010) explored factors for citizen engagement in the German context by using political participation theory and information systems acceptance theory. It is also witnessed that studies have usually revolved around e-governance portals in developed nations like Germany, France, USA etc where political stability and technology led development has always been higher (Asongu and Nwachukwu, 2016). Also, the studies have generally studied practices related to e-governance for voting, community development, bill payment services, tax payment etc., while none of them has addressed governance related issues in times of uncertainty. Furthermore, studies have not explored the intervention of political culture in driving e-participation which by and large impacts the behaviour of the individuals (Haselip et al., 2015; Singh and Sahu, 2008; Kabra et al., 2017). Results from Serrat et al.(2016) claims that political culture has a positive impact on the participation of citizens , but they have not tested the hypothesis under uncertain or risk averse situations. The objective of the present study is explore the relations of behavioural enablers of e-participation of citizens towards achieving financial resilience post natural disasters. The study is guided by understanding the interdependency of two theoretical school of thoughts which are discussed in the section 2.1. The review of theories is discussed from the viewpoint of the present study and required hypothesis is proposed which would be tested with empirical data.

Unified Theory of Acceptance and Use of Technology (UTAUT)

There have been umpteen cases where various information systems theory have been used to explain the behaviour of the users (Al Athmay, 2015; Orong and Hernandez, 2019; Zhou et al., 2010; Abubakar and Ahmad, 2013). Most of the theories have behavioural intention being used as the outcome which have antecedents like perceived ease of use, perceived usefulness, attitude, subjective norm, societal influence and many more. Each of the theories viz theory of planned behaviour , theory of reasoned action, technology acceptance model, diffusion of innovation theory have used various permutations and combinations of the above mentioned constructs. Venkatesh et al. (2003) developed the unifying theory which integrated these into one theory UTAUT and resolved most of the shortcomings of the same. The theory since its inception has also been validated and extended by multiple authors in different contexts. Scholars have also challenged the use of only UTAUT to explain behavioural traits of the people and some additional theories like UMEGA have also been proposed which have also tried to integrate multiple theories to explain governmental actions (Dwivedi et al. 2017). The model has also helped in explaining e-governance amongst citizens and society. In the context of governance,

the model has been extended with moderating variables like age, gender, voluntariness, experience and culture (Venkatesh et al., 2012; Kahlilzadeh et al., 2017). It is because the theory measures behaviour which then leads to actual usage, the early studies have largely been empirical in nature without actually testing in with longitudinal data.
Studies have indicated that while UTAUT is good for explaining behaviour, it only marks partial behaviour and which calls for explaining the same with other organizational theories (Dwivedi et al., 2017; Dwivedi et al., 2018; Rodrigues et al., 2016). Although, studies have integrated UTAUT with different theories like resource based view theory, stakeholders theory, social capital theory etc, but a mixed theoretical model is missing in the context of explaining the behaviour of citizens when dealing with the government. The challenge becomes multiple as the responses of government affect the behaviour of citizens and it a reciprocatively impact on behaviour rather than unidirectional (Gundelach, 2016; Vatanasakdakul et al., 2017;). The study therefore aims to integrate CVM and UTAUT to explain the behaviour of citizens. The context of present study is unique as it aims to address the challenges of understanding the behaviour of citizens for making e-payment on government portals and contribute towards disaster relief funds.

Need for theory Integration

The central objective of the paper revolves around understanding the attitude of the citizens to participate towards offering payment on the government portals for development of disaster struck areas in the country. Thus, “attitude” towards the behaviour is defined as “an individual's positive or negative feelings about performing a behaviour” (Fishbein & Ajzen, 1975). “Actual Usage” in this study is operationally defined as continuous and consistent usage of crowdfunding platform by financial donors to make a contribution towards disaster relief operations after a natural disaster. As “Actual Usage” is a result of “Attitude” of human being which is empirically tested by earlier literature, it is important to discuss and debate how and why studying attitude is more important as compared to any other construct.

Attitude is measured and empirically validated by multiple studies in the past and forms a key construct in behavioural studies whether it is TRA, TAM, DOI or UTAUT. Attitude irrespective of its roots grounded in these theories have also been instrumental in explaining human behaviour (Hung, Chang, & Kuo, 2013; Akinyemi, Asani, & Adigun, 2013; Jahangir & Begum, 2007; Adesina & Ayo, 2010). Studies have also posted that attitude is a function of beliefs of individuals which are driven by self or by others and they lead to a particular behaviour. Similar connotations were also proposed by Davis et al. (1989) when perceived ease of use and perceived usefulness was used as drivers for attitude. With time immemorial, it has been validated by multiple studies that perception is different forms have positively impacted the attitude of an individual. An in depth analysis of the studies also confirm that most of the researchers have tested the model with people who are not exposed to any uncertain phenomenon (Shaw and Gupta, 2015; Zagefka and James, 2015). Also, a longitudinal study with uncertain situations could also change the attitude of the people. Thus, it is important to include constructs in theoretical models which would capture and measure the effect of participatory role of citizens and their political bend towards understanding their overall behaviour for e-participation of citizens post disasters.
The theoretical model can be referred from Figure 1 and the hypothesis development can be referred to as follows:

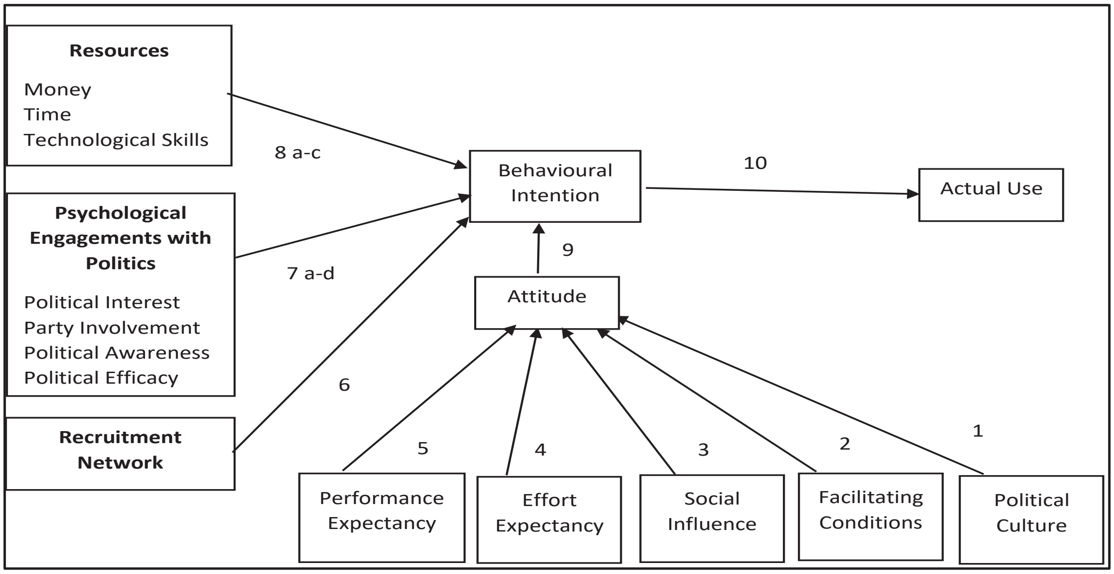

Figure 1: Theoretical Model for the study with proposed hypothesis

Hypothesis Development

It is also worthwhile to note that political beliefs unlike general beliefs are driven not only selfish motives but usually by community benefits. Most of the attitude and perception based studies conducted have measured these constructs at an individual level as the technology, service or process was individual driven. On the contrary, political actions are taken for the community and not for an individual and thus the drivers of belief could not be the same as explained by existing theories. The e-participation as a construct measured in this study would also not benefit the same person, but to a different section of the society through political intervention. While studies from Mizrahi and Vigoda-Godat (2009) confirms that citizen participation in public decision making has a positive impact on the trust on the government, but they have not discussed how trust would impact their behaviour towards participation which is a reverse phenomenon. There is a difference in opinion presented in the literature between the relationship between attitude and action of government in building trust of people and attitude and action of governance in building trust (Jones et al., 2015; Jacob and Singhal., 2017). There exists a hair line difference between the two as on one hand there is government which is a seasonal ruling party while on the other hand it is governance which is a phenomenon and could be run irrespective of the government in power (Paik, 2018; Strömblad and Bengtsson, 2017). Therefore, it is important to relate attitude of citizens with political culture rather than with political parties. The democratic political culture referred to in literature (Loveless, 2013; Tessler and Gao, 2008; Almond and Verba, 1963) is a construct which has found to have relationship with attitude of citizens and thus the present study hypothesizes:

H1: There is a positive effect of democratic political culture (PC) on citizen's attitude (AT) towards e-participation for financial resilience.

The other hypothesis were derived from existing studies on UTAUT which tests the key constructs to understand attitude. These relationships are discussed in literature umpteen number of times are therefore not discussed at length in this paper.

H2: There is a positive effect of facilitating conditions (FC) on citizen's attitude towards e-payment for financial resilience.
H3: There is a positive effect of social influence (SI) on citizen's attitude towards e-payment for financial resilience.
H4: There is a positive effect of effort expectancy (EE) on citizen's attitude towards e-payment for financial resilience.
H5: There is a positive effect of performance expectancy (PE) on citizen's attitude towards e-payment for financial resilience.

It is also discussed and well established in the information science literature that attitude of the respondent is linked with its positive behavioural intention towards using any technology. While this relationship is grounded in literature, it is more important that validate the same in the context of disaster relief operations. While usage of technology and attitude has mostly been studied in the context of technologies which are either less established or the response from the expected users were uncertain. The present study extends the contexts also towards understanding the same for a cause where the rate of returns of uncertain and at times negligible. It is in the light of the same that the study explores the behaviour of the respondents from civic voluntary model's viewpoint as well. It can therefore be hypothesized that:
H6: There is a positive effect of recruitment network (RN) on citizen's behavioural intention (BI) towards e-payment for financial resilience.
H7a: There is a positive effect of political interest (PIN) on citizen's behavioural intention towards e-payment for financial resilience.
H7b: There is a positive effect of political involvement (PIV) on citizen's behavioural intention towards e-payment for financial resilience.
H7c: There is a positive effect of political awareness (PAW) on citizen's behavioural intention towards e-payment for financial resilience.
H7d: There is a positive effect of political efficacy (PEF) on citizen's behavioural intention towards e-payment for financial resilience.
H8a: There is a positive effect of financial resources (FR) on citizen's behavioural intention towards e-payment for financial resilience.
H8b: There is a positive effect of time to engage (TE) on citizen's behavioural intention towards e-payment for financial resilience.
H8c: There is a positive effect of knowledge of using technology (KT) on citizen's behavioural intention towards e-payment for financial resilience.

It is debated that attitude of a respondent is used to explain his/her behaviour and behaviour invariably explains the actual usage of technology. Studies have tested these propositions in multiple scenarios and for multiple technologies. Most of these scenario are linked to the beneficiaries being the respondents themselves. However, literature pertaining to technology usage of e-governance and society indicates that citizen participation and their behaviour differs on various occasions and therefore is unpredictable. However, most of the studies have reported that attitude of citizen's positively influence their behaviour which in turn positive effects the actual contribution towards societal development. It can therefore be hypothesized that:

H9: There is a positive effect of attitude on citizen's behavioural intention towards e-payment for financial resilience.
H10: There is a positive effect of citizen's intention on making actual payment (AP) of financial resilience.

RESEARCH DESIGN

Survey Instrument

The proposed theoretical framework and hypothesis is a resultant of a three step approach which began with identification of constructs and operationally defining them from interdisciplinary literature in order to holistically define the scope, followed by identifying the items for measurement of each construct. Lastly, the final instrument was pre tested for content validity by experts after which the final instrument was used for data collection. We reviewed literature and scales used in crowdfunding and humanitarian supply chain related to objectives of the study. The literature was used to finalize the operational definitions of the study along with the first draft of the instrument with each construct and its corresponding items. Referring to the operationalizing concepts laid by of Dubey et al. (2018), we adapted the scale in the context of humanitarian supply chain and integrated it with crowdfunding. Each of the items was measured on a five point Likert scale to ensure higher variability among survey responses (Dubey et al. 2019; Dwivedi et al. 2013; Kim et al., 1999).

As a last step before proceeding with data collection, the instrument was pre tested for its content validity. The instrument was shared with eight experts and experienced researchers in order to share their feedback on the appropriateness of items, clarity in presentation and reducing the ambiguity in placement and formulation of the instrument (De Villis, 1991). Using Dillman (2007) guidelines, we further requested the experts to assess the instrument and validate that the items and constructs are indicating and appropriate for the context of the study. The comments of the panel of researchers were shared with each other and a unanimous suggestions were incorporated in the questionnaire to revise it. (Chen and Paulraj, 2004). As the instrument would be used for collecting data from financial donors in India, the instrument was also shared with the disaster wing of Oxfam over an email. The agency being a pioneer in involving poverty alleviation and financial aiding of affected people post disaster was used for the second round of content validation. We requested their feedback and required changes were made to make the instrument highly valid on content.

The final instrument was then used in the pilot study before actual data collection with the participants of World Disaster Congress held in India. The questionnaire was shared with the potential presenters in the international conference in order to ensure that the final instrument is valid and reliable. We received a total of 58 responses out of a total of 247 target respondents. The results of the pilot survey were useful in finalizing the structure of the instrument which was then used for the data collection process.

Data Collection

The study used individual financial donors made towards Kerala floods as unit of analysis for the study. The study used Kerala floods because of its degree of severity. Over 11 straight days of tempestuous rainfall, nearly 25 trillion litres of water fell on Kerala—an area of 38,800 square kilometres cramped with mountain ranges; third-highest population density in the country; and, 44 rivers with 61 dams—with apocalyptic fury (Venkatesh and Kuttappan, 2018). The state government has estimated the preliminary loss at Rs 20,000 crore, which is around 15 per cent of the state's GDP estimate for 2018-19. According to risk management agency, Care Ratings, floods have affected more than four million people, a significant percentage of them labourers. In August alone, people would lose wages worth Rs 4,000 crore. More than one million people are in relief camps that would take around Rs 300 crore a month to maintain. More than 12,000 kilometres of roads have been damaged hindering speedy relief and rebuilding operation. Kerala is not prone to catastrophe unlike north eastern states of India. Thus, it belongs to a geographic category of non-recurring disaster. The study gathered data by circulating questionnaire on the platform of Humanitarian ID. From the earthquake in Nepal in April 2015 to the hurricane in Haiti in October 2016. Humanitarian ID is the first choice to manage humanitarian contact lists in large scale emergencies. The list have more than 18,000 responders across the globe connected and working towards the disaster related operations. The questionnaire was posted as a weblink and the administrator was requested to spread this across the network. The respondents were also asked to repost the link in different channels. Data collection was done between July 2018 to September 2018 and two waves of postage of questionnaire was done over the span of 6 weeks. One of the pre requisite of submitting the questionnaire and checking the eligibility of respondents was submission of proof of payment made towards Kerala relief fund which are operationally defined as donors in this study. We received total of 439 responses of which only 354 were valid based on their eligibility of respondents and authenticity of the data. Data was then tested for missing values and the overall sample size of 321 valid data points were used for the study. Brief profile of the respondents can be referred to from the table below.

Demographic Variables		No. of respondents
Age	25-30 years	78
	30-35 years	62
	35-40 years	82
	40-45 years	25
	45-50 years	43
	50+ years	31
SEC group	A1	45
	A2	110
	B1	94
	B2	46
	C	13
	D	8
	E1	3
	E2	2
Geographical Distribution based on their native state	North India	52
	South India	129
	East India	36
	West India	69
	Central India	35
How much time have you stayed in Kerala?	Haven't stayed	123
	Less than 1year	34
	1 – 3 years	70
	3- 5 years	54
	5+ years	40
Education	No formal education	35
	Primary School Qualification	67
	Secondary School Education	58
	College Qualification (Diploma/ Certificate)	13

	Professional Qualification (CA/CS)	7
	Undergraduate Degree	104
	Post Graduate Degree and Above (Master's/PHD)	37
Gender	Male	179
	Female	142
	Others	0
Nature of Job	Not Working	106
	Part Time Working	27
	Full Time Working	188

Table 1: Demographic Profile of Respondents

The distribution of respondents from Table 1 depict that the their exists almost an inverse relationship between the age of the respondent and its financial contribution through e-governance portals. Earlier studies have also discussed similar trends wherein older generation are still not as much tech savvy as the younger generation is. This could be one of the reasons for the trend seen in this study as well. It is also seen that upper most consumption class was the mostly contributing towards financial well-being of the society. This although does not follows the trends of earlier studies wherein the richer class don't express their interest in societal development, but some of the recent studies have also confirmed the trend along the lines of the present study as well. Lastly, the geographical distribution of respondents was skewed towards Southern part of India. It is seen that most of the people who live in south Indian states have made the contributions. The study makes the results interesting as a sizable number of people who have not lived in Kerala have also contributed towards the development of the state.

As the data collection is empirical in nature, it is important to check the non-response bias in the data. We employed Armstrong and Overton (1977) suggestions for checking the responses received from non-respondents, early respondents and late respondents. By taking a sub-sample of 55 respondents, we tested that there is no significant difference between early and late respondents in our study for the constructs of the study. We also did not observe any significant difference between the profile of the respondents and non-respondents. Thus, our study is free from non-response bias.

The proposed hypothetical model was tested using Structured Equation Model (SEM). Unlike regression based methods, SEM allows simultaneous modelling of relationships among multiple independent and dependent constructs (Chin, 1998; Urbach and Ahlemann, 2010). SEM has its advantages in distinguishing between independent and dependent variable and more importantly between endogenous and exogenous latent variables (Hair et al., 2010). Preacher and Hayes (2017) distinguishes the use of covariance based SEM and partial least square based SEM and the present study fulfils majority of the criteria for PLS-SEM as it is more appropriate in an exploratory research and the developed framework is new. Smart PLS was used to perform the analysis and it takes care of the distribution of the data and does not care about its normalcy.

MEASUREMENT MODEL

The model was tested for its composite reliability followed by discriminant validity and confirmatory factor analysis. The results from Table 2 report that average variance extracted (AVE), construct reliability, Chronbach's alpha and range of factor loading of all the constructs and their respective items. As proposed by Chin (1998) and validated by multiple studies that any item in a questionnaire tends to be retained if its standardized loading should be greater than 0.7. The preliminary analysis dropped 7 items from the initial questionnaire and the remaining items with their responses were used for further analysis. A bootstrap analysis of 1000 resample gave significant results for the remaining items at 0.01 significance value. The results showed a considerate improvement in the construct reliability and convergent validity after dropping those seven items. The results of the final items and their corresponding values can be referred to from Table 2. Smart PLS 3.0 was used to derive the results and it was found that the construct validity of each of the items of every construct was found to be significant expect performance expectancy (PE) and Societal Influence (SI).

Table 2: Reliability and validity results

It was also found that the AVE value of all the constructs was more than the threshold of 0.5. The convergent validity of the items was tested by examining the cross loadings and the results confirmed that there was no measurement items whose loading was more on any other construct which was not theoretically assigned to it. Hair et al. (2010) also proposed that the discriminant validity was examined by comparing square root of AVE of each construct with the correlation score of each pair of latent variable and it was found that the square root of AVE was greater for all the constructs. Table 3 can be referred to for the results. It can be observed that the square root of AVE score for the entire model is more than the threshold value of 0.7 as suggested by Hair et al. (2010). With the two satisfying criteria, we can confirm that these constructs share more variance with their respective measurement items and have lesser association with other constructs. The results fall in line with most of the previous studies which have tried and integrated multiple theories to test a phenomenon. The next step is to test the proposed hypothesis in this study.

Table 3: Correlation and AVE matrix between constructs

The hypothesis testing is done using multiple tests and one of the prominent ones is to check for the coefficient of determination of the model. The value of R square (coefficient of determination) is the measure of how much variation which is explained by the model. Three values for R square were calculated for attitude, behavioural intention and actual usage as all the three were dependent variables which were explained by constructs of UTAUT, CVM and the integrated model respectively. It was found that the overall exogenous factors explained 42% of the variation in the intention of use of e-payment services for financial wellbeing. While the value is acceptable by most of the published literature, it was worthwhile to discuss the reasons and justifications for the same which is done in the subsequent section. It was also found that the CVM model based independent constructs explained 31 % of the attitude towards use of e-payment services. Lastly, the behavioural intention only explained 21.2 % of the variation of the actual usage which confirms that intention does not explains the actual usage solely (Urbach and Ahlemann, 2010) and there might be other factors apart from the behavioural ones which could explain the phenomenon of usage.

Table 4: R square and path co-efficient matrix (hypothesis testing)

The next step is to calculate path coefficients in order to find the degree of relationship between constructs (Wixom and Watson, 2001) which was carried out using bootstrapping with 1000 resampling process. The results of the bootstrapping process are presented in Table 4. The results were assessed by looking at the coefficient paths using the t-statistics. The process helped us in calculating the structural path coefficients of all the hypothesized relationships. The effect size of the overall model was then calculated using Cofen's F square value and are presented along with their respective value of their coefficient of determination in Table 4. The results show that political culture, performance expectancy and effort expectancy have higher effect on their endogenous LV which along with the distributed effect of the other constructs have multiplicated larger impact on the endogenous LV behavioural intention. Seven out of ten hypothesis were supported while the remaining six were not supported (Refer fig 2). The results from hypothesis testing reveal that there was a positive significant impact on attitude by political culture, performance expectancy and effort expectancy. The other UTUAT relationships of the second degree also have a positive impact on each other viz. attitude having positive impact on behavioural intention and it in turn positively impacting actual usage of e-payment portals by citizen for financial development of disaster victims. The results also revealed that constructs related to societal (facilitating conditions, societal influence) and psychological engagement (political efficacy, political awareness) have weak significant predictors to behavioural intention of citizens to make financial contributions. Lastly, it is seen that recruitment network, resource based constructs (technological skills, time, money) and part of psychological constructs (party involvement and political interest) have non-significant predictors for understanding behavioural intention of citizens making financial contributions for disaster victims. It is unlike the earlier studies which have used resource based view theory and have shown that resources play an important role in the development of the community, the present study indicates that it would not really impact the behaviour of citizens to make financial contributions.

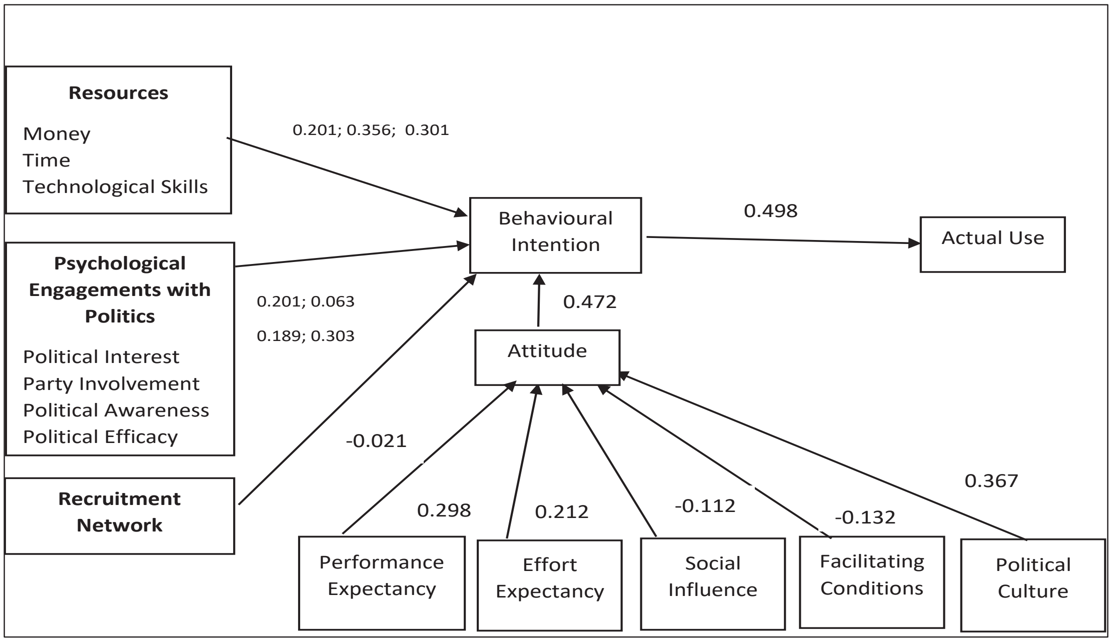

Figure 2: Results of hypothesis testing and structural model

Discussion of Results

Financial resilience of disaster affected victims is the key theme of the study and the study has understood the effect of political culture and perception of citizens for e-payment towards the financial development of victims. The participation of NGO and donations routed through them has been studied in the past while with the advent of technology, the study integrates the multiple theories from diverse literature to understand the attitude of citizens of the country who are involved into financial donations for emergency relief victims. Results reveal that effort expectancy, performance expectancy and democratic political culture have significant positive impact on attitude of the citizens for making e-payment towards Kerala disaster relief funds. The results reveal that H1 has the highest significant value amongst all the relationships. The study has extended UTAUT model with democratic political culture and its positive impact confirms that while measuring e-payment behaviour especially in the governance setting, it is important to include and test the effect of political culture (Abdulwahab, 2012). The results partially is in line with the cultural models in politics proposed by Naranjo-Zolotov et al.(2018) which confirms that participation of citizens are affected by governance of the country. As the payments were made to the state government of the country, the results may vary with donors perception towards other states of the country. The data had a mix of people who were and who were not the natives of Kerala which confirms that overall the effect of domicile does not really play an important role in the analysis. The study also presents that societal influence and facilitating conditions have played a non-significant role towards attitude of the donors. Most of the earlier studies (Hihorst, 2003; Poblet, 2010; Pakdebugree et al., 2011; Zhao et al., 2015) have confirmed that societal influence and facilitating conditions happen to be strong positive significant contributors towards attitude of the end users. But as the present study deals with behaviour of donors for a financial cause, both the constructs have not contributed significantly. As disaster is a seasonal or at times rare phenomenon and impacts the economy in the short run, the donors also are active for a short run. Thus, unlike studies which measure attitude for mostly a technology or a service which exists and will exist in present and will exist in future also, the present study measures the attitude which is also seasonal along with the disaster. The financial contributions made are based on an event and thus the attitude of donors are perpetual and may not be permanent (Lai, 2017). The study also confirmed that 64.3% of the respondents believe that making a payment through e-payment channels for KCMDRF would contribute towards financial resilience of the affected people. It also confirms that 81% believe that e-payment would help in improving status of life of the affected individuals and 72.4% believe that local and state governance play a vital role in achieving financial resilience in a disaster affected area. These results are mostly consistent with studies pertinent to e-governance (Mansoori et al., 2018; Becerra et al., 2015) in the past but are largely an outcome of role of citizens in e-democratic policies and practices made by the government. Citizens are also an equal and important stakeholder in achieving financial resilience as per the findings of this study.

While Weng et al. (2015) confirm that past experience contributes to citizen's perception towards e-governance, but this study does not confirm such results as the geography of Kerala has not faced floods of similar intensity in the past. One prime reason which is why citizen's democratic participation and engagement in high could be political image of the state government in the development of the state over the years. Report by Kerala government (2018) confirms that Kerala has been one of the most successful states in terms of its economy in the past 2 decades and that might have contributed towards positive perception of individuals towards its development. Choudhary and Neeli (2018) asserted that good governance also involves launching of schemes and policies are the right time and involve citizens wherever required. The present study adds to the findings as e-payment portals were launched and easily accessible to the local masses through easily accessible online channels (Strömblad and Bengtsson; 2017; Shi et al., 2010). Moreover, the government also promoted people to contribute for the development which would have acted as social stimulus for making financial donations. Under times of crises, citizen engagement is mostly done through online channels by government and similar instances were also seen with Kerala government which has a total of 762 tweets urging for making financial contributions which were retweeted by 1.3 lakh people (GOI, 2018). This ensures pro activism of government which would have ensured a positive attitude leading to positive behavioural intention and eventually payment. E-payment has an important construct called "privacy and security" which has been discussed by past literature but the present study did not incorporated it as the transactions were made through secure channels embedded in mobile apps like Google pay and therefore chances of commitment a fraud was negligible. While the results of delineated UTAUT model reveal that most of the constructs contribute towards attitude, the results also reveal that attitude also significantly positively transforms into behavioural intention of citizens (Munene et al., 2018; Meth et al., 2015). It can be confirmed with consensus that attitude has a positive impact on behavioural intention, but because behaviour was also measured from CVM model, it is important to look at the constructs of CVM to understand their effect on the behaviour of citizens. Citizen engagement through government is also a result of active discussion forums, chat sessions, inter citizen discussions (Ertas, 2015). The discussion also helps in arising political alignment of the citizen and vice versa (Hofman et al., 2016) but the study did not find any such evidence in this regard as the e-payment portals had no option of discussing with peers and getting to know their opinion. The government also did not displayed the total amount of money transacted to the public which probably is one reason why facilitating conditions and societal influence did not significantly contributed towards developing the attitude. Apriori to this, political beliefs of the public would have helped them to make payments for Kerala more than other states where floods caused human losses like Assam and Bihar. That's primarily one of the reasons why we could observe that the hypothesis proposing positive influence of political awareness towards

making financial contributions was supported in this study. Results also confirm that political interest of citizens positively impacts the intention to pay. Shi et al. (2018) asserted that political involvement of citizens and their know how of functioning of governance makes them more participative and in turn helps them to take decisions to support or not support government initiatives. In a recent study similar results were confirmed by Garrity(2015) which confirmed that digital media helps citizens to know about governance and eventually take actions against their activities. The participation of citizens are relatively more when their development is concerned rather than community development (Aldrich et al., 2015; Linnerooth-Bayer et al., 2015) while this study proves that there has been a significant positive impact of political interest of donors in making up their mind to make financial contribution.
Social Media channels have also helped to increase individuals digitally efficacy and contextually it has helped them to know about their government as well (Meth et al., 2015; AlAwadhi and Morris, 2008). Results from the study also confirms that political efficacy has a significant positive impact on e-payment behaviour of the citizens. One of the primary reason for the positive and significant impact could be the wider coverage of Kerala floods by media and corrective actions which government took for the disaster affected people. While political efficacy is not an after result of a short run coverage of Kerala politics by media, but over a prolonged effect of the how government initiatives have helped in the development of the state. This study results are in line with previous literature (Balckburn, 2014; Suzuki, 2015) as well which confirms that a well-read citizen and stronger media presence contributes to higher degree of political efficacy. With stronger positive political efficacy, they tend to contribute towards government initiatives for development of society and disaster is one such natural epidemic which needs political intervention to achieve both financial and economic resilience. Disaster has also helped economies grow, with Japan as a prime example. The growth is therefore dependent on strong governance and more than that citizen's faith on governance. E-payments by citizens for development of Kerala adds to similar theoretical reasoning with similar results.
Recruitment network plays a significant role in mobilizing citizens and inclining them towards political parties and their participation in political activities (Deen, 2015). Studies confirm that recruitment network has shown positive effect on citizen engagement by political propagandas organized by political parties (Oni et al., 2017; Paton and Johnston, 2017). However, this study has failed to support the hypothesis. It can be understood that the context of recruitment network remains insignificant in disaster relief operations as government does not organize any political briefings to involve citizens support. While financial funding has donors contribution as a major source, it is unlikely that government makes a point to use political pressure to draw money from people. The results support the study by Oni et al.(2017) which confirms that recruitment network comes in handy when there is a benefit of the government while the present study aims to understand the intentions of donors for the development of disaster hit community and government only acts as a mediator which is why the hypothesis has not been accepted. The results also confirm mildly significant values for sub constructs of resources of CVM. Literature has discussed that CVM resources factors comprises of three elements: money, free time and civic skill which help the citizens to participate in politics of a nation. As the respondents were spread across the country and donated significant amount of money for flood relief victims, corollary to the proposition we can confirm that those were economically sound, had enough time to take decision and were civically equipped to understand the dynamics of their contribution. The study although has not discussed whether the donations were made voluntarily or under some obligation as it would add to explanation of their behaviour to make e-payments on governance portals. People who belong to higher SEC level would be more involved into politically activity (Weng et al., 2015) and would have then made contributions for the development. The

demographic profile of the present study also confirms the same. That's probably one of the prime reason all the three sub hypothesis were accepted in this study.
It can be studied from past literature that most of the donors have either experienced similar situations earlier in their life or have been psychologically affected by the current one (Choudhary and Neeli, 2018). An in depth discussion with the respondents revealed that most of them have made financial contributions for disaster relief operations in the past. It is important to note that none of them made voluntary contributions in the past while a handful of those made it for out study which indicates that it would be worthwhile to explore the control variable of voluntariness in the present model for future study. 83% of the respondents were operating a smart phone from the past decade and were exposed to online money transactions through mobile apps and internet banking. 93% of the respondents have also used e-payment earlier to government in forms of utilitarian amenities and taxes. These could some reasons why resources and its sub constructs have received a positive significant impact on e-payment intentions of the respondents.
Figure 2 denotes the sig value of all the hypothesis. The overall model depicted that 3 out of 10 hypotheses were found to be insignificant. The findings also reveal that although resources construct had positive impact on behaviour, the impact was higher for constructs like performance expectancy, effort expectancy and political culture towards behavioral intention of citizens to make payments. Thus actual payment which is driven by intentions of citizens is a function of constructs drawn from information science theory (i.e. UTAUT) and governance theory (i.e. CVM) but behavioral traits are more driven by IS theories. The study recorded non-significant results of hypothesis and apart from intuitive and literature supported reasons which are mentioned above, there could be some challenges based on research design as well. The diversity of respondents in terms of their geographic location, their domicile, their SEC and most importantly the timing for making payment could lead to hypothesis not being accepted. Their interest in state democracy and their views about the same could differ from central government which could have also be reasons for insignificant hypothesis. CVM based studies in the past have also ascertained that role of citizens and their educational qualification and their experience plays a significant role in their participation. The present study has taken care of both the aspects but could have incorporated the effect of frequency and impact of floods on the psychology of the citizens in the country. Due to dearth of studies measuring the control effected these variables, the present study could be extended with inclusion of these control variables.

THEORETICAL AND PRACTICAL CONTRIBUTIONS

The study extends single stage theoretical viewpoints of explaining behavioural intention of viewpoints of citizens by integrating CVM and UTAUT. The study also extends UTAUT framework by adding political culture as a construct for explaining attitude and therefore the behaviour of citizens. The study discusses the concept of e-payment of on a government portal and therefore integration a governance and a information systems theory makes the theoretical model more robust. While earlier studies have tried to integrate CVM models with TPB and TAM models but they have also highlighted that the models could be extended with better theories. As UTAUT incorporates multiple IS theories together, use of UTAUT with CVM would produce robust results than its constituent theories. In a disaster related scenario, where e-payment practices are time bound, it becomes interesting to understand momentary behaviour of citizens rather then continuous behaviour which most of the earlier studies have discussed. The study also presents a contextual understanding of behaviour under disaster which is a seasonal event which causes disruption in financial and economic status of people. The understanding of politics and citizen's thoughts and views about the government could also explain their payment behaviour towards governance portal for development of society. Thus, the study tests the hypothesis from technological constructs and governance constructs to explain behaviour and therefore the contribution of citizens towards redevelopment of Kerala after the floods. The study also uniquely places itself in bringing forth concept of voluntary payment of citizens rather than forced and mandate payment like taxes and utility bills which also cater towards development of the country. While trust and security are key constructs which most of the technology based behavioural studies discuss, the present study omit them as the payment is recorded through UPI and bank transfer on government portals. The inclusion of attitude also adds an intermediary construct to explain behaviour which earlier theories like theory of planned behaviour used. The study however does not use moderating variables like gender or age or SEC levels as earlier studies have pointed out that these demographic factors have insignificant effects on developmental activities. The study can be further mediated with knowledge based constructs which could explain behaviour of citizens and their contributions for social cause and development. Results also reveal that societal influence and facilitating conditions which play an integral role in most of the behavioural studies have proved to have negligible effect on behaviour of citizens in this case. The social interaction of citizens making financial contributions is minimal which could be further controlled and its combined effect could be measured for understanding payment behaviour. Since political intervention is a mandatory activity in achieving financial resilience post natural disaster, the study could separate the role of non-government bodies and citizens for making financial contributions and extend this model further.

CONCLUSION AND LIMITATION OF STUDY

The study contributes to e-payment literature by integrating governance and information systems theory. The integration of constructs from both the theoretical literature brings a unique model in the context of financial relief operations for victims post disasters. The study tests the model in an Indian scenario where state government plays a different role from central government and thus the study brings fresh perspectives by discussing the local governance viewpoint in comparison to governance in general. Discussion of Kerala floods as a case study makes the results more interesting as the state is better in a lot of parameters like literacy and governance and yet faced one of the biggest floods in Indian history. The study collected behavioural data from people who contributed in rebuilding of Kerala by their financial contribution towards KCMDRF and the results highlighted some behavioural patterns which earlier studies on technology and governance has not recorded. The study found that three out of ten hypothesis found insignificant relationships and counterintuitive arguments were presented in the study to understand the plausible reasons behind it. The study tested a new belief which is political culture as a part of UTAUT theory which became an antecedent to attitude which would explain behaviour of citizens. The results contribute towards theory extension for both CVM and UTUAT which is first of its kind and more importantly in a disaster scenario. The study also highlights the importance of understanding state politics by citizens which could impact their decision for making a contribution. The study presents a unique amalgamation of theoretical lenses to understand how political know how, interest and alignment of citizens affect their decision making towards development of the state under crisis situation. Disaster relief operations have financial resilience as one of the key indicators and the study posits political culture which makes the study unique as although “political culture” is a construct developed over time but its effect needs to be captured for a short run payment window. The study also has some shortcomings and could be further developed with careful diligence in other disaster scenario. The results cannot be generalized as the intensity of disaster, political understanding of citizens for different states and more important the degree of financial contributions made by the citizens differ. The present study has used data from different parts of the country which could have given a heterogeneous responses while homogeneity could be considered by collecting responses from people with similar domicile, SEC levels and political interests. The study only measures behaviour of citizens contributing towards governance portals while it could be extended to NGO's and other private organizations also. It is also worthwhile to test the effect of voluntariness in making financial contributions to make the model robust.

Abstract

In this paper, development of advanced and novel macros for MINITAB environment, described allowing users to perform certain statistical and experimental design analyses: (i) a curve-fitting macro examining 14 fundamental algorithms on a response-predictor dataset to extract the best relationship(s), (ii) a macro for comparing two experimental designs using relative efficiency, (iii) a macro analyzing Latin square designs with sub-samplings,(iv) a macro for orthogonal contrasts of treatments/groups, (v) a macro performing multivariate path coefficient analysis (MULTPATH), (vi and vii) macros for analyzing stability analysis (univariate and multivariate i.e. AMMI[1]) of genotypes in plant breeding . In a field experiment, 20 of recently-bred maize (*Zea mays* L.) genotypes were examined under 2 drought-stress environments along with the control, and grain yield (YLD), seeds per ear (SPE), and ear length (EL) were scored to identify the superior hybrids. Results showed a non-significant difference between, genotypes, blocks and stress levels for ear length trait as a multiple-observation Latin square design. Moreover, the relative efficiencies (RE) showed that LS design has a lower RE than its lower-level designs. Orthogonal contrast comparison indicated a significant difference between two groups of maize genotypes (9 genotypes vs 11 genotypes). According to the results of curve-fitting, our macro could unravel a specific kind of the exponential curves with the highest R-sq(adj) index (91.54%). Path coefficients analysis revealed that independent variables EL and SPE had no significant direct effects on the dependent variable YLD. The univariate stability analysis introduced genotype BARAKAT-74, GARZA, and DKC-6101, BOLSON were the most stable genotypes in drought stress conditions. Finally, the AMMI stability showed that AMMI2 model was the best model and it introduced the stable, high-yielding and moderate-tolerant maize genotypes in this experiment. The macros presented here could be utilized in various areas of biological sciences, especially plant breeding, to perform advanced statistical and experimental design analyses.

Keywords: AMMI model, curve fit, experimental designs, global and local macro, non-linear, path analysis.

Introduction

A crucial task in statistical analyses is finding the best fitting model for a dataset, which may include a dependent/response and one or more causative factor(s) or casual variable(s). In regression analyses, typically one of the variables, often called response or dependent variable, is of particular interest and may be denoted as y . The other variables, i.e., x_1, x_2, x_3, …., x_k, usually called explanatory, regressor, or independent variables, are primarily utilized to predict or explain the behavior of dependent variable *y* (Seber and Wild, 2003). Regression analysis reveals the changes in response variable with the value of a vector consisting of predictors (independents), where multiple linear regression and most of the experimental design models are special forms of a linear regression model (Olive, 2017). Sometimes, the appropriate mathematical form of the relationship of two variables (e.g., response and independent) is known (e.g., linear regression), except for some unknown constants or coefficients (called parameters). In most of the statistical analyses, particularly in biological sciences, in contrast to physical sciences, the underlying processes are generally complicated and not well understood. This means that we have little or no idea about the shape of the association, and the object is to simply find the best-fitting function. Accordingly, finding the best model fitting a dataset is of interest and is mainly the target of studies. Many statistical approaches are being used in various fields of studies, e.g., biological and agricultural trials. Data generated are subjected to statistical analyses to extract the best/real relationships among the variables; the relationship may be simple, or multiple, linear regression line; or it could be more complex, e.g., quadratic, cubic, logarithmic, natural logarithmic, inverse or other variants. One may wish to compare efficiencies of experimental designs via relative efficiency (RE); or compute path coefficients involving independent and dependent variables; or make orthogonal contrasts or group comparisons following analysis of variance. For some of these procedures, computer programs are being proposed, which can be implemented in MINITAB, which is simple and user-friendly statistical software, with a programming language interface. MINITAB (MINITAB, 2018) is powerful statistical (Karafilowska, 2004) software that has a wide range of statistical procedures and graphical capabilities. In MINITAB, macros for many statistical procedures, experimental designs and algorithms can be handled (Arminian *et al*., 2008). MINITAB macros are easily edited, customized, and maintained, and can be made more powerful with a higher-level MINITAB macro programming environment (Mathews, 2005).

Drought is detrimental environmental stress in agriculture, and therefore the goal of conventional plant breeding programs. A review of recent advances in drought tolerance suggests that, to a certain extent, selection for high seed yield under non-stress conditions directly improves yield under water constraints (Sserumaga et al., 2018). Maize (*Zea mays* L.), after wheat and rice, is the third most important crop in the world, has the highest cropping area in some parts of the world, such as Nigeria, which is due to its high productivity, wide adaptability and particularly simple cultivation, processing, storage and exchange (Oyekunle *et al.,* 2017).

In this paper, we present and describe some advanced macros for MINITAB, saved in the form of "*.mac" and apply them in the study the grain yield and some other traits of maize plant under drought stress. These macros are designated as 1) curve-fitting macro, 2) macros for comparing the relative efficiency (RE) of two experimental designs, followed by estimation of the number of replication required for the second design to be as efficient as the first (targeted) design, 3) a macro for performing multivariate path coefficient analysis (MULTPATH) and its components, 4) macros for computing stability analysis univariate including parametric and nonparametric (under work), and more important, multivariate methods of stability analysis especially AMMI (additive main effects and multiplicative interaction), in plant breeding. The statistical procedures being covered in the proposed MINITAB software are described as follows.

Materials and methods

This experiment was conducted in which, 20 of recently-bred maize hybrids (some as dual-purpose: grain and forage) were examined in a field experiment under 3 irrigation management regimes, i.e. control, drought-treatments at kernel milk stage (R3) and kernel dough stage (R4) according to Ransom (2013) and Nielsen (2018). The experiment was performed at the Institute of the agricultural research center of Ilam province, Iran, in the city of Mehran (32:33º, 38:53´, 22:58"N; 46º, 2:23´, 9:19"E) in the 2017-2018 cropping year. The design was a factorial experiment design with two factors*:* drought and genotypes in 3 blocks and 3 samplings per each block. Before planting, the soil was examined for texture, drainage, and percentage of mineral elements. It has a good-drainage. Organic humus, like compost, and livestock manure were added to the soil in fall to improve drainage and a nutrient-rich soil formation. Maize needs a high level of nitrogen for better growth, and therefore excess fertilizer is needed to be added during planting and during the growing season. Grain yield (tons ha^{-1}), ear length (EL: cm), and a number of kernels per rows of the ear (SPE) were measured for each sampling per block. The harvesting time occurred when most all of the maize planted has reached “black layer” or in other terms, physiological maturity. This is accompanied by developing a black layer at the tip of the kernels, where they attach to the cob.

MINITAB is one of the world's powerful, user-friendly, reliable and statistical quality control software that performs numerous statistical analyzes. It also has a fascinated environment for writing and executing programming functions as exec, global and local functions called macros. Unlike environments like R, the MINITAB macros are more accurate and simpler. To execute commands, you need to enable the command line prompt (MTB >), click anywhere within the session window to activate it, then follow the path: 'Edit> Enable macros' (or: Editor> show command line) and type: "MTB > %mymacro in front of the command prompt, followed by clicking the ENTER key. Then the macro is executed and the results are achieved in the session window. The “%” sign is needed in front of the commands to perform a macro (global or local) which is written by users. MINITAB programming capabilities enable the users to provide their powerful macros according to the fields of study. MINITAB has three macro types. The first one is the most simplified preliminary programming command called "exec" or executive. The 2nd and more complex is called "global macros," and the 3rd and the most advanced is called "local macros." MINITAB accepts data in simpler formats than other statistical software. There are particular ways to call/recall a dataset into MINITAB. The first and the simple procedure is entering (typing) the data directly into worksheet cells. The second way is to open and recall a dataset file that has previously been saved using MS Excel, Notepad or other environments, e.g., "*.txt" or "*.dat" file extensions. In the following, we describe the statistical methodologies and the design of the experiments discussed in this paper. In the results and discussion, we explain the results of each macro step-by-step.

1- Analysis of designed experiments with MINITAB

1-1- Latin square (LS) design with subsampling

Latin squares (LS) are types of designs sometimes called double grouping designs, in which the treatments are grouped into replicates in two different ways (Cochran and Cox, 1957). They are, as usual, the simplest form of row-column designs. They are used to compare *t* treatments in *t* rows and *t* columns, where rows and columns represent the two types of blocking factors (Hinkelmann and Kempthorne, 2008). Of course, “row” and “column” terms are optional and majorly used in agriculture sciences, and first to third factors in other branches like physics and chemistry. Latin squares have origins in agricultural experiments and have applications in the social and behavioral sciences (Richardson, 2018a&b). The statistical equation (model) of a Latin square design with sub-sampling is as follow:

$y_{ij(k)l} = \mu + R_i + C_j + T_{(k)} + e_{ij(k)} + \varepsilon_{ij(k)l}$ (or: $y_{ijl} = \mu + \rho_i + \gamma_j + \tau_k + e_{ij} + \delta_{ijl}$

$$e_{ij} \sim^{iid} N(0, \sigma_e^2)$$
$$\delta_{ij\ell} \sim^{iid} N(0, \sigma_d^2)$$
$$i = 1, \ldots, t,\ j = 1, \ldots, t,\ k = 1, \ldots, t,\ \ell = 1, \ldots, n$$

where $y_{ij(k)l}$ denotes the observation of *i*th row, *j*th column, *k*th treatment and *l*th sample; μ = grand mean, R_i = row effect, C_j = column effect, $T_{(k)}$ = treatment effect, $e_{ij(k)}$ = main error and $\varepsilon_{ij(k)l}$ = sampling error [i = 1, . . . , t; j = 1, . . . , t; k = 1, . . . , t; and ℓ = 1, . . . , n.] In addition, the number of degrees of freedom for the sub-sampling error = $t^2(n-1)$. Treatments, columns, and rows may be necessarily fixed or random. The computerized analysis of the Latin square design with sub-sampling is tedious and has been impossible until now, justifying our main reason for introducing a MINITABMINITAB macro for this kind of design. We provide here a method for analyzing this type of design in MINITAB. In this paper, we analyze the maize ear length trait (EL) as an LS design with subsampling to show the method of executing the relevant macro we wrote.

1-2- Relative efficiency (R.E.)

Latin square design with sub-sampling and rectangular, repetitive, split-factorial and factorial-split, split-split-plot and split-block designs, are generally used in agricultural studies performing via MINITAB. In this context, we wrote some complementary macros for DOE (designs of experiments) for estimating and comparing the relative efficiency (RE) of two experimental designs. In designed experiments, the RE of a given design relative to another design is specified as the number of replicates of the other design needed to gain the equal result as one replicate of the first (Oladugba *et al*. 2013). Suppose we have performed an RCBD (randomized complete block design) in the field, and we analyzed it as a CRD (completely randomized design), and we are interested to know which design would give higher efficiency. In this case, it can be concluded that computing relative efficiency is a tool by which determining the magnitude of the reduction in experimental error due to blocking is achieved as:

$$R.E. = \frac{(r-1)E_b + r(t-1)E_e}{(rt-1)E_e}$$

Where *Eb* and *Ee* stand for block and error mean squares, and also *t* and *r* stand for the number of treatments and replications (or blocks), respectively, in the RCB design (Gomez and Gomez, 1984). If the error *d.f.* is less than 20, the *R.E.* value should be multiplied by the adjustment factor *k* defined as:

$$k = \frac{[(r-1)(t-1)+1][t(r-1)+3]}{[(r-1)(t-1)+3][t(r-1)+1]}$$

Moreover, blocking is essentially affecting the difference in the magnitude of experimental error between a CRD and an RCBD; hence the value of the *R.E.* is indicative of the gain in precision due to blocking (Gomez and Gomez, 1984). It is assumed that the CRD is the simplest design among all existing designs. When only two factors are examined, then the CRD is equivalent to a *t*-test. If the RCBD design has RE greater than 100, then analyzing it as a CRD would need to have more replications to achieve the accuracy of an RCBD. Our written macros also compute the number of replications needed for the ‘lower’ (less efficient) design to be as accurate as the ‘upper’ (more efficient) design. These macros compare the relative efficiency of RCBD to that of CRD, and also of Latin square design (LS) to RCBD and CRD. We designated our macros as *RB2CD*, *LS2CD*, *LS2RBc,* and *LS2RBr*. The *RB2CD* macro compares RB design to CD, *LS2CD* macro compares Latin square design to CD, *LS2RBc* macro compares Latin square to RB when columns are supposed to be blocks, and *LS2RBr* macro compares Latin square to RB when rows are supposed to be blocks. In this paper, we compare the RE of the analyzing LS design with its equivalent RB and CD designs to show the method of executing the macros written.

1-3- Orthogonal contrasts (group comparisons) between factors (e.g., treatments in experiments)

Suppose, the null hypothesis is: $H_0 = \mu_1 = \mu_2 = \mu_3 = ... = \mu_k$. One may test it by means of one-way ANOVA. However, if one is interested in determining how precise differences existing between the groups, then rejecting the omnibus test requires not performing mean comparisons/contrasts. However, all the information required to compare the factors in the trial using simple pair-wise comparisons is not possible. In such a case, it is necessary to do single-degree-of-freedom, orthogonal contrasts. To do this, the ANOVA table information is needed, especially replication number and error mean square. The orthogonal contrast technique is mentioned as a simple and efficient approach to analyzing the experimental data in order to obtain, e.g., the main, interaction and nested effects, for group mean comparisons and/or specific residuals. In addition, it could be an alternative means of analyzing experimental data without a definite structure, such as experiments with additional treatments (Cristina and Nogueira, 2004).

Thus, the estimation of the significance of the comparisons is a valuable task, especially in agricultural trials, and preparing a good program that is simple and comprehensive in performing this kind of analysis is needed. In this context, we wrote a macro called "*contrast*, which simply performs any group comparisons and gives the user a P-value, whereby he/she is able to find that a specific group comparison is or is not significant. The most attractive part of this macro is where it estimates the orthogonal coefficients for the group comparisons automatically, which is a hard task. In many other programs, the user has to insert them manually into the program, which is time-consuming and tedious. Here we perform a contrast test with "*contrast*" macro we wrote for its functionality and outputs, comparing a group of factors with other groups (s), as come in the results and discussion part of this paper. This macro is the best program for doing orthogonal contrasts because it does not require any coefficient definition and insertion by the user.

2- Studying variables relationships using MINITAB

2-1- Curve fitting algorithms and MINITAB macro results

Considering a single independent (x) and a given response (y) variable, a simplified linear regression equation may be fitted as: $y_i = \beta_0 + \beta_1 x + \varepsilon_i$, where the model $y \approx \beta_0 + \beta_1 e^{\beta_2 x}$ is a nonlinear model, being nonlinear in β_2, where β_0 refers to intercept, β_1 and β_2 to slopes of the equation and e is natural logarithm (Seber and Wild, 2003). Even when a linear approximation exists and works fine, a nonlinear model may still be applied for clearly interpreting the parameters (Seber and Wild, 2003). There are numerous nonlinear models in statistics, and the above-mentioned one is a type that may be used instead. The algorithms discussed in this paper and supplemented in our "*curvfit*" macro, are applicable to all fields of science. Users may, however, for obtaining information about statistical curve fitting algorithms, refer to nonlinear materials in Seber and Wild (2003). Our macro advantage is that it seeks the most suitable curve fit algorithm between 15 algorithms implemented in the macro.

As Sokal and Rohlf (1995) denoted, linear regression is not always enough to assess the differences among some sample means. So instead of a linear trend, some relations in nature might best be expressed via fitting a curvilinear regression. It is said that the linear regression approach is not sufficient for most biological situations and majority of nonlinear approaches applied to biological or agricultural situations can be categorized into three types: a) exponential growth curves, b) negative exponential and c) Michaelis–Menten (1913) model which has been widely used for enzymatic and chemical kinetic reactions (Lawal, 2014), and also growth models (like logistic growth model and Gompertz growth model), which have main roles in biology. Simplifying the complicated curve fits or nonlinear forms is a good way to better investigate such trends. According to Johnson and Bhattacharyya (2010), such transformations are used to transform the response to approximate a linear relation. So, as they mention, the data could be transformed to a nearly straight-line relationship, or one can try to linearize the relation of two variables by plotting a transformed y response variable or some other transformed y with the independent x variable. They count some types of transformations or nonlinear models and their corresponding linearized forms including power and root forms (mentioned above in our macro), and concluded that sometimes a specific nonlinear association is mainly suggested and that while initial information regarding the form is not in hand, a study of the scatter diagram may often show the proper linearizing transformation (Johnson and Bhattacharyya, 2010). Data transformation in regression has been suggested by Zar (2014), as he mentions that transforming the independent variables has no effect on ”Y” distribution but transforming the “X” may generally linearize data.

2-2- Path coefficient analysis

Path coefficients analysis (Fig. 1), an extension of multiple regression analysis and a powerful tool for studying causal associations among a set of normal variables, has been detailed in the literature (Wright, 1934; Li, 1975; Dewey and Lu, 1959; Kang, 2015). A path coefficient analysis entails exogenous, endogenous, intervening or intermediate variables and an ultimate dependent variable. In the path model, a path coefficient resembles the direct effect of a variable (causal variable) (Pedhazur, 1997; Wuensch, 2016). In addition, for each path toward an endogenous variable, a path coefficient, i.e. “*pij”,* refers to the effect of an independent variable *i* on *j*th variable. Next, the square of a path coefficient gives the proportion of the affected variable's variance (Wuensch, 2016). The interrelationships between such variables are indicated using the one-headed arrow (direct path coefficient); two-headed arrows represent correlation coefficients between pairs of variables (for details see Arminian *et al*., 2008). Path coefficient analysis has been used in various fields of study, e.g., biological sciences, social studies, and agricultural fields, such as plant breeding. Plant breeders have, indeed, used path analyses to identify useful traits as selection criteria to improve crop yield (for example, see Sidwell *et al*., 1976; Kang *et al*., 1983; Board *et al*., 1997, 2003; Kang, 2015).

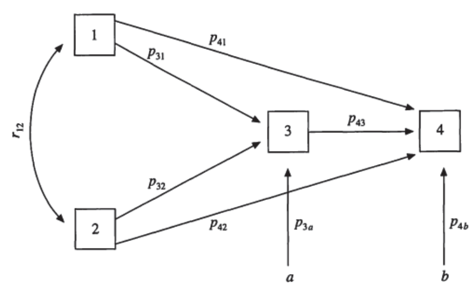

Fig. 1. A given path diagram for the relationship between a dependent (4), 2 exogenous (1 and 2) and 2 endogenous (3 and 4) variables, (courtesy of Pedhazur (1997). Path coefficient analysis is described by Wright (1934) and later by Li (1975). Single-headed arrows represent direct effects (Pij), whereas double-headed arrows represent correlation coefficients (rij) in the model.

The complete guide regarding path coefficient analysis is given above as reported by researchers (Pedhazur, 1997; Wuensch, 2016). The benefit of path coefficient analysis is that it allows decomposition of a correlation coefficient into its components, i.e., direct (the path coefficient, involving the direct effect of predictor variable upon its response variable) and, indirect effect (of a predictor variable on the response through another predictor) (Dewey and Lu, 1959). Carey (1998) in an introduction to multiple regression and path coefficient analysis with a new macro for SAS called PROC CALIS, mentions that the main advantage of path analysis is when there are two or more dependent variables are present which is so called as “multivariate multiple regression”. In addition, Carey (1998) indicated that path analysis can also be used to decompose the variance of a single dependent variable. The PATHSAS macro by Cramer *et al*. (1999) is another SAS macro that performs path analysis. Kang (2015) brought in details in a computer program called "Kang_SASPath" and gave an example of performing path coefficient analyses. This program also determines index weights for developing selection indices for plant breeding.

In agriculture, path analysis has been applied by plant breeders to help identify beneficial characters as selection criteria to improve crop yield (Dewey and Lu, 1959; Milligan *et al*., 1990). MINITAB "*MULTPATH.MAC*" macro gives descriptive statistics, path coefficient analysis (direct and indirect effects of the causative parameters influencing intervening variables or a final dependent one). The macro also tests the significance of each direct effect divided by its related standard error. The complete version of this macro is available in Arminian *et al.* (2008). We suggest applying and using this MINITAB macro and other macros introduced in this paper on earlier versions of MINITAB, like 13, but not 18. To run the macro, the procedure is as follows: suppose the executive file is available in the path *'D:\MINITAB14\Macros\multpath.mac'* and one dependent and two independent variables are in this order (dependents, independents: left to right, respectively) within the worksheet columns C1 to C3.

MTB>%multpath c1-c3.

```
*   Elements of m.3 matrix for 4 independents:
*
*      P1Y   r12P2Y   r13P3Y   r14P4Y  ..
*    r12P1Y     P2Y   r23P3Y   r24P4Y  ..
*    r13P1Y   r23P2Y     P3Y   r34P4Y  ..
*    r14P1Y   r24P2Y   r34P3Y     P4Y  ..
*    ......   ......   ......   ......  ..
*    Path equations specify the path model, through m.3
*    i.e e.g.: r1Y = P1Y + r12P2Y+ r13P3Y+ r14P4Y + ...
```

The above lines represent the framework of the basic matrix of path coefficient analysis. In our macro outputs (results and discussion part of this paper), the first rows of the results represent original data, followed by descriptive statistics, e.g., the number of observations, mean, SE mean, standard deviation, minimum, first and third quartile, median, min, and max. Correlation coefficients are accompanied by their respective significance levels. In the next part, macro performs linear multiple regression analysis for dependent(s) versus independent variable(s), respectively [when more than one dependent is present, the macro performs this analysis for all dependent-independents variable pairs. For this, regression equation, along with variance inflation factor (VIF), statistical tests, such as R-squared, and importantly analysis of variance table of regression are constructed Arminian *et al*., 2008). The term VIF or simply variance inflation factor distinguishes multicollinearity in regression analysis. When there is a correlation between predictors (i.e., independent variables) in a given model, this is known as multicollinearity, which can adversely affect the regression results. The VIF parameter estimates the inflation rate of the variance of a regression coefficient due to multicollinearity in the model. Mathematically, $VIF=1/(1-R^2i)$. Finally, Durbin-Watson statistics of the regressions are estimated. Most regression problems including time series data show positive autocorrelation. In this case, the Durbin-Watson statistic is a test that shows that the residuals from a linear regression or multiple regression are independent (Montgomery *et al.,* 2012). The lower values of this statistic are desirable.

3- Stability analysis in plant breeding using MINITAB

3-1- univariate parametric stability analysis of genotypes

We have written and evaluated two MINITAB advanced macros called "*MINISTAB.MTB*" for analysis of 20 parametric stability statistics, "*NONMINISTAB*" for nonparametric analyses, and "*AMMI.MAC*" for additive main and multiplicative interaction (AMMI) model, respectively, for use in plant breeding. The MINISTAB computes most sophisticated parametric stability statistics, such as Finlay-Wilkinson (1963), Eberhart and Russell (1966), and much more (Roemer, 1917; Plaisted and Peterson, 1959; Wricke, 1962, 1964; Hanson, 1970; Hussein *et al.*, 1970; Shukla, 1972; Freeman and Perkins in Freeman, 1973; Pinthus, 1973; Francis and Kannenberg, 1978; Lin *et al.*, 1986; Becker and Léon, 1988; Lin and Binns, 1988; Kang, 1998). Such univariate stability analysis is beneficial in plant breeding so that recently an R package (https://cran.r-project.org/web/packages/stability/stability.pdf) is being developed called "stability" to identify superior and stable genotypes under diverse environments. This package extracts and performs Eberhart and Russell ANOVA (1966), Fin-lay and Wilkinson (1963) Joint Linear Regression, Wricke (1962, 1964, 1965) Ecovalence, Shukla's stability variance parameter (1972) and Kang's (1993) simultaneous selection for high yielding and stable parameter. Of course, although this and other G×E analysis programs are being used extensively nowadays, they extract some of the stability parameters and not all of them. Our MINITAB macros for univariate stability part, extract 20 stability parameters which will be discussed later. Our target was to estimate all of these parameters because we see that many researchers are still using univariate parameters, although multivariate methods for GE like GGEBiplot and AMMI, may be the best choices or alternatives. For stability analyses, current maize data set (grain yield or YLD as tons ha^{-1}) was used. The dataset involved 20 genotypes and 3 environments (drought stress levels) with 3 replications.

3-2- multivariate parametric stability analysis of genotypes

Additive main effect and multiplicative interaction (AMMI) is a useful approach to perform stability analysis in plant breeding, which is done here using a macro called AMMI for MINITAB. Of course, some other AMMI programs are included in known softwares like GENSTAT or written like that developed by Rodrigues *et al*. (2015). The AMMI macro we provided for MINITAB environment is nearly a complete one, which provides almost all information a user needs for AMMI approach. Among the different approaches to investigate multivariate stability analysis, AMMI is a good choice and according to Gauch (2006), AMMI partitions the overall variation into main effects of genotype and environment, and also genotype by environment interactions. With our *AMMI* macro, 3 types of data could be computed: 1) genotype, environment, replication and trait(s), one by one, respectively, arranged left to right. 2) genotype, environment, trait(s), respectively, as above but without replication. 3) a two-way table of E×G (environment by genotype) interaction. When executing this macro, a window pops up prompting the user to enter some crucial info as follows:

```
…………..…
                AMMI.MAC
  Local macro performing Additive Main Effects and Multiplicative Interaction (AMMI)
analysis of an ANOVA data or an ExG table of means,
….
  Example calling statements:
  1: Two-way data serial (data in 3 columns: Gen, Env, and Response),
     e.g.,in C4-C6 columns. Then, at command prompt type, MTB> %AMMI C4-C6.
*****
  2: Data in 4 columns, e.g., Gen, Env, Rep & Response in C4-C7, as MTB>%AMMI C4-
C7
*****
  3: Two-way data matrix of E by G (E in rows and G in columns),
     E.g., if G1-G10 genotypes mean in C11-C20, MTB>%AMMI C11-C20.
*****
  Note: The order of data must be as above.
  To exit the macro at any stage, press CTL + Pause/Break buttons.
  Copyright(C) April 2018. A. Arminian. Ilam university, Iran.
  All rights reserved.     E-mail:   arminian_a@yahoo.com
…………………….
```

As shown, the program accepts 3 types of data as input: 1) Two-way data serial (data in 3 columns: Gen, Env, and Response, respectively, left to right order), 2: Data in 4 columns: Gen, Env, Rep & Response, e.g., in C4-C7, as MTB>%AMMI C4-C7, 3: Two-way data matrix of E by G (E in rows and G in columns), e.g., if G1-G10 genotype means are located in C11-C20 columns, the command must be executed as MTB>%AMMI C11-C20. The AMMI macro written here calculates more advanced functions than other AMMI programs, such as GENSTAT, including: ANOVA tables of stability and AMMI with Gollob (1968) and Cornelius (1993) *F* functions, descriptive statistics, Finlay-Wilkinson (Finlay and Wilkinson, 1963) regression output, nominal yield estimates, use of supplementary approach in stability analysis (Pacheco *et al.,* 2005), and also graphical representations of the stability parameters as biplots (Fig. 4) and surface plots as referred by Kang and Gauch (1996). A fictitious dataset consisting of genotypes (G), environments (E), and replication (courtesy of Gauch, 1992) is given in appendix no. 5.

Results and discussion

Latin square (LS) design with subsampling

For the maize data of this experiment, 3 of genotypes were examined in 3 columns (as drought stress) with 3 samples per each block. The map of the trial is as below (Table 1):

Table 1. map for the multi-observation (sub-sampling) Latin square design in this experiment

Control	Drought-1	Drought-2
BARAKAT 2 22, 22, 18	**BARAKAT-4 19, 21, 19**	**BOLSON 21, 18, 16**
BARAKAT 4 18, 20, 20	**BOLSON 19, 19, 20**	**BARAKAT- 16, 14, 19**
BOLSON 18, 20, 24	**BARAKAT-2 18, 15, 15**	**BARAKAT- 23, 19, 21**

According to table 2, five columns of data, represent the block, drought stress (column1), genotype (treatment) and sampling as factors and ear trait were enough to do a Latin square with sub-sampling. Figure 2 shows the method for entering data of map above into MINITAB.

Table 2. A part of the data set of maize for analyzing the Latin square design with subsampling

Genotype	ENV=Stress	Block	Sample	EL
BARAKAT-2	Control	1	1	22
BARAKAT-2	Control	1	2	22
BARAKAT-2	Control	1	3	18
BARAKAT-2	Control	2	1	19
BARAKAT-2	Control	2	2	16
BARAKAT-2	Control	2	3	20
BARAKAT-2	Control	3	1	21
BARAKAT-2	Control	3	2	21

The calculations are performed through MINITAB worksheet windows as STAT » ANOVA » General Linear Model » Model: LE, and Factors: Block, Stress, and Genotype. The results are:

Analysis of Variance

Source	DF	Seq SS	Adj MS	F	P
Genotype	2	26.741	13.370	2.63	0.097
Block	2	7.185	3.593	0.71	0.506
Stress	2	19.185	9.593	1.88	0.178
Error	20	***101.852***	5.093		

Total 26 154.963

For the analysis of the final variance, we must formulate another table with the sums (or averages) of the treatments over the samples and perform the analysis of variance to give the following results.

Analysis of Variance

Source	DF	Seq SS	Adj MS	F	P
Genotype	2	80.22	40.11	0.98	0.504
Block	2	21.56	10.78	0.26	0.791
Stress	2	57.56	28.78	0.71	0.586
Error	2	***81.56***	40.78		
Total	8	240.89			

The main target of such tables is to construct the sub-sampling error SS as: **101.852-(81.56/3=27.19)=74.66**.Then the final ANOVA table is:

Analysis of Variance:

Source	DF	Seq SS	Adj MS	F	P
Genotype	2	26.741	13.370	2.63	0.097
Block	2	7.185	3.593	0.71	0.506
Stress	2	19.185	9.593	1.88	0.178
Error	20	101.85	5.09		
&$\text{Error}_{\text{Exp}}$	2	***27.66***	13.59	3.28	0.061
$\$$$\text{Error}_{\text{samp}}$	18	74.66	4.15		
Total	26	154.963			

z&*Lack –of-Fit*
$*Pure Error*

For ease of use, we provided a local macro for lower versions of MINITAB, like 14, which can extract important parameters from the table of analysis of variance, such as the degree of freedom, sampling error, and MS. To execute this macro, as said, datasets must be located in 5 columns similar to Figure 2. To do this, activate the session window and in front of the command line prompt (MTB>) type: MTB > %latss c1-c5 (OR: Block-EL) followed by pressing the ENTER key. During the execution of the program, MINITAB asks the user 2 questions in which they should enter the number of treatments and the sum of squares of the two designs. The results are:

MTB > %latss c1-c5
Executing from file: D:\MINITAB14\MACROS\latss.MAC
Dataset:

Row	Genotype	Block	Stress	Sample	EL
1	BARAKAT-2	1	Control	1	22
2	BARAKAT-2	1	Control	2	22
……					
27	BARAKAT-74	3	Drought-2	3	21

ANOVA for original data (subsampled):

Factor	Type	Levels	Values
Genotype	fixed	3	BARAKAT-2, BARAKAT-74, BOLSON
Block	fixed	3	1, 2, 3
Stress	fixed	3	Control, Drought-1, Drought-2

<u>Analysis of Variance for EL, using Adjusted SS for Tests</u>

Source	DF	Seq SS	Adj SS	Adj MS	F	P
Genotype	2	26.741	26.741	13.370	2.63	0.097
Block	2	7.185	7.185	3.593	0.71	0.506
Stress	2	19.185	19.185	9.593	1.88	0.178
Error	20	**101.852**	101.852	5.093		
Total	26	154.963				

S = 2.25668   R-Sq = 34.27%   R-Sq(adj) = 14.56%

* ANOVA for summated data over samplings:

Factor	Type	Levels	Values
Treat.	fixed	3	BARAKAT-2, BARAKAT-74, BOLSON
Block.	fixed	3	1, 2, 3
Column.	fixed	3	Control, Drought-1, Drought-2

<u>Analysis of Variance for Response, using Adjusted SS for Tests</u>

Source	DF	Seq SS	Adj SS	Adj MS	F	P
Treat.	2	80.22	80.22	40.11	0.98	0.504
Block.	2	21.56	21.56	10.78	0.26	0.791
Column.	2	57.56	57.56	28.78	0.71	0.586
Error	2	**81.56**	81.56	40.78		
Total	8	240.89				

S = 6.38575   R-Sq = 66.14%   R-Sq(adj) = 0.00%

Enter number of TREATS, and SAMPLINGS, respectively:
DATA> 3 3

Enter ESS of the 1st and 2nd ANOVA tables, respectively:
DATA> 101.852 81.56

* --------------------------------
Lack-of-Fit SS: 27.1867

* --------------------------------
sub-sampling=Pure Error SS: 74.6653

* ---
Degree of freedom for sub-samp: 18.0000

* ----------------------------------
Sub-sampling Error MS: 4.14807

As you can be seen through the results above, the final ANOVA table for this experiment includes two types of errors called ErrorExp and Errorsamp. Interestingly when we analyzed the original data containing samples by MINITAB 18.1 and defining the ANOVA model as STAT » ANOVA » General Linear Model » Fit model: Response: LE. And the factors are Block, Stress, and Genotype. Then the constructed table is as follows:

Analysis of Variance

Source	DF	Adj SS	Adj MS	F-Value	P-Value
Block	2	7.185	3.593	0.71	0.506
Stress	2	19.185	9.593	1.88	0.178
Genotype	2	26.741	13.370	2.63	0.097
Error	20	101.852	5.093		
Lack-of-Fit	2	27.185	13.593	3.28	0.061
Pure Error	18	74.667	4.148		
Total	26	154.963			

As could be seen from the results above, there is not significant difference between blocks, drought stress levels, and 3 genotypes. The current result is likely due to fewer genotypes used in this little Latin square design. As a result, the user can simply, analyze Latin squares with multi-observation or sub-sampling via MINITAB 18.1 as discussed above. So, “Error” term denotes the Experimental error and Pure-Error is the sampling error. This table contains all the information we achieved through our macro and some handy calculations. So, when the MINITAB 18.1 is present, the user should use it. We think no one used this ability of MINITAB 18 for doing Latin squares with sub-sampling. Of course, most of the reports, refer to lack-of-fit and pure error as components of the regression approach. But this can be used for analysis of latin square with sub-sampling or mult-observation design.

Relative efficiency (R.E.)

Suppose, we analyzed the above Latin square without sub-sampling or averaged over samplings (Table 1), and we invoke *ls2cd* macro. We analyze this design firstly as a simple Latin square and then as RBD to compare the results (Table 3).

Table 3. data set for Latin square design of ear length trait of maize

↓	C1-T	C2-T	C3	C4	C5	C6
	Genotype	Stress	Block	YLD	EL	SPE
1	BARAKAT-2	Control	1	10.13	20.67	34.67
2	BARAKAT-2	Control	2	7.44	18.33	35.67
3	BARAKAT-2	Control	3	5.52	20.00	31.67
4	BARAKAT-2	Drought-1	1	10.35	16.67	24.33
5	BARAKAT-2	Drought-1	2	6.37	19.67	26.00
6	BARAKAT-2	Drought-1	3	5.54	16.00	21.00
7	BARAKAT-2	Drought-2	1	11.57	19.33	28.33

The attributed ANOVA table will be constructed as follows:

Analysis of Variance for EL, using Adjusted SS for Tests

Source	DF	Seq SS	Adj SS	Adj MS	F	P
Block	2	2.395	2.395	***1.198***	0.26	0.791
Stress	2	6.395	6.395	***3.198***	0.71	0.586
Genotype	2	8.914	8.914	4.457	0.98	0.504
Error	2	9.062	9.062	***4.531***		
Total	8	26.765				

S = 2.12858   R-Sq = 66.14%   R-Sq(adj) = 0.00%

To run the program, you need to type in the command line as:

General Linear Model: Forage versus Treat

```
MTB > %ls2cd
Executing from file: D:\MINITAB14\MACROS\ls2cd.MAC
……
*       Example calling statement:
*    to run the macro (if executing file located
*    in macros folder of minitab) in session window type:
*    MTB> %ls2cd
```

```
**********************************************************
 Relative efficiency of LS to CR design:

 Please Enter: 'Block MS', 'Column MS', 'Error MS'
   and 'Treatment number', respectively
DATA> 1.198  3.198  4.531 3

Relative efficiency of RBD to CRD as a percent is:
 R.E.(%):    74.2551

Needed replications to perform the design as a CRD having the same efficiency
as LS:
Replications:    2.22765
```

According to the results above, the LS has a lower relative efficiency than CR design, and should we organize this 3 genotypes as a CR design, not an LS design. Analyzing this design as an RB design where rows considered as blocks, produces the results as:

MTB > %ls2rbr

```
Relative efficiency of LS to RB designs, where rows considered as blocks

 Please Enter 'Block MS', 'Error MS' & 'Treatments numbers', respectively
DATA> 1.198  4.531 3

Relative efficiency of LS to RB, where Rows considered as Blocks (%):
%R.E.    63.4032
```

If the relative efficiency of a given design, e.g., Latin square to CRD, is greater than 1, then Latin square design is more efficient than CRD and vice versa. If the relative efficiency of RBD is greater than that of CRD, the trial should be managed as an RBD, instead of CRD. However, the question arises: How many replications will be needed if one tries to run the current RCBD as a CRD to achieve the same accuracy? Or simply, how many more replications of an e.g. CRD would be necessary to gain the similar (same) precision as RBD for computing the treatment means? Our macro estimates the number of replication needed to run the trial as a CRD. For details of the equations used, see Gomez and Gomez (1984).

Regarding the comparison of an LS design against an RCB design through RE estimation, Gomez and Gomez (1984) pointed out: “the additional column-blocking, made possible by the use of an LS-design, is estimated to have increased the experimental precision over that of the RCB design with rows as blocks by 266%; whereas the additional row-blocking in the LS design did not increase precision over the RCB design with columns as blocks.

Orthogonal Contrasts

For the LS design comparing 20 genotypes of maize in this experiment, suppose we want to compare 9 of the 20 corn genotypes (from BARAKAT-2 to GARZA) against the remaining 11 genotypes (HYDRO to ZP-606) for the EL trait. The data on treatments are given, but the coefficients given here need not be defined or inserted manually when executing our macro “*contrast*”, because this macro estimates them automatically (Table 4), while other programs like SAS are not able to do this at all.

Table 4. Twenty corn genotypes tested in this experiment
for comparing 2 groups in an orthogonal contrast comparison.

C1-T	C2
Gen	EL
BARAKAT-2	157.67
BARAKAT-74	179.00
BOLSON	180.99
DKC-6589	193.33
DKC-5901	147.99
DKC-6630	164.01
DKC-7211	183.34
DRAGMA	187.35
GARZA	145.67
HYDRO	170.67
INOVE	180.33
KSC-704	180.00
KSC-705	172.00
MASYL	193.32
MAYMAY-70	177.33
MIMI	156.66
NS-6010	179.68
NS-770	183.99
ZP-600	179.66
ZP-606	177.31

In this table, 9 and 11 genotypes are categorized into 2 adjacent groups. Note that the user can define up to 4 groups in this macro, but it must be ensured that there is no interference between genotypes in the groups. That is, all observations of a given group are placed within that group. The ANOVA table for these 20 genotypes, which has been analyzed as a 2-factor design (ignoring of the interaction effect) is:

Analysis of Variance for EL, using Adjusted SS for Tests

Source	DF	Seq SS	Adj SS	Adj MS	F	P
Block	2	1.631	1.631	0.815	0.28	0.757 ns
ENV	2	95.192	95.192	47.596	16.25	0.000 ***
GEN	19	366.693	366.693	19.300	6.59	0.000 ***
Error	156	456.787	456.787	2.928		
Total	179	920.303				

As seen, there is a significant difference between 20 genotypes for EL trait, affirming t that orthogonal contrast to be done. If the file "*Contrast*" is located within the MACROS folder of MINITAB main root folder, as discussed earlier, in the enabled session window of MINITAB, type the following command and respond to the prompts and enter the information requested as follows:

MTB > %contrast c2

Contrast comparisons

Data Display

Row	EL	Coeffs	D.f.	SS=MS	F	P value
1	167.67	1.00000	1	43.2230	14.7620	0.0001771
2	179.00	1.00000				
3	180.99	1.00000				
4	193.33	1.00000				
5	147.99	1.00000				
6	164.01	1.00000				
7	183.34	1.00000				
8	187.35	1.00000				
9	145.67	1.00000				
10	170.67	-0.81818				
11	180.33	-0.81818				
12	180.00	-0.81818				
13	172.00	-0.81818				

```
14  193.32  -0.81818
15  177.33  -0.81818
16  155.66  -0.81818
17  179.68  -0.81818
18  183.99  -0.81818
19  179.66  -0.81818
20  177.31  -0.81818
```

According to results above, there is a significant difference between two groups of genotypes (9 against 11 genotypes). If this comparison is performed with the independent or 2-*t* test, the results will be as follows, in which there is no significant difference between the two groups, and this emphasizes that such comparison must be realized with the contrast method.

```
Two-Sample T-Test and CI: EL1, EL2

      N    Mean  StDev  SE Mean
EL9    9   172.2   17.0      5.7
EL11  11  177.27   9.32      2.8

Difference = mu (EL1) - mu (EL2)
Estimate for difference:  -5.11818
95% CI for difference:  (-19.01478, 8.77842)
T-Test of difference = 0 (vs not =): T-Value = -0.81  P-Value = 0.435  DF = 11
```

After entering the information necessary for the test, the main output of the macro is displayed, in which "*coeffs*" refers to the orthogonal coefficients for the test. It is important that these coefficients be estimated in the order in which their sum equals zero and for two groups (here 9 versus the rest 11 genotypes), the signs of the first group coefficients are opposite of the first group. However, the results of the test with one degree of freedom suggest that there was a significant difference between the two groups. In other words, the first 9 genotypes are different (P<0.001) from the remainder 11 maize genotypes.

Curve fitting

To run this macro, it is necessary that the traits *i.e.* the length of the ear (EL) and the number of grains per ear (SPE) to be located in 2 columns, such as c4 and c5, and type in the front of the command line prompt as *MTB>% curvfit c4 c5*, after activating the window session. In the following, the results will be as follows:

```
%"curvfit" C4 C5
….
Note *  Example calling statement:
Note *  Dependent and Independent variables must be raw data
Note *  e.g. in C4 & C5 columns of the worksheet, respectively.
Note *  Then type in session window as:
Note *  MTB> %curvfit c4 c5.
Note *----------------------
      …..
Data:
```

Constant	13.558	0.586	23.15	0.000	
X	0.1795	0.0174	10.32	0.000	1.00

Y = A + BX:
Regression Equation: $EL = 13.558 + 0.1975SPE$

Trend 1 shows a linear relationship between the two response variables (EL or ear length) and the predictor (SPE or number of seeds per ear), and in the analysis of variance, *F* index has a significant condition, which is also low (35.37%). And due to this low-level coefficient of determination, it is better to apply and fit other regression models to this data set.

Trend 2:
Analysis of Variance

Source	DF	Adj SS	Adj MS	F-Value	P-Value
Regression	2	352.253	176.127	54.88	0.000

X2	0.00329	0.00212	1.55	0.122	61.59

Y = A + BX + CX^2:
Regression Equation: $EL = 16.70 - 0.030SPE + 0.00329SPE^2$

The second trend is a quadratic trend between two maize traits. *i.e.* EL and SPE, with A nonsignificant slope but constant, and a low R^2 such as that for linear trend, and so, will not be mentioned as the best trend for the two data sets measured.

Trend 3:
Analysis of Variance

Regression Equation: $\text{EL}' = 0.03979 + 0.3807\text{SPE}'$

According to the above results, almost all (except for one) of the fourteen trends had a low coefficient of variations although they having significant regression coefficients, they were not proportional to the pair of variable EL and SPE. But one of them, a sophisticated trend, that had largely a high coefficient of determination (R^2=91.54%) has been considered. The greater R^2 suggests a stronger relationship. Of course, according to MINITAB Company, a high R-squared does not necessarily show that the model fits well. It may be a surprise, but one can look at the fitted line plot and also the residual plot. Our macro was able, to realize the almost real relationship between the trait of the EL response and the predictive trait of the SPE. Thus, this macro searches and finds the best relationship equation among 14 equations defined, for a dependent variable and relevant independent variable, and could be easily applied by researchers in various fields of study, especially genetics.

Path coefficient analysis

In this real experiment, the grain yield per hectare (YLD) was considered as the ultimate dependent or response variable and considered the two traits of EL(ear length) and SPE(the number of seeds per ear) as predictive or affective (causative) variables. Of course, it should be noted that there was no linear relationship between YLD and the two traits in this experiment, and instead, there were nonlinear relations. Thus, we note that in these calculations do not look for the direct, strong and significant direct effects of the predictors on the dependent. However, put the data of the three traits listed in Table 2 into 3 adjacent columns in the MINITAB worksheet, so that the dependent YLD is placed in the first column of the left, then other independent variables were put in the second to the last column (as shown in Table 2) and then in the front of the command line in session window, do by typing the following command and reply to the questions while popping up. An interesting innovative and exquisite problem about MINITAB 18 is that, unlike other previous versions, it separates the executable unnecessary commands from the numerical results of the session window, and the numerical results, such as the JMP software, are divided into segments, which also have the storage functionality, both text, and image.

In outputs, the dependent variable (grain yield or YLD) is associated with independent variables (EL and SPE) in the linear equation, e.g., YLD = 6.36 + 0.120*EL - 0.0026*SPE. In this equation, 6.36 is the constant (intercept) and 0.120 and 0.0026 are the slopes (β_1 *and* β_2) of the linear equation. The “VIF” or variation inflation factors of two independent traits were lower 10, and *F* test of ANOVA table was nonsignificant too. Nevertheless, the multiple linear equation indicated the nonlinearity of the model, and the determination coefficient of the model (1%) proves that linear model does not fit the data and so other models should be evaluated, which has been discussed earlier.

In the last part of the macro output, the matrix results are presented. The “*m.1*” matrix represents the correlation coefficients of all independent variables (EL and SPE) with the relevant dependent variable (YLD). Then, direct effects of independent variables on the dependent variable, along with *t*-test and P-values, are presented. The direct effects of grain yield (YLD) variable on two independents EL and SPE (0.106664 and -0.008002, respectively) were not significant (P>0.05). Finally, “*m.3*” matrix shows direct (diagonal) and indirect effects (off-diagonal elements). The U or residuals of path analysis were 0.994788, indicating the proportional effects of unknown factors on the dependent variable (Figure 2). We suggest drawing the path diagram by means of specific graph builders like *Graphviz*. Analyses mentioned above showed that the "*MULTPATH*" macro may be practically used by many researchers in various fields of study, especially agriculture and biological sciences. For more information refer to our MULTPATH paper published (Arminian *et al.,* 2008).

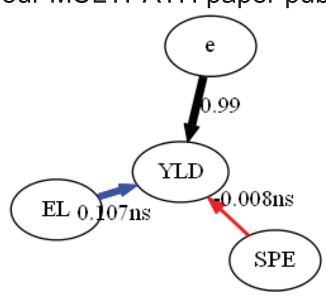

Fig. 2. Path analysis with dependent (YLD or grain yield) and 2 independent variables (EL or ear length and SPE or number of seeds per ear) in maize. One- and two-headed arrows for EL and SPE denote direct effects (coefficients) and simple Pearson correlation coefficients, respectively. U: residual. *(P<0.05); **(P<0.01).

Univariate parametric stability

The "*MINISTAB*" exec macro operates as follows: as mentioned, for stability analyses, our maize data set (grain yield) was used. The dataset tests consisted of 20 genotypes in 3 environments (drought stress) with 3 replications (Table 5).

Table 5. The effect of 20 genotypes in 3 environments at 3 blocks(replicates) on grain yield of maize

↓	C1-T	C2-T	C3	C4
	Gen	ENV	Block	YLD
1	BARAKAT-2	Control	1	10.13
2	BARAKAT-2	Control	2	7.44
3	BARAKAT-2	Control	3	5.52
4	BARAKAT-2	Drought-1	1	10.35

Before executing the *MINISTAB* macro, it is essential that data be first subjected to ANOVA, whose results are as follows. The ANOVA table as a 2 factorial experiment in randomized completely design via GLM schedule in MINITAB 14, is performed through Stat>General linear model> and the result is as follows:

Analysis of Variance for YLD, using Adjusted SS for Tests

Source DF Seq SS Adj SS Adj MS F P

Block 2 145.874 145.874 72.937 26.38 0.000 **
Gen 19 494.437 494.437 26.023 9.41 0.000 **
ENV 2 10.244 10.244 5.122 1.85 0.161 ns
Gen*ENV 38 180.862 180.862 4.760 1.72 0.014 *
Error 118 326.313 326.313 2.765
Total 179 1157.731

S = 1.66294 R-Sq = 71.81% R-Sq(adj) = 57.24%

According to the ANOVA results, there was a significant difference for blocks, genotypes and their effects. So the stability analyses like AMMI could be logically performed. To perform the stability macros, suppose the files and their subroutines are located in a local drive (here D:\). For executing the univariate stability "*MINISTAB*", follow these steps: *File > Other files > Run an exec > Select files > "D:\MINISTAB folder" > Ministab.* To choose the main macro file (*MINISTAB*) and execute it, the following table is used for the dataset as arranged in a matrix (G×E) form where rows denote the genotypes and columns denote the environments or locations (Table 6):

Table 6. Data of grain yield sorted as a two-way table (G×E) suitable for the stability analysis by MINISTAB macro:

	Env1	Env2	Env3	Genotypes means	Gen
1	7.7000	7.4200	8.2600	7.7933	BARAKAT-2
2	8.4400	8.4300	8.4900	8.4533	BARAKAT-74
3	5.3400	5.0500	5.2700	5.2200	BOLSON
...	...	...	...	...	...
20	11.4600	12.0100	11.8600	11.7767	ZP-606
21	8.8355	8.2710	8.6830	8.5965	
22	0.2390	-0.3255	0.0865		

The order of the data matrix must be, as shown above, i.e., the data must be arranged for example from the first column (e.g. C1) to the next columns (here e.g. C4), left to right. Of course, local macros do not have such limitations as in our *AMMI* macro. Of course, we adjusted the MINISTAB macro to construct the two-way table (Table 6) automatically from a design table (Table 5), which will be employed later. As genotype-by-environment interaction effect(GE) was significant (prerequisite of stability analysis), so the stability analysis was performed. For this, the *MINISTAB* executive macro produced the following output, in which some parameters are taken from ANOVA table, which must be inserted as requested by macro, including the number of environments and replications, error MS and confidence level ($1-\alpha$):
MTB > Execute "D:\MINISTAB_parametric stability\MINISTAB.MTB" 1.

Executing from file: D:\MINISTAB_parametric stability\MINISTAB.MTB

How many Environments(Locations)do you have? Please choose At must 3500).
DATA> 3

Enter EMS(Error Mean Square); R(Replications number); and Confidence level in C3501 as DATA>prompt, respectively.
DATA> 2.765 3 .95

Using the above outputs for the MINISTAB macro, stable varieties via univariate stability parameters were distinguished. For example, BARAKAT-74 was considered to be the most stable maize genotype on the basis of the Si^2 criterion of Roemer (1917), CVi index of Francis and Kannenberg and Pi of Lin and Binns stability indices, and also genotype GARZA was the most stable genotype based on the stability indices of Wi^2 of Wricke, Si^2 of Shukla, Plaisted and Peterson and F-test of Shukla test. Genotype DKC-6101 was the most stable genotype on the basis of stability tests of Plaisted, Di^2 of Perkins and Jinks, Di of Lin and Binns. Genotype BOLSON was the most stable according to the deviation of Eberhart and Russel. However, it is obvious that some genotypes as mentioned above could be selected as stable genotypes against various fluctuating environments (here drought stress). Another point of view which is important is that the selection approach could be not only on the basis of stability parameters but should be remembered on the basis of yield. In this subject, GARZA was a high yielding genotype, and BARAKAT-74 was a good-yielding too. Thus, one can select GARZA as a stable and high-yielding genotype. To achieve the most stable genotype, one may include a known genotype as the control in the experiment. This macro is useful for plant breeders and geneticists working on yield stability.

Multivariate parametric stability analysis of genotypes

According to the data set (Table 5), we organize such data, so that genotypes and environments (or locations) must be numerical but not characters (as Table 7).

Table 7. Four column data set organized for most common form of AMMI analysis.

↓	C1	C2	C3	C4
	GEN	ENV	Block	Response
1	1	1	1	10.13
2	1	1	2	7.44
3	1	1	3	5.52

To execute the macro, it is best to place the program file inside the Macros folder of MINITAB and then type in the front of the command line: %AMMI C1-C4. The program then runs and gives the following results.

```
****************************************************************************
*                   AMMI.MAC
*   Local macro performing Additive Main Effects and Multiplicative
*   Interaction (AMMI) analysis on an ANOVA data or an ExG table of means,
…….

Do you work with Locations instead of Environments(Y/S)?
n

Do you work with a two-way (ExG or LG) table (genotypes in columns) (Y/S)?
n
```

In this part of the program, MINITAB asks the user to specify whether it is dealing with columns of data or with a matrix or two-way table of genotypes and environments (locations)?. The key merit of our program over other stability analysis programs is that the user can enter both columns of data or a matrix or two-sided table of info.

Results showed that variation attributable to genotypes (G), and their interaction (G×E), each was significant. Thus, decomposition of the GE effect into IPCA scores via AMMI method should be examined. The AMMI analysis showed that 2 IPCA scores accounted for almost all the variation relative to G × E as 91.86 and 8.14%, respectively. So the AMMI2 model is the best model for this data set. For this, the biplot of first and second scores against genotype means and environment means, and each other was drawn, which represented the separation of 20 genotypes and 3 environments in 2D space or other complicated ones (Fig. 3).

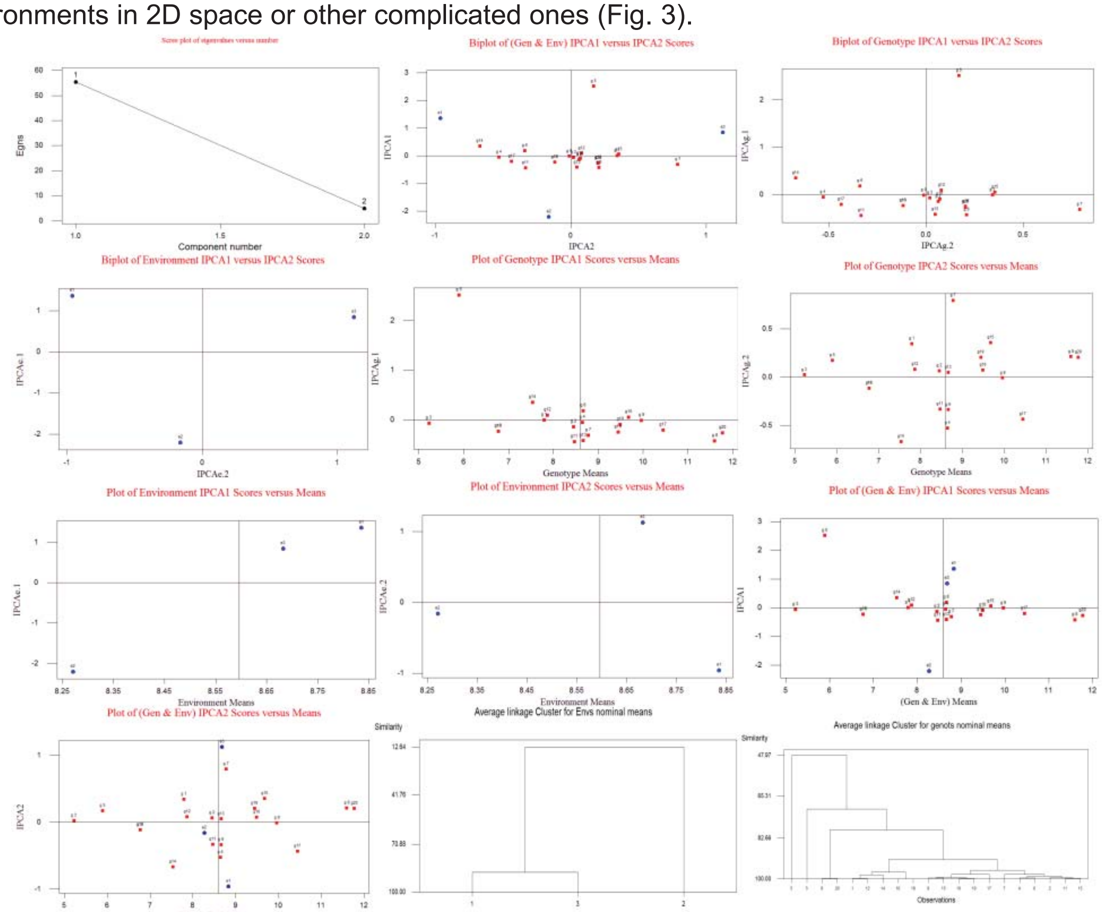

Fig. 3. Most of the graphs obtained by the AMMI macro in this experiment including two first components, biplots of IPCA scores, and IPCA scores against genotypes and environments mean.

As can be seen from the figure above, two of the IPCA scores were able to account for all (100%) of the variation in the GE interaction, based on which required biplots were plotted.

Accordingly, two IPCAs were drawn against each other and the distribution of genotypes and environments (under stress and control) was investigated. Accordingly, genotype 5 has the highest IPCA1 score, and genotypes such as 3, 9, 12, 13 and 16, which were located in the center of the biplot, possessed nearly zero interaction effect and had more general stability. Likewise, genotypes 7 and 14 had the highest and lowest IPCA2 scores, respectively. Genotypes 8 and 20 had the highest grain yield and showed good stability and can be considered as the most stable and high yielding corn genotypes in this research. Genotypes 3 and 5 had the least yield and were sensitive. The results of PCA and cluster analysis were consistent, so that the genotype 5 was located in a separate cluster (low grain yield and the highest IPCA1), and then the genotype 3 was located in another separate cluster (the lowest grain yield and IPCA was about zero, and then genotypes 8 and 20 were in the same group with highest grain yield and high IPCA1), and the remaining genotypes were in the same category, which had a moderate performance and stability. In the control conditions, the highest grain yield and then, respectively, in stress in the dough and milk stage, were the highest grain yield. When there is more than 2 IPCA scores or more than 2 environments, the AMMI macro produces IPCA1 vs IPCA2, IPCA1 vs IPCA3, IPCA2 vs IPCA3, Gen & Env means vs IPCA3 and IPCA4, a 3D surface plot, a contour plot of genotype IPCA1, IP CA2 & IPCA3 scores and moren (Fig. 4).

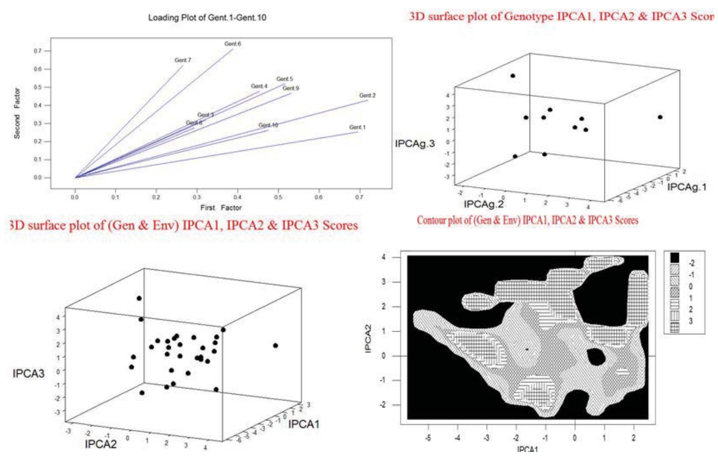

Fig. 4. Loading plot, 3-dimensional plot of first 3 IPCA scores of AMMI,

In this case, Oyekunle *et al.* (2017) studied the stability of 18 maize cultivars adapted to tropical environments using AMMI method, during 2 years, and have been able to evaluate the interaction of GE and introduce and select superior and stable cultivars in different regions, and also explore the relationship between regions. As in the present study, they showed that the main effect as well as the interaction effect of GE of grain yield were significant. In their research, Bipolt AMMI accounted for only 90.5% of the diversity of interactions and based on this, the distribution and separation of maize genotypes and environments were performed and the most stable and the high-yielding genotypes were identified. Likewise, Sserumaga *et al.* (2018) studied grain-yield stability of maize tropical hybrids under drought and optimum conditions in Africa and reported that locations, genotypes and their interaction were significant, and accordingly introduced superior drought stable and high-yielding cultivars. Such researches demonstrate the potential and value of AMMI strategy in surveying stability analysis in crops such as corn.

Another capability of our AMMI macro is regression fitting of genotypes via the Finlay-Wilkinson method versus environment means, whereby more stable genotypes in the experiment are identified. For example, the results of this approach for fitting Finlay-Wilkinson regression for genotype 1 versus environment means are as follows:

****** Pairwise correlation between gen & env means *****

***** Along with a Finlay_Wilkinson linear regression fit ****

Correlations: Gent.1, Emeans

Pearson correlation of Gent.1 and Emeans = 0.554
P-Value = 0.626

In the results below, the regression of each genotype with the environments mean is estimated as a stability schedule. For example for genotype 1, there was not a significant linear relationship, and a low *r-squared* and may other trends exist but was a high positive linear trend for genotypes 3 and 9.

Conclusions

We present in this paper some macros for conducting statistical analyses for different experimental designs using MINITAB, which is a user-friendly platform. The macros introduced here allow users to do many analyses that may not be possible with other platforms. We hope all researchers, especially agriculturists and biologists, would benefit from these programs. These macros are listed as follows: (1) a macro for analyzing the Latin square designs with subsampling: This applies when there is more than one sampling in a replication of a Latin square design and is rarely done due to the difficult analysis process. (2) a macro for analyzing the relative efficiency of an experimental design, which is suitable to compare different designs to increase the efficiency of the experiments. (3) a macro performing orthogonal contrasts that are used when contrasts or group comparisons are done following an ANOVA. Our macro does this task better than any other macro where it estimates the contrasts coefficients automatically. (4) macro for curve fitting when nonlinear trends are used other than linear trends when a cause and effect is tested. (5) a macro called MULTPATH to do path coefficient analysis, along with estimating and testing the significance of direct effects and also related standard errors. (6) some macros to analyze univariate or classic parametric stability analysis of genotypes. (7) a macro called AMMI to do multivariate parametric stability analysis (AMMI) which is a useful means to study the stability analysis in plant breeding programs. All the achievements in this paper on the stability analysis of the corn plant have led to the identification of the best and high-yielding relatively new corn genotypes that can be used in areas with problems such as drought stress. It should be noted that all of these results are easy to accomplish in Windows XP and 7 with MINITAB 13. The macros presented in this paper could be easily obtained by emailing the first author of this paper.

Acknowledgements

The first author expresses his deepest thanks to professor Manjit S. Kang, Department of Plant Pathology, Kansas State University, Manhattan, Kansas, USA for reviewing this manuscript and also to professor Hugh G. Gauch, Jr., Cornell University, Ithaca, the USA for his nice help and comments while preparing the AMMI macro.

ABSTRACT

This paper attempts to demonstrate the utility of machine learning in an inventory case with the aim of demonstrating empirically that machine learning can be an important tool to optimally tackle supply chain problems. More specifically, we examine the usefulness of advanced machine learning techniques, including neural networks, auto neural networks, and decision trees to forecasting backorders happening in a supply chain. Following, we compare these methods with a more traditional one, logistic regression and parse out the differences. We conclude that the use of machine learning techniques for forecasting backorders provide more precise forecasts than traditional forecasting techniques such as logistic regression. By implementing our auto neural model, businesses can more accurately predict the backorder status of a product, in turn, minimize cost by more efficient inventory control, and increase profits by higher customer satisfaction. Future research could be directed to investigating other supply chain phenomena such as transportation management, demand forecasting, inventory levels, cash-to-cash cycles, supplier quality and production planning using machine-learning techniques to increase the robustness and generalizability of this approach

KEYWORDS: backorder, machine learning, inventory management, forecasting

INTRODUCTION

Customer satisfaction has always been at the center of marketing and operations management to grow market share and gain competitive advantages (Anderson et al. 1994). Therefore, supply chain managers have focused their efforts in better managing product inventory and preventing stock outs to improve customer satisfaction and retention. However, stock outs still occur causing backorders. Backorder can be defined as “a customer order that cannot be fulfilled, and for which the customer is prepared to wait for some time ” (Business dictionary).

The level of products that go into backorders and the days they remain are significant indicators of the firm`s customer service and efficiency in managing its inventory management. If backorders are not dealt with properly, it will have a significant impact on the firms's revenue, market share, credibility and customers' trusts and may end up with a lost sale. Disappointing customers will indirectly drive the customer into the hands of a competitor.

On the other hand, the appropriate actions to avoid backorders would put extra pressure on different stages of the supply chain, which will increase the overall costs as well as the associated transportation costs (Carter and Rogers, 2008). Moreover, the globalization has created an environment where customers' demands and expectations are highly probabilistic, which made traditional supply chain management systems less effective (Simchi-Levi et al., 2008). This results in errors in demand forecasting and backorders. Accordingly, many companies started to utilize algorithms to predict the backorder status of products to avoid the tangible and intangible costs. Reliable inventory systems are also key to avoid and handle backorders. Optimizing supply chain means providing customer what they want and when they want. If that does not happen, this will leave a `bad taste` in the customer's mouth, which will hurt the company's revenue.

With the easiness of accessing low cost, high computing power machines, machine learning and big data has started to alter the analytical processes of business decision making. A highly studied topic in supply chain management is the issue of inventory management, which is a crucial activity for any business as they try to determine the decision of when, and how much to order, in a highly dynamic market. Many of the approaches so far viewed the issue primarily as an optimization problem. Identifying the supplies at risk of backorder before the event would be another way to address the problem allowing the firms to respond to the issue (Vijayan,2008).
In the literature, the main antecedents discussed of backorders are current inventory level of products, lead time, in transit quantity, forecasted sales, actual sales (demand), minimum recommended amount in stock and identified issue of products (e.g. damage due to packaging or deck problems) (Koh, 2004, Chandra&Grabis, 2008, Koh, Saad, & Jones, 2002). Through this analysis, we may be able to answer which variables play a bigger role in backorder status of a product. Accordingly, companies can predict the backorder status of a product and align their supply chains, which in turn, will minimize the inventory costs and improve customer satisfaction.

This paper attempts to demonstrate the utility of machine learning in an inventory case with the aim of providing insight on the predictive powers of various techniques and demonstrate empirically that machine learning can be an important tool to optimally tackle supply chain problems.

In this study, we examine the usefulness of advanced machine learning techniques, including neural networks, auto neural networks, and decision trees to forecasting backorders happening in a supply chain. Following, we compare these methods with a more traditional one, logistic regression and parse out the differences.

LITERATURE REVIEW

In a general sense, the demand during a stock out is either lost or completely backordered. Although, there might be customers who are willing to wait, the majority would place more emphasis on time utility resulting a lost sale case. There are several models in the literature combine backorders and lost sales. The first attempt to this issue was made by Montgomery et al. (1973). Quyang and Wu (1999) followed with a model that incorporated varying lead-time with a fixed reorder point. Hariga and Ben Daya (1999) combined backorders and lost sales in scenarios of partial and full demand information. Abad (2000) increased the complexity of the model by including exponential decay in a perishable good context.

All the aforementioned papers brought forward mathematical models to predict backorder or lost status and through that what should be the inventory level. Our paper purely approaches the issue from a machine learning perspective. The major contribution of the paper is assessment of different learning classifiers algorithms such as neural networks and decision trees, based on specific methods to deal with the class imbalanced problem in a real supply chain scenario.

THEORETICAL DEVELOPMENT/MODEL

Data Description

The original data includes 22 columns and 1.048.576 rows primarily interval and some binary data. Explanations of the variables are presented in the Table 1.

Variable Name	Explanation
Went_on_backorder_Yes	If the product went to backorder or not
Deck_Risk_yes	The products that might remain in the deck/shop/stock
Forecast 3 month	The demand estimated for 3 months
Forecast 6 month	The demand estimated for 6 months
Forecast 9 month	The demand estimated for 9 months
In_transit_quantity	The total number of products that are currently being shipped from one location to another
Lead_time	The time taken from release of an order to production and shipment
Local_bo_quantity	Amount of overdue stock orders
Min_bank	Minimum recommended amount in stock.
National_inv	Current inventory level of different products
Oe_constraint	Products that are facing operational limiting factors such as bottleneck

Sales_1_month	Actual sales for 1 month
Sales_3_month	Actual sales for 3 month
Sales_6_month	Actual sales for 6 month
Sales_9_month	Actual sales for 9 month
Potential_Issue_Yes	Potential damage
Pieces_past_due	Products overdue from source
Perf_6_month	Source average performance in last 6 months
Perf_12_month	Source average performance in last 12 months
Ppap_risk_yes	Risks associated with packaging and production
Rev_stop_yes	Revenue status for product
Stop_autobuy_yes	Whether automatic selling process has been stopped or not

Table 1: Variable Descriptions

Data Preparation

In the dataset, since our target variable (Went_on_backorder_Yes) has only 9235 out of 1.048.576 observations, which consists of less than %1 of the data, we used stratified hold-out method and randomly undersampled the frequent event (Went_on_backorder_No) to have a balanced sample. That is, we created a new sample with 18470 observations, of which our target variable consisted 50%.

We have used the impute data node in SAS Enterprise Miner to impute missing values which consisted of 5.98% of the sample. The method it has used was taking the mean of the columns and replacing them with a value. We used this technique not to distort the current distribution of data. Moreover, since the skewness and Kurtosis values were more than 2 and 7, respectively, which is a sign of violation of normality assumption, we transformed the data with log10 method to meet this assumption. The descriptive statistics of the data is presented in Table 2.

VALIDATE	EMWS1.Part_VALIDATE	7388

Table 3: Partition Summary

Data Mining Techniques

Since the target variable that we are interested is a binary variable (backorder status: Yes or No), we decided that it would be first appropriate to conduct a logistic regression analysis, in which we used stepwise approach to find the best model, with all the input variables. Afterwards, we used decision tree, neural network and autoneural methods. Moreover, we conducted a principal component analysis (PCA) and then repeated aforementioned methods to find the best model to predict our target variable. Finally, we compared the models to find the best one according to “misclassification” and “average square error (ASE)” assessment. We used SAS Enterprise Miner for all the models and model comparison. The diagram created for aforementioned models and data preparation is presented in the Figure 1 below.

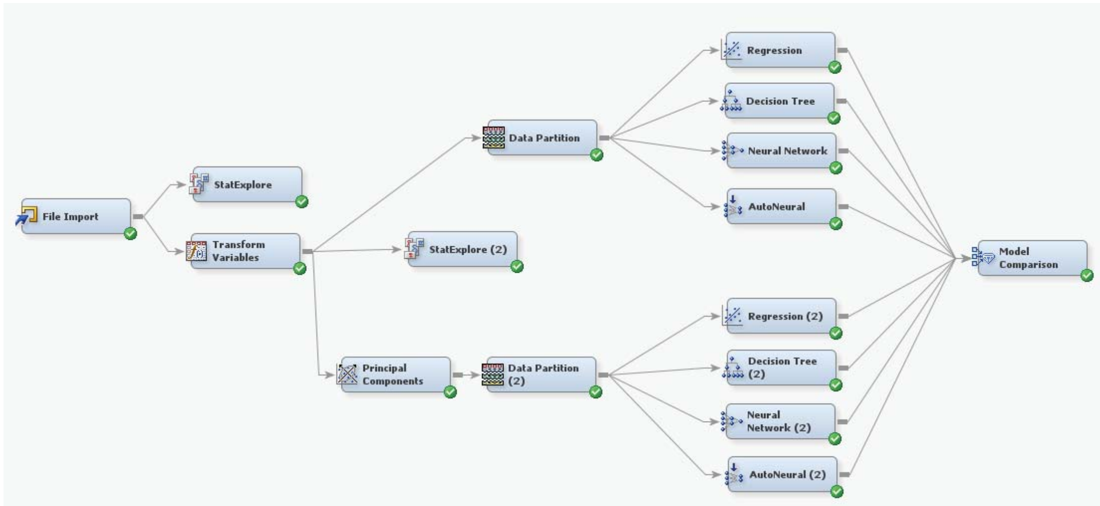

Figure 1: SAS Enterprise Miner Diagram.

Findings

a. Logistic Regression_1:

According to the logistic regression outputs provided in Table 4 below, we observed that the overall model including 21 predictor variables is statistically significant (p <.0001).

Likelihood Ratio Test for Global Null Hypothesis: BETA=0

-2 Log Likelihood		Likelihood		
Intercept Only	Intercept & Covariates	Ratio Chi-Square	DF	Pr > ChiSq
15362.914	9966.767	5396.1474	12	<.0001

Table 4: Overall Model Evaluation Results.

Of the 21 predictor variables 12 were significant: forecast_3 month, forecast_6 month, in_transit_qty, lead-time, local_bo_qty, min_bank, national_inv, pieces_past_due, sales_3_month, deck_risk_yes, ppap_risk_yes, and stop_auto_buy_yes. Furthermore, exp (b) values (odd ratios) of significant variables show that with the increase in those variables that are over 1.0 (forecast_3 month, forecast_6 month, local_bo_qty, pieces_past_due, sales_3_month, deck_risk_yes, stop_auto_buyYes), it would be more likely to face a backorder status (See the results in Table 5).

Table 5: Results of Logistic Regression_1 Analysis.

The classification table (See Table 6) provides the required information to calculate the model accuracy (proportion of correct predictions), sensitivity (proportion of positive cases correctly classified as positive) and specificity (proportion of negative cases correctly classified as negative) and precision (proportion of predicted positive cases that were correctly classified as positive). This model has 81.71% accuracy, 80.5% sensitivity, 82.91% specificity and 82.49% precision based on validation model.

Classification Table

Data Role=TRAIN Target Variable=went_on_backorderYes Target Label=went_on_backorderYes

c. Neural Network_1

Neural Networks (NN) are nonparametric models originated from the studies of the brain and nervous system. They are particularly useful in forecasting and modeling due to their data driven nature. NNs respond better to data that includes misspecification, linearity violation, outliers and re-estimation (Hill et al., 1996).

This model has an 85.77% accuracy, 87.46% sensitivity, 84.08% specificity and 84.60% precision based on validation model (See Table 9).

Classification Table

Data Role=TRAIN Target Variable=went_on_backorderYes Target Label=went_on_backorderYes

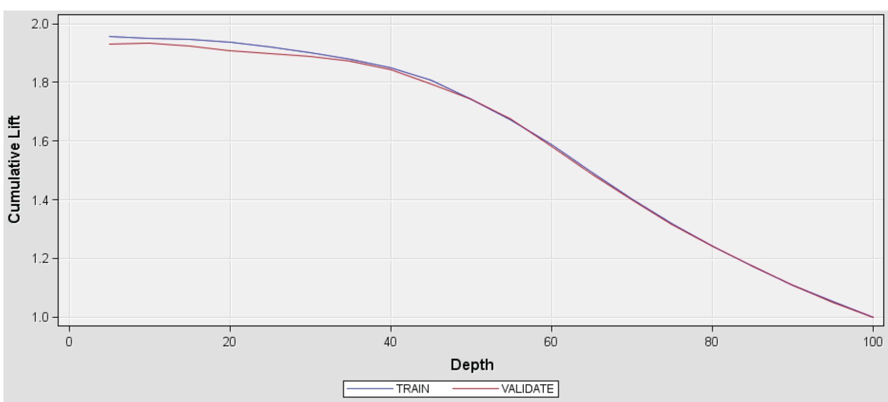

Figure 6: Cumulative Lift of the Autoneural_1 Model

e. Principal Component Analysis (PCA):

As we had a large number of input variables, we wanted to see whether a lower number of components explained a significant portion of the variance. Therefore, we have conducted PCA analysis in SAS miner, came up with 16 PCs, and used these components in our following models to improve the predictive power. We almost did not lose any variance by this reduction (99.2% variance explained). The only downside of this approach is that we do not specifically know the individual effect of each variables and composition of the components. (See the summary of the PCA in Table 11 and Figure 7).

```
Total number of input variables: 21
Maximum number cutoff of principal components: 20
Cumulative proportional eigenvalue cutoff: 0.99
Proportional eigenvalue increment cutoff: 0.001
Number of the selected principal components: 16
Total variation explained by the selected principal components: 0.992772248
```

Table 11: Summary of the PCA

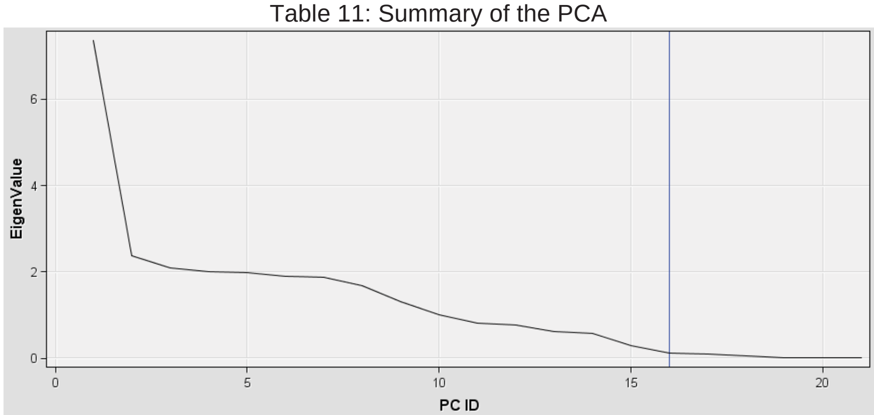

Figure 7: Suggested Number of Principal Components

f. Logistic Regression_2:

According to the logistic regression outputs provided in Table 12 below, we observed that the overall model including 16 PC s is statistically significant (p <.0001).

Likelihood Ratio Test for Global Null Hypothesis: BETA=0

-2 Log Likelihood Intercept Only	-2 Log Likelihood Intercept & Covariates	Likelihood Ratio Chi-Square	DF	Pr > ChiSq
15362.914	10058.610	5304.3041	12	<.0001

Table 20: Comparison of the Models Based on ASE of the Validation Models.

Autoneural_1 model provides the lowest misclassification rate (12%) and the lowest average squared error (9%). Autoneural_1 model also performs better than the other models in terms of accuracy, precision, specificity and sensitivity (See Table 21). In other words, the model that uses autoneural algorithm with all input variables provides the highest predictive power in this case.

Model	Accuracy (%)	Sensitivity (%)	Specificity (%)	Precision (%)
Logistic Regression_1	81.71	80.50	82.91	82.49
Decision Tree_1	85.92	87.73	84.10	84.66
Neural Network_1	85.77	87.46	84.08	84.60

Decision Tree_2	81.85	86.70	76.98	79.02
Neural Network_2	85.93	89.12	82.75	83.78
Autoneural 2	84.98	86.22	83.73	84.12

Table 19: Performance of the Models Based on Accuracy, Sensitivity, Specificity and Precision

MANAGERIAL IMPLICATIONS / CONCLUSIONS

Backorder is a serious supply chain problem, affecting an inventory system's level of service, efficiency and customer satisfaction. The ability to detect parts with the highest probability of shortage before it occurs can be leveraged as an opportunity rather than a risk, which can lead to a competitive advantage. In this project, we have investigated different algorithms in order to come up with a forecasting model for this imbalanced data problem, where the occurrence of a backorder is rare but important.

We have used logistic regression, decision trees, neural networks and auto neural data mining techniques to predict our target variable, backorder status. In the second phase, we investigated whether using principal component analysis, which resulted in 16 principal components, would improve the predictive power of our modeling. For comparison, we used the model misspecification rate and Average Squared Error (ASE) criteria. We also considered the accuracy, sensitivity, specificity and precision of the models. Although not dramatically different, the first auto neural model comes up with the best performance of .12 misclassification rate and .09 ASE among the other models. The model also has the highest accuracy rate (87.2%), sensitivity (88.49%), specificity (85.95%) and precision rates (86.29%)

Overall, we can conclude that the use of machine learning techniques for forecasting backorders provide more precise forecasts than traditional forecasting techniques such as logistic regression. By implementing our auto neural model, businesses can accurately predict the backorder status of a product, in turn, minimize cost by more efficient inventory control, and increase profits by higher customer satisfaction. The importance level of the variables in the model also calls for attention. Operations managers should pay greater attention to forecast levels for 3 months as well as maintaining a balanced national inventory level. Defining a minimum and maximum level of national inventory level is recommended.

Future research could be directed to investigating other supply chain phenomena such as transportation management, demand forecasting, inventory levels, cash-to-cash cycles, supplier quality and production planning using machine-learning techniques to increase the robustness and generalizability of this approach.

UNIX administrator ISP compliance: The impact of focused SETA workshops on heuristics, biases, and trust

John P. McConnell
Nova Southeastern University
Email: jm3967@mynsu.nova.edu

ABSTRACT

Information security policy compliance is crucial to the success of healthcare organizations. UNIX administrators maintain servers that house PHI/PII. The use of cognitive heuristics and biases may influence compliance behavior. This study evaluates the effect of SETA workshops on heuristics, biases, and trust using credentialed security scans on servers.

KEYWORDS: Knowledge Sharing, Privacy and Security, SETA, ISP Compliance, Heuristics, and Biases

INTRODUCTION

The healthcare industry is a complicated network of hospitals, providers, independent laboratories, payers, pharmacies, imaging centers, and public health departments centered on patients and their health (Dixon, 2016). The ability to safely and efficiently store, process, and exchange information about patient care between the healthcare industry participants is key to improving patient medical outcomes and lowering the cost of healthcare (Office of the National Coordinator for Health Information Technology, n.d.; Steinbrook, 2009; Thieme, 2016). In the United States, the implementation of information technology has been encouraged by the federal government. The United States Patient Protection and Affordable Care Act (ACA) of 2010 provided incentives to organizations to apply technology to the healthcare system. Additionally, the American Recovery and Reinvestment Act (ARRA) of 2009 allocated $145B for health care spending which included $30 billion to modernize the information technology infrastructure of health care organizations (Ajami & Bagheri-Tadi, 2013). Both laws contain provisions defining the privacy and security requirements necessary to protect patient personal health information (Steinbrook, 2009; Thieme, 2016). The goal of these laws was to encourage the use of technology to reduce healthcare costs by improving efficiency, reducing medical errors, reducing care duplication, and improving coordination of care among medical providers (Amarasingham, Plantinga, Diener-West, Gaskin & Powe, 2009; Office of the National Coordinator for Health Information Technology, n.d.). The move from paper-based health records to electronic health records that are shared among diverse organizations has resulted in a greater risk of data breaches and violations of patient's protected health information (PHI) and personally identifiable information (PII) (McFarland, 2012).

The foundation for the safeguarding of health information in the United States was established in two pieces of legislation: The Health Insurance Portability and Accountability Act (HIPAA) of 1996 and the Health Information Technology for Economic and Clinical Health Act (HITECH) of 2009. HIPAA provided the definition of PHI and set forth the minimum necessary standards for sharing any form of PHI as well as the regulations for the electronic interchange of PHI (Bernstein & Hartsell, 2013; Thieme, 2016). The HITECH Act expanded on HIPAA's definitions of security controls and further defined proper management of electronic health information, as well as providing financial incentives for electronic health record usage as well as meaningful use of health information technology (Bernstein & Hartsell, 2013; Hersh et al., 2016; Runyon, 2017).

The HIPAA Privacy Rule provided standards related to the disclosure and use of PHI, the rights of patients to access or correct their data, and patient's rights to request an audit of accesses and usage of their PHI (Avancha, Baxi, & Kotz, 2012; McFarland, 2012; Steinbrook, 2009). The goal of the Privacy Rule was to protect patient privacy rights while still allowing for the benefits of electronic health records (Avancha et al., 2012). The HIPAA Security Rule provided specifications and standards that covered entities should implement to ensure the confidentiality, integrity, and availability of PHI (Koch, 2017). Three categories of safeguards were defined to direct organizations in how best to protect PHI including physical safeguards, administrative safeguards, and technological safeguards (Avancha et al., 2012). Administrative safeguards include policies, procedures, and administrative actions related to security management, vulnerability and risk assessment, workforce security training, incident reporting, and contingency planning (Koch, 2017). Physical safeguards include facility access controls, computer controls, and device and media security controls (Avancha et al., 2012). Technical safeguards include access controls, audit controls, integrity management, authentication, and transmission controls for PHI (U.S. Department of Health and Human Services, 2013). Both the Privacy Rule and Security Rule outline civil and criminal penalties for the privacy violations (McFarland, 2012). The cost of data breaches can be significant for covered entities, but patients may also bear a significant cost when their PHI is stolen (Koch, 2017). In 2018, in the United States the average cost of a single data breach was $7.91 million which included the costs of detection, notification, response, and lost customer revenue (Ponemon Institute, 2018). In 2018, HIPAA penalties and settlements levied on nine healthcare systems and insurance companies totaled $28,683,400 (HIPAA Journal, 2019). Given the potential liabilities associated with data breaches and privacy violations it is imperative that healthcare organizations secure their computing resources by following the HIPAA and HITECH guidelines.

While many organization's servers are Windows based, a significant number of larger, back-end systems are UNIX based to capitalize on increased server processing power, reliability, security, and clustering technology (Bajgoric, 2006; Beuchelt, 2013; Hussain et al., 2015). In terms of hospital EMR systems, which house a significant amount of HIPAA protected patient data, Epic and Cerner represent 61% of the market for EMR implementations in inpatient hospitals in the United States (Newman, 2019; Shrivastava, 2018). The Epic EMR application, the industry leader for hospital EMR systems, only supports UNIX based operating systems including IBM UNIX (AIX), HP UNIX (HP-UX), and RedHat Linux (Epic, 2018; Newman, 2019). Larger Cerner EMR customers use high-end UNIX and Linux servers for the back-end databases while smaller hospitals use the Windows server based version of the Cerner EMR product (Shrivastava, 2018). As of May 2019, Linux/UNIX servers represent 69.8% of all active web servers worldwide (W3Techs, 2019). In the Amazon cloud, Linux/UNIX images represent 89.42% of the servers and Windows represents 10.54% of the servers out of a total of 963512 images (Cloud Market, 2019). When considering the total distinct known vulnerabilities from 1999 to 2019, the top six operating systems are Linux-based and Linux variants (CVE Details, 2019). The top six Linux variants have 12,635 known vulnerabilities and the top four Windows operating systems have 3,062 vulnerabilities (CVE Details, 2019). Clearly, there are significant vulnerabilities with Linux and UNIX systems that need to be addressed to protect the systems that house HIPAA protected data (Caballero, 2013; Santara, 2013).

PROBLEM

Most research in information security policy (ISP) compliance has focused on the end-user compliance intention and compliance behavior (Albrechtsen & Hovden, 2010; Dang-Pham, Pittayachawan, & Bruno, 2017; Hanus & Wu, 2016; Ifinedo, 2012; Kraemer & Carayon, 2007;

Safa, Von Solms, & Furnell, 2016). While end-users are critical to organizations reducing the threat of information security breaches, another group of specialized users has the highest privilege levels and legitimate access to the vast amount of confidential PHI and PII data stored on their systems—server systems administrators (Beuchelt, 2013; Kraemer & Carayon, 2007). Systems administrators are super users on servers and are responsible for operating system installation, configuration, patching, user management, monitoring, data backup, implementation of security controls, disaster recovery, and testing (Inshanally, 2018; Santara, 2013). Common information security threat vectors for servers include network, security, or operating system misconfiguration, unpatched operating systems or device firmware, privileged account access, and unsecured data or backups (Caballero, 2013; Donaldson, Siegel, Williams, & Asalm, 2015). From February 2017 to February 2019, server related incidents resulted in the loss of 6,651,957 individual's PHI records (U.S. Department of Health and Human Services Office for Civil Rights, 2019). Server related incidents were due to hacking and IT incidents (89%), unauthorized access and disclosure (11%), and theft (<1%) (U.S. Department of Health and Human Services Office for Civil Rights, 2019). Server breaches were responsible for 46% of all healthcare PHI breaches from February 2017 to February 2019 (U.S. Department of Health and Human Services Office for Civil Rights, 2019). These vulnerabilities and statistics demonstrate the importance for server administrators to consistently follow organizational ISP to ensure the confidentiality, integrity, and availability of healthcare systems, and the PII, and PHI contained therein.

Human factors have gained prominence as a significant risk factor for information systems security (Colwill, 2009; Ifinedo, 2014; Safa et al., 2015). To strengthen the human aspect of information security, information systems policies were developed that enhance security, decrease vulnerability to security breaches, and ensure legal compliance (Furnell & Clarke, 2012; Ng, Kankanhalli, & Xu, 2009). Unfortunately, researchers have found that employees frequently circumvented information systems policies when workload increased (Albrechtsen & Hovden, 2010; Guo, Yuan, Archer, & Connelly, 2011; Kraemer & Carayon, 2007) or when they felt the information systems policies were a nuisance (Renaud, 2012; Sedighi, van Splunter, Brazier, van Beers, & Lukosch, 2016). Siponen, Mahmood, and Pahnila (2014) identified employee failure to follow information systems policies as a key threat to the security of an organization. An additional risk is that employees can make errors due to cognitive limitations, task demands, organizational, social, or environmental factors (Dismukes, Berman, & Loukopoulos, 2007; Safa & Von Solms, 2016). Most of these studies have evaluated end-user ISP compliance. Compliance of UNIX systems administrators (UXA), however, is even more significant as the data housed on the back-end UNIX servers may contain PHI, PII, financial data, or intellectual property.

Information security knowledge is frequently scattered throughout organizations and many organizations have not developed an effective information security knowledge sharing program (Belsis, Kokolakis, & Kiountouzis, 2005; Flores, Antonsen, & Ekstedt, 2014; Safa & Von Solms, 2016). Additionally, organizational silos, where there is a rigid functional division between teams, can negatively impact social interaction and knowledge sharing (Oparaocha, 2016). Trust is key for knowledge sharing relationships (Dang-Pham, Pittayachawan, & Bruno, 2016; Safa & Von Solms, 2016). The most effective way of increasing security knowledge sharing and cyber skills is through effective security education, training, and awareness (SETA) programs (Oltsik, 2017). Wash and Cooper (2018) found SETA programs to be the most effective means of changing the security behaviors of end-users. Bauer and Bernroider (2017), in assessing the impact of information security awareness on end-user compliance behavior, found that security awareness significantly positively influenced attitude toward compliance and provided a weak negative relationship to neutralizing behaviors. These studies have focused on the effectiveness of SETA programs on ISP compliance of end-users. Although ISP compliance of server administrators is crucial to protecting the organization's data, to the author's knowledge, studying the effectiveness of targeted SETA workshops and their influence on UNIX server administrators has not been researched.

The research problem that this study will address is that some UNIX administrators may fail to completely implement organizational ISP believing the threat of privacy breaches to be primarily a problem for Windows servers. This failure may leave UNIX servers open to potential systems disruption, loss of proprietary or confidential data, harm to organizational reputation, potential loss of revenue, or financial loss due to litigation or fines (Donaldson et al., 2015; Kraemer & Carayon, 2007). It is crucial to investigate the cognitive processes (heuristics and biases) that UXA may employ which can result in inadequate information security threat appraisal, inflated coping appraisal, and could encourage ISP non-compliance. It is vital to understand of how specially designed SETA programs influence UXA use of heuristics and biases. This research is needed as implementing HIPAA mandated security and compliance with organization ISP are key to the successful protection of healthcare organizational assets, including patient PII, and PHI (Koch, 2017; Ng et al., 2009). Also, this research will help fill the gap on SETA program effectiveness with UNIX server administrators.

PURPOSE

The main goal of this research is to empirically assess how SETA workshops influence UNIX administrator's use of cognitive heuristics and biases and how those biases influence knowledge of security vulnerabilities and their severity, information security response-efficacy, information security self-efficacy, and ultimately compliance behavior with ISP and protection of PII and PHI. It is crucial that organizations comply with the U.S. federal government's guidelines in the HIPAA Privacy and Security rules to ensure the confidentiality, integrity, and availability of PHI and minimize the risk of breaches and potential fines (Avancha et al., 2012; U.S. Department of Health and Human Services, 2013). Additionally, this research will seek to understand how the focused SETA program affects UNIX administrator trust and ISP compliance behavior. Finally, by integrating Protection Motivation Theory (PMT) components, this research will assess the impact of server administrator focused SETA programs on UNIX administrator's threat appraisal (perceived threat severity, perceived threat vulnerability), coping appraisal (response efficacy and self-efficacy), and ultimately ISP compliance behavior.

RESEARCH QUESTIONS

RQ1: How do formal knowledge sharing arrangements and support for knowledge transfer, in the form of SETA workshops, influence UXA security threat appraisal and coping appraisal?
RQ2: How does UXA trust in the Information Security team influence ISP compliance?
RQ3: How does information security knowledge sharing, in the form of SETA workshops, impact UXA use of cognitive heuristics and biases?
RQ4: How does the use of cognitive heuristics and biases impact UXA threat and coping appraisals?

HYPOTHESES

H1: Formal knowledge sharing arrangements, in the form of a focused SETA workshop and ISCs, significantly negatively influences UXA use of the availability heuristic.
H2: Formal knowledge sharing arrangements, in the form of a focused SETA workshop and ISCs, significantly negatively influences UXA use of optimism bias.
H3: Formal knowledge sharing arrangements, in the form of a focused SETA workshop and ISCs, significantly negatively influences UXA use of confirmation bias.

H4: Formal knowledge sharing arrangements, in the form of a focused SETA workshop and ISCs, significantly positively influences UXA trust.
H5: Trust in the Information Security Team by UXA significantly positively influences UXA ISP compliance behavior.
H6: The availability heuristic significantly negatively influences UXA information security threat appraisals.
H7a: Optimism bias significantly negatively influences UXA information security threat appraisal.
H7b: Optimism bias significantly positively influences UXA information security coping appraisal.
H8a: Confirmation bias significantly negatively influences UXA information security threat appraisal.
H8b: Confirmation bias significantly positively influences UXA information security coping appraisal.
H9: UXA security threat appraisal significantly positively influences UXA ISP compliance behavior.
H10: UXA security coping appraisal significantly positively influences UXA ISP compliance behavior.

LITERATURE REVIEW

Security education, training & awareness

The sharing of information security knowledge, experience, and insights can improve organizational performance and help to ensure the security of data (Safa & Von Solms, 2016). Development of a formal means for information security knowledge sharing can help to foster sharing of ideas, experiences, tools, and processes to improve security and protect an organization's information systems assets (Flores et al., 2014). Making users aware of the current and evolving information security risks, threats, vulnerabilities, and their severities, the speed with which the threats propagate, and the potential impact to the organization is crucial to information security policy compliance (Guo et al., 2011; Safa et al., 2016; Siponen et al., 2014). Dang-Pham et al. (2017) found that security awareness also improved the diffusion of information security practices (knowledge sharing) throughout the organization. Safa and Van Solms (2016) found that information security knowledge sharing benefitted business, increased employee information security self-efficacy, and improved ISP compliance.

The development of an information security knowledge sharing culture is an important goal for any organization that has critical information systems assets (Flores et al., 2014; Razmerita, Kirchner, & Nielsen, 2016; Safa & Van Solms, 2016). End-user education is important and developing knowledge sharing processes that include the information security team and UXA is crucial to any organization that has UNIX servers hosting business critical data (Bauer, Bernroider, & Chudzikowski, 2017). It is beneficial to build both formal and informal knowledge sharing networks within organizations as they have been found to be significant contributors to awareness and mitigation of information security risks (Dang-Pham et al., 2017; Safa & Von Solms, 2016; Yoo, Sanders, & Cerveny, 2018). Encouraging relationships between employees across team boundaries is also helpful to developing and enabling an effective social network that fosters knowledge sharing (Bauer et al., 2017; Ifinedo, 2014; Oparaocha, 2016). Connelly and Zweig (2015) found that distrust was a predictor of knowledge hiding behaviors which are detrimental to effective knowledge sharing in organizations. Consequently, it is important to encourage trusting relationships between the information security team and the UXA for an effective information security knowledge sharing culture (Dey & Mukhopadhyay, 2018; Rutten, Blaas-Franken, & Martin, 2016). Sedighi et al. (2016) found that social interaction was a key component of knowledge sharing. Therefore, creating regular interactions between the information security team and UXA is crucial to development of reciprocal, trusting relationships that enable knowledge sharing and improved security awareness and ISP compliance behavior.

SETA programs are a means for organizations to minimize the risk of insider caused security failures (Burns, Roberts, Posey, Bennett, & Courtney, 2015). SETA programs are an important antecedent and positively influence information security behavior, and appropriately designed SETA programs can help reduce the human information security risk to organizational assets (Whitman & Mattord, 2012). Users are the weakest link for information security and SETA programs can help to reduce the potential attack surface of organizations by improving the ability of users to identify and prevent information security breaches (Furnell & Clarke, 2012; Gardner & Thomas, 2014). Posey, Roberts and Lowry (2015) found that SETA programs were positively correlated with both perceived threat severity and response efficacy indicating that they are an effective way of encouraging information security behavior and ISP compliance. SETA programs should be regular and recurring due to the dynamic nature of information security threats and vulnerabilities (Posey et al., 2015). In a study of SETA effectiveness, Yoo et al. (2018) found that the psychological flow factors including feedback, immersion, challenge, autonomy, and social interaction significantly improved psychological ownership and SETA program effectiveness. Yoo et al. (2018) suggested using relatable security scenarios that challenged employees could improve ownership and ISP compliance.

Bauer et al. (2017), in a study of ISP compliance at banks, found that developing a comprehensive, multi-modal information security awareness program was key to successfully establishing an information security culture in an organization. The goal of their research was to define specific propositions that could be used by information security management in banks to establish and maintain an effective information security awareness (ISA) program (Bauer et al., 2017). Also, Bauer et al. (2017) sought to develop an understanding of how users' perceptions of the ISA program influence their ISP compliance. The three banks studied had implemented ISA programs but with very different processes and procedures (Bauer et al., 2017). The most successful bank, in terms of information security awareness and employee engagement, conducted regular ISA campaigns using different modalities which encouraged high levels of interaction and dissemination of critical security knowledge (Bauer, et al., 2017). The regular contact included daily emails, intranet postings, weekly themes, and quizzes as well as role modeling both positive and negative behaviors (Bauer, et al., 2017). Another bank required employees to sign IS agreements and performed periodic monitoring of employees IS behavior (Bauer et al., 2017). This was viewed by some employees as a lack of trust from the organization toward the employees. Bauer et al. (2017) found that individuals used different neutralizing behaviors to justify ISP non-compliance. The third bank Bauer et al. (2017) studied had just begun an ISA program and provided little insight into SETA effectiveness. Two primary areas of design for ISA were proposed by Bauer et al. (2017): structural design and communicational design. Structural recommendations included media rich interventions that appeal to multiple learning styles; implementation of regular review and revision so that ISA programs evolve with the dynamic IS threat landscape; and customizing the ISA programs toward the recipients (Bauer, et al., 2017). The communicational recommendations Bauer et al. (2017) identified included: limited use of security vernacular; matching the security awareness messages to the recipient's personality; driving for two-way discussions including IS reflection and ISP enforcement; effectively using positive and negative role models and using role play; and constantly seeking feedback about ISA program effectiveness so that the programs remain relevant and provide an effective means of sharing IS knowledge with employees.

Albrechtsen and Hovden (2010) developed and tested information security workshops where security personnel acted as facilitators for end-users to discuss relevant security scenarios. This small group atmosphere lead to collaborative, two-way dialogs and fostered participation and collective reflection to gain insights from one another (Albrechtsen & Hovden, 2010). Safa et al. (2016) integrated social bond theory and involvement theory and found that knowledge sharing, collaboration, intervention, experience, commitment, and personal norms were all correlated to attitude toward compliance with ISP. Sedighi, et al. (2016) found reputation, reciprocity, altruism, and knowledge self-efficacy were all positively related to quantity and quality of knowledge sharing while effort and time were negatively related to both.

Organizations spend a great deal of money on SETA programs in the hopes of increasing employee ISP compliance and engagement but employees continue to cause significant security breaches due to their failure to comply with ISP (Yoo et al., 2018). Managers need to understand what psychological antecedents may improve the effectiveness of SETA programs and increase employee compliance (Yoo et al., 2018). Yoo et al. (2018) sought to identify the factors that influence psychological flow and how they impact SETA effectiveness and ultimately ISP compliance behavior. The constructs tested by Yoo et al. (2018) included: challenge, feedback, autonomy, immersion, social interaction, flow, psychological ownership, SETA effectiveness, self-efficacy, and security compliance intention. The components of flow (feedback, immersion, challenge, autonomy, and social interaction) all significantly influenced psychological ownership and SETA effectiveness (Yoo et al., 2018). An important detail found by Yoo et al. (2018) was that training must be at an appropriate level to challenge but not overwhelm the participant to support engagement. Psychological ownership and SETA effectiveness significantly influenced security behavioral intention (Yoo et al., 2018). Yoo et al. (2018) suggested using relatable scenarios to help in connecting employees to the SETA content. Yoo et al. (2018) brought the concept of flow into the knowledge management realm in terms of the impact that flow has on SETA.

Dang-Pham et al. (2017) noted that employee information security failures can lead to security breaches causing substantial financial loss for organizations. SETA programs are effective in reducing the cost of breaches but cannot eliminate the problem of employees not following ISP due to negligence or malicious intent (Dang-Pham et al., 2017). Developing a security knowledge sharing culture may help employees gain the information security knowledge, develop an informal knowledge sharing network, and further reduce breaches caused by human error (Dang-Pham et al., 2017). Dang-Pham et al. (2017) investigated the factors that help to develop an information security knowledge sharing culture through the lens of Social Network Analysis, the Theory of Planned Behavior, and Accountability Theory to identify how employees use formal and informal networks to gain and share security knowledge. Encouraging regular interactions between employees is important as some information security knowledge sharing occurs during those informal dialogs (Dang-Pham et al., 2017). Also, developing trusting relationships with individuals increased formal and informal sharing between employees (Dang-Pham et al., 2017). Educating users regarding the benefits of ISP compliance, rather than just how to comply with the policy, was more effective in supporting self-efficacy and inter-employee sharing (Dang-Pham et al., 2017).

Ifinedo (2014) integrated the Theory of Planned Behavior, Social Behavioral Theory, and Social Cognitive Theory to provide additional insights into why employees comply or fail to comply with ISP. Ifinedo (2014) used nine constructs that were developed from prior research including: attachment, involvement, commitment, personal norms, attitude toward compliance, subject norms, locus of control, self-efficacy, and behavioral intention. Socialization, personal norms, social norms, self-efficacy, and group dynamics positively influenced ISP compliance intention (Ifinedo, 2014). These results suggest that managers should encourage formal and informal socialization of employees to increase trust and establish relationships that influence positive behaviors and discourage negative or malicious behaviors (Ifinedo, 2014). Perceived control also had a positive impact on ISP compliance intention (Ifinedo, 2014). Developing a better understanding of the organizational and social factors that influence ISP compliance allows organizations to prepare for and encourage appropriate behavior to safeguard security.

By adequately managing the information security knowledge and social norms of the organization managers can better control the antecedents of positive behavior while applying social pressure to curtail negative behavior.

Chen, Chen and Wu (2018) developed a model of ISP compliance based on an Awareness-Motivation-Capacity perspective. The significant influencers of ISP compliance intention included information security awareness (awareness of the ISP and potential threats), capability to comply (self-efficacy and controllability), and motivation to comply (penalty and reward) (Chen et al., 2018). Educating employees about the importance of information security can be achieved through SETA programs (Chen et al., 2018; Dang-Pham et al., 2017). The same programs can also inform employees about the organizational ISP and introduce them to the potential security threats facing the organization (Chen et al., 2018). Engaging and audience appropriate SETA programs will also influence information security self-efficacy and ISP compliance (Chen et al., 2018; Ifinedo, 2014).

Trust

Trust is a complex concept and frequently tailored in research to the specific discipline being studied (McKnight, Cummings, & Chervany, 1998). From the perspective of a consumer using an information technology artefact, trust can help overcome risk and insecurity (McKnight, Choudhury, and Kacmar, 2000). In a seminal study on trust, McAllister (1995) identified two types of trust: affect-based trust, and cognitive-based trust. Antecedents to affect-based trust included citizenship behavior, and interaction frequency (McAllister, 1995). Antecedents to cognitive-based trust include reliable role performance, cultural-ethnic similarity, and professional credentials (McAllister, 1995). McAllister's (1995) research studied trust and its influence on interpersonal cooperation in organizations which is relevant for the current research. From McAllister (1995), reliable role performance can relate directly to the reliability of the information security team's knowledge sharing with the UXA. Trusting the information security team's recommendations on security best practices may cause concerns about information accuracy, privacy, as well as perceived reliability of the information security team's understanding of how to secure the UNIX servers (Gefen, Karahanna, & Straub, 2003).

Gefen et al. (2003) integrated a trust model into the Technology Acceptance Model (TAM) framework. While their research was related to trust in an online vendor, their work can be integrated into the current research model given that the information security team, in facilitating the SETA program, act as a resource to the UXAs, and the team's reputation and experience can influence the UXA's trust in the relevance of the training. By extended TAM, Gefen et al. (2003) found that information integrity and institutional trust played a significant role in the attitudes and intention to use. Antecedents to trust that Gefen et al. (2003) found significant included: calculative-based, institution-based structural assurances, institution-based situational normality, and perceived ease of use (from TAM). These antecedents include features relevant to the current research. Calculative-based trust includes the cognitive processes that the UXA use to evaluate the information security team's trustworthiness. Gefen et al. (2003) identified antecedents to institution-based structural assurance to include structural safeguards, legal guarantees, and regulations that influence trust. Institution-based situational normality is the social context of the information technology artifact (Gefen et al., 2003). With respect to the current research, the ISP forms the basis for institution-based structural assurance, noted by Gefen et al. (2003), and provides the guidelines, processes, and rules surrounding information system security.

Lowry, Posey, Bennett, and Roberts (2015) developed a model based on Reactance Theory and Fairness Theory that included constructs of organizational trust, SETA programs, information security policy compliance, reactive ISP non-compliance (reactive computer abuse), and explanatory adequacy. There was a significant negative relationship between organizational trust and reactive computer abuse (ISP non-compliance behavior) (Lowry et al., 2015). This implies that trust in the organization can reduce ISP non-compliance behavior. Additionally, the SETA program developed by Lowry et al. (2015) had a significant positive influence on explanatory adequacy which in turn was a significant contributor to positive trust formation. Trust was also a significant mediator between explanatory adequacy and reactive computer abuse (Lowry et al., 2015). Finally, Lowry et al. (2015) found that the SETA programs reduced employees' perceptions of lost freedom and external control experienced when enhanced security policies were implemented.

Development of interpersonal relationships and social networks are significant contributors to knowledge sharing within an organization (Oparaocha, 2016). SETA programs and communities of practice can help in both formal and informal sharing of knowledge, the development of collaborative relationships, and the building of trust (Dang-Pham et al., 2017; Oparaocha, 2016). Supportive social networks can also improve relationships and encourage fostering of both cognitive-based and affective-based trust (Dey & Mukhopadhyay, 2018; Rutten et al., 2016). Trust is key for knowledge sharing relationships and the development of those relationships through an effective SETA program can be beneficial to the organization and encourage information security engagement and compliance (Dang-Pham et al., 2016; Safa & Von Solms, 2016).

Research conducted by Dey and Mukhopadhyay (2018) sought to understand how affective organizational commitment, behavioral intention, and affective trust influence knowledge sharing behavior. Knowledge sharing is key to organizational competitiveness, but it is reliant on individuals' willingness to share explicit and implicit knowledge (Dey & Mukhopadhyay, 2018). It is important to understand the factors that motivate knowledge sharing behaviors to increase organizational effectiveness (Dey & Mukhopadhyay, 2018). The constructs selected for their model included: affective trust, knowledge sharing intention, affective organizational commitment, and knowledge sharing behavior (Dey & Mukhopadhyay, 2018). Affective commitment mediated the relationship between knowledge sharing intention and knowledge sharing behavior and made the relationship significant (Dey & Mukhopadhyay, 2018). These results suggest that it is important to increase employee affective commitment to the organization in order to increase knowledge sharing behavior. Trust is also an important mediator of the relationship between knowledge sharing intention and knowledge sharing behavior (Dey & Mukhopadhyay, 2018). Trust between employees and trust between the employee and the organization are key to willingness and effective knowledge sharing (Dey & Mukhopadhyay, 2018). Given the importance of trust and organization commitment it is important to build social bonds between employees at all levels of the organization. A collaborative SETA program can help to foster social bonds and trust and increase organizational commitment of UXA.

Trust is a key component of knowledge sharing but very little is known specifically about the impact of low levels of trust on explicit and implicit knowledge sharing (Rutten et al., 2016). The knowledge sharing constructs studied by Rutten et al. (2016) were divided into explicit knowledge sharing and implicit knowledge sharing types. Explicit knowledge sharing types included: instructions, templates, and emails (Rutten et al., 2016). Implicit knowledge sharing types included: directly contacting a person, informal news, and tips & tricks (Rutten et al., 2016). Rutten et al. (2016) found that affective-based trust had significantly more influence on knowledge sharing for both implicit and explicit types of knowledge sharing. In terms of implicit knowledge sharing, affective-based trust was significantly more influential. These results demonstrate the need for socialization and the building of trust relationships in organizations for knowledge sharing to be effective (Rutten et al., 2016). The success of knowledge sharing, and knowledge management relies on the willingness of the individuals in the organization to share information, knowledge, skills, tips, and wisdom (Rutten et al., 2016). By better understanding how cognitive and affective-based trust influence knowledge sharing the community can develop a fuller understanding of how to facilitate better communication, collaboration, and knowledge sharing.

Van Vuuren (2016) proposed a new IT Security Trust (ITST) model to help understand how trust influenced security compliance for information systems. This model linked trust, knowledge sharing, and ISP compliance to better understand how to develop an information security culture (Van Vuuren, 2016). Van Vuuren (2016) used the term Information Security DNA to define the organizational culture inclusive of information security. Their model included organizational security trust, relationship trust, self-trust, social and home trust along with components that are knowledge sharing related-SETA, knowledge, training and education, understanding and acceptance (Van Vuuren, 2016). Additionally, Van Vuuren (2016) integrated two constructs related to PMT into their model including perceived security implications and risk perception. Each form of trust, self-trust, relationship trust, organizational security trust, and information security DNA based trust influenced security awareness and security knowledge sharing (Van Vuuren, 2016). The goal, like Flores et al. (2014), was to develop an information security based organizational culture formation model that included the influence of trust (Van Vuuren, 2016). Believing that trust is the cornerstone to organizational effectiveness, knowledge sharing, information security, and relationships Van Vuuren (2016) augmented the ITST model to integrate the key behavioral trust components.

Heuristics & biases

Kahneman (2011) referred to the two cognitive systems of decision making as System One and System Two. System One is the intuitive, implicit, involuntary, and nonverbal cognitive system (Kahneman, 2003). According to Kahneman (2003), intuitive judgements may harken to evolutionary history and occur “between the automatic operations of perception and the deliberate operations of reasoning” (p. 697). The intuitions provided by System One come to mind quickly with little reflection—they are automatic once a stimulus occurs (West, Meserve, & Stanovich, 2012). For example, a loud noise or gunshot draws immediate attention as System One quickly assesses the situation and determines if fight or flight is necessary. Also, when walking down the street, someone that is approaching is assessed by System One to evaluate the situation and quickly determine if the individual should be avoided. These analyses are pre-cognitive, and frequently termed intuitions (Tversky & Kahneman, 1974). Intuitions, which rely on similarity and accessibility rather than true logic or probabilities, can be flawed due to the use of cognitive heuristics (Kahneman, 2011; Tversky & Kahneman, 1974). Heuristics are mental short-cuts used to make inferences about situations, and they require a minimal amount of information and cognitive processing power (Gilovich & Griffin, 2013; Marsh, Todd, & Gigerenzer, 2004; Roberts, 2004). As opposed to algorithmic means of solving a problem, heuristics, by their nature, do not guarantee a correct answer (Gilovich & Griffin, 2013; Roberts, 2004). Heuristics provide a means of finding an adequate solution to a problem without having to consider all possible causally relevant information (Marsh et al., 2004). They also help to reduce constrained working memory (Kahneman, 2011; Toplak, West, & Stanovich, 2011). Examples of heuristics that influence decision making include: anchoring, availability, illusion of pattern, subjective confidence, the law of small numbers, prediction by representativeness, and the illusion of understanding (Kahneman, 2011).

System Two, the reasoning and analytical system, is where deliberate thought occurs (Kahneman, 2011). System Two is activated whenever a problem presents itself to which System One cannot provide a fast and reasonable answer (Kahneman, 2011). Unfortunately, System One frequently will answer a difficult or challenging question with an associated question (heuristic) that is easier to draw from memory (Kahneman, 2003). Attribute substitution can allow System One to answer a question that was not asked resulting in faulty decision making (Gilovich & Griffin, 2013). One of System Two’s responsibilities is to monitor System

One to ensure correct decisions are made (Kahneman, 2003). To reduce cognitive load, however, System Two may accept faulty System One responses due to what Kahneman (2011) terms lazy monitoring. If System Two is activated and engaged it may reject potentially biased System One intuitions but that activation is cognitively taxing (Kahneman, 2003). Kahneman (2003) found that individuals made aware of their use of heuristics were able to correct the intuitive judgement.

Epstein (2014), in the field of cognitive psychology, defined the two cognitive systems as the experiential system and the rational system. The experiential system functions outside individual's awareness and influences interpretation of feelings, behaviors, and events (Epstein, 2014). The experiential system is non-verbal, and activation requires minimal cognitive demand (Epstein, 2014). A key feature of the experiential system relevant to the current research is that it has the potential to learn from experience (Epstein, 2014). The rational system reflects an individual's personal understanding of logic and is uniquely human (Epstein, 2014). It represents conscious reasoning, verbal thought, tends to be affect free, considers cause & effect, is slower processing, and requires higher cognitive load (Epstein, 2014).

To judge the frequency or probability of an event an individual may assess the availability of associations related to the event (Tversky & Kahneman, 1974). Rather than taking the time to find an actual probability it is easier to estimate a probability based on the ease that one recalls occurrences of a similar event - termed the availability heuristic (Kahneman, 2011; Kliger & Kudryavtsev, 2010; Tversky & Kahneman, 1974). Pachur, Hertwig, and Steinmann (2012), in assessing how the availability heuristic influenced individual's judgement of risks, found that the availability heuristic significantly influenced general perceived risk. Since the question of frequency is difficult to answer without more information an easier question is substituted—how easily can examples of the event be recalled (Kahneman, 2011). If examples come to mind easily the frequency is estimated to be high and if examples are difficult to imagine the frequency is assumed to be low (Tversky & Kahneman, 1974). System One does not have the means to properly apply probability theory and the reliance on availability as an assessment of actual probability can lead individuals to faulty evaluations of risk (Kahneman, 2011). This is relevant to the current research as perceived threat can influence ISP compliance behavior.

Toplak et al. (2011) analyzed the use of the Cognitive Reflection Test (CRT) to assess cognitive performance. They found that the CRT predicted an individual's propensity toward cognitive errors (Toplak et al., 2011). Toplak et al. (2011) studied intelligence and working memory and found both were moderately predictive of rational thinking skills and cognitive performance. The conclusion was that the quick acceptance of the System One data was primarily due to cognitive load and the miserly cognitive processing of System Two (Toplak et al., 2011). These findings are in line with Kahneman's (2011) lazy monitoring performed by System Two. Toplak et al. (2011) warned that while the intuitive processing of System One may be useful it can also be dangerous due to the propensity to over simplify problems and underestimate risk.

Ferreira, Garcia-Marques, Sherman, and Sherman (2006) investigated heuristic problem-solving skills to understand what actions might encourage System Two engagement. Using modified versions of Tversky and Kahneman's (1974) heuristic problem set, Ferreira et al. (2006) found that providing priming instructions to participants helped them to resist System One intuitions and engage System Two reasoning. Kliger and Kudryavtsev (2010) defined priming as an unconscious process that occurs when a current stimulus increases the availability (recall) of past associations. Increased use of System Two resulted in significantly improved performance on the heuristic problems (Ferreira et al., 2006). Interestingly, Ferreira et al. (2006) concluded that automatic (System One) and controlled (System Two) processing are independent but can also be used in parallel. Education and practice can improve the reliability of System One's intuitions (Kahneman, 2003). An example of learned intuition can be found in chess masters who can quickly evaluate a chess board, analyze possible outcomes, and make moves seemingly instantaneously (Kahneman, 2003). This identifies the potential to improve the intuitive responses of UXA through effective and engaging SETA programs.

Optimistic bias is another bias that can result in dangerous neglect of risks (Rhee, Ryu, & Kim, 2012). Optimistic bias leads one to assess situations in self-serving ways (Rhee et al., 2012). This fundamental underestimate of risk can enhance perceived invulnerability to negative events and lead to inappropriately low levels of safeguarding behaviors related to information security (Rhee et al., 2012). Optimistic bias is a protective measure to protect the self, and reduce both anxiety and stress (Rhee et al., 2012). Rhee et al. (2012) found, in a study of information security perceptions of technology executives, that they perceived the security risks but that optimistic bias allowed them to conclude that their organization were at a much lower risk of security breach than other organizations. Rhee et al. (2012) suggested information security training is key to reducing optimistic bias and improving security practices within organizations. Optimistic bias can also cause individuals to discount future consequences, for example, one may believe they are not at risk of intrusion and therefore not protect personal privacy (Acquisti, 2004). Interestingly, this behavior was noted in both naïve and sophisticated individuals (Acquisti, 2004).

Confirmation bias and optimism bias are closely related and can significantly influence decision making (Kahneman, 2011). With confirmation bias, one gives greater validity to information that supports rather than contradicts one's beliefs (Sternberg, 2004). Tsohou, Karyda, & Kokolakis (2015) suggested that confirmation bias may lead individuals to believe that hackers are not sophisticated or dangerous and discount the threat caused by nation states, organized crime, or terrorists. Kahneman (2011) identifies confirmation bias as a System One heuristic and it is therefore easily activated when making decisions. System Two must be engaged to contradict a System One confirmation bias but in most situations, individuals do not devote the cognitive energy to disprove their beliefs (Kahneman, 2011). The exaggeration of events caused by the news can reinforce confirmation bias and result in faulty assumption of risks—discounting risks with higher probabilities over risks that are more easily available (Kahneman, 2011).

Kahneman's work has had significant influence on the finance industry in researching investment decisions, but using his concepts in the information security area, to the author's knowledge, has been limited. Building on Kahneman's (2011) heuristics and biases work in assessing risk, this study will also assess how cognitive bias may influence UXA decisions regarding their security threat and coping appraisals. Heuristics and biases associated with the dual-process theory are applicable to the information security realm given they may influence administrators' decisions. System One's automatic and intuitive assessments can be prone to error (Kahneman, 2011). The associative System One tends to best-guess answers to questions with available data even when that data is not completely relevant to the posed question (Pennycook et al., 2013; West et al., 2012). Kahneman (2011) referred to this as the shotgun effect. Another potential area of concern is the way that System One deals with ambiguities and competitive hypotheses eliminating options before cognitive awareness (Kahneman, 2003). When System Two is not actively monitoring System One, to assess the validity of the decisions, errors may occur (Kahneman, 2011; Toplak et al., 2011). Security risks and threat vectors in information security continue to evolve (Caballero, 2013). It is crucial to have competent and engaged administrators that acknowledge the threats and mitigate the risks (Caballero, 2013). Based on the prior research noted above, simple acceptance of System One responses may cause administrators to be oblivious of the threats and vulnerabilities they face. By better understanding what heuristics impact how decisions are made, what biases may result, and learning how to encourage System Two processing, organizations may be better prepared to manage their administrators and security risks (Kahneman, 2011; Pennycook et al., 2013; West et al., 2012).

An example of the potential use of the availability heuristic may be UXA incorrectly assessing a lower security risk to their servers because they more easily recall data breaches, security alerts, or reported fixes associated with Windows servers from the news. Without a correct assessment of potential risks, the UXA may not perceive the true threat severity or threat vulnerabilities to their servers. This bias can potentially result in insufficiently secured servers, leaving them at higher risk of breach. This failure may leave UNIX servers open to potential systems disruption, loss of proprietary or confidential data, harm to organizational reputation, potential loss of revenue, or financial loss due to litigation or fines (Donaldson et al., 2015). This research is needed as implementing HIPAA mandated security and compliance with organization ISP are key to the successful protection of healthcare organizational assets, including patient PII, and PHI (Koch, 2017; Ng et al., 2009).

Protection motivation theory

Several key theories have been used to assess and predict information security behaviors. Ng et al., (2009) integrated the Theory of Planned Behavior, Healthcare Behavioral Theory, and Expectancy-Value Theory to create their framework. Siponen, Pahnila, & Mahmood (2010) integrated Protection Motivation Theory (PMT), Deterrence Theory, Theory of Reasoned Action, Diffusion of Innovation Theory, and rewards theory to predict compliance behavior. Siponen et al., (2014) integrated the Theory of Planned Behavior, Theory of Reasoned Action, Cognitive Evaluation Theory, and PMT to understand users' intention to comply with policy. Ifinedo (2012) combined PMT and Theory of Planned Behavior to assess employee compliance with ISP.

Protection Motivation Theory is frequently used to understand compliance with ISPs and security procedures (Hanus & Wu, 2016; Safa, et al., 2015; Siponen, et al., 2014). PMT was initially proposed by Rogers (1975) to help understand how health behaviors were influenced by fear appeals. Rogers (1975) theorized that relevant sources of information that influenced behavioral change include environmental data (verbal persuasion and observational learning) and intrapersonal data (personality and prior experience). These sources are evaluated through a cognitive mediation process that assesses the threat and coping potential which leads to adaptive or maladaptive coping behaviors (Rogers & Prentice-Dunn, 1997). Threat appraisal includes the positive factors of extrinsic and intrinsic rewards offset by negative factors of the perceived severity and perceived vulnerability to potential threats (Posey et al., 2015; Rogers & Prentice-Dunn, 1997). The coping appraisal is an assessment of how the individual can cope with, adapt to, and change behavior to avoid the danger (Rogers & Prentice-Dunn, 1997). The factors related to coping appraisal include an individual's self-efficacy and response efficacy (Posey et al., 2015). Response efficacy is an evaluation of the effectiveness of the proposed behavior to reduce the probability of the negative event (Rogers & Prentice-Dunn, 1997). Self-efficacy is the belief that one is capable of the adaptation necessary to mitigate the negative event (Rogers & Prentice-Dunn, 1997). Fear influences the evaluation of severity and vulnerability and indirectly influences behavioral intention (Rogers & Prentice-Dunn, 1997). Siponen et al. (2014) found perceived severity of threat and perceived vulnerability to be positively correlated with ISP compliance. Appropriate threat appraisal can be manifest through increased knowledge and awareness of information security risks, vulnerabilities, and organizational policies and procedures (Albrechtsen & Hovden, 2010; Guo, et al., 2011; Safa & Von Solms, 2016; Siponen, et al., 2014). Coping appraisal can be also be positively influenced by information security knowledge sharing and awareness (Safa, et al., 2015; Siponen et al., 2010). Rogers and Prentice-Dunn (1997) noted that there are numerous cognitive heuristics and biases that can influence both appraisal processes in the PMT model. Cognitive heuristics can lead to cognitive biases and influence daily decision-making without our awareness (Kahneman, 2011). As such, it is important to understand how heuristics and biases may influence the threat appraisal of UXA. If threats are perceived as “Windows problems” the precognitive choice to resist ISP implementation on UNIX servers may put the organization at considerable risk.

In a study of home computer users, Hanus and Wu (2016) evaluated how awareness, a potential antecedent of desktop security behavior, influenced user’s security actions. Hanus and Wu (2016) extended PMT by defining the multi-dimensional construct of awareness (threat awareness and countermeasure awareness) to understand how awareness may influence desktop security behaviors. The goal of this study was to determine if threat awareness and countermeasure awareness, as antecedents of PMT, influence desktop security behavior (Hanus & Wu, 2016). Hanus and Wu (2016) demonstrated that research into the antecedents of PMT can provide a clearer picture into security behavior. Hanus and Wu (2016) identified both threat awareness and countermeasure awareness as key points for training to improve desktop security behavior. Hanus and Wu (2016) proposed that there may be a hidden variable that influences the relationship between threat awareness and perceived vulnerability that has not been discovered through existing research. Hanus and Wu (2016) demonstrate how PMT can be extended by including awareness. Awareness can be facilitated through effective training and knowledge management within an organization (Bauer et al., 2017; Dang-Pham et al., 2017).

Bélanger, Collignon, Enget, & Negangard (2017) in a study of early adopter password compliance, found that perceived threat severity and perceived threat vulnerability were positively related to attitude toward ISP change. Organizational triggers and ISP awareness had a positive correlation with attitude and intention to comply (Bélanger et al., 2017). Interestingly, Bélanger et al. (2017) found that subjective norm and self-efficacy did not significantly influence intention to conform to ISP for early adopters. While the research model was primarily based on the Theory of Planned Behavior their inclusion of perceived threat severity and perceived threat vulnerability from PMT helped to inform their model and, as their results indicated, were crucial to understanding the antecedents to attitude and intention (Bélanger et al., 2017).

Posey et al. (2015), investigated the impact of SETA programs on PMT. Specifically, Posey et al (2015), evaluated constructs frequently unused when applying PMT to information security contexts, including response costs, intrinsic and extrinsic maladaptive behaviors, and fear. The goal of the research by Posey et al. (2015) was to fully test PMT in an information security context adding SETA as an antecedent and organizational commitment as a moderating variable to better understand information security behavior. SETA was positively correlated with both perceived threat severity and perceived response efficacy indicating that SETA programs are an effective way of encouraging information security behavior (Posey et al., 2015). Appropriately designed SETA programs can help reduce the human information security risk to organizational assets (Van Vuuren, 2016; Whitman & Mattord, 2012). Posey et al. (2015) noted that SETA programs should be regular and recurring due to the dynamic landscape of information security.

Safa et al. (2015) conducted research to identify the factors that influence user’s information security conscious behavior by integrating the Theory of Planned Behavior (TPB), PMT, and adding potential antecedent factors of information security awareness, organizational policy, experience, and involvement. Security conscious behavior by users can help to mitigate information security risk (Safa et al., 2015). The study found that by increasing a user’s awareness of risks and vulnerabilities, improvements in attitude and information security conscious behavior can be achieved (Safa et al., 2015). Additionally, engaging users in the process of securing their systems, and educating them regarding potential threats improves threat appraisal and self-efficacy and positively influences information security conscious behavior (Safa et al., 2015). Knowledge sharing and collaboration are key components of this model in terms of information security awareness, organizational policy (and communication), involvement, engagement, and behavior (Safa et al., 2015). By combining TPB and PMT with additional antecedents Safa et al. (2015) helped to provide a better understanding of the need to consider behavioral and knowledge management aspects of information security.

One of the challenges in ISP compliance studies that use PMT noted by Boss, Galletta, Lowry, Moody, and Polak (2015) is the focus on intention rather than actual behavior. Boss et al. (2015) found few studies had been conducted that evaluated actual security behavior (Boss et al., 2015). Boss et al. (2015) conducted four field experiments to evaluate PMT. In one experiment, focused on the use of data backups, Boss et al. (2015) manipulated the fear-appeal construct and found in high-fear-appeal scenarios the significant influencers of intention and actual behavior were perceived threat severity, perceived threat vulnerability, fear, response efficacy, self-efficacy, and response costs. In the low-fear-appeal scenarios only perceived threat vulnerability and response costs influenced behavioral intention and actual compliance (Boss et al., 2015). In the high-fear-appeal manipulation, behavioral intention correlated with behavior at 0.710 while in the low-fear appeal manipulation the correlation was only 0.407 indicating that the high-fear-appeal was significantly more effective in encouraging actual behavior. For future research Boss et al. (2015) recommended manipulating the fear-appeal levels, using the full framework of PMT, as well as evaluating actual behavior not just behavioral intention.

Information security policy compliance

Although organizations spend considerable money on information security technology, users are still a major source of failures that result in information security breaches costing organizations substantial financial loss (Safa et al., 2016). ISPs elucidate the required security processes employees must follow to ensure the confidentiality, integrity, and availability of organizational information technology resources (D’Arcy & Lowry, 2019; Van Vuuren, 2016). ISPs include formalized procedures, guidelines, and technical controls that employees must follow to meet organizational security requirements (Cram, Proudfoot, & D'Arcy, 2017; Lowry & Moody, 2015). The human aspects of information security must be understood to reduce the risk of information security breaches (Van Vuuren, 2016). Users’ ignorance, apathy, resistance, and mischievous nature can result in human error and cause information security breaches (Bélanger et al., 2017; Safa et al., 2016). Compliance with ISP can help to mitigate information security risk (Ifinedo, 2014). Unfortunately, employee’s noncompliance with ISP is “the key threat” for organizational information security (Siponen et al., 2014, p. 217). Given the critical nature of organizational data and the significance of human behavior in protecting data, developing an understanding of what factors encourage and discourage ISP compliance will help to protect organizations (Bélanger et al., 2017; Carlton & Levy, 2015; Van Vuuren, 2016).

Siponen et al. (2014) combined PMT, the Theory of Reasoned Action (TRA), and Cognitive Evaluation Theory (CET) to develop an integrated theory that better explains end user ISP compliance. The following constructs were included: perceived severity, perceived vulnerability, response efficacy, and self-efficacy (from PMT); normative beliefs, intention to comply, and behavioral compliance (from TRA); and rewards (from CET) (Siponen et al., 2014). The model proposed by Siponen et al. (2014) accounted for 51% of the variance explained for intention to comply with ISP. Attitude (0.420) and normative beliefs (0.327) were the highest correlations with intention to comply with ISP (Siponen et al., 2014). This implies that organizational and relational factors do have a substantial impact on ISP compliance. The other factors, which were all significant, indicate that it is important to make sure employees are aware of security vulnerabilities and risks and trained on how to comply with ISP (Siponen et al., 2014). Knowledge management, in the form of knowledge sharing, training, and collaboration, all improved intention and behavioral compliance with ISP (Siponen et al., 2014). By making users aware of the vulnerabilities, risks, and potential impacts of information security breaches through effective SETA organizations can help to reduce noncompliance with ISP and improve information security.

Safa et al. (2016) sought to identify the factors that influence ISP attitude toward compliance through the lens of Social Bond Theory and Involvement Theory. Specifically, how does information security knowledge sharing, information security intervention, and collaboration influence attitude toward compliance (Safa et al., 2016). The factors Safa et al. (2016) identified through a literature review included: information security knowledge sharing, information security collaboration, information security intervention, information security experience, attachment, commitment, personal norms, attitude towards ISP compliance, and ISP compliance behavioral intentions. Information security knowledge sharing, collaboration, intervention, commitment, and personal norms all significantly influenced attitude toward compliance with ISP (Safa et al., 2016). While attachment was not a significant influencer of attitude toward compliance with ISP, attitude toward compliance with ISP was a significant predictor of ISP compliance behavioral intention (Safa et al., 2016). Information security knowledge sharing is key to improving user awareness and results in improved attitude towards ISP compliance and behavioral intention (Safa et al., 2016). Additionally, as socialization between the information security team and users was found to contribute to compliance behavior, organization managers should encourage information security knowledge sharing and development of robust intervention programs (Safa et al., 2016).

Nurse et al. (2014), in a study to understand insider threat, developed a framework for characterizing insider attacks that included a catalyst event, actor characteristics, attack characteristics, and organizational characteristics. To help identify the propensity to attack they combined elements of precipitating event, with the individual actor characteristics of psychological state, personality characteristics, historical behavior, attitude towards work, motivation to attack, skill set, and opportunity (Nurse et al., 2014). Also included in their model were observed physical and cyber security behaviors, enterprise role, type of actor, and state of relationship (Nurse et al., 2014). Attack characteristics included the type of attack, the object, the steps, and the step goals (Nurse et al., 2014). Lastly, the organizational characteristics included in the model developed by Nurse et al. (2014) included the type of asset and the perceived vulnerability. Nurse et al. (2014) applied the framework to three real-world cases of information security insider attacks. The framework Nurse et al. (2014) developed demonstrates the complexity of understanding ISP non-compliance by insiders. Nurse et al. (2014) showed the variety and significance of actor characteristics and how those characteristics interact with organizational characteristics to result in an information security attack.

In a detailed literature review regarding organizational ISP, Cram et al. (2017) developed a research framework to understand best practices for ISP development. The framework included five influencing relationships: (1) influences on design and implementation of ISP; (2) influence on employees and organization; (3) influence of employees and organization on ISP compliance; (4) influence of ISP compliance on organization's objectives; (5) and ISP maintenance (Cram et al., 2017). Key factors and commonly used theories were identified for each influential relationship and included: Systems theory, Grounded theory, Critical Social theory, Actor-network theory, Social Cognitive theory, Deterrence theory, Protection Motivation Theory, Theory of Planned Behavior, Rational Choice Theory, Control theory, and the Theory of Organizational learning (Cram et al., 2017). Several key findings of Cram et al. (2017) are relevant to the current research. First, Cram et al. (2017) identified the factors important for ISP design and maintenance. Second, Cram et al. (2017) demonstrated the importance of security awareness, clear consequences for non-compliance, as well as the influences of personality traits and culture on interpreting and complying with ISP. Finally, their research identified key areas of research that are needed for compliance to result in organizational security objectives (Cram et al., 2017).

It can be challenging to evaluate actual ISP compliance given the risk of social desirability bias that can occur in interviews and self-reported surveys (Redmiles, Acar, Fahl, & Mazurek, 2017). The use of scenarios and hypotheticals can help to remove the focus on the participant and may provide better insight into non-conforming behavior (Crossler et al., 2013). Rather than doing point-in-time studies, Crossler et al. (2013) suggested the use of longitudinal studies and field experiments can provide a much more valid picture of information security behaviors (Crossler et al., 2013). When evaluating intention to perform security behaviors, researchers are challenged to determine if participants have responded with over or under-reported counts as compared to actual behaviors (Egleman & Peer, 2015). As intention to comply with ISP can be a more socially desirable response, care must be taken to mitigate the risk of social desirability bias when designing research studies (Redmiles et al., 2017). Given these risks, it is preferred to study actual information security behavior rather than relying on self-reported intention to comply to truly understand the behaviors and develop valid and reliable behavioral models (Crossler et al., 2013).

THEORETICAL DEVELOPMENT/MODEL

Based on the literature review, there are several notable gaps that need further investigation. First, research on ISP compliance has focused primarily on end-user compliance intention (Albrechtsen & Hovden, 2010; Dang-Pham et al., 2017; Hanus & Wu, 2016; Ifinedo, 2012; Safa et al., 2016). It is crucial, however, to understand the determinants of server administrator ISP compliance behavior to better ensure the confidentiality, integrity, and availability of PII and PHI data contained on their servers.

Second, this study will focus on formal knowledge sharing arrangements from the security knowledge sharing framework developed by Flores et al. (2014). Specifically, this research will investigate how SETA workshops, designed specifically for server administrators, affect information security knowledge sharing and ISP compliance behavior. Concentrating on this specific user group for education is unique and will help to evaluate the effectiveness of workshops that use server administrator focused scenarios.

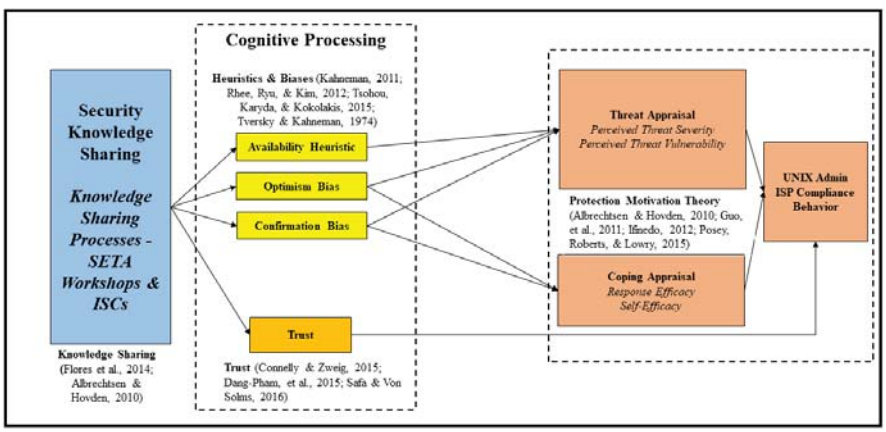
Third, trust is a crucial precursor to information security awareness, knowledge sharing, risk perception, and can be effective in reducing non-compliance (Lowry et al., 2015; Moqbel & Bartelt, 2015; Van Vuuren, 2016). It is therefore important to understand how the trust the UXA have in the information security team influences the effectiveness of the SETA programs and ISP compliance behavior. Ideally, the SETA workshops will improve the relationships between the UXA and information security team resulting in increased ongoing communication, improved awareness of threats, and ultimately enhanced compliance behavior.

Fourth, cognitive heuristics can lead to biased decision making and biased evaluation of information security threats and risks (Pachur et al., 2012; Rhee et al., 2012; Toplak et al., 2011; Tsohou et al., 2015). The inappropriate use of heuristics can prevent UXA from honestly assessing the true risks that may impact their servers potentially reducing ISP compliance behavior. SETA programs can be an effective means of reducing bias and improving security behaviors (Rhee et al., 2012). While Rogers and Prentice-Dunn (1997) mention that cognitive biases may influence both assessment processes in PMT, they did not introduce the construct in their model, and did not tie it to PMT threat appraisal. Through the SETA program, awareness should increase, encouraging a more appropriate understanding of the vulnerabilities that exist for their servers. It is crucial to minimize the use of cognitive heuristics in order to minimize biased decisions and improve appropriate threat assessment and response appraisal. The development of server administrator-oriented SETA workshops may improve awareness, reduce UXA use of cognitive heuristics, and improve threat assessment, coping appraisal, and ISP compliance behavior.

Fifth, PMT has been established as an effective model for evaluating ISP compliance intention and behavior (Boss et al., 2015; Johnston, Warkentin, & Siponen., 2015). Threat appraisal and coping appraisal have been found to be positively influenced by SETA programs (Posey et al., 2015). They have also been established as precursors of compliance intention and behavior (Boss et al., 2015; Siponen et al., 2014). While Posey et al. (2015) are the only researchers identified that have integrated SETA and PMT, their focus was limited to end-user behavioral intention. Also, Posey et al. (2015) did not include the influences of trust and heuristics and biases or SETA effectiveness.

Finally, while behavioral intention is frequently taken as an indicator of behavior, it was noted by Crossler et al. (2013), that actual behavior may not follow reported intention due to social desirability biased self-reporting. Boss et al. (2015) also found that intention differed significantly from actual implementation of security controls. This study will investigate actual UXA ISP compliance behavior by running and analyzing credentialed security scans on servers. Using credentialed security scans of security measures implemented by UXA following the SETA workshops will afford unique insights into the effectiveness of the training in terms of actual implementation of security controls and ISP compliance behavior.

The proposed research model, based on the literature review, can be found in Figure 1. It integrates the security knowledge sharing portion of the Information Security Organizational Knowledge Sharing Framework (Flores et al., 2014), cognitive heuristics and biases (Kahneman, 2011; Tversky & Kahneman, 1974; Tsohou et al., 2015), trust (Connelly & Zweig, 2015; Dang-Pham et al., 2016; Safa & Von Solms, 2016), and Protection Motivation Theory (PMT) (Albrechtsen & Hovden, 2010; Guo et al., 2011; Ifinedo, 2012; Posey et al., 2015).



Information Security Policy Cognitive Processing Model

Research Design

This quantitative research will be conducted in a pretest and posttest experimental and control group design. In this method, both the control group and the experimental group complete pretest and posttest surveys (Sekaran & Bougie, 2013). The experimental group will participate in three new SETA workshops. The independent variable for this model is security knowledge sharing from the Information Security Knowledge Sharing Framework developed by Flores et al. (2014). Security knowledge sharing is operationalized through SETA workshops designed specifically for the server systems administrators. Trust is integrated into the model as it has been demonstrated to influence the effectiveness of security education (Van Vuuren, 2016). The trust of the UXA in the information security team may influence ISP compliance. Security education has been found to positively influence threat and coping appraisal from PMT (Safa et al., 2015; Woon, Tan, & Low, 2005). The use of the availability heuristic, however, can negatively influence correct assessment of risk (Hertwig, Pachur & Kurzenhäuser, 2005; Pachur et al., 2012). The affect heuristic, optimism bias, and confirmation bias can influence both threat and coping appraisal (Tsohou et al., 2015). The inappropriate use of cognitive heuristics may result in biases which influence UXA security threat and coping appraisals and reduce overall ISP compliance (Kahneman, 2011; Pachur et al., 2012). Education has been demonstrated to influence the use of heuristics and biases and improve estimation of risk (Kahneman, 2003). The SETA workshops may reduce the use of inappropriate heuristics, afford a more appropriate estimate of threat to UNIX servers, and improve ISP compliance. PMT has been used extensively to describe the influence of threat and coping appraisal on security intention and behavior (Hanus & Wu, 2016; Safa, et al., 2015). Posey et al. (2015) demonstrated that SETA programs influenced the constructs of PMT (threat assessment and coping appraisal).

Variables

Security Knowledge Sharing - SETA Workshops

Security workshops will be designed that are appropriate to the job functions of UNIX and Windows server administrators (Beuchelt, 2013; Inshanally, 2018; US Department of Health and Human Services, 2013). The organizational Information Security and Risk Management Plan (ISRMP) will be used to prioritize the top eight behavioral information security risks facing the organization that are relevant to server administration. This document prioritizes risk as very high, high, moderate, and low and prioritizes risks based on the criticality consistent with the NIST Cyber Security Framework (NIST, 2018). By identifying and prioritizing the risks, specific behaviors can be targeted that are evaluated as having the greatest benefit to the organization and mitigate the greatest amount of risk. The specific behaviors will be matched to governmental recommendations to ensure compliance with legal requirements (Avancha et al., 2012; Koch, 2016; US Department of Health and Human Services, 2013). Workshop format will be constructed based on prior research as well as the SANS standards for developing an integrated security training, awareness, and education program (Wilson & Hash, 2003).

The SETA program will be developed and conducted as a series of small-group security workshops that include information security team members, UXA, and Windows administrators within the CIT group of the organization (Albrechtsen & Hovden, 2010). The goal of the workshops will be to encourage connection, collaboration, discussion, and information security knowledge sharing between the participants. After a scenario is reviewed during the workshop participants and discussion has completed the information security team members may suggest additional ideas, tools, or processes that had not been considered. Additionally, online learning tools will be utilized between workshops to reinforce skills learned during the workshops.

Trust

Trust is a measure of the confidence that the UXA have in the competence, reliability, dependability, and responsibility of the information security team (McAllister, 1995). Without an adequate level of trust the recommendations and warnings from the security team may be dismissed resulting in ISP non-compliance (Dang-Pham et al., 2016; Safa & Von Solms, 2016). Trust will be assessed through use of survey questions based on prior research.

Cognitive Heuristics

The cognitive heuristics evaluated in the present research include the availability heuristic, optimism bias, and confirmation bias. The use of these heuristics can influence UXA estimation of risk and vulnerability associated with their UNIX servers (Kahneman, 2011; Pachur et al., 2012; Tversky & Kahneman, 1974). Additionally, optimism bias and confirmation bias may influence UXA coping appraisal. Questions and scenarios to assess the use of the heuristics and biases will be developed based on prior research.

Threat Appraisal

Threat appraisal is an evaluation of the UXA perceived severity and perceived vulnerability to information security threats (Posey et al., 2015; Rogers & Prentice-Dunn, 1997). Perceived vulnerability and perceived severity may be influenced by cognitive heuristics which may be influenced by an increased knowledge and awareness of information security risks and vulnerabilities (Albrechtsen & Hovden, 2010; Guo, et al., 2011; Safa & Von Solms, 2016; Siponen, et al., 2014). Perceived severity and perceived vulnerability will be assessed via survey.

Coping Appraisal

Coping appraisal is an assessment of how the UXA perceives that they can cope with, adapt to, or mitigate the information security risk (Rogers & Prentice-Dunn, 1997). Coping appraisal considers the UXA's information security self-efficacy and information security response efficacy (Posey et al., 2015). Response efficacy is an assessment of how effective the proposed behavior can reduce the probability of the negative event (Rogers & Prentice-Dunn, 1997). Self-efficacy is the belief that one can make the changes needed to mitigate the risk (Rogers & Prentice-Dunn, 1997). Self-efficacy and response efficacy will be assessed via survey.

ISP Compliance Behavior

UXA ISP compliance behavior will be assessed quantitatively. A random sample of UNIX servers managed by experimental group participants will be evaluated using Tenable Nessus vulnerability management tool. The total number of critical, high, medium, and low vulnerabilities will be assessed prior to and three months following the SETA workshops. Tenable scans of servers provide a detailed report of discovered vulnerabilities related to the server operating system, networking, and applications and includes a synopsis, description, solution, risk factor, Common Vulnerability Scoring System (CVSS) base score, CVSS temporal score, references, and output for each vulnerability (Tenable, 2017). Additionally, the CVSS total score, will be used to evaluate the implementation of specific security countermeasures presented during the SETA workshops. CVSS is a common security metric used to evaluate information security (Hayden, 2010). Using credentialed security scans of security measures implemented by UXA following the SETA workshops will afford unique insights into the effectiveness of the training in terms of actual implementation of security controls and ISP compliance behavior. This research is needed as implementing mandated security and compliance with organization ISP are key to the successful protection of healthcare organizational assets, including patient PHI and PII (Koch, 2017; Ng et al., 2009).

Control variables

Age, gender, experience, and education will be used as control variables in the present research.

Population and Sampling

The population for this research is made up of the UXA in a major university and hospital system in the mid-Atlantic United States. The CIT organization manages 600+ UNIX physical and logical servers located in three data centers in two states as well as the District of Columbia. The administrators are responsible for the servers running enterprise wide applications including the electronic medical record system, pathology labs, radiology, web services, information security servers, student information systems, precision medicine systems, document management system, change control systems, as well as numerous departmental systems that house PHI and PII. Presently there are eight UXA in CIT and 51 other UXA in other teams in the organization.

Sampling Method

A listing of all active UXA will be obtained from the information security manager within the CIT organization. Administrators will be assigned to two groups using convenience sampling (for group 2) and random sampling (for group 1). Group one will be the control group and will consist of eight UXA outside of the CIT organization that will complete the existing organizational online information security compliance education module. The existing training is a ten-minute general information security online learning module required for all organization members. Group two, the experimental group, will participate in three newly designed SETA workshops developed specifically for UXA.

Subjects

The CIT UXA team is made up of individuals with a wide variety of technical experience and educational background. The team consists largely of senior administrators with 75% of UXA having 10 or more years of experience. In terms of educational attainment, 50% of the UXA have completed a college degree. With regard to gender the CIT UNIX team is 100% male. This is not unusual given the gender imbalance noted in IT (Gorbacheva, Beekhuyzen, vom Brock, & Becker, 2019). Additionally, this reflects the gender representation in the population of UXA in the institution.

Data collection techniques

Two types of data will be collected. First, a survey instrument will be used that integrates previously validated questions from prior empirical research. The survey will be developed and administered using Qualtrics. The survey instrument will assess the following constructs: trust, self-efficacy, response-efficacy, perceived vulnerability, perceived severity, information security knowledge sharing, as well as the availability heuristic, optimism bias, and confirmation bias. The second set of data points will be the analysis of security controls implemented on a sampling of servers prior to and three-months following the security workshops and online virtual modules. While a great deal of security research has focused on behavioral intention it was noted in the literature review that this is not always a true assessment of information security behavior (Crossler et al., 2013). To mitigate this possible response bias, credentialed Tenable Nessus scans will be run on a sample of UNIX servers prior to and three-months following the workshops to quantitatively determine if the administrator implemented security changes. The number of critical, high, medium, and low vulnerabilities and the total Common

Vulnerability Scoring System (CVSS) score will be used to assess compliance changes made in the three-months following the SETA training. Last, baseline data will be collected for the following: third-party and core operating systems levels (Brotherston & Berlin, 2017; CIS, 2018; Hayden, 2010); root login capabilities (Beuchelt, 2013); password settings (Beuchelt, 2013; Brotherston & Berlin, 2017); user ids with empty passwords (Beuchelt, 2013; Brotherston & Berlin, 2017); use of multifactor authentication (CIS, 2018); status of SELinux (Beuchelt, 2013; CIS, 2018); status of central log management (CIS, 2018); all running services (Beuchelt, 2013; Brotherston & Berlin, 2017; CIS, 2018); and status of local firewall (Beuchelt, 2013; CIS, 2018).

Safa and Von Solms (2016) performed confirmatory factor analysis to test their measured variables. Convergent validity was evaluated with factor loading and as a result three items were dropped (Safa & Von Solms, 2016). Composite reliability was confirmed with Cronbach's alpha and discriminant validity tests verified the independence of the remaining constructs (Safa & Von Solms, 2016). Moqbel and Bartelt (2015) assessed discriminant and convergent validity for their survey instrument by performing factor analysis and tested composite reliability by examining Cronbach's alpha. All results exceeded the recommended statistical thresholds (Moqbel & Bartelt, 2015). Moqbel and Bartelt (2015) used the square root of average variance extracted (AVE) to assess discriminant validity for all their constructs. Ifinedo (2014) examined the convergent validity, internal consistency, and discriminant validity of their survey instruments. Composite reliability was confirmed via factor loading tests (Ifinedo, 2014). Convergent validity was verified using AVE (Ifinedo, 2014). Finally, Ifinedo (2014) confirmed discriminant validity by assessing the AVE and the square root of AVE. Hanus and Wu (2016) evaluated their model using partial least squares structural equation modeling (PLS-SEM). Exploratory factor analysis resulted in a total of 37 factors in their survey instrument (Hanus & Wu, 2016). Reliability of the model was confirmed with composite reliability and Cronbach's alpha (Hanus & Wu, 2016). Convergent validity was confirmed using AVE and discriminant validity was confirmed by testing cross loadings (Hanus & Wu, 2016). Siponen et al. (2014) tested convergent validity by factor loading and AVE which resulted in six items being dropped. Discriminant validity was evaluated by assessing correlations between all constructs (Siponen et al., 2014). Additionally, the variance extracted, and the square root of variance extracted met the corresponding statistical recommendations (Siponen et al., 2014). Reliability was evaluated using Cronbach alpha and all items exceeded the recommended levels (Siponen et al., 2014). Safa et al. (2016) tested convergent validity by using factor loading resulting in two items being removed from their survey instrument. Internal consistency was evaluated Cronbach's alpha and all factors exceeded the recommended threshold (Safa et al., 2016). Discriminant validity was evaluated using the square root of variance extracted and again all items exceeded the recommended thresholds (Safa et al., 2016).

Following are the survey instrument items for each construct in the model. Modifications to existing, previously validated instruments are indicated by italics. Unless otherwise noted, all items are based on a 7-point Likert scale ranging from (1) strongly disagree to (7) strongly agree which is consistent with the prior instrument's usage.

Trust

In Safa and Von Solms (2016) instrument, "colleague's" was replaced with "information security team's" to evaluate the UXA trust in the information security team. In Moqbel and Bartelt's (2015) instrument, the phrase "personal cloud computing companies" was replaced with "the information security team members" to assess the UXA trust in the information security team.

TR1: I believe that my *information security team's* information security knowledge is reliable (Safa & Von Solms, 2016).

TR2: I believe that my *information security team's* information security knowledge is effective (Safa & Von Solms, 2016).
TR3: I believe that my *information security team's* information security knowledge mitigates the risk of information security breaches *for my servers* (Safa & Von Solms, 2016).

Self-Efficacy

For Ifinedo's (2014) instruments the references to "computer" were changed to "servers" to reflect the focus on systems administrator's enterprise servers.

SE1: I have the necessary skills to protect my *servers* from information security threats (Ifinedo, 2014).
SE2: I have the expertise to implement preventative measures to stop people from getting my organization's confidential information stored on my *servers* (Ifinedo, 2014).
SE3: I have the skills to implement preventative measures to stop people from damaging my *servers* (Ifinedo, 2014).

Response Efficacy

For Ifinedo (2012) and Hanus and Wu's (2016) instruments the references to "computer" were changed to "servers" to reflect the focus on systems administrator's enterprise servers. The addition of patient information to RE2 reflects the focus of the present research in the context of an academic teaching hospital.

RE1: Enabling the security measures on my *servers* is an effective way to deter hacker attacks (Ifinedo, 2012).
RE2: The preventative measures available to me to stop people from gaining access to my organization's *servers* and data are adequate (Ifinedo, 2012).
RE3: Frequently applying security patches on my operating system is an effective way of preventing hacker attacks on my *servers* (Hanus & Wu, 2016).

Perceived Vulnerability

For Siponen et al. (2014) and Hanus and Wu (2016) the references to "computer" were changed to "servers" to reflect the focus on systems administrator's enterprise servers. VU3 was extended to include additional types of information security threats.

VU1: My *servers* could be subjected to a serious information security threat (Siponen et al., 2014).
VU2: My organization could be subjected to a serious information security threat (Siponen et al., 2014).
VU3: I believe that trying to protect my company's *servers* and information will reduce illegal access to it (Ifinedo, 2012).

Perceived Severity

For Siponen et al. (2014) and Hanus and Wu (2016) the references to "computer" were changed to "servers" to reflect the focus on systems administrator's enterprise servers. SV4 was expanded to include a wider range of information security threats.

SV1: An information security breach in my organization would be a serious problem for me (Siponen et al., 2014).
SV2: An information security breach in my organization would be a serious problem for my organization (Siponen et al., 2014).
SV3: I believe that having my *servers* infected malware, virus, or similar infection would be a serious problem (Hanus & Wu, 2016).

Information Security Knowledge Sharing

SKS1: I frequently share my information security knowledge in my team in order to decrease information security risk (Safa et al., 2016).
SKS2: I think information security knowledge sharing helps me to understand the usefulness of information security policies in my organization (Safa et al., 2016).
SKS3: I think information security knowledge sharing is a valuable practice in my organization (Safa et al., 2016).

Cognitive Heuristics

New questions will be developed to evaluate the use of the availability heuristic, representativeness heuristic, affect heuristic, optimism bias, and confirmation bias. As the use of heuristics is a function of System One, a time limit will be used for all the cognitive heuristics questions to minimize the use of analytical (System Two) reasoning (Finucane et al., 2000; Gertner, Zaromb, Roberts, and Matthews, 2016; Kahneman, 2011). The availability heuristic impacts the estimation of probabilities and participants will be asked to rank common operating systems and applications vulnerabilities and those responses will be compared to actual statistics (Kahneman, 2011; Kliger & Kudryavtsev, 2010; Tversky & Kahneman, 1974). Confirmatory bias will be tested using a fictional scenario, similar to the technique of Fischer et al. (2011) where participants are presented a scenario, asked to make an initial decision, then provided six confirming and six disconfirming bits of additional information they can choose to review, and then asked to choose again. The level of confirmation bias will be determined by subtracting the number of disconfirming from the confirming choices selected (Fischer et al., 2011; Gertner et al., 2016). To evaluate representativeness bias, Gertner et al. (2016) used scenarios that encouraged base rate neglect where subjects are provided statistical information and then counterintuitive data. Similarly, the present research will utilize a security related scenario to evaluate use of the representativeness heuristic. Rhee et al. (2012) found that optimism bias was based on a measure of risk perception and controllability. To develop a quantitative measure for optimism bias, the results of the perceived vulnerability (VU1 and VU3), self-efficacy (SE2 and SE3), and response efficacy (RE3) questions will be used. These items indicate complete confidence that all security threats will be prevented (SE2, SE3, and RE3) and focus specifically on the administrator's servers (VU1 and VU3). The affect heuristic will be evaluated using questions associated with the administrator's perceptions (feeling) of their value to the organization as well as their feelings regarding the organizational ISP. Administrators who feel unvalued by the organization may be less prone to comply with ISP as the organization and ISP are viewed negatively—Slovic, Peters, Finucane, and MacGregor (2005) identified this is a high risk, low benefit affect-based decision. All cognitive heuristic based questions will be pilot tested with non-participants to ensure clarity. Additionally, the questions will be discussed with an expert in the field of cognitive decision making to assess the reliability and validity of the questions. Participant's responses to AV1-AV4 will be compared to the CVSS ratings which indicate actual vulnerabilities.

Availability heuristic questions:

AV1: Microsoft servers have more vulnerabilities than Linux/UNIX servers.
AV2: There are more security vulnerabilities, alerts, and patches related to Windows servers than Linux/UNIX servers.
AV3: A Windows server containing PII/PHI is likely to be breached.
AV4: A Linux/UNIX server containing PII/PHI is likely to be breached.

Optimism bias questions:

OPT1: Our organization has the means to control information security threats.
OPT2: Our organization has the ability to execute security practices to avoid information security threats.
OPT3: The likelihood that my servers will be disrupted due to information security breaches in the next 12 months is low.

Confirmatory bias scenario:

CB Screen 1: Your organization plans on implementing a new web server to provide customers' access to HIPAA protected PII data. In order to provide the highest level of security, would you recommend the web server be implemented on the Windows or UNIX/Linux operating system?
CB Screen 2: On the next screen you will be presented with additional data points you can choose to review to inform your decision. You will have 45 seconds to select as many items for review as you would like. You must choose at least one item. Each review costs you one virtual dollar. You have a total of $12 available. Once you have completed reviewing additional information please select again the operating system you would recommend for the web server. Please select continue to move to the next page.
CB Screen 3: Informational data points are below. Once you have reviewed any you wish to view you please select the operating system you would recommend.
L1 (+): Administrators benefit from the freedoms offered by the system administration methods in Linux (IONOS, 2019).
L2 (-): Porting of applications for Linux distributions is not the focus of many hardware and software companies (IONOS, 2019).
L3 (+): There are fewer demands on the hardware due to reduced operating systems overhead in Linux (IONOS, 2019).
L4 (-): Several professional programs (i.e. Microsoft Windows, Microsoft SharePoint, Microsoft Visio) do not work with Linux (IONOS, 2019).
L5 (+): Remote function access is integrated into the native operating system on Linux distributions (shell and terminal) (IONOS, 2019).
L6 (+): Licensing costs are minimal.
W1 (+): Windows server is new administrator friendly due to the intuitive operations of the graphical user interface (IONOS, 2019).
W2 (-): The licensing costs for Windows can be high and can increase with each user (IONOS, 2019).
W3 (+): Windows is compatible with popular Microsoft programs like SharePoint and Exchange (IONOS, 2019).
W4 (-): Windows servers are vulnerable to malware (IONOS, 2019).
W5 (-): The use of mandatory graphical user interface on Windows servers results in significant resource utilization for basic operating systems function (IONOS, 2019).
W6 (-): Windows servers are prone to user errors and security attacks through the integrated interface (IONOS, 2019).

Data Analysis Strategies

To test the structural model, partial least squares structural equation modeling (PLS-SEM) is frequently used (Hanus & Wu, 2016; Ifinedo, 2012; Safa & Von Solms, 2016). This method will allow for the examination of the paths of the model as well as the relationships between the variables (Hanus & Wu, 2016; Safa & Von Solms, 2016). Chi-square with degrees of freedom can be used to evaluate the global fit of the model (Safa & Von Solms, 2016). Goodness of fit index and adjusted goodness of fit index can be used to evaluate the fit between predicted values and observed values (Safa & Von Solms, 2016). To test the measurement model, confirmatory factor analysis (CFA) will be used to test the measured values against the constructs (Safa & Von Solms, 2016). CFA will be used to evaluate discriminant and convergent validity (Boss et al., 2015). Convergent validity can also be verified using average variance extracted (Hanus & Wu, 2016; Ifinedo, 2012; Posey et al., 2015). Cronbach's alpha will be used to evaluate internal consistency (Safa & Von Solms, 2016). Descriptive statistics (mean, standard deviation, skewness, and kurtosis) will be calculated for all of the constructs. Finally, paired t-tests will be used to help evaluate the influence of the SETA programs on UXA ISP compliance for the experimental group.

Implementation Plan

This survey will be administered electronically through the company's email and intranet. It will be sent to the UNIX systems administrators in the CIT group. Additionally, baseline statistics will be developed via the Tenable Nessus scans. The data point collected include: percentage of administrator's production servers sending data to centralized log management system (Splunk); percentage of administrator's production servers performing Nessus vulnerability scans; percentage of administrator's production servers performing credentialed Nessus vulnerability scans; percentage of administrator's production servers that have implemented kernel hardening; percentage of administrator's production servers with kernel at recommended patch level; percentage of administrator's production servers running antivirus software; and percentage of administrator's production servers that have implemented ISP password rules.

During the second phase of the research a set of security scenarios applicable to the business environment and related to server management will be developed. These will be utilized during a SETA program. The SETA program will be developed and conducted as a series of small-group security workshops that include information security team members and UXA within an organization. The goal of the workshops will be to encourage connection, collaboration, discussion, and information security knowledge sharing between the participants. After a scenario is reviewed with the workshop participants and discussion has completed the information security team members may suggest additional ideas, tools, or processes that had not been considered. Also, during this phase, online learning modules will be provided to participants in the experimental group to reinforce skills learned during the SETA workshops.

At the conclusion of phase three the initial questionnaire will be distributed to the UXA to evaluate any significant changes in scoring for any of the model's factors. UXA ISP compliance behavior will be assessed by analyzing seven percentages for specific security implementations for all the production UNIX servers managed by each UXA. Percentages are frequently used for analyzing and presenting security metrics as they are easily interpretable and can clearly indicate positive or negative change (Brotby & Hinson, 2013, Hubbard & Seirsen, 2016; Hayden, 2010, Jaquith, 2007). Three months following the workshops, Tenable Nessus scans will be used on the same data points to evaluate actual compliance with ISP. Discriptive statistics will be used to determine if significant changes were made.

ABSTRACT

Supplier selection is a critical process that directly affects overall firms' performance. There are various factors that come into play when firms are establishing supplier selection criteria. One of the key factors that directly influence firms' decision towards establishing supplier selection criteria is their relationships with current and previous suppliers. In this study, we qualitatively explore the impact of few decision biases that generates from firms' relationship with existing or previous suppliers on firms' supplier selection criteria for new suppliers. Focus group interviews were used as a tool to collect qualitative data. The data was analyzed and results revealed that the selection criteria for new supplier is affected by reference point bias in decision making based on failed relationship between firm and a supplier.

KEYWORDS: Decision making, supplier selection, firms' relationships, selection criteria

INTRODUCTION

Firms today are faced with immense competition that demands improved quality, delivery, performance and responsiveness from organizations and focusing on reduced cost at the same time. Firms are finding different ways to leverage their supply chains and particularly, evaluating role of suppliers in their activities. Prahalad and Hamel (1993) identified the increasing role outsourcing of non-core activities of the firms. This helps organizations to focus more on their core activities to add value. Role of supplier is integral towards performance and attractiveness of entire supply chain. Supplier selection is important based on the fact that "it commits resources while simultaneously impacting such activities as inventory management, production planning and control, cash flow requirements, and product quality" (Narasimhan, 1983). There exist a range of supplier selection criteria, supplier evaluation and selection techniques including Data Envelopment Analysis (DEA), mathematical programming (including linear programming, integer linear programming, integer non-linear programming, goal programming, multi-objective programming), Analytic Hierarchy Process (AHP), case base reasoning, Analytic Network Process (ANP), Fuzzy set theory, Simple multi-attribute rating technique, genetic algorithm (Ho, Xu, & Dey, 2010). Supplier selection decision not only depends on cost and quality concerns but also various risk factors. Our study will mainly focus on the supplier selection criteria and sub-criteria. Ojala and Hallikas (2006) analyzed supplier investment risks, whereas Olson and Wu (2006) focused on broader categories of supply chain risks (internal and external) and their

controllability. Various studies have modeled uncertainty and risks in selection of supply chain partners. (Cohen & Lee, 1988; Graves & Willems, 2000; Lee & Billington, 1993; Thomas & Griffin, 1996) but there is lack of literature that explain biases in future supplier selection criteria based on existing and previous supplier relationship. In this study, we explore the impact of firms' current and previous supplier relationship on future supplier selection criteria. The key research question is "What are the decision-making biases that come into play while selecting future suppliers based on firms' relationship with existing and previous suppliers?"
We use focus group to explore the degree to which decision biases come into play while establishing supplier selection criteria based on previous and current supplier relationships. Following is literature review conducted to engrain the phenomena of supplier selection and decision biases through previous studies. Literature also helps to come up with the scope of discussion in focus group study. Next is the methodology section that gives the rationale and procedure of using focus group in this study followed by the data analysis and discussion sections. Conclusion section gives an overall summary of the whole study, processes involved and ultimate findings.

LITERATURE REVIEW

A critical decision in any of firms strategy is to decide what to buy and what to make (Platts, Probert, & Canez, 2002). When producing a specific product within a firm is beneficial and when it is feasible to outsource it. These are the decisions that force any firm to go out of its boundary and interact with other players in the market i.e. suppliers. Now on what basis firm should make this decision is answered by Transaction Cost Economic theory. This theory states that economic cost of transaction will decide if a particular transaction is worth taking or not (Williamson, 1981). This cost will also identify the structure of governance as well that whether it should be market, hierarchy or alliance (Williamson, 1975). According to McIvor (2009) there are four basic hurdles and difficulties in conducting transactions. These hurdles are bounded rationality, opportunism, small numbers bargaining, and information impactedness. He referred to bounded rationality as "the cognitive limitations of the human mind, which increases the difficulties of understanding fully the complexities of all possible decisions." Opportunism was defined as "decision makers acting with guile, as well as out of self-interest." Small numbers bargaining was defined as "the degree to which the buyer has alternative sources of supply to meet its requirements." And lastly, information impactedness was defined as "the presence of information asymmetries between the buyer and supplier, which means that either party may have more knowledge than the other." Further moving on he explained that these costs and transactional difficulties are further enhanced in the presence of asset specificity, uncertainty and infrequence. So, procurement becomes a critical decision for any organization when deciding on buy vs make problem.
Procurement is one of the critical activities and widely research topic in supply chain literature. Procurement function, in today's business environment has a pivotal role to play in firm's strategy formulation (Moses, 2011). Managing supply chain partners effectively directly affects firm's performance (Collins, Worthington, Reyes, & Romero, 2010). Supplier selection is one of critically researched domain of procurement literature. Too many criteria for supplier evaluation have been used in different context in the literature (Kumar Kar & K. Pani, 2014) but the basis on which these criteria are filtered and used is still vague. Some classic work of Busch (1962) and Dickson (1996) focused on supplier selection criteria like "quality", "delivery schedule" and "warranties". Further studies also highlighted the importance of "price", "technical" and "production" capability, "financial position", "vendor reputation", "post-sale services" and "past business records". After 1990s there was a shift from quantitative criteria to qualitative criteria for supplier evaluation. (Kumar Kar & K. Pani, 2014). As the onset of globalization come into

play, further development in criteria occurred including “geographic locations”, “exchange rates”, “tariffs and customs”, trade restrictions”, “quality management” and other environmental factors. (Braglia & Petroni, 2000; Choi & Hartley, 1996; Cusumano & Takeishi, 1991; Narasimhan, Talluri, & Mendez, 2001; Talluri & Narasimhan, 2005).

Research has shown that supplier’s knowledge can affect buyer’s ability to learn and bring change (Jarratt, 2004), however this mainly depends upon the degree of positive relationship that exist between buyer and supplier. Integrating with supplier depends mainly on the success of buyer-supplier relationship (Vanpoucke, Vereecke, & Wetzels, 2014) which is largely based on supplier’s selection and evaluation process.

programming (linear programming, integer linear programming, integer non-linear programming, goal programming, multi-objective programming), Data Envelopment Analysis (DEA), Analytic Hierarchy Process (AHP), case base reasoning, Analytic Network Process (ANP), Fuzzy set theory, Simple multi-attribute rating technique, genetic algorithm (Ho et al., 2010). Kannan, Haq, Sasikumar, and Arunachalam (2008) used interpretive structural modeling and AHP for analyzing green suppliers. In another article, Hsu and Hu (2009) evaluated suppliers incorporating hazardous substance management through ANP. Büyüközkan and Görener (2015) used Fuzzy AHP for sustainable supplier selection with incomplete information. In a study by Shaw, Shankar, Yadav, and Thakur (2012), fuzzy AHP and multi-objective linear programming was used to select suppliers for developing low carbon supply chain. Sarkis and Dhavale (2015) focused on Bayesian framework and Monte Carlo simulations for supplier selection for sustainable operations.

In spite the fact that use of supplier selection and evaluation criteria is highly case specific, the buyers’ decision is not always objective. AHP gained importance because it has the ability to address human subjectivity in decision making and it can bring out non deterministic requirements (Saaty, 1994). AHP helps to decompose the problem into a hierarchy of sub-problems that are more easily comprehended and can be analyzed independently. AHP can also measure the degree of consistency in priorities which making a supplier selection. Our study focuses on the fact that this change in priorities and supplier selection criteria is highly influenced by a buyer’s relationship with existing or past suppliers. Decision biases come into play when setting priorities in selection criteria for a particular supplier and it directly affects degree of risk an organization is willing to take being a buyer. This is where decision theory comes into play.

As explained by Transaction Cost Economic theory, bounded rationality of human beings increases the difficulties in transaction. Hence role of decision making and rationality needs to be explored in the area of supply chain. According to H. A. Simon (1955) human beings are rational decision makers and they always act in their self-interest to get the best outcome of their choice and preferences. This was the basic assumption of “homo economicus” and it was also prevailed in the field of supply chain management in the form of institutional economic theory and transaction cost economics (Grover & Malhotra, 2003; McNally & Griffin, 2004; Rindfleisch & Heide, 1997). Even though basic assumption of human rationality has ruled the Supply Chain Management, but a new field of research has emerged within Supply Chain Management which has challenged this basic assumption and is known as Behavioral Supply Chain Management. It is defined by Carter, Kaufmann, and Michel (2007) as “The Study of how judgement in supply management decision-making deviates from the assumptions of homo economicus”. In his article, he reviewed a wide-ranging literature which is based on judgement and decision-making biases and integrated it by making taxonomies which can then be used in the field of supply management by supply managers and researchers. Literature has provided ample proof that human beings frequently violate the assumption of rationality and make biased decisions leading to results which are not fully optimal (Fischhoff, Slovic, & Lichtenstein, 1978;

Kahneman & Tversky, 1972; H. Simon, 1957; Thaler, 1985). Hence role of biases in Supply Chain decision-making cannot be ignored.

There are many areas where role of biases can be investigated in supply chain management. But supply chain management begins from selecting suppliers. So, supplier selection criteria and decision-making process is one the central task in supply management. It has been mainstream topic of research in the domain of supply chain management in which suppliers are selected on the principles of rationality drawn from transaction cost economics theory (Choi & Hartley, 1996; Grover & Malhotra, 2003; Huang & Keskar, 2007; McNally & Griffin, 2004; Weber, Current, & Benton, 1991). Even though majority of research are based on mathematical optimization of selection of supplier and its decision-making, but involvement of human beings makes it prone to use of heuristics and biases in decision making (Carter et al., 2007; Chan, 2003; Cook, 1992; Das & Teng, 1999; Karpak, Kumcu, & Kasuganti, 1999; Kaufmann, Michel, & Carter, 2009). It results in suboptimal solutions because one may discard other alternatives available and instead just accept satisficing solution which H. Simon (1957) explained as to choose "good enough" instead of optimal solution (Carter et al., 2007).

There are many biases which can be relevant in decision-making process of supplier selection. Carter et al. (2007) studied around 76 biases and using cluster analysis he came up with 9 categories of biases which are relevant in the context of supply chain management. Out of these 9 categories, Reference Point Bias is one of bias which can potentially affect the decision-making process of supplier selection. For simplicity and focus, in this paper we will stick to this bias only and will explore its effect on supplier selection criteria. According to Carter et al. (2007) "The reference point bias occurs when evaluations and adjustments from an initial position or reference point are usually insufficient". So, it can be argued that when selecting specific supplier and manager or company may create a reference point which can be its previous suppliers and it starts evaluating and adjusting the new supplier according to its experience with the previous supplier and this evaluation and adjustments can be insufficient according to the reference point bias.

According to Tversky and Kahneman (1974) the basic heuristic used for simplification of complex phenomenon by human beings is to start with an initial point and then alter and assess their opinions based on it. So suppliers may base their initial point as previous suppliers and make adjustments based on that experience but researchers have indicated that this alteration is usually insufficient to make optimal decision (Slovic, Fischhoff, & Lichtenstein, 1977). Similarly, when it comes to negotiating with a new supplier then organization can make the initial offer based on the previous supplier so it will lead to biased negotiation between the two parties because previous studies has shown in many experiments that final agreement in negotiations are biased towards the initial offer (Galinsky & Mussweiler, 2001). Moreover, it has also been reported that even when initial point is selected arbitrary still human beings fall prey to this bias leading to inefficient decision making so in supplier selection case even if there is no previous supplier experience but still organization may start comparing it to randomly initial points (Epley & Gilovich, 2005). Carter et al. (2007) explained this phenomenon nicely with an example related to buyer supplier relationship. According to him "For instance, a buyer might demand only incremental improvements in price levels from a supplier, because the current price level "anchors" the buyer judgment. In reality, however, the supplier's price may be far too high." This shows that Reference Point bias have the potential to effect supplier selection criteria because reference point can only be considered as rational if initial point is best indication of future selection which they are not (Hogarth, 1987).

THEORETICAL DEVELOPMENT/MODEL

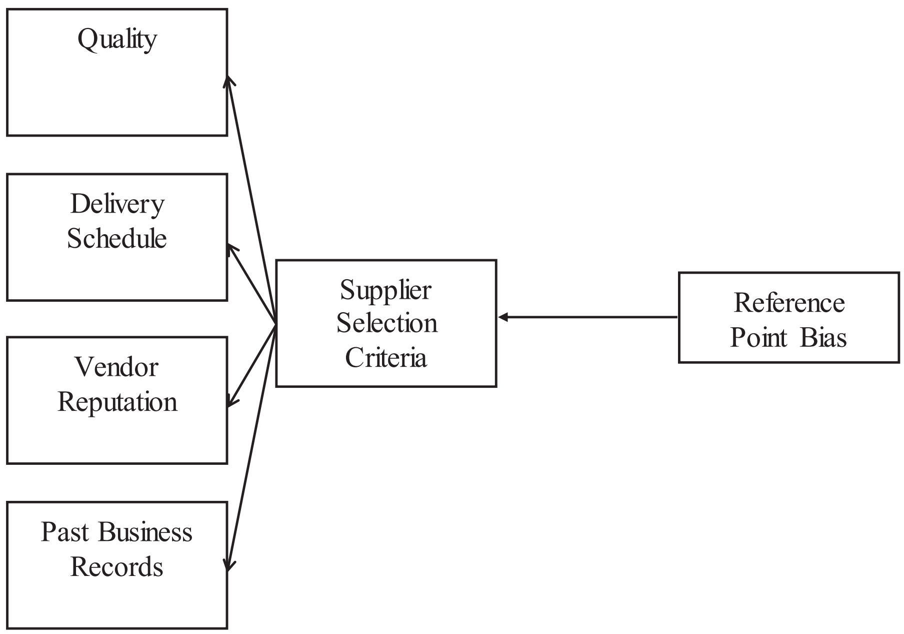

Fig 1

METHODOLOGY

Literature review and focus group discussion was adopted as a method to conduct this study. Focus group is among the top used techniques used in social sciences as a tool to execute research (Alfalla-Luque, Medina-Lopez, & Schrage, 2013). Many studies in the area of Supply Chain Management has used focus group as a research tool for example (Oehmen, De Nardo, Schönsleben, & Boutellier, 2010; Tate, Ellram, Bals, Hartmann, & Van der Valk, 2010) and it has also been used in general Operations Management field as well (Binder & Edwards, 2010; Dey, Hariharan, & Clegg, 2006). Focus group is about a well-organized discussion among a group of 6-12 members on a specific topic (Kitzinger, 1999; Tate et al., 2010). Focus group was useful for our study because we were doing exploratory study to find what biases come into play in supplier selection criteria. Focus group discussions characterize specific themes that are explored in depth (Bryman, 2015). Gibbs (1997) highlighted the importance of use of focus group as a tool that may reveal respondents' attitudes, beliefs, experiences and reactions that might not be possible to cater through other means of data collection like surveys.

Experts from different industries were selected for focus group. These experts are currently or have already worked for more than 6 years, in procurement department of their companies which was responsible for supplier selection. Brief profile of the experts is given below in the table:

No.	Name	Company	Designation	Education	Experience
1	Muhammad Bilal	Coca Cola	Procurement Specialist	MBA	7 years
2	Anayat Ali	Coca Cola	Procurement Manager	MBA	8 years
3	Haris Ali	HUBCO	Procurement and Planning Manager	Mechanical Engineer	10 years
4	Sheikh Latif	Packages Ltd.	Planning and Production Manager	MBA	15 years
5	Syed Muhammad Ahmed	Ali Murtaza and Co.	Procurement Manager	Master's in economics	8 years

Initially, a telephonic interview was conducted with these experts and objectives of the study were conveyed to them. Questions were explained that would be discussed in focus group discussion and their consent was taken if they are ready to participate in the study. It was also inquired that if they believe that they are eligible to answer the required questions.

Tool

An interview guide was developed including few leading questions that cover the scope of selection criteria and different biases that may come into play while applying those criteria. Questions along with interview guide are attached in Appendix 1.
In the focus group, the experts were first about the general importance of supplier in overall supply chain. Everyone was of the view that relationship with supplier is a strategic key to success of whole supply chain. After the initial brainstorming on the role of supplier, focus group was moved towards the supplier selection criteria and role of bias in decision making. Review of the objectives was also repeated in focus group discussion. The focus group was managed and moderated by one of the researchers. Participants were also requested that they should give an overall view about supplier instead of specific point of view from the perspective of their individual companies to make it more general. A qualitative analysis was conducted on the discussion held during focus group and results from preliminary literature review were also incorporated.

Procedure

The focus group discussion was planned using a semi-structured interview guide and some key topics were drawn in the guide. Before discussing the decision biases, the respondents were asked about the key criteria they use for selection of suppliers in their respective organizations. Respondents came up with different responses. Thus in the arguments section, both before and during discussion responses of the respondents are discussed. Two researchers were present during focus group discussion; one leading the discussion and other took notes. The interview lasted for around ninety minutes. Interview was recorded and transcribed for the purpose of analysis. Nvivo 11 was used to analyze the themes present in the transcribed interview.

Data Analysis

Transcribed material were analyzed through thematic analysis (Boyatzis, 1998). Initially six themes were identified for coding 1-6. Further transcribed material was scrutinized and all statements were reviewed to be associated with one or more themes. This allowed extracting subthemes. Table I shows the themes for code 1-6:

	Name
	Supplier selection criteria and effective procurement
	supplier screening process
	Bias in selecting new supplier
	Effect of previous supplier on new supplier selection
	Relationship sensitivity
	Common factors of failed supplier relationship

Table I

RESULT

The thematic analysis of transcribed material expanded into six themes with various sub-themes shown in table II. Two themes related to supplier selection criteria and supplier screening process whereas four themes concerned biases in decision making process, effect of previous supplier relationship on new supplier selection, supplier sensitivity and reasons behind failed supplier relationships.

Sr. No.	Themes	Sub-themes
1.	Supplier selection Criteria and effective procurement	1a. Competitiveness and cost 1b. Depends upon market, category of product and technical specifications
2.	Supplier screening process	2a. Research and Development 2b. Service level 2c. Suppliers' experience
3.	Bias in selecting new supplier	Bad relationship affects decision
4.	Effect of previous supplier on new supplier selection	4a. Intuition 4b. More subjective 4c. Increased resistance 4d. Reduced leverages to new suppliers 4e. Reference points
5.	Relationship sensitivity	5a. Industry and nature of supplies 5b. Integrity 5c. Compliance 5d. Sharing knowledge
6.	Common factors of Failed supplier relationships	6a. Delayed payments 6b. Delayed deliveries

Table II

Supplier Selection and Effective Procurement

The initial responses covered both positive and negative aspects of supplier selection criteria. Supplier selection was discussed to be the most critical aspect of procurement process and it was also revealed that firms might bear high cost for overlooking this important dimension. Negative aspects revealed that it might be take ample time in trying to risk averse in this regard. So it is a trade-off between the risk a firm might be willing to take and cost they are interested in spending in selecting appropriate supplier. Vendors play a strategic role; world is transforming into a global village so organizations cannot rely on one supplier because they need competitiveness and cost cutting.
There is enormous literature available on supplier selection. Weber et al. (1991) carried out an extensive literature on supplier selection criteria and noted that quality, net price and delivery ranked at the top by 13 articles. Production facilities and capabilities were also present in the list of important criteria. 26 criteria were summarized into 8 factors including finances, consistency, relationship, flexibility, technological capability, reliability, price and customer service (Choi & Hartley, 1996).
The respondents in focus group also conform to the supplier selection criteria as highlighted in the literature discussed. Supplier selection and effective procurement largely depend upon the market, technical specifications of the products and a set of pre-qualifications including quality, suppliers' financial performance, logistics (delivery schedule) and price
Role of supplier selection in effective procurement also varies from industry to industry. There are some industries where there is monopoly of suppliers and organizations are left with little or no leverage on the suppliers. Almost all respondents agreed to some key supplier selection criteria as quality, price, financials, sustainability, and above all technical specifications. Technical qualification is one of the most important criteria a supplier has to meet in supplier selection process of an organization. One of the respondents commented:
"It works like filtering layers. The first filter is technical qualification. For example, there are some technical qualifications a supplier has to meet in my organization like few ISO standards, OHSAS etc. After these technical qualifications have been met, then we consider the second layer that is much flexible and might vary from supplier to supplier. For example, a supplier might be charging higher prices but giving value added services so we would be willing to pay high price for value added services."

Supplier Screening Process

The second theme that was coded as a part of thematic analysis is suppliers' screening process. Two important considerations are there to discuss in supplier screening process. At the first level market intelligence system plays a pivotal role in supplier screening process in an organization. Industries in Pakistan are highly fragmented and it is very easy to gather intelligence about repute of various suppliers in the market. Secondly, firms' own knowledge management systems are important in screening the key suppliers from a range of available suppliers in the market. Procurement function also generates information that helps future decisions.
Internet has also played a significant role in finding out suppliers that qualify firms' criteria. The discussion also revealed that background check on the supplier is also an important element in the screening process. Organizations need to check litigations on suppliers before extending business terms with them. All the respondents agreed to the fact that their respective organizations have an appropriate supplier screening process in practice.

Bias in Selecting Supplier

The most critical stage of focus group interview starts with this theme. Initially, the discussion was mainly centered at identifying the key criteria for supplier selection and supplier screening process. After icebreaking and preliminary discussion, the participants in the discussion were introduced to the phenomena of decision biases. Moderator presented a situation to the respondents in which their relationship with the supplier is affected due to some reason and now they are considering to switch supplier. So whether or not, the selection criteria or screening process will remain the same or it will be altered owing to some cognitive bias. There was a mix of responses from the participants in the focus group. Some participants commented that there exists a positive relationship between relationships with supplier and bias in future supplier selection and some participants responded that it purely depends on the circumstances and the degree of relationship sensitivity between buyer (organization) and supplier. This discussion allowed a new theme to emerge (relationship Sensitivity) discussed further.
The key argument raised in discussing decision biases is that the organization (procurement function) will become more sensitive in selecting new supplier. Definitely changes will be incorporated in the process of supplier selection because every organization wants to avoid the same mistake happening twice.

Effect of Previous Supplier Relationship on new Supplier Selection

A more critical theme “Effect of previous supplier relationship on new supplier selection” emerged that highlighted different sub-themes in the coding process. All participants in the focus group discussion agreed to the fact that previous suppliers’ relationship definitely affects the selection of new suppliers.
“You might be more considerate about something you overlooked. It is a continuous development and learning process. If you have to select a new supplier, the very first challenge is to break you comfort zone. If you willing for this, you have to reform your criteria and SOPs for supplier selection.”
Another comment was that human element has to be reduced while refining the supplier selection criteria, which is not completely possible. There will be a human element and an unintentional decision bias might exist while selecting new supplier. In fact Chen and Chao (2012) identified a highly structured mechanism to evaluate suppliers based on multi-criteria decision making (MCDM) but the baseline criteria on which this model works is highly subjective and prone to human error. Another sub-theme that emerged from this theme is reduced leverage to the new supplier. Respondents believed that there are different leverages a firm may extend to their suppliers in terms of flexible lead time or timely payment schedules. When switching suppliers, the firm might reduce these leverages by focusing on strict lead times or demanding extended payment schedules. Trust is one of the reasons that will play a pivotal role in differentiating firms’ relationship with previous and new supplier.
In order to explore the phenomena of decision biases, the moderator also asked about some of the bad experiences, the participants had with their suppliers that prove to be an anchor or reference point when making a decision of selecting new supplier. This phenomena is well grounded in literature as Behavioral Supply Management (BSM) and has raised the level of attention given to the deviations from standard assumptions of rational paradigms in decision making (Kaufmann, Carter, & Buhrmann, 2012). In many situations, reference-dependent valuation affects decision makers’ behaviors that diverge from rationally optimized decision otherwise.

Relationship Sensitivity

As discussed above, bias in supplier selection also emerged a new theme that is sensitivity in buyer-supplier relationship. The phenomenon of sensitivity was discussed by majority of the participants in focus group that may affect supplier selection decision. Degree of sensitivity in relationship depends on nature of supplies. For routine supplies, the relationship is quite sensitive as there a number of alternatives available. For strategic suppliers, the degree of sensitivity is quite low. Sensitivity also comes into play when buyer and supplier share the same process. As in case of outsourcing where an outsourced partner completes a part of a firm's process. In this case the relationship will be entirely different as the firm and its supplier are sharing common objectives. Sensitivity also depends on risk involved. Dupont, Bernard, Hamdi, and Masmoudi (2018) studied the impact of delivery failure risk on supplier selection decision. Higher the risk involve, greater would be the sensitivity of the relationship between buyer and supplier.

Common Factors of Failed Buyer-Supplier Relationship

The last theme that emerged from coding was the key factors that contribute towards failure of buyer supplier relationship. There are two key factors from buyer (firm) and supplier's end: Delayed payments and delayed deliveries respectively. Lack of trust is also an important reason that contributes towards a failed buyer-supplier relationship. Kim and Choi (2015) theorized two orthogonal aspects in buyer-supplier relationships: (1) relational posture (means to what extent the firms regard each other as cooperative partners) and (2) relational intensity (means to what extent the operations of buyer and supplier are linked together. Based on these dimensions, a typology was developed that defined four types of buyer-supplier relationships: Deep, Sticky, Transient and Gracious. A sticky relationship is based on lack of trust and information sharing and most probably results in failure.

DISCUSSION

The in-depth examination of impact of decision biases on supplier selection unfolded different dimensions explained above in various themes and sub-themes. Supplier selection impacts effective procurement and becomes a reason for firms' effectiveness. There exists a significant positive relationship between procurement process and firm performance (Othman, Abd Rahman, Sundram, & Bhatti, 2015). Effective supplier selection is imperious for cost saving and thus offering better quality to customer (Tracey & Leng Tan, 2001). Screening suppliers is also an important aspect of procurement process. Conforming to the outcomes of our focus group discussion on supplier screening process, Rezaei, Fahim, and Tavasszy (2014) proposed a two layer model for supplier selection airline industry. The first phase is conjunctive screening phase in which the initial set of potential suppliers is reduced to a smaller set prior to a comprehensive analysis for final selection. Then, in the second phase, a quantitative model is used to evaluate suppliers against different criteria and sub-criteria.
Bias in decision making process comes into play at two stages: while establishing the selection criteria and while making final selection of the supplier. The interviews revealed strong concerns about interplay pf bias and supplier selection criteria. Bias

largely depends upon the degree of relationship sensitivity between buyer and supplier. Sensitivity can be affected by various factors like risk, price, lead time and quality. When establishing supplier selection criteria, it is evident from focus group interviews that reference points deeply affect supplier selection process and may deviate decision maker from highly rational and optimizing approach towards more intuitive and subjective decision making. Failed relationships become a trigger towards relationship sensitivity in future suppler relationship and can also be a source of decision bias especially when there is a need to make immediate switching decision. The failed relationship will become a reference point and new supplier will be screened and evaluated on the basis of that reference point. We use insights from transaction cost economics theory that explains that decisions are driven through bounded rationality and information impactedness. Our results conforms with the McIvor (2009) four elements in transaction cost economics theory.
Our qualitative analysis showed that there is indeed an impact of previous buyer supplier relationship on establishing supplier selection criteria for a new supplier and decision can be biased based on degree of sensitivity of the relationship with the previous supplier.

CONCLUSION

The qualitative study explored the key supplier selection criteria that may be affected by any decision-making bias based on existing and past supplier relationship and relationship sensitivity. The results through focus group discussion revealed that there is indeed an impact of decision bias on supplier selection criteria and it largely depends on intuition and subjectivity of the decision maker. The participants in focus group shared their own experiences in their respective organizations that further solidify our propositions. Thematic analysis was conducted in Nvivo 11 and based on the transcribed interviews, six themes emerged with various sub-themes.
One major limitation of this study is that the results are reported from the outcome of discussion with one focus group. There are two key process involved in supplier selection: supplier selection criteria and supplier evaluation. Supplier evaluation is majorly based on quantitative modeling techniques. This study focused primarily on supplier selection criteria.

"Supplier Selection and Decision Biases" Interview

Introductory Protocol

To facilitate our note-taking, we would like to audio tape our conversations today. Please sign the protocol form. For your information, only researchers on the project will be privy to the tapes. which will eventually be transcribed for the study. Essentially, (1) all information will be held confidential, (2) your participation is voluntary and you may stop at any time if you want to. Thank you for your willingness to participate.

We have planned this interview to last no longer an hour. During this time, we have few questions that we would like to cover.

Signature (consent to do the interview)

____

Introduction

We are students of Lahore University of Management Sciences (LUMS) and currently studying a course on Decision Behavior as a mandatory requirement of our PhD program. You have been selected to speak with us today because you have been identified as someone who has a great deal of experience in procurement decisions in an organization. Our research focuses on understanding the criteria based on which a firm choses it supply chain partners (vendors). What role is played by different biases in decisions making process and what are the challenges you face while establishing criteria for procurement decisions.

Vendor Selection Criteria:

Upfront Questions:

1. What do you think is the role of selection criteria in selecting appropriate vendors for the organization?
2. Prioritize some of the key supplier selection criteria while making a decision.
   Probes: [What is your rational behind this prioritizing? Has this criteria sustained or has it changed over time?]
3. Do you think you selection criteria are influenced by any bias?
   Probe: [What bias you might think has come into play while making vendor selection decision?]
4. How frequently your organization changes vendors?
   Probe: [To what extent vendor selection criteria changes as you switch from one supplier to another].
5. How sensitive is an organization's relationship with particular vendors?
   Probe: Do you think this sensitivity of the relationship affects your future vendor selection?
6. Suppose you have 1-2 minute to conclude our talk about role of supplier relationship that might bias your decision for future supplier selection, how would you conclude that?

Back-end questions:

1. What are supplier selection criteria in general?
2. What biases might come into play based on buyer-supplier relationship?
3. How these biases affect future supplier selection?
4. What are prioritizing principles of supplier selection criteria in absence of any decision bias?

5. What are prioritizing principles of supplier selection criteria in presence of any decision bias?

DECISION SCIENCES INSTITUTE

Digitalizing Supply Chains: Potential Business Benefits and Challenges

Abubaker Haddud

ABSTRACT

Digital transformation continues to change business landscapes and it is important to understand aspects related to such transformation. We present a research examining potential benefits and challenges associated with digitalizing supply chains. We analyze survey data collected from 74 respondents examining predetermined 10 potential benefits and 10 potential challenges. We ranked these benefits and challenges to highlight their degree of importance. This paper can greatly benefit parties interested in understanding aspects related to supply chain digitalization and how to effectively manage digital transformation within the entire value chain. Such understanding helps managers identify key business areas digitalizing supply chains directly impacts.

KEYWORDS: Digital supply chain, Digital transformation, Benefits, Challenges

INTRODUCTION

Businesses use more and more of smart technologies within different business functions, and supply chain management is one of the key areas that is directly impacted by such adoption. Gartner provides definitions to ‘digitization’ and ‘digitalization. Digitization is defined as “the process of changing from analog to digital form, also known as digital enablement” (Gartner IT Glossary - 1). Whereas, digitalization is defined as **“**the use of digital technologies to change a business model and provide new revenue and value-producing opportunities; it is the process of moving to a digital business (Gartner IT Glossary - 2). In this study, we focus on the ‘digitalization’ processes exploring aspects related to more use of digital technologies within supply chains. More adoption of smart technologies leads to more level of digitalization of different supply chain functions. Recent developments concerning digitalization are expected to play an increasingly significant role in the management and design of global supply chains (Klötzer and Pflaum, 2017). Therefore, organisations should not consider “if” they set-up a digital strategy and get their organisation and environment ready for the digital transformation rather take the required actions as soon as possible and bring the digital transformation to life (Bienhaus and Haddud, 2018). Thus, it is very important that businesses understand key aspects related to digital transformation and where within the business it is occurring most. Supply chain management is a key business function that has seen a great deal of technology utilizations. Companies continue to seek ways to achieve competitive advantages through the adoption of more smart technologies within their internal supply chains as well as with their extended external chains that involve strategic business partners. Therefore, it is important to study the impact digitalizing supply chain would have on the operations and performance of the entire supply chain and to identify key potential business benefits and key potential challenges associated with such trends. This paper seeks to answer the following two questions:

1. What are the key potential business benefits that are likely to result from digitalizing supply chains?
2. What are the key potential challenges that businesses are likely to face when digitalizing supply chains?

Answers to these questions will provide a useful reference that decision makers can use to help them decide what emerging technologies to use and where to implement them in areas related to main elements of value chains. The answers also provide a list of potential challenges that managers need to be aware of when embarking on digitalizing supply chain initiatives that help with the implementation and operations of new acquired technologies. This paper is structured as follows: the next section provides a literature review about supply chain management, digital transformation, and digital supply chain. After that, the research methodology and method are presented. Next, results and discussions of the collected data are presented covering the two main themes of this paper as 'potential benefits' and 'potential challenges. Finally, conclusions, recommendations, and future research suggestions are included in the last section of the paper.

LITERATURE REVIEW

Supply Chain Management

Supply chain management deals with the movement, and storage, of raw materials, work-in-progress, and finished goods from the point of origin to the point of customer buying and receiving the finished goods. Supply chains are divided into two main parts: internal supply chains that consist of activities and units within a firm, and external supply chain that includes activities based in external business parties such as suppliers, distributors, retails, and customers. Integration and coordination between the internal and external parts of supply chains is crucial to the performance of supply chains as a whole value network.

Supply Chain Management is more than just managing the follow of materials. It is the oversight of material, information, and financial flows inside and outside an organization. Flows move from supplier to manufacturer to wholesaler to retailer to consumer (and back). It is concerned with planning, implementing and controlling the flows of raw materials, inventory and finished goods from the point of origin to the point of consumption, and covers purchasing, the manufacturing process and customer delivery. Lately, with the emphasis on "green," one would incorporate environmental considerations at each stage of supply chain management including post-consumer disposal. We think the information flow part is important when we discuss digitalization. One way of effectively integrating the different parts of value chains is through the use of smart technologies that ensure effective coordination and smooth operations. In this paper, we seek to identify key potential benefits and challenges related to digitalizing supply chains so that decisions are made to further improve the performance of entire supply chains (internal and external) which will lead to better overall organizational performance.

Digital Transformation

Digital transformation can be simply defined as the use of technology to radically improve performance or reach of companies (Westerman et al., 2014) and it is currently an important trend that many industries are embracing, and it creates some disruptions to the business norms. Digital transformation is a transformation that impacts business activities, processes, competencies, and models to fully leverage the changes and opportunities brought by digital technologies (Demirkan et al., 2016). Digital transformation is normally driven by internal factors such as: the continuous need to improve processes and entire workplace. Also, to effectively integrate information systems within the company and with external partners to enhance overall management of processes and to reduce costs. Externally, companies continue to invest in digital transformation to meet ever-changing customer demands and to meet supply chain management needs (Pflaum et al., 2019). Supply chain management is one of the key business areas that have seen a huge adoption of different technologies and it contributes greatly to the digital transformation of businesses as a whole. The next section discusses aspects of digital supply chains and the main theme of this paper is to identify key businesses benefits and challenges associated with digitalizing supply chains.

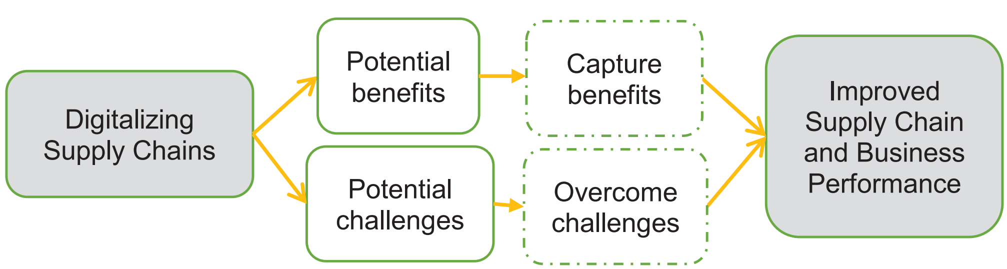
Digital Supply Chains

Digital Supply Chain (DSC) is defined as “an intelligent process that leverages innovative solutions with emerging technological means to generate new forms of revenue and business value for organizations” (Büyüközkan and Göçer, 2017). Digital supply chain relies on key drivers that consist of technologies, digitization, integration, collaboration and coordination (Iddris, 2018). The transformation process into a digital supply chain requires three key enablers: a clear definition, new capabilities, and a supportive environment (Alicke et al., 2017). The main goal of the digital supply chain is to deliver the right product into the customer's predefined spot as quickly as possible (Pereira et al., 2017). Therefore, digitalizing supply chain is no easy task and it requires effective strategies and robust implementation measures in place. In order to gain the necessary support for implementing digital supply chain initiatives, it is crucial that decision makers appreciate the potential benefits such move would bring to the business. This paper provides insights about 10 potential benefits businesses may gain from digitalizing supply chains and identifying the key impacted areas. Such information can greatly help interested decision makers with appreciating the impact more digitalizing in supply chains would have on their management and performance. Furthermore, this paper provides information about 10 key potential challenges that businesses are likely to face when acquiring the necessary capabilities and technologies to digitalize supply chains. Such information is crucial in helping decision makers understand the readiness status of key business areas and supply chain elements in order to gauge the possible occurrence of any of the highlighted potential challenges. Thus, preventive measures and other actions can be taken ahead of any digital supply chain initiatives to ensure a smooth and effective implementation and management of any new initiatives.

CONCEPTUAL RESEARCH FRAMEWORK

Figure 1 shows the conceptual framework for this research. It illustrates that digitalizing supply chains initiatives will lead to businesses gain potential benefits. Once these benefits are capitalized and captured, the overall supply chain and business performance improves. It also illustrates that digitalizing supply chains initiatives will likely face a number of potential challenges. Handling and overcoming such challenges will lead to better supply chain management and business performance. The two boxes with dashed lines are not the focus of this study. These areas are relevant to the study but need future research attention.

Figure 1 Conceptual research framework



METHODS

An online survey was utilized to collect the primary data for this research capturing the perceptions of respondents about aspects related to digitalizing supply chains. This research study was approved by Southwest Minnesota State University's Institution Review Board in September 2018 and the used online survey consisted of six main parts (see Figure 2). Three parts are included in this paper (parts 1, 3, and 4). First, General Information section (7 questions). Second, the respondents were asked to rate their perception about 10 potential benefits related to digitalizing supply chains. Third, the respondents were asked to rate their perception about 10 potential challenges related to digitalizing supply chains.

Figure 2 Survey development and structure

Main parts of used survey					
1	2	3	4	5	6
General Information (*7 questions*)	Influence of Technological Trends on SCM (*7 examined technologies*	Benefits from Digitizing Supply Chains (*10 examined benefits*)	Challenges Associated with Digitizing Supply Chains (*10 examined challenges*)	Impact of Digitizing Supply Chains on Five Lean Manufacturing Tools (*5 examined items under each tool = 25 items in total*)	Potential Impacts of Digitizing Supply Chains on The Seven Types of Manufacturing Wastes (*5 examined items under each waste = 35 items in total*)

The developed survey statements related to the examined potential benefits and challenges were extracted from information presented in a number of refereed academic journal articles as presented in Table 1.

Table 1: Sources used to develop the examined survey statements [benefits and challenges]

Examined benefits	**Source**	**Examined challenges**	**Source**
Improved visibility across chains and better traceability of processes and products	Musa et al., 2014	Challenges related to integrating different systems across the network	Majeed and Rupasinghe, 2017; Murphy, 2017
Better information-sharing and supply chain integration	de Mattos and Barbin Laurindo, 2015	Managing the transformation process from an existing company to its digitalized equivalent	Lee and Lee, 2015; Pflaum et al., 2017; Ryan and Watson, 2017

Quicker responses to changes in demand, effective inventory and logistics management, and reduction in supply chain complexity	Garrett, 2014; Gao et al., 2015	Lack of robust preparation and understanding	Howells, 2016
Supply chains become able to react more effectively to changes in the marketplace	Haddud and Khare, 2018.	Required financial investments from all supply chains players to design and deploy technologies and solutions necessary to digitize supply chains.	Haddud et al., 2017
Better demand forecasting accuracy and optimization of ordering process.	Bonnes, 2014; Ittmann, 2015	Employees' resistance to new technologies and practices	Haddud et al., 2017
Improved operational efficiencies, improved service quality, and greater resource efficiency.	Tseng et al., 2011; Ngai et al., 2011	Challenges with supply chain management integration requirements.	Haddud et al., 2017
Supply chains become more responsive to resolve supply chain-related operating problems, e.g., complex distribution problems	Haddud and Khare, 2018.	Access to/ availability of the required skilled human resources	Ryan and Watson, 2017
Supply chain designs become; flexible, open, agile, and collaborative	Petrick and Simpson, 2013	Risks and variabilities that may arise from the use of ecosystems	Lee and Lee, 2015; Riggins and Wamba, 2015
More effective delivery route planning and inventory planning	Haddud and Khare, 2018.	Diversity of adopted business models within the different supply chain entities and organizations.	Haddud et al., 2017
Enhanced employees' internal collaborations, communications, and engagement levels	Haddud et al., 2016	Supply chains in general not ready for such a change and lack the required architecture	Bughin et al., 2015; Jin et al., 2014; Li et al., 2015

Data were collected in November and December 2018 using an online survey created on Google Forms. Respondents were either authors or co-authors of papers in the Decision Science Institute (DSI) annual conference proceedings and the Emerald's Journal of Manufacturing Technology Management from 2015 to 2018. The email invitations were sent to 923 respondents and 79 completed surveys were received. This makes the response-rate as 8.55%. However, five of the received surveys were incomplete and were excluded from the data analysis process. Therefore, the total number of usable received survey responses was 74. The profile of respondents in this study is shown in Table 2. The respondents' years of work experiences was self-reported into four categories. Also, the respondents were categorized into three main areas of expertise and the remaining had different fields and were placed under one category as ‘other’. Furthermore, the respondents either worked for academia, industry, or both. The respondents’ levels of knowledge about ‘supply chain management’, ‘lean operations’, and ‘digital supply chains’ were also probed. Therefore, and based on the self-reported levels of knowledge the respondents had about these themes, it is fair to say that the respondents who completed this survey are knowledgeable about the examined themes and the perceptions they provided can be considered valid, reliable, and credible.

Table 2: Profile of Participants

	Question	Frequency (n=74)	Percentage (%)
Years of work experience in current field	• 1 - 5	13	17.56
	• 6 - 10	20	27.02
	• 11 - 20	19	25.67
	• 21 +	22	29.72
Field and main area of expertise	• Supply Chain and Operations Management	32	43.24
	• Lean Manufacturing	9	12.16
	• Manufacturing/production/logistics	19	25.67
	• Other	14	18.91
Sector	• Academia	52	70.27
	• Industry	10	13.51
	• Both	12	16.21
Level of knowledge – used scale (Low) 1 – 7 (High)		***Mean values***	
	• Knowledge of Supply Chain Management	5.66	
	• Knowledge of Lean Operations	5.46	
	• Knowledge of Digital Supply Chains	4.73	

The IBM Statistical Package for the Social Sciences (SPSS) version 24 was used to analyze the collected data in this study. First, statistical results will be presented in Table 4 about the 10 examined potential benefits. Second, the same statistical results are also presented in Table 5 for the 10 examined potential challenges. Item mean values, standard deviation, Cronbach’s alpha, and factor loadings were all calculated and presented for each examined survey statement and were included in the two tables.

RESULTS AND DISCUSSIONS

Reliability and Validity of Used Survey Constructs

Reliability is defined as the proportion of variance in observed test score that is related to true scores (Cronbach, 1951; McDonald, 1999; Lo and Yeung, 2006) of the scale items in the same construct (DeVellis, 1991; Hinkin, 1995). Therefore, Cronbach alpha values were used to examine the consistency and reliability of the items used in each of the two used survey constructs. As shown in Table 3, the Cronbach alpha coefficient values for the used potential benefits construct ranged from 0.895 to 0.903 (see Table 4 for all item values) and the potential challenges construct had values ranged from 0.655 to 0.715 (see Table 5 for all item values). Rivard and Huff (1988) suggest that Cronbach's values exceeding alpha coefficient of 0.7 thresholds provide reliability evidence for internal consistency of the measurement scales.

Although an acceptable reliable coefficient is normally 0.7 or higher, lower thresholds are sometimes used in the literature (Santos, 1999). For new instruments, constructs with reliability values as low as 0.5 are also acceptable (O'Leary-Kelly and Vokurka, 1998). The Cronbach alpha coefficient values for all the used items in the two used constructs were all above 0.655. Because the closer to 1 the Cronbach alpha coefficient value is, the more reliable the used construct becomes (Cohen et al., 2003), it can be concluded that the reliability of used survey constructs be considered as a reliable research tool. Therefore, we believe that each of the examined items under the two used survey constructs are adequate and provide a thorough picture of the examined benefits and challenges associated with supply chain digitalizing. Also, each of the used items, within each construct, is directly related to the main theme (either benefits or challenges) of the construct and all of the used statements are inter-related. Thus, we relate the high Cronbach alpha coefficient values of the two used constructs to these two main factors.

Table 3 Used survey constructs' validity and reliability tests results

Used Scale	Number of items	Items factor loadings ranges	Cronbach's α value ranges
• Potential benefits	10	0.486 to 0.633	0.895 to 0.903
• Potential challenges	10	0.577 to 0.795	0.655 to 0.715

Given the fact that the survey instrument used in this study was developed for this study and it had not been used before, an exploratory factor analysis (Principal Component) was used to examine its construct validity. This analysis helps to determine how, and to what extent, each item within the two used constructs is linked to their underlined factors (Yee-Loong Chong et al., 2009). Hair et al., (2006) state that the rule-of-thumb is that factor analysis values greater than 0.30 should be considered significant, values greater than 0.40 should be considered more important, and values that are 0.50 or greater should be considered very significant. As shown in Table 3, item's factor loading values ranged from 0.486 to 0.633 for the used 10 items under the potential benefits construct (see Table 4 for all item values). Also, item's factor loading values for the used 10 items in the potential challenges construct ranged from 0.577 to 0.795 (see Table 5 for all item values). With the exception of one item, under the used potential benefits construct, that had a factor loading value of 0.486, the remaining items within the same construct and all of the other 10 items within the potential challenges construct had factor loading values above 0.5. Therefore, the construct validity of the used two constructs in this study is very significant.

Results and Discussions for Potential Benefits

This research is looking at how digitalizing supply chains impacts the performance and management of supply chains. The research also seeks to identify key benefits businesses are likely to gain from such digitalization. 10 pre-determined potential benefits were examined in this study using a five-point Likert scale. The included 10 examined benefits statements in Table 4 were the used survey statements presented to the targeted respondents to respond to. As it is presented in Table 4, the highest rated potential benefit was 'improved visibility across chains and better traceability of process and products' with an overall mean value of 4.75. Enhancing supply chain visibility has been one of the capabilities that businesses continuously seek to improve, and it is very crucial to the performance of value networks (Busse et al., 2017; Maghsoudi and Pazirandeh; 2016). The adoption of different technologies within supply chains has a strong potential in improving the supply chain visibility and to provide businesses with traceability capabilities that further enhance the management of supply chains (Dubey et al., 2018; Raman et al., 2018; Srinivasan and Swink, 2018). Our research has confirmed the cruciality of digitalizing supply chain management on improving supply chain performance and management through more effective visibility capabilities.

The second top rated potential benefit was 'better information-sharing and supply chain integration' with a mean value of 4.49. It is important to mention that data and information are seen as crucial business assets and businesses continue to seek better ways to capture valuable data and, more important, analyze it to extract meaningful information that can help in making crucial business decisions. Without the use of smart and advanced technologies to capture and analyze data, such process would be very challenging. Thus, digital transformation and the adoption of different technologies, particularly within supply chains, helps capture and share data and information across the entire value chain that not only includes businesses, but it extended to included suppliers, distributers, retailers, and customers. In this study, we were able to confirm the importance of such benefit businesses would gain from more digitalization of supply chains. The third highest rated potential benefit was 'quicker responses to changes in demand' (mean=4.44) and the fourth top rated potential benefit was 'supply chains react more effectively to marketplace changes' (mean=4.42). The ability of businesses to effectively respond to ever-changing marketplace challenges is very crucial (Moyano-Fuentes et al., 2016). Businesses will need to create a good balance between responsiveness and efficiency (Hugos, 2018). Adoption of different smart technologies within supply chains is likely to improve companies' responsiveness capabilities (De Propris and Pegoraro, 2019; Kayikci, 2018). Our study confirmed the importance of such benefit to supply chain management. In the fifth place, respondents rated 'Better demand forecasting accuracy and optimization of ordering process' with mean value of 4.36. Big data analytics leads to better demand forecasts (Lee, 2017); leading retailers have been using point-of-sales data to optimize forecasting (Aryal et al., 2017). In this study, we confirmed the importance of digitalizing supply chains in helping companies plan more accurate demand forecasts and make better procurement decisions.

Table 4: Statistical results for examined benefits

Examined benefits	Mean	Std. Deviation	Cronbach's Alpha	Factor loadings	Rank	Impact on
Improved visibility across chains and better traceability of processes and products	4.75	0.619	0.902	0.486	1	Visibility
Better information-sharing and supply chain integration	4.49	0.71	0.898	0.535	2	Visibility
Quicker responses to changes in demand, effective inventory and logistics management, and reduction in supply chain complexity	4.44	0.687	0.896	0.607	3	Agility
Supply chains become able to react more effectively to changes in the marketplace	4.42	0.686	0.899	0.536	4	Agility
Better demand forecasting accuracy and optimization of ordering process.	4.36	0.674	0.895	0.633	5	Efficiency

Improved operational efficiencies, improved service quality, and greater resource efficiency.	4.34	0.731	0.9	0.52	6	Efficiency
Supply chains become more responsive to resolve supply chain-related operating problems, e.g., complex distribution problems	4.32	0.724	0.896	0.597	7	Agility
Supply chain designs become; flexible, open, agile, and collaborative	4.29	0.716	0.896	0.595	8	Agility
More effective delivery route planning and inventory planning	4.23	0.755	0.9	0.515	9	Efficiency
Enhanced employees' internal collaborations, communications, and engagement levels	3.85	0.938	0.903	0.517	10	Collaboration

The sixth, seventh, and eighth ranked potential benefits were 'Improved operational efficiencies, improved service quality, and greater resource efficiency' (mean=4.34); 'Supply chains become more responsive to resolve supply chain-related operating problems, e.g., complex distribution problems' (mean=4.32); and 'Supply chain designs become; flexible, open, agile, and collaborative' (mean=4.29). Technology trends such as Industrial Internet of Things and Industry 4.0 envision improved operational efficiency (Preuveneers et al., 2017); P&G and Wal-Mart had significantly improved operational performance through the use of Broadcast Driver Architecture and other IT tools (Pu et al., 2018). In this study, we further confirm the importance of digitalizing supply chains on improving supply chain's and organizational efficiencies. The ninth ranked potential benefit was 'More effective delivery route planning and inventory planning' (mean=4.23). The use of different smart technologies leads to better inventory management. For example, one of the key benefits from adopting blockchain technology is better inventory management without the need for double-verifications (Wang et al., 2019); use of RFID technologies has led to better inventory management (Nair and Anbuudayasankar, 2016). Therefore, there is a clear proportional relationship between the level of supply chain digitalization and inventory management improvement and this research has confirmed the importance of this benefit.

Finally, the tenth ranked potential benefit was 'Enhanced employees' internal collaborations, communications, and engagement levels' (mean=3.85). Digitalizing supply chains contributes to what is known as 'closed-loop supply collaboration' and the utilization of more digital technologies is likely to lead to a better collaboration performance. It is expected that more supply chain digitalization will strengthen the collaboration between members of the entire value networks. However, this potential benefit was ranked the least among the 10 examined potential benefits and perhaps further studies may investigate this point further.

Results and Discussions for Potential Challenges

The purpose of using this construct was to identify key potential challenges that businesses are likely to face when adopting more digitalization within their supply chains. 10 predetermined challenges were included in this construct and respondents were asked to report their level of agreement with the examined statements. The included 10 examined challenges statements in Table 5 were the used survey statements presented to the targeted respondents to respond to As Table 5 shows, the highest rated potential challenge was 'challenges related to integrating different systems across the networks with an overall mean value of 4.43. This remains as a key challenge related to technology diffusion that businesses continue to face when implementing new technological solutions into their business environments (Valmohammadi, 2016; Bröring et al., 2017; Haddud et al., 2017). In this study, we confirmed the importance of such a challenge and thus businesses need to be aware of this potential issue so that necessary actions are taken to overcome any possible integration challenges. 'Managing the transformation process from an existing company to its digitalized equivalent' potential challenge was rated as the top second challenge (mean=4.29). Transforming a traditional supply chain into a digital ecosystem is a complicated process that requires a lot of planning and execution strategies. In this study, this challenge seemed very crucial to the process of digitalizing supply chains and this goes in line with other studies indicating a similar challenge such as (Lavikka et al., 2017; Schallmo and Williams; 2018; Wiseman, 2019). Furthermore, 'Lack of robust preparation and understanding' can be seen as part of challenges associated to managing digital transformation and this challenge was ranked in the third place with a mean value of 4.22. Some businesses find themselves forced to react to a certain technological trend that necessitates acquiring certain technologies in order to catch up with other market leaders in adopting similar technologies. In some cases, some businesses may lack the required preparation and understanding of how to acquire and implement these new technologies. This is likely to cause difficulties in integrating the new technologies and may result in serious challenges. In this study, respondents perceived such a challenge as one of the top three challenges associated with digitalizing supply chains that businesses need to be aware of. The fourth ranked potential challenge was related to required financial investment from all supply chain players (mean=4.21). In order for supply chains to digitize in an effective manner, all the involved parties should possess certain technical capabilities that allow effective technology implementation and operations. Some parties, particularly smaller suppliers, may lack the financial and human skills required to invest in new emerging technologies (Martinsuo and Luomaranta, 2016) and such technical improvements can lead to huge financial burdens (Kumar and Shoghli, 2018).

Table 5: Statistical results for examined challenges

Examined challenges	Mean	Std. Deviation	Cronbach's Alpha	Factor loadings	Rank	Challenge core source
Challenges related to integrating different systems across the network	4.43	0.601	0.696	0.645	1	Technology diffusion
Managing the transformation process from an existing company to its digitalized equivalent	4.29	0.615	0.704	0.613	2	Technology diffusion
Lack of robust preparation and understanding	4.22	0.755	0.715	0.577	3	Human factor
Required financial investments from all supply chains players to design and deploy technologies and solutions necessary to digitize supply chains.	4.21	0.838	0.706	0.749	4	Technology diffusion
Employees' resistance to new technologies and practices	4.06	0.82	0.692	0.795	5	Human factor
Challenges with supply chain management integration requirements.	4.04	0.701	0.658	0.679	6	Technology infusion

Access to/ availability of the required skilled human resources	3.94	0.837	0.682	0.739	7	Human factor
Risks and variabilities that may arise from the use of ecosystems	3.85	0.744	0.664	0.649	8	Technology infusion
Diversity of adopted business models within the different supply chain entities and organizations.	3.76	0.864	0.703	0.651	9	Business models
Supply chains in general not ready for such a change and lack the required architecture	3.69	1.002	0.655	0.647	10	Business models

In the fifth place came the potential challenge of ‘Employees’ resistance to new technologies and practices’ (mean=4.06). By default, employees are resistant to change particularly when they are comfortable with what they do, and because any change would require changing their routine. Employees’ resistance to change has been identified as one of the key challenges related to supply chain initiatives (Wiseman, 2019). This study has confirmed the importance of such a potential challenge to change so that businesses take this into account when planning more digitalization of supply chains. The sixth ranked potential challenge was ‘challenges with supply chain management integration requirements’ (mean=4.04). Supply chain integration refers to integrating regional supply chains into an integrated global supply network (Agrawal and Narain, 2018). Digitalization of information flows and system integration makes it much more challenging in terms of data security and protection of intellectual property (Wei et al., 2019). Therefore, in this study, we confirmed this challenge and believe that supply chain digitalization processes will likely face a similar challenge and businesses should consider this carefully before embarking on any new digitalization initiatives.

The remaining four potential challenges had mean values below 4.0. These results imply that these examined potential challenges are not crucial anymore. For example, ‘Access to/ availability of the required skilled human resources’ had a mean value of 3.94 and perhaps the reason why this potential challenge was ranked relatively low was because the marketplace has seen entrance of more skilled human resources due to universities and other educational institutions had introduced programs that equip graduates with the necessary skills required for todays’ technology sectors. Furthermore, in the eighth place, ‘Risks and variabilities that may arise from the use of ecosystems’ had a mean value of 3.85 and we think this is because more businesses are using ecosystems and it is becoming a norm rather than a ‘feared hype’. In the ninth place, ‘diversity of adopted business models within the different supply chain entities and organization’ had a mean value of 3.76. Most businesses follow common business structures that fit the nature and size of their business and these do not differ greatly from the business models of other business partners. Thus, any supply chain digitalizing initiatives implemented across the same value chains are not likely to face a challenge related to business models compatibility.

Finally, the least perceived crucial potential challenge was ‘supply chains in general not ready for such a change and lack the required architecture’. This result was no surprise because many businesses have implemented some degree of technological solutions within their supply chains. Embracing more emerging technologies usually builds on existing capabilities and infrastructures and this was not perceived to be a major challenge to more digitalization of supply chains.

CONCLUSIONS

Concluding Remarks

The two main themes of this paper were; 1) identifying key potential benefits from digitalizing supply chains; and 2) identifying key potential challenges associated with digitalizing supply chains. The results revealed that businesses may gain the following main benefits: 1) Supply chains become more visible and this leads to better processes and products traceability. 2) digitalizing supply chains leads to better information-sharing and supply chain integration. 3) supply chains become able to react more effectively to changes in the marketplace that allows quicker responses to changed demand through better demand forecast. 4) digitalizing supply chains improves overall operational efficiencies. 5) more effective inventory management and supply chains become more flexible. As indicated in Table 4, these benefits have direct impacts on supply chain's; agility, efficiency, visibility, and collaboration.

On the other hand, digitalizing supply chains is likely to face several potential challenges that may include: 1) challenges related to integrating different systems across the network. 2) difficulties with managing the transformation process and lack of robust preparation and understanding. 3) investing in new technologies may lead to financial burden for small businesses. 4) employees' resistance to new technologies and practices. 5) supply chain management integration requirements. As indicated in Table 5, these challenges can be categorized into four main groups; technology diffusion, technology infusion, business models, and human factor.

Recommendations

It is recommended that businesses continue to explore the benefits that emerging technologies would bring to their current supply chain structures and operations and decide what technologies to acquire. By using the identified 10 potential business benefits in this study, businesses can identify the business areas that require improvements and then decide what technologies to adopt. On the other hand, it is very important that decision makers be aware of the associated potential challenges that are likely to face when embarking on supply chain digitalization initiatives so that necessary measures are taken in order to avoid the occurrence of any of these challenges and to ensure a smooth implementation and management of new technologies.

Future Research Suggestions

It is recommended that similar studies are conducted to explore the impact of digitalization on other business functions to further identify where more technologies can be adopted within businesses and to further identify any possible challenges associated with the process. It is also recommended that similar research studies are conducted as case studies exploring similar aspects on companies that have greatly invested in technology adoptions and that are market leaders in this field. It is also important to learn aspects related to implementing digitalization initiatives and to identify key best practices. Furthermore, our study explored potential benefits and challenges related to digitalization of supply chains and we recommend that other studies are conducted to explore the development of digitalization frameworks that help businesses with the implementation and management of new technologies. More importantly, to explore how to actualize and maximize the benefits and to minimize the challenges. It would be interesting to survey a larger sample size and perhaps use more open-ended questions where respondents can report other potential benefits and challenges in addition to the predetermined ones in this

study. We believe that it would also be interesting to replicate the study across different industries and sectors to gauge if there are any key similarities or differences with how businesses approach digitalization initiatives.
Finally, digitization allows for more accurate tracking of parts and processes. While here we look at the supply chain moving in one direction, a bigger topic of “de-manufacturing” can be researched which looks at the complete life cycle of a product. This will contribute to closer analysis of green supply chains.

ABSTRACT

With the advent of digital technologies, digitalization is no more an option for firms but a compulsion for survival. The extant practitioner and academic literature frequently state the confusion on how successful digital transformation of firms should take place. Hence, it is important to identify the specific organizational and technological elements which need to be fortified to achieve digitalization. This study proposes a Digitalization Maturity Model (DMM) and identifies six organizational dimensions critical for a successful digital transformation which mature across four stages. The proposed framework will be validated from practitioners through semi structured interviews and an updated version will be finalized after incorporation of suggestions and feedbacks. The final maturity model will provide firms a comprehensive digital strategy for their successful digital transformation.

KEYWORDS: Digitalization, digital transformation, maturity model

INTRODUCTION

The next big thing for the business world is the rise of digital technologies and their diffusion in companies which is consequently changing the traditional business landscape. Digitalization refers to “the integration of digital technologies to transform activities, processes, actors, and goods from analogue to digital to facilitate new forms of value creation” (Hagberg et al., 2016). Value creation by these technologies can be leveraged when the firm has a clear and well-designed digital strategy. This digital strategy is crucial for firms as it directs them towards the right path and guides them about the appropriate set of actions which need to be carried out to achieve digitalization (Hess et al., 2016). Existing studies mention the use of relevant technologies (Liao et al., 2017; Rüßmann et al., 2015) and their benefits (Cenamor et al., 2017; Gunasekaran et al., 2018; Hannola et al., 2018) yet, is scarce on the guidance of its realization and implementation of digital strategy in firms (El Sawy et al., 2016; Hess et al., 2016). The shift in role of employees, changes in organization structure, enhancement of skills and competences, emergence of systems thinking and an alignment of the IT-business strategies call for a new way of strategizing (Lee et al., 2012; Tripsas, 2009).

The extant literature repeatedly mentions the need of an implementation framework of digital technologies (Strozzi et al., 2017). The lack of clarity in terms of the firms digital transformation journey has been mentioned in several studies (Horváth et al., 2019; Yeh et al., 2018).

Zangiacomi et al. (2017) states that the digital transformation of an organization is a complex process and the lack of clarity about the elements involved can result in failed transformations. The specific aspects which need to be focused, what capabilities shall be developed, which competences are required and which organizational form shall best serve the digital transformation need to be investigated and identified (El Sawy et al., 2010; Kahre et al., 2017; Wu et al., 2016). Firms require guidelines as to which set of tasks, activities and technologies they should focus on in order to achieve digitalization (Boutetière et al., 2018; Breunig et al., 2016; El Sawy et al., 2016). Keeping in view this important research gap this study aims to answer the following research questions:

RQ1: What are the different stages of the digital transformation journey an organization goes through?

RQ2(a): What are the critical organizational factors which are modified at each stage of the transformation journey?

RQ2(b): What changes need to be made in the organizational elements to lead a successful digital transformation?

The maturity model we propose intends to identify different hierarchical progression stages for all firms which lie on the continuum from traditional state to digitalized state. This study aims to provide firms with a guideline for their transformation to the digitalized state. The aim is to identify those dimensions or aspects of digitalization which need to be focused and developed so that a firm achieves digital maturation. The need for a maturity model is of critical importance at this point in time as firms are in need to know a systematic evolution path which would guide their digital transformation (Kane et al., 2015). Maturity models serve as an assessment tool where firms can assess their current state and take guidance on their to-be state through the evolution shown (Becker et al., 2009).

LITERATURE REVIEW

The importance of Maturity Models has been well versed in the extant literature. MM aids in the transformational journey of organizations providing them with a stepwise pathway towards their final goal. They serve as assessment and improvement tools which provide an as-is picture of the firm and also the way forward. It is a framework which describes the evolution of a particular concept across different levels. The different levels represent the extent of sophistication and maturity for each particular knowledge area (Guédria et al., 2015). These knowledge areas vary according to the domain being studied and are derived from the relevant literature. This multistage development serves to provide a guideline for effective hierarchical progression which cannot be undone or reversed easily (Poeppelbuss et al., 2011).

The concept of MM has been mostly used in the IS literature for describing the maturity of different concepts in the field. A few examples are the Nolan's Growth Stage Model (Nolan, 1973), Capability Maturity Model (CMM) (Paulk et al., 1993), Business Process Management Maturity Model (BPMM) which was a variation of the CMM and focused on how firms could achieve excellence in their business processes (De Bruin et al., 2005; Röglinger et al., 2012; Tarhan et al., 2016). Since then, a lot of work has been done in different disciplines which study and propose the maturity of different aspects such as supply chain management maturity (Lockamy III et al., 2004), IT-Business alignment maturity (Luftman, 2004), e-business maturity (Gottschalk, 2009), e-government maturity (Andersen et al., 2006; Darem et al., 2010; Kim et al., 2010), Interoperability maturity (Guédria et al., 2015), IT architecture maturity (Eckhardt et al., 2014; Ross, 2003), IS/ICT management maturity (Curry et al., 2012; Renken, 2004), Enterprise Resource Planning System use (Holland et al., 2001; Nightingale et al., 2002) and informatics capability (Cosic et al., 2012; Liaw et al., 2017). The operations and supply chain literature has not appreciated the use of maturity models and therefore has a dearth of such studies. Only a few studies use the maturity model concept and describe the maturity of supply chain management processes (Lockamy III & McCormack, 2004) and maturity of supply chain analytics in logistics management (Wang et al., 2016).

Maturity Models and Digitalization

In light of the above maturity models, this study proposes a digitalization maturity model and highlights the essential elements which play a pivotal role in the digital transformation. Digitalization refers to the "integration of digital technologies to transform activities, processes, actors, and goods from analogue to digital to facilitate new forms of value creation" (Hagberg et al., 2016). The business world of today competes in the ability of firms to utilize the relevant information and create value out of it. On part of the firms, this requires the right strategies and the right mix of people, processes, technologies and organization design, all of which complement one another to achieve the desired value (Yeow et al., 2018). The new era requires new digital capabilities which aid in making use of digital technologies and extracting benefit from them.

In the realm of digitalization, a few industry reports have proposed different variations of maturity models for the digitalization of businesses (Deloitte, 2018; Leadership, 2019; Solis et al., 2016; tmforum, 2019). Similarly, a conference article by Shahiduzzaman et al. (2018) also talks about the maturity of digital businesses. These studies have identified a multitude of basic dimensions which are important for digitalization by providing a birds-eye view of the changes these dimensions go through. However, these studies are descriptive and do not provide enough guidance about the stages of digital maturity for a business. The proposed Digitalization Maturity Model (DMM) provides insights on the dimensions, stages of progression and the cumulative nature of value created and capability development at each stage of digitalization.

Methodology

The methodology for this study consists of two parts. In the first part, the literature on the maturity model and digitalization is reviewed to propose a Digitalization Maturity Model. While the second part will cater the validation of the proposed maturity model. Description of both the parts is given below.

1. Proposing a Digitalization Maturity Model

The aim of this study is to develop a maturity model for the digitalization of organizations which could guide firms in their digital transformation journeys irrespective of which level the firm is at. We aim to propose strategic guidelines for transformation which could help digitally naive firms, firms with mediocre digital proficiency or firms which are about to reach their digital maturity. The two important components of the maturity model i.e. levels and dimensions are literature driven and are specific to each domain (Van Looy et al., 2013). The dimensions for the maturity model were finalized based on the review of digitalization and maturity model literature. A similar approach has been followed in earlier studies of maturity model development (Gottschalk, 2009; Guédria et al., 2015; Holland & Light, 2001; Kim & Grant, 2010; Rosemann et al., 2004).

The selection of dimensions for a maturity model depends on the specific discipline which is being studied. The literature on that discipline informs about the factors which are crucial for its development and progression (Pöppelbuß et al., 2011). The two major benchmark maturity models which serve as a guide for others are the Capability Maturity Model and the Business Process Management Maturity Model. Studies in the IS domain usually follow the CMM while in management literature the BPMM is usually followed. The dimensions can be segregated into the technology-related dimensions and non-technology related dimensions.

However, these dimensions are yet to be identified for the digitalization of organizations and their hierarchical trajectory needs to be investigated. The adoption of digital technologies does not assure a firms digitalization rather it's the collection of different resources and activities which need to be orchestrated such that the firms' objectives are achieved (Loonam et al., 2018; Sirmon et al., 2011). Multiple studies have proposed infrastructure, technology, people & skills, organization changes, strategy and culture as the most important dimensions which aid in shaping the digitalization of firms (Ardolino et al., 2018; Brettel et al., 2014; Brynjolfsson et al., 2000; Gölzer et al., 2017; Kamble et al., 2018; Li, 2018; Oswald et al., 2017; ÖZTÜRK, 2017; Wulf et al., 2017). The aforementioned studies provide guidance and a direction for digital transformation of firms and inform the critical aspects which need to be developed and enhanced to achieve digitalization.

2. Model Validation

To test the proposed DMM we will conduct structured interviews with practitioners from industry. These practitioners will be from the top management of firms who are involved in the strategic decision making and digital transformation of their firms. As the model is not constrained to a specific industry and can be applicable to all types of organizations. We intend to conduct interviews with 15-20 managers belonging to the Manufacturing Sector, Banking, Telecommunication and Software Industry. We will use the snowball approach to identify respondents suitable to validate the proposed DMM. The managers will be given the model and explained the transformation from Level 1 to Level 4 across all dimensions and asked if the model applies. The suggestions and recommendations from these managers will be incorporated in the proposed model to come up with a final version of the DMM which will incorporate industrial feedback and validation. If necessary, NVIVO software tool will be used to segregate and categorize the content of interview feedback.

DIGITALIZATION MATURITY MODEL

The DMM we propose constitutes of four levels of maturity across six dimensions derived from the review of digital transformation and maturity model literature which has been mentioned above. Based on the aforementioned factors, we select the dimensions of our Digitalization Maturity Model (DMM) to be Human Capital, Organization structure, Operations, Digital Technology, Intra-enterprise integration and Data. A brief description of each of the dimensions is given below. A level-wise description of each dimension and how it evolves is given in table 1.

Dimensions of Digitalization Maturity

Human capital is defined as "the knowledge that employees take with them when they leave the firm, including individual knowledge, skills and abilities" (Kim & Grant, 2010). Human Capital is a crucial element for any change management journey as employees are the ones who must manage the change and adapt according to the transformation requirements. *Organization Structure* depicts the "power and responsibility structure formed in the managing process" (Ramezan, 2011). The organization structure plays a critical role in leveraging the use f its resources which are cumulatively at work to create value for the firm. *Operations* are defined as "the set of activities that creates value in the form of goods and services by transforming inputs into outputs" (Heizer et al., 2017). As the firm evolves and adapts to the changing market dynamics the way operations are conducted within an organization also changes. *Digital Technology* refers to those technologies which characterize the digitalization era such as Internet of Things, Additive Manufacturing, Cyber-Physical systems, Cloud and Big Data Analytics (Rüßmann et al., 2015). *Intra-Enterprise Integration* is represented as “the systems being connected, data is shared in the organization, applications can interoperate and the business processes are coordinated with IS and other processes” (Giachetti, 2004). *Data* is defined as “elementary descriptions of objects’ properties (e.g. activities, events and/or transactions) generated by observation with different forms” (Ardolino et al., 2018).

Levels of Digitalization Maturity

Level 1 - Computerization is defined as the use of computers and telecommunication technologies in organizations which changes the roles & responsibilities and levels of organizational efficiency (Kraut et al., 1989). It enables firms to carry out minor and very basic tasks with the help of the internet and few computers in the organization.
Level 2 – Interaction depicts the upgradation of the technology and characterizes the interaction the new technology initiates among the different levels of the organization. The technology at this level facilitates connectivity and interaction within and between hierarchical levels.
Level 3 – Integration depicts the use of technologies which facilitate decentralization in organizations and enable integration. The functional silos eliminate, and the processes of each department become interdependent.
Level 4 – Continuous Improvement is the final stage of the maturity model depicts the digitalization of the firm and is characterized by defined and repeatable processes which are highly dependent on IT systems in the firm. This stage is characterized by the conversion of raw data into actionable information with the help of analytics capability and technology. The IT systems in the firm develop the ability to foresee internal and external changes and respond proactively. Similarly, the employees at this stage are specialized in their specific knowledge domains and are always at an outlook of improving processes and taking technological initiatives for the betterment of the firms' survival and profitability.

Levels / Dimensions	**Level 1** ***(Computerization)***	**Level 2** ***(Interaction)***	**Level 3** ***(Integration)***	**Level 4** ***(Continuous Improvement)***
Capability	Uninterrupted Routine Tasks - Traditional way of work	Connectivity - Technical interconnectivity	Visibility - IT capabilities leveraged	Digital Dexterity - Business intelligence
Digital Technology	Internet - Traditional state with minimal technology	Internet of Things - tags, sensors, RFID start being used for specific tasks	Cloud Computing - Cloud serves as a data storage mechanism	BDPA - Utilization of data through different tools
Human Capital	Digital Novice - Production workers/frontline workers - High cynicism	Digital Competent - Problem Solvers - Gain knowledge and skills for technical initiatives	Digital Proficient - Employees are able to manage machine and systems	Digital Expert - knowledge workers - Data scientists and software engineers
Operations	Mechanized - Mostly manual operations	Islands of Automation - IT incorporated in business processes to some extent	Initial Digitalization - Majority tasks and processes are automated	Digitalization - Automatic monitoring of processes

Gillani et al., Digitalization Maturity Model

Data	Data Generation - Information generation is minimal - No storage	Data Acquisition - Data acquired from web and other sources - Data transmitted to some adhoc storage	Data Storage - Processes for data storage and processing - Information generated in the organization is digitized	Data Analysis - Data is inspected, transformed and analyzed to extract value from it
Organization	Mechanistic - Higher levels of hierarchy - Vertical decision making	Coordination - Coordination between departments increases for technical issues	Decentralization - Cross functional teams are formed - Decision making allocated to subunits to some extent	Organic - Employees are empowered - Data driven culture - Minimal hierarchy
Intra-enterprise integration	Network Level - Physical heterogeneity of machines or devices - Integration goal in connectivity	Data Level (vertical integration) - Integration goal is data sharing between subsystems and organizational units	Application Level (horizontal integration) - Integration goal is interoperability	Business Process Level - Tight business integration is achieved - Applications support
Value Created	Local Optimization - optimize a specific task	Interoperability - IT efficiency - Reduced cost	Integration - Process optimization	Strategic Agility - Speed to market - responsiveness

ABSTRACT

This study identifies best practices for the operational implementation of data analytics in manufacturing. Case studies from literature and personal research are evaluated to find potential areas where useful practices have been observed. The results show that best practices can be identified in analytics architecture, interdisciplinary communication, and systems modeling.

KEYWORDS: Best practices, manufacturing analytics, system modeling, interdisciplinary communication, analytics architecture

INTRODUCTION

Data analytics has become a major source of competitive advantage in many industries. The concept of Analytics Capability has been defined as an important strategic resource to improve operational performance (Srinivasan & Swink, 2018). Usually big data architectures, algorithms and methods are regarded as generally applicable, once the data have been transferred into the analytics applications' data stores. Sensors are seen as a source of big data, as well as web pages, log files, e-mail, and documents (Katal et al. 2013). The manufacturing industry in particular is the focus of numerous activities when it comes to the extraction of valuable information from data collected at the shop floor (Rameshwar et al. 2019). However, the manufacturing domain differs from other domains particularly due to the following characteristics (Wunck & Baumann, 2017):

- The machines, tools and devices, i.e. the physical representations of the data sources, can have an expected useful life of more than 30 years.
- Due to the long operating life, manufacturers need a migration path to implement innovative applications without being forced to prematurely renew their machines.
- Legacy machines need to be upgraded with additional sensors, processors and interfaces. This upgrade process is known as a retrofit process.

Other important characteristics of manufacturing systems are:

- Manufacturing systems have been expressly designed for a purpose. Causal relationships between system objects are usually clear and need not be rediscovered by analytics algorithms.
- Manufacturing systems have a distinct boundary between the physical processes themselves and the logical event stream derived from process behavior. The physical

processes transform material and energy during a certain timespan and can be modeled by differential equations, while changing conditions in the processes or external stimuli are best modeled by discrete events. Data analytics applications should exploit this wealth of a-priori-information rather than discard it.
- The ubiquitous availability of cheap IoT (Internet of Things) devices with integrated sensors, processors and wireless networking gave rise to a multitude of small engineering startups offering retrofitting services for traditional manufacturers. Many of these engineering firms have a strong background in computer science, but lack profound knowledge from both digital signal processing and manufacturing engineering.
- Domain specialists such as manufacturing engineers need to verify requirements for analytics software written by data scientists with a computer science background. This process is difficult as both parties have different viewpoints on a manufacturing system.

When it comes to applications like data mining or knowledge discovery, the strong physical foundation of manufacturing processes requires certain precautions, which oftentimes are not known to data scientist coming from the enterprise or business intelligence domain. This study aims to outline some of the necessary preconditions for data analytics implementations in manufacturing to be successful.

LITERATURE REVIEW

The literature review focuses on data analytics implementations in the manufacturing domain and aims to identify potential knowledge areas that are unique as compared to other application domains.

Common applications for knowledge discovery and analysis in manufacturing include (Polczynski & Kochanski, 2010): Detection of root causes of deteriorating product quality, identification of critical and optimal manufacturing process parameters, prediction of effects of manufacturing process changes, and identification of root causes and prediction of equipment breakdown. Works by Gröger et al. (2012) find data mining applications in manufacturing limited to quality analysis, failure analysis, maintenance analysis, and production planning analysis.

A conceptual architecture for data-driven manufacturing process optimizations is proposed by Gröger et al. (2012). Their Advanced Manufacturing Analytics Platform comprises three layers, data integration, process analytics, and process optimization. This corresponds roughly to the three layers of data discovery, data integration, and data exploitation suggested by Miller & Monk (2013). For generic IoT applications, a model with five layers, sensor, gateway, middleware, application, and business has been proposed (Wu et al. 2010). Wunck & Baumann (2017) introduce an architecture model from the perspective of value added by information processes. Their IVCOR model is adapted from the SCOR process model and utilizes the analogies between physical products and information products.

Rabelo et al. (2003) emphasize the strong connection between systems dynamic modeling by differential equations and discrete event modeling supply chain simulations. Their hybrid modeling approach for supply chain simulation combines dynamic and discrete system models, which is a modeling approach also useful for localized manufacturing systems. Castillo & Smith (2002) review various formal modeling methodologies for control of manufacturing cells. They conclude that language-based methodologies (e.g. process algebra, temporal logic) are not friendly to potential users, as these are more abstract than machine-based methodologies (e.g. finite automata, Petri nets). Negahban & Smith (2014) focus on the application of discrete event simulation to a broad and extensive range of manufacturing system design and operation problems.

The following references illustrate a broad range of data processing methods. Sun et al. (2018) combine sophisticated signal processing algorithms (compressed sensing) with deep learning to monitor and predict the condition of bearings in rotary machinery systems. They present an innovative method for automatic feature extraction and classification, which traditionally is a tedious manual process. Their method uses raw sensor data, sampled according to the Nyquist-Shannon sampling theorem. Zhang et al. (2018) propose a generic data analytics system for manufacturing production. They address small manufacturers who cannot afford a professional data analytics team. Users are not expected to have prior knowledge or experience in data analytics. Mulrennan et al. (2018) model plant energy profiles from historical production schedule data. The data is stored in various sources and does not conform to a common sampling rate or data type. Evans & Boreland (2018) present a study aimed to demonstrate statistical models that can identify variance components in photovoltaic manufacturing. Kibira et al. (2015) integrate data analytics and simulation methods to support manufacturing decision making. They discuss various standards that might support manufacturing analytics at different levels to measure, collect, represent, and exchange data. Sardana et al. (2015) predict the health of a spindle and its bearings using fast fourier transform analysis and a graph clustering algorithm. A wavelet-based method for feature extraction in injection molding is described by Wunck (2017).

Katal et al. (2013) recommend good practices on a very abstract level for big data applications regarding data dimensions, unique keys, data structure, data access technology, privacy concerns, data quality, scalability, and interdisciplinary cooperation. Best practices for managing predictive models in a production environment are summarized by Chu et al. (2007) from the perspective of a software company.

IMPLICATIONS

Based on the findings in the literature and various industry projects carried out by the author, several candidate areas for best practices have been identified. For each area, recommendations and explanations are given.

Analytics Architecture

It is a common characteristic of current Big Data concepts to assume that all data generated by data sources (e.g. sensors in manufacturing) will be transported to cloud storage before any data processing is performed (Wunck & Baumann 2017). Apart from performance issues, this practice contravenes one of the most important engineering principles: the principle of abstraction. Abstraction applied to data analytics implies the existence of layers with different algorithmic tasks corresponding to physical layers in the manufacturing system.

In the physical layer, signals are the dominating data source. Many important signals are analog signals read by suitable sensors. Equidistant sampling as mandated by signal processing theory (e.g. Nyquist-Shannon theorem) yields highly redundant data streams. Sampling in longer time intervals however bears the risk of falsified data due to aliasing effects.

<u>Proposals:</u>

- Data analytics should follow an architecture model that takes into account the different time scales, real time requirements and data volumes in manufacturing systems. Useful layers in an architecture model are the signal layer and the event layer. Signals are processed according the principles of digital signal processing, events are derived from signals and are processed in a higher layer.

- Sensor signals from analog process variables should be sampled with the lowest possible sample rate that conforms to the laws of digital signal processing. After sampling, a data compression method should be applied to the sampled data (e.g.wavelet-based compression or other methods based on orthogonal transformations).

Interdisciplinary Communication

According to Katal et al. (2013), business leaders and IT leaders should work together to yield more business value from the data. While this is certainly true, the interdisciplinary communication in the manufacturing domain requires more than goodwill of the stakeholders involved. The manufacturing domain specialists may be viewed as the customers of an analytics service to be delivered by the data scientists. It is the customers' task to validate the requirements posed on the analytics programs to be developed. If the requirements are phrased as domain requirements, a great risk of misunderstanding on the developers' side exists. If the requirements are too formal, the customers are likely to not validate the requirements correctly. Formal specification, though, is a valuable tool towards fault analysis and error-free implementation, both of which are crucial in manufacturing. As was stated by Castillo & Smith (2002), formal methods such as finite automata are more understandable for manufacturing engineers than other formal methods. Timed regular expressions (Wunck 2015) and domain specific languages (Wunck 2016) turn out to be helpful in bridging the gap between manufacturing domain requirements and formal specifications.

<u>Proposal:</u>

- Requirements for analytics tasks should be specified using a formal approach that is both understandable to manufacturing engineers and useful for analytics implementations.

System Modeling

Manufacturing systems can be modeled either on a physical level (differential equations or similar tools) or on an event stream level. Due to the widespread use of sensor-equipped IoT devices, the physical level and the system dynamics associated with it become more important. Once analog values from physical process variables are used as data sources for analytics programs, sampled system laws such as the Nyquist-Shannon theorem must be observed. This includes the careful design of the measuring chain regarding eigenfrequencies of the systems and cutoff frequencies of low pass filters. Otherwise measured values might be falsified, leading to false conclusions later on.

Many physical processes in manufacturing are feedback-controlled. Some controller algorithms switch to different control strategies during different phases or segments of the process. If analytics is applied using raw sensor data from a process, it might be helpful to precisely identify those segments and apply individual algorithms tailored to the respective segments. For example, in injection molding the machine's screw velocity is under closed-loop control during injection, while in the holding/cooling phase the machine switches to closed-loop control of hydraulic pressure. Usually, different sample rates are used for the different segments (Wunck & Ruoff, 2016).

Engineering control theory sets great value on the stability of computer controlled systems. Stability means that a system's output experiences only small deviations when its inputs are changed by a small amount. System dynamics and thus stability can be modified by feedback loops. Feedback of information might threaten system stability and must therefore be carefully analyzed. Unstable systems have a tendency to oscillate. Measures to prevent unwanted oscillation are damping the system to reduce its response times. The well-known bullwhip effect observed in distribution channels and supply chains is an example of an unstability in a system of firms.

Proposals:

- Manufacturing systems should be modeled using a hybrid approach, which takes into account both the dynamic properties and the discrete event stream.
- Physical manufacturing processes should be partitioned into segments with different sample rates or control strategies before applying analytics at a higher level.
- Analytic procedures that seek to compensate observed deviations by feedback must be carefully analyzed regarding system dynamics and potential instability.

DISCUSSION AND CONCLUSIONS

This paper presented an attempt to collect some best practices for manufacturing analytics. These might be helpful for both domain specialists and analytics implementers. Analytics methods and algorithms are indeed generic and universally applicable. However, the manufacturing domain has some intricacies that must be taken into account for analytics projects to deliver on their promises. Future works might be directed to identify additional areas for best practices in manufacturing.

ABSTRACT

This paper investigates how bank CEO risk-taking incentives influence bank lending decisions. Consistent with the existing CEO incentive literature, we find that CEOs with higher risk-taking incentives (vega) tend to relax their lending standards in bank loan contracts to pursue higher compensation. We find that banks with a high vega tend to charge a significantly lower loan spread, demand fewer loan covenants, and have lower probability to seek collateral. Results become weaker when banks have strong corporate governance mechanisms, supporting the proposition that high CEO risk-taking incentives may create an agency problem between a bank manager and shareholders.

KEYWORDS: CEO incentives, Bank loan contracts, Corporate governance, Agency problem.

INTRODUCTION

Managerial risk-taking behavior in both financial and non-financial firms has been an attractive focus for the lens of many researchers (Hubbard and Palia, 1995; Houston and James, 1995; Knopf, Nam and Thornton, 2002; Coles, Daniel, and Naveen, 2006; Chen, Steiner and Whyte, 2006; Acharya and Naqvi, 2012). Excessive CEO risk-taking in the financial sector especially has been blamed for playing a crucial role in the build up to the 2008-2009 financial crisis. Acharya and Naqvi (2012) develop a theoretical model to show that bank over-lending may result from managers' desire to receive higher compensation in the presence of an agency problem between a bank manager and shareholders.

Other studies have revealed a positive correlation between option compensation and risk-taking incentives, thus increasing bank risk taking and bank-specific default risk (Jeitschko and Jeung, 2005; Mehran and Rosenberg, 2007; Balachandran, Kogut and Harnal, 2010; Bebchuk, Cohen and Spamann, 2010; Fahlenbrach and Stulz, 2011; Hagendorff and Vallascas, 2011). For example, Coles, Daniel and Naveen (2006) suggest that the higher vega gives executives incentive to implement more aggressive debt policy and invest more in riskier assets (e.g. R&D). Similarly, DeYoung, Peng, and Yan (2013) show that banks in which CEOs have high risk-taking incentives (high-vega banks) exhibit substantially larger amounts of both systematic and idiosyncratic risk. Although recent studies have confirmed that CEO risk-taking incentives increase bank risk exposure, whether such exposure affects bank lending decisions has not to date been examined. Specifically, in this paper we investigate the effects of bank CEOs' risk-taking incentives (vega) on bank loan contracting.

Our paper focuses on private debt financing for several reasons. First, the bank loan market has become a predominant source of external funding in the US (Chava, Livdan and Purnanandam, 2009; Graham, Li and Qiu, 2008). Second, a large number of scholars have discussed the determinants of bank loan contracts, such as borrower reputation (Sufi, 2007), borrower accounting quality (Bharath, Sunder and Sunder, 2008), anti-takeover provisions (Klock, Mansi and Maxwell, 2005), and board quality (Fields, Fraser and Subrahmanyam, 2012). Third, the capabilities and incentives of banks to collect information and monitor borrowers are significantly better than those for public bondholders or investors (e.g., Fama, 1985; Diamond, 1984; Roberts and Sufi, 2009; Roberts, 2015).

We attempt to answer the following four questions regarding the vega effects on bank loan contracts: (i) Do banks with higher vega charge lower interest rates on loans?; (ii) Do vega effects on bank loan contracts also exist in non-price terms?; (iii) Are vega effects eliminated by strong corporate governance mechanisms?; and (iv) Do vega effects still hold after adjusting for other CEO compensation schemes and CEO characteristics?

We evaluate these questions by using a sample of 20,502 loans to 5,102 U.S. firms between 1992 and 2014. We obtain all accounting variables and stock prices from the Compustat database and the Center for Research in Security Prices (CRSP). Corporate-governance and CEO-compensation-related variables come from RiskMetrics and ExecuComp. We collect bank loan data from the DealScan database. Empirical results indicate that CEO risk-taking incentives in term of vega are significantly and negatively correlated with bank loan spread. That is, with high CEO vega incentives, banks charge lower interest rates on loans after controlling for lender and borrower characteristics, macroeconomic factors, and other loan conditions. The evidence remains strong when we control for industry and year fixed effects, loan purpose and type, as well as for CEO characteristics. For example, banks with higher vega will charge a 1.5642 lower basis-point ($e^{0.0199} \times 1.5334 = 1.5642$) loan spread per each one-standard-deviation increase in vega. As the average loan spread in our sample is 142.4940 basis points ($e^{4.9593}$), a one-standard-deviation increase in vega lowers a firm's bank loan interest rate an average of 1.1 percent ($1.5642 \div 142.4940 = 1.1\%$). Furthermore, a lower 1.5642 basis point of loan spread is around 36 percent of the estimated coefficients for the effects of corporate tax avoidance and of social capital in Hasan et al. (2014, 2017). Accordingly, this effect of bank CEO risk-taking incentives on loan spread is not only statistically significant, but is also economically important.

We further find evidence that bank managers with high vega tend to impose fewer covenants on loans (especially general covenants) and are less likely to require collateral. All our main results are statistically and economically significant and are robust to specifications with different sets of explanatory variables (namely, lender, borrower and loan characteristics, and macroeconomics).

In further testing, we examine in greater detail whether the effect of CEO vega derives from the agency cost channel. We argue that, if CEO vega is viewed as a representation of agency cost, then its effect would be outweighed when bank corporate governance quality is weak. Our results provide supportive evidence for this governance channel, confirming that our main findings of a vega incentive effect are driven primarily by banks with weak corporate governance. Hence, our results suggest that the influence of CEO vega derives from an agency problem between bank managers and shareholders.

We further investigate whether banks with high vega would react differently to borrower creditworthiness assessments when a firm takes greater risks. We conduct a subsample analysis by partitioning firms by risk measure (market beta, idiosyncratic and cash-flow volatilities) into high and low groups. The results show that the negative association between vega and loan spread occurs primarily in firms with higher risk-taking strategies.

As a robustness check of our findings, we consider alternative measures of compensation and the effect of CEO characteristics on bank loan contracts and find similar results. In addition, we find that the negative effect of vega on loan spreads becomes stronger for small banks. Finally, we use a change regression to control for the omitted-variable bias and the results remain supportive of our hypothesis.

Our work contributes to the literature in two ways. First, we add to the literature on executive-compensation contracting and bank-lending behaviors. A few studies have recently focused on the CEO risk-taking incentives inherent in bank compensation that affect bank performance, on riskier bank investment choices and the business policies of U.S. banking companies in the short period before and during the financial crisis of 2008 (Acharya and Naqvi, 2012; DeYoung, Peng, and Yan, 2013; Bhagat and Bolton, 2014; Cheng, Hong and Scheinkman, 2015; Chesney, Stromberg and Wagner, 2016; Gande and Kalpathy, 2017). Different from previous studies, we provide evidence of the relationship between vega and loan contracting from a lender's point of view, i.e., we follow the studies of Coles, Daniel, and Naveen (2006, 2013) to calculate CEO risk-taking incentives (vega) and find that banks with high vega compensation may reduce lending interest rates and relax lending standards in the interests of their own wealth. Results become weaker, however, when banks have strong corporate governance mechanisms, supporting the view that high CEO risk-taking incentives may create an agency problem between a bank manager and shareholders. Thus, our results provide a reference for scholars, policy makers, and market investors for assessing the significance of the influence of CEO risk-taking incentive on bank lending decisions.

Second, this paper provides an explanation of the determinants of bank loan contracts from a new perspective: the supply side. The determinants of bank loan contracts from the demand side have already been studied extensively (Strahan, 1999; Sufi, 2007; Bharath, Sunder and Sunder 2008; Graham, Li and Qiu, 2008; Lin et al., 2011), and recently include political connections (Houston, Jiang, Lin, and Ma, 2014), tax avoidance (Hasan, Hoi, Wu, and Zhang, 2014), and social capital (Hasan, Hoi, Wu, and Zhang, 2017). Different from these previous studies, we propose that a key factor in bank loan contracts are CEO risk-taking incentives from the supply side. Based on this view, this paper also adds to the literature on bank loan contracts.

LITERATURE REVIEW AND HYPOTHESIS DEVELOPMENT

Conflict of interest between shareholders and managers is a key agency problem for firms (Jensen and Meckling, 1976; Jensen, 1986). Firms can use equity-based compensation schemes to motivate CEOs' efforts to take on risky projects, thus ameliorating the principal-agent conflict (Jensen and Meckling, 1976; Myers, 1977; Guay, 1999; Smith and Stulz, 1985; Bolton, Mehran, and Shapiro, 2015). During the financial crisis of 2008, the U.S. economy experienced its worst recession since the Great Depression of the 1930s with the collapse of many of its largest banking and financial institutions. As a result, bank executives faced widespread criticism for driving the excessive risk taking that ignited the disastrous financial crisis. A growing number of academic researchers discuss the impacts of equity-based compensation contracts and whether government should do more to limit executive compensation (Fahlenbrach and Stulz, 2011; Balachandran, Kogut and Harnal. 2010; Hagendorff and Vallascas, 2011; DeYoung, Peng and Yan, 2013; Chesney, Stromberg and Wagner, 2016).

In early studies of deregulation of the banking industry, many authors have made efforts to examine the problem of equity-based compensation and bank performance. For example, Houston and James (1995) and Hubbard and Palia (1995) suggest that compensation contracts create incentives for CEOs to take risks. Equity incentives embedded in CEO compensation contracts are strongly associated with bank performance and this relationship is stronger in deregulated interstate banking markets. Moreover, the deregulation of the banking industry during the 1990s provides a natural experiment for investigating how firms adjust their executive compensation contracts as the environment in which they operate becomes relatively more competitive (Brewer, Hunter and Jackson, 2004). They show evidence that riskier banks had significantly higher levels of equity-based compensation in the post-deregulation period, as did banks with greater investment opportunities.

Other recent studies examine the impact of CEO compensation structure on bank risk taking. Fahlenbrach and Stulz (2011) use US banking data to uncover the existence of a relationship between bank performance, stock returns and returns on assets with equity incentives. They find that banks led by CEOs whose have better manager-shareholder alignment was associated with significantly worse performance during the crisis. In other words, financial strategies such as stock holding or option compensation may encourage CEOs to engage in more risky projects to increase their future equity value. Some empirical studies find that the sensitivity of CEO equity and option holdings to stock volatility has an impact on bank risk taking (e.g., Chen et al., 2006; Mehran and Rosenberg, 2007; Hagendorff and Vallascas, 2011; Boyallian and Ruiz-Verdú, 2015).

Acharya and Naqvi (2012) develop a theoretical model to show that bank over-lending may result from bank managers' desire to receive higher compensations. Acharya and Naqvi (2016) further show that, if a bank is awash with deposits from investors, the manager will be more likely to undertake high-risk projects to pursue his/her own self-interest and may sanction excessive loans by lowering lending standards, which can lead to asset price bubbles and sow seeds for future bank failure. Both of these papers report that over-lending may result from bank managers' desire to receive higher compensation, which is an agency problem between managers and shareholders.

To the best of our knowledge, however, no empirical research has to date investigated the specific relationship between vega and bank risk taking in loan contracts. Our research contributes to the literature in that CEOs with higher vega tend to take greater risks by setting up mechanisms to decrease the price of loans and relax lending standards on bank loan contracts. Therefore, we propose the following hypotheses:

Hypothesis 1: Banks with higher CEO vega are more likely to charge lower loan spreads.

In addition to the price of a loan, other non-price terms can also be imposed if banks consider control benefits to be a harmful agency problem. Some of these terms are found in Graham, Li, and Qiu (2008) and Rahaman and Zaman (2013) with covenants and collateral requirements. Therefore, our second hypothesis is as follows:

Hypothesis 2: Banks with higher CEO vega tend to impose more favorable non-price terms on loans.

DATA AND METHODOLOGY

Vega Measure

Following Core and Guay (2002), Coles, Daniel and Naveen (2006), we first define vega as the dollar amount change in the CEO stock and option portfolio per one-percent change in the standard deviation of the annualized stock return (stock-return volatility). Then, to generate annual estimates of *Vega*, for fiscal years 1992-2005 we use the "one-year approximation" method, which explains about 99 percent of the variation in option portfolio values and sensitivities that one would obtain from having full information about option portfolios. For fiscal year 2007 and later, however, it is unnecessary to use approximation (OA) in Core and Guay (2002), because all firms on Execucomp disclose information with complete portfolios of exercised and unexercised stock options in the outstanding equity tables using the new-format rules for DEF14A filings. For 2006, 84 percent of firms' report using the new format, while the rest report under the old format.

For calculation of vega under the new reporting format, Execucomp provides option data in the current year and previously granted options, which include the number of options granted, option exercise price, time to maturity, the firm's expected dividend yield, the firm's expected stock return volatility, and the risk-free interest rate for that year. All the above variables are inputs to estimate option values and sensitivities from the formulas in the Black–Scholes option-valuation model (1973), modified by Merton (1973) to account for dividends:

$$\text{Option value} = [\mathrm{S}e^{-\mathrm{dt}}\mathrm{N}(\mathrm{Z}) - \mathrm{X}e^{-\mathrm{rt}}\mathrm{N}(\mathrm{Z} - \sigma \mathrm{T}^{(1/2)})] \qquad (1)$$

where Z is $[\ln(S/X)+T(r-d+\sigma^2/2)]\sigma T^{(1/2)}$; N is the cumulative probability function for normal distribution; S is stock price; X is the option-exercise price; σ is the expected stock-return volatility; r is the natural logarithm of risk-free interest rate; T is option time to maturity, in years; d is the natural logarithm of dividend yield.

The sensitivity of option value with respect to a 0.01 change in stock-return volatility (where N' is the normal density function) is:

$$[\partial(\text{option value})/\ \partial(\text{stock return volatility})] * 0.01 = e^{-\mathrm{dt}}\mathrm{N}'(\mathrm{Z})\mathrm{S}\mathrm{T}^{\left(\frac{1}{2}\right)} \times 0.01 \qquad (2)$$

The vega of all vested and unvested options awards are summed for each executive-year to obtain our vega of option portfolio.

To calculate vega with pre-2006 data, since Execucomp only provides firms' detailed reports for the current year's option grants, we therefore use the one-year approximation method in Core and Guay (2002) to estimate data on previously granted options. We consider three option portfolios: the current year's option grants, the portfolio of unvested options from previously granted awards, and the portfolio of vested options. CEOs' incentives are given by the summation of the incentives from these three portfolios.

For the current year's option grants, we obtain the number of options granted during that year, the stated exercise price, and maturity (based on expiration date), along with the firm's expected dividend yield, the firm's expected stock-return volatility, and the risk-free interest rate for that year, all from Execucomp, are used to estimate option values and sensitivities from formulas described earlier.

To calculate the portfolio of previously granted unvested options, we make assumptions based on exercise price and times to maturity as in Core and Guay (2002). First, we estimate the total number of options in the portfolio and the average exercise price of each option. We net off the total number of options granted in the current year from the number of unvested options to estimate the number of previously granted unvested options. We then calculate the difference between the reported intrinsic value of all unvested options and the intrinsic value of the current year's grants. Finally, we subtract the average intrinsic value of each option in the portfolio from the stock price to obtain the average exercise price of each previously granted unvested option. If a firm grants options in the current year, the time to maturity of previously granted unvested options is set to the actual maturity of current year option grants minus one. If no option grants are made in the current year, we assume that the average maturity of previously granted unvested options is nine years.

For vested options, we calculate the average exercise price based on the realizable value and number of vested options. The maturity of vested options equals the maturity of unvested options minus three.

The vega is the sum of the vega of the current year options plus previously granted options (both vested and unvested).

Data and Variables

We start with all companies with standard industrial classification (SIC) codes between 6000 and 6300 that intersect in the Standard & Poor's Compustat and ExecuComp databases. Following Fahlenbrach and Stulz (2011), we exclude firms not in the lending business nor those in the traditional banking industry, such as online brokerages, payment processors, or investment advisors (SIC 6282). Our sample includes both depository institutions (commercial banks and savings institutions) and investment banks. Given the availability of data from the ExecuComp database, we choose 1991 as the first year of the sample. As we need to calculate the rate of change in our main variables at year *t* based on the data at year *t* – 1, our sample is further restricted to include firms with at least two years of data. Thus, the effective results period begins with 1992. The final sample contains 20,502 bank-year observations from 1992 through 2014.

Loan data are collected from the DealScan database, which consists of information about *loan spread*, *loan maturity*, *size*, and other non-price terms. The main dependent variable used in this research is *Spread*, which is defined as the natural logarithm of all-in spread in DealScan (spread over LIBOR or equivalent). Variables in loan characteristics include *Maturity* (natural log of loan maturity in months), *Loan size* (natural log of amount of loan in US$ million), *Performance* (a dummy variable that equals one if the loan facility uses performance pricing), *Collateral* (a dummy variable that takes a value of one if a loan is secured, and zero otherwise), *GenCov* (number of general covenants), and *FinCov* (number of financial covenants).

The firm characteristics are from Compustat: *Assets* (natural log of the total assets of the firm), *Leverage* (long-term debt plus debt in current liabilities divided by total assets), *Tangibility* (net property, plant, and equipment divided by total assets), *Profitability* (earnings before interest, taxes, depreciation, and amortization (EBITDA) divided by total assets), *MB* ([total assets – book value of equity + price × common shares outstanding]/total assets), *CF-volatility* (standard deviation of quarterly cash flows from operations over the four fiscal years prior to the loan initiation year scaled by the total debt), *Z-score* (modified Altman's Z-score [1.2 × working capital + 1.4 × retained earnings + 3.3 × EBIT + 0.999 × sales]/total assets).

Lender characteristics are from Compustat Bank: *L_Asset* (log of total assets in billions of dollars), *L_ Leverage* (ratio of assets to book value of equity), and *L_loandep* (ratio of average balance of loans to average balance of deposits). Macroeconomic factors are *Credit*

Spread (the difference between the AAA corporate bond yield and BAA corporate bond yield) and *Term Spread* (the difference between the 10-year Treasury yield and the 2-year Treasury yield).

CEO compensation and characteristics include *Delta* (Dollar change in wealth associated with a one-percent change in the firm's stock price in US$ million), *CEO inside debt ratio* (the value of inside debt divided by the total value of shares and options owned). We define a CEO's inside debt as the sum of the balance in the CEO's pension fund and nonqualified deferred compensation), *TDC1* (this variable includes salary, bonus, stock awards, option awards, long-term incentive plans, and other annual compensation such as perquisites and other personal benefits in $million), *CEO age* (the CEO's age when the company signs the bank loan contract), *CEO gender* (The gender of the executive officer), and *CEO tenure* (the number of years the CEO held his/her position in the company before signing the bank loan contract).

Bank governance variables include, *Board size* (Number of board directors), *Independent directors* (the percentage of outside directors), *Female* (the proportion of female directors on the Board), *Duality* (a dummy variable for when the CEO also holds the position of Chairman of the Board) and *Busy board* (boards in which the majority of the outside directors are labeled "busy," i.e., if he/she holds three or more directorships).
The measures for credit risk of borrowers include *Beta high* (a dummy variable that equals one if the beta of borrowers is larger than the sample median and zero otherwise), *Idiorisk high (*a dummy variable that equals one if the idiosyncratic risk of borrowers is larger than the sample median and zero otherwise) and *CF volatility high (*a dummy variable that equals one if the cash flow volatility of borrowers is larger than the sample median and zero otherwise). Appendix summarizes all variable definitions.

Summary Statistics

Table 1: Descriptive Statistics

	Mean	Q25	Median	Q75	Standard deviation
Vega	5.5677	4.4080	5.9953	6.9332	1.5334

Assets	7.0936	5.7812	7.0817	8.3575	1.9935
Tangibility	0.3000	0.0906	0.2288	0.4664	0.2517
Leverage	0.3494	0.1795	0.3282	0.4779	0.2447

Profitability	0.1139	0.0791	0.1184	0.1658	0.1373
MB	0.6991	0.6244	0.7319	0.8233	0.2064
Z_score	1.4804	0.7903	1.5605	2.4105	2.8178
CF volatility	1.8469	0.0332	0.0769	0.1886	38.6948
Credit spread	-0.8962	-1.0200	-0.8300	-0.6900	0.2883
Term spread	-3.0729	-5.8400	-2.6400	-0.5500	2.4514

The mean, median values of bank loan spread in Table 1 are 4.9593 and 5.1648. The average spread is 4.9593 ($e^{4.9593}$ = 142.4940 basis points), with a standard deviation of 0.8248. The value of *Vega* from 1992 to 2014 is positive in all firms under consideration, which is reasonable and consistent with the previous literature on quantifying methods of vega (Coles, Daniel and Naveen, 2006; DeYoung, Peng and Yan, 2013). The mean value of *Vega* is 5.5677 with the standard deviation of 1.5334 respectively.

The average of *L_Asset*, *L_ Leverage*, and *L_loandep* are 12.3910, 12.5954, and 0.8357, respectively. Regarding loan characteristics, the average of *Maturity, Loan size, Performance, Collateral, FinCov, GenCov* are 3.5975, 4.7611, 0.3887, 0.4658, 0.5862 and 1.0187, respectively. In other words, the loan contracts under consideration have a mean maturity of 37 months (exponential of 3.5975). The mean value of loan size is US$ 117 million (4.7611 in natural logarithm). A loan contract in the sample has, on average, 2.7695 general covenants (maximum of 10 covenants) and 1.7971 financial covenants (maximum of 7 covenants) for the borrowers. For the characteristics of borrowing firms, the average *Assets, Tangibility, Leverage, Profitability, MB, Z-score and CF volatility* values are 7.0936, 0.3000, 0.3494, 0.1139, 0.6991, 1.4804 and 1.8469, respectively. The last two rows provide the summary statistics for the macroeconomics variables. The average of *Credit spread* and *Term spread* are -0.8962 and -3.0729, respectively.

In Table 2, we divide the sample into high- and low-vega banks based on the median of *Vega.*

Table 2: Loan, borrower, and lender characteristics for banks with high and low vega

This table presents the mean comparison of loan, borrower, and lender characteristics between firms with high and low vega. *t*-test deployed to compare the mean. *, ** and*** denote significance at 10%, 5% and 1% levels, respectively.

Variables	High vega firms	Low vega firms	Differences	*t*-statistics
Spread	4.9667	5.0451	-0.0784***	-4.58
L_assets	13.6704	12.2265	1.4439***	46.89

MB	0.6803	0.7042	-0.0238***	-5.52
Z-Score	1.5654	1.2037	0.3617***	4.93
CF volatility	1.4369	4.5633	-3.1263***	-2.72

CEO age	4.0301	4.0327	-0.0026***	-1.70

We use a *t*-test to determine the significance of the difference in the means of all variables between the two groups and report the results for this preliminary univariate test. Most of the mean comparisons show a significant difference at the one-percent level. Banks with high vega tend to charge a significantly higher *Spread* than those with lower vega. Banks in the high-vega group also ask for less collateral as well as impose a lower number of covenants (both general and financial) compared to those in the lower-vega group.

We also report the Pearson's correlation coefficient matrix in Table 3

Table 3: Correlation matrix

This table presents the Pearson correlation matrix between all the variables. The sample period is from 1992 to 2014. * and ** denote significance level at 5% and 1%, respectively.

(20) L_assets	0.20**	-0.01	0.13**	0.00	-0.37**	0.60**	-0.06**	-0.03**	1.00		
(21)*CEO age*	0.07**	0.00	0.06**	0.00	0.16**	-0.10**	-0.04**	0.19**	0.00	1.00	

As expected, we find a negative and significant correlation between *Spread* and *Vega*. The correlation coefficients between bank compensation regarding vega and other loan terms such as *collateral* requirements and *general* and *financial covenants* are also negative and significant at the one-percent level. The correlation coefficient between *Spread* and other control variables such as *L_leverage* and *CEO age* are significantly negative, indicating that banks with high leverage in their capital structure and those with older CEOs are also associated with a significantly lower spread in their loans.

Methodology

Following the studies of Coles, Daniel, Naveen (2006), DeYoung, Peng, and Yan (2013) and Hasan, Hoi, Wu, and Zhang (2014, 2017), we use an ordinary least squares (OLS) regression to investigate the effects of CEO risk-taking incentives in terms of *Vega* on bank loan spread:

$$\mathrm{Spread}_{\mathrm{i,t}} = \alpha_0 + \alpha_1 \mathrm{Vega}_{\mathrm{i,t-1}} + \beta' \mathrm{F}_{\mathrm{i,t-1}} + \theta' \mathrm{Z}_{\mathrm{i,t}} + \gamma_{\mathrm{i}} + \mu_{\mathrm{t}} + \varepsilon_{\mathrm{i,t}} \quad (3)$$

where the dependent variable is *Spread* and the main explanatory variable is *Vega*. Specifically, $Spread_{i,t}$ is the natural logarithm of the bank loan spread for loan *i* in year *t*; $Vega_{i,t-1}$ represents CEO risk-taking incentives, captures the change in the dollar value of CEO wealth for a 0.01-unit change in stock return volatility for bank *i* in year *t-1* (Coles, Daniel and Naveen, 2006, 2013). $F_{i,t-1}$ is a vector of control variables for lenders and borrowers *i* in year *t-1*, including lender and borrower characteristics. $Z_{i,t}$ is the vector of the control variables for loan and macroeconomic factor *i* in year *t*. γ_i and μ_t represent the fixed effects of industry and year, respectively, and $\boldsymbol{\varepsilon_{i,t}}$ represents the error term of the regression. We also control for loan primary purpose and loan type. In all specifications, the *t-statistics* reported are based on heteroscedasticity at firm-level robust standard errors (White, 1980).

To test the effect of CEO risk-taking incentives on other non-price loan terms, we use various regression methods. The Poisson regression is used to test the influence of *Vega* on the total number of covenants and on general and financial covenants individually, as follows:

$$\mathrm{Ln}\left(\mathrm{E}\left(\mathrm{Y}\middle|\mathrm{Vega}_{\mathrm{i,t-1}}, \mathrm{F}_{\mathrm{i,t-1}}, \mathrm{Z}_{\mathrm{i,t}}\right)\right)_{\mathrm{i,t}} = \alpha_0 + \alpha_1 \mathrm{Vega}_{\mathrm{i,t-1}} + \beta' \mathrm{F}_{\mathrm{i,t-1}} + \theta' \mathrm{Z}_{\mathrm{i,t}} + \gamma_{\mathrm{i}} + \mu_{\mathrm{t}} + \varepsilon_{\mathrm{i,t}} \quad (4)$$

The dependent variables used in this form, $Y_{i,t}$ are different non-price terms of a bank loan contract for firm *i* in year *t*, namely, *Totalcov*: the total number of covenants in a loan contract; *Gencov*: the number of general covenants; and *Fincov*: the number of financial covenants. Since the number of covenants in a loan contract are countable data, the Poisson regression is a reasonable method to analyze the effect of private benefits of control. This methodology is also widely used in the bank-loan literature, such as Graham, Li, and Qiu (2008) and Hasan, Hoi, Wu, and Zhang (2014).

Regarding loan terms, we also deploy a probit regression model using *Collateral* as the dependent variable. *Collateral* is a dummy that equals one if a bank requires collateral on a loan provided to the company, and zero otherwise. The equation of the probit model is as follows:

$$\Pr\left(\mathrm{Collateral}_{\mathrm{i,t}} = 1 \middle| \mathrm{Vega}_{\mathrm{i,t-1}}, \mathrm{Z}_{\mathrm{i,t}}\right) = \Phi(\alpha_0 + \alpha_1 \mathrm{Vega}_{\mathrm{i,t-1}} + \beta' \mathrm{F}_{\mathrm{i,t-1}} + \theta' \mathrm{Z}_{\mathrm{i,t}} + \gamma_{\mathrm{i}} + \mu_{\mathrm{t}}) \quad (5)$$

EMPIRICAL RESULTS

Bank CEO Risk-taking Incentives and Loan Spread

In this section, we examine the relationship between bank CEO risk-taking incentives and bank loan spread. Table 4 shows the regression results based on Equation (3).

Table 4: Bank's CEO risk-taking incentives and Bank loan spread

This table present the ordinary least squares (OLS) regression results of bank CEO risk-taking incentives on bank loan spread.

$$Spread_{i,t} = \alpha_0 + \alpha_1 Vega_{i,t-1} + \beta' F_{i,t-1} + \theta' Z_{i,t} + \gamma_i + \mu_t + \varepsilon_{it}$$

where the dependent variable $Spread_{i,t}$ is the natural logarithm of bank loan spread for loan *i* in year *t*; $Vega_{i,t-1}$represents the incentives for the CEO of bank i in year *t-1*; $F_{i,t-1}$is a vector of control variables for borrowers and lenders *i* in year *t-1,* including borrower and lender characteristics; $Z_{i,t}$ is a vector of control variables for loans and macroeconomic factors *i* in year *t.* γ_i and μ_t represent the fixed effect of industry and year, respectively. In all specifications, the *t-statistics* reported are based on heteroscedasticity at firm-level-robust standard errors (White, 1980). The sample period is 1992-2014. All the variables are defined in Appendix A *, ** and *** denote the significance level of 10%, 5% and 1%, respectively.

Our focus is the coefficient of Vega on bank loan spread. For the robustness of our results, we conduct five specifications in the regression setting. The first controls for industry and year fixed effects only; the second adds controls for loan purpose and type; the third for lender characteristics; the fourth for borrower characteristics; and the fifth for CEO age, loan characteristics and macroeconomic factors.

Consistent with our expectation, negative and significant coefficients are observed in all specifications, even though we have controlled for all potential factors, indicating that banks with higher vega compensation schemes will charge lower spreads for bank loans. Thus, the results support our hypothesis 1 that banks with higher CEO vega are more likely to charge lower loan spreads.

Specifically, the coefficients of Vega are significant at the one-percent level from a -0.0156 to -0.0605 decrease in log loan spread. For example, in Model (3), the coefficient of Vega is -0.0199, which shows that, on average, banks with higher vega will charge lower loan spreads. Thus, banks with higher vega will charge a 1.5642 lower basis-point ($\mathbf{e}^{\mathbf{0.0199}} \times 1.5334 = 1.5642$) loan spread per each one-standard-deviation increase in vega. As the average loan spread in our sample is 142.4940 basis points ($e^{4.9593}$), a one-standard-deviation increase in Vega lowers a firm's bank loan interest rate an average of 1.1 percent ($1.5642 \div 142.4940 = 1.1\%$). Furthermore, the lower 1.5642 basis-point loan spread is around 36 percent of the estimated coefficients for the effect of corporate tax avoidance and for the effect of social capital in Hasan, Hoi, Wu, and Zhang (2014, 2017). Accordingly, the effect of bank CEO incentives on loan spread is not only statistically significant but is also economically important.

Concerning lender characteristics control variables, L_assets, L_leverage, and L_loandep, the first two is significantly negative in relation to spread and the last is significantly positive in Model (3). However, when we add the control variables of borrower characteristic in Model (4), the coefficient between lender control variables and spread all become insignificant. In Model (5) we include all control variables so that, while L_assets and L_leverage remain insignificant, the coefficient of L_loandep becomes negatively significant at 10 percent. However, our Hypothesis 1 is more strongly supported since significant negative impacts of Vega to spread are evident in all specifications.

Concerning borrower characteristics, loan spread is significantly negatively associated with Asset and Profitability, which is consistent with the notion that firms can reduce their financing costs when they are larger in size and better performing (Graham, Li, and Qiu, 2008). Conversely, firms that use greater debt in their capital structure are charged more when they seek new loans from banks, consistent with the findings of Chava and Roberts (2008) and Hasan, Hoi, Wu, and Zhang (2014). Regarding loan characteristics, the results indicate that loans with shorter maturities, smaller amounts, and without performance pricing have higher loan spreads, while the existence of collateral requirements and general covenants in the previous period seems to increase the spread for current bank loans. Macroeconomic factors, such as term spreads, show positive and significant effects on financing costs. Overall, the effects of the control variables exhibit a similar pattern as reported in the existing literature.

Bank CEO Risk-taking Incentives and Non-Price Terms

We next examine whether CEO vega compensation drives banks to relax their lending standards in non-price terms for borrowers. Following Graham, Li, and Qiu (2008) and Hasan, Hoi, Wu, and Zhang (2014), we use different non-price terms as dependent variables in Table 5. In Models (1) to (3), following Equation (3), we use the Poisson regression with total covenants (TotalCov), general covenants (Gencov), and financial covenants (Fincov) as dependent variables. Model (4) employs a probit model of the probability of a firm being required to provide collateral for a loan (following Equation (5)).
Models (1) to (3) relate to covenants in loan contracts. The vega is negatively correlated with the number of covenants at a one-percent significance level. However, when we consider both general and financial covenants, it seems that Vega significantly affects only the number of general covenants. The coefficient of Vega for financial covenants in Model (3) is negative, but not significant. Finally, in Model (4), the probit model indicates that high-vega banks are less likely to seek collateral for their loans. The results in Table 5 are all consistent with our hypothesis 2 that banks with higher CEO vega tend to impose more favorable non-price terms on loans.

Table 5. Bank CEO risk-taking incentives: Non-price terms

This table presents the results of bank CEO risk-taking incentives on non-price terms. Specifications (1), (2), and (3) follow the equation forms:

$$Ln(E(Y|Vega_{i,t-1}, F_{i,t-1}, Z_{i,t}))_{it} = \alpha_0 + \alpha_1 Vega_{i,t-1} + \beta' F_{i,t-1} + \theta' Z_{i,t} + \gamma_i + \mu_t + \varepsilon_{it}$$

where the dependent variables, $Y_{i,t}$ are different terms of a bank loan for loan *i* in year *t*. For Poisson regression: *Totalcov* is the total number of covenants of a loan contract; *Gencov* is the number of general covenants, and *Fincov* is the number of financial covenants.
Specification (4) follows a probit regression model of the probability that collateral is required when firm *i* takes a loan in year *t*:

$$Pr(Collateral_{i,t} = 1|Vega_{i,t-1}, F_{i,t-1}, Z_{i,t}) = \emptyset(\alpha_0 + \alpha_1 Vega_{i,t-1} + \beta' F_{i,t-1} + \theta' Z_{i,t} + \gamma_i + \mu_t)$$

where $Vega_{i,t-1}$ represents the private benefits of control for firm *i* in year *t-1*; $F_{i,t-1}$ is a vector of control variables for borrowers and lenders *i* in year *t-1*; $Z_{i,t}$ is a vector of control variables for loans and macroeconomic factor *i* in year *t.* γ_i and μ_t represent the fixed effect of industry and year, respectively. In all specifications, the *t-statistics reported* are based on heteroscedasticity at firm-level-robust standard errors (Hubert-White, 1980). The sample period is 1992-2014. All the variables are defined in Appendix A. *, ** and *** denote the significance level of 10%, 5% and 1%, respectively

The CEO Risk-taking-incentive Effect: Corporate-Governance Channels

The literature on corporate governance suggests that a good governance mechanism is a fundamental instrument to reduce agency problems. For example, Adams and Mehran (2012) argue for a positive relation between bank performance and board size. In other studies, a higher number of independent directors is associated with lower bond yields and higher credit ratings (Bhojraj and Sengupta, 2003); outside directors have greater incentives to monitor management because of reputation considerations (Fama and Jensen, 1983; Weisbach, 1988); and the probability of financial statement fraud is lower for firms with independent boards (Beasley, 1996). Regarding the gender issue, Adams and Ferreira (2009) suggest that female directors have better attendance records than male directors, and gender-diverse boards allocate greater effort to monitoring. Moreover, Dayton (1984) argues that board duality reduces efficiency monitoring by directors due to the excessive concentration of power in one person's hands. Fich and Shivdasani (2006) show that firms with busy boards tend to be detrimental to corporate governance.

This study proposes that the effect of CEO risk-taking incentives derives from the corporate governance channel. The agency problem that stems from compensation could be the reason why banks charge lower loan spreads or provide more favorable non-price terms to borrowers. Therefore, in banks with diverse corporate governance, the vega incentive may have a different effect on bank loan contracts. Based on prior studies, we suggest that the agency problem of CEO risk-taking incentives could be increased (reduced) when banks have weak (strong) governance practices. Thus, in this section, we further examine this issue by conducting an analysis of sub-samples representing weak and strong governance practices. Following Hoechle, Schmid, Walter, and Yermack (2012), we use several different variables to measure corporate governance structure. We divide the sample into subsamples based on banks' governance measures (*board size, independent director ratio, female directors, CEO duality*, *busy board*) and run the baseline regressions for each subsample according to Equation (3). If CEO risk-taking incentives are viewed as an agency problem, then we would expect the effect of *Vega* to be more (less) significant when firms are associated with weak (strong) corporate governance quality.

Panels A and B of Table 6 present the results of subsamples for firms with weak and strong governance practices.

Table 6: CEO risk-taking incentives and bank loan spread: Evidence from bank governance channels

This table presents OLS regression results for CEO risk-taking incentive on bank loan spread by considering different levels of bank governance. First, we divide the sample into subsamples based on banks governance's measures (Board size, Independent board, Female, Duality, and Busy board). Second, we run the regressions for each subsample. The empirical model is:

$$Spread_{i,t} = \alpha_0 + \alpha_1 Vega_{i,t-1} + \beta' F_{i,t-1} + \theta' Z_{i,t} + \gamma_i + \mu_t + \varepsilon_{it}$$

where $Spread_{i,t}$ represents the natural logarithm of bank loan spread for loan *i* in year *t*; $\mathrm{Vega}_{i,t-1}$ is the change in the dollar value of CEO wealth for a 1% change in stock return volatility that a bank grants to its CEO in $million; $F_{i,t-1}$ is a vector of control variables for borrowers and lenders *i* in year *t* − 1; $Z_{i,t}$ is a vector of control variables for loans and macroeconomic factors *i* in year *t;* γ_i and μ_t represent the fixed effect of industry and year respectively; and $\varepsilon_{i,t}$ is the random error. In parentheses are *t*-statistics based on standard errors adjusted for heteroskedasticity (White, 1980). Superscripts *, **, and *** denote significance at the 10%, 5%, and 1% levels, respectively. To save space, we do not report the coefficients for industry and year dummies.

Weak corporate governance proxies in Panel A are defined as follows: Banks with (1) board size higher than the median; (2) a ratio of independent directors greater than median; (3) more female directors than the median; (4) CEO duality equal to zero; (5) busier boards than the median. Across all models, in banks with weak corporate governance, the coefficients of *Vega* are significantly negatively related to loan spread. For example, in Model (1), the coefficient is –0.0370, indicating that banks with higher vega compensation tend to charge lower loan spreads than banks with low board size. However, in banks with strong corporate governance (Panel B), the coefficients of *Vega* are all insignificant. These results add further support to our hypothesis 1, i.e., banks with greater vega tend to charge a lower bank loan spread, especially when these banks have weak corporate governance. More importantly, this result implies that high CEO risk-taking incentives create an agency problem between bank manager and shareholders.

Bank CEO risk-taking Incentives and Riskiness of Borrowers

In this section, we further examine the relationship between CEO risk-taking incentives and bank loan spread by considering borrower credit risk. Riskier borrowers (such as small borrowers, borrowers with less cash, and borrowers that are harder for outside investors to value) must pay more for their loans and rely more on bank financing (Machauer and Weber, 1998; Strahan, 1999). As a normal fact of business, high risk may result in high profit, since the higher loan-rate premium encourages a bank to take the deal. If our hypothesis is correct, we should find that our results mainly come from high-risk borrowers as a result of bank over-lending behaviors. We thus conduct a subsample analysis based on Equation (3). We use three variables to measure firm riskiness: First, *Beta* is the equity beta from regressing daily excess returns on market excess returns over the previous two years, and is a well-known regression measure of systematic risk (Blume, 1971), especially when applying robust methods in the statistical literature (Chan and Lakonishok, 1992). Second, *Idiosyncratic risk* (*Idiorisk*) is the standard deviation of residuals obtained from regressing daily stock excess returns on market excess returns over the previous two years. Measured from a market model regression, high idiosyncratic uncertainty will negatively affect firm-level investment (Gilchrist, Sim and Zakrajsek, 2014). Another study shows that idiosyncratic risk is important in explaining changes in firm financial soundness (Atkeson, Eisfeldt and Weill, 2014). Finally, *Cash-flow volatility* (*CFvol*) is the volatility of daily returns over the previous two years. High cash-flow volatility results in a pattern of underinvestment or undervaluing of the firm by outsiders (Scordis, Barrese and Wang, 2008; Minton, Schrand and Walther, 2002). Higher volatility is related to lower investment (Minton and Schrand, 1999). Thus, lack of investment may encourage high cash-flow volatility in a firm that uses bank loans as a capital-mobilization channel. In this study, firms are defined as high- (low-) risk borrowers if *Beta*, *Idiorisk* and *CFvol* are above or equal to (below) the sample median.

Table 7 presents the regression results for the subsample analysis. The relation between *Vega* on loan spreads is stronger for borrowers with high risk. The coefficient of *Vega* for firms with high idiosyncratic volatility is –0.0272, which is significant at the one-percent level. In contrast, the coefficient of *Vega* for firms with low idiosyncratic volatility is –0.0072, which is not statistically significant. Similarly, the coefficients of *Vega* for firms with high beta and cash-flow volatility are significantly negative at -0.0144 and -0.0160, whereas the coefficients for firms with low beta and low cash-flow volatility are -0.0129 and -0.0153, which are not significant.

Table 7: CEO risk-taking incentives and bank loan spread: Credit risk of borrowers

This table presents OLS regression results for CEO risk-taking incentives on bank loan spread by considering credit risk of borrowers. First, we divide the sample into subsamples based on borrower risk (beta, idiosyncratic risk and cash-flow volatility). Second, we run the regressions for each subsample with bank loan spread as the dependent variable. The empirical model is:

$$Spread_{i,t} = \alpha_0 + \alpha_1 Vega_{i,t-1} + \beta' F_{i,t-1} + \theta' Z_{i,t} + \gamma_i + \mu_t + \varepsilon_{it}$$

where $Spread_{i,t}$ represents the natural logarithm bank loan spread for loan *i* in year *t*; $Vega_{i,t-1}$ is the change in the dollar value of CEO wealth for a 1% change in stock return volatility which a bank grants to its CEO in $million; $F_{i,t-1}$ is a vector of control variables for borrowers and lenders *i* in year *t* − 1; $Z_{i,t}$ is a vector of control variables for loans and macroeconomic factors *i* in year *t;* γ_i and μ_t represent the fixed effect of industry and year respectively; and $\varepsilon_{i,t}$ is the random error. In parentheses are *t*-statistics based on standard errors adjusted for heteroskedasticity (White, 1980). Superscripts *, **, and *** denote significance at the 10%, 5%, and 1% levels, respectively. To save space, we do not report the coefficients for industry and year dummies.

ROBUSTNESS CHECKS

Control for CEO Characteristics and Other Compensation Schemes

CEO characteristics and other forms of CEO compensation may also affect considerations of loan spread when banks negotiate contracts with creditors (Donelson, Jennings and McInnis, 2014; Kabir, Li, and Veld-Merkoulova, 2013). In this study, we claim that CEO vega represents a form of executive compensation, although not a compulsory regular form such as salary, bonus or stock options. However, the economic intuition of vega, in terms of either agency cost proxy or the complementary incentive-alignment effect, may be more meaningful in comparison with other forms of compensation. Therefore, to confirm that our results are not biased by other CEO characteristics and compensation, such as *CEO tenure*, *CEO gender*, *TDC1*, *Delta*, and *CEO inside debt ratio,* we additionally include the latter in our regressions.

Table 8 presents the regression results of bank CEO risk-taking incentives on bank loan spread by considering CEO characteristics and other CEO compensation. Across all specifications, the coefficients of *Vega* are significantly negatively related to loan spread, even when we control for CEO characteristics and other compensation. For example, in Model (4), the coefficient of *Vega* is -0.0258, which is statistically significant with t-statistics of -2.94. Thus, the evidence still supports our hypothesis 1.

Table 8: Robustness check (I): Control for CEO characteristics and other CEO compensation
This table presents ordinary least squares (OLS) regression results for the influences of CEO vega incentives on bank loan spread by considering CEO characteristics and other CEO compensation as control variables. The empirical model is:

$$Spread_{i,t} = \alpha_0 + \alpha_1 Vega_{i,t-1} + \beta' F_{i,t-1} + \theta' Z_{i,t} + \gamma_i + \mu_t + \varepsilon_{it}$$

where $Spread_{i,t}$ represents the natural logarithm of bank loan spread for loan *i* in year *t*; $Vega_{i,t-1}$is the change in the dollar value of CEO wealth for 1% change in stock-return volatility that a bank grants to its CEO in \$million; $F_{i,t-1}$ is a vector of control variables for borrowers and lenders *i* in year $t-1$; $Z_{i,t}$ is a vector of control variables for loans and macroeconomic factors *i* in year *t;* γ_i and μ_t represent the fixed effect of industry and year respectively; and $\varepsilon_{i,t}$ is the random error. In parentheses are *t*-statistics based on standard errors adjusted for heteroskedasticity (White, 1980). Superscripts *, **, and *** denote significance at the 10%, 5%, and 1% levels, respectively. To save space, we do not report the coefficients for industry and year dummies.

Bank Size Analysis

Bank size can be also considered an important factor in the determination of bank lending decisions (Berger and Bouwman, 2009 and 2013). To some extent, bigger banks are associated with strong corporate governance, more market power, good reputation and trust, since they can easily mobilize deposits (even at lower rates) and attract higher loan demands (even at higher rates) compared to small banks. However, if downside risks were revealed, shareholders may suffer greater losses and, thus, risk-taking incentives should be less preferred in more profitable firms (Keeley, 1990). Demsetz, Mark and Philip (1996) suggest that high franchise value banks operate more safely than those less highly ranked. Meanwhile, John and Qian (2003) show that pay-performance sensitivity declines with bank size, which supports the idea that managers of larger banks will choose to maintain current performance levels rather than opt for a risky project. In other words, according to traditional theory, bigger or more profitable banks may not willing to take risks in order to avoid unexpected effects to their business. Therefore, we expect that our results will be stronger in the small-bank subsample. We therefore run a baseline regression according to Equation (3) that includes the variable *Small bank* and its interaction term *Vega*. *Small bank* is a dummy variable where bank size is lower than the sample median.

Model (1) of Table 9 displays the results of the bank size test. The interaction term of *Vega* and *Small bank* is negative and significant, showing that the effect of CEO risk-taking incentives on loan spreads is stronger for small banks. For example, the effect of *Vega* in the small-bank group is –0.0436 (–0.0337 – 0.0099 = –0.0436), whereas the effect in the large-bank group is –0.0099.

Table 9: Robustness check (II): Bank size analysis and the change regression

This table presents the results of the effect of bank CEO vega incentives on different bank sizes and presents the change regression results of the effect of bank CEO risk-taking incentives (*Vega*). Model (1) follows the below equation form:

$$Spread_{i,t} = \alpha_0 + \alpha_1 Vega_{i,t-1} + \alpha_2 Vega_{i,t-1} \times Small\ bank_{i,t-1} + \alpha_3 Small\ bank_{i,t-1} + \beta' F_{i,t-1} + \theta' Z_{i,t} + \gamma_i + \mu_t + \varepsilon_{i,t}$$

where $Spread_{i,t}$ represents the natural logarithm of bank loan spread for loan *i* in year *t*; $Vega_{i,t-1}$is the change in the dollar value of CEO wealth for a 1% change in stock-return volatility that a bank grants to its CEO in $million; $\mathrm{Small\ bank}_{i,t-1}$ is dummy variable that equals

1 if the bank size is smaller than the sample median and 0 otherwise; $F_{i,t-1}$ is a vector of control variables for borrowers and lenders *i* in year *t* − 1; $Z_{i,t}$ is a vector of control variables for loans and macroeconomic factors *i* in year *t*. γ_i and μ_t represent the fixed effect of industry and year respectively; and $\varepsilon_{i,t}$ is the random error.

Model (2) follows the below equation form:

$$\Delta Spread_{i,t} = \alpha_0 + \alpha_1 \Delta Vega_{i,t-1} + \beta' \Delta Firm_{i,t-1} + \theta' Z_{i,t} + \varepsilon_{i,t}$$

where the dependent variable $\Delta Spread_{i,t}$ is the change in loan spread for firm *i* in year *t* from year *t-1*. $\Delta Vega_{i,t-1}$ represents the change in bank CEO risk-taking incentives, *Vega i* in year *t*-1 from year *t*-2. $\Delta Firm_{i,t-1}$ represents the change in firm characteristics for lenders and borrowers *i* in year *t*-1 from year *t*-2. $Z_{i,t}$ is the vector of the control variables for loan and macroeconomic factors *i* in year *t*.

In all specifications, the *t*-statistics reported are based on heteroscedasticity (White, 1980). The sample period is 1992-2014. All the variables are defined in Appendix A. *, ** and *** denote significance levels of 10%, 5% and 1%, respectively.

Change Regression

Following the study of Chava, Livdan, and Purnanandam (2009), we utilize a change-regression analysis to determine whether the loan spread for a given bank is adjusted after a significant increase in their vega. If our agency-cost view is correct, we should observe that banks charge lower spreads when their vega incentives increase. The regression model is as follows:

$$\Delta Spread_{i,t} = \alpha_0 + \alpha_1 \Delta Vega_{i,t-1} + \beta' \Delta F_{i,t-1} + \theta' Z_{i,t-1} + \varepsilon_{i,t} \qquad (6)$$

We compute the change in the main dependent, explanatory, and control variables. In the above formula, $\Delta Spread_{i,t,}$ is the change in loan spread in year *t* from year *t-1*. The main explanatory variable, $\Delta Vega_{i,t-1}$, is the change in vega from year *t-2* to year *t-1*. $\Delta F_{i,t-1}$ is a vector of change in lender and borrower characteristics for firm *i* in year *t-1* from year *t-2*. $Z_{i,t-1}$ is a vector of control variables for firm *i* in year *t-1* from year *t-2*.

Model (2) of Table 9 above shows the results of the change regressions. The change in vega ($\Delta Vega$) significantly and negatively affects the change in loan spread. Thus, the results support our agency-cost view that banks charge lower spreads when their CEO risk-taking incentives increase, which is consistent with our main expectation and shows that our results are not driven by any omitted-variable bias.

CONCLUSION

Banks commonly use equity-based compensation schemes to motivate CEO efforts to take on risky projects, then ameliorate the principal-agent conflict. However, bank executives have faced widespread criticism for driving excessive risk taking that ignited the disastrous 2008 financial crisis. Acharya and Naqvi (2012) develop a theoretical model to show that bank over-lending may result from managers' desire to receive higher compensation. Furthermore, Acharya and Naqvi (2016) show that managers are more likely to undertake high-risk projects to pursue their own self-interest and to sanction excessive loans by lowering lending rates and loosening lending standards, all of which leads to asset price bubbles and sows seeds of future bank failure. Based on their model implications, this study provides the first empirical evidence of how CEO risk-taking incentives (vega) influence bank lending decisions.

We find that vega is negatively and significantly related to loan spread and less stringent non-price terms such as fewer financial and general covenants and a lower probability of collateral requirements. Our results are robust even we control for CEO characteristics and other compensation schemes. Thus, we find that banks with high CEO risk-taking incentives may reduce lending interest rates and relax their lending standards for their own wealth concerns. This effect becomes weaker when banks have strong corporate governance mechanisms, supporting the notion that high vega may create an agency problem between a bank manager and shareholders. Thus, our results provide a reference for scholars, policy makers, and market investors for assessing the significant impact of vega in bank lending decisions.

APPENDIX

Variables	Definition	Data source
Panel A: CEO risk-taking incentive variable		
Vega	Nature log of the dollar amount change of CEO stock and option portfolio per 1 percent change in standard deviation of the annualized stock return (US$ million)	Execucomp
Panel B: Loan characteristics		
Spread	Natural logarithm of loan spread.	DealScan
Maturity	Natural logarithm of loan maturity in months.	DealScan
Loan size	Natural logarithm of loan amount US$ millions.	DealScan
Performance	Dummy variable, equal to one if a loan facility uses performance pricing, and zero otherwise.	DealScan

Collateral	Dummy variable, equal to one if a loan is secured, and zero otherwise.	DealScan
Gencov	Number of general covenants.	DealScan
Fincov	Number of financial covenants.	DealScan
Loan type	Dummy variable for loan types, including term loan, revolver greater than one year, revolver less than 1 year, and 364-day facility.	DealScan
Loan purpose	Dummy variable for loan purposes, including corporate purposes, debt repayment, working capital, takeover, etc.	DealScan
Panel C: Firm characteristics		
Assets	Natural logarithm of total assets in US$ millions.	Compustat
Leverage	Long-term debt and debt in current liabilities divided by total assets.	Compustat
Tangibility	Net property, plant, and equipment divided by total assets.	Compustat
Profitability	Earnings before interest, taxes, depreciation, and amortization (EBITDA), divided by total assets.	Compustat
MB	Market value of net assets to book value of net assets ratio.	Compustat and CRSP
Z-score	Modified Altman's Z-score (1.2 × working capital + 1.4 × retained earnings + 3.3×EBIT + 0.999×sales)/Total assets.	Compustat
CF-volatility	Standard deviation of quarterly cash-flows from operations over the four fiscal years prior to the loan initiation year, scaled by total assets.	Compustat
Panel D: Lender characteristics		
L_Asset	Log of total assets (billions of us dollars).	Compustat Bank (CB)
L_ Leverage	Ratio of assets to book value of equity.	Compustat Bank (CB)
L_loandep	Ratio of average balance of loans to average balance of deposits.	Compustat Bank (CB)
Panel E: Macroeconomic factors		
Credit spread	Difference between AAA corporate bond yield and BAA corporate bond yield.	Datastream
Term spread	Difference between 10-year and 2-year Treasury yields.	Datastream
Panel F: CEO compensation and characteristics		
CEO age	Natural logarithm of Age of CEO. Age of the CEO when the company signs the bank loan contract.	Execucomp
CEO gender	The gender of the executive officer	Execucomp
CEO tenure	Natural logarithm of CEO tenure. Number of years the CEO held his/her position in a company before he/she signed the bank loan contract.	Execucomp
TDC1	We follow the definition of TDC1 in ExecuComp to calculate this variable. TDC1 includes salary, bonus, stock awards, option awards, long-term incentive plans, and other annual compensation such as perquisites and other personal benefits (including termination or change-in-control payments, 401K plans, etc). ($millions)	Execucomp

CEO inside debt ratio	Natural logarithm of CEO D/E (the value of inside debt divided by the total value of shares and options owned. We define the inside debt of the CEO as the sum of the balance in the CEO's pension fund and nonqualified deferred compensation	Execucomp and SEC Edgar DEF 14A Filings
Delta	Natural logarithm of dollar change in wealth associated with a 1% change in the firm's stock price (in US$ million)	Execucomp
Panel G: Bank governance mechanisms		
Busy board	Boards in which the majority of the outside directors are labeled "busy." A director is labeled "busy" if he/she holds three or more directorships	Risk Metrics
Board size	Number of board directors	Risk Metrics
Independent Directors	The percentage of outside directors	Risk Metrics
Duality	A dummy variable for when the CEO also holds the position of Chairman of the Board.	Risk Metrics
Female	The proportion of female directors in the board	Risk Metrics
Panel H: Credit risk of borrowers		
Beta	Firm's equity beta from a market model of daily returns in excess of three-month T-bills using previous two-year data, where the market is represented by the value-weighted CRSP index	CRSP
Idiosyncratic volatility (Idiorisk)	The standard deviation of the residuals obtained from a market model of daily returns in excess of three-month T-bills using previous two-year data, where the market is represented by the value-weighted CRSP index	CRSP
CF volatility	Firm's cash flow volatility using the previous two-year daily data	CRSP

ABSTRACT

This study explores the connection of independent directors to operating performance. Independent directors' connection is measured by their primary companies' lobbying activities. We find that firms with independent directors from a lobbied company have significantly positive impact to the operating performance. Reduction in the firm's financing costs can be a channel through which outside directors' connection affect firm operating performance. Our evidence suggests that in addition to monitoring and advising functions, independent directors can contribute their connection through political influence to the operating performance of the appointed firms.

KEYWORDS: Independent Directors, Lobbying Activities, Operating Performance

INTRODUCTION

Board existence play an important role on advising and monitoring (Coles et al, 2008; Adams and Ferreira, 2007; Adams and Mehran, 2003; Agrawal and Knoeber, 2001). Each firms represented by many directors. Board of directors consist of inside directors and outside directors (often called independent directors). Independent directors have no right on removing firms' assets. After the SOX regulation on 2002, firms are required to have independent directors of more than 50% of the total board members. These independent directors might work as an executives on other companies (Agrawal and Knoeber, 2001), even more as CEO. Firms where they work as executives called primary company.

Existing literature has shown that contribution of independent directors to firm performance is insignificant (MacAvoy, Cantor, Dana, and Peck, 1983; Bhagat and Black, 1999, 2002; Hermalin and Weisbach, 1991; Klein, 1998) or even negative (Agrawal and Knoeber, 1996). There are exceptions Rosenstein and Wyatt (1990) who show that stock price reacts positively to the nomination of independent directors to the board. Holthausen, and Larcker (1999) find a positive relationship between the fraction of independent directors and market-to-book ratio.

Connection often related to political connection. Prior literature presents only inconclusive evidence on the effect of corporate political activity on firm operating performance (Faccio, 2006; Goldman et al., 2009; Cooper et al., 2010; Hill et al., 2013; Chen et al., 2015; Ansolabehere et al., 2004; Hadani and Schuler, 2013). When it comes to lobbying activities, Hill et al. (2013) and Chen et al. (2015) both find a positive link between firm performance and lobbying expenditures. Other researches find either no link (Ansolabehere et al., 2004) or a negative link (Hadani and Schuler, 2013) between corporate lobbying and firm performance. Lobbying activities found to be positively related to financial performance (Chen et al 2015; Borisov et al 2015). The study of Duchin et al (2010) suggests that independent directors might affect appointed firm positively on their operating performance.

Independent directors which primary company executes lobbying activities called ID-PCL. We aim to study whether appointed firm with ID-PCL have better or lower firm performance.

After the SOX regulation on 2002, firms are required to have independent directors of more than 50% of the total board members. With major rules of board of directors which are advising and monitoring (Coles et al, 2008; Adams and Ferreira, 2007; Adams and Mehran, 2003; Agrawal and Knoeber, 2001), appointed firms with ID-PCL would likely to have a better firm performance. Daily experience of independent directors from their primary company might help on how they monitoring and advising appointed firms.

In this study, we wanted to see how independent directors affect the performance of their appointed firms through their connection which is lobbying activities of their primary companies. Previous studies mention the regulatory definition of an independent directors (e.g., Duchin, Matsusaka, and Ozbas, 2010; Cohen, Frazzini, and Malloy, 2012). Baysinger and Hoskisson (1990) mention that board is an important instrument of internal control. Larger boards potentially bring more experience and knowledge and offer better advice (Dalton, Daily, Johnson, and Ellstrand, 1999), complex firms should have larger boards size, which open an opportunity to welcome independent directors from various primary companies. This phenomenon supported when appointed firm bring CEO's of other firms to join the board members as independent directors shows that each firm at least have independent directors with primary company.

Most of the papers in the literature examine board characteristics such as the fraction of independent directors or specific types of independent directors and their relationship to corporate performance and policies.

Agrawal and Knoeber (2001) suggest that independent directors are senior managers in other firms and these directors play a political role. Furthermore, they focus on the independent directors that can aid dealings of a firm by using their skills to predict or affect government and prospective business collaboration, because these directors have friendship with decision makers and experience to cut deal with government.

The question of whether the appointed firms with ID-PCL have a better operating performance has been difficult to test due to simultaneity between lobbying activities of the independent director's primary company and firm performance. To address this issue we run natural experiment using modified difference-in-difference following Coles et al (2014). Also, we run two-stage least square to help us as our lobbying activities might be exogenous. To overcome endogeneity issue, we adopt the pre and post SOX event in 2002 and see the changes of the independent directors' composition between 2002 and 2003 while adjusting to the new regulation. We find that appointed firms with ID-PCL have a better operating performance.

We document a positive relation between independent directors (measured by lobbying activities of the independent director's primary company) and operating performance (measured by return on assets, return on equity and net profit margin). These findings supported by previous literatures showing independent directors tend to have wider networking and experience and thus affect areas such as tax rates (Richter et al., 2009), regulatory oversight

(Bonardi et al., 2006; Lux et al., 2011), tariffs (Mayda et al., 2010), and government contracts (Goldman et al., 2013).
We next explore possible channel on independent directors and operating performance. Study of Anderson et al (2004) suggests that cost of debt are related to board independence. Hovakimian et al, (2001) explain on how firm move based on the tradeoff between cost and benefit of debt to adjust capital structure. Hackbarth & Mauer (2012) study on how firm predict on priority structure including financial leverage.
Furthermore, we wanted to test whether the existence ID-PCL could lower cost of debt. To do so we regress ID-PCL with cost of debt. We find that firms with ID-PCL have lower cost of debt. This results shown that the appointed firms with ID-PCL have a better operating performance which shown through our channels that firms with ID-PCL would enjoy lower cost of debt.
The main contribution of this paper is to enrich literature for the function of the board. Compared with previous studies of board functions as monitoring and advising (Coles et al, 2008; Adams and Ferreira, 2007; Adams and Mehran, 2003; Agrawal and Knoeber, 2001), we provide a new angle to argue that independent directors could also bring connection through beneficial social networking into the appointed firm. This kind of networking is profitable for the company, shown by lower cost of debt through the existence of ID-PCL. By the existence of ID-PCL with networking and political influence, could lower the assymetric information problem and open wider opportunities for the firm.
The rest of the paper is organized as follows. Section 2 contains the literature review and hypothesis development, while Section 3 discusses the data and methodology. Section 4 presents and analyzes the empirical results. Section 5 figures the endogeneity issue. Section 6 displays robustness test. Section 7 concludes. Variable definitions are explained in Appendix A.

LITERATURE REVIEW

Independent Directors' Connection and Firm Operating Performance

NYSE and Nasdaq regulations approved by the SEC in 2002 go beyond SOX and require a majority of directors on the board to be independent. Firms responded to the new regulations by significantly increasing the representation of independent directors on their boards and committees over time. Fama and Jensen (1983) theorize that the board of directors is the highest internal control mechanism responsible for monitoring the actions of top management. There are lots of theoretical and empirical result which shown the function of board of directors as monitoring and advising the firm, or both. Particularly, the outside independent directors are into that roles inside the board. Masulis and Mobbs (2014) suggest that independent directors are attracted by available board seats. Outside independent directors are expected to avoid potential conflict of interest (Ryan and Wiggins, 2004) that can reduce their monitoring capacity. While Fracassi and Tate (2012) mention that firm with powerful CEO are appointing directors that have a background story or ties to them. Agrawal and Knoeber (2001) discuss whether outside director with political background are valuable to firms and the results shown that outside directors are valuable.
Nguyen and Nielsen (2010) mention that the after effect of the death of independent directors, firm value decreased. Fahlenbrach et al (2016) suggest that departure of independent directors impact stock and operating performance of the firms negatively. Independent director and inside director have their own roles on affecting firm operating performance. Fama and Jensen (1983) find that inside directors are more likely to possess superior information that, together with their experience, allows them to contribute to firm value. When board allows both independent directors and inside directors to perform their roles optimally then they are valuable to the firm. Thus, firms with ID-PCL would have a better operating performance.
This reasoning leads to our hypotheses:

H*₁*:* *Firms with ID-PCL are associated with better operating performance

Independent Directors' Connection and Cost of Debt

Larger firms are more likely to have external contracting relationships (Booth and Deli, 1996) and, thus, require larger boards (Pfeffer, 1972). Knyazeva, Knyazeva, and Masulis (2013) find that larger firms tend to draw experience director candidates even from distant location. Helleand & Sykuta (2004) find that the number of political directors increases as firms shift from market to political competition.

Firms most likely scout CEO from other company as their independent directors (Fahlenbrach et al., 2010). If the CEO is actively involved in lobbying activities from their primary company, he will most likely agree to the decision made by the CEO's as independent directors in the appointed firms. Hwang and Kim (2009) mentioned that 87% boards are precisely independent but only 25% are socially independent. This means that independent directors are more likely ties to the firms. In this paper, we wanted to show empirically that the existence of independent directors which primary company execute lobbying activities have positively strengthened appointed firm operating performance. Hill et al (2013) shares that shareholders value the lobbying activities pursued by management on their behalf. Ryan et al (2004) mentioned that independent directors have bargaining power over CEO.

Lobbying activity was a critical component in the rise and fall of the firms. Corporate lobbying activities are applied most likely from in-house lobbyist or lobbying firms. Corporation can also spend on gifts, meals and free trips for legislators. In general, since corporate lobbying activities are associated with a firm's business strategy and culture and bring multitude of advantages, lobbying activities could bring more connections to the firm. Lobbying activities are formed to influence other parties who are decision-maker [Lobbying are more likely connected to political activity: Agrawal and Knoeber (2001), de Figueiredo and Tiller (2006), Fisman (2001), Ansolabehere et al. (2004), Hillman et al. (2004), Fan et al. (2007), Kim (2008), Alexander et al. (2009), Goldman et al. (2009), Igan et al. (2009), Cooper et al. (2010), Yu and Yu (2011), and Hill et al. (2013).] Lobbying activities also open to a wider networking and thus affect areas such as tax rates (Richter et al., 2009), regulatory oversight (Bonardi et al., 2006; Lux et al., 2011), tariffs (Mayda et al., 2010), and government contracts (Goldman et al., 2013).

This reasoning leads to our hypotheses:

H*₂*:* *Firms with ID-PCL are associated with lower cost of debt.

DATA, METHODOLOGY AND KEY VARIABLES

Data

Directors data was taken from RiskMetrics database for the years 1996 to 2015. We focus on directorships within RiskMetrics database. RiskMetrics contains individual director information for the S&P 1500 firm variables resulting in 190,441 director-firm-year observations. We filtered the "board affiliation" variable, then we exclude executive directors and only retrieve independent directors' data.

In 1995 there was Lobbying Disclosure Act which requires a registration and reporting on lobbying activities. Registrant must file reports detailing the issue of lobby and the total amount spent. Brasher and Lowery (2006) develop a different test on new model of corporate political activity with Hoover's Handbook, while others test on the corporation provided by Fortune 500 and 1000. Our lobbying expenditure data taken from Center for Responsive Politics (CRP) website [https://www.opensecrets.org/lobby/] that provides lobbying expenditure of registered firms that covers public firm, private firms and institutions not limited only to US data. The CRP data includes lobbying, PAC contributions, and soft money categories. The CRP used the amount reported by the organization (including both in-house lobbying and external lobbyist filings) as the total lobbying expenditure for the period. Even if an organization does not report, the CRP sums lobbying expenditures reported by its external lobbyist. Lobbying data are available from 1998. Since the CRP does not use company identifiers (e.g., CUSIP, PERMNO, etc) we manually verified the names of the public firms to ensure the matching of RiskMetrics and CRP lobbying data. Lobbying expenditure data was recorded one by one as one firms might have a lot of independent director coming from different primary company. Accounting variables are obtained from Compustat database and stock return are generated from CRSP. Institutional ownership data are obtained from Thomson 13F report. To construct data from firm-year-director data (primary company) into firm-year data we create our own Ticker for director names, since director identifier is not available for every director on the list. To match the data of RiskMetrics and Compustat we use CUSIP identifier. To match the data of RiskMetrics and CRSP we use GVKEY.

Measuring ID-PCL (Independent Director with Primary Company That Lobby)
Our measurement for ID-PCL (independent directors with primary company that lobby) is the lobbying expenditure spent by independent director's primary company. RiskMetrics contains individual director information for the S&P 1500 firm variables resulting in 190,441 director-firm-year observation. Applying the "board affiliation" variable, we exclude executive directors and only retrieve independent director data. From Risk Metrics data, there are 141,474 independent directors-years observations. Then filtered by "primary company" variable we exclude independent directors without primary company and resulting 97,366 independent directors-firm-year observation with primary company. Here we generate our own ticker for each director [Names of the directors are many. Some with tittle, some with space. We generate our own ticker for directors to match repetition of director-primary company easier.]
Filtering the year from 1998 – 2015 give us 97,366 independent directors with primary company, there are 19,318 primary company which spent lobbying expenditure. We exclude all the primary company with no record on CRP lobbying data. We sum up the amount based on the appointed firms and put it as lobbying expenditure for the appointed firms. We sum up the total lobbying expenditure of the ID-PCL from the same firm which leads us to the final 12,318 firm-year observation. We collect accounting variables and other variables needed based on 1,743 unique appointed firms.

Measuring Firm Operating Performance
Most of the literatures measure firm performance with return on assets (ROA), return on equity (ROE), and net profit margin (NPM). Following paper Gompers (2010) we measure firm operating performance as ROA, ROE and NPM. [Appendix A shows variable explanations used in this paper].

Possible Channel
To extend our evidence on the effect of ID-PCL to firm operating performance, we run regression of ID-PCL to cost of debt. Previous research (construct cost of debt as total interest expense plus capitalized interest divided by total assets. We construct cost of debt measured by total interest expense for long debt divided by total debt, since we wanted to see the effect of the long-term cost of debt specifically.

Control Variables
Consistent with prior literature, control variables include controls for firm characteristics: firm size (log sales), dividend, leverage, and return; director characteristics: independence (percentage of independent director) female on board (dummy variable with condition of 1 if at least one female on board and 0 otherwise), board size (total number of the board); and

governance control: takeover index (construct by Cain et al), institutional ownership (percentage of ownership of the shares), e-index (the sum of cboard, labylw, lachtr, supermajor, golden parachute, ppill) following Gompers (2010) paper, and herfindahl index (the sum of squared market share).

Summary Statistics

Table 1 reports descriptive statistics for the sample of S&P 1500 appointed firms with independent director which primary company execute lobbying activities. The minimum of lobbying activities of $0 are reported on CRP lobbying data. Some primary company have been active on lobbying activities, however there are some years that they report $0 lobbying expenditure. Previous lobbying studies use the minimum reporting amount of lobbying expenditure which is $10,000 [see paper Borisov et al 2015 for further details on the lobbying expenditure reported]. We include those $0 lobbying activities as long as they are recorded in CRP lobbying data. The average of $840 million per year is the lobbying activities of the primary company. Since one firm will have a combination of several independent directors from different primary companies, the highest dollar amount of ID-PCL is $1,3 billion. Firms with ID-PCL have an average of 5% return on assets, average of 10% of return on equity and 5% of net profit margin. The size of the appointed firms with ID-PCL is included in the top rank firms that needs larger board with wider networking.

Notes: This table presents Pearson's correlations of variables. Bolded values indicate correlation significance at 5 percent level or better. All variables are defined in the appendix.

EMPIRICAL RESULTS

To test whether firms with ID-PCL have a better firm operating performance, we run ordinary least square (OLS) regression for all our dependent variables: return on assets, return on equity, net profit margin, and cost of debt.

ID-PCL and Firm Operating Performance

We study the ID-PCL effect on firm operating performance in order to find the relationship by using return on assets (ROA), return on equity (ROE) and net profit margin (NPM) as the measurement of operating performance and use following models for estimation:

$$ROA_{i,t} = \beta_0 + \beta_1 \log(ID\text{-}PCL)_{(t-1)} \ \ \beta_{2-5} Firm\ Characteristics_{i,(t-1)} + \beta_{6-9} Director\ Characteristics_{i,(t-1)} + \beta_{10-13} Governance\ \ Controls_{i,(t-1)} + Year\ Dummies_{i,t} + Industry\ Dummies_{i,t} + \varepsilon \quad (1)$$

$$ROE_{i,t} = \beta_0 + \beta_1 \log(ID\text{-}PCL)_{(t-1)} \ \ \beta_{2-5} Firm\ Characteristics_{i,(t-1)} + \beta_{6-9} Director\ Characteristics_{i,(t-1)} + \beta_{10-13} Governance\ \ Controls_{i,(t-1)} + Year\ Dummies_{i,t} + Industry\ Dummies_{i,t} + \varepsilon \quad (2)$$

$$NPM_{i,t} = \beta_0 + \beta_1 \log(ID\text{-}PCL)_{(t-1)} \ \ \beta_{2-5} Firm\ Characteristics_{i,(t-1)} + \beta_{6-9} Director\ Characteristics_{i,(t-1)} + \beta_{10-13} Governance\ \ Controls_{i,(t-1)} + Year\ Dummies_{i,t} + Industry\ Dummies_{i,t} + \varepsilon \quad (3)$$

Where ROA is the ratio of total assets divided by net income. ROE is the ratio of total equity divided by net income and NPM is the ratio of sales divided by net income. ID-PCL is the log of the sum of lobbying expenditure of primary company's independent directors of firm *i* in year *t*. For controlling unobserved factors of a firm, we use a fixed effect model to control the time effect by using year dummies to capture factors which affect all firms at the same time and use 48 Fama industry classification to control industry effect to capture all firms in the same industry. All variables are winsorized at 1% and 99%.

Table 3 reports the results of ID-PCL and firm operating performance. We examine each dependent variable with single regression in model (1), model (3) and model (5), and including all control variables in model (2), model (4) and model (6). Coefficient of ID-PCL are positive and significant in 1% level, respectively, indicating that firms with ID-PCL have a better operating performance of 0.06% return on assets, 0.2% of return on equity and 0.12% of profit margin and statistically significant in 1% level after controlling firm characteristics, director characteristics and governance control.

Table 3: Effect of ID-PCL on Firm Operating Performance

Adj. R.Sq	0.067	0.183	0.071	0.172	0.055	0.059

This table reports OLS estimates of the relationship between ID-PCL and operating performance. Firm operating performance is measured by: ROA= net income divided by total assets in year t. ROE= net income divided by total equity in year t.; NPM=net income divided by total sales in year t. Independent variable is ID-PCL= lobbying expenditure executed by primary company of independent director in year t. Control variables for firm characteristics, director characteristics and governance characteristics. The samples are from S&P 1500 with coverage of CRSP and COMPUSTAT files annually, for the years 1998-2015. All regressions include Fama and French 48 industry fixed effects and year fixed effects. t statistics in parentheses * p < 0.05, ** p < 0.01, *** p < 0.001 indicate the regression coefficient significantly different from zero at the 5%, 1% and 0,1% levels, respectively.

ID-PCL and Cost of Debt

We want to extend our analysis and give more evidence through some channels on ID-PCL and firm operating performance. We test leverage and cost of debt as the channels. To test the channel of independent director with primary company lobbying expenditure, we study the ID-PCL to book leverage (BL), market leverage (ML) and cost of debt with these following models:

$$COD_{i,t} = \beta_0 + \beta_1 \log(ID\text{-}PCL)_{(t-1)} + \beta_{2\text{-}5}\,Firm\ Characteristics_{i,(t-1)} + \beta_{6\text{-}9}\,Director\ Characteristics_{i,(t-1)} + \beta_{10\text{-}13}\,Governance\ Controls_{i,(t-1)} + Year\ Dummies_{i,t} + Industry\ Dummies_{i,t} + \varepsilon \quad (4)$$

Where cost of debt measured by interest expense of long-term debt divided by total debt. ID-PCL is log of the sum of lobbying expenditure of primary company's independent directors of firm *i* in year *t*. For controlling unobserved factors of a firm, we use a fixed effect model to control the time effect by using year dummies to capture factors which affect all firms at the same time and use 48 Fama industry classification to control industry effect to capture all firms in the same industry. All variables are winsorized at 1% and 99%.

Table 4 report the results of ID-PCL and cost of debt. Coefficient of ID-PCL are negative and significant in 1% level, respectively, indicating that firms with more independent director with primary company that lobby (ID-PCL) have a lower cost of debt of 2%. Economically significant when the firms with ID-PCL would enjoy a lower cost of debt. In addition to Gamba & Triantis (2008) that shows the cost of external financings is on of key factor to financing flexibility that determine firm's growth.

ENDOGENEITY ISSUE

Difference in difference

Endogeneity is a common issue in the literature on boards of directors (Hermalin and Weisbach, 2003). Endogeneity is an important issue for corporate governance study (Coles et al 2011). Specifically, there is possibility that ID-PCL and firm operating performance variables are high due to an unobserved variable. However, it is not easy to find an instrument that is related to ID-PCL but is not related to any operating performance variables. Following paper Coles et al (2014) we run a natural experiment to help us address endogeneity concerns.

We use the SOX rules in 2002 which require all listed firms to have a majority of independent director on their board. Because the rules were adopted after the passage of SOX, we refer to 2003 as the starting year of Post-SOX period. Pre-SOX noncompliant firms were required to have majority of independent director (Engel et al, 2007; Linck et al, 2009). With this, an exogenous increase was found in ID-PCL.

Following Coles et al (2014 we modify the Bertrand and Mullainathan (2003) difference-in-difference (DID) methodology. The difference will be reflected on the possibility that SOX have a direct effect on operating performance and the channel.

We modify the typical DID setup to see the effect of ID-PCL (with the term called "clean" effect). Commonly, DID setup for Q, for example, would be the regression of Q on three dummy variables: *Post-SOX, Noncompliant*, and interaction term *Post-SOX x Noncompliant*, where *Post-SOX* is an indicator variable that equals one if the year is 2003 or later and equals 0 otherwise, and *Noncompliant* is an indicator variable that equals one if the firm was not in compliance in 2002, and equals 0 otherwise. ID-PCL is not included in the above condition, and only focus on the coefficient of *Post-SOX x Noncompliant*. However, this coefficient will capture the effect that we want to isolate and the direct effect of SOX.

This table reports OLS estimates of the relationship between ID-PCL and cost of debt. Cost of debt is measured by: cod = total interest expense for long debt divided by total debt in year t. Independent variable is ID-PCL= lobbying expenditure in year t-1. Control variables for firm characteristics, director characteristics and governance characteristics. The samples are from S&P 1500 with coverage of CRSP and COMPUSTAT files annually, for the years 1996-2015. All regressions include Fama and French 48 industry fixed effects and year fixed effects. *t* statistics in parentheses * $p < 0.05$, ** $p < 0.01$, *** $p < 0.001$ indicate the regression coefficient significantly different from zero at the 10%, 5% and 1% levels, respectively

We take ROA as an example in the equation and run this regression to all our dependent variables. The controls in the regression include independent variables used in the *ROA, ROE and NPM* regression in Table 3 and the individual dummies, and the interactions of the independent variable with the three key dummy variables: *Post-SOX, Noncompliant*, and *Post-SOX x Noncompliant*. Then we calculate joint test for $\beta_1 + \beta_3 + \beta_4 = 0$ for each dependent variables to find the "clean" estimate.

To estimate the effect of ID-PCL, we run the modified regression which includes ID-PCL and the interaction of ID-PCL with the three dummy variables:

$$\begin{aligned} \textit{Return on Assets}_{i,t} = {} & \beta_0 + \beta_1 \log(\textit{ID-PCL})_{(t-1)} + \beta_2\, \textit{POST-SOX} \times \log \textit{ID-PCL}_{(t-1)} \\ & + \beta_3\, \textit{Non Compliance} \times \log \textit{ID-PCL}_{(t-1)} \\ & + \beta_4\, \textit{POST-SOX} \times \log \textit{ID-PCL}_{(t-1)} \times \textit{Non Compliance} \\ & + \beta_5\, \textit{POST-SOX} + \beta_6\, \textit{Non Compliance} \\ & + \beta_{7\text{-}10}\, \textit{Firm Characteristics}_{i,(t-1)} + \beta_{11\text{-}14}\, \textit{Director Characteristics}_{i,(t-1)} \\ & + \beta_{15\text{-}18}\, \textit{Governance Controls}_{i,(t-1)} + \textit{Year Dummies}_{i,t} + \textit{Industry Dummies}_{i,t} + \varepsilon \end{aligned} \quad (5)$$

Table 5 provides the result of the clean estimates. Briefly, we present only the clean estimates for the total estimates of ID-PCL on each of the four variables of interest including the channel (return on assets, return on equity, net profit margin, and cost of debt). To make it easier to compare, we report the base case regression (model 2, 4, 6 of Table 3, and model 5 of Table 4).

The results in Table 5 shows that parallel to the base case, the estimates based on an exogenous shock to ID-PCL have the same sign and statistically significant in 1% level.

Table 5: Clean Estimates

Table 6: Model 5 (COD)	-0.000229*** -3.58	-0.0329** -2.13

Instrumented Variables

We run two-stage least square (2sls) with instrumented variables. We use regulatory changes to adopt more independent boards following Sarbanes-Oxley Act (SOX) regulation, which required firms to have a majority of independent directors (for a similar approach, see Duchin, Matsusaka, and Oguzhan (2010)). At the first stage we regress the exogenous variable changes

in the composition of independent director of appointed firm using the changes in regulation of SOX on 2003 as the exogenous variable and at the second stage we replace the fitted variable from the first stage.
Panel a, b, c and d of Table 6 presents the results of the test for the omitted variable problem. Each table runs five models to regress ID-PCL with each dependent variables: model (1) single

regression, model (2) include only control of firm characteristics, model (3) include only control of director characteristics, model (4) include only control of governance and model (5) include all control variables. Comparing to the result of OLS regression, firms that changed from less to more independent directors against firms that already had independent boards, we find that ID-PCL is significantly and positively associated with operating performance and the channels: return on assets, return on equity, net profit margin, cost of debt. The results are consistent with Table 3, and Table 4.

ROBUSTNESS TESTS

For robustness test we wanted to test whether the result would be the same when we change the measurement of operating performance. Following Chen et.al (2015) we change measurement of operating performance into financial performances: cash from operation, income before extra items, and net income.

We run the OLS regression with the following models similar to equation 1 and 2 and include all control variables:

$$\begin{aligned} \textit{Net Income}_{i,t} = {} & \beta_0 + \beta_1 \textit{ log ID-PCL}_{(t-1)} + \beta_{2\text{-}5}\textit{ Firm Characteristics}_{i,(t-1)} \\ & + \beta_{6\text{-}9}\textit{ Director Characteristics}_{i,(t-1)} + \beta_{10\text{-}13}\textit{ Governance Controls}_{i,(t-1)} \\ & + \textit{Year Dummies}_{i,t} + \textit{Industry Dummies}_{i,t} + \varepsilon \end{aligned} \tag{6}$$

$$\begin{aligned} \textit{IBEI}_{i,t} = {} & \beta_0 + \beta_1 \textit{ log ID-PCL}_{(t-1)} + \beta_{2\text{-}5}\textit{ Firm Characteristics}_{i,(t-1)} \\ & + \beta_{6\text{-}9}\textit{ Director Characteristics}_{i,(t-1)} + \beta_{10\text{-}13}\textit{ Governance Controls}_{i,(t-1)} \\ & + \textit{Year Dummies}_{i,t} + \textit{Industry Dummies}_{i,t} + \varepsilon \end{aligned} \tag{7}$$

$$\begin{aligned} \textit{CFO}_{i,t} = {} & \beta_0 + \beta_1 \textit{ log ID-PCL}_{(t-1)} + \beta_{2\text{-}5}\textit{ Firm Characteristics}_{i,(t-1)} \\ & + \beta_{6\text{-}9}\textit{ Director Characteristics}_{i,(t-1)} + \beta_{10\text{-}13}\textit{ Governance Controls}_{i,(t-1)} \\ & + \textit{Year Dummies}_{i,t} + \textit{Industry Dummies}_{i,t} + \varepsilon \end{aligned} \tag{8}$$

ID-PCL is log of the sum of lobbying expenditure of primary company's independent directors of firm *i* in year *t*. For controlling unobserved factors of a firm, we use a fixed effect model to control the time effect by using year dummies to capture factors which affect all firms at the same time and use 48 Fama industry group to control industry effect to capture all firms in the same industry. All variables are winsorized at 1% and 99% level.
Table 7 reports the results of OLS regression between ID-PCL and three dependent variables of financial performance for robustness test. Each model represents each dependent variable with all control variables. Coefficient of ID-PCL are positive and significant in each model, respectively, indicating that firms with more independent director with primary company that engage in lobbying activities (ID-PCL) have a better financial performance. This is in line with the finding of Chhaochharia and Grinstein (2007) that shows the announcement of SOX rules in 2002 which to fix auditing of US public company (Coates and John (2007) is significantly affect firm value.

CONCLUSSIONS

This study presents empirical evidence on the firms with the existence of ID-PCL (independent director with primary company engaged in lobbying activities) have a better firm operating performance. Previous literature stated that the existence of independent directors is expected to have roles in monitoring and advising management, we find that the firms with ID-PCL have a better operating performance through their social networking. Furthermore, using cost of debt as the channel, we find that firms with ID-PCL do have lower cost of debt. Existence of ID-PCL in the board formation is the reflection of wider networking and more experience of the independent director on influencing decision makers. This brings bigger opportunities to the appointed firms by having independent directors coming from public listed firms, private company and institutions as well. The results are robust with an alternative measurement of operating performance which are cash from operation, income before extra items and net income.

This paper contributes a different angle of board function as networking source. Networking is reflection of connection and advantageous for the firms while generating financing decisions. Moreover, we show lobbying activities from different point of views. Most of the studies on lobbying activities find direct effect of the lobbying activities itself to other dependent variables while our paper use lobbying activities of the primary company of independent director and see the effect on appointed firm as networking function. This is in line with previous study of Balsmeier et al (2014) that mention independent director from primary company which is innovative firms increase patenting activities. Masulis and Mobbs (2011) mention that foreign independent directors make better cross-border acquisition. Our paper is the first paper on measuring independent director from their primary company's activities that provide economically significant evidence.

APPENDIX

A. Variable Definition

Variable	Definition	Data Source
ID-PCL	Lobbying expense measured by natural logarithm of dollar amount of lobbying expense of independent director primary company	CRP lobbying data
ROA	Measured by net income divided by total assets (ni/at)	Compustat
ROE	Measured by net income divided by total equity (ni/ceq)	Compustat
NPM	Measured by net income divided by total sales (ni/sale)	Compustat
COD	Measured by interest expense of long term debt/ total debt (intl/tdebt)	Compustat
Control Variables:		
Firm Characteristics		
SIZE	Measured by total sales (sales)	Compustat
DIV	Measured by cash dividend (data item 127)	Compustat
LEV	Measured by long term debt divided by total debt (dlt/tdebt)	Compustat
RET	Measured by buy hold return	CRSP
Director Characteristics		
IND	Measured by number of independent director divided by total number of boards	Risk Metrics
AGE	Age of the independent director	Risk Metrics
TENU	Measured by number of year independent director has been working in the company	Risk Metrics
FEM	Dummy variable which equals to 1 if at least 1 female director listed, 0 otherwise	Risk Metrics
Governance Characteristics		
TOI	Takeover likelihood	Cain et al
IO	Average of institutional ownership	Thomson Reuter 13F
eIndex	Sum of (cboard,labylw,lachtr,supermajor,GoldenParachute,ppill)	Risk Metrics
HHI	Sum of square market share	Compustat

ABSTRACT

This study highlights the role that social networks play in a corporate tax aggressive. We construct a comprehensive social network using data on Taiwan-listed companies that arises from education background, prior experience, and other social activities such as training courses, business forums and meetings of CEO and CFO during the period from 2010 to 2014. We find that the social networks of CEO, CFO help reduce (increase) corporate tax avoidance. Those findings suggesting that the information on a range of tax avoidance strategies is share among firms by the corporate network ties of CEO and CFO.

KEYWORDS: Corporate Governance, Corporate Social Network, Corporate Tax Aggressive

INTRODUCTION

Corporate tax avoidance is an important research topic in both finance and management, attracted more attention of scholars. Prior literatures show the benefits of tax aggressive on firm earning target, reduce tax burden, increase cash flow (Hanlon, 2005), reduce cost of equity capital (Chi et al., 2014). Numerous studies also pointed out the potential penalty costs of implement tax avoidance (Mills et al., 2013), damage to firms and manager reputation(Chen et al., 2010) and how to firms exercise tax evasion by adopting tax strategies, tax planning (Frank et al., 2009).

At the same time, social capital has been a subject of attractive topic not only economic but also in other science fields. Social networks play as an important role in all social and economic transactions (Butler & Gurun, 2012). Social network impact to firm behavior because they promote the diffusion of new ideas and allow network firms to study vicariously from each other's experience (Bizjak et al., 2009; Fracassi & Tate, 2012). The pros and cons of social topic that received significant attention in academic research. One line of research explores the benefits of social network to their firms. From the perspective of *Information and Resource Hypothesis*, social connection ties provided more helpful information that cannot be acquired from other sources to corporate decision making (L. Cohen et al., 2008; Horton et al., 2012;

Renneboog & Zhao, 2011). In addition, *Quality Hypothesis* suggests that CEOs' external social networks can be used to assess CEO quality (Butler & Gurun, 2012). *Reputation Hypothesis* explored that greater external social networks represent individual personal quality, talent, past success and reputable figures (Renneboog & Zhao, 2011).

A numerous of literatures show that CEO networks do not constitute valuable resources, further resulting in several negative outcomes. From the perspective of *Power Hypothesis*, CEOs can use social network in order to gain more power over the board and acquire self-dealing compensation arrangements beneficial to themselves (Belliveau et al., 1996). Subrahmanyam (2008) shows that a CEO's pre-existing network can harm governance practices. Fich and Shivdasani (2006), Malmendier and Tate (2009) suggest that executive social networks result in less time to monitor.

Based on this emerging line of research to elicit the value of CEO and CFO social networks, we explore the role of corporate social networks in corporate tax avoidance. We assume that the relationship between social networks and tax avoidance has not received much studied from scholar, partly due to the limit of data and measurement difficulties. We explore two research questions: (1) whether the external social networks influence corporate tax avoidance; (2) whether the effects of social networks on tax aggressive vary between CEOs and CFOs.

To examine the tax aggressiveness of firms, we adopt on multiple measures of tax aggressiveness drawn from the literature. Specifically, we use two effective tax rate measures and two book-tax difference measures: long-term effective tax rate (defined as total tax expense divided by pre-tax income), long-term cash effective tax rate (defined as total refund income tax divided by pre-tax income), the permanent book-tax difference measure advanced by Lennox, et al. (2013). Firms that are more tax aggressive have lower effective tax rates (ETRs) and higher permanent book-tax differences. We follow Freeman (1978) to construct two main variables to measures the network ties of CEO and CFO by direct connections to assess actual influence (degree) and indirect connection measures to capture information collection ability (closeness). Our sample is constructed a comprehensive social network of Taiwan listed companies that arises from employment, education background, prior experiences, and other social activities such as training courses, business forums, and meetings. These social ties are tracked over span 5 years, from 2010 to 2014. Our final sample firm for the main test contains more 6,700 firm year observation for 1115 firms.

We find that firms with higher CEO social network have a significant higher effective tax rate (ETRs) and lower permanent book tax difference, while our results show the positive relation between CFO and tax avoidance for all three our tax measure. Next, we use the instrumental regression to reduce endogeneity problems. We find statistically and economically significant evidence that firm have lower (higher) tax avoidance if theirs CEOs (CFOs) are social connected, supporting for our main results. In addition, we also perform robustness tests by using alternative measure tax avoidance consist of effective tax rate and effective cash rate, and alternative social network includes Betweenness and Eigenvector, and Tobit regression. Our main results hold under all specifications. Finally, we examine the interaction between CEOs (CFOs) personal traits such as powerful and background and their network ties effect on tax aggressive [See Appendix A for variables definition]. We find the statistic empirical evidence supported for our main results.

Our study adds several findings to the extant literature on the ways in which social network affects tax aggressive. Firstly, unlike (Coff, 2002), who explore the effect of abilities and knowledge of CEO and CFO on firm performance and financial report, our study and the work of (Hanlon & Heitzman, 2010) is closely related, we focus on the directly the ties between tax avoidance and social network. To our best knowledge, we are the first in the literature to document evidence both CEOs and CFOs have impact to corporate tax aggressive by constructing a comprehensive social network from their employment, education and other experience. Second, our research adds more evidence about the impact of social network in

finance and accounting to firm decision, especially on firm's tax related decisions. Finally, we also show the consistent empirical that the interaction between CEO's and CFO's background and their social network significant impact on tax avoidance.
The remainder of this paper is organized as follows. Section 2 reviews related literature and develop our hypothesis. Section 3 provides a description of the data and the research methodology. Section 4 presents and analyzes empirical results. Finally, section 5 offers the conclusion drawn from this study.

LITERATURE REVIEW AND HYPOTHESIS DEVELOPMENT

Tax Aggressive

Taxes represent a significant cost to the firm and shareholder. Tax savings often increase after-tax income, cash flow and shareholder wealth. Therefore, all firms and shareholders generally expected minimize corporate tax payments through tax aggressive activities. Phillips et al. (2003), Hanlon (2005) find that tax avoidance is an effective income management tool for a firm to achieve their earning target, while also reducing tax burden and increasing cash flow. Tax avoidance is valued by shareholders so that firms are willing to participate in tax planning if it is considered as value-increasing activities. Desai and Dharmapala (2006) pointed out the positive relation between tax avoidance and firm value. Dyreng et al. (2010) recognize that firms adopting various tax strategies (even possibly illegal) to reduce taxes. Further, the reduction in a firm's effective tax rate provided by tax avoidance is potentially a positive signal to investors, thereby reducing the cost of equity capital (Chi et al., 2014; Inger, 2014; McGuire et al., 2014). Firms can reduce their tax burdens through four primary ways: multinationality, tax havens, intangible assets, and transfer pricing aggressiveness. Firms can reduce their tax burdens by "offshore sheltering", it allows firms to syphon their profits to foreign subsidiaries where the tax rate is lower. For example, National Public Radio disclosed that companies such as Pfizer, Microsoft, and Google were taking advantage of offshore tax havens. Companies also may create complex structures involving tax-indifferent related parties to avoid detection by auditors and tax authorities.
Shackelford and Shevlin (2001) find the unbalance between aggressive financial reporting and tax avoidance. Frank et al. (2009) suggested that firms might use tax planning, aggressive tax reporting for their tax avoidance. Phillips et al. (2003) show that adopt compensation policy based on after tax -performance leads to less effective tax rates. Agree with point, Rego and Wilson (2009) pointed that a positive tie between compensation and aggressive tax reporting, they find no relationship between this aggressiveness impact to firm performance in the future or is as a result of inefficient management. Rego and Wilson (2012) point out those companies provide incentive compensation to engage in tax aggressive activities. In addition, Dyreng et al. (2008) finds that the quality of corporate governance, institutional ownership, debt policy and international operations are also related to firm's tax avoidance activities. Minnick and Noga (2010) examine corporate governance's role in a firm's choice of tax strategies. Governance plays important role for choosing long-term tax management. Company with different governance structure may be purse difference type’s tax management. Chen et al. (2010) find that ownership structure can also associated with aggressive tax, family owners are less tax aggressive than no-family firms to avoid other cost and potential penalties.
Although, the most obvious benefit of tax avoidance is maximizing firm value, tax saving is greater but one of the important cost of tax aggressiveness is the potential penalty (Mills et al., 2013), negative publicity (Lisowsky, 2009; Wilson, 2009); be labeled as “poor corporate citizens” (Hanlon & Slemrod, 2009) and potential reputation damage to firms and their managers (Chen et al., 2010; Graham et al., 2014; Rego & Wilson, 2009). According to recently survey by Graham et al. (2014), 69% of tax executives agree that potential harm to their firms’ reputations

when they make a decision about tax planning strategies. Managers implementing tax avoidance strategies are also personally exposed to the risk of penalties and fines, and damage to their reputations. Moreover, Austin and Wilson (2015) argue that another reason firms refrain from tax aggressive is the associate with loss of reputation with customers. They show the evident that reputable and valuable-brand firm names companies have higher effective tax rates. Also, in poorly managed companies, tax avoidance secrets may be exploited to obscure rent extraction by managers, resulting in future negative abnormal profits (Desai & Dharmapala, 2006). In addition, tax avoidance was used to hide the accumulation of bad news by managers, leading to the risk of stock price crash (J.-B. Kim et al., 2011)

Effects of Social Network

Social capital is an important research topic in both finance and management, attracted more attention of scholars. Social capital is the value of reputation, resources, and social actions embedded in relationships among people (Adler, 2001; Adler & Kwon, 2002; Carrie R. Leana & Buren, 1999; Lin, 2001). A social network is the media through which social capital is created, maintained and used. Thus, firms recently pay more attention to invest for social capital to get the benefits from acquiring richer resources. Although, the ties between social capital and business performance has received a numerous previous studies but detailed investigate about the role and influence of the establishment and maintenance of top executives' external networks on managerial effectiveness and strategic leadership is still limited.
External social networks refer to the relationships of executive with individuals outside the firm (Cao et al., 2006). Engelberg et al. (2012) pointed out that social network are established through education background from the same highest ranked programs. Collins and Clark (2003) argued executives' network are created when they have a larger set outside ties, such as external boards and managerial services, customers or competitors, alliance partners, government agencies, and trade associations. External networks play as an important role in all social and economic transactions, are often regarded as a valuable organizational resource and convey important strategic value to the company (Butler & Gurun, 2012; Engelberg et al., 2012). Social network theory suggests that social capital benefits not only through the ties themselves, but also their connection structures (Burt, 1997). Social network impact to corporate behavior because they promote the diffusion of new ideas and allow networked firms to study vicariously from each other's experiences (Bizjak et al., 2009; Fracassi & Tate, 2012). Adler and Kwon (2002) find that the impact of social network on firm behavior may depend on characteristics of both firm's relations to other firms and the kind of knowledge being share across those relations. Next, the benefits and potential drawbacks of external networks are discussed. From a positive perspective, social networks connection as facilitating information flows between individuals or companies. Many network advantages are from information collection. First, social ties help firms access to a broader source of information at a lower cost and improve information quality, correctness, and levels of specific details and timeliness (Adler & Kwon, 2002; Horton et al., 2012). Second, social ties help firms access information and knowledge from external parties thence combine acquired information with their own existing knowledge to explore new learning opportunities and even to formulate new competitive strategies (Grant, 1996; Kogut & Zander, 1992). Third, networks may enable firms to develop more effective corporate strategies from accessing valuable information, firms may formulate and implement useful competitive strategies (Ahuja & Katila, 2004; Athanassiou & Nigh, 2002; Geletkanycz & Hambrick, 1997). In addition, external social connections improve the sharing of information thus reduce the possibility of deception, error, and misconduct and allow networked firms to learn vicariously from each other's experiences (Baker & Faulkner, 2004; Fracassi, 2017; Kilduff & Tsai, 2003) argued that managers are influenced when making investment decision and other corporate finance decisions by their social partner.

On the other side, socially influential people may abuse their reputation or power to hide their misconduct lead to ineffective manage that may be detrimental to the firm and shareholders (Jack Dorminey et al., 2012). Bebchuk and Fried (2006) find an empirical that executives using their power to impact board and compensation to get excessive compensation arrangements are not necessarily related to performance. The social ties of executives and directors impose greater information asymmetry in equity markets. L. Cohen et al. (2008) provide empirical evidence that social networks alter the increasing probability of informed trades in a company's stock. Hwang and Kim (2009) show that companies with board members who are personally connected to the CEO have higher CEO compensation, lower pay-performance sensitivity, and lower turnover-performance sensitivity. Chidambaran et al. (2011) find that the abilities of fraud are higher when CEO have the connections outside.

Recent studies argued the ties among social networks and tax strategies and tax policy decision. Hanlon and Heitzman (2010) studies the impact of directors networks and their social connections to other firms on tax-avoidance behavior. They strongly find empirical evidence that an interlocked board member was influential in spreading the use of an installment sales tax shelter. Brown (2011) finds evidence that network ties via board interlocks influence the discrete tax policy decision at the focal firm adopting the corporate-owned life insurance tax shelter. Larcker et al. (2013) provide evidence that board of director connections have an economic impact on the firm performance; better-connected firms earn significantly higher risk-adjusted returns and experience higher gains in profitability. In addition, Brown and Drake (2014) network ties created by executive director impact on tax avoidance

The Role and Influence of CEOs and CFOs

The role of managers in the firm's activities is topic to debate among researcher. According to (M. D. Cohen et al., 1972), Hannan and Freeman (1977) pointed out that the success of an organization is determined largely by its quality of products, core competency, life cycle, and to some extent even luck, and not by CEO ability. On the contrary, the upper echelon theory assumed that top executives make a significant contribution to firm performance, the organization's results reflect the values and abilities of top managers (Hambrick & Mason, 1982; Harris & Helfat, 1997; Hayes & Schaefer, 2000). Agree with this view, the human capital theory proposes that the knowledge and abilities of top managers can be an important determinant of firm performance ((Amit & Schoemaker, 1993; Becker, 1962; Coff, 2002).

Prior research has focused on analyzing the impact of CEOs on firm performance rather than CFO's. Scholars assume that CFOs are CEO agents (Graham & Harvey, 2001) and a CEO has the power to replace a CFO who does not follow the CEO's preferences. Agree with this view, Mian (2001) assumed that CEOs who occupy higher positions of power in the firms than to CFOs, as a result have the ability to impact the compensation, job security, future career opportunities, and financial reporting decisions of their CFOs (Feng et al., 2011; Krishnan et al., 2011). However, the important role of CFO also emphasized in prior literatures. CFO is considered as the second most important financial manager of the company after CEO in the enterprise hierarchy. CFOs are typically in charge of financial planning, budgeting, internal control and financial reporting (Gore et al., 2007; Kaufman, 2003), which helps them to have a significant understanding of firm weath. CFOs often supervise the process of making financial statements and are considered as supervisory agencies for financial reporting quality. Moreover, compared to other executives, CFOs is in a unique position to perform accounting operations, such as structuring transactions, selecting an inappropriate accounting method or implementing false journal entries. Prior studies have found that CFOs have a significant impact on firm's financial reporting (GE et al., 2011; Geiger & North, 2006). Although CFOs may generate a significant impact on the firm's financial decisions, they do not act alone if without CEO's guidelines and policy support. As the business partner of CEO, CFO creates the decision power to deliver desirable business results by collaborating with CEOs related in companies' financial decisions (Jiang et al., 2010). Agree with this views, Feng et al. (2011) argue that CEOs use their power to promote shareholder goals or put pressure on CFOs to manipulate reporting systems and excessive performance. He also argued that CEO pressure is the main driver of CFO regarding accounting manipulation. A recently survey of 141 CFO by public companies find that that 17% of CFO reports were pressured to misjudge their results by their company's CEOs during the past 5 years [More detail please refer at: The fear of all sums, CFO magazine. URL: ⟨http://www3.cfo.com/article.cfm/3005788⟩ (accessed 10.06.13)]. Dichev et al. (2013) surveyed 169 CFOs, of which 91% reported that pressure as a motivation to manage earnings. Therefore, the Securities and Exchange Commission's (SEC) recent regulations (e.g., Section 906 of the Sarbanes-Oxley Act, effective July 30, 2002; Section 302 of the Sarbanes-Oxley Act, effective August 29, 2002; The SEC June 27 Order in 2002) require both CEOs and CFOs to take responsibility for corporate financial reports, reflecting an understanding of the CEO and CFO collaboration on financial reporting and policy decisions.

Hypothesis Development

Prior scholars most research about CEO specific heterogeneity such as education, personal characteristics, or personality traits, but less study researches about the social network of CEOs, also CFO. The benefit and cons of personal connections are discussed by prior research. Personal connection leads to better analyst performance (L. Cohen et al., 2008), investment allocation efficiency (Duchin & Sosyura, 2013), more efficient mergers and acquisitions (M&A) decisions (Cai & Sevilir, 2012). On the other hand, personal ties also have some cons such as leading to deteriorate corporate governance and monitoring of managers, to lower pay-performance and turnover-performance sensitivities (Fracassi & Tate, 2012; Hwang & Kim, 2009).

We acknowledge that deeply research on the both CFO's and CEO's social network influence to firm performance is less studied. Our research question considers that whether CEOs and CFO who are most important top executive in firms use their personal connect to impact firm's performance through by tax avoidance activities. It tests following hypothesis: CEO's, CFO's social network is positive (negative) associated with corporate tax aggressive.

DATA SOURCE AND RESEARCH METHODS

For exploring the value of CEO's and CFO's corporate social network and its effect on tax aggressive, this study adopts regression models in which the proxies of CEOs' and CFOs' social network are regressors. The following introduces the research methodologies, including dataset, variable candidates, and the regression models.

Data Source and Sample Selection

Our sample selection starts with all Taiwan-listed firm on the Taiwan Economic Journal database from 2010 (tax reforms) to 2014 fiscal years. The initial sample consists of 10,914 firm-year observations. We first conduct screen the data to minimize observations with errors and to obtain the necessary data for empirical analysis. We eliminate foreign registrants and firms designated as real estate investment trusts (REITs) because these firms are subject to different tax rules. We continue delete observations that do not have sufficient data for calculating the at least one of the three measures of tax avoidance: long term effective tax rate (ETR1), long term cash effective tax rate (ETR2) and permanent book-tax differences (BTD). Then, we truncated our long term effective tax rate (ETR1), long term cash effective tax rate (ETR2) to the range from 0 to 1.

To calculate the effects of CEOs', CFOs' corporate social networks, our study also used the Taiwan Economic Journal database which collects detailed information on the identity of all CFO, CEO from proxy statements, annual reports, and corporate websites. These CFO and CEO' profiles include information on: (1) working experiences; (2) educational background; and (3) training courses and social meetings. We further eliminated firm-year observation with any missing values to calculate the CEO and CEO social network measures.
We then retain firm-year observations for which we have data available for our control variables (defined below). Finally, we retain firm-years for which we have data available for our governance and incentives variables. As a result, sample sizes for the ETR1, ETR2, and BTD measures are 5,699, 5,706 and 5,810 firm-year observations, respectively. Note that for some of the tests, there are fewer observations due to additional data limitations.

Measures of Social Network

Social networks are a broad construct, including numerous dimensions, and no single indicator can effectively and completely capture all dimensions of the concept of a social network. We define three ties representing the dimension of social networks as follows:

- *We identify the formal tie if CFO and CEO who share current and past employment positions outside the firms or other industrial associations.*
- *We identify the informal tie if CFO and CEO who went to the same educational background or memberships in the same school alumni association.*
- *Other social network ties are identified if CFO and CEO are required to attend training courses or conference meetings held by the authorities, and these training/meeting records should be disclosed in an annual report.*

We follow the Fracassi and Tate (2012) and used other dimension of social network, including educational platform, previous experience, training course and social meeting, from detailed primary information on CFO and CEO to construct a social network index with the degree centrality of the CEOs, CFOs. Centrality measures the overall embeddedness of a personal company in the network that includes of all firms. In the context of this research, centrality is amount of vertices that an CFO or CEO is tied to. It pointed out the level that a CFO or CEO takes a strategy position in their network (Wasserman & Faust, 1994). We follow Freeman (1978), Renneboog and Zhao (2011) and El-Khatib et al. (2015) to construct different social network measurement consist of closeness, degree, betweenees and eigenvector.

(1) *Degree* is the sum of all links that a CFO or CEO has with other individuals in the network divided by the total number of companies in the network. Brass and Burkhardt (1993) assumed that the greater the degree of centrality is, the more prestige CFO or CEO has within the network, and well-connected executives are likely to be more visible.
(2) *Closeness* is the inverse of the sum of the (shortest) distances between a director or executive and all other individuals in a network. It indicates how efficiently the director or executive can obtain information from other individuals in the network.
(3) *Betweeness* measures how often the director or executive lies on the shortest path between any other two individuals of the network.
(4) *Eigenvector* is a measure of the importance of the director or executive in the network. It takes into account the extent to which the director or executive is connected with external highly connected directors or executives.

In this study, we adopt two corporate social network measures based on degree centrality which measures direct (local) connections to assess actual influence; and closeness which indirect connection measures to capture information collection ability (El-Khatib et al., 2015; Renneboog & Zhao, 2011), we then use *betweeness* and *Eigenvector* for our robustness test. In our dataset, we set CEO's and CFO's social network as an indicator variables coded as one if the value is higher than mean of it by each year, zero otherwise.

Measures of Tax Aggressiveness

We follow Chen et al. (2010), Dyreng et al. (2008) to adopt two tax-avoidance measures based on a long term effective tax rate (ETR1) and a long term cash effective tax rate (ETR2). We use a measurement period of three years to avoid significant year-to-year variations on a single-year tax avoidance measure, and also to alleviate concern about potential survivorship bias associated with the use of horizons longer than three years. ETR is set as missing when the denominator is zero or negative. We truncate ETR to the range [0,1]. As expressed in Eq. (1), the first measure, ETR1, is the ratio of total tax expense over the most recent three years scaled by total pre-tax income net over the same period. It discovers the company's tax evasion through permanent book-tax differences, such as investing in municipal bonds and participating in tax shelters.

$$ETR1_{i,t} = \frac{\sum_{t=1}^{t=t+2} \text{Total income tax expense}_{i,t}}{\sum_{t=1}^{t=t+2} \text{Pre\_tax book income}_{1,t}} \qquad (1)$$

As shown in Eq. (2), our second measure, ETR2, calculates long term cash effective tax rate by using the total refund income tax to chief financial officer over last three years scaled by total pre-tax income over the same period of time. The reason for our selection this tax measure is: firstly, cash effective tax rates take into account the tax benefits of employee stock options, whereas GAAP effective tax rates do not; secondly, cash effective tax rates are not affected by changes in accounting estimates such as the valuation allowance or tax contingency reserve (Dyreng et al., 2008). We acknowledge that this measure is better matching between taxes paid and the income to which these taxes relate, it also considers both permanent and temporary book-tax differences.

$$ETR2_{i,t} = \frac{\sum_{t=1}^{t=t+2} \text{Refund income tax to chief financial officer}_{i,t}}{\sum_{t=1}^{t=t+2} \text{Pre\_tax book income}_{1,t}} \qquad (2)$$

Many prior research also used a variety of book-tax difference measures for tax avoidance, where book-tax difference is defined as the difference between income reported to the capital market and that reported to the tax authorities. Large book-tax differences can also reflect for accrual manipulation (or a combination of tax avoidance and accrual manipulation), or simply represent for the differences in financial and tax accounting rules. Thus, book-tax difference measures are likely to be appropriate for our research question. We follow Frank et al. (2009), Lennox et al. (2013) to adopt other tax-avoidance measures based on permanent book-tax differences (BTD) which is specifically design to capture the effect due to aggressive tax planning activities. As expressed in Eq. (3), the third measure, BTD is define as:

$$BTD_{i,t} = \frac{\text{Pre\_tax book income}_{i,t} - \left(\frac{\text{Total income tax expense}_{i,t}}{Law\ tax\ rate_{i,t}}\right)}{\text{Total income tax expense}_{i,t}/law\ \text{tax rate}_{i,t}} \qquad (3)$$

For robustness check, we follow Lennox et al. (2013), (Chen et al., 2010); Dyreng et al. (2010) to construct effective tax rate (ETR3) and Cash effective tax rate (ETR4). Details can be found in the Appendix A.

Basic Statistics

Table 1 provides the results of our sample composition. Panel A presents for the ETR1 group, ETR2 group in Panel B, and BTD group in Panel C. As shown, the means of there our tax aggressive measure variables are 0.148, 0.127 and 2.593 with a standard derivation of 0.118, 0.121 and 4.840 for ETR1, ETR2 and BTD, respectively. These values are similar to those reported in Dyreng et al. (2008) and Dyreng et al. (2010), suggesting that our sample representativeness is reasonable. The means of CEOs range from 0.529 to 0.638, while the means of CFOs range from 0.836 to 0.888. The means of SIZE, MB, LEVER variables range from 15.018 to 15.04, from 1.991 to 1.988, from 0.482 to 0.484, from 15.018 to 15.042, respective. ESUB, PPE, INTAN and DFI has the mean value approximate 1.013, 0.299, 0.017, 0.475, respectively.

Notes: This table provides the descriptive statistics for the dependent and control variables, with the data covering the period of January 1, 2010 to December 31, 2014. All variables are defined in Appendix A.

Table 2 provides the correlation results. Our results show the positive correlation between CEO's social network (CEO closeness, CEO degree) and two effective tax measures (ETR1, and ETR2), and negative correlation with permanent book tax difference (BTD). These empirical results indicate that higher corporate social network from CEO lead to lower tax aggressive. Table 2 also findings a significantly negative correlation between the CFO's social network (CFO closeness and CFO degree) and ETR1, ETR2, indicating that higher social network from CFO positive impact tax aggressive. Our results showed the significantly negative correlation between ETR1, ETR2 and BTD3. In addition, the correlations among CEO's, CFO's social network variables (CEO closeness, CEO degree, CFO closeness, CFO degree) are all significantly. These results provide us with a first glance at the relationship between CEO's, CFO's social network and tax aggressive prior to the regression analysis.

Notes: The correlation statistics are provided for the empirical variables, comprising ETR1, ETR2, BTD, CEO closeness, CFO closeness, CEO degree, CFO degree, SIZE, MB, LEVER, NOL, ΔNOL, ROA, ESUB, PPE, INTAN, DFI, RD. The data covers January 1, 2010 to December 31, 2014. All variables are defined in Appendix A

EMPIRICAL RESULTS

Effects of Corporate Social Network on Tax Aggressive

This section explores how the corporate social network affect tax aggressive, we follow Chen et al. (2010) to adopt a multivariate regression model as following:

$$\begin{aligned} TAXAGG_{i,t} = \alpha_0 &+ \beta_1 NETWORK_{i,t-1} + \beta_2 SIZE_{i;t-1} + \beta_3 MB_{i,t-1} + \beta_4 LEVER_{i,t-1} \\ &+ \beta_5 NOL_{i,t-1} + \beta_6 \Delta NOL_{i,t-1} + \beta_7 ROA_{i,t-1} + \beta_8 ESUB_{i,t-1} + \beta_9 PPE_{i,t-1} \\ &+ \beta_{10} INTAN_{i,t-1} + \beta_{11} DFI_{i,t-1} + \beta_{12} RD_{i,t-1} + YearDummies \\ &+ IndustryDummies + \varepsilon_{i,t} \end{aligned} \quad (4)$$

Where the dependent variable tax aggressive ($TAXAGG_{i,t}$) represents the long term effective tax rate (ETR1); long term cash effective tax rate (ETR2) and permanent book-tax differences (BTD) for company i in year t. The independent variables include corporate social network ($NETWORK_{i,t-1}$) which represents the CEO's social network (CEO closeness and CEO degree) and CFO's social network (CFO closeness and CFO degree), firm size ($SIZE_{i;t-1}$), market to book value ($MB_{i,t-1}$), leverage ratio ($LEVER_{i,t-1}$), net operating loss ($NOL_{i,t-1}$) and change in net operating loss ($\Delta NOL_{i,t-1}$), return on asset ($ROA_{i,t-1}$), equity method ($ESUB_{i,t-1}$), total plant, property and equipment ($PPE_{i,t-1}$), intangible assets ($INTAN_{i,t-1}$), income from foreign operations ($DFI_{i,t-1}$), research and development activities ($RD_{i,t-1}$) [Larger companies and firm complexity access to tax planning strategies that could be exhibit more tax evasion activities (e.g., Chen et al., 2010)]. *YearDummies* and *IndustryDummies* represent the industry and year dummy variables, respectively.

Table 3 presents separate results using closeness (Panel A) and degree (Panel B) to measure the social network of CEOs and CFOs. We begin our empirical analysis by providing a deeper understand of whether corporate social network affect tax aggressive. Table 3 shows the coefficients of CEO's and CFO's social network both are statistically significant almost at the 1% for all empirical results. The coefficients of CEO closeness and CEO degree are significantly positive, ranging from 0.010 to 0.014, significance at the 1% level for all ETR1 and ETR2 sample. An increase in CEO's social network has a clearly negative impact on BTD, ranging from -0.416 to -0.598, significance at the 1% level. These empirical results suggest that firm with a higher external social network of CEO is associate with lower tax aggressive. The coefficients of CFO's social network are negatively significant for two effective tax measures (ETR1 and ETR2), ranging from -0.010 to 0.018 at almost the 1% level, while the coefficients of CFO's external network range from 0.343 to 0.552, positive significant on BTD sample at least at the 5% level for both Panel A and Panel B, implying that CFOs with a higher external social network are more likely to participate tax aggressive activities.

The majority of control variables also show significant coefficients that are mostly consistent with our conjectures and prior literature. The coefficients of MB have significantly negative effect on ETR1 and ETR2, positive effect on BTD at the 1% significance level, respectively. As shown, the coefficients of NOL are statistically significant at the 1% level with an expected sign for our three tax aggressive measurements, indicating that firms with higher net operating loss are less likely to be associated with tax evasion. In the contrary, we also find that increases in change in net operating loss (ΔNOL) are associated with a higher tax avoidance. There is a significantly positive relation between RD and tax aggressive measures ETR1, and significantly negative relation between RD and BTD. These results mean that firms in with greater research and development activities also have a higher level of tax avoidance. Finally, our empirical results finding no correlation between foreign operating firms and tax avoidance. The most of above empirical results are suggested by Chen et al., (2010).

Notes: This table provides details of the social network effect on the tax aggressive from Eq. (4). The regression model is as follows:

$$TAXAGG_{i,t} = \alpha_0 + \beta_1 NETWORK_{i,t-1} + \beta_2 SIZE_{i;t-1} + \beta_3 MB_{i,t-1} + \beta_4 LEVER_{i,t-1} + \beta_5 NOL_{i,t-1} + \beta_6 \Delta NOL_{i,t-1} + \beta_7 ROA_{i,t-1} + \beta_8 ESUB_{i,t-1} + \beta_9 PPE_{i,t-1} + \beta_{10} INTAN_{i,t-1} + \beta_{11} DFI_{i,t-1} + \beta_{12} RD_{i,t-1} + YearDummies + IndustryDummies + \varepsilon_{i,t}$$

Where the dependent variable is tax aggressive ($TAXAGG_{i,t}$) for company i in t year. The independent variables include corporate social network ($NETWORK_{i,t-1}$), firm size ($SIZE_{i;t-1}$), market to book value ($MB_{i,t-1}$), leverage ratio ($LEVER_{i,t-1}$), net operating loss ($NOL_{i,t-1}$) and change in net operating loss ($\Delta NOL_{i,t-1}$), return on asset ($ROA_{i,t-1}$), equity method ($ESUB_{i,t-1}$), total plant, property and equipment ($PPE_{i,t-1}$), intangible assets ($INTAN_{i,t-1}$), income from foreign operations ($DFI_{i,t-1}$), research and development activities ($RD_{i,t-1}$). *YearDummies* and *IndustryDummies* represent the industry and year dummy variables, respective. The tax aggressive ($TAXAGG_{i,t}$) includes the long term effective tax rate (ETR1); long term cash effective tax rate (ETR2) and permanent book-tax differences (BTD) for company i in year t. Corporate social network ($NETWORK_{i,t-1}$) represent for the CEO's social network (CEO closeness and CEO degree) and CFO's social network (CFO closeness and CFO degree). All variables are defined in Appendix A. The *t*-values examine whether the regression coefficient is significantly different from zero. ***, **, and * indicate significance at the 1%, 5%, and 10% levels, respectively.

Endogenous Concern

The Effect of Corporate Governance

External and internal monitoring may play an important role in firm tax aggressive activity. Minnick and Noga (2010), Lanis and Richardson (2011) argued that quality of corporate governance has significant impact on tax aggressive activity. Therefore, unobservable variables that are common to corporate governance can also generate a positive relation between corporate social network and tax aggressive (the omitted-variable bias). We follow Hartzell and Starks (2003), Cremers and Nair (2005), Del Guercio et al. (2008), E. H. Kim and Lu (2011) adopt board size (BS), independent director (ID) and board and supervisor ownership (BSO) variables which assume play in sharping governance to our following regression model as following:

$$TAXAGG_{i,t} = \alpha_0 + \beta_1 NETWORK_{i,t-1} + \beta_2 GOVERNANCE_{i;t-1} + \beta_3 SIZE_{i;t-1} + \beta_4 MB_{i,t-1} + \beta_5 LEVER_{i,t-1} + \beta_6 NOL_{i,t-1} + \beta_7 \Delta NOL_{i,t-1} + \beta_8 ROA_{i,t-1} + \beta_9 ESUB_{i,t-1} + \beta_{10} PPE_{i,t-1} + \beta_{11} INTAN_{i,t-1} + \beta_{12} DFI_{i,t-1} + \beta_{13} RD_{i,t-1} + Year\ Dummies + Industry\ Dummies + \varepsilon_{i,t} \quad (5)$$

Where the governance variables ($GOVERNANCE_{i;t-1}$) includes the number of board members ($BS_{i;t-1}$), the percentage of independent directors ($ID_{i;t-1}$), the percentage of board and supervisor ownership ($BSO_{i;t-1}$). All variables are defined in Appendix A [The remaining control variables are the same as those in Eq. (4)]

Table 4 presents separate results using closeness (Panel A) and degree (Panel B) to measure the social network of CEOs and CFOs. Our results show the coefficients of BS has a positive significant impact on ETR2 at 0.002 at least the 5% level and negative significant impact on BTD, ranging from -0.123 to -0.143 at the 1% level. While BSO has a significant impact on ETR1 at 0.001 at the 5% level. In addition, the coefficients of ID range from 0.137 to 0.142, significance at the 1% levels on BTD for both panels. These results indicate that corporate governance variables have significant impact on tax aggressive activity. Table 4 show that CEOs have a significantly positive impact on two tax effective measures (ETR1 and ETR2) and negative impact on BTD at the 1% level for all our sample. For the CFO's social network, the coefficients of CFOs have significantly negative impact on all ETR1, ETR2 and positive impact to BTD at least the 5% level. These results of Table 4 are similar to our prior empirical results.

Notes: This table provides details of the effects of corporate social network on tax aggressiveness by using firm fixed-effect regressions to control for the influences of unknown firm characteristics that affect social network and tax avoidance. The regression model as follow:

$$TAXAGG_{i,t} = \alpha_0 + \beta_1 NETWORK_{i,t-1} + \beta_2 GOVERNANCE_{i;t-1} + \beta_3 SIZE_{i;t-1} + \beta_4 MB_{i,t-1} + \beta_5 LEVER_{i,t-1} + \beta_6 NOL_{i,t-1} + \beta_7 \Delta NOL_{i,t-1} + \beta_8 ROA_{i,t-1} + \beta_9 ESUB_{i,t-1} + \beta_{10} PPE_{i,t-1} + \beta_{11} INTAN_{i,t-1} + \beta_{12} DFI_{i,t-1} + \beta_{13} RD_{i,t-1} + Year\ Dummies + Industry\ Dummies + \varepsilon_{i,t}$$

Where the dependent variable is tax aggressive ($TAX_{i,t}$) for company i in t year. The independent variables include corporate social network ($NETWORK_{i,t-1}$), corporate governance ($GOVERNANCE_{i;t-1}$), firm size ($SIZE_{i;t-1}$), market to book value ($MB_{i,t-1}$), leverage ratio ($LEVER_{i,t-1}$), net operating loss ($NOL_{i,t-1}$) and change in net operating loss ($\Delta NOL_{i,t-1}$), return on asset ($ROA_{i,t-1}$), equity method ($ESUB_{i,t-1}$), total plant, property and equipment ($PPE_{i,t-1}$), intangible assets ($INTAN_{i,t-1}$), income from foreign operations ($DFI_{i,t-1}$), research and development activities ($RD_{i,t-1}$). *YearDummies* and *IndustryDummies* represent the industry and year dummy variables, respective. The tax aggressive measures ($TAXAGG_{i,t}$) include the long term effective tax rate (ETR1); long term cash effective tax rate (ETR2) and permanent book-tax differences (BTD) for company i in year t. Corporate social network ($NETWORK_{i,t-1}$) represent for the CEO's social network (CEO closeness and CEO degree) and CFO's social network (CFO closeness and CFO degree). Corporate governance ($GOVERNANCE_{i;t-1}$) includes the number of board members (*BS*), the percentage of independent directors (*ID*), the percentage of board and supervisor ownership (*BSO*). All variables are defined in Appendix A. The *t*-values examine whether the regression coefficient is significantly different from zero. ***, **, and * indicate significance at the 1%, 5%, and 10% levels, respectively

Instrumental Regression

For reducing the endogeneity problem caused by missing variables, we use the instrumental variables model, and the adopted instruments include corporate governance variables. First, we adopt two governance variables related to internal monitoring by the board. We adopt the number of board member (BS) in our regression. Prior studies indicate that larger board tend to be less effective monitors (Eisenberg et al., 1998; Jensen, 1993; Lipton & Lorsch, 1992; Yermack, 1996). Next, we include the percentage of independent directors on the board (ID). The monitoring role played by independent directors has been widely documented. For example, Weisbach (1988) finds that CEO turnover following poor performance is positively related to the fraction of outside directors. Second, to capture the strength of external monitoring, we follow Hartzell and Starks (2003) and estimate institutional ownership concentration by the percentage of institutional ownership (IO). Previous studies document the important role institutional investors play in shaping corporate governance (Cremers & Nair, 2005; Del Guercio et al., 2008; Edmans et al., 2011; Hartzell & Starks, 2003; E. H. Kim & Lu, 2011). The selection of instruments is due to the reason well-governed firms prefer to have highly-skilled executives and directors such as highly externally-tied executives and directors (Benton, 2017; Davis & Greve, 1997; Fracassi & Tate, 2012; Mcdonald et al., 2008). The regression model as following:

1st Stage:

$$NETWORK_{i,t-1} = \alpha_0 + \gamma_1 INSTRU_{i;t} + \beta_1 SIZE_{i;t-1} + \beta_2 MB_{i,t-1} + \beta_3 LEVER_{i,t-1} + \beta_4 NOL_{i,t-1} + \beta_5 \Delta NOL_{i,t-1} + \beta_6 ROA_{i,t-1} + \beta_7 ESUB_{i,t-1} + \beta_8 PPE_{i,t-1} + \beta_9 INTAN_{i,t-1} + \beta_{10} DFI_{i,t-1} + \beta_{11} RD_{i,t-1} + Year\ Dummies + Industry\ Dummies + \eta_{i,t} \quad (6)$$

2st Stage: (7)

$$TAXAGG_{i,t} = \alpha_0 + \delta_1 \widehat{NETWORK}_{i,t-1} + \beta_1 SIZE_{i;t-1} + \beta_2 MB_{i,t-1} + \beta_3 LEVER_{i,t-1} + \beta_4 NOL_{i,t-1} + \beta_5 \Delta NOL_{i,t-1} + \beta_6 ROA_{i,t-1} + \beta_7 ESUB_{i,t-1} + \beta_8 PPE_{i,t-1} + \beta_9 INTAN_{i,t-1} + \beta_{10} DFI_{i,t-1} + \beta_{11} RD_{i,t-1} + Year\ Dummies + Industry\ Dummies + \varepsilon_{i,t}$$

In the first-stage, the dependent variable is corporate social network ($NETWORK_{i,t-1}$). The instrumental variables ($INSTRU_{i;t}$) includes the percentage of institution ownership ($IO_{i;t-1}$), the number of board members ($BS_{i;t-1}$), the percentage of independent director ($ID_{i;t-1}$). In the second-stage, the dependent variable is the tax aggressive measure, which is defined as ETR1, ETR2 and BTD. The remaining control variables are the same as those in Eq.(4). All variables are defined in Appendix A.

We separate the results using closeness in Panel A and degree in Panel B to measure the social network of CEOs and CFOs. Table 5 shows the results of the instrumental variable regression in which we use two-stage least squares to estimate the coefficients. In the first stage, our IVs have the significant effect on corporate social network. The findings are largely consistent with our expectations. The second-stage regression results reported in Table V show the robustness of our findings to controlling for endogeneity and simultaneity biases. The coefficients of
$\widehat{CEO}$ are significantly positive impact on ETR1 and ETR2, ranging from 0.080 to 0.117, significance at the 1% levels and significantly negative effect, ranging from -5.460 to -6.708, significance at the 1% level on BTD. It strongly implies and consistent evidence that higher CEO's social network are associated with lower degrees of tax avoidance.

Our results also present $\widehat{CFO}$ has a significantly negative impact on ETR1, ranging from -0.233 to -0.655 at the 5% level for our all sample. In addition, the coefficients of $\widehat{CFO}$ is significantly negative on ETR2 (as shown in Panel B of Table 5) at the 5% level and significantly positive on BTD (as shown in Panel A of Table 5) at the 1% level. The results of Table 5 are similar to our empirical results and there is no evidence of reverse causation or simultaneity bias. However, we consider instrumental variables regressions as one of several different techniques for controlling endogenous levels and ignoring variable biases and presenting other tests below.

Table 5: Endogenous concerns: Instrumental regression results

Notes: This table provides details of the effects of corporate social network on tax aggressiveness by using instrumental regression. The model is:

1st Stage:

$$NETWORK_{i,t-1} = \alpha_0 + \gamma_1 INSTRU_{i;t} + \beta_1 SIZE_{i;t-1} + \beta_2 MB_{i,t-1} + \beta_3 LEVER_{i,t-1} + \beta_4 NOL_{i,t-1} + \beta_5 \Delta NOL_{i,t-1} + \beta_6 ROA_{i,t-1} + \beta_7 ESUB_{i,t-1} + \beta_8 PPE_{i,t-1} + \beta_9 INTAN_{i,t-1} + \beta_{10} DFI_{i,t-1} + \beta_{11} RD_{i,t-1} + Year\ Dummies + Industry\ Dummies + \eta_{i,t}$$

2st Stage:

$$TAXAGG_{i,t} = \alpha_0 + \delta_1 \widehat{NETWORK}_{i,t-1} + \beta_1 SIZE_{i;t-1} + \beta_2 MB_{i,t-1} + \beta_3 LEVER_{i,t-1} + \beta_4 NOL_{i,t-1} + \beta_5 \Delta NOL_{i,t-1} + \beta_6 ROA_{i,t-1} + \beta_7 ESUB_{i,t-1} + \beta_8 PPE_{i,t-1} + \beta_9 INTAN_{i,t-1} + \beta_{10} DFI_{i,t-1} + \beta_{11} RD_{i,t-1} + Year\ Dummies + Industry\ Dummies + \varepsilon_{i,t}$$

In the first-stage, the dependent variable is corporate social network ($NETWORK_{i,t-1}$). The instrumental variables ($INSTRU_{i;t}$) includes the percentage of institution ownership ($IO_{i;t-1}$), the number of board members ($BS_{i;t-1}$), the percentage of board and supervisor ownership ($BSO_{i;t-1}$). In the second-stage, the dependent variable is the tax aggressive measures ($TAXAGG_{i,t}$). The control variables are firm size ($SIZE_{i;t-1}$), market to book value ($MB_{i,t-1}$), leverage ratio ($LEVER_{i,t-1}$), net operating loss ($NOL_{i,t-1}$) and change in net operating loss ($\Delta NOL_{i,t-1}$), return on asset ($ROA_{i,t-1}$), equity method ($ESUB_{i,t-1}$), total plant, property and equipment ($PPE_{i,t-1}$), intangible assets ($INTAN_{i,t-1}$), income from foreign operations ($DFI_{i,t-1}$), research and development activities ($RD_{i,t-1}$). YearDummies and IndustryDummies represent the industry and year dummy variables, respective. The tax aggressive ($TAXAGG_{i,t}$) includes the long term effective tax rate (ETR1); long term cash effective tax rate (ETR2) and permanent book-tax differences (BTD) for company i in year t. Corporate social network ($NETWORK_{i,t-1}$) represent for the CEO's social network (CEO closeness and CEO degree) and CFO's social network (CFO closeness and CFO degree). All variables are defined in Appendix A. The t-values examine whether the regression coefficient is significantly different from zero. ***, **, and * indicate significance at the 1%, 5%, and 10% levels, respectively.

Robustness Tests

Hanlon and Heitzman (2010) recommend that researchers carefully consider the appropriateness of tax avoidance measures. We consider whether other tax aggressive measures can significant impact to the corporate social network. A large of prior researches by Desai and Dharmapala (2006), Dyreng et al. (2008), Dyreng et al. (2010), Minnick and Noga (2010) use effective tax rate (total income tax expense divided by pretax income) and cash effective tax rate (cash tax expense divided by pretax income). As our knowledge, effective tax rate captures the effect on financial accounting earnings, meanwhile cash effective tax rate captures the effect of cash outlay. Therefore, financial reporting income and taxable income generally differ, effective tax rate and cash effective tax rate will also differ. We adopt effective tax rate (ETR3) and cash effective tax rate (ETR4) to examine the robustness test, as shown in Panel A of Table 6. Next, we consider how alternative measures of corporate social network impact on tax aggressive, as shown in Panel B of Table 6. We use Betweenness and Eigenvector to measure for corporate social network of CEOs and CFOs. We then include it as our independent variable in Eq.(4). Finally, to obtain a clearer picture on the relation between tax aggressive and corporate social network, we examine whether using other regression can lead to other results. We use Tobit regression to test our main hypothesis with ETR1, ETR2, ETR3, ETR4 as dependent variables, as shown in Panel C of Table 6. The selection Tobit regression due to the reason that our tax aggressive measures are truncated in range from zero to one, therefore, using Tobit regression is appropriate with our dependent variables.

In Panel A of Table 6, the coefficients of CEO closeness are significantly positive, ranging from 0.011 to 0.012, significance at the 1% level. CEO degree also have a significantly positive impact on ETR3, ETR4, from 0.009 to 0.013 at the 1% level. The results suggest that higher CEOs corporate social network can lead to a decrease in tax aggressive. In addition, the coefficients of CFO closeness range from -0.011 to -0.014, significant at the 5% and the 1% levels. CFO degree has a negative significant impact on ETR3, ETR4, from -0.006 to -0.009, at the 10% level. These results posit that an increase in CFOs social network can lead to an increase in tax evasion. The results in Panel A of Table 6 are similar to our main results, it indicates the association between tax aggressive and corporate social network is economically significant as well and the sign as we expected.

Panel B of Table 6 shows that CEOs betweenness have a positive impact on ETR1, ETR2 and negative impact on BTD, significance at the 1% level. In addition, the coefficients of CEOs eigenvector range from 0.011 to 0.012, significance at the 10% level on ETR1. These results indicate that a higher CEOs corporate social network lead a decrease tax aggressive. Our results show that CFOs betweeness have a significant negative impact on ETR1, ETR2 at the 1% significance level, and a significant positive impact on BTD at the 10% significance level. While the impact of CFOs eigenvector on our tax aggressive measures is not clearly. The results in Panel B of Table 6 are as our expectations and support to our main results that better CEO's (CFO's) corporate social network can significantly decrease (increase) tax aggressive.

In Panel C of Table 6, CEO closeness has significantly positive effects on all our tax aggressive measures, ranging from 0.030 to 0.123, significance at all the 1% level. The coefficients of CEO degree are also significant positive, ranging from 0.014 to 0.085, significance almost at the 1% level. Our results show the coefficients of CFO closeness are significant negative, ranging from -0.034 to -0.094, significance at the 1% level; CFO degree are also significant negative, ranging from -0.012 to -0.068. These results are similar to our prior empirical results, implying that better CEO's (CFO's) corporate social network is associated with lower (higher) tax aggressive

Table 6: Robustness tests

Notes: This table provides the robustness results for the corporate social network effect on the tax aggressive. Our sample covers the period from January 1, 2010 to December 31, 2014. All variables are defined in Appendix A. In Panel A, the alternative measures of tax aggressive is effective tax rate (ETR3) and cash effective tax rate (ETR4), as our dependent variables in Eq. (4). In Panel B, we examine alternative measure of corporate social network. CEO betweenness and CEO eigenvector measured for social network of CEOs, CFO betweenness and CFO eigenvector measured for social network of CFOs, as our independent variables in Eq. (4). In Panel C, we provide the results of the Tobit regression. The t-values examine whether the regression coefficient is significantly different from zero. ***, **, and * indicate significance at the 1%, 5%, and 10% levels, respectively

The Effects of CEO Power on Tax Aggressive

Powerful CEOs can use their power through appointment and recruitment activities. Fracassi and Tate (2012) showed that firms with more powerful chief executive officers (CEOs) are more likely to add new directors with pre-existing network ties to the CEO to minimize search costs or exploit inside information about director quality. We re-estimate the regressions including the interaction between CEO power and corporate social network to examine whether external network connections with powerful CEOs impact tax avoidance activities. The regression model as following:

$$\begin{aligned}\mathrm{TAXAGG}_{i,t} = \alpha_0 &+ \beta_1\mathrm{NETWORK}_{i,t-1} + \beta_2\mathrm{CEOPOWER}_{i;t} + \beta_3\mathrm{NETWORK}_{i;t-1}\mathrm{xCEOPOWER}_{i;t}\\ &+ \beta_4\mathrm{SIZE}_{i;t-1} + \beta_5\mathrm{MB}_{i,t-1} + \beta_6\mathrm{LEVER}_{i,t-1} + \beta_7\mathrm{NOL}_{i,t-1} + \beta_8\Delta\mathrm{NOL}_{i,t-1}\\ &+ \beta_9\mathrm{ROA}_{i,t-1} + \beta_{10}\mathrm{ESUB}_{i,t-1} + \beta_{11}\mathrm{PPE}_{i,t-1} + \beta_{12}\mathrm{INTAN}_{i,t-1} + \beta_{13}\mathrm{DFI}_{i,t-1}\\ &+ \beta_{14}\mathrm{RD}_{i,t-1} + \mathrm{YearDummies} + \mathrm{IndustryDummies} + \varepsilon_{i,t}\end{aligned} \quad (8)$$

where the dependent variable $\mathrm{TAXAGG}_{i,t}$ presents for ETR1, ETR2, BTD in company i in a given year. The main independent variables are corporate social network include social network of CEOs and CFOs, the CEO power dummy variable ($\mathrm{CEOPOWER}_{i;t}$), and their interaction. All variables are defined in Appendix A [The remaining control variables are the same as those in Eq. (4)]

Table 7 presents separate results using closeness (Panel A) and degree (Panel B) to measure the social network of CEOs and CFOs. Our results show that the coefficients of CEOPOWER range from -0.010 to -0.015, significance at least the 5% on ETR1 and ETR2 for both panel, indicating that firms with higher CEO power lead to higher tax aggressive, these results are line with the prior empirical results of Laguir and Staglianò (2014). We examine whether tax aggressive requirement serves as a channel by including the interaction terms, NETWORK × CEOPOWER, in our regression model. Table 7 shows the coefficients between CEO's social network and CEO power, ranging from 0.017 to 0.024, significantly positive impacts on ETR1 and ETR2 at the 1% level as shown in both panel A and panel B, and negative effect on BTD3 at the 10% level as shown in Panel B. These results indicate that the interaction between CEO power and CEO's social network lead a lower tax aggressive. Our finding also presents the coefficient of interaction between CEO power and CFO's social network is insignificant different from zero, implying that CEO power does not affect the relation between CFO's social network and tax aggressive.

Notes: This table provides details of the effects of CEO power on the tax aggressiveness. The regression model is:

$$\begin{aligned} TAXAGG_{i,t} = \alpha_0 &+ \beta_1 NETWORK_{i,t-1} + \beta_2 CEOPOWER_{i;t} + \beta_3 NETWORK_{i;t-1} x CEOPOWER_{i;t} + \beta_4 SIZE_{i;t-1} + \beta_5 MB_{i,t-1} + \beta_6 LEVER_{i,t-1} \\ &+ \beta_7 NOL_{i,t-1} + \beta_8 \Delta NOL_{i,t-1} + \beta_9 ROA_{i,t-1} + \beta_{10} ESUB_{i,t-1} + \beta_{11} PPE_{i,t-1} + \beta_{12} INTAN_{i,t-1} + \beta_{13} DFI_{i,t-1} + \beta_{14} RD_{i,t-1} \\ &+ YearDummies + IndustryDummies + \varepsilon_{i,t} \end{aligned}$$

Where the dependent variable is tax aggressive ($TAX_{i,t}$) present for the long term effective tax rate (ETR1); long term cash effective tax rate (ETR2) and permanent book-tax differences (BTD) for company i in year t. The main independent variable is corporate social network includes

CEO's social network (CEO closeness and CEO degree) and CFO's social network (CFO closeness and CFO degree). CEOPOWER is dummy variable that equals one is the CEO is chair, zero otherwise. $NETWORK_{i;t-1}xCEO\_POWER_{i;t}$ is the interaction between social network and CEO power. All variables are defined in Appendix A. The *t*-values examine whether the regression coefficient is significantly different from zero. ***, **, and * indicate significance at the 1%, 5%, and 10% levels, respectively

The Effects of CEOs Background on Tax Aggressive

The financial and/or accountant background of CEOs can play an important role in determining the quality of financial reporting, it helps them keep a deeper understanding of financial and accounting issues, they therefore can make proper accounting decisions and improve the financial reporting process. Custódio and Metzger (2014) show the statistic that 41% of the CEOs have previous experience in the financial industry or in a financial role. This study showed the significant effect of financial expert CEOs on firms' financial policies, such as cash holdings, debts, and share purchases. CEOs who have a professional qualification in finance and/or accounting do not participate directly in overseeing the accounting process and the preparation of financial statements but they may set the tone from the top and impact to the CFOs decision (Feng et al., 2011). However, to the best of our knowledge, the impact of CEOs' financial or accountant experience on tax aggressive are unexplored. In this section, we examine whether CEOs with financial and/or accounting backgrounds interact with corporate social network are associate with tax aggressive. We re-estimate our regressions model as following:

$$\begin{aligned} TAXAGG_{i,t} = \alpha_0 &+ \beta_1 NETWORK_{i,t-1} + \beta_2 CEOfin\_acc_{i;t} + \beta_3 NETWORK_{i;t-1}xCEOfin\_acc_{i;t} \\ &+ \beta_4 SIZE_{i;t-1} + \beta_5 MB_{i,t-1} + \beta_6 LEVER_{i,t-1} + \beta_7 NOL_{i,t-1} + \beta_8 \Delta NOL_{i,t-1} \\ &+ \beta_9 ROA_{i,t-1} + \beta_{10} ESUB_{i,t-1} + \beta_{11} PPE_{i,t-1} + \beta_{12} INTAN_{i,t-1} + \beta_{13} DFI_{i,t-1} \\ &+ \beta_{14} RD_{i,t-1} + YearDummies + IndustryDummies + \varepsilon_{i,t} \end{aligned} \quad (9)$$

where the dependent variable $TAXAGG_{i,t}$ presents for ETR1, ETR2, BTD in company i in a given year. The main independent variables are corporate social network include social network of CEOs and CFOs, CEO has financial and/or accounting background is as a dummy variable ($CEOfin\_acc_{i;t}$), and their interaction. All variables are defined in Appendix A [The remaining control variables are the same as those in Eq. (4)]

In Panel A of Table 8, the coefficients interaction between $CEOfin_{acc}$ and CFO closeness are significantly negative at 10% level on ETR1, and positive impact on BTD with the coefficient 1.268 at the10% level. As shown in panel B, we also find the coefficient of CFO degree and $CEOfin_{acc}$ is -0.027, negative significant at the 10% level on ETR1. These results indicate that firms with financial and/or accountant CEOs connect with CFO's social network are more likely implement tax aggressive. Our empirical results are consistent with prior researches and clarify more detail the interaction between CEO and CFO on tax avoidance (Hsieh et al., 2018).

Notes: This table provides details of the effects of CEOs have financial and/or accounting background on the tax aggressiveness. The regression model is:

$$TAXAGG_{i,t} = \alpha_0 + \beta_1 NETWORK_{i,t-1} + \beta_2 CEOfin\_acc_{i;t} + \beta_3 NETWORK_{i;t-1} x CEOfin\_acc_{i;t} + \beta_4 SIZE_{i;t-1} + \beta_5 MB_{i,t-1} + \beta_6 LEVER_{i,t-1} + \beta_7 NOL_{i,t-1} + \beta_8 \Delta NOL_{i,t-1} + \beta_9 ROA_{i,t-1} + \beta_{10} ESUB_{i,t-1} + \beta_{11} PPE_{i,t-1} + \beta_{12} INTAN_{i,t-1} + \beta_{13} DFI_{i,t-1} + \beta_{14} RD_{i,t-1} + YearDummies + IndustryDummies + \varepsilon_{i,t}$$

Where the dependent variable is tax aggressive ($TAX_{i,t}$) present for the long term effective tax rate (ETR1); long term cash effective tax rate (ETR2) and permanent book-tax differences (BTD) for company i in year t. The main independent variable is corporate social network includes CEO's social network (CEO closeness and CEO degree) and CFO's social network (CFO closeness and CFO degree). *CEOfin_acc* is dummy variable that equals one is the CEO have accounting or financial background, zero otherwise. $NETWORK_{i;t-1}xCEO\text{fin\_acc}_{i;t}$ is the interaction between social network and CEOs has financial and/or accounting background. All variables are defined in Appendix A. The *t*-values examine whether the regression coefficient is significantly different from zero. ***, **, and * indicate significance at the 1%, 5%, and 10% levels, respectively.

The Effects of CFOs Background on Tax Aggressive

Prior research has shown that CFOs are typically in charge of financial planning, budgeting, internal control, and financial reporting quality (Gore et al., 2007; Kaufman, 2003). In addition, CFOs have significant impact on accounting decisions such as choosing accounting methods and making accounting adjustments (Geiger & North, 2006; Gore et al., 2007; Mian, 2001). Previous researches also assumed that accounting background and related experience can influence financial reporting and CFO performance. A recent survey reports that, among the CFOs of Fortune 100 firms, 32% had worked as controllers and 9% had served in corporate audit (Russell Reynolds Associates, 2012) [More details refer at: Where do CFOs come from? Profiles and career patterns of Fortune 100 chief financial officers. Available at: [(http://www.russellreynolds.com/content/where-do-chief-financial-officers-cfos-come-from)]. Hoitash et al. (2016) show that firms with accountant CFOs are more risk averse, accountant CFOs are negatively (positive) impact with firm value in high-growth (low-growth) industries. We examine whether the interaction between CFOs' accounting backgrounds (accountant CFOs) and corporate social network are associate with tax aggressive. We re-estimate our regressions model as following:

$$\begin{aligned}\mathrm{TAXAGG}_{i,t} = {} & \alpha_0 + \beta_1\mathrm{NETWORK}_{i,t-1} + \beta_2\mathrm{CFOfin\_acc}_{i;t} + \beta_3\mathrm{NETWORK}_{i;t-1}\mathrm{xCFOfin\_acc}_{i;t} \\ & + \beta_4\mathrm{SIZE}_{i;t-1} + \beta_5\mathrm{MB}_{i,t-1} + \beta_6\mathrm{LEVER}_{i,t-1} + \beta_7\mathrm{NOL}_{i,t-1} + \beta_8\Delta\mathrm{NOL}_{i,t-1} + \beta_9\mathrm{ROA}_{i,t-1} \\ & + \beta_{10}\mathrm{ESUB}_{i,t-1} + \beta_{11}\mathrm{PPE}_{i,t-1} + \beta_{12}\mathrm{INTAN}_{i,t-1} + \beta_{13}\mathrm{DFI}_{i,t-1} + \beta_{14}\mathrm{RD}_{i,t-1} + \mathrm{YearDummies} \\ & + \mathrm{IndustryDummies} + \varepsilon_{i,t}\end{aligned} \quad (10)$$

where the dependent variable $TAXAGG_{i,t}$ presents for ETR1, ETR2, BTD in company i in a given year. The main independent variables are corporate social network include social network of CEOs and CFOs. CFOs has both financial and accounting background set as a dummy variable ($CFOfin\_acc_{i;t}$), and their interaction. All variables are defined in Appendix A [The remaining control variables are the same as those in Eq. (4)]

Table 9 shows that $CFOfin\_acc$ are significantly impact on our tax aggressive measures. The coefficients interaction between $CFOfin\_acc$ and CFO's corporate social network are significantly negative, ranging from -0.023 to -0.029, significant at least the 5% level on ETR1 and ETR2 for both panel A and panel B. We didn't find any evidence about the interaction between $CFOfin\_acc$ and CEO's corporate social network. As a result, CFOs which higher social network and accountant background are lower the effective tax rate, leading more like engage corporate tax aggressive.

Where the dependent variable is tax aggressive ($TAX_{i,t}$) present for the long term effective tax rate (ETR1); long term cash effective tax rate (ETR2) and permanent book-tax differences (BTD) for company i in year t. The main independent variable is corporate social network includes CEO's social network (CEO closeness and CEO degree) and CFO's social network (CFO closeness and CFO degree). *CFOfin_acc* is dummy variable that equals one is the CFO have both accounting and financial background, zero otherwise. $NETWORK_{i;t-1} xCFO\mathrm{fin\_acc}_{i;t}$ is the interaction between social network and CFO has both financial and accounting background. All variables are defined in Appendix A. The *t*-values examine whether the regression coefficient is significantly different from zero. ***, **, and * indicate significance at the 1%, 5%, and 10% levels, respectively.

CONCLUSION

This study examines whether and how corporate social network are related to corporate tax aggressive. We constructed a comprehensive social network of Taiwan listed companies that arise from education background, prior experience, and other social activities such as training course, business forum, and meetings in the period span 5 year from 2010 to 2014. Our empirical results show that social network, is a statistically and economically meaningful determinant of the corporate tax aggressive. We also show the consistent evidence by using instrumental regression and robustness test to support for our main findings. Those funding imply that firms share tax strategies by social networks ties.

In summary, our study extents the literature by linking the social network to firm, a better understanding of the effect of network ties on tax aggressive. Our research contributes to prior literatures by following ways: Firstly, this paper is the first to document that individual's social capital associated with the position within the social network affects outcomes of tax avoidance; Secondly, we investigate both the impact of CEO and CFO network ties to corporate tax avoidance, CEOs/CFOs occupying higher places in the overall network hierarchy are less (more) perform tax avoidance strategies; Finally, our finding show the evidence of the interaction between powerful, academic background and network ties impact to tax evasion.

APPENDIX A: DEFINITIONS OF VARIABLES

Variable	Description
Tax aggressiveness	
Long term effective tax rate (ETR1)	Total income tax expense over last three year scaled by total pre-tax income over the same period of time based on Dyreng et al. (2008); Minnick and Noga (2010).
Long term cash effective tax rate (ETR2)	Total refund income tax to chief financial officer over last three year scaled by total pre-tax income over the same period of time based on Dyreng et al. (2008); Minnick and Noga (2010).
Effective tax rate (ETR3)	Total income tax expense scaled by total pre-tax income over the same based on Richardson and Lanis, (2007); Huseynov and Klamm (2012); Lennox, et al. (2013).
Cash effective tax rate (ETR4)	Total refund income tax to chief financial officer scaled by total pre-tax income based on Dyreng et al.,2008;Khurana and Moser2009; Chen et al. (2010).
Permanent book-tax differences (BTD)	Pre-Tax Income-(Income tax expense/ Law tax rate)]- [(Deferred income tax expense/law tax rate)] based on Frank, Lynch, and Rego (2009); Lennox, et al. (2013).
Social Network	
CEO closeness	CEO's social network which measured by closeness. CEO closeness set as an indicator that equal one if the value is higher than mean of it by each year, zero otherwise.
CFO closeness	CFO's social network which measured by closeness. CFO closeness set as an indicator that equal one if the value is higher than mean of it by each year, zero otherwise.
CEO degree	CEO's social network which measured by degree. CEO degree set as an indicator variable that equal one if the value is higher than mean of it by each year, zero otherwise.
CFO degree	CFO's social network which measured by degree. CFO degree set as an indicator variable that equal one if the value is higher than mean of it by each year, zero otherwise.
CEO betweenness	CEO's social network which measured by betweenness. CEO betweenness set as an indicator that equal one if the value is higher than mean of it by each year, zero otherwise.
CFO betweenness	CFO's social network which measured by betweenness. CFO betweenness set as an indicator variable that equal one if the value is higher than mean of it by each year, zero otherwise.
CEO eigenvector	CEO's social network which measured by eigenvector. CEO eigenvector set as an indicator variable that equal one if the value is higher than mean of it by each year, zero otherwise.
CFO eigenvector	CFO's social network which measured by eigenvector. CFO eigenvector set as an indicator variable that equal one if the value is higher than mean of it by each year, zero otherwise.
Firm characteristics	
SIZE	Logarithm of market value of equity for a firm at the beginning of a year.
MB	Market-to-book ratio for a firm in a given year, measured as market value of equity divided by book value of equity.
LEVER	Leverage for a firm in a given year, measured by long-term debt scaled by lagged total assets.

NOL	Indicator variable that equals 1 if tax loss carry forward is positive at the beginning of year t, and 0 otherwise.
ΔNOL	Change in loss carry forward for firm in a given year, scaled by lagged total assets.
ROA	Return on assets for a firm in a given year, scaled by total assets.
ESUB	Equity income in earning for a firm in a given year, scaled by lagged total assets.
PPE	Property, plant, and equipment for a firm in a year, scaled by lagged total assets.
INTAN	Intangible assets for a firm in a given year, scaled by lagged total assets.
DFI	Foreign pre-tax income scaled by lagged total assets; Missing values of foreign pre-tax income are set to zero.
RD	Natural logarithm of research and development activities expenditure. Missing values of research and development expense are set to zero.
Governance characteristics	
ID	The percentage of directors who are independent.
BS	The number of board members.
IO	The percentage of institution ownership.
BSO	The percentage board and supervisor ownership.
CEOPOWER	Equal to one if the CEO is chair, zero otherwise.
CEOfin_acc	Equal to one if CEO have a financial and/or accountant background, zero otherwise.
CFOfin_acc	Equal to one if CFO have both accountant and financial background, zero otherwise.

ABSTRACT

This paper extends the UTAUT 2 by adding the concept of irrational opposition to adoption of wearable health tracker in a corporate wellness setting. Our proposed model incorporates all the UTAUT 2 constructs and adds the new idea of irrational opposition. UTAUT 2 focused on those ideas that can be categorized as rationally processed by the user. However, not all human behavior is rational. We seek to identify the impact of irrationality on the decision as well as potential drivers of that irrationality. In this paper, a preliminary instrument is developed and validated to measure irrational opposition.

KEYWORDS: Healthcare management, UTAUT 2, Consumer technology adoption, Irrational opposition, Health trackers

INTRODUCTION

Corporations seek to improve worker health due to the cost of medical care for workers. Because of this, corporate wellness programs are common in many larger corporations. One potential area for technology in this case is the use of wearable health trackers. These trackers can provide information about heart rate of the subject throughout the day. By using these trackers, the subjects may be able to gather data that they can use to improve their health. In addition, the subject may share this information with their primary care physician.

Voluntary adoption of these health trackers may help with effectiveness of the corporation's wellness program. However, participation in both wellness programs, as well as the use of a health tracker are usually voluntary. This paper seeks to identify those factors, which contribute to a subject using a health tracker. Conversely, this may provide insight into obstacles to adoption.

Because of the similarities to choices on consumer-level technology adoption decisions, the bulk of our theoretical model is based on Unified Theory of Acceptance and Use of Technology 2 (Venkatesh et al., 2012). The constructs in UTAUT 2 are largely rational or social. However, there is also an irrational basis for resistance to some actions. Because of this, based on Prototype/Willingness Model and Automotive Model we added the construct of “Irrational Opposition” in order to capture some of the less rational potential reasons for opposition to adoption.

This paper seeks to:
1. Apply a UTAUT 2 based model to a real-world application
2. Add to the theoretical model by attempting to measure irrationality

LITERATURE REVIEW

In this section most important theories and models related to the adaption of health trackers as well as irrational opposition behavior are reviewed. Three streams of literature have reviewed: (1) Technology Acceptance Models, (2) Theories related to Irrational Opposition, and (3) Adoption of Wearable Health Trackers. The following subsections summarize the most relevant literature in above aforementioned streams.

Technology Acceptance Models

Technology acceptance studies is a major field of interest amongst IS researchers. Studies in this stream analyzing the mechanisms and antecedents of IT artifacts adaptions. Since health trackers are one of the most novel IT artifact, their adaption can be investigated through the lens of technology acceptance models.

Many different models are proposed by various researchers to explain the antecedents and mechanism of new technologies adaption. Davis (1989), in one of the most fundamental papers of this field, proposed Technology Acceptance Model (TAM). In TAM model, two famous antecedents are used to predict the IT adoption: Perceived Usefulness (PU) and Perceived Ease of Use (PEOU). PU and PEOU predict the Behavioral Intention which directly influences Actual Behavior. This model was derived from The Theory of Planned Behavior developed by Ajzen (1991).

After the introduction of TAM, researchers aimed to increase the predictability of the model or fit the model into new contexts. Given these objectives, new constructs were added to TAM and new relationships were suggested. Venkatesh and Davis (2000) developed TAM 2 by considering Theory of Reasoned Action (Ajzen and Fishbein 1980; Fishbein and Ajzen 1975) as a complement for TAM. They added subjective norm, voluntariness, and image as social influence constructs, accompanied by job relevance, output quality, and results demonstrability as cognitive instrumental process constructs.

In another substantial work, Venkatesh et al. (2003) studied most prominent information technology acceptance models and combined their constructs. Their effort led to the development of a unified theory, called Unified Theory of Acceptance and Use of Technology (UTAUT). UTAUT model consists of Performance Expectancy, Effort Expectancy, Social Influence and Facilitating Conditions as the antecedents of behavioral intention. Moreover, they have considered four moderators, namely, gender, age, experience and voluntariness, all of which were already studied and supported in previous studies (Venkatesh and Morris, 2000).

Venkatesh et al. (2012) extended UTAUT model and developed UTAUT 2 addressing the technology adoption in the consumer context. Hedonic motivation, Price value and Habit were added to this model in order to fit the UTAUT into consumer context. Additionally, Voluntariness of use is also eliminated as it was not relevant any more. UTAUT 2 can be a great foundation for this research as health trackers are belonging to consumer context. In this regard, this model is selected for studying the adaption of health trackers.

Irrational Opposition

Most of the aforementioned researches are highly focused on behavioral intention. It is widely proved that accurately measuring behavioral intention is necessary to predict the behavioral intention. However, a question arises here: Is knowing the behavioral intention also sufficient to predict the actual behavior?

Warshaw and Davis (1985) argued that the behavioral intention and actual behavior should be disentangled. They defined and explained that Behavioral expectations can also be used to complement the behavioral intention in predicting the actual behavior. According to these findings, this paper tries to study related theories and identify a new factor which could complement the behavioral intention to predict the actual behavior.

Webb and Sheeran (2006) also examined that whether changing behavioral intentions engenders behavior change. Conducting a meta-analysis, they determined that the relationship between behavioral intention and behavior is not always consistent.

Number of theories are proposed to explain the inconsistency of behavioral intention and actual behavior. Automotive Model argues that sometimes the concept of intentional behavior is not equal to goal-directed behavior (Bargh, J. A. 1990). The core idea of this model is that behavior sometimes are unintentional (Gollwitzer and Bargh 2005). So, it is possible that the intention alone, could not predict the behavior thoroughly.

Another related theory is Prototype/Willingness Model (Gerrard et al. 2008) which suggests that sometimes humans are acting a behavior in a non-logical way. In these conditions decision makers perform a behavior which is not rational. For instance, people know that smoking is harmful but they do it. In this case, they have intention to not smoke, but they are willing to do that.

This paper tries to measure all of these mechanisms using a new construct called Irrational Opposition. This construct refers to all of the decisions made by humans that are not based on solid logic or in a rational way.

Adoption of Wearable Health Trackers

Wearable health trackers are referring to the electronic devices being wore by individuals and are able to track health measures, such as heart beat, blood pressure, or oxygen saturation. Smart watches and Fitbit are great examples of wearable health trackers which are commonly being used nowadays.

In one of the earliest researches focusing on the adoption of wearable health trackers (WHTs), Nasir and Yurder (2015) investigated the perceptions of users and physicians about WHTs. TAM model has been used and extended by adding perceived risk and compatibility constructs, in order to fit to the context. However, this study did not provide any empirical support for the proposed hypotheses and WHT acceptance model.

In another similar work, Lunney, Cunningham, and Eastin (2016) tried to blend TAM with TPB model in order to develop a framework for the context of wearable fitness technologies adoption. They used structural equation modeling (SEM) technique in order to test their hypotheses. Based on the results, they claimed that wearable fitness technologies use is significantly related to perceived health outcomes of these devices. As one of the suggestions for future researches, they have indicated that there is a need to focus on motivation, as well as habit formation through goal-setting.

Zhang et al. (2017) aimed to explore factors that influence the WHTs adoption intention. They considered technical attributes, health attributes, and consumer attributes. They have also used TAM model and integrated it with health belief model, snob effect and conformity and reference group theory. The results suggested that adoption of WHTs is being influenced by all of the three considered attributes simultaneously, namely, technical, health, and consumer. Authors have also suggested to pay more attention to the special groups of people who may have different characteristics in their intention to use WHTs.

Lee and Lee (2018) examined the factors influencing individual's intention to adopt a WHT. Considered factors in this research are interpersonal influence, personal innovativeness, and self-efficacy, attitudes toward a wearable fitness tracker, health interests, and perceived expensiveness of the device. Subjects of this research were students which are highly different with the subjects of our paper who are employees of a firm. Based on a logistic regression analysis, it is observed that consumer attitudes, personal innovativeness, and health interests had significant and positive impact on the intention of WHT adoption. Moreover, they have compared two groups of subjects who differed in the knowledge about the WHTs and observed that intention to adopt was stronger among who were aware of WHTs than among who were not aware.

Finally, in one of the most recent studies, Shin et al. (2019) conducted a systematic literature review on the topic wearable activity trackers and categorized the researches into six major themes which are as follows:

1. Acceptance, adoption, and abandonment
2. Behavior Change
3. Patient treatment and medical settings
4. Technology focus
5. Self-monitoring data centered
6. Privacy

Based on the analysis of 78 articles in the acceptance, adoption, and abandonment theme. Authors suggest that this theme of research is bridging "Technology" and "Users" which is identical to other technology acceptance contexts. They have argued that WHTs are highly complex devices which are needed to be understood comprehensively from various perspectives. In this regards, authors called for interdisciplinary awareness about the current landscape of WHTs use.

Theoretical Contributions

This paper aims to add irrational opposition construct to UTAUT 2, in order to increase the predictability power of model in the Health Tracker context. Theoretical contributions of this paper are as follows:

1. Introducing Irrational Opposition construct and its antecedents to technology acceptance literature.
2. Adding Irrational Opposition construct to UTAUT 2 model and analyze its possible relationships with UTAUT 2 constructs.
3. Considering two different paths (Rational Path and Irrational Path) in UTAUT 2 framework.

The rest of this paper is as follows: in section 3 research model is delineated and the related hypotheses are introduced. In section 4 the methodology is proposed and the instrument development procedure is explained. In section 5 the future works are described and the action plan is defined. Lastly, section 6 conclude this paper.

RESEARCH MODEL AND HYPOTHESES DEVELOPMENT

The model is based primarily on the established UTAUT2 model (Venkatesh, 2012). We have also added "image" and "compatibility" based on the Moore and Benbasat, 1991.

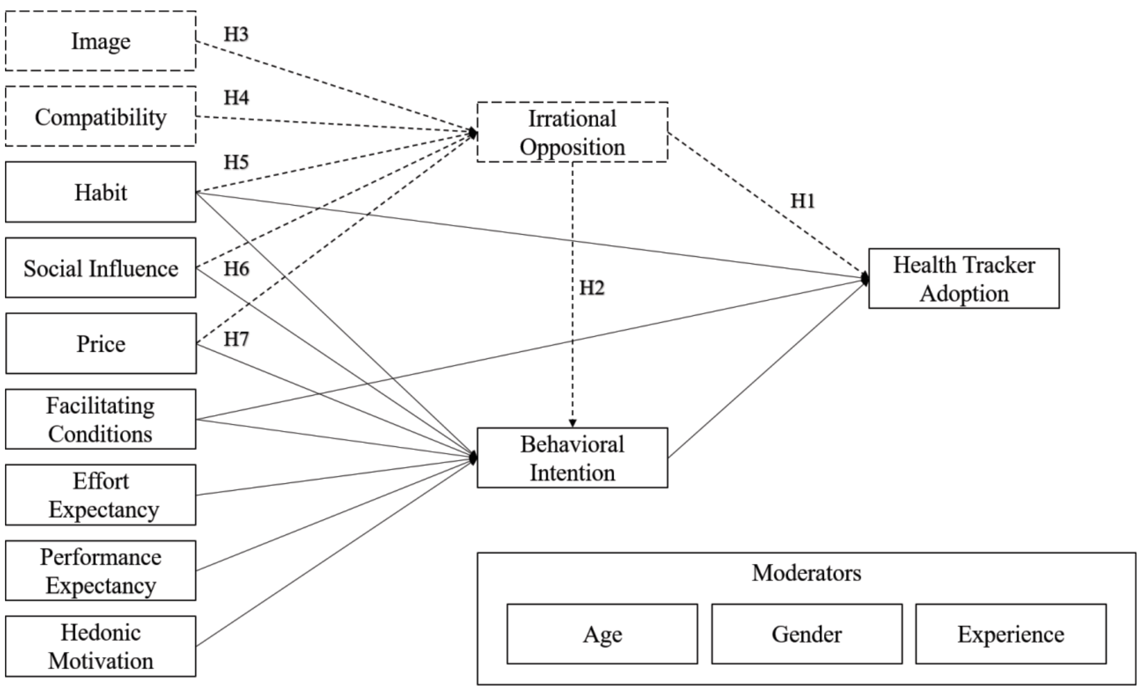

Figure 1- Research Model

The additional construct of "irrational opposition" is based on the concept Behavioral Willingness from Gerrard et al. (2008). The purpose of adding irrationality to the UTAUT 2 model is to attempt to increase the explanatory power of the model. It is notable that, to keep research model simple, the impact of moderator factors on the relationship are not drawn.

The first hypothesis of this paper is related to the main idea of this paper: the impact of irrational opposition on use behavior. Based on Prototype/Willingness Model and Automotive Model, which are reviewed in the previous section, the behavior of decision makers is not always rational. The reason for their behavior could have roots in their irrationality. Moreover, as the irrational opposition is always some type of resistance to a specific behavior, therefore in our study, it has destructive effect on the adoption of wearable health trackers. Consequently, the first hypothesis of this paper is developed as follows:

> Hypothesis 1: *Irrational opposition is negatively associated with the adoption of wearable health trackers.*

On the other hand, irrational opposition can decrease the intention to adopt wearable health tracker. This impact is not the same with the impact of irrational opposition on use behavior as it performs in another layer of behavior. In some cases, the irrational opposition may fundamentally decrease the intention of doing something which is rationally reasonable. This hypothesis is also consistent with the Prototype/Willingness Model.

> Hypothesis 2: *Irrational opposition is negatively associated with the intention to adopt wearable health trackers.*

The next five developed hypotheses are related to the antecedents of irrational opposition. The first antecedent is Image which came from both the paper of Moore and Benbasat (1991). In our paper, the image is defined as the perceptions of subjects about a person who uses health tracker. Some people may think that if someone uses health trackers it means that he or she is not healthy enough or even unattractive. However, some other people may think that if a person uses health tracker he is smart and attractive. This image of a person who uses health tracker will influence the irrational opposition. In this condition, their inappropriate thoughts about the user of health tracker may form an opposition to use wearable health trackers.

> Hypothesis 3: *Image of people about a person who uses health tracker risk is negatively related to irrational opposition.*

Next hypothesis is related to the compatibility of health trackers with people's job and lifestyle. For instance, if a person greatly uses his or her hands during work, the health trackers which should be worn around the wrist will not be compatible with the job. Hence, if using wearable health trackers are not compatible with people's lifestyle or job, they will immediately reject using that. Individuals do not want to use those health trackers because they prefer their lifestyle or routine over tracking their health condition. This opposition is not reasonable because in many cases people can slightly change their lifestyle, and change how they do their job or even how they use health trackers and satisfy requirements of both. In this regards, if wearable health tracker does not seem compatible with the individuals' lifestyle or routine tasks, they may exhibit irrational opposition to use health trackers.

> Hypothesis 4: *Compatibility of wearable health tracker with individual's lifestyle or job is negatively associated with irrational opposition*.

In addition to the influence of added constructs on irrational opposition, the original UTAUT2 constructs may also have impacts on the irrational opposition. We hypothesized that Habit, Social Influence, Price may also influence the irrational opposition. In many studies using Prototype/Willingness Model, it is proved that social influence will form the willingness of a behavior which could be in contrast with their actual intention. Habit can also be influential on

irrational opposition. For instance, consider a person who has not worn any watch or bracelet at all. This person does not want to use wearable health trackers because his habit is in sharp contrast with the adoption of these devices. Price can also lead to the formation of irrational opposition. Individuals may initially get disappointed by the price of a product without understanding and considering its real potential and benefits. If the knowledge of a person about wearable health trackers and their potential benefits is limited, then their high price may raise an irrational opposition to adopt them.
Based on above discussion, the final hypotheses of this paper are developed as follows:

Hypotheses 5: *Social influence is negatively related to the irrational opposition.*
Hypotheses 6: *Habit is negatively related to the irrational opposition.*
Hypotheses 7: *Price is negatively related to the irrational opposition.*

METHODOLOGY

The questions used to measure the UTAUT 2 constructs were adopted directly from the questions used in the UTAUT 2 model. However, the construct of Irrational Opposition was new to this model. Because of this, new measurement questions were developed according to the following methodology.

15 new questions were developed and printed on 3x5 cards. Raters were given the cards and asked to categorize them according to which construct they belonged to. The raters consisted of one current research faculty member and two Ph.D. program students. On the first pass, the correlation of questions to the desired construct was poor with only 28.89% of questions correctly being categorized.

For the second pass, new, established constructs were added and the phrasing of the new questions was changed to reduce ambiguity and bring the phrasing more in line with affirmative statements. On the second pass, 88.89% of the questions were categorized with the appropriate construct. This percentage of correctly categorized questions was acceptable.

Next, of the questions relating to the new construct, they were ordered from best to worst, in order to reduce the number of final questions to four. In order to facilitate this task, the authors provided the raters with 4 general conceptual facets to be measured for the construct. Each rater then selected the question that they felt was the best question in order to represent the conceptual area.

The four conceptual facets were: avoidance of beneficial activities, avoidance of information, resentment of company and social perception or image.

After the raters ordered the questions, a winner for each conceptual facet was selected, resulting in a total of 4 questions to measure the constructs.

The UTAUT 2 questions and the 4 new questions are to be administered via a survey using Survey Monkey. The subjects will be selected by queries to number of companies.

FUTURE WORK

As it is explained in the previous section, this paper will use survey as the methodology to test the hypotheses. In this regard, the next step of this research will be data collection. To collect the data, the population is identified as all of the employees in the United States. The number of firms should be selected from the companies who are willing to initiate health programs in near future or have already implemented these programs.

Afterwards, first, a pilot test can be done with a small random sample of the employees within one firm to test the validity and wording of questionnaire. The wording of questionnaire will be revised after the pilot test and then the survey will be distributed through survey monkey to the entire sample for the final phase.

In the next step, the collected data will be cleaned and used to test the developed hypotheses. Based on the results of hypotheses testing, the possible explanation for the results will be investigated and explained in order to provide insights about the topic.

RESULTS-CONTINGENT MANAGERIAL IMPLICATIONS

In this section, the managerial implications of this paper are discussed. One of the objectives of this research is to provide insights for healthcare managers and help them identify practices which can enhance the adoption of health trackers. If the results support the hypotheses, a number of suggestions are proposed that can be used to reduce the negative impact of irrational opposition to health tracker adoption. These results-contingent suggestions are discussed below:

1. Companies should emphasize the value of the product and clarify its benefits in comparison with the price. It should be shown that the price of a health tracker is reasonable considering the benefits from them. Companies can also provide some financial aid (such as loans) for employees to help them to buy the health trackers. It is also notable that since the price is also one of the antecedents for behavioral intention, by implementing the suggested practices, behavioral intention can also be enhanced directly.

2. The second possible way to reduce the irrational opposition could be by promoting the image of health tracker users. This can be achieved through advertisements, flyers, banners, and campaigns. The main idea is to show that the individuals who adopt the health trackers are smart, popular, and cool. This also needs the commitment of senior and junior managers. They should use health trackers during their work to show to the employees that even their managers and supervisors are using these products. By implementing these suggestions, the image of health trackers can be enhanced and consequently, the irrational opposition may be reduced.

3. In order to reduce the irrational opposition, companies can study the existing work processes and tasks within the company and, if it is possible, modify them to be compatible with the adoption of health trackers. By doing that, employees initially see the compatibility of their work processes with health tracker adoption and the probability of their opposition due to the insubstantial compatibility issue will be reduced.

4. Lastly, companies can also help in changing the employees’ habits. They can allocate incentives for first months of health tracker adoption in order to transform health tracker usage into a habit. Employees initially may adopt the health tracker to receive the participation incentives, but after a while, using health trackers may be turn into a habit for them. For instance, if employees adopt smart watches, they can get used to other features of smart watches and therefore continue using them permanently. In other words, by considering incentives for the participants, companies can try to push the health trackers into employees’ daily routine and habits. Incentives could also mitigate the effect of health

trackers' high price. Consequently, incentives may reduce the irrational opposition through two different paths: (1) Turning health tracker into a habit of employees, and (2) Reduce the negative effect of health trackers' high price.

In contrast, if the results do not support the role of irrational opposition to health tracker adoption, it can be concluded that the subjects are highly rational when they decide on the technologies concerning their health and wellness. If this occurs, further research can investigate the role of irrational opposition in other types of health-related information technologies, in order to see whether the observed rational behavior is limited to health trackers or if it is generalizable to other health-related information technologies.

CONCLUSION

Wearable health trackers are one of the most influential novel ITs that are capable of improving humans' health substantially. In the recent years, companies have tried to utilize health trackers and combine them with health reward programs, in order to increase enhance the health condition of their employees. However, it is not clear to what extent employees are willing to participate in the health programs and adopt health trackers. In this regard, this paper expanded the unified theory of acceptance and use of technology (UTAUT 2) in order to fit the model to health tracker contexts.

This study proposes a theoretical model for the adoption of wearable health trackers as part of a corporate wellness program. A new construct called Irrational Opposition is introduced which can prevent the wider adoption of wearable health trackers. Moreover, Image and Compatibility constructs were added to the model, which are identified in previous studies. It is hypothesized that image, compatibility, social influence, habit, and price may be antecedents of irrational opposition.

To be able to test the hypotheses, measurement instrument is needed for each construct. As the irrational opposition is a new construct, a preliminary instrument is developed and validated using the Q-sort methodology. For all other constructs, items were collected from previous studies and reworded to fit the context. The next step of this study will be a pilot test to refine the instrument. Afterwards, a large-scale survey will be conducted to measure each construct using developed and validated instruments to test the hypotheses.

To conclude, reviewing literature on technology acceptance and wearable health trackers and extending UTAUT 2, this paper brings forward the concept of irrational opposition and proposes a valid measurement instrument for it considering the context of wearable health trackers adoption in corporate health programs.

APPENDIX

Instrument

<u>Compatibility (CO)</u>

CO1. Using a health tracker is compatible with all aspects of my health.
CO2. Using a health tracker is completely compatible with my current situation
CO3. I think that using a health tracker fits well with the way I like to stay in shape.
CO4. Using a health tracker fits into my exercise style

Performance Expectancy (PE)

PE1. I find a health tracker useful in my daily life.
PE2. Using health tracker increases my chances of achieving things that are important to me.
PE3. Using health tracker helps me accomplish fitness goals more quickly.
PE4. Using health tracker increases my ability to maintain good health.

Effort Expectancy (EE)

EE1. Learning how to use a health tracker is easy for me.
EE2. My interaction with a health tracker is clear and understandable.
EE3. I find health trackers easy to use.
EE4. It is easy for me to become skillful at using a health tracker.

Social Influence (SI)

SI1. People who are important to me think that I should use a health tracker.
SI2. People who influence my behavior think that I should use a health tracker.
SI3. People whose opinions that I value prefer that I use a health tracker.

Facilitating Conditions (FC)

FC1. I have the resources necessary to use a health tracker.
FC2. I have the knowledge necessary to use a health tracker.
FC3. A health tracker is compatible with other technologies I use.
FC4. I can get help from others when I have difficulties using a health tracker.

Hedonic Motivation (HM)

HM1. Using a health tracker is fun.
HM2. Using a health tracker is enjoyable.
HM3. Using a health tracker is very entertaining.

Price Value (PV)

PV1. Health trackers are reasonably priced.
PV2. Health tracker are a good value for the money.
PV3. At the current price, health trackers provide a good value.

Habit (HT)

HT1. The use of health trackers has become a habit for me.
HT2. I am addicted to using a health tracker.
HT3. I must use a health tracker.
HT4. Using a health tracker has become natural to me.

Behavioral Intention (BI)

BI1. I intend to continue using a health tracker in the future.

BI2. I will always try to use a health tracker in my daily life.
BI3. I plan to continue to use a health tracker frequently.

Irrational Opposition (IO)

IO1. Although both healthy and unhealthy workers are participating, if I participate in a company health-related program, my co-workers may think I am not healthy.
IO2. I am not willing to use health tracker, even if it could increase my chances of survival in an emergency.
IO3. I do not want more information on my physical health or well-being.
IO7. Any initiative that the company produces is probably bad for employees.

Use

Please choose your usage frequency for each of the following:
a) Health tracker
b) Blood Pressure monitor
c) Fitness Software
d) Diet Journal
e) Fitness Journal
f) Exercise Equipment
Note: Frequency ranged from “never” to “many times per day.”

Image

“Imagine a one of your male/female colleagues is not participating in the health tracker program. How would you describe him/her using the following characteristics?”

1. Cool
2. Smart
3. Independent
4. Popular
5. Self-Conscious
6. Unattractive
7. Immature
8. Dull
9. Confused
10. Nerd

Age

Age was measured in years.

Gender

Gender was coded using a 0 or 1 dummy variable where 0 represented women.

Experience

Experience was measured in months.

Use

Use was measured as a formative composite index of both variety and frequency of mobile Internet use.

ABSTRACT

The purpose of this study is to explore the underlying support services demand as way to improve the operational processes of educational technology. This allows for an alignment between the short-term service schedule and the expected users demand for short-term support. Enterprise system data at a large U.S. university was used to model the demand for service support in educational technology. Significant negative coefficients supported our claims that service demand, training requirements, and in-class repairs slowly decline during the semester, whereas lamp replacement demand grows as the semester progress. The idea of operational analytics to measure short-term trend in service demand was used as empirical signal technology managers could use in technology management.

KEYWORDS: *Educational Technology; Technology Management; Support Services Demand; Support Service Management; Cross-directional Trend*

INTRODUCTION

Technology and the system itself are maintained through support service operations, including incident and maintenance management techniques in a manner common to information technology (IT) service management conducted within most organizations (McNaughton, Ray, & Lewis, 2010). Technology is essential in accomplishing the primary organizational operations (Croteau & Bergeron, 2001; Mithas, Ramasubbu, & Sambamurthy, 2011; Tallon, Kraemer, & Gurbaxani, 2000) and has become a tangible resource utilized by organizations to enhance their capabilities. Instructional technology, however, can be more prone to frequent incident and maintenance requests as it is often a technology originally designed to be employed in business office settings and was adapted for use in classrooms. Instructional technologies are similar in form, but operationally function differently than its original design. For example, unlike office use situations instructional technology in each classroom is prone to be used by variety of different instructors within each day, on different days of the week, from semester to semester. Therefore, technology support services demand surges from low to high or high to low at different times within the semester. Thus, the support service structure of information technology in traditional applications is potentially different from similar technology used in unique environment, such as educational technology. As Antonenko, et al. (2017) pointed out that much of the educational technology development has been driven by the considerations of what can be developed using the existing technologies, rather than what should be developed for the users need. Cunningham & Kwakkel (2017) explored forecasting of technological change in the context of high-tech organizations. Stormi, et al., (2018) presented a forecasting model that predicts demand for industrial services which is directly related to the installed base, such as repair, maintenance, and remanufacturing. Giannì & Franceschini, (2003) proposed a model in e-commerce that analyses the ways in which managers can obtain information regarding customers need over time to perform more personalized service. Ishak & Newton (2018) in their study indicated that user resistance to new technology feasibly can be predicted. These studies do not investigate the short-term trend direction that could be of useful to offset resource requirement and help to improve the resource planning efficiently. As the service landscape changes with increasing technological demands, and as the field adopts a stronger transformative approach towards the entire service eco-system, undertaking service demand planning and their support management becomes critical (Subramony, et al., 2017). Unfortunately, little attention has been devoted towards the investigation of support services demand and quantifying the magnitude of the effect of support services demand in educational technology management.

In this regard, broader industry technology management literature may be a guide for understanding the impact on the support services demand. Unfortunately, the broader industry technology management differs from educational technology in its environment and types of service required (Banerjee & Igbaria, 1993). For example, the short-term trend in support services demand is different in its creation in educational technology system that occurs within the semester. This induces the concept of differences in technology use is dependent on service categories resulted from semester variations in educational environment as oppose to quarterly variations in broader industry technology environment. Thus, we conceptualize that there is a short-term (upward or downward) trend in demand for support service within a semester in educational technology environment is specific to a service category. This within the semester increasing or decreasing demand is referred to as short-term trend as oppose to long-term trend that exists over the years.

LITERATURE REVIEW

Determining the frequency to which systems once adopted are maintained and the frequency to which technology support staffs are called into a classroom for routine and/or emergency support associated with successes attained in classrooms can broaden the understanding of technology support management. This area might seem intuitive as equipment manufacturers provide predictions for the frequency of upkeep, but the landscape of universities creates complicated technology integrations because the technology is often different from one department to another and different from one time to another with the variability being when the technology was installed and the prevalent technology at that time to suit the demands of the departments. In addition, hardware and/or technology systems frequently require unexpected on-site modification, once adopted to attain successful operation and create a challenge to the management.

The literature on the integration of technology and its management in the university classrooms has focused on technology adoption (Kopcha & Sullivan, 2006), technology use (Shelton, 2014), and success of students' technology-enhanced learning (Thinnukool, 2018). To some lesser degree researchers have focused on the process used by universities to select technology for the long-term and adoption of technology, a common research area, is one of the barriers associated with the efficient integration and management of instructional technologies (Reid, 2014). Ironically, the amount and frequency of technological support service provided by staff required to attain satisfactory functionality across a university's classroom technologies are key predictors to the faculty's use and adoption. In many cases, the institutional policy along with individual academic departments might drive the adoption of new instructional technology (McPherson & Whitworth, 2008; Shelton, 2014). However, the decisions for technology adoption or its use are usually made by two different stakeholders (Lanzolla & Suarez, 2012). In their study, they have noted that the benefit of technology adoption will not materialize unless it is being used. Salmon and Angood (2013) observed midlevel administrators pursue cost-efficient solutions to satisfy a majority of technology users' need.

However, the question has grown from, if the resources invested will enhance education to, if installed, when and how often will the university be called upon to service the technology and what are the key determinants (Choudhury, Hartman, and Coussens, 2018). The optimal mixture of factors and the frequency of support dedicated to these technologies have not been well considered in previous research studies. In fact, to our knowledge no empirical research study has been done in understanding or estimating the support services demand in educational technology. The most identifiable trend associated with instructional technology has been the increasing amount and different types of technology used by students and faculty. While the users of technology are often identified as a major barrier to the adoption and use of technology (Butler & Sellbom, 2002; Reid, 2014), sometime due to anxiety associated with the technology use (Igbaria & Parasuraman, 1989), we propose the frequency to which a university's staff must dedicate support services to these technologies may also be a barrier.

ABSTRACT

Prior work demonstrated that a project management course for information systems and technology majors has a specific curricular role for teaching agile project management concepts and practices. This paper expands on the prior work, describing a course module for delivering agile content. As agile methods were and still are a marked departure from more traditional methods, we propose that agile therefore requires an equally non-traditional teaching method. Team-Based Learning, an active learning pedagogy, was used to engage students in the spirit of agile software development. Said pedagogy is described and its effectiveness supported with in-course assessment results.

KEYWORDS: Agile, Project Management, Team-Based Learning

INTRODUCTION

The question of where to teach agile in the information systems curriculum was partially addressed in our prior paper (Landry & McDaniel 2016), where we contended that a course in information systems (IS) project management was a good choice. Our approach followed three principles in defining agile content for a project management course: (1) agile alongside, (2) agile across, and (3) agile project, not product. Not wishing to tout agile as a silver bullet, and recognizing the variety of different approaches to IS project management, we did not scrap the traditional methods, but taught agile alongside them. We found that agile topics might span all ten PMBOK® areas, and so we decided to attempt to identify topics across all ten PMBOK areas of project scope, cost, schedule, quality, communication, risk, resource, integration, procurement, and stakeholder management (Project Management Institute, 2017). Finally, keeping in mind that the target course was IS project management, we decided to avoid the non-project management agile topics, such as pair programming, and focus instead on only the project management-related agile topics.

Having provided an answer to the *where* question, we then addressed the related *what* question, by identifying the specific topics across the PMBOK areas, as well as defining a preliminary set of seven learning outcomes for agile project management (PM). The topics we chose were daily standups, Kanban boards, and burndown charts. We integrated these into a cohesive set of exercises. The learning outcomes for agile coverage were as follows:

1. Evaluate the suitability of agile methods for use in a given project and organization context
2. Analyze project proposals using multiple techniques
3. Compare and contrast traditional versus agile project management
4. Demonstrate an awareness of agile project management basic terminology and concepts across multiple PMBOK areas.
5. Apply agile PM principles and techniques for managing in multiple PMBOK areas
6. Discuss the soft skills and abilities of project managers
7. Complete team-based work applying the principles and tools of project management

Building on the approach of the prior paper, we now further examine the teaching and learning of agile methods in the project management curriculum. In this paper, we consider the question, *Is Team-Based Learning an effective pedagogy for educating students in agile project management?* This is an important question for educators in computing disciplines where project management is taught. As agile project management adoption continues to increase, it is important that graduates be prepared to flourish in this new environment. Students should have a strong background in agile methods, knowing that they are different from traditional methods, and that this difference isn't trivial or arbitrary. As a professional, they must be able to thrive in both traditional and agile environments, understand the differences, and if necessary, make decisions regarding the methodology to use. The selection and use of a project management methodology will affect future project successes and failures. The discovery of effective teaching methods, and their improvement, is essential to the preparation of future agile project management professionals.

BACKGROUND

The background for our approach stems from three areas: agile in project management, active learning in agile project management, and team-based learning.

Agile in Project Management

Agile, according to the Project Management Institute, is best defined by the Agile Manifesto, which it considers to be the "original and official definition of agile values and principles" (Alliance 2017, p. 150). In the manifesto (Beck et al., 2001), the 17 signing authors introduced their ground-breaking software development approach with the declaration:

> We are uncovering better ways of developing software by doing it and helping others do it. Through this work, we have come to value:
>
> Individuals and interactions over processes and tools
> Working software over comprehensive documentation
> Customer collaboration over contract negotiation
> Responding to change over following a plan

That is, while there is value in the items on the right, we value the items on the left more.

The authors go on to define 12 guiding principles behind the Agile Manifesto:

- Our highest priority is to satisfy the customer through early and continuous delivery of valuable software.
- Welcome changing requirements, even late in development. Agile processes harness change for the customer's competitive advantage.
- Deliver working software frequently, from a couple of weeks to a couple of months, with a preference to the shorter timescale.
- Business people and developers must work together daily throughout the project.
- Build projects around motivated individuals. Give them the environment and support they need and trust them to get the job done.
- The most efficient and effective method of conveying information to and within a development team is face-to-face conversation.
- Working software is the primary measure of progress.
- Agile processes promote sustainable development. The sponsors, developers, and users should be able to maintain a constant pace indefinitely.
- Continuous attention to technical excellence and good design enhances agility.
- Simplicity--the art of maximizing the amount of work not done--is essential.
- The best architectures, requirements, and designs emerge from self-organizing teams.
- At regular intervals, the team reflects on how to become more effective, then tunes and adjusts its behavior accordingly.

In the nearly 18 years since the publication of the Manifesto, the approach has been implemented in various methods, including eXtreme Programming (XP) and Scrum (Lindstrom and Jeffries, 2004). For many years it was difficult to find reliable numbers on agile adoption, or empirical evidence of agile's effectiveness. Within the last five years, however, an empirical study of 1,002 projects found that agile methods had a positive impact on two dimensions of project success: efficiency and overall stakeholder satisfaction against organizational goals (Serrador and Pinto, 2015).

Agile has been identified as belonging to six published standards relevant to information systems and project management education. While the roots of agile go back as far as the turn of the millennium, the IS 2002 and MSIS 2006 (Gorgone et al., 2006) curriculum models provide no mention of agile methods. By the end of the first decade of the 2000's, though, agile was making headway. The IS 2010 model curriculum (Topi et al., 2010) suggests that "agile methods" be taught in the Systems Analysis and Design course. The Project Management Body of Knowledge (PMBOK®), published by the widely recognized Project Management Institute (PMI), was updated to include coverage of agile, offering an Agile Certified Practitioner (PMI-ACP®) certification (Project Management Institute, 2017), and the Agile Practice Guide (Alliance, 2017). The Schwalbe (2019) and Marchewka (2015) textbooks on project management provide coverage of agile methods. Finally, a preliminary report on an CIS curriculum model (Longenecker et al., 2016) and MSIS 2016 (Topi et al., 2017) list project management as a key outcome, and there are mentions in several places that students should gain a novice understanding of agile methods, including as a topic in the prescribed IS project management course.

Active Learning in Agile Project Management

Three prior studies have found empirical support for the effectiveness of active learning methods in teaching agile project management concepts. McAvoy and Sammon (2005) had students engaged in a workshop exercise where students debated the potential effectiveness of agile methods (Extreme Programming) in two project case scenarios. The teams then carried out a weighted scoring exercise, applying critical adoption factors. A total of 92% (22 of 240 students reported that the active learning approach was useful in increasing their understanding of agile methods. Schmitz (2018) developed a role-play simulation of the Scrum methodology called Scrummy to introduce agile project management concepts and practices to three cohorts of health informatics majors. He reasoned that an active, team-oriented, face-to-face learning method that solved problems with tacit knowledge was a good fit with the actual values and practices of agile project management. His results indicated that student self-efficacy for concepts introduced in the role-play exercise were higher than for concepts taught in lecture only and that self-efficacy post-test scores were statistically higher than pre-test. Another study set out to compare active learning methods to lecturing in an IT project management context. Sibona, Pourreza, and Hill (2018) used an origami (Japanese paper-folding) exercise as the basis for an active learning exercise on Scrum. Their results found that most students preferred active learning to lecture, found the active learning exercise to be more engaging, and that when both methods were used, that lecture come first, followed by active learning. The authors recommended the lecture→active approach, due to the variety of learning styles encountered and a reasonable amount of support for the effectiveness of lecture in the sample.

Team-Based Learning

The active learning pedagogy chosen for the project management courses sampled in this study is Team-Based Learning (TBL). TBL is a specific technique for using teams in courses that is sometimes confused with the general use of teams in courses. The specific TBL initiative adopted by the co-authors was devised by Larry Michaelsen and others and is described in their publications (Michaelsen, Knight, & Fink, 2004; Michaelsen & Sweet, 2008; Parmalee & Michaelsen, 2010). TBL has been used across a wide range of disciplines, including the natural sciences, social and behavioral sciences, legal studies, the humanities, and business (Knight, 2004). TBL can be used in classes of various sizes, making large classes feel smaller (Michaelsen, 2004). TBL has also been used successfully in international situations (Cragin, 2004) and applied in the electronic classroom (Freeman, 2004).

According to Michaelsen, for TBL to be successful, key practices must be faithfully incorporated, including the following:

- backward design
- team formation
- pre-class individual learning
- readiness assurance process
- application activities
- peer evaluation

Each of the TBL practices listed above were incorporated into the project management course and in delivering the agile project management lessons. A brief description of each TBL method follows.

Backward Design

With backward design, the teacher begins by asking: “what do we want our students to be able to do with the knowledge by the end of the course and afterwards?” Then, the teacher defines good course objectives, and activities that enable application of knowledge towards the objectives.

Team Formation

TBL relies on the use of permanent, balanced teams of 5-9 students each.

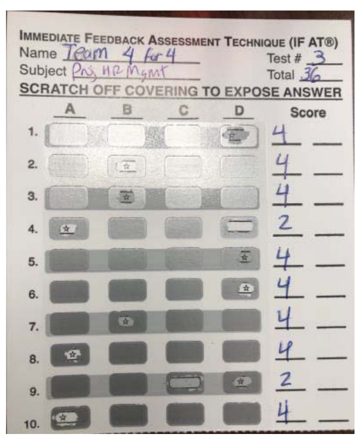
Pre-Class Individual Learning

In order for the students to have high-quality experiences during the team activities, each student must come prepared. This independent learning phase usually consists of an assigned reading.

Readiness Assurance Process

Following pre-class learning students experience the readiness assurance process, or RAP. The RAP consists of readiness assurance tests (RATs), which include individual and team tests, called iRATs and tRATs, along with grade appeals and clarifications. The tRAT It is the same test as the iRAT but given to the collaborating teams. The teams complete items on a scratch-off card, like a bingo game card, which gives them immediate feedback and the ability to answer in multiple attempts (for fewer and fewer points). The appeals and clarification phases provide a review of what was missed. Figure 1 provides an example of the Information Feedback Assessment Technique (IFAT®) that is used for the tRAT score sheet.

Figure 1. IF-AT®



Application Activities

Once knowledge has been assessed/assured through the RATs, students are then prepared for applying that knowledge. Application activities may be completed by teams and/or individuals. Team activities stimulate learning through collaboration and critical thinking within the team and competition and discussion across teams to bring about deeper individual learning in the applied knowledge areas.

Peer Evaluation

Anonymous peer evaluation is used to help make team members accountable to each other. The peer evaluations are part of each individual's grade.

Team-based learning is a suitable pedagogy for a project management class with coverage of agile methods alongside traditional methods. Teamwork is an important aspect of project management, and TBL relies heavily on collaborative learning. TBL's use of permanent teams lends itself to activities that use teams, such as daily standups. TBL's emphasis on collaboration and critical thinking is helpful for getting students to objectively analyze project management methods, such as comparing traditional methods to agile methods. Schmitz (2018) similarly pointed out the values that underlie agile methodologies—specifically, the preference for collaboration through face-to-face interaction that is described in the Agile Manifesto. He used an active learning approach—role-play simulation—for teaching and learning agile concepts and practices.

APPROACH

The topical content chosen for the IS project management courses was based on the idea that the agile development process includes not only software development activities, but project management as well. As we wanted to actively engage students in an applied agile experience, we looked for agile practices that could be carried out, or performed, in nearly authentic instances. We choose three activities: daily standup meetings, Kanban boards, and burndown charts. Daily standup meetings, also called daily scrums, are brief, once-per-day collaborative get-togethers where a development team addresses three sets of issues: progress from the prior day, intentions in the current day, and obstacles encountered or anticipated. A Kanban board is a visualization tool that depicts the status of task progress through a left-to-right flow of a task card across status "swimlanes". A burndown chart is a bar chart depicting daily work remaining for a timeboxed period. Taken together, these three agile practices focus on project schedule management, providing an alternative approach to traditional project scheduling. Furthermore, these activities span across multiple PMBOK areas, including project resource, scope, and communication management. We designed the lesson in such a way as to integrate the three activities into a single set of related activities.

The approach we took in teaching agile concepts and practices in the IS project management curriculum was to create a course lesson module using the TBL pedagogy. The following section describes our coverage and delivery of agile project management using the components of TBL.

Backward Design

We started with the question of "what do we want our students to be able to do with their knowledge of agile methods by the end of the course and afterwards?" This question was largely answered by our prior paper (Landry & McDaniel, 2016), which concluded that agile coverage across PMBOK areas, alongside traditional PM, and project not product would be emphasized, and by the prior section of this paper, which operationalized this coverage through an integrative problem-solving assignment on daily standups, Kanban boards, and burndown charts. The agile-related learning outcomes we developed for the three agile PM sub-topics were as follows.

By the end of the course, the student will be able to:

- Walk through a daily standup meeting, identifying, assigning, and reporting completed tasks while addressing obstacles.
- Update a Kanban board, given the results of that day's standup meeting.
- Create a burndown chart, calculating average velocity and estimated completion date.

Key takeaways include the need to assign (or volunteer for) work, check on its progress, and document its completion systematically; how to use a simple tool like a whiteboard to create a visual of work in its various states of completion; and how a team's recent productivity is useful for predicting future progress.

Team Formation

A total of 59 students were enrolled in three course sections of project management—two sections of an undergraduate course and one section of a graduate course—in the spring of 2019. At the beginning of the semester a total of seven (7) undergraduate and five (5) graduate teams, comprised of between four to six members each, were formed. Teams were formed to be demographically and academically balanced. Every attempt was made to not isolate a female member. There was a mix of U.S.-born and international students in the graduate course. Most importantly, strong academic performers were dispersed.

Pre-Class Individual Learning

All three sections were provided with readings and some lecture for preparation. Textbook readings (Schwalbe 2019 and Marchewka 2015) were assigned to the undergraduate and graduate students, respectively. All three sections were assigned reading materials published on the course management site. Students in the graduate course were assigned two articles (Lindstrom and Jeffries 2004; Serrador & Pinto 2015) to read in addition to the other content. The lecture and readings across all three sections introduced the students to the concept of how agile is different from traditional software development; reviewed key aspects of the Agile Manifesto; and covered topics such as iterative planning, timeboxing, incremental releases, individual roles, daily standups, Kanban boards, story points, burndown charts, velocity, and sprint estimation.

Readiness Assurance Process

Prior to the readiness assurance process, the students in each section were given written guidance on RAT coverage, as follows.

"<u>RAT-2b Agile Planning</u>

Our RAT #2 will take place in our class meeting this week. It will follow the format of prior RATs, with the iRAT followed by the tRAT, and then appeals and clarifications. The 10 items on agile planning will cover the following topics: agile manifesto, product backlog, iterative, incremental, sprints, daily stand-ups, kanban, velocity, burndown, timeboxing, and story points."

Of the ten agile items on the RAT, we are most interested in those mapped directly to upcoming application activities. These were five items closely linked to the application of agile concepts for daily standups, Kanban, and burndown:

1. In agile development projects, ___ is the primary measure of progress. (Ans: d)
   a. daily stand-up c. Gantt
   b. iteration d. working software

2. A unitless metric for the relative size of a requirement is ___. (Ans: b)
   a. escaped defects c. daily standups
   b. story points d. timeboxing

3. A project whose sprint velocity is 9 story points per day at the end of Day 4, and with 54 story points remaining will finish at the end of what day? (Ans: d)
   a. 13 c. 5
   b. 6 d. 10

4. At the end of Day 1 of a sprint there are 75 story points worth of work remaining, and at the end of Day 6 there are 50 story points of work remaining. What is the project's current velocity, in units of story points per day? (Ans: b)
   a. 25 c. 4
   b. 5 d. 50

5. In the middle of a sprint, a Kanban board with three swimlanes looks as follows: 7 cards in the left-most lane, and 5 cards in the right-most lane. What's the status of this project? (Ans: c)
   a. Everything is going as it should
   b. The team has run out of work to do, and so the sprint should conclude
   c. The team is not working on anything, even though there are tasks to be completed
   d. Nothing has gotten done yet

Application Activities

The students in all three sections received three application activities in total, and the graduate class received a fourth. The common application activities were: (1) a team application activity—agile project planning role play, (2) midterm exam problems, and (3) final exam problems. All application activities covered daily standups, Kanban boards, burndown charts, and computation of velocity and estimated day of completion. The graduate class also completed a homework assignment on creating an agile PM spreadsheet.

<u>Team Application Activity: Agile Project Planning Role Play</u>

In the class period following the RAP, students were given a team application activity on Agile Project Planning. The activity was a role play. One of the teams in the class section volunteered to role play, while the other teams observed. Students read their part from a script given out to the class. The script was written to incorporate agile manifesto values and principles. The roles were Narrator, Scrum Master, Assistant (to the scrum master), and three other Team Members. Together, the team walked through several days of daily standup meetings, following the script, and standing in front of the class, using the whiteboard. The scrum master would ask for a volunteer, and a team member would raise their hand and volunteer, reading their line. The assistant would write up a Kanban card complete with time estimate and team member's name. Then, the card would be placed in the (hopefully) correct swimlane among the three, labeled "to-do", "doing" and "done" from left-to-right. Some team members reported work completed, and the assistant then had to move a Kanban card from one swimlane to the next. A team member might report an obstacle that would lead to a discussion and possible actions taken. All of this was in the script. Mistakes were possible. By the end of the last day, the team in front of class, along with the teams observing, drew a burndown chart with work remaining bars for each day of the sprint. The assistant was asked to complete, with the team's help, the velocity and estimated day of completion. Each of the observing teams were then given a list of questions to answer in their teams.

Midterm Problems

The second application activity was in the form of problems given on the midterm exam. There were 20 points (20%) of problems given to each class section. Like the team application activity, these problems asked students to complete a Kanban board, draw a Kanban card, draw a burndown chart, and calculate velocity; and estimated day of completion, showing their work.

Final Exam

Similar to the midterm exam, the students in all three sections were given problems to complete. The final exam problems were worth between 13% (graduate class) and 15% (undergraduate classes) of the course grade.

Peer Evaluation

The students were evaluated on their semester-long team performance, using a peer evaluation instrument administered by Catme.org (Loignon et al., 2017; Ohland et al., 2012; Loughry et al., 2007). There were four items, each evaluated on a five-point scale, plus peer-to-peer comments. Students were required to differentiate scores across two dimensions: every item had to have at least one student scored as less than 5, and every student had to be less than 5 on at least one item. As previously mentioned, the peer evaluation grade weight was 8-10% of the final grade.

RESULTS

In this section, we will discuss the results of the iRAT, tRAT, team application activity, midterm exam, final exam, and peer assessment by using both quantitative and qualitative analysis to compare sections and aggregate mastery levels. The results are based on 57 students because one student from each of the undergraduate sections was absent the day of the agile readiness assessments.

iRAT

A one-way between subjects analysis of variance (ANOVA) was conducted to compare the effect of iRAT scores for the three class sections. Table 1 provides the means and standard deviations for evaluations conducted in the three classes. There was a significant effect on the iRAT scores on the class sections at the $p<.05$ level [$F(2, 54) = 5.11$, $p = .009$]. Post hoc comparisons using the Tukey HSD test indicate that the mean score for the graduate class and the undergraduate class with 18 students were significantly different. However, the undergraduate class with 11 students did not significantly differ from the other classes.

In Pre-Class Individual Learning, there is not a definitive way to figure out what each student did. However, the wide variance in iRAT scores combined with the qualitative feedback from students in post-hoc surveys indicate that not all students did their pre-RAT preparation.

tRAT

A one-way between subjects ANOVA was conducted to compare the effect of tRAT scores for the three class sections. There was a significant effect on the tRAT scores on the class sections at the $p<.05$ level [$F(2, 54) = 15.42$, $p = .000$]. Post hoc comparisons using the Tukey HSD test indicated that the mean score for the graduate class and both undergraduate classes were significantly different. However, the two undergraduate class did not significantly differ from one another.

Table 1: Readiness assessment, midterm and final exam results

	Classes					
	Undergraduate (N=11)		Undergraduate (N=18)		Graduate (N=28)	
Evaluation	Mean	Std. Dev.	Mean	Std. Dev.	Mean	Std. Dev.
iRAT	52.73%	29.78%	45.28%	31.03%	71.61%	26.04%
tRAT	82.73%	4.67%	83.89%	16.85%	98.21%	3.90%
Midterm	88.64%	24.92%	78.05%	24.92%	89.55%	13.44%
Final	78.79%	16.55%	77.22%	22.35%	89.74%	18.60%

As is typically the case with iRATs, individual performance varied widely, and although mean iRAT scores for each class section seem to differ, these differences were not statistically significant. Also as expected, tRAT scores were higher than the individual iRAT means. The iRAT-to-tRAT means by section went from 52.73.% to 82.73%, 45.28% to 83.89%, and 71.61% to 98.21%. Collaborating teams performed at a higher level than the individual student.

Team Application Activity

Although the team application activity was not graded, there is qualitative evidence that students were engaged in the activity and thought critically. There was evidence of (a) correct performance, (b) identification and correction of mistakes, (c) critical analysis of the case, and (d) insightful observations.

The volunteer teams in all three sections were able to walk-through the script and complete their assigned tasks with little or no intervention by the instructor. Nearly all of their actions were correct. Visible mistakes were identified by the observing teams and corrected for everyone to see. Here is a summary of performance on each of the activity questions:

1. Is the Day 5 Kanban board correct?

Issue surfaced: A volunteer team in one section made a mistake by assigning a Kanban card to the "to-do" swimlane, rather than the "doing." This enabled a clarification: if a task is identified and immediately assigned to an individual, it goes right to the "doing" swimlane.

2. Is the Assistant's estimate of the work remaining correct?

Issue surfaced: There was a discrepancy in velocity calculation. Some teams calculated by subtracting the sum of work completed from the work remaining at Day 1, then dividing by the number of days elapsed. However, this was a mistake, as some work was added during the sprint, and this additional workload was not accounted for. The correct calculation was to subtract work remaining on the last day from the work remaining on the first day, then dividing by the elapsed days.

3. When will the work be completed? Will it be finished by the end of the sprint?

Result: All teams realized that the work planned would not be completed by the end (Day 14) of the sprint, based on the now-corrected calculation of estimated day of completion, compared to the actual last day of the sprint given to them.

4. What, if anything, do you think went wrong? What could the Scrum Master have done about it?

Issue surfaced: In the undergraduate classes the teams realized that in the script, the scrum master did not ask the "what obstacles?" question, and that there was one task that stayed in the "doing" swimlane for a long time. They reasoned that surfacing obstacles might have cleared the way for the task to be completed.

Insightful questions: The graduate class also asked insightful, critical questions that led to discussion. One team asked if an obstacle was found to delay a sprint, and if that obstacle required an infrastructure fix, would that additional work qualify for a new Kanban card and result in additional work completed. The prevailing recommendation was to not count the infrastructure fix as work completed. A team's productivity, or velocity, should be based on completing its own work—such as software development for a software team. Another team asked what should happen to tasks that were not completed correctly. The recommendation was to move the task back to a prior swimlane ("doing") rather than writing a new "correction" card, although arguments were presented for both options.

Midterm Exam

The midterm exam questions that were used to assess the student's retention of the agile topics include the following:

- Assume that in an agile project sprint, tasks T1 and T2 have already been completed; Miriam is working on task T3; Fred has started task T4; and tasks T5, and T6 have not yet been assigned for anyone to work on. Draw a Kanban board correctly depicting the status of all these activities. (5 pts.)

- Draw a detailed Kanban card (not board) for a task T9-design database, whose size is estimated to be 20 story points, and with Bill and Sue assigned to work on it. (5 pts)

- At the end of Day 3 of a sprint there are 90 story points worth of work remaining, and at the end of Day 6 there are 30 story points of work remaining. What is the project's current velocity, in units of story points per day? (Show your work) (5 pts.)
- A project whose sprint velocity is 15 story points per day at the end of Day 4, and with 90 story points remaining, will finish at the end of what day? (Show your work) (5 pts.)

A one-way between subjects ANOVA was conducted to compare the effect of midterm exam scores for the three class sections and no significant effect was found at the $p<.05$ level [$F(2, 54) = 2.52$, $p = .090$]. The undergraduate class with 18 students had scores range from 15% to 100% with three students having scores between 15% and 45%. The other undergraduate sections scores ranged between 70% and 100% for the same questions.

Overall, 85.96% of students, or 49 out of 57, performed at a satisfactory level or better on the midterm's agile assessment activity (where satisfactory is defined as the minimal passing level, of 70% for undergraduates and 80% for graduate students).

Final Exam

The final exam questions (not shown) were variants of the midterm questions. A one-way between subjects ANOVA was conducted to compare the effect of final exam scores for the three class sections and no significant effect was found at the $p<.05$ level [$F(2, 54) = 2.63$, $p = .082$]. Results show that for two of the class sections, final exam performance matched that of the midterm. The undergraduate class with 11 students, scored significantly lower on the final exam section [$t(10) = 15.788$, $p = .000$) as compared to the midterm exam. The final exam scores for both undergraduate sections were statistically the same ($t(27) = 0.20$, $p = .843$).

Overall, 75% of students, or 42 out of 56, performed at a satisfactory (minimal passing) level or better on the culminating assessment activity—the agile application activity items on the final exam. The 85.96% to 75% regression of the mean performance is not unexpected. The agile material was older material covered in the first half of the course. Students were studying for and taking multiple, comprehensive final exams. Additionally, some students admitted to allocating study time strategically towards the courses where their effort would make the most difference in their final grade.

Peer Evaluations

The mean peer evaluation score was 92.5 with scores ranging from 81 to 100 on a scale whereby 100, 90, 80, 70, and 60 correspond to 5, 4, 3, 2, and 1 on a five-point scale.

DISCUSSION

For about ten years now, agile has made its way into IS curricula through its appearance in specific model curricula and textbooks. We contend that agile coverage in a project management course should include agile topics specifically related to project management and that cut across multiple PMBOK areas. The three areas we cover—daily standups, Kanban boards, and burndown charts—can be delivered in sequence and tie together well. They bring together PMBOK areas of scope, schedule, communication, and resource management.

The focus of this paper was to test whether an active learning pedagogy—Team-Based Learning—would be effective in delivering agile concepts and practices. It was thought that a pedagogy that used teams, collaboration, and face-to-face problem-solving would be fitting for learning about agile practices and values.

Results from three independent sections of two different project management courses provided evidence that students, both at the undergraduate and graduate levels, progressed as expected through a team-based learning pedagogy to eventually master agile learning outcomes. Individual performance on the iRAT varied, ranging from means of 52.73% to 71.61% across the three sections. Collaborative teams scored at means of 82.73% to 98.21% on team RATs. Individual performance on agile content on the midterm exceeded iRAT performance with means ranging from 78.06% to 89.55%, and did not drop off significantly on the final exam, as means ranged from 77.22% to 89.74%. While 85.96% of students mastered agile PM at the midterm, 75% did so by the final exam. The noticeable drop-off from the midterm to the final exam was evaluated further. It turned out that it was almost entirely due to undergraduate students. A total of 22 of 27 graduate students, or 81.4%, scored at a minimal (80%) passing level on the final exam agile items, while 19 of 29 undergraduate students, or 65.5%, scored at a minimal (70%) passing level. The proportion of passing students we expect for a learning outcome is usually 80%. This total was achieved by the midterm exam, but not for the final. For the final, the graduates achieved this, but the undergraduates did not.

Qualitative evidence observed during team application activities indicated that student teams were engaged, performing at a mostly correct level, were learning from mistakes, and were insightful. We attribute the design of the exercises, which enabled hands-on authentic problem solving and collaboration, enabled the discovery of insights and the detection and correction of mistakes.

Peer evaluation scores indicated that perceived student preparation and performance in the teams varied, and that, overall, a high degree of satisfaction with teammate performance was reported. The satisfaction with teammate performance is indirect evidence that students perceived the pedagogy to be effective.

Together, the pattern of student performance through the team-based learning activities, the midterm performance, the final exam performance (partially), and the qualitative evidence, along with reported team satisfaction provides evidence that our active learning approach for delivering agile methods coverage was effective.

IMPLICATIONS

The implication for this research is that effective agile project management can be taught and student learning assessed using the team-based learning pedagogy. In future studies, researchers might consider introducing variables such as student learning styles, student self-efficacy, and combinations of lecture and active learning methods to more fully explain variance in student performance. For undergraduate student retention, the problem of the final exam drop-off in performance is a phenomenon to be explored.

FUTURE DIRECTIONS

Future directions include development of higher order evaluative questions or case scenarios for the final exam that challenge students to compare traditional project management methods against agile methods. The current study demonstrated that students, especially at the graduate level, gained enough insight so as to be prepared for the higher order thinking. What remains is how to design a useful exercise, such as a case study or role play, that enables students to compare traditional and agile methods.

DECISION SCIENCES INSTITUTE
Designing Classroom Project Management for the Virtual Student Team

Diane Kutz
University of South Florida

Matthew Mullarkey
University of South Florida
Email: mmullarkey@usf.edu

ABSTRACT

Virtual teams are a reality in today's work environment. Students can learn to navigate the virtual team environment in properly designed university courses. Many courses in project management are offered online and naturally employ technology to support these virtual team environments. As such, they provide an opportunity for the design of virtual team workspaces. This paper explores a series of iterative interventions used to design a collaborative virtual student team environment. Using a guided, emergent design approach we also propose a means to evaluate the effectiveness of this environment with regard to team cohesion, team commitment, and team collaborative climate.

KEYWORDS: Project Management, Technology Enabled Collaboration, Virtual Team Project Management, Online Project Management Classroom, Virtual Student Team

INTRODUCTION

The motivation for this research arose from (1) business demand that employees demonstrate an ability to operate in virtual team environments, and, (2) university requirement for needed improvements in educating students in online project management courses. The researchers' experience suggested that whether these students were undergraduates with limited work experience or graduate students with substantial work experience, the challenges were relatively similar – how do students effectively collaborate in an online environment to accomplish team-based assignments in a course? And, how might their fulfillment of virtual team assignments more fully prepare them for the needs of employers in the digital economy of distributed asynchronous team environments?

As project management faculty, the researchers observed that it appeared that the majority of students approached online virtual team assignments with a parsing activity using a form of 'divide and conquer' to complete the teamwork assignments in the course. In this approach, students segmented and separated the component parts of the project work required and set off to independently complete their requisite piece of work. At a final point in time, approaching the due date of the assignments, students then compiled the pieces and submitted the finished project. We found that this approach was less than ideal for both the quality of the project completed and for teaching students essential behaviors for collaboration in a virtual project team environment. For example, this parsing approach effectiveness was highly conditional on the virtual team's ability to actually determine the proper component parts of a project activity at the outset of the project. And, perhaps most importantly, often resulted in team conflict, missed deadlines, low satisfaction with group work, and poor team performance overall.

Instructors that routinely experienced difficulties with virtual team performance expressed a desire to develop and establish an effective collaborative virtual team environment. Researchers using a guided, emergent elaborated action design research approach in situ worked with these instructors to iteratively design, build, evaluate and implement an innovative approach to a technology-centric solution to more effective student virtual team performance.

This problem is practice-inspired because it comes from the need for universities and employers to train adults to successfully implement project work in virtual team environments. If the university is to train students to be effective in the virtual environment that is today's project management environment, then the university must teach the students how to effectively function in a virtual team environment.

This problem is research-ingrained because research has shown that positive team member relationships have a positive impact on team effectiveness and the design of effective online classroom environments to replicate work environments is essential to undergraduate and graduate student success in the workplace. Fernandez and Jawadi (2015) stated that "high quality relationships have been identified as a key factor in enhanced team performance." Virtual teams suffer from the lack of physical proximity that leads to organically developed relationships, and this is a hindrance on the development of good team member relationships (Handy, 1995), (Townsend, DeMarie, & Hendrickson, 2000). Therefore, a substitute for this physical proximity and organically developed relationships needs to be established in order to facilitate strong team relationships. And, the university project management course must offer a means for students to learn this essential capability.

LITERATURE REVIEW

Literature Review of Virtual Teams

The body of research on project management, effectiveness, and relationship building in traditional co-located teams is expansive (Pauleen, 2003). However, increasingly project managers are finding themselves charged with managing a project team where either all or some of their team members are working at a location other than the project manager's locale. "Virtual teams are here, and they are here to stay" (Bell & Kozlowski, 2002). In a 2014 article by Keith Ferrazzi, published in Harvard Business Review, Ferrazzi stated, "When my firm, Ferrazzi Greenlight, recently surveyed 1,700 knowledge workers, 79% reported working always or frequently in dispersed teams" (Ferrazzi, 2014).

There are many definitions of virtual teams with most definitions focusing on the nature of the dispersed locations and use and usefulness of technology (Martins, Gilson, & Maynard, 2004). For this study, virtual teams are defined as "teams whose members use technology to varying degrees in working across locational, temporal, and relational boundaries to accomplish an interdependent task" (Martins et al., 2004). Leadership in virtual teams requires a different mix of skills than those required of leaders in co-located teams (Pauleen, 2003). Virtual team leaders are challenged by having to essentially interpret personal and contextual signals from team members through the use of electronic communications with no visual cues or signals ("Global Work, Bridging Distance, Culture and Time," 1995).

Literature Review of Trust and Communication in Project Management

Trust is a vital ingredient when people work together (Ferrazzi, 2012). "Building and maintaining trust in the traditional, physical workplace is difficult enough, but the process is even tougher in a virtual environment, where people often have to work with people they haven't met in person" (Ferrazzi, 2012). According to Ferrazzi, upon initial formation team members tend to trust early, and they operate under what he calls "swift trust; however this swift trust will wain over time, but it can be replaced by "interpersonal trust" if the team successfully bonds and builds this more lasting trust (Ferrazzi, 2012).

According to Ferrell and Kline (2018), "In order for virtual teams to reach peak performance, trust and effective communication among team members must be developed." They further describe high trust teams where:

- Team members expect other members to follow through on commitments and interdependencies.
- There is a willingness to be vulnerable when uncertainty arises.
- Team members are confident that others take action for the good of the team (Ferrell & Kline, 2018).

However, by the very nature of their dispersion and reliance on technology, virtual teams encounter a multitude of barriers when it comes to building trust. They go on to state that barriers "are contextual and predominantly arise from the inherent challenges of geographical dispersion" and they discuss the importance of focusing on team building activities that focus on the sharing of personal values and experiences as well as the importance of communicating frequently (Ferrell & Kline, 2018).

Ferrell and Kline (2018) highlight that virtual teams need to use both communication-focused technology and coordination-focused technology effectively. They classify technology used in an attempt to replicate face-to-face communication, such as email, instant messaging, telephone, and video conference, as communication-focused technology. Whereas they classify technology focused on improving the coordination of tasks, such as project management software, desktop virtualization, file sharing tools, scheduling tools, and co-creation tools, as coordination-focused technology. They assert that "communication-focused technology is the backbone of trust-building communication in virtual teams, coordination-focused technology refers to a complementary set of tools that can be leveraged more peripherally to enhance trust and coordination among team members" (Ferrell & Kline, 2018).

Literature Review of Team Development and Team Building

Kozlowski and Ilgen (2006) make a distinction between team development and team building. They state that team building refers to formal efforts to make modifications to existing processes, whereas team development is a more informal process initiated by the team members to establish social structure and work processes that are effective for the team. Research typically views team development as an initial forming process of a team and, because teams are not always static in membership, as a continuous process over the life of the team (Bell & Kozlowski, 2002).

Hackman (1992) focused on the importance of factors that are considered “glue” that bonds team members to each other. When Steve Jobs was asked about teamwork how he envisions teams working together in a 1995 interview, he shared a parable of rocks in a rock tumbler (Elmer-Dewitt, 2011). Jobs said that “… through that group of incredibly talented people bumping up against each other, having arguments, having fights sometimes, making some noise, and working together they polish each other and they polish the ideas, and what comes out are these really beautiful stones” (Elmer-Dewitt, 2011).

The Jobs’ parable offers not only the parallel between rocks in a rock tumbler and team members on a team but also the lesson of the liquid and grit. Jobs’ neighbor in the analogy did not just put rocks in the tumbler, rather he “…put them in the can with a little bit of liquid and a little bit of grit powder…” (Elmer-Dewitt, 2011). The liquid and grit are the professional relationships built between team members working closely together that result in interpersonal trust and lead to effective team performance. Bell and Kozlowski (2002) state that “team orientation represents the affective bonds that connect members to the team and its mission”. More recent literature purports that team relationship building is comprised of four distinct approaches that may be combined (Aga, Noorderhaven, & Vallejo, 2016). They find that these approaches are goal-setting, developing interpersonal relations, clarifying roles, and employing problem-solving techniques (Aga et al., 2016). Ferrazzi (2012) makes the point that:

> “When assembling a virtual team, managers often assume that people will mainly be interested in what their fellow team members can do, as opposed to who they are as individuals. Wrong! When looking at a resume, CV, or bio of someone, people will often latch onto personal details, such as hobbies and other outside interests, including charities the person supports. Why? Because they want to get a better sense of that individual and to see if they might have anything in common” (Ferrazzi, 2012).

Bruce Tuckman (1965) introduced the stages of team development model, identifying that teams go through four distinct phases: forming, storming, norming, and performing. Each of these phases includes some amount of relationship building, with the greatest amount happening in the forming phase. The researchers purport that if a team spends adequate time in the forming phase, establishing relationships, that their journey through storming and norming will be brief and they will move on to performing much faster than if they neglect to take the time and effort to adequately navigate the forming phase.

Teams progress through these stages naturally in co-located teams as team members interact spontaneously throughout the day; however, leaders must take a more active role in regards to relationship development in virtual teams where spontaneous communication is rare, and team communication exists over computer-mediated technologies (Liao, 2017). “The importance of relationship building in a virtual environment and methods to build relationships are significant factors when practitioners engage in virtual work” (Pauleen, 2003). There have been numerous studies on relationship building in traditional co-located teams (Pauleen, 2003) and organizations spend a lot of money on team building training and exercises, yet most of this training has been focused on co-located teams. Nonetheless, the prevalence and reliance on virtual teams are growing, and it is vital for organizations, and by extension instructors, to gain a comprehensive understanding of the importance of team building and its relationship to project success.

Discussion and Research Questions

Project teams must operate in virtual environments where team members are separated geographically, temporally, and technologically. In these environments, effective teams must possess a different set of capabilities needed to build trust, establish relationships, communicate, and coordinate the project work. Existing literature further suggests that these capabilities must be exercised throughout the course of the project for the most productive team effort. Consequently, university instructors must consider approaches that build these capabilities proactively and avoid the typical student approach to shortcut virtual team project management.

The secondary literary review research, however, offers little in the way of project management course design to inform instructors seeking to educate students in virtual team effectiveness in project management courses. Our work with students in existing project management courses offered an opportunity to methodically introduce and evaluate a series of course improvements designed to increase virtual team effectiveness through improved student team performance.

Our research asks the following research questions:

RQ1: How can successful virtual team project management environments be adapted to an educational project management course environment?

RQ2: How can we co-create and design with students an effective virtual team project management environment?

RQ3: What might the evaluation approach for the elements of this new virtual team project management environment take?

METHODS

The researchers used an action research grounded approach to co-create and co-evaluate with students the design of an adaptive virtual team project management environment. We chose a guided, emerge design-centered approach consistent with the design science research (DSR) paradigm (Hevner, March, Park, & Ram, 2004). DSR acknowledges that information systems and technology-enhanced socio-technical systems often result from an iterative approach to the build and evaluation of multiple alternatives. When conducted in situ with participants of the socio-technical system, an action design science research (ADR) approach is ideal for principles of researchers' and participants' reciprocal shaping and mutually influential roles (Sein, Henfridsson, Purao, Rossi, & Lindgren, 2011). Using an elaborated ADR (eADR) method (Mullarkey & Hevner, 2019) we worked with students to iterate through stages of Diagnosis, Design, and Implementation establishing the critical principles of an effective virtual project management team environment in a university course. Throughout the process, we evaluated each artifact of this socio-technical system leading to a number of modifications that became part of the planning and execution of successive iterations of the system.

eADR Interventions and Diagnosis
As a soci-technical system creation and evaluation was critical to both the online course and the virtual project management team environment, it proved critical to design interventions

with student and researcher (including faculty) participants that were informed by theory and prior research in a Diagnosis stage. The first intervention was to institute a requirement that all student teams host an initial video conference meeting, via an online platform of their choice, focused only on team introductions and professional relationship building prior to any discussion of team assignments. The teams were also required to post minutes of this meeting to their team homepage in the Canvas Learning Management System for instructor review.

The goal of these initial meetings focused on establishing a collaborative atmosphere with open communications among team members. This intervention was successful but it led to a need to establish a more complete model for an effective collaborative virtual teamwork, hereby entitled Collaborative Virtual Team Project Management Classroom Environment. From the initial diagnosis in this eADR stage, we explicated the requirements of this environment and determined implementation and evaluation plans for the said environment, focusing on continuous improvement each semester in the courses taught by one of the researchers. “A design science approach places emphasis on achieving clarity in the goals and underlying theoretical constructs for a new artifact and carefully evaluating how well the new artifact meets those goals” (McLaren, Head, Yuan, & Chan, 2011).

As an output of the Diagnosis stage, the researchers established a model of the collaborative virtual team project management classroom environment (Figure 1). Each of the interventions listed in this model are design components expected to improve team cohesion, commitment, and collaborative climate leading to improved project management effectiveness. The interventions selected correspond to the communication-focused technology and coordination-based technology presented by Ferrell and Kline (2018).

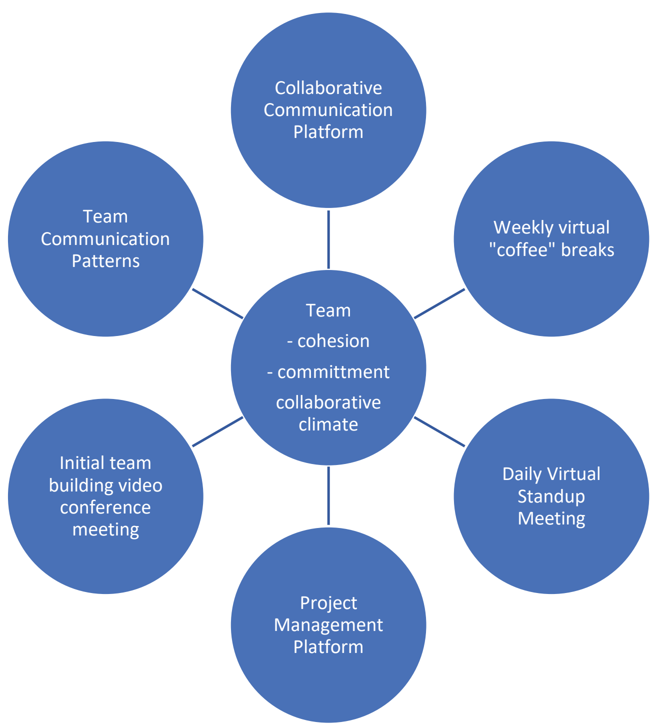

Fig. 1. Collaborative Virtual Team Project Management Classroom Environment

eADR Design Interventions

Graduate Students enrolled in MG 670-I03 (Leading High-Performance Teams) during the spring 2019 semester were tasked with serving as Subject Matter Experts (SMEs) to recommend an adaptive virtual team project management environment. They were required to conduct an evaluation in teams during each virtual team intervention in order to identify key performance indicators (KPI's) and Objectives and Key Results (OKR's) for each of the proposed interventions. Their research assignment appears in Appendix A, and the student team composition is listed in Appendix B. The student submissions were reviewed, and their intervention recommendations appear below, in order of intervention. Because we could involve multiple project teams, we could integrate evaluations from each and generate a richer triangulation of the evaluations across subject teams.

Team Intervention #1: Initial Team Building Video Conference Meeting – Team #4

Team #4 discussed the importance of an initial team building video conference meeting to establish initial rapport and to set expectations and team goals. They proposed that Zoom would be the best video conferencing platform upon which to hold this meeting as it is easy to use, affordable, and allows for a large number of participants.

Team #4 stressed that it was important that the goal of the initial meeting was to bring about informal iteration among team members – to see each other, self-introduction, pursue any common interests and hobbies. They also recommended that the meeting include games, a personality test, and an informal discussion on a topic such as a favorite place to vacation, a favorite movie, or another topic of interest. Interestingly, this is consistent with the work Team #5. These items served as "ice-breakers" to get everyone talking and sharing items that are not project related but which helped build team rapport.

Team Intervention #2: Daily Virtual Standup Meeting – Team #1

Team #1 wrote about their daily "standup meeting". The goal of the typical standup meeting is to quickly cover project progress since the prior meeting, discuss intended progress over the next period and to address any 'blockages' to progress or 'stuck' tasks that needed to be addressed.

As this was a virtual team, the standup meeting was held via a video conferencing platform. The team considered Google Hangouts and Skype, and Canvas Big Blue Button (Integrated conferencing in the Canvas Learning Management System (LMS)) as options, but they indicated that the project team should select the platform that best suits their needs as they all have relatively similar features. Most specifically, they pointed out that the team should choose one that team members are already familiar with in order to reduce the learning curve.

Team #1's evaluation indicated that they felt that a daily virtual standup meeting would be difficult and not necessary for students in a project management course so they proposed a weekly video standup meeting. The goal of the standup meeting would remain the same, but the frequency would be weekly.

Team Intervention #3: Weekly Virtual Video "Coffee Break" – Team #5

The Virtual Video Coffee Break is supposed to be a time that is dedicated to a virtual team to recreate the spontaneous conversations that would traditionally take place in an office environment. The CEO of GitLab, a remote-only company with 200 employees, compares this type of intervention to "the time someone working in an office might spend chatting while walking to meetings, grabbing a coffee in the break room, or having lunch together in person" (People Matters Editorial Team, 2017).

Team #5 entitled this intervention the "WeeklyTeam Recess." Team #5 purported that, instead of a specific weekly meeting focused on spontaneous conversations, the team should implement this intervention at the beginning of every meeting. They recommended that teams spend at least 10 minutes on this activity and that it takes place on the virtual conference platform whereupon the team holds their other team meetings.

Team Intervention #4: Team Collaborative Communication Environment – Team #3

The Collaborative Communication Environment (CCE) consists of the tools selected by the team in order to interact and accomplish tasks in a virtual setting. The makeup of a CCE is dependent on a multitude of variables, such as team size and project complexity with the following as components:

- Basic Messaging / Text Communication
- E-mail
- Phone – person to person and conference call
- Video Chat
- Small Video Conference (no add-ons, just basic video)
- Large Video Conference (with add-ons, such as screen and file share)
- Project Management Platform
- Document Control and Change/Revision Tracking
- Centralized Team Operations Center
- Virtual Water Cooler

Team #3 proposed a CCE Component Selection Matrix after several iterative evaluations of the components involved (Table 1).

Component	**Recommendation**
Basic Message / Text Communication	GroupMe
E-mail	Canvas Course Platform
Phone – Person to person	Cell Phones
Phone – Conference Call	Freeconferencecall.com
Video Conference	Zoom
Project Management Platform	Wrike
Document Control & Change Revision Tracking	Google Docs
Virtual Water Cooler	Yammer or Sococo

Table 1. CCE Component Selection Matrix

Team #3 stressed that while this matrix serves as a basic recommendation, consideration should be made to ensure that all team members will have the necessary access and training to utilize each tool.

The above components are pretty traditional but the Virtual Water Cooler component is a relatively unique component worthy of additional discussion. According to Paris (2016), virtual water coolers serve three purposes:

- It gives a team a chance to bond.
- It can inspire new ideas.
- It reinforces ties and a sense of belonging (Paris, 2016).

Team #3 indicated that "Water coolers allows the team to step outside of the typical work environment of e-mails and phone calls and collaborate with each other to achieve common ground or bounce ideas off one another". They proposed the use of Yammer or Sococo. The transition to some virtual water coolers may be easier for those familiar with social media platforms as Paris (2016) indicated that Yammer is very similar to Facebook. Sococo actually "… replicates an actual office with conference rooms, offices, and hangout spots" (Paris, 2016).

Team Intervention #5: Project Management Software Tool – Team #6

Team #6 researched many different project management software platforms before coming to their recommendation of using Wrike. They selected this product because of its flexibility, clear visibility of key information regarding not only the big picture but also the little details, their integrated forms, as well as their impeccable integration with email and Google Apps.

Team Intervention #6: Team Communication Patterns – Team #2

Team #2 first defined communication patterns as to how information is disseminated between team members. They referenced an MIT-sponsored study of 21 different organizations over seven years, that identified three key elements of communications patterns: energy, engagement, and exploration (Pentland, 2012). This same study noted that social time is attributed to over 50% of the positive responses in team communication patterns (Pentland, 2012).

Team #2 concluded the following in regards to team communication patterns:

- Ensure face-to-face communication is implemented in a minimum of 30 minutes per week utilizing online video conference tools discussing assignments and projects.
- Incorporate in one video session out of the month, socialization and do not discuss school or assignments. Use this session for bonding and establishing trust and openness within the team.
- Create a log and document after each virtual session and include the percentage of the collaboration that contributed to the assignment or project. Track results until the project is completed.
- Include clarification exercises into video sessions for example: after someone asks a question, clarify and confirm what was asked to establish clarity and understanding. This can be included in the documentation log for tracking.
- Ensure recap meeting notes are established after each face-to-face meeting and confirm action items and next steps for each team member.

RESULTS

The various project team iterations through the eADR Design stage lead to the following model of a collaborative virtual team project management environment.

Design Principle 1: Initial Team Building Video Conference Meeting

This activity is a virtual project team requirement that the newly formed virtual team, relatively quickly upon team formation, conduct an initial team building video conference with the specified purpose of establishing initial relational rapport. This video conference will be hosted on the Zoom platform with a requirement that all participants share their video camera. It will be focused specifically on informal communication among team members and facilitated with the use of ice breaker activities, such as the two truths and a lie activity or asking questions such as where would you vacation if money was not a consideration. It is imperative that this meeting does not focus on project details, but rather focuses on establishing initial team rapport.

Design Principle 2: Weekly Virtual Standup Meeting

This activity is a requirement that the team spends a short period of time every week dedicated to discussing the accomplishments the day before, the plan for the day ahead, and any issues that have the potential to hinder their performance of the planned activity. The purpose of the meeting is to keep the team up to date on team progress as well as to identify any potential delays that need to be proactively addressed. The concurrent, authentic evaluation of this design artifact identified that a daily standup meeting would not be practical for an online course, so a weekly standup meeting via the Zoom Video Conference platform was made standard for the initial video conference meeting.

Design Principle 3: WeeklyTeam Recess

The purpose of the Weekly Team Recess is an attempt to replicate spontaneous communication found in co-located teams and to build team rapport and the connection that co-located teams make organically by way of their close proximity to each other. The intervention in situ found that a weekly organized video conference would not be practical for student teams in an online class so this activity is designed to be a part of the team's regular video conference meetings. The title of this intervention was identified as the WeeklyTeam Recess and was made a part of the regular weekly video team meetings. The teams will spend the first 10 minutes or so of each team video conference meeting focusing on socializing and ice breaker activities, such as those proposed for Intervention #1.

Design Principle 4: Team Collaborative Communication Environment

The purpose of the team collaborative communication environment is to define the tools that the virtual team will use to perform all communications. This includes messaging, phone calls, video conferencing, and document control with change/revision tracking. The Design Stage established the standards for the collaborative communication environment for the online classroom as displayed in Table 1 (above).

Design Principle 5: Project Management Software Tool

This design principle established the project management software that the team will use to track all of the project details, including tasks, schedules, resources, etc. In the initial intervention, the student team recommended the Wrike platform. However, the researchers (aka faculty) noted the need to integrate the project writing/publishing software with external tools, such as Outlook and Google Docs. Working together, the team chose to use the Monday.com platform and established a partnership Monday.com.

Design Principle 6: Team Communication Patterns

The intervention of team communications patterns refers to the methods by which the team members communicate throughout the project. The teams determined that the student teams would be required to conduct all meetings via the standard video conference platform, Zoom, using video so all members can see each other throughout the meeting. This iteration determined that conferences that do not incorporate the video aspect resulted in participants not focusing fully on the conversation at hand. Additionally, this design principle requires the student teams to document each virtual meeting, including the percentage of collaboration by team member and to post this documentation to their team Canvas homepage. This documentation would not only include the minutes of the meeting, but it would also recap all action items and next steps for each team member.

Design Summary

A summation of the complete model of collaborative virtual team project management classroom environment is presented in the table below.

Initial Team Building Video Conference Meeting	Video Conference focused on socializing and building team rapport - Software: Zoom
Weekly Virtual Standup Meeting	Quick weekly meeting focused on what we did, we are we doing, are there any issues - Software: Zoom
WeeklyTeam Recess	First 15 minutes of every meeting focused on social conversation - Software: Zoom
Team Collaborative Communication Environment	Groupme, Canvas Course Platform, Cell Phones, Freeconferencecall.com, Zoom, Google Docs
Project Management Software Tool	Software: Monday.com
Team Communication Patterns	All meetings conducted via Zoom with Video enabled Documentation of all meetings include percentages of collaboration, a recap of action items, next steps

DISCUSSION AND CONCLUSION

Initially, the researchers focused on establishing a collaborative virtual team project management environment in the classroom that would mimic that of the corporate environment. This was accomplished with the help of the graduate students enrolled in MG 670-03 (Leading High-Performance Teams) during the spring 2019 semester, as the majority of them were all currently working in a corporate virtual team project management environment. Student teams were assembled and each team selected an intervention to research in order to identify key performance indicators (KPI's) and Objectives and Key Results (OKR's) for their intervention.

The student created a virtual team environment was then examined in situ with the intention of adapting it to the classroom environment, while keeping the tie to the corporate environment. This was undertaken in order to meet the goal of more fully preparing students for the needs of employers in the digital economy. The eADR research activity leads to the proposed specific design principles for implementation in a future project management course. The complete student assignment is provided in Appendix A and the student team composition is listed in Appendix B.

Lastly, the researchers developed the evaluation criteria utilized to evaluate the resultant model of a collaborative virtual team project management environment, in terms of its effectiveness in improving team cohesion, team commitment, and team collaborative environment. The evaluation of an implemented course will be the topic of future research, as explained in the next section.

The use of the eADR method within the DSR paradigm offered researchers a means to co-design the principles for an improved virtual team project environment in an online course. Doing so offers faculty the opportunity to integrate the resultant design principles into a course with a high(er) expectation of success. This approach can be used in a multitude of course design and avoid the situation where an instructor uses a more common trial-and-error approach to course design or one reliant exclusively on theoretical models.

FUTURE RESEARCH DIRECTION

The above-designed model of a collaborative virtual team project management environment will be implemented in an online classroom and its use will be monitored for its effectiveness in improving team cohesion, team commitment, and team collaborative environment. According to Huang et. al (2003), "Team cohesion refers to the mutual attraction of team members and the closeness that team members feel towards each other" (Huang, Wei, Watson, & Tan, 2003). Accordingly, they state that "team commitment refers to the team spirit, a sense of loyalty and dedication to a team" and "team collaboration climate refers to the degree to which a team can work well together" (Huang et al., 2003). The intention is to administer a survey to the student teams at the beginning of the semester, before introducing the model, and at the end of the semester after they have worked with the model for the entire semester. This survey will be an online survey embedded in their Canvas course. The questions to be used are based on existing measurement instruments adapted from (Huang et al., 2003) and they can be found in Appendix C.

Appendix A

Assignment #1: MG 670-I03 : Virtual Team Environment Research Paper

There are six teams and six interventions, so each team will research one of them. The selection process will be handled on a first come, first served basis, and the selection will be handled based on replies to the Announcement Post. Please do not begin the paper until you receive confirmation that your team was assigned that intervention. Once you have received confirmation, please complete your paper on the intervention of choice by your team.

The team will research and write up a paper meeting the following goals:

- Provide an overview of the intervention
- Provide a detailed description of the intervention and all that it entails
- Discuss the objective of the intervention
- Explain the key performance indicators (KPI's) that should be evaluated for the intervention (the measures by which the effectiveness will be evaluated)
- Explain the specific Objectives and Key Results (OKR's) of the intervention (the characteristics of the intervention)
- Discuss any interventions other than those six listed here that your team feels should be considered in establishing an effective virtual team environment.
- Present specific recommendations for the implementation of their intervention in a future project management course.

Team Intervention #1: Initial Team Building Video Conference Meeting

Note: One of the OKR's should be the video platform for the meeting.

Team Intervention #2: Daily Virtual Standup Meeting

Note: One of the OKR's should be the video platform for the meeting.

Team Intervention #3: Weekly Virtual Video "Coffee Break"

Note: One of the OKRs should be the video platform for the meeting and you should also determine a more suitable name than "Coffee Break"

Team Intervention #4: Team Collaborative Communication Environment

Note: This includes but is not limited to file sharing, chat, communication guidelines for when to use what form of communication (phone call, email, chat, group message, conference call, video meeting, etc). This environment may also include a project management tool.

Team Intervention #5: Project Management Software Tool

Note: This may include a team collaborative environment.

Team Intervention #6: Team Communication Patterns

Note: This should include all team communication guidelines.

Appendix B

Student Team Composition

Team #1:

Shantel Perry, Preston Ray, Erica Sykes, and Melissa Van Otten

Team #2:

Tianna Bateman, Jennifer Bekeny, Kimberly Chambers, and Zoie Hill

Team #3:

Katie Coan, William McEllen, Deborah Taylor, and Kaila Timbs

Team #4:

Aubrey Hudson, Vrinda Pisharody, Kayla Stewart, and Harlan Winston II

Team #5:

Lindsey McKie, Kyle Winn, Kristen Nohrstedt, and Joshua Studdard

Team #6:

Waverly Polak, Matthew Rider, and Siddharth Pandya

Appendix C

Survey Questions adapted from (Huang et al., 2003)

Questions measuring team cohesion (Seashore, 1954)

- Do you feel that you are really a part of your student work team?
  (1) Really a part of my work team.
  (2) Included in most ways.
  (3) Included in some ways, but not in others.
  (4) Don't feel I really belong too much.
  (5) Don't feel I really belong at all.

- If you had a chance to do the same kind of work in another student work team, how would you feel about moving to another team?
  (1) Would want very much to stay where I am.
  (2) Would rather stay where I am than move.
  (3) Would make no difference to me.
  (4) Would rather move than stay where I am.
  (5) Would want very much to move.

- How does your work team compare with other student teams on each of the following points?
  (1) Very much better to (5) Very much worse.

  a. The way people get along together.
  b. The way people work together.
  c. The way people help each other.

Questions measuring team commitment (Larson and LaFasto, 1989)
(1) False to (4) True.

- Achieving our team goal(s) is a higher priority than any individual objective.
- Team members believe that personal success is achieved through the accomplishment of the team goal(s).
- Team members are willing to devote whatever effort is necessary to achieve team success.

Questions measuring collaborative climate (Larson and LaFasto, 1989)
(1) False to (4) True.

- We trust each other sufficiently to accurately share information, perceptions, and feedback.
- We help each other by compensating for individual shortcomings.
- We can trust each other to act completely and responsibly in performing our individual tasks.

The Impact of Mobile Order Ahead Apps on QSR queuing

Thomas R. Robbins
East Carolina University
Email: robbinst@ecu.edu.edu

ABSTRACT

Order ahead mobile apps are becoming increasingly popular at Quick Serve Restaurants. These apps allow customers skip the line when arriving at the store. We investigate the hybrid queuing system created by these applications. Using discrete event simulation, we examine the impact these apps can have on system performance.

KEYWORDS: Queuing Systems, Simulation Analysis, Retail Operations

INTRODUCTION

The availability and use of order ahead mobile applications has become quite common in the quick serve restaurant business. Apps are available from restaurants including McDonald's, Chick-fil-A, Chipotle, Starbucks, Moe's, Noodles and Co., Subway and many others. The Wall Street Journal reports that food and drink apps were downloaded more than 155 million times in 2017; a 35% increase over 2016 (Stevens 2018). My local Starbuck's manager reports 7.5% of her business now comes from mobile orders.

While the functions provided vary from app to app, most allow users to order and pay for their food remotely. When arriving at the restaurant the user is able to skip the line and pick up their pre-made order, often at a special Mobile Order Pick-Up location. These apps create a hybrid queuing system that alters both the real and perceived behavior of the queuing system. In this paper we explore the implications these hybrid queues have from both the customer and service provider's perspective.

The functionality of order ahead applications varies from restaurant to restaurant. Some have built in loyalty programs that allow customers to earn discounts and free items. Most apps have integrated mapping and GPS systems to allow customers to find the nearest restaurant location. Most apps also allow users to reorder previous orders and some allow users to set up favorite items for easy reordering, and nearly all the apps support some level of menu item customization. Virtually all the apps support a pay function that manages the financial transaction as part of the ordering transaction, though some also allow a pay at the store option.

The order processing and fulfillment process also has some variations from app to app, but most follow a basic format. The user picks their restaurant and selects their menu items. The customer can then select the scheduled time for their order to be ready. Most applications have a minimum lead time, but also allow the order to be scheduled further into the future. Minimum times are generally about 10-15 minutes, and most apps allow scheduling pick up an hour or more in the future. Once the order is placed the financial transaction is processed and an order ticket is printed at the store. Some apps, such as McDonalds and Chick-fil-A, do not finalize the order until the customer is at the store and clicks the "I'm here" button. GPS tracking disables the button until the customer is at the store location. This helps prevent accidental orders to the wrong store, but significantly reduces the order ahead time and significantly alters the queuing system behavior. When the customer arrives at the store, they generally skip the line and go to a special pick up area. If their food is ready, they pick it up immediately and the service is complete. If the food is not ready, because the customer arrived early, or the order was late, they wait in a separate queue for their order to be completed.

The remainder of this paper is organized as follows. In the next section we review the relevant literature. We thee describe the Order Ahead Hybrid Queuing System and our simulation approach. The next section presents an analysis of our simulation results for an overall scanning experiment, we then present a separate experiment that isolates the impact of the order ahead percentage. We conclude with a summary of our findings.

LITERATURE REVIEW

Queuing systems are widely studied in the operations literature. Queues may form whenever jobs arrive to a service location; when all servers are busy the jobs wait in queue until a server becomes available. The behavior of the queuing system is governed by several key parameters. The arrival process characterizes the statistical distribution of new jobs presenting themselves for service. The service process characterizes the statistical distribution of the service performed on the job. Performance varies significantly based on the systems utilization, the long-term proportion of time that each server is actively working versus waiting for a new job to service, and the number of servers present in the system. Under several widely accepted assumptions, such as exponentially distributed inter arrival and service time and a first come first served protocol, closed form solutions are available and widely known (Gross 2008). The M/M/N model describes the long run statistical characteristics of a multi-server queue with exponential interarrival and service time. Standard performance metrics for basic queuing systems include average wait time, average total service time, average queue length, and system utilization.

As systems become more complex, and assumptions are relaxed, it becomes increasingly difficult to accurately characterize queuing system behavior. The introduction of balking and/or reneging, customers who arrive but decide not to enter the queue, or who leave the queue before being serviced, leads to the M/M/N/k + M queuing model (Gans, Koole, and Mandelbaum 2003). Customers who balk or renege are said to be impatient, and their behavior can dramatically alter the behavior of the queuing system. This phenomenon has been widely studied in the call center space. As other assumptions are relaxed, for example the service or arrival process distributions, exact closed form solutions become less viable and approximation or discrete event simulation become more popular methods of analysis (Law 2007).

Queues can be physical, virtual, or hybrid combinations of the two. In a physical queue customer stand in line. Traditional retail outlets are served by physical queues. A key characteristic of a physical queue is the visibility of the queue's length and the speed of service. Customers enter the line with full visibility of the number of customers ahead of them and have constant visibility of the queue's length, giving them insight into the speed of service. In a multi-server system, there may be separate queues for each server, but more commonly the queues are pooled into a single queue served by multiple servers. Pooling is more efficient technically but may be perceived as a longer wait due to the longer pooled queue and this may lead to increased balking. In some cases, the choice of queues is based on a customer class, for example priority lines at airport check-in and security, or at hotel check-in.

In a virtual queue there is no physical line for customers to stand in, instead some proxy for a customer is placed in a virtual line. The quintessential example of a virtual queue is the call center, but other examples include restaurant pager queues, ticket queues, or even print queues. Hundreds of papers have been published on call centers; (Gans, Koole, and Mandelbaum 2003) and (Aksin, Armony, and Mehrotra 2007) provide excellent summaries and literature reviews. An important characteristic of the virtual queue is limited visibility, and therefore limited insight into how long the potential wait might be. In a general call center, the caller has no idea how many callers are already in queue, though in some systems a system announcement will give an estimated hold time.

A variation of the physical queue is the ticket queue. In a ticket queue the customer is given a number and they begin service when their number is called. By limiting the visibility of the queue, ticket queues have the potential to significantly alter both the customer's perception of the queue, and their behavior (Kuzu 2015). Ticket queues have been used in environments from the DMV to the deli counter at the local grocery store. In a ticket queue the customer can compare their number to the now being served number and observe the rate at which customers are served to estimate a wait time. Pager queues are often used at full-service restaurants and an estimated wait time is often provided along with the pager, but without special effort on the part of the customer to monitor progress, no updates are available to the initial estimate. While physical queues often implement a first come first serve prioritization mechanism, virtual queues can easily implement alternative service disciplines.

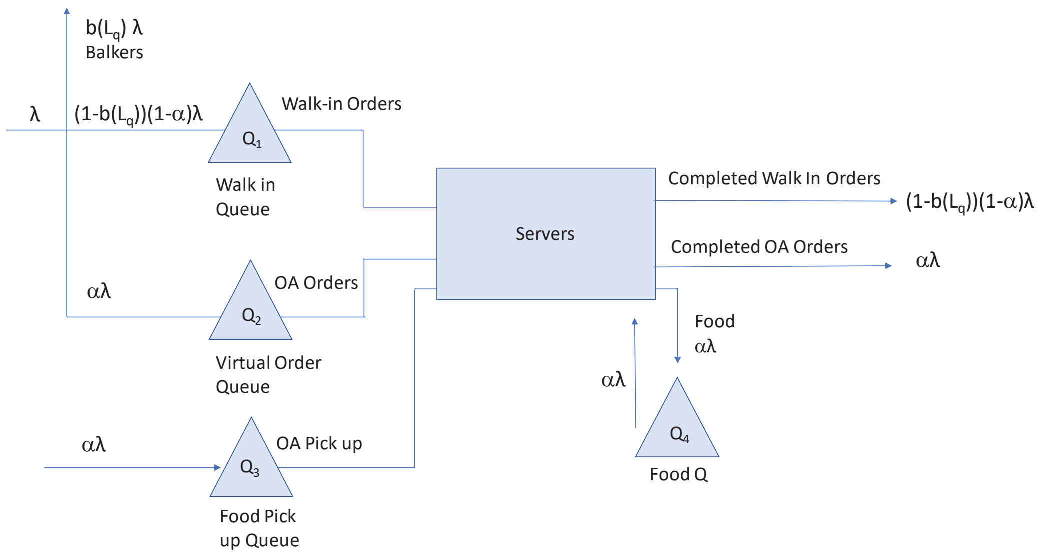
We define a hybrid queue as a linked queuing system that contains at least one physical and one virtual queue. A well-known example is the *Fastpass* system used on popular attractions at Disney theme parks. The hybrid queuing system includes a physical queue for walk up customers along with a virtual queue for Fastpass customers. The Disney Fastpass system is described in (Cope, F. Cope, and E. Davis 2011). A hybrid queuing system for airport security checks is proposed and analyzed via simulation in (de Lange, Samoilovich, and van der Rhee 2013). In both these systems a subset of customers are put in a virtual queue and assigned a reservation time. These customers then join the physical queue at a priority point at their reservation time. A basic version of a hybrid queueing system is used in full-service restaurants that accept reservations. Walk in customers are queued based on arrival time, while customers with reservations jump to the front of the line at their reservation time.

Order ahead apps create a somewhat different type of queuing system; an environment we refer to as the Order Ahead Hybrid Queue (OAHQ). The system contains multiple queues, physical and virtual. The system has the potential to impact the retail establishment in multiple ways. The order ahead capability will clearly impact the service experience of the order ahead customer, and potentially the walk in customer as well. Larson (1987) discusses the issue of social justice in queuing systems that result from what he terms slips and skips. A skip occurs when a customer arrives and is serviced before a current customer, the initial customer having been skipped over. The skipped customer feels victimized, having been treated unfairly. The slipping customer may feel a sense of satisfaction based on their reduced waiting time, but may also feel guilt for having violated a social norm. Stevens (2018) reports on customers who order ahead, but still wait in line to avoid the stigma associated with cutting the line. From a financial perspective the faster service time, along with the potential discounts earned, may lead the order ahead customer to increase their dining frequency. Multiple studies investigate the relationship between faster service and increased revenue (Akilimalissiga, Sukdeo, and Vermeulen 2017, Perdikaki, Kesavan, and Swaminathan 2011, Allon, Federgruen, and Pierson 2011, Lu et al. 2013). Additionally, by removing some customers from the physical queue the order ahead capability may reduce the perceived waiting time for walk in customers and reduce the number of customers who balk.

THE ORDER AHEAD HYBRID QUEUE

The Order Ahead Hybrid Queue system contains a combination of virtual and physical queues. While there are multiple variations for configuring the order ahead process, we develop a model that can represent most configurations. A diagram of the system is outline in Figure 1.

Figure 1 - Queuing System

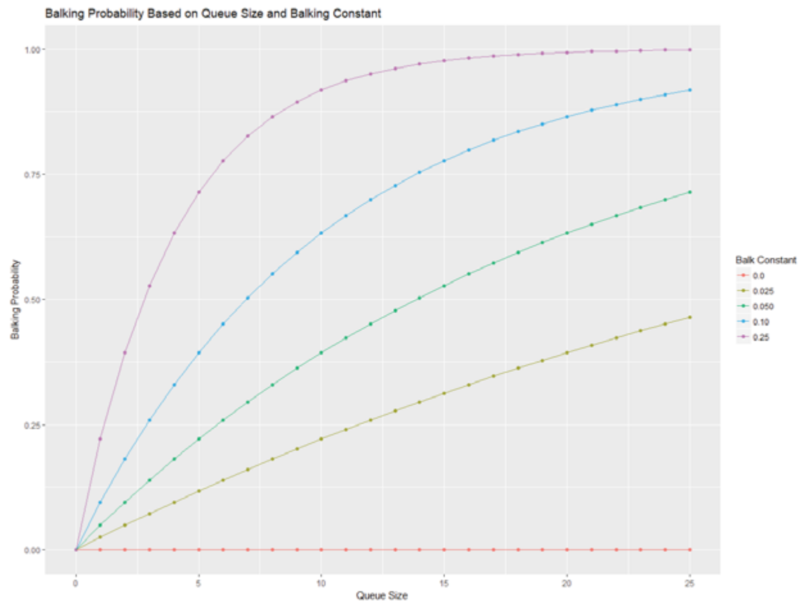


Orders arrive at a rate λ. α percent of the order arrive as virtual order ahead orders, while 1-α percent of the arrivals are physical walk-in customers. Walk in customers observe the physical queue and a proportion of them determine the line is too long and they balk. The decision to balk is based on the length of the queue and the balking constant ($b(L_q)$). The balking decision is based on the number of customers currently in queue. In our model the probability the customer balks is given by

$$p_B = 1 - e^{-k_b n} \qquad (1)$$

Where *n* is the observed number of customers currently in the queue and k_B is the balking constant. If k_B is zero, then customers are infinitely patient, and none balk. As k_B increases the likelihood of balking increases. Figure 2 shows the probability a new customer balks based on queue size and a range of balking constants.

Figure 2 - Balking Probability Graph



The time required to process an order by an average server is a lognormally distributed random variable with mean μ^{-1} and standard deviation σ_{μ}. Walk in customers who decide not to balk enter the walk-in queue (Q1). OA Orders arrive at a rate of $\alpha\lambda$. When the order arrives, it is placed in a virtual queue (Q2). Each order has an associated ready time, which we assume in our model is 20 minutes after the order is placed. Each order is assigned an early start and late start time. In our model we assign the early-start time as 4 times the average service time, and the late start time as 2 times the average service time.

The system includes 3 physical queues and 1 virtual queue.

1. Walk-In Queue: the line that walk-in customers enter to wait for service. Serviced on a first come first serve basis.
2. Order Ahead Virtual Queue: the queue of order ahead orders. Serviced based on scheduled time.
3. Pick Up Queue: a physical queue where order ahead customers wait to pick up their items.
4. Meal Queue: a physical queue where food is kept awaiting customer pickup. Serviced based on order number.

A pool of homogeneous servers service the entire queuing system. Idle servers accept work based on the following prioritization scheme.

1. OA Orders due in sooner than the late start time
2. Walk in Customers
3. OA Orders due sooner than the early start time.

In order to evaluate the performance of the queuing model, we conduct a series of designed experiments. In the first experiment we evaluate the system over a wide variety of input characteristics. Based on the assumptions for our system discussed previously, we define the following set of 6 experimental factors. High and low values are defined to cover a broad range of service scenarios.

Table 1-Experimental Factors

	Factor	**Low**	**High**
1	Proportion ordering ahead (α)	5%	40%
2	Offered System utilization (ρ)	25%	90%
3	Average service time	2 mins	8 mins
4	Balking Constant (*k*)	0	.25
5	Number of Servers (*n*)	1	5
6	Average OA Arrival Shift	-2 mins	+2 mins

The offered utilization represents the average system utilization that would occur if all arrivals were served, in other words without balking. The average OA Arrival Shift represents the mean of the distribution of the physical arrival of an order ahead customer, relative to the scheduled ready time. We assume that the physical arrival time is characterized by a normal distribution with a standard deviation of 2 minutes. So, with a zero valued shift, a customer would on average arrive at the agreed upon time, but half of the customers would arrive early. A negative shift implies a larger proportion arriving before the scheduled time.

Given the relatively large number of experimental factors, a well-designed experimental approach is required to efficiently evaluate the experimental region. A standard approach to designing computer simulation experiments is to employ either a full or fractional factorial design (Law 2007). However, the factorial model only evaluates corner points of the experimental region and implicitly assumes that responses are linear in the design space. However, this system is likely to exhibit non-linear responses, for example queue length will have a decidedly non-linear relationship with utilization. Based on this we chose instead to implement a Space Filling Design based on Latin Hypercube Sampling as discussed in (Santner, Williams, and Notz 2003). Given a set of d experimental factors and a desired sample of n points, the experimental region is divided into n^d cells. A sample of n cells is selected in such a way that the centers of these cells are uniformly spread when projected onto each of the d axes of the design space. We chose our design point as the center of each selected cell. This experimental design allows us to select an arbitrary number of points for any experiment.

Simulation Approach

Our model is evaluated using a straightforward discrete event simulation model at each design point. The purpose of the model is to predict the long term, steady state behavior of the queuing system. The model generates random numbers using a combined multiple recursive generator (CMRG) based on the Mrg32k3a generator described in (L'Ecuyer 1999). Common random numbers are used across design points to reduce output variance. To reduce any start up bias we use a warmup period of 250 customers, after which all statistics are reset. The model is then run until approximately 50,000 customers have been serviced and summary statistics are collected. For each design point we repeat this process for 25 replications and report the average value across replications. Our initial analysis is based on an experiment with 1,000 design points.

The specific process for each replication is as follows. The input factors are chosen based on the experimental design. The average arrival rate is calculated based on the specified service time, number of servers, and offered utilization rate as

$$\lambda = \rho N \mu \tag{2}$$

That arrival rate is then used to generate Poisson arrivals for the replication. Each new customer generated includes an exponentially distributed interarrival time, and a lognormally distributed service time. When a customer arrives a Bernoulli random variable is used to determine if it is an OA or walk in customer. For walk-in customers the probability of balking is determined based on the current walk-in queue length and the balking constant according to equation (1). Another Bernoulli random variable used to evaluate the customer's balking decision. Our model assumes customers that join the walk-in queue remain patient and do no abandon. We also assume that since order ahead customers pay at order time they do not balk.

When the OA Customer arrives, the model determines if the food is ready. If it is ready the customer picks up the food and ends service. Our model assumes a pick-up area, so customers can pick up their prepared food without server involvement. If the customer arrives before their food is ready that are placed in queue 3 and wait until the food is finished. In this scenario services ends when the food is ready, and the total service time is equal to their wait time in Q3.

Over the course of the simulation we collect statistics on the following performance metrics:

1. **Average Queue Size**: the average size of the walk-in physical queue.
2. **Maximum Queue Size**: the maximum size of the walk-in physical queue.
3. **Realized Utilization**: the proportion of time servers are actively working on customer orders.
4. **Average Wait Time**: average time a customer spends waiting; from arrival time until their order is taken.
5. **Proportion Waiting**: the proportion of walk-in customers that must wait prior to their order being taken.
6. **Average Time in System**: the average time a customer spends in the restaurant, from arrival time until their order is filled.
7. **Proportion Balking**: the proportion of walk in line customers who balk.
8. **Number of Times Jumped**: the average number of times a walk-in customer is jumped over by an order ahead customer.
9. **Proportion Jumped:** the proportion of walk-in customers that are jumped by an order-ahead customer.
10. **Average # Jumping Over**: the average number of customers an order ahead customer jumps over.

After all design points have been evaluated, we re-run the experiments. All design factors are repeated with the exception of the OA percentage. In the second run the OA percentage is forced to zero. This allows us to determine the impact the OA customers had on the system. Common random numbers are utilized to minimize the variance and isolate the impact of the OA stream.

SIMULATION ANALYSIS

Baseline Metrics

Before examining the impact of the Order Ahead process, we review the baseline experimental region. Our initial design parameters give us a wide range of scenarios. Key performance metrics for the baseline case are shown in Table 2.

Table 2- Baseline Performance Metrics

	Min	Avg	Median	Max	Range	StdDev	Skewness
Average Queue Size	0.003	0.456	0.292	4.579	4.576	0.525	2.690
Max Queue Size	4.340	9.948	8.770	46.080	41.740	4.488	2.789
Realized Utilization	0.249	0.547	0.559	0.876	0.627	0.163	-0.130
Average Wait	0.302	99.04	50.57	1,265.41	1,265.11	142.19	3.522
Proportion Waiting	0.9%	31.5%	30.1%	80.3%	79.3%	18.8%	0.326
Average Time in System	125.2	399.0	376.7	1,667.0	1,541.8	195.7	1.850
Proportion Balking	0.0%	4.1%	2.4%	21.8%	21.8%	4.3%	1.267
Number of Times Jumped	0.000	0.000	0.000	0.000	0.000	0.000	NA
Proportion Jumped	0.0%	0.0%	0.0%	0.0%	0.0%	0.0%	NA
Avg Number Jumping Over	0.00	0.00	0.00	0.00	0.00	0.00	NA

The data in Table 2 shows that our experimental region covers a very wide range of operational scenarios. The key performance metrics cover the range of practical operating scenarios. The distribution of these metrics strongly positively skewed. They also demonstrate the significant volatility present in queuing systems. Figure 3 illustrates that while the median queue size is small, the distribution of avenge queue size is strongly right skewed, with average queue sizes ranging up into the range of 2. While an average queue size of 2 seems small recall that in queues the queue is volatile. Figure 4 shows the distribution of the maximum queue size; demonstrating that queues can balloon up to more than 20 even with a low average queue.

Figure 3 – Baseline Average Queue Size

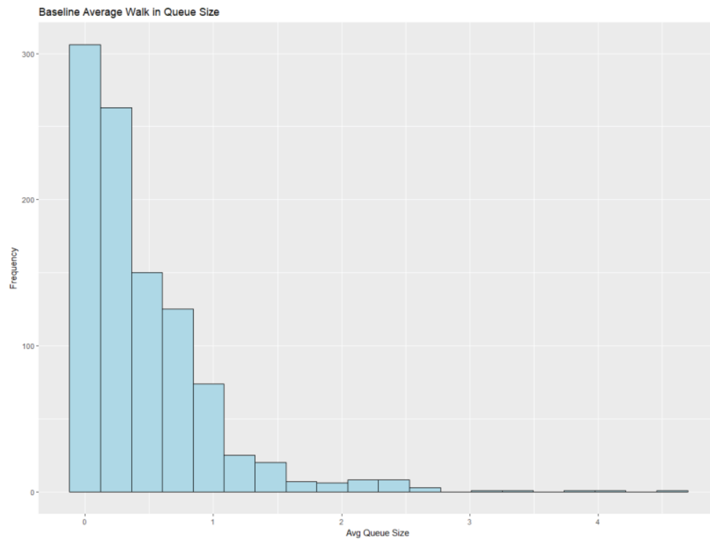


Figure 4-Baseline Maximum Walk in Queue Size

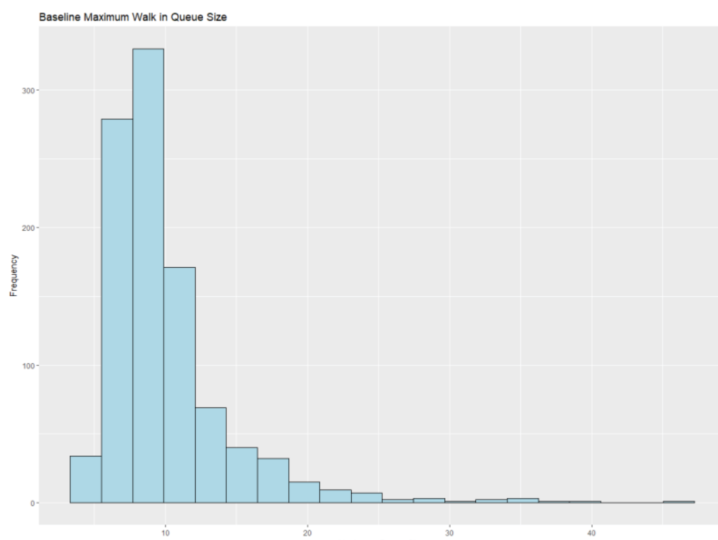


Impact of Order Ahead

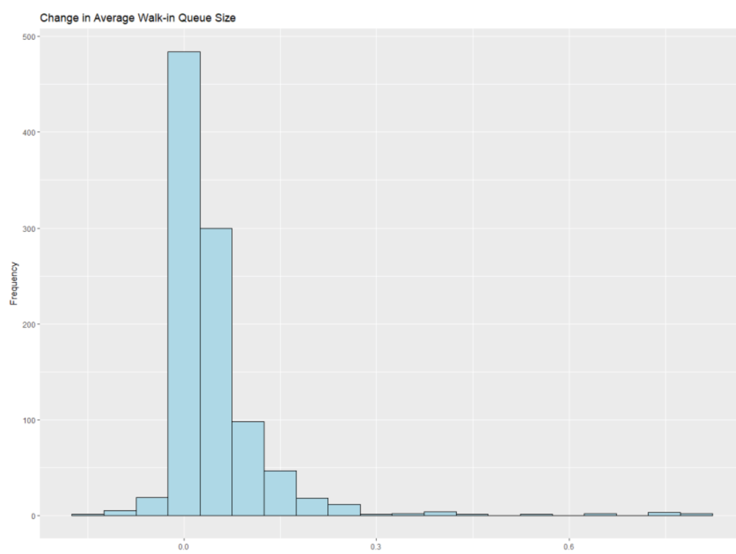
We now turn our attention to the impact Order Ahead customers have on the queuing system. We first examine the impact of OA across the experimental region, Table 3 summarizes the difference that occurs in each of core performance metrics as order ahead is introduced. Recall, that in our experimental design space the proportion of orders that are order ahead varies from 5% to 40%.

Table 3- Change in Key Metrics with OA Capability

	Min	Avg	Median	Max	Range	StdDev	Skewness	pvalue
Average Queue Size	-0.130	0.048	0.024	0.817	0.947	0.085	4.761	2.59E-62
Max Queue Size	-2.320	0.239	0.200	4.320	6.640	0.618	1.173	3.14E-32
Realized Utilization	-0.039	0.000	-0.001	0.085	0.123	0.014	1.192	8.34E-01
Average Wait	0.294	113.78	55.51	1411.59	1411.30	163.01	3.266	3.03E-88
Proportion Waiting	-9.9%	-0.7%	-0.3%	8.0%	17.9%	2.0%	-0.777	5.27E-25
Average Time in System	6.9	66.1	58.6	444.8	437.9	41.1	2.127	6.30E-280
Proportion Balking	-2.5%	0.4%	0.2%	3.6%	6.1%	0.5%	1.545	1.89E-93
Number of times Jumped	-1.990	-0.174	-0.078	0.000	1.989	0.241	-2.888	0.00E+00
Proportion Jumped	-22.2%	-5.1%	-3.5%	0.0%	22.2%	4.6%	-1.143	0.00E+00
Avg Number Jumping Over	-4.65	-0.53	-0.34	0.00	4.65	0.58	-2.299	0.00E+00

Figure 5 shows a histogram of the change in average queue size when order ahead customers are introduced. Note that a positive number indicates a reduction in the observable (walk-in) queue length. Order Ahead reduces the queue length in 94.8% of our design points.

Figure 5- Change in Average Queue Size



In Figure 6 we examine the distribution of the change in the average wait time for walk in customers. This figure shows the data is highly skewed in the opposite direction. In 82.8% of the design space the average wait time increases. Taken together these two graphs show that walk-in customers face shorter but slower moving lines when Order Ahead customers are present.

Figure 6-Change in Average Wait Time

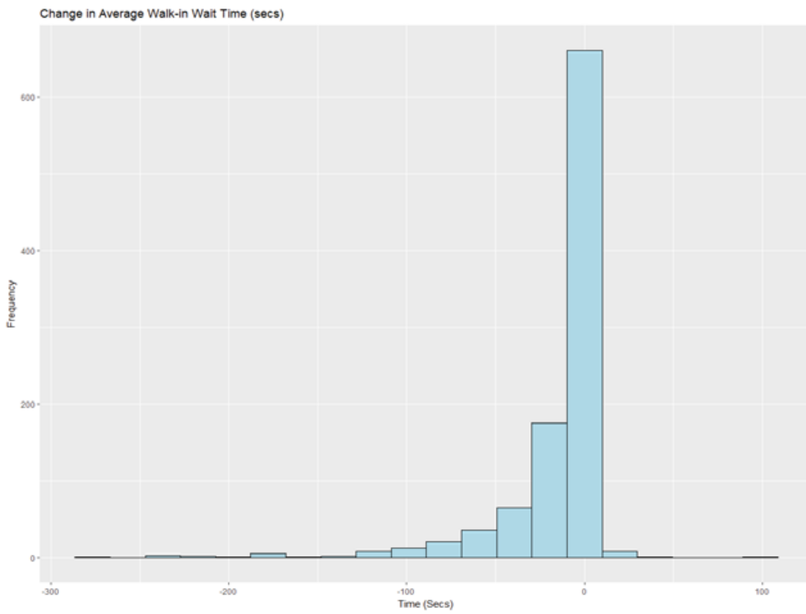


Figure 7 shows a histogram of the change in the Total Time in System for all customers. The overall time in system is reduced in all simulation scenarios.

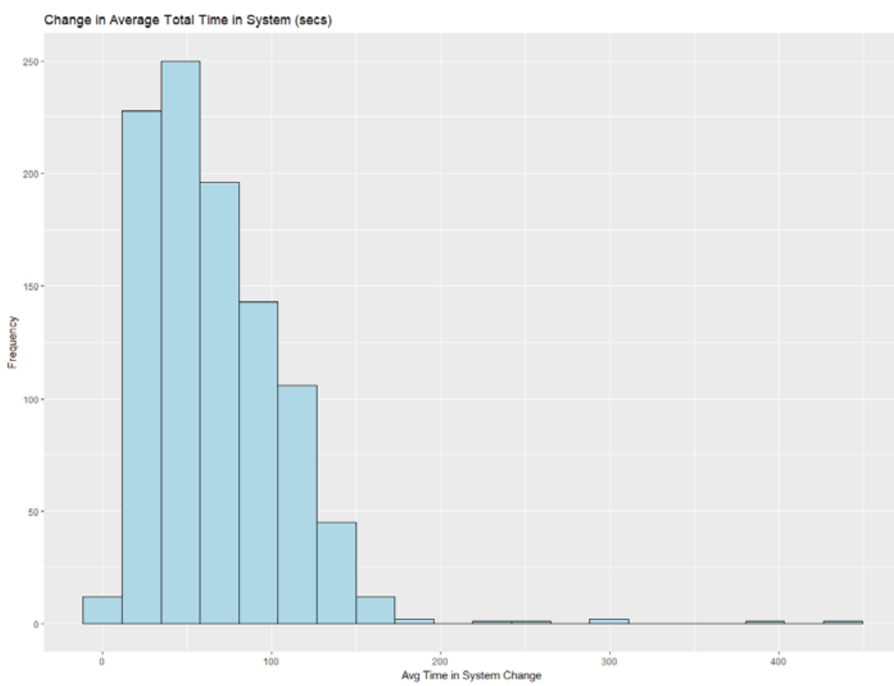
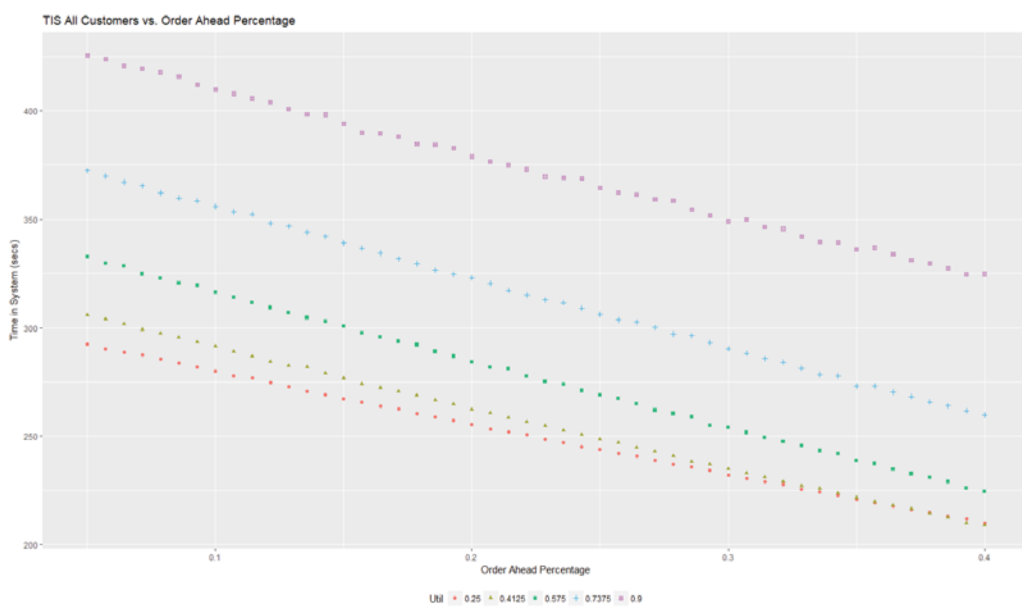
Figure 7-Change in Average TIS



Experiment 2
We now conduct a second statistical experiment. The purpose of this experiment is to isolate the impact that the proportion of customers that order ahead has on overall operations. We use a simple experimental design with two factors, Proportion Ordering Ahead (α) and Offered System Utilization (ρ). We evaluate the model at 5 different utilization levels and 50 different values for the proportion ordering ahead, for a total of 250 design points. This provides us with the ability to analyze how performance metrics vary with order ahead percentage for a range of system utilizations. All the other experimental factors are set at their midpoint, with the discrete parameter Number of Servers (*n*) rounded up to 3.

We first examine the impact on the Time in System. Figure 8 shows the Time in System for all customers, while Figure 9 shows it for Walk In Customers and Figure 10 shows it for Order Ahead customers.
Table 4 shows how the TIS metric changes as the order ahead percentage varies from it's low to high values. The impact of order ahead customers is relatively clear from these graphs. Overall Time in System is reduced as wait time is dramatically reduced for Order Ahead customers. The reduction is effectively linear with the proportion of order ahead customers. As demonstrated in experiment 1, the improvement for overall customers comes in part at the expense of walk in customers. Time in System for walk in customers increases as the proportion of order ahead customers increases.

Figure 8- Time in System All Customers



The increase is very slight, almost trivial for low to moderate levels of utilization. Only when utilization is high is there a meaningful increase. For lower levels of utilization, the order ahead service can be provided during idle time, even when the order ahead percentage is high. Finally, the time in system for order ahead customers, while very short, does increase with order ahead rate. As order ahead rates increase the average wait time increases roughly between 30-50%. Walk-in customer time is barely impacted under low to moderate system utilization levels. In the 2nd highest utilization level total time increases 7%, while in the highest utilization level the time in system increases about 20% as the proportion of order-ahead customers increases from 4% to 40%. The primary effect of the order-ahead capability is to reduce the overall time in system. As the order ahead percentage increase from a low (5%) level to a high (40%) level the overall time in system is reduced by about 30%. This is achieved by shifting food preparation service to the time before a customer arrives, when they are in-transit to the store.

Figure 9-Time in System Walk in Customers

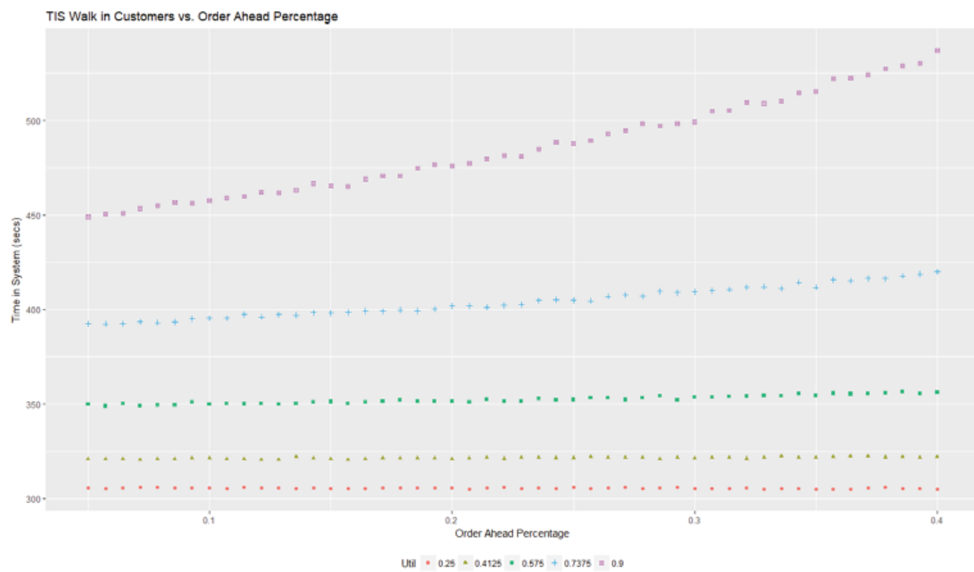


Figure 10-Time in System Order Ahead Customers

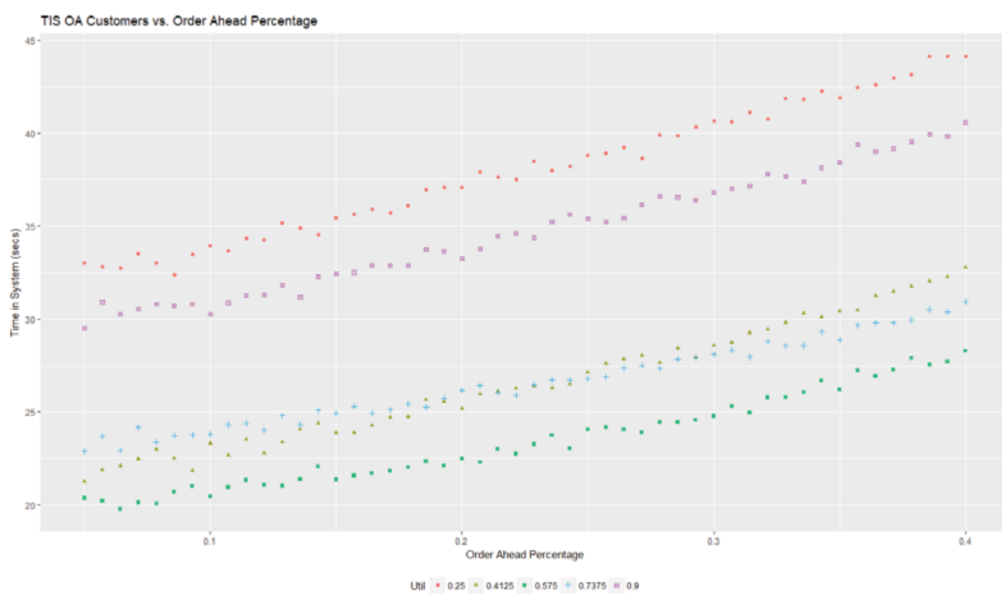

Table 4- TIS Metrics over Range of Order Ahead Proportion

	Time in System											
	All Customers				Order Ahead Customers				Walk In Customers

SUMMARY AND CONCLUSIONS

Mobile Order Ahead apps are becoming increasingly popular in the quick serve restaurant space. Customers who use these apps see significant benefits. Their orders are prepared prior to their arrival and their wait time is virtually eliminated. These customers go to the front of the line and often get their food almost immediately. Additional benefits often accrue to the customer through loyalty programs and discounts. Benefits also accrue to the restaurant as they capture customer data and potentially increase dining frequency.

Our analysis indicates that overall the mobile application increases the efficiency of the system as a whole. By completing food preparation before the customer arrives the total waiting time for all customers is reduced. The walk-in customer also sees the benefits as overall system efficiency improves although they may feel slighted as customers arrive and skip the line.

This preliminary analysis examines the effect of order-ahead apps over a broad range of operating characteristics. Our analysis is primarily descriptive, analyzing the impact of a reasonable set of operating assumptions. From an operations perspective, further prescriptive analysis is possible to determine optimal operating policies for scheduling walk-in vs. order-ahead service. From a marketing perspective further analysis of the loyalty and purchase frequency benefits that come with order-ahead systems is warranted.

ABSTRACT

Back doors - in the software context - are passwords that – for useful or malicious reasons - bypass normal authentication. Backdoors, therefore, are exploited to hack into IT systems such as the accounting software. Such attacks are pervasive and can lead to enormous costs to the organization including loss of brand value, loyalty to customers and compliance penalties. Although there are efforts to address specific areas of the issue, so far, there are no integrated solution to address this problem. By including legal, ethical, international, policy and technical aspects, we develop a holistic policy level framework to address this issue.

KEYWORDS: Backdoors, Framework, Security, Auditing

INTRODUCTION

Back doors are not only a threat to accounting software, but also to the internal controls of an organization and as such must be addressed by auditors. This issue can only be tackled with multiple aspects ranging from policy issues, technical resolutions to international cooperation. After performing a literature review discussing general and specific Backdoor related threats in AIS, we propose a framework to address threats from Backdoor vulnerabilities.

LITERATURE REVIEW

General IT related threats

While the role of Information Technology in adding organizational value has become increasingly clear (Brynjolfsson & Saunders 2010; Masli et al, 2011; Tambe & Hitt 2012), it has come with its own set of issues. Information technology (IT) weaknesses pose a threat to organizations (Haislip, Peters, & Richardson, 2016). Such weaknesses take longer to fix, are associated with subsequent restatements, less accurate forecasts, higher audit fees, and lower earnings quality, and at times may lead to executives losing their titles (Kim, Richardson, & Watson, 2018). This threat is further exacerbated as Accounting is increasingly becoming dependent on Information Technology (Bansah, 2018). Pervasive use of computers, along with recent compliance requirements, has increased the importance of Information Technology (IT) in auditing services. Consequently, there is growing emphasis on assuring the integrity of internal control related to information systems for complying with the internal control assurance requirements of Section 404 of the Sarbanes-Oxley Act of 2002 (SOX) (U.S. House of Representatives) (Borthick & Bowen, 2008). Therefore, auditors need to place high priority on enhancing the overall effectiveness of auditors' work on internal control, particularly with respect to information systems (O'Donnell & Rechtman, 2005). Vulnerabilities such as backdoors pose a serious threat to AIS. Using a comprehensive integrated approach, this paper proposes a framework to address this threat.

Accounting and Information Technology Security

The role of Information Technology in the financial and accounting routines is becoming more pervasive. Controls are increasingly being embedded in IT systems (Allen, et al. 2006). Accounting information systems however are just as vulnerable as typical IT systems. For example, the Ransomware attack in Ukraine was through a software update coupled to an accounting system (Srinivasan, 2017; Perlroth, Scott, & Frenkel 2017). This threat has been researched all over the world. The research findings (Table 1) suggest that AISs have been found to have weaknesses all over the world. Therefore, it is imperative that these pervasive weaknesses be studied, and addressed. This has led to more cross-discipline research involving accounting and IT (Brandas, Stirbu, & Didraga, 2013; Mihalache, 2011). This paper attempts to do the same in one area of weakness: Backdoors. Problems such as backdoors in accounting software stand at the intersection of IT and Accounting disciplines (Murthy, 2016). The solution framework in the paper may also solve other challenges in IT and AIS.

Table 1: Studies in AIS control issues across the world

AUTHOR(S)	YEAR	COUNTRY	DETAILS
Rajeshwaran & Gunawardana	2009	Sri Lanka	Security controls inadequately implemented.
Abu-Musa	2004	Egypt	Weaknesses in security controls identified.
Abu-Musa	2006	Saudi-Arabia	Financial losses due to internal and external computerized accounting information systems security breaches.
Zweilf	2009	Jordan	Threats to accounting systems including unauthorized access.
Hanini	2012	Jordan	Threats to information systems originate from internal sources that include intentional threats.
Polo & Dima	2013	Kenya	Failure in many cases is due to weak governance and audit monitoring rather than the inadequacy of systems.
Muhrtala & Ogundeji	2013	Nigeria	Organization employees and outsiders' key threats to information assets.
Hood & Yang	1998	China	Information security was found to be inadequate.
Singh & Gupta	2017	India	Results highlight the importance of consistent top management

			support, organizational information security culture and a proper monitoring system for information security effectiveness in organizations.
Riad	2009	United Kingdom	Companies suffer from various security incidents.

Backdoors

Backdoors – often called hardcoded passwords - are userids, passwords or other data, in the source code that are - for practical or malicious purposes - used to bypass regular security protocols. Practical non-malicious backdoors help in case of lost or forgotten passwords. While there are non-malicious practical applications of backdoors, organizations become vulnerable to potential hidden malicious code. By their hidden nature, backdoors in software are difficult to verify and can only be hypothesized. The malicious potential of backdoors is well documented (Table 2). History is replete with examples of hacking attacks through backdoors that consequently cost companies millions of dollars in damages (Kim et al., 2011).

Table 2: Representative list of backdoor attacks in the recent past

YEAR	DETAILS
2016	Some older routers built on the WiMAX technology contain backdoor accounts that appear to have been introduced somewhere along the devices' supply chain.
2016	Wickedly Clever USB Stick Installs a *Backdoor* on Locked PCs
2016	PokemonGo Ransomware installs Backdoor Account and Spreads to other Drives
2017	74 countries hit by WannaCrypt ransomware backdoor
2017	*Backdoor Code* Discovered in Popular Bitcoin Mining Equipment

Over the years, these backdoors have experienced new developments (Klaus, 1997). It could be a programmer writing the original code or an intruder with access to change the code (Landwehr et al, 1994). A malicious coder can hide code to make the software weak or bypass normal authentication checks (Dai et al, 2012). Such hidden code can originate from, or result in spyware, adware, trojans and ransomware (Table 3). The recent cases of ransomware attacks and data breaches have brought to the forefront the importance of addressing backdoors in software (Deepa & Thilagam, 2016). Just like any other IT security situation, it is a tradeoff between security and convenience – or in some cases- as in the Apple case (McLaughlin, 2016) suggests – a tradeoff between security and privacy.

Table 3: Backdoor Variants and related malicious methods.

TYPE	DETAILS
Ransomware	Using backdoors to companies Information Systems.
SQLinjection	Deliberately input Weak code.
Trojans	Can be used to input backdoors using pretext of updating.
Default passwords	People often do not change default password.

Auditor's role in internal control

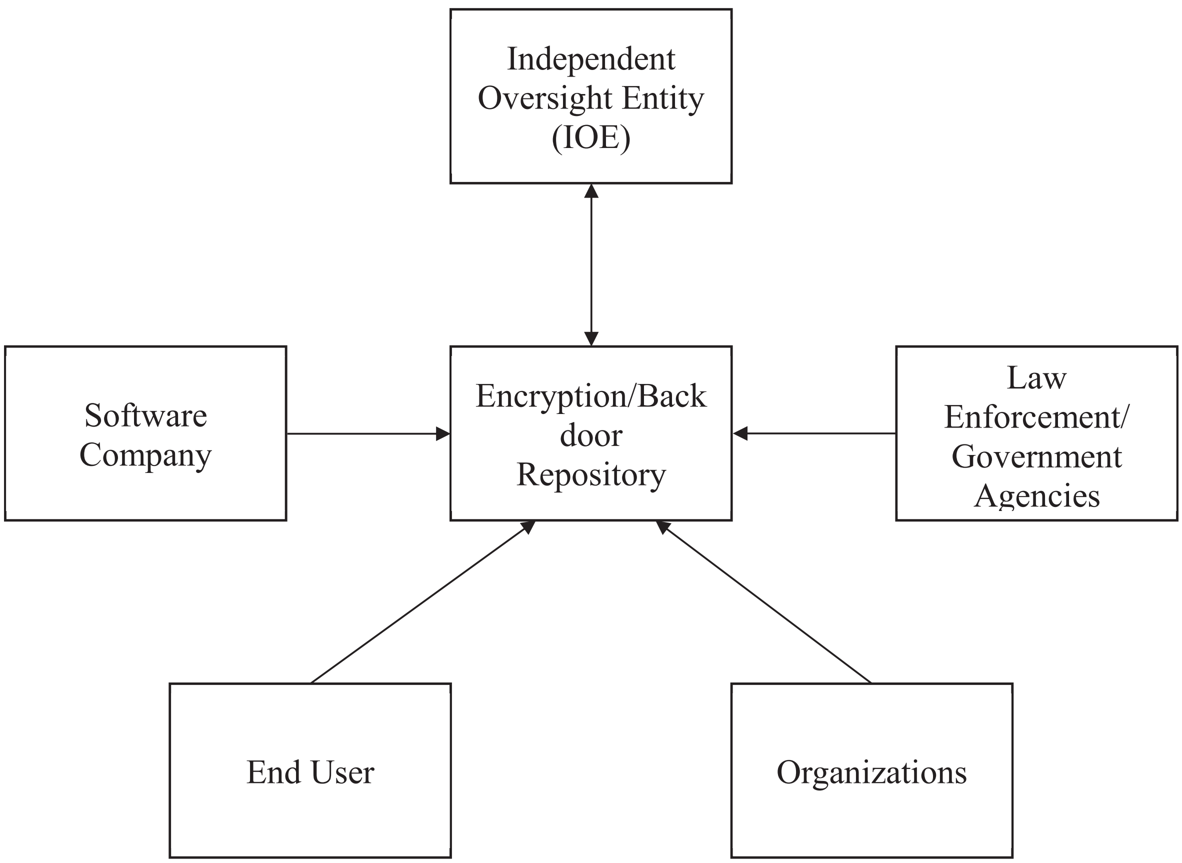
Table 4 provides a representative list of policies, legislation and frameworks addressing source code manipulations. Large public companies are required to have an integrated audit in accordance with SOX. Independent auditors are required to attest to the effectiveness of controls (Huang, Hung, Yen, Chang, & Jiang, 2011). According to SOX Section 302, management must annually certify to the completeness of accuracy of financial reporting by the CEO and the CFO. SOX Section 404 requires management's acknowledgement of its responsibility for establishing and maintaining adequate internal control over financial reporting and auditor attestation of the effectiveness of internal controls over financial reporting (Weidenmier & Ramamoorti, 2006). Information Technology is playing a pivotal role in corporate governance and SOX compliance. However, while IT is an enabler (Weidenmier & Ramamoorti, 2006) in managing risk, it itself becomes a source of risk. IT vulnerabilities open the organization to attacks. Auditors need to address this problem. To do so, a good understanding of the system is vital (Qian, Ward, & Blaskovich, 2012). One of the roles of the IT organization is to inform audit about challenges and ways to mitigate these challenges (Wilkin & Chenhall, 2010). Informing accounting professionals in IT related threats might help them in working with IT teams to identify, assess and mitigate e-business risks (Henderson, Lapke, and Garcia, 2016). To satisfy SOX internal control requirements, companies need to choose and implement suitable IT security frameworks (Wallace, Lin & Cefaratti, 2011).

Table 4: Representative list of policies addressing source code manipulations	
LEGISLATION	
SOX	Sarbanes-Oxley Act -2002
HIPAA	Health Insurance Portability and Accountability Act -1996
GLBA	Gramm-Leach- Bliley Act – 1999
FISMA	Federal Information Security Management Act -2002
FRAMEWORKS	
COBIT	Control Objectives for Information and Related Technologies is a created by ISACA for information technology (IT) management IT governance
COSO-ERM	Committee of Sponsoring Organizations of the Treadway Commission
ITIL	ITIL, formally an acronym for Information Technology Infrastructure Library, is a set of detailed practices for IT service management (ITSM) that focuses on aligning IT services with the needs of business
CMM	The Capability Maturity Model is a used to develop and improve an organization's software development process.
ISO	For IT organizations, ISO standards can reassure management and users that data and processes are safe -- and worth the investment.

PROPOSED FRAMEWORK

There are many cases of backdoors attacks due to technical issues such as hidden malicious code. However not all backdoor solutions are technical. While there are many technical approaches to addressing backdoors (Schuster, Rüster, & Holz, 2013 jul and nov; Pewny, et. al. 2015; Opaska 1986; Miyani, 2016), IT systems cannot be completely secured through technology alone. Behavioral and policy aspects need to be considered too (Sherif, Pitre, & Kamara, 2016). The ethical conundrum in the Apple situation – for example - is not a technical issue but an ethical decision. In many cases, backdoor attacks are not due to technical issues but due to lack of organization policies - for example requiring a change of the password from the initial default password to a more secure one. If not changed, the default password is vulnerable and can be exploited. Therefore, an all-encompassing framework covering all aspects is required. Unlike extant research, this framework brings together all stakeholders. The Backdoor problem encompasses legal, ethical, international, policy and technical issues. We propose a framework to address the problems associated with backdoors. Figure 1 provides the various stakeholders that contribute to the framework.

Figure 1: Proposed Backdoor Governance Framework



Independent Oversight entity

The Independent oversight entity (IOE) will be responsible for deciding the policies rules and regulation regarding use of backdoors. Often, there are ethical issues due to conflict between privacy (one greater good) and protection of life (another greater good). The proposed independent oversight entity will decide by navigating the delicate balance between privacy and protection of life. Such decisions – for example – will allow a backdoor into a system to help enforcement authorities reveal or tap into communications among terrorists. Such decisions can be arrived at by voting among member countries. Releasing a backdoor could be to protect the lives and open fraudulent hidden accounts in a software etc. All software developers will be required to submit a secret backdoor to their products. This backdoor can be accessed only when the IOE agrees to allow access to it.

The IOE can also create an alert system that will alert users about any dangers such as viruses. Just like the International Federation of Reporting Standards (IFRS) pursues standardization, an international code of conduct will be required from software products as well.

IOE Composition

The problem is international in nature with attacks often originating from another country. Therefore, the independent oversight entity needs to be an international entity. The IOE could be a combination of the Governments, Industry consortiums, and software consortia. An international consortium, perhaps a part of the United Nations, in collaboration with industry consortia would be able to oversee and maintain the repository of checksums (explained later) and backdoors for certified software and updates. Industry experts on technical, political, legal and ethical issues would serve as advisors.

Software development companies

The responsibility of member software companies is to upload all checksums (such as MD5 message-digest algorithm) and backdoors of their software - and subsequent updates - to the software repository. MD5 is a one-way cryptographic function is used for authentication. Using such cryptographic functions, organizations can promise privacy through encryption to all. However, in exacerbating circumstances, such as terrorism, fraud -for the greater good - the software can be accessed to protect others. Software owners should promise privacy with exceptions such as terrorism and uncovering of fraud.

Software Repository

The IOE can maintain the repository for checksum and backdoors.

Checksums**-** The software repository will keep all checksums MD5 of the certified software and software updates uploaded by the software companies. These will be publicly available for all to cross-check. This way organizations and individuals can check for any changes to the source code of the software by crosschecking it with the data in the repository. By providing such a facility, auditors can be more confident of the security of their software.
Checksum techniques can verify the integrity of information (Cohen, 1987). We will use MD5 - a widely used checksum algorithm - as an illustration (Klaus, 1997). These have other broader implications too that are of interest in auditors - such as protecting against unintended corruption in files, accidental deletion and modification (Cohen 1992). For example: If you input "Dallas Cowboys," the MD5 created is **5a40b7cccc2a230895881416edda4622**. You cannot get Dallas Cowboys from this value. It there is any change to the string a new value will be created. https://www.md5hashgenerator.com/. This concept applies to entire software code also. Even if there is a small change in the code, the MD5 created will be different. Therefore, software with 200 million lines of code can still be cross-checked for changes. In case of open source software, software development organizations can create a MD5 hash to allow users to check for potential changes to their code. Millions of lines of code cannot be manually checked against

changes. Therefore, an MD5 would allow users to check for changes in their code by comparing their code with the MD5 in the public domain. This can be done for every version and patch as well. For example, Harn et al, (1992) and Okamoto & Masumoto (1990) recommend a signature system to avoid being exploited by unlicensed distributors of the program. Other hash techniques include SHA1, SHA256, SHA384, SHA512, MACTripleDES and RIPEMD160 (Banday, 2011).

Backdoors**-** The software repository will also keep software backdoors uploaded by the software companies. These will not be available in the public domain. Software development companies can continually change backdoors for each version or update. Each of these backdoors will be required to be deposited to the repository. Access to such backdoors can be accessed only through many levels of checks. These checks could be available through litigation, subpoenas, and court orders etc. We discuss this in the next section.

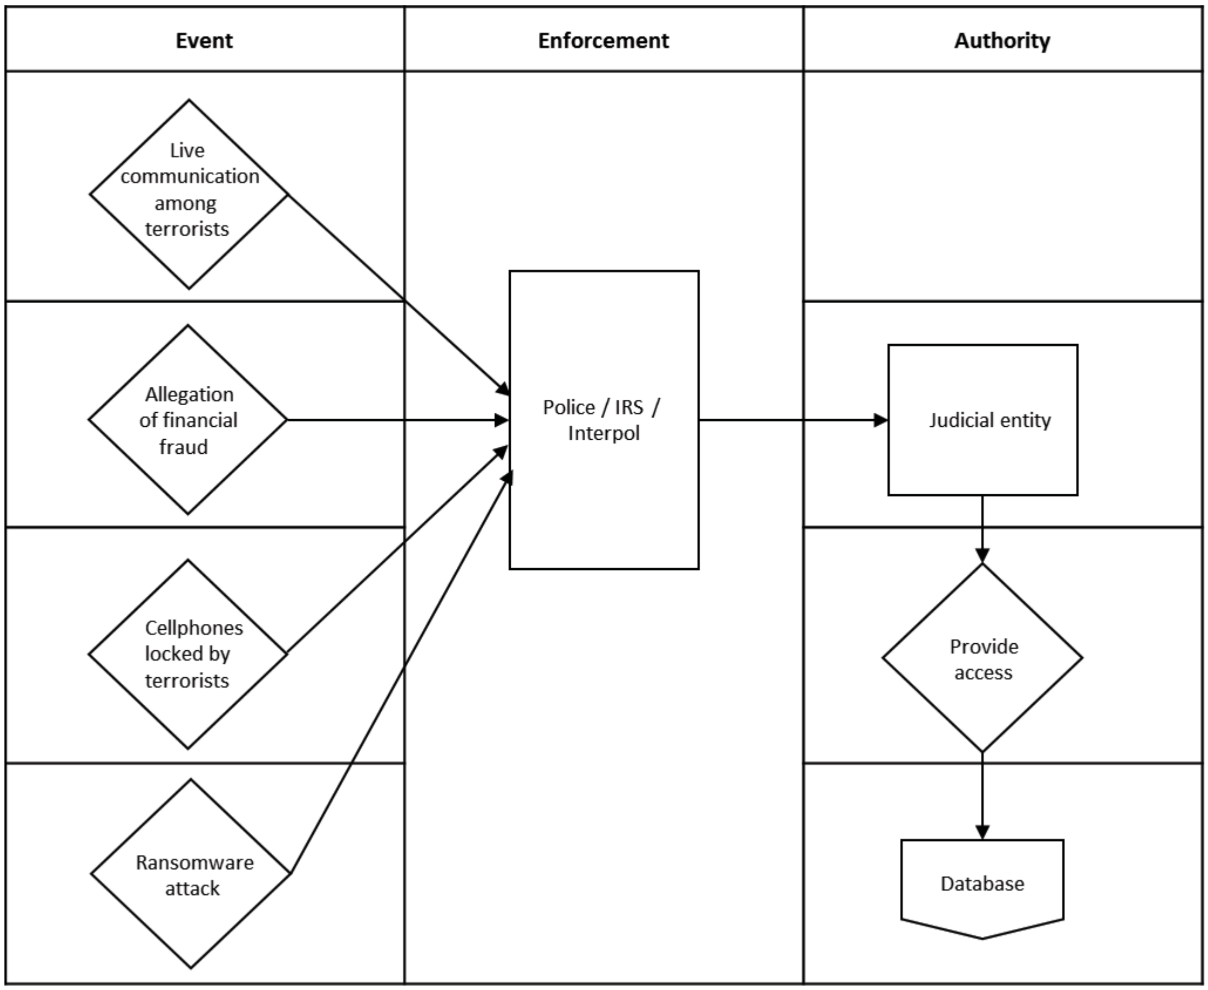
Enforcement Authorities

Enforcement authorities can ask for warrants to obtain the backdoor for individual software entities by petitioning the IOE. By considering the ethical issues and the decision between privacy and safety, IOE may or may not give access to the backdoor. Depending on the issue, the IOE could range from a local judge to international judiciary committee. The flow diagram is shown in Figure 2.

Terrorists can exploit Backdoors (Morris, 2017). Furthermore, encryption technologies protect criminal and terrorist organizations too (Valeri & Knights, 2000; Lee et al, 2016). Encrypted software, systems, communications etc., could be dangerous in the hands of wrong people. Encryption technology allows terrorists to communicate without being monitored by government agencies (Keene, 2011). The risks of having no access to such systems- in other words going dark - are real and endangers nations and therefore lawful access is needed (Corn 2015, 2017). The security and privacy that a software promises, becomes a liability when used by terrorists. In such rare cases, a decision needs to be made by the IOE to figure whether protection of lives overrides privacy.

There are other applications of this framework too. In the accounting context, sometimes enforcement agencies need access to accounting details in accounting software. Once a legal case is reviewed, enforcement authority would be able to get a warrant to get into the software through the backdoor from the repository.

Figure 2: Event Flow Diagram



Individual End-Users

Individual users of accounting software –such as freelance accounting services providers- have critical information about customers. Such users are particularly vulnerable, as they are usually unaware of vulnerabilities and are not protected by organization level controls. This could lead to loss of private customer information, destruction of data and loss of customer trust. To avoid being victims of backdoors attacks, individual users can crosscheck software and their updates from the encryption repository (figure 1). Much like the presidential alert system, end users can register for alerts and repositories can provide alerts to threats.

Organizational End-Users

Policy

For organizational end users, the stakes are higher as the loss of data could be costly due to lawsuits, breach of privacy, and loss of trust by clients. As systems become more robust against attack, only human errors and fallibility remains. Many organizations recognize that their employees, who are often considered the weakest link in information security, can also be great assets in the effort to reduce risk related to information security (Bulgurcu, Cavusoglu, & Benbasat, 2010). Therefore, there can be a policy level enforcement by the organization specifically addressing backdoor attacks.
For organizations, the framework (figure 1) will relieve them of the cost of monitoring every software application. Auditors need to be aware of the compliance requirements too. These include The Sarbanes-Oxley Act of 2002 (SOX), the Health Insurance Portability and Accountability Act of 1996 (HIPAA), and The Payment Card Industry Data Security Standard (PCI DSS). The above-mentioned frameworks can help the auditing departments in ensuring proper internal controls in IT. They can combine these frameworks with established IT control frameworks such as COBIT and COSO.

“User-developed” software and BYOD

Many organizations also use internally developed “User-developed” software that can be prone to malicious intent (Lewis et al., 2009). The problem gets compounded with combinations of insourcing, outsourcing, cloud computing, virtualization, and mobile computing among other environmental challenges (Debreceny, 2013). Auditors need to be cognizant of even end user vulnerabilities as ‘bring your own device’ (BYOD) policies are becoming pervasive (Utter & Rea, 2015). Viruses can find their way through employee devices into the organization systems.

Conclusion and Future Directions

Although IT mitigates risk, it in turn adds risk (Wilkin and Chenhall, 2010). One such risk involves backdoors. Backdoors attacks have cost organizations millions of dollars. The damage can be in the form of breaches of privacy, loss of data, loss of brand value, destroyed data, the loss of customer confidence and even loss of lives.

This attempts to cover all aspects of the backdoor ecosystem by developing policy level framework. Using such a framework could help solve many problems such as misuse of available backdoors, ransomware attacks, financial fraud, viruses, industrial and international espionage, and terrorism. The framework encompasses international, country, company, and individual levels. This framework will help individual users, organizations and countries protect against backdoor vulnerabilities.

Internet of Things (IOT) devices are increasing becoming pervasive in homes as well as in businesses. These too are vulnerable to backdoor attacks (Maras, 2015). In future IOT devices can be included in the above-mentioned framework.

Recommended Policies for individual users

- Use the proposed framework
- Update administrative passwords as soon as possible
- Do not install or update software from non-validated sites
- Periodically cross check changes to software and its updates

Recommended Policies for auditors

- Use the proposed framework
- Update administrative passwords as soon as possible
- Restrict employees from installing or updating software
- Periodically cross check changes to software and its updates
- Forbid vendors from direct access to install or change code without administrative monitoring
- Use software - such as Assembla and Bitbucket - to monitor software
- Manage BYOD policies
- Use only software from genuine certified vendors
- Monitor and maintain software audit logs
- Accept code with digital signatures only

Limitations of Framework

One challenge is to include employee developed software into the framework. This is particularly important as software developers are also employees. Employees often build small programs such as in Excel, Access and Visual Basic. Employees with malicious intent may have a hidden backdoor to the application they develop. Additionally, these are small programs that are at times, amateurishly built and do not have proper security checks (Cale, 1994). The risk magnifies if the employee developer has malicious intentions.

ABSTRACT

Human mobility pattern mining is invaluable to transportation decision-making because it enables public and private entities to reduce operational cost, improve system performance, and promote shared mobility modes of transportation. We offer two data mining approaches to a dockless shared mobility service in Washington, D.C. The authors used data collected from two different operators. We outline the geohashing technique combined with data mining methods to provide a promising alternative to the existing model. We intend to provide a better understanding of commuter movements at different levels of spatiotemporal resolution.

KEYWORDS: Big data, Business intelligence, Shared-use mobility, Pattern mining

BACKGROUND

City officials promote active transportation to enhance the sustainability of transportation systems. Micromobility options provide affordable and convenient alternatives within these systems. Bicycle and scooter-sharing schemes are two typical modes of this service. Unlike the traditional dock-based model, free-floating, non-station based, or “dockless” sharing systems offer the flexibility to pick up and leave the shared vehicle (bike or scooter) in any accessible locations across the operational area. This system is meant to supplement the dock-based model. However, it has the potential to compete with the traditional dock-based model as it has lower upfront operating costs, more flexibility, and may accommodate people with disabilities (Rahim Taleqani et al., 2019). The traditional dock-based service fails to cover the gap between the docking stations and points of arrival/departure. Dockless systems allow the geolocation of every single bike or scooter. The geo-localized data collected by operators contains valuable mobility information about users’ commuting patterns such as trip length, time, visited locations, etc.

In the transportation field, human mobility is much more complex and stochastic as it entails interpersonal variability, including gender, age, income, daily activity patterns, destinations, routes, and modes of transportation. Data collected on dockless mobility systems could reveal many implicit and explicit patterns. In general, mobility pattern mining could be at the micro or macro level and provide insight into individual or group mobility. Mobility pattern mining and trajectory prediction are the focus of many studies in transportation, mobile computing, infectious disease modeling, and other areas (Lu et al., 2012; Shahraki et al., 2017). Spatial and temporal data of individual entities are generally captured in the form of global positioning system (GPS) data points (Liu et al., 2015).

Abundant research is focused on modeling human mobility and forecasting movement trajectories with various methods, including Markov chain (MC), Artificial Neural Network, Bayesian network, and finite automaton. In general, most existing literature falls into two broad categories: 1) spatiotemporal prediction, 2) next location prediction.

Individual mobility can be captured with devices such as GPS receivers or smartphones. The latitude, longitude, and timestamp are collected at various frequency rates, depending upon the device's capability. The result is a sequence of locations with a different time for each location.

Various approaches and techniques have been applied to spatiotemporal data points. Spatiotemporal modeling aims to discover prominent daily temporal habits as well as predict future individual activities (Scellato et al., 2011; Zheng and Ni, 2012). Spatial movement modeling facilitates next location prediction (Bayir et al., 2010; Lv et al., 2014), residence time prediction (Baumann et al., 2013; Chon et al., 2012), life pattern mining (Bayir et al., 2010; Ye et al., 2009), and identification of departures from a mobility routine (Mcinerney et al., 2013; Smith et al., 2014). Lu and his team implemented a series of Markov Chains to analyze the travel patterns of 500,000 individuals during the post-civil war period in Cote d'Ivoire. Individual trajectories are collected by tracing mobile phone call data. They improved the predictability to as high as 88% by considering the uncertainties of movements using entropy, the frequencies, and the temporal correlations of individual trajectories. They concluded that human mobility behavior is far from random and that historical behavior greatly influences individuals' movements (Lu et al., 2013).

In wireless communication, the quality-of-service guarantee can be achieved if enough resources are reserved before a new cell arrives. Hence, the system has to predict the exact number of the next-crossing cell. Shiang-Chun et al. proposed a neural network prediction scheme to predict the location of the mobile host. Their work efficiently improves the accuracy of mobile hosts trajectory prediction, increases the success probability of resource reservation, and enhances bandwidth utilization(Liou and Lu, 2003). The University of Colorado's adaptive control of home environments project developed a smart house that observed the lifestyle of the inhabitants and learned to infer and accommodate their needs such as adjusting the thermostat, turning on a particular configuration of lights. Motion detectors track occupants, and a neural network approach is used to predict the next room the person will enter and the activities in which that person will be engaged (Mozer, 1998). In response to a similar problem, Akoush and Sameh presented a novel hybrid Bayesian neural network model to address the uncertainty for predicting locations on cellular networks. Unlike the conventional approach, which is based on dynamic tracking, their method is based on topology-independent user tracking. This method reduced the cost of tracking significantly (Akoush and Sameh, 2007). They concluded that Bayesian learning for neural networks predicts location better than standard neural network techniques because it uses a well-founded probability model to represent uncertainty about the relationships being learned. Instead of using Markov chains, Bayesian networks, and neural networks, Petzold et al. proposed using global and local state context prediction to address human mobility with context information. Their work originated in branch prediction techniques which are used in CPU design but was modified to handle context prediction. They modeled two-level two-state predictors with local and global first-level histories. The model is used by simulating the predictors with behavior patterns of people walking through a building as a workload. Findings show excellent performance, but exhibit differences in training and retraining speed and in their ability to learn intricate patterns (Petzold and Bagci, 2003).

One of the challenges with the previous methods is the absence of a reliable data collection at consistent spatial and temporal resolution. The contribution of this research is a geohash-based data mining approach to detect underlying patterns in daily commutes. The ability to look at different resolutions could address a range of problems from urban design related issues such as blocked entry/exit building access, old city infrastructure to inter/intra city transportation management issues, including the lack of comprehensive enforcement on reckless commuters.

The remainder of the article is structured as follows. In the next section, we introduce the details of pattern mining and clustering methods. We then discuss the findings from each method and a possible way for visualization. We conclude the article with a synopsis of our research contributions and a discussion of opportunities for future research.

METHODOLOGY

Pattern Mining

The scooter/bicycle movement could be seen as a **shopping basket analysis** problem. Techniques used in this field seek to understand influences on the purchase of other items. The findings help retailers enhance sales and revenue by cross-selling or up-selling. With some modification, the same approach could be applied to a shared-use mobility system. Because of privacy, users are anonymous, so we focus on the movement of the vehicle and the importance of prior location on traveling to the next location. We describe the transaction as a sequence of bike/scooter movements during the day of the week for a specific user. The series could be either a sequence of check-out or check-in locations. Each transaction is composed of a set of items. An Item is defined as a region of interest during a time frame (period). The goal is to understand a group of spatiotemporal items that occur together frequently. For example, as described in Table 1, “A_6”, “B_6” as region “A” and “B” during 6 a.m.

Apriori algorithm is a classical algorithm for frequent mining of itemsets and relevant association rules. There are three metrics to measure association:

Support indicates the popularity of an itemset, as measured by the proportion of transactions in which an itemset appears. As shown in Table 1, the support of {C_5} is 4 out of 8 or 50% or the support of {C_5, B_6, C_7} is 2 out of 8, or 25%.

Confidence indicates the probability of item Y (consequent) as a destination when item X (antecedent) is the prior location as an origin, expressed as {X -> Y}. It is measured by the proportion of transactions with item X, in which item Y also appears. In Table 1, the confidence of {C_5 -> B_6} is 3 out of 4, or 75%.

$$\textbf{Confidence}\ \{\mathbf{C_5} \rightarrow \mathbf{B_6}\} = \frac{\textbf{Support}\ \{\mathbf{C_5}, \mathbf{B_6}\}}{\textbf{Support}\{\mathbf{C_5}\}} \quad (1)$$

Lift indicates the likelihood of item Y as a destination when item X is the origin while controlling for how popular item Y is. Similarly, the lift of {C_5 -> B_6} is 1, implying that there is no association between items. A lift value higher than 1 implies that item Y is likely to be selected if item X is the origin, while a value less than 1 means that item Y is unlikely to be chosen if item X is the origin.

$$\boldsymbol{Lift}\{\boldsymbol{C_5} \rightarrow \boldsymbol{B_6}\} = \frac{\boldsymbol{Support}\{\boldsymbol{C_5}, \boldsymbol{B_6}\}}{\boldsymbol{Support}\{\boldsymbol{C_5}\} \times \boldsymbol{Support}\{\boldsymbol{B_6}\}} \quad (2)$$

Table 1: Transactions vs. Items

Transactions	Items
1	A_6, B_6, C_7, H_12
2	A_6, B_6, C_7
3	A_6, B_6
4	A_6, D_11
5	C_5, B_6, C_7, H_12
6	C_5, B_6, C_7
7	C_5, B_6
8	C_5, D_11

Clustering

Feature Extraction with Restricted Boltzmann Machine (RBM)

The Boltzmann machine is energy-based unsupervised nonlinear feature learner. It consists of hidden and visible neurons (units) in a fully-connected bipartite graph. Previous research using RBM as feature extraction tools was conducted by Hinton (Tieleman, 2008). Because the RBM uses the hidden units to model the correlation of the data set, the expected value of the hidden units of a learned RBM can be viewed as the extracted features of visible units. Empirical research shows that using these extracted features in place of the data itself yields significant improvements in several tasks (Cai et al., 2012; Zhang et al., 2018). One of the significant advantages of RBM is that the extracted features of a learned RBM can be used as input for training another RBM to capture much higher-order abstract features, and this procedure could be repeated as many times as needed to build a deeper network.

T-distributed stochastic neighbor embedding

t-distributed stochastic neighbor embedding (tSNE) (LJPvd and Hinton, 2008) is a method to reduce the dimensionality of the dataset while preserving neighborhood structure to visualize the structure of the data before clustering. Unlike Principal Component Analysis (PCA), it is a non-linear, probabilistic method with a random walk on neighborhoods graphs to find structures within the data. It converts the similarities of data points to a joint probability distribution to minimize the divergence between two distributions: distribution of the original data points (high dimensional dataset) and distribution of dimensionality reduced dataset.

Density-based spatial clustering of applications with noise (DBSCAN)

DBSCAN locates clusters as areas of high density by counting the number of points in the region of a specified radius. Data points with a density above a specified threshold are constructed as clusters. The DBSCAN algorithm is able to discover clusters with an arbitrary shape such as linear, concave, oval, etc. Additionally, unlike some clustering algorithms, it does not require the predetermination of the number of clusters. DBSCAN has been proven in its ability to process massive databases (Ester et al., n.d.; Taleqani et al., 2019). DBSCAN basically needs two parameters: 1) the minimum distance (eps) between two points to be considered as a neighbor, 2) the minimum number of points (min_samples) to form a dense region. Together, these two parameters define density. Higher min_samples or lower eps indicate a higher density necessary to build a cluster. The parameters estimation is a critical DBSCAN. A too-small value of eps results in a large number of outliers, while very large numbers render few large clusters. The eps should be chosen based on the k-nearest neighbors' distance graph. The value of k corresponds to min_samples. Min_sample, as a general rule of thumb, can be derived from the number of dimensions (minPoints ≥ D + 1). The larger the min_samples, the better for datasets with noise.

EXPERIMENTS AND RESULTS

Case Study

For this research, the District of Columbia (D.C.) is selected because it is one of the rare cases in which the dockless operators publicly share real-time data. As of September 2017, the District Department of Transportation (DDOT) conducted a dockless demonstration to evaluate the pros and cons of this type of shared mobility. From September 2017 through June 2018, seven dockless operators participated in a D.C., pilot demonstration. Mobike, Lime, Spin, and Ofo operated traditional pedal bicycles. JUMP provided motorized or electric-assist bikes. Skip Bird, and Lime operated electric scooters. During the period, more than 625,000 dockless trips were made by approximately 233,700 unique users using the seven companies.

Data for six active dockless programs are available through the public application programming interface (API). These programs include Jump (Neon Red), Lime (Green), Spin (Orange), Skip (Yellow), Bird (Black), Lyft (Pink). However, only two of them, Lime and Lyft, provide the correct availability status of the vehicles in a given time. To be consistent with our analysis, we used only the data from these two companies. To use the data for the other four companies, we could approximate the speed of the vehicle by computing movement and timer intervals. However, this is not a very reliable method because we are not able to identify if a vehicle is moving because a user is using it or because the bikes are on a truck being moved around the city for rebalancing.

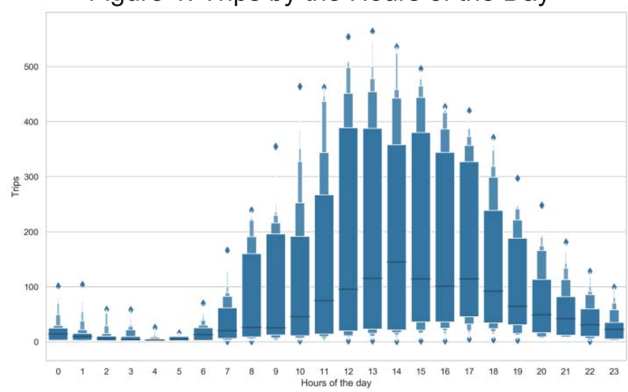
Data were live-streamed through their APIs for a period of one month, from March 15 to April 15. Data were retrieved every minute for a higher degree of time resolution and an in-depth understanding of mobility. The dataset before preprocessing has almost 33 million data points. These data include the bike/scooter ID, geographic coordinates (latitude and longitude), and timestamp of the available bicycle (at one-minute temporal resolution). Further steps were necessary to convert the bike/scooter availability data into trips. Since users are anonymous, we focus only on the movement of an individual vehicle and report the number of trips made by a vehicle.

Trips summary

Temporal patterns

The mean duration of a trip for both operators was approximately 15 minutes while the mean for a Lime trip is 16 minutes, and Lyft trips take 7.5 minutes on average. The tendency towards longer trips by Lime users is significant and may be partially due to the design of the vehicle or the popularity due to the availability of Lime vehicles across the region. However, the longer time does not mean longer traveled distance as a user might travel a short distance but put the scooters/bikes on hold for further use. The temporal popularities of the two shared mobility services are shown in Figure 1. The trip start times are aggregated to the nearest hour of a day. We see an expected daily pattern, with the majority of trips taking place during daylight hours, especially the midday period, for both operators. However, fewer rides in early morning imply that this mode is not popular for the early morning commute.

Figure 1: Trips by the Hours of the Day



In Figure 2, there is no visible monthly cyclic pattern, which might be because of inclement weather during March and April and corresponding interruptions in services. For example, on March 21, unlike Sundays, the low number of trips was due to high precipitation, and on April 14 because high winds were reported. In terms of days of the week, we expect a higher number of trips during the weekend, as shown in Figure 3.

Figure 2: Trips by the Days of the Month

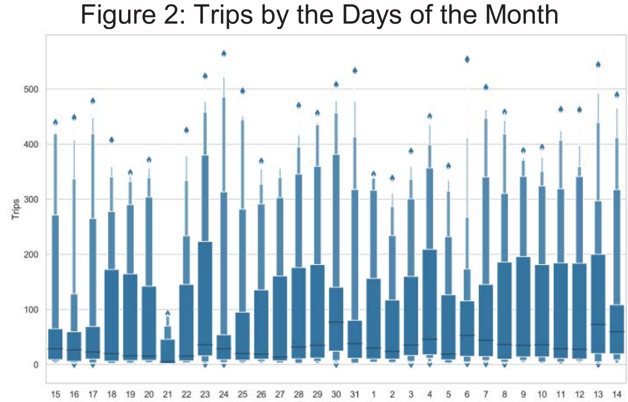


Figure 3: Trips by the Days of the Week

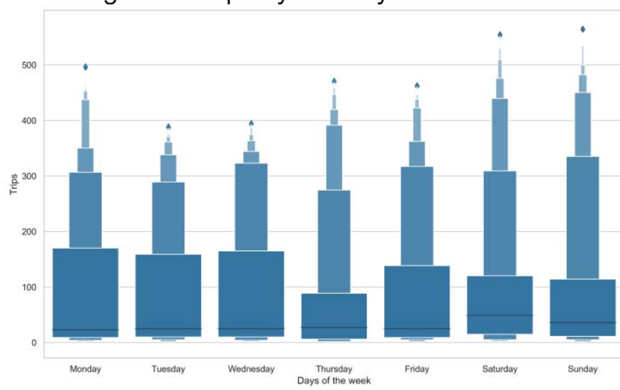

Spatial Patterns

The spatial pattern of mobility is critical to both city planners and operators. For this purpose, we used the concept of geohash tessellation to partition Washington, D.C. into equal size polygons. The advantage of using geohash over transportation analysis zone parcel data is that we can use different resolution (granularity level) to discover any movement pattern as small as 1 foot by 1 foot. Figures 4 and 5 illustrate the net flow of trips by region based on geohash 6. The dark red rectangles indicate a higher number of outgoing trips, and grays rectangles imply a higher number of incoming trips. Trips made through Lyft had sporadic patterns and extended to Arlington and Reagan National Airport. In comparison, trips made through Lime mostly happened in D.C. areas with three imaginary layers of outgoing, incoming, then another layer of outgoing trips from the center to surroundings.

Figure 4: Net Flow of Trips for Lime

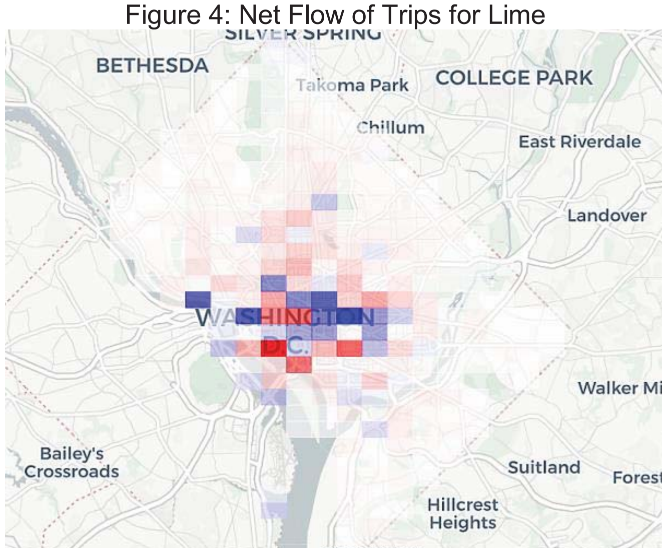

Figure 5: Net Flow of Trips for Lyft

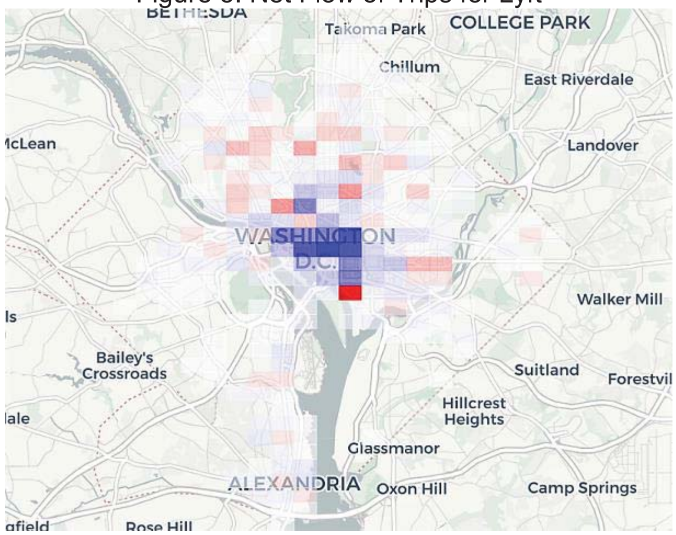
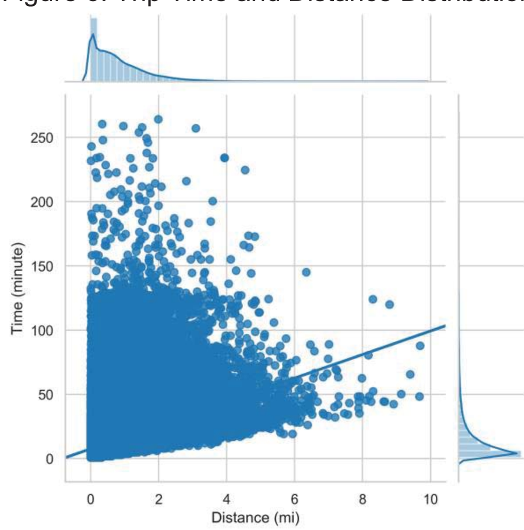


Dockless time offers a relaxed version of shared mobility transportation options, so we expect a very stochastic spatial pattern from the traditional model. Figure 6 shows the trip distance and time distribution. A Manhattan (city block) distance method is used to calculate the distance between the origin and destination of a trip. As expected, there is a linear relationship between time and distance as shown by a tendency toward longer distances in less time. This could be because of the distance approximation method. Both time and distance are heavily right-skewed (with mean of 0.82 miles and 15 minutes) with some outliers. In terms of speed, the maximum is less than 20 mph, which is the limit with a mean of 4.5 mph.

Figure 6: Trip Time and Distance Distribution



From an operational perspective, there were only three bicycles available, which might either indicate the status as a pilot project or the unpopularity of bikes under dockless programs (Table 2). Surprisingly, Lime has fewer scooters available but made the higher turnover per scooter with almost 651 unique scooters active each day on average, with each making 5.8 trips. A low market share might be due to the fact that Lyft had recently debuted the service in Washington, D.C., and had achieved less popularity. The other key factor is that when a user has some credit on his account, they are highly unlikely to switch to other operators. Consequently, we are expecting Lyft operation statistics to improve over time.

Table 2: Trip Statistics

Operator	Lime		Lyft
Type	Bicycle	Scooter	Scooter
Total number of unique vehicles that made a trip	3	2064	2596
The average number of vehicles that made a trip per day	1.2	650.94	279.29
The average number of trips per vehicle per day	1.8	5.8	1.6
The average time in service per vehicle per day (minutes)	35.3	93.89	12.3
The average distance traveled per vehicle per day (miles)	1.12	0.98	0.04

One critical aspect of dockless programs is their higher degree of sprawl across a region. This may result in vehicles being parked close to personally preferred locations rather than in areas with high public demand. Therefore, we expect some locations to be considered as sink points when the vehicles are unused for most of the day while some other locations are considered hot spots with little idle time. The average idle times are 1.36 and 1.15 minutes for Lime and Lyft, respectively. However, some geohases experience the larger value of idle time. Figures 7 and 8 demonstrate the average daily percentage of the time that a bike is inactive (unused). For instance, regions close to the National Mall, the Tidal Basin, and the Arboretum (as tourist attractions) experience lesser idle time per vehicle as vehicle turnover is fairly high. On the hand, some regions like metro stations, parks and residential have larger idle time per vehicle as vehicles might stay longer until next check-out.

Figure 7: Idle Time of Lime Vehicles in Minutes

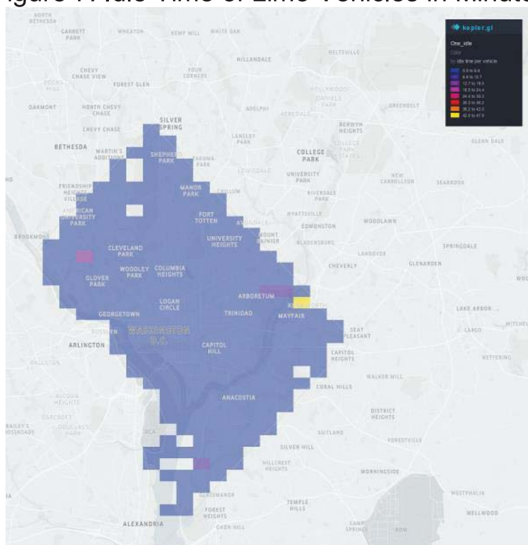


Figure 8: Idle Time of Lyft Vehicles in Minutes

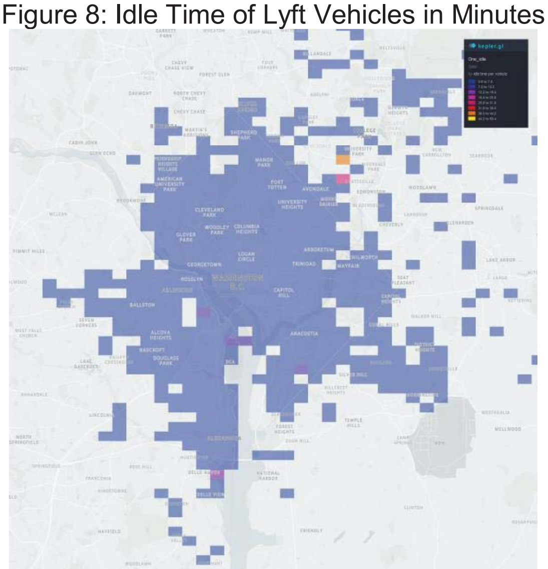

Visitors are likely to travel to tourist attractions and then explore the area on foot to visit points of interest which are close by. Because visitors travel in groups, finding the right number of vehicles to travel together may not be possible, which leads to walking on foot instead of riding bikes/scooters. The other surprising fact is that very close to the sink regions, there is a region with less idle time (high turnover) implying that the area works as a virtual hub or meeting point for users to find a scooter when they are getting out of the sink regions. As explained earlier, the difference between Lime and Lyft could be that Lime was well-established before Lyft and has a higher market share. These findings will help operators rebalance their vehicles across the city to improve asset utilization and increase revenue. This information also could be used for customized pricing to offer some incentive to users to travel to regions with higher idle times.

Data-driven pattern mining

In this section, because of limited computational power available, we only used a subset of data which included one week from March 25 to March 31.

Sequence Mining

For the first step, we used a sequence mining technique to find a set of frequent geohashes (regions) visited at a different time of the day. We understand that, because there are no fixed docking stations under the dockless system, movement patterns are highly sprawled and stochastic. This leads to a lower value of support and confidence of the Apriori algorithm, respectively. Unlike in dock-based models, vehicle movements happen between fixed locations, so the support and confidence values are higher. The findings can be categorized into three groups: 1) groups of visiting points making one-leg trips (Figure 9), 2) groups of three-visiting points making two-leg trips (Figure 10), and 3) a group of four visiting points making three-leg trips. We focus only on the three-leg trips, as shown in Figure 11. The starting leg is illustrated in a light color and last leg in dark blue. There are two significant series of visiting points (numbered locations in Figure 11). One series started with the first leg from Franklin square to a point near the White House. The second leg takes longer, ending at a point near Capitol Hill. The last leg ended at Capitol Hill and the Library of Congress. The second important series of locations started at Madame Tussaud's museum area close to many shops, restaurants, museums, and galleries and ended at the Smithsonian Museum on the National Mall. The second leg extended to the Washington Monument and finally finished on the side of the National Mall next to the Lincoln Memorial. These two patterns imply that most commuters are probably tourists exploring the D.C attractions, Access to bike/scooter data offers an opportunity for a company such as Lime to rebalance its inventory while considering the location of its assets as well those of its competitors

Given that dockless scooters/bikes can be left virtually anywhere, we can assume that vehicles are most often parked at the most convenient locations for their users. This information could be used daily to rebalance vehicles across the city to match demand. This information can also be used by competitors like Capital Bikeshare (with fixed docking stations) to assess the optimality of current docking station locations.

Figure 9: Frequent 1-leg Trips

Figure 10: Frequent 2-leg Trips

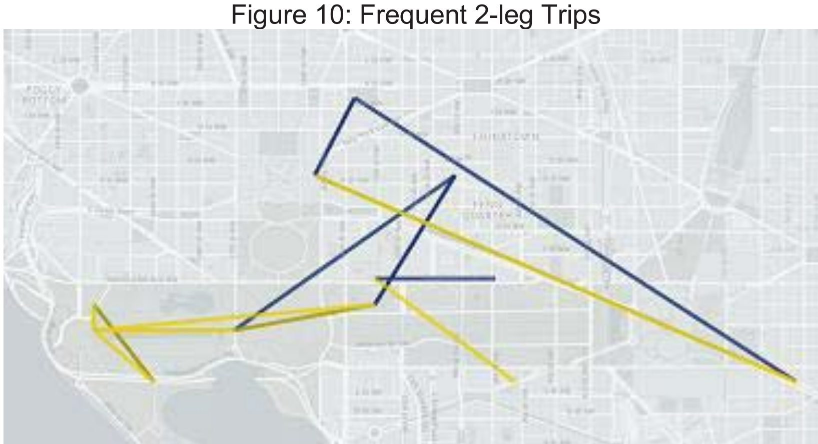

Figure 11: Frequent 3-leg Trips

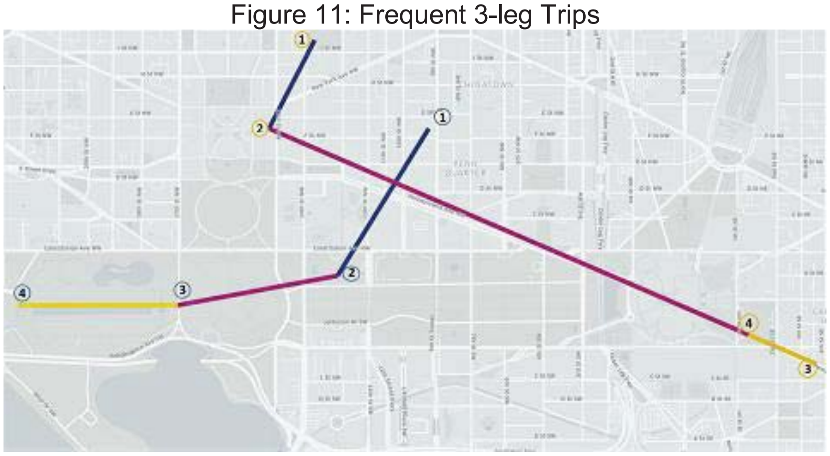

Clustering Similar Groups

In the second step, we tried to find groups of movement with some kind of similarities. Hence we do the clustering based on DBSCAN as described earlier in the methodology section. Feature extraction is done by the RBM method to extract 20 latent features in the dataset. For determining eps and minimum points for the DBSCAN algorithm, we calculated the k-nearest neighbor distance. The value of k is set to 22 and corresponds to minimum points. Next, these k-distances are plotted in ascending order. The aim is to determine the “knee,” which corresponds to the optimal eps parameter. A knee corresponds to a threshold where a sharp change occurs along the k-distance curve.

We employed the t-SNE algorithm to reduce the dimensionality of the dataset and visualize the structure in 2D space. The resulting plot is shown in Figure 12. The plot shows the presence of dense regions with arbitrary shapes surrounded with very tight empty space.

We also checked the silhouette score as an extra validation method for evaluating the consistency within the clusters of data. The coefficient ranges from -1 to +1. Values near 0 indicate that the object is on the border of two clusters. The silhouette score is based on the assumption of convex clusters, so their expected values in a non-convex case are generally smaller. However, we want to maximize silhouette scores ($\boldsymbol{silhouette} \rightarrow \mathbf{1}$) and at the same time avoid a large number of clusters.

We instantiated the DBSCAN model with eps = 0.003 and minimum samples = 22. As DBSCAN marks noisy points with the label -1, the resulting plot is shown in Figure 13. The total number of clustering, excluding noise, is 48. Moreover, eps = 0.003 is associated with the highest silhouette scores equal to 0.93, which indicates that the overall clustering is reasonably correct. We can also observe two fundamental results: the noise points (marked with a cross) are not isolated in the t-SNE representation, and some clusters are partially split. This is not a failure of the algorithm, but a direct consequence of the dimensionality reduction. In the original space, all noise points are not density-connected to any point in the sample but can be overlapping or close to some points in the t-SNE visualization. A large number of clusters is expected for the context of dockless shared mobility as movement patterns are individually shaped. For the purpose of this paper, we analyzed the five most significant clusters.

Figure 12: Visualization of Reduced Dimensions by t-SNE

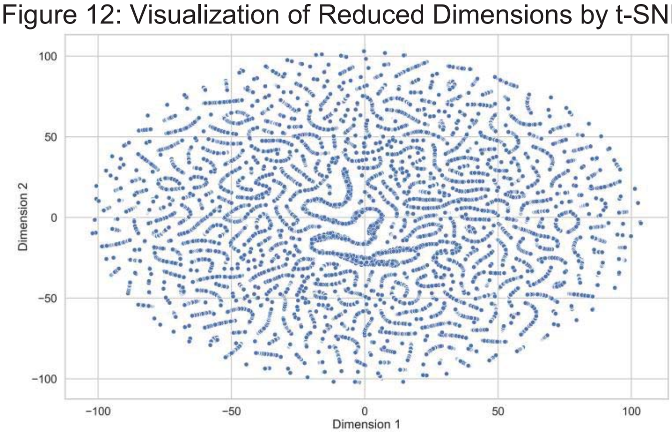

Figure 13: Visualization of Clusters in Reduced Format
