ABSTRACT

This paper examines the impact of economic and geopolitical events on stock market dependence using copula statistical theory. We focus in particular on the time periods before and after oil price shocks and the 2017 political crisis among the Gulf Cooperation Council members (i.e. the Qatari blockade), to examine possible changes in the dependence structure between the Qatari stock market and other stock markets in a group of emerging and advanced countries. Our findings show that the time varying dependence behaviour is associated strongly with the oil price crash and the geopolitical crisis in the region. The findings also show that the 2008 GFC has a stronger impact than the price shocks and political crisis.

KEYWORDS: Stock markets, Oil prices, financial crisis, Geopolitics, Qatari blockade, Market dependence structure, Copula, GCC

INTRODUCTION

Over the past three decades, the member countries of the Gulf Cooperation Council (GCC) have made a significant effort to improve the profitability, the efficiency, and the size of their capital markets. A sustainable privatization program and independent capital market regulators have improved the integration among the GCC stock markets, strengthening each financial market and attracting local capital investment in the GCC region (Basher, Nechi and Zhu, 2014; Alotaibi and Mishra, 2017). However, at the same time, such rapid financial integration among the GCC countries may be exposing them to financial, economic, and political crises that could result in a greater restriction on capital mobility (Karolyi and Stulz, 2003; Balcilar et *al*., 2015 and Belkhir et al., 2017).

In the GCC area, two major events have occurred since the 2008 global financial crisis. Since June 2014, oil prices have dropped sharply after a period of stability at around $105 per barrel. The prices have remained low, dropping to $26.19 per barrel on 11 February 2016. The average oil price in the period between June 2014 and the end of 2017 was about $50 per barrel. Multiple causes as well as the consequences of such oil price fluctuation have been identified and discussed in the recent literature (Baffes *et al.*, 2015; Fantazzini, 2016; Prest, 2018).

Further, on 5 June 2017, the country quartet of Saudi Arabia (SA), the United Arab Emirates (UAE), Egypt, and Bahrain proclaimed they were breaking diplomatic and economic ties with Qatar, citing many political reasons and accusations. Consequently, the transcontinental imports of goods to Qatar have been handicapped since the suspension of all air and sea travel links between Qatar and the quartet. The sanctions have had diverse impacts in the short run, particularly on trade, capital, and human flow.

While the economic aspects of the oil price crash and the Qatari blockade have been examined in existing literature, the association between these two particular events and the stock market integration in the region has not yet been investigated. However, several arguments advocate that such a relationship or linkage exists. First, some previous studies have documented that stock market dependence is affected by financial and economic crises. Rizvi *et al. (2017)* claimed that throughout the Asian financial crisis (1997), the integration of the Japan stock market with global stock markets declined. (Yang et al., (2015) document that the dependence between international stock markets has been affected by the global financial crisis of 2008. Second, political crises, such as wars, terrorist attacks, and other catastrophic events, may affect the economic and financial integration between countries. Enders and Sandler, (1996) and Enders et al. (2002) find that acts of terrorism negatively affect the foreign direct investment (FDI) flows of the countries involved. Frijns et al. (2012) conclude that political crises with certain characteristics generally reduce the level of stock market integration in these regions.

This paper falls under the recent strand of literature that analyses the impacts of economic and political crises on cross-market linkages. Specifically, we examine the stock market dependence structure between the Qatari stock market and other country stock markets, focusing on the period of the pre- and post-oil price shock and the pre- and post-2017 GCC political crisis period.

The study of the Qatari stock market is critical for several key reasons. First, GCC countries are among the major oil producers in the word and Qatar is one of the largest suppliers of natural gas reserves to the global economy, following Iran and Russia. Therefore, its stock market may be affected by oil price fluctuations. Second, since May 2014, Qatar has been reclassified from a frontier market to an emerging market and become a more attractive destination for investors and for portfolio managers. Third, despite its segmentation from international markets, the Qatari financial market is very sensitive to regional political events. From this perspective, the Qatar financial market offers an interesting case study for analysing the effects of a political crisis on regional and international financial integration through an investigation of the impact of the blockade, commonly known as the Qatar-Gulf crisis (Q-GC), which begin 5 June 2017. Fourth, few empirical studies have examined the dependence between Qatar and other financial markets by employing the copula approach, which is used in describing the dependence between random variables**.** Finally, to the best of our knowledge, no empirical research regarding the dependence between the Qatar stock market and other stock markets can be found in the literature. The findings of the paper have important implications for cross-market risk managers and international asset pricing.

This paper fills the void in the extant literature by investigating the dependence structure between Qatar and the GCC emerging stock markets and developed stock markets and by identifying the different regimes that resulted from the decrease/fluctuation in oil prices since 2014 and the Q-GC since June 2017. In this paper, we discuss the impact of these two major economic and political events that can explain the presence of structural breaks when examining the dependence structure between the Qatari stock market and the set of emerging and developed stock markets.

To depict a significant dependence structure among the stock markets, we use the Student's-*t* copula construct (see (Demarta and McNeil, 2007 for more details). This construct is a well-known measure that can generate joint symmetric tail dependence and capture the positive and negative extreme dependencies. Furthermore, we employ a time-varying copula model to describe the effects of exogenous events on the dependence structure of the studied series.

The rest of the paper is organized as follows. Section 2 reviews the related literature. Section 3 describes the models and estimation method. Section 4 presents the data and some statistics. Section 5 provides the empirical results. Finally, Section 6 concludes.

LITERATURE REVIEW

During the last few decades, substantial empirical research has investigated the dependence structure among financial markets because of its implications for investors, portfolio managers, hedging strategy design, and risk management (e.g. Mokni and Mansouri, 2017; Al Nasser and Hajilee, 2016; Hussain and Li, 2018; Yang *et al.*, 2015); Abul, Nechi and Zhu, 2014; Hao and He, 2018).

Specifically, several studies investigate the bi-directional relationship between stocks and financial markets (Coelho et al., 2007; Lucey and Muckley, 2011; De Groot et al., 2012; Claus and Lucey, 2012; Karanasos et al., 2016; Yang and Hamoi, 2013; Aloui and Hkiri, 2014). However, most of these examine the dependence structure between developed and emerging stock markets (Mokni and Mansouri, 2017); Yang and Hamoi 2013; Hussain and Li, 2018), emerging and frontier stock markets (De Groot et al., 2012), and developed, emerging, and frontier stock markets (Yang et al., 2015; Mimouni et al., 2016). Overall, the findings are mixed and seem to depend on the periods and the stocks markets investigated as well as the econometric methods used.

For instance, Hatemi (2012) examines the financial linkages between the UAE and the US stock markets between 7 June 2005 and 5 April 2011. He finds evidence of the integration between the markets and that the degree of integration is higher during periods when the two markets are falling rather than rising. Claus and Lucey (2012) conclude that segmentation levels vary among the Asia Pacific stock markets, indicating a limited degree of integration among them.

Al Nasser and Hajilee (2016) apply the bounds testing technique to explore the existence of long- and short-run linkages between emerging stock markets (Brazil, China, Mexico, Russia, and Turkey) and advanced financial markets (the US, UK, and Germany). They find evidence of the existence of short-run integration between emerging and advanced stock markets. In their long-run exploration, they find that Germany's stock market is the only determinant of integration with emerging economies. Using Archimedean copulas, Yang et al. (2015) inspect the dynamic dependence among developed, emerging, and frontier stock markets. Their findings indicate evidence of strong dependence between the investigated European stock markets and a weak dependence between frontier markets and others. The authors also find that dependence is asymmetric among these markets.

In a more recent contribution, Mokni and Mansouri (2017) analyse the conditional dependence between international stock markets in three different time intervals: pre-crisis, subprime and debt crisis, and post the two crises. Using a long memory GARCH-copula model approach, they find a significantly strong correlation between European markets.

Taking China as a case of study, Hussain and Li (2018) examine the dependence pattern of China on six developed stock markets (the US, Canada, Japan, Australia, the UK, and Germany). Using dynamic copula constructs and extreme value theory, the authors find that the dependence varies over time. The findings show a substantial dependence between China and each of the Asian and European countries, and, conversely, a weak dependence between China and the US.

Other empirical studies examine stock market dependency in other regions. For example, Mensah and Alagidede (2017) apply copula models to explore the dependence structure of African stock markets (South Africa, Egypt, Kenya, and Nigeria) with the UK and US markets. The results indicate that the dependence is dynamic; it is weak in Egypt, Kenya, and Nigeria and strong in South Africa. In addition, the results support that the dependence between the studied stock markets is asymmetric, suggesting that stock return co-movement diverges in bear and bull markets.

However, there is no study that examines the dependence structure in the GCC countries. This means that few empirical studies have considered the relationships between the GCC member stock markets and other international stock markets.

In the context of the GCC countries, most studies focus on crude oil and its relationship with stock markets (e.g. (Ma et al., 2014; Nusair, 2016; Jouini and Harrathi, 2014; Mohanty et al., 2011; Arouri, Lahiani and Nguyen, 2011). The conclusions of these studies are mixed. For example, Naifar and Al Dohaiman (2013) find that oil prices have a significantly positive impact on GCC stock markets. Arouri, Lahiani, and Nguyen (2011) and Akoum et al. (2012) reveal similar findings. Nusair (2016) investigates the dynamic relationship between oil price shocks and GCC countries. He finds that positive oil price changes are significant in all the GCC countries with the expected positive sign. In addition, he finds that negative oil price changes are significant only in Kuwait and Qatar. In contrast, Al Janabi, Hatemi-J, and Irandoust (2010) find that the relationship between oil price and stock markets is insignificant.

However, only a few past studies examine the dependence between the GCC members' stock markets and other international stock markets. For instance, Abul, Nechi, and Zhu (2014) employ copula theory to analyse the dependence structure of seven GCC stock markets (Bahrain, Kuwait, Oman, Qatar, SA, Abu Dhabi, and Dubai) in terms of daily returns between 2004 and 2013. They find significant evidence indicating that GCC stock markets are characterized by persistent and strong volatility. They also find that dependence is asymmetric. Another study (Aloui and Hkiri, 2014) investigated empirically the short- and long-term relationships among six GCC stock market returns (Bahrain, Kuwait, Oman, Qatar, SA, and UAE) over the 2005-2010 period. The authors found that co-movement depends on both frequency and time and is strongly affected by a financial crisis.

Some other studies have documented that stock market dependence is influenced by financial and economic crises. For example, Rizvi and Arshad (2017) argue that throughout the Asian financial crisis, the integration of the Japan market with global stock markets declined. Yang et al. (2015) document how the global financial crisis of 2008 affected the dependence between international stock markets. These same results are supported in the works by Mensi et al. (2014) and De Groot et al. (2012). Recently, Karanasos et al. (2016) focused on two financial crises: the 1997 Asian financial crisis and the 2008 global financial crisis. They observe how the interdependence among eight stock markets intensifies during crises periods due to contagion effects. In addition, Mokni and Mansouri (2017) provide evidence that the dependence among European stock markets is strongly affected not only by the global financial crisis but also by the European crisis of 2010-2011. The dependence increases during crisis periods. In contrast, Alotaibi and Mishra (2017) show that the degree of integration in the GCC stock markets declines after the 2008 global financial crisis. In addition, Fayyad and Daly (2011) show that Qatar, UAE, and the UK are more responsive to oil shocks than the US and the other GCC financial markets. Extending this existing literature, our study seeks to identify the different regimes resulting from the decrease and fluctuations in oil prices since 2014.

While the influence of financial economic crises on the dependence between stock markets has been investigated, the impact of political crises has not. In existing literature, acts of terrorism are considered as the main proxy for political crises (see, for instance, Kollias et al. 2011; Kollias et al., 2013; Mnasri and Nechi, 2016; Kolaric and Schiereck, 2016). In these studies, the impact of the political crisis on the financial market is investigated based on the marginal distribution of the stock prices or returns. None of these studies has investigated the political crisis effects on the dependence or on the conditional correlations between two distributions. Moreover, among the existing research, this empirical paper is the first to study the impact of the political crisis on the dependence between stock markets by considering the Qatari blockade as a proxy for political crises.

Motivated by examining the dependence structure between Qatar and other financial markets, this paper advocates the use of copula functions, which have become popular as flexible models in this field. To detect an interpretable dependence structure among financial data, we use the Student's t copula model (see Demarta et al., 2005 for more details). This model is a well-known measure that can generate joint symmetric tail dependence and capture the positive and negative extreme dependencies. We use the time-varying copula construct that allows us to model extreme events such as the oil shocks prevalent since mid-2014 and the Qatar blockade since June 2017.

METHODOLOGY

The empirical objective of this paper is to demonstrate that it is economically and statistically relevant to jointly model the behaviours of two different stock returns using a flexible copula approach that accommodates the presence of tail dependence and the time variation due to various economic and political events. In a first stage, we estimated a battery of static copula models and their corresponding time varying constructions (Gaussian, Student'*s*, and *SJC*). Then we selected the suitable copula by using the log likelihood and AIC information criteria. As shown in the appendix A, the static student's-*t* copula and its dynamic version perform better in almost all pairs of return series.

In this section, the $ARMA(p,q) - GARCH(1,1) - skT$ model is first described for the marginal process of each stock return. Then, the static student's-*t* copula and the used estimation method are introduced. The third subsection describes the time varying dependence structure modeling using copula.

Marginal processes

In the empirical financial studies, asset returns $r_{i,t}$ display common features called stylized facts, as for example autocorrelation and heteroscedasticity. The $GARCH$ specifications are known to be the suitable models for these financial return series (Bensaïda, 2015). Likewise, the optimal selection of an appropriate conditional distribution function is fundamental for the robustness of the copula construction (Joe, 2005; Ning, 2010; So and Yeung, 2014). Consequently, among various $GARCH$ specifications we select an $ARMA(p,q) - GARCH(1,1) - skT$ which is one of the suitable models allowing to capture the conditional heteroscedasticity of financial asset returns (Fei et al. 2017).
The marginals of the daily index returns, denoted r_t, consist of estimating the following model:

$$r_t = a_0 + \sum_{i=1}^{p} a_i r_{t-i} + \sum_{i=1}^{p} b_j \varepsilon_{t-j} + \varepsilon_t, \quad (1)$$

$$\sigma_t^2 = c_0 + c_1 \sigma_{t-1}^2 + d_1 \varepsilon_{t-1}^2, \quad (2)$$

Where the filtered returns $x_t = \varepsilon_t / \sigma_t$, $t = 1, \dots, T$, are assumed to be iid and $x_t \sim skT(0,1,\nu)$, with $\nu > 2$ corresponds to the number of degree of freedom distribution as proposed by (Hansen, 1992).

The estimation of the parameters of this $ARMA(p,q) - GARCH(1,1) - skT$ model are performed by the maximum likelihood (ML) method. Following the prior empirical studies (see for instance Jondeau and Rockinger, 2006; Fei et al. 2017) we fix the lag orders in the conditional variance (equation 2) at one since this specification is employed to capture the conditional heteroscedasticity of financial asset returns. We also used the Akaike Information criterion (AIC) to determine the optimal AR and MA lag order combination $(p\ ,q)$.

The static student's-*t* Copula

Any d-dimensional function, defined on $[0,1]^d$, with marginal distributed as standard uniform is commonly known as a d-dimensional copula C. Sklar's theorem states that all density funaction F with margins $F_1, \dots, F_d$can be expressed as

$$F(x_1, \dots, x_d) = C\big(F_1(x_1), \dots, F_d(x_d)\big) \quad (3)$$

Any copula C can be employed join various univariate density functions $F_1, \dots, F_d$ to create a multivariate density function F with margins $F_1, \dots, F_d$.

$$C(u) := C(u_1, \dots, u_d) = F\left(F_1^{-1}(u_1), \dots, F_d^{-1}(u_d)\right) \quad (4)$$

In the equation (4), F_1^{-1} correspond to the quantile functions of the margins. The copula C may be considered as the density function of the component wise probability transformed random vector$(F_1^{-1}(\mathrm{X}_1), \dots, F_d^{-1}(\mathrm{X}_d))'$.

The standardization of the marginal distributions guarantees that the copula remains invariant. Particularly, the student'*s-t* copula construction noted by (υ, μ, Σ) is identical to that of $t_d(\upsilon, 0, \Sigma)$ distribution where ρ is the correlation matrix implied by the dispersion matrix Σ. The unique copula is thus given by

$$C_{\nu,\rho}^{t}(u) = \int_{-\infty}^{t_\upsilon^{-1}(u_1)} \dots \int_{-\infty}^{t_\upsilon^{-1}(u_d)} \frac{\Gamma\left(\frac{\nu+d}{2}\right)}{\Gamma\left(\frac{\nu}{2}\right)\sqrt{(\pi\nu)^{\mathrm{d}}|\rho|}} \left(1 + \frac{x'\rho^{-1}x}{\nu}\right)^{-\frac{\nu+d}{2}} dx, \tag{5}$$

In this formula υ corresponds to the number of degree of freedom and t_υ^{-1} is the quantile function of a standard univariate student (t_υ) distribution. The notation can be simplified when considering the bivariate case and the notation becomes $C_{\nu,\rho}^{t}$.

Practically, the simulation of the student's-t copula is possible and can be performed by generatating a multivariate t-distribution random vector $\mathrm{X} \sim t_d(\upsilon, 0, \rho)$ by empolying the normal mixture construction (3) and then return a vector $U = (t_\upsilon(\mathrm{X}_1), \dots, t_\upsilon(\mathrm{X}_d))'$. It is also noted that the density of the t copula may be achieved using the equation (4) and implemented for the estimation resolutions has the form. This Student density distribution can be represented as follows:

$$c_{\nu,\rho}^{t}(u) = \frac{f_{\upsilon,\rho}(t_\upsilon^{-1}(\mathrm{u}_1), \dots, t_\upsilon^{-1}(\mathrm{u}_d))}{\prod_{i=1}^{d} f_\upsilon(t_\upsilon^{-1}(\mathrm{u}_i))}, u \in (0,1)^d, \tag{6}$$

where $f_{\upsilon,P}$ corresponds to the joint density of a $t_d(\upsilon, 0, \mathrm{P})$-distribution random vector and $f_\upsilon$is the density of the univariate standard t-distribution with υ degrees of freedom.

Properties of the student's-*t* Copula

To describe the dependence structure between two distributions by using any copula construction, it is important to evaluate Kendall's rank correlation allowing the depiction of the correlation between two entire marginal distributions. It is also important to assess the tail dependence coefficients to describe the pattern of dependence at the right and let tails of the distributions.

- Kendall's Rank Correlation

$$\rho_\tau(X_1, X_2) = E\left(sign\left(X_1 - \widetilde{X_1}\right)\left(X_2 - \widetilde{X_2}\right)\right), \tag{7}$$

where $\left(\widetilde{X_1}, \widetilde{X_2}\right)$ is a second independent couple with the identical distribution as (X_1, X_2).

It is important to note that kendall's tau rank correlation ρ_τ depends only on the copula but no (and not on the marginals (X_1 and X_2). The Kendall's tau rank correlation is presented by:

$$\rho_\tau(X_1, X_2) = 4\int_0^1 \int_0^1 C(u_1, u_2) dC(u_1, u_2) - 1. \tag{8}$$

- Tail Dependence Coefficients

The coefficient of upper tail dependence of X_1 and X_2 is defined by

$$\lim_{q \to 1^-} P\left(X_2 > (F_2^{-1}(q) \backslash X_1 > F_1^{-1}(q)\right) = \lambda_u, \tag{9}$$

provided the limit $\lambda_u \in [0,1]$ exists, and the coefficient of lower tail dependence, defined by

$$\lim_{q\to 0^+} P\left(X_2 > (F_2^{-1}(q)\backslash X_1 > F_1^{-1}(q)\right) = \lambda_l, \tag{10}$$

provided the limit $\lambda_l \in [0,1]$ exists. Thus these coefficients are limiting conditional probabilities that both margins exceed a certain quantile level given that one margin does.

The copula-based forms are $\lambda_u = \lim_{q\to 1^-} \frac{\bar{C}(q,q)}{1-q}$, $\lambda_l = \lim_{q\to 0^+} \frac{C(q,q)}{q}$, (11)

where $\bar{C}(u,u) = 1 - 2u + C(u,u)$ is the survivor function of the copula.

Estimation of the Student's- t copula

Writing $X_i = \left(X_{i,1}, \ldots, X_{i,d}\right)'$ for the i^{th} data vector, the method involves estimating the j^{th} marginal df F_j by

$$\hat{F}_j(x) = \frac{1}{n+1}\sum_{i=1}^{n} 1_{\{X_{i,j}\le x\}}. \tag{12}$$

The pseudo-sample from the copula is then constructed by forming vectors $\hat{U}_1, \ldots, \hat{U}_n$

$$\text{where } \hat{U}_i = \left(U_{i,1}, \ldots, U_{i,d}\right)' = (\hat{F}_1(X_{i,1}), \ldots, \hat{F}_d(X_{i,d}))'. \tag{13}$$

We notice that, even though the marginal vectors $X_1, \ldots, X_n$ are independent and identically distributed, the pseudo-sample data are dependent, because the marginal estimates $\hat{F}_j$ are issued from the entire original data vectors through the univariate samples $X_{1,j}, \ldots, X_{n,j}$.

Under some mathematical assumptions we can use the maximum likelihood method to estimate the parameters ν and ρ of $\text{student's} - t$ copula. The estimates are found by maximizing

$$\log L(\nu, \rho; \hat{U}_1, \ldots, \hat{U}_n) = \sum_{i=1}^{n} log c_{\nu,\rho}\left(\hat{U}_n\right) \tag{14}$$

Where $c_{\nu,P}^{t}$ denotes the density of the t copula in (6).

The time varying t-copula

There are evidence that dependence among financial assets does not remain constant over time (see Bouyé and Salmon, 2009) and Longin and Solnik, 2001). The dependence dynamics have important implications on the portfolio diversification reallocation strategies and help to identify how two assets behave jointly in various economic and financial conditions. Time-varying copulas are commonly considered as the dynamic generalizations of a Pearson correlation or Kendall's tau. In practice, time-varying copulas are frequently supposed to follow an autoregressive moving average (ARMA) (p, q) process, Patton (2006). Especially for the student's-t copula, the time varying copula construction is expressed as follows:

$$\rho_t = \Lambda\left(\Psi_0 + \Psi_1\rho_1 + \Psi_2\frac{1}{q}\sum_{j=1}^{q} \Phi^{-1}\left(u_{t-j}\right).\sum_{j=1}^{q} \Phi^{-1}\left(v_{t-j}\right)\right) \tag{15}$$

Where $\Lambda(x) = (1 - e^{-x})(1 + e^{-x})^{-1}$ is the modified logistic transformation. This transformation insure that the time varying coefficient of correlation be comprised in the interval $[-1,1]$.

DATA AND DESCRIPTIVE STATISTICS

Our empirical investigation relies on data from *Thomson Reuters Eikon* enhanced for the period spanning from August 1998 to June 2018. There are 14 countries in the sample divided into three groups: The first consists of the leading indices in GCC countries (Qatar, Saudi Arabia, United Arab Emirates, Oman, Kuwait and Bahrain. The second group is composed of four developed countries (USA, France, Germany and UK). The last group consists of four emerging financial markets (China, Turkey, Russia and India). The choice of these countries is based on the strength of the economic, financial and political relationship between Qatar and the others. The period of the empirical investigation is chosen to include the periods of pre and post oil price shocks and the pre and post 2017th GCC political crisis. This particular period covers also the global financial crisis (2007-2008) which significantly affected the volatility and the dependence between the stock markets of different nations.

The returns are calculated from the composite index of the major stock exchange in each country. Table 1 reports the summary statistics for the data series. The table shows that the GCC countries have the highest average returns among the three groups of countries studied (0.017 for GCC countries, 0.006 for the developed countries, and 0.0112 for the emerging ones). The highest volatility, measured by the standard deviation, is detected for the return series of the emerging countries (2.05); however, the GCC countries have the lowest variability with a standard deviation of 1.22. The comparison among countries shows that the Qatari stock market offers the highest average returns (0.033) and the highest volatility (2.507) among all the markets studied. Table 1 also shows that most return series exhibit skewness and excess kurtosis.

The Jarque-Bera test confirms this departure from the normality. The Ljung-Box test results suggests the presence of serial correlation in almost all return series. Moreover, the autocorrelation of the squared return series (Q^2 (10)) reveals that the dependence at long horizon is high enough to suggest a presence of ARCH effects. In addition, to test the stationarity, the ADF and PP unit root tests are performed and they fail to reject the hypothesis of stationarity for all return series indicating that the log first differencing is satisfactory to induce stationarity in prices.

The simplest way to describe the interdependence between financial markets is the use of the unconditional correlation coefficient (i.e., Pearson’s coefficient of correlation r) matrix. Graphically a scatter plot is also useful in describing the patterns of unconditional correlations.

The objective is to examine the direction and magnitude of market linkage or interrelationship without necessity to explore the driving forces, such as causalities, of the studied linear relationship. From a financial viewpoint, (Cheung and Ng, 1996)Cheung and Ng (1996) suggest that statistically significant correlation coefficients between inter-regional stock markets on the equal calendar day is considered as indication of spillover effects from the market to another.

Figure 1 displays the scatter plot and reports the correlation coefficients of daily returns and their respective significance levels.

The scatter plots clearly indicates the presence of extreme correlation and, thus, a presence of tail dependence for almost the return pairs. The tail dependence occurs in both the upper right and the lower left tail of the returns distribution pairs.

Moreover, the correlation patterns between returns seems to be non-linear. Accordingly, the Pearson’s correlations may be over- or under-estimated.The reported values show that the correlations between Qatari daily returns and the other GCC countries are positive and significant. On average, the correlation of the Qatari market equals 0.19; this value is higher than that obtained by Bley and Chen (2006) and lower than that obtained by Basher et al. (2014). The difference is mainly due to the periods studied and the frequency of the data in the previous studies. The Qatari market is more closely linked to the other GCC member markets than to the other emerging and developed markets studied. This indicates that the market integration is stronger locally (GCC area) than globally.

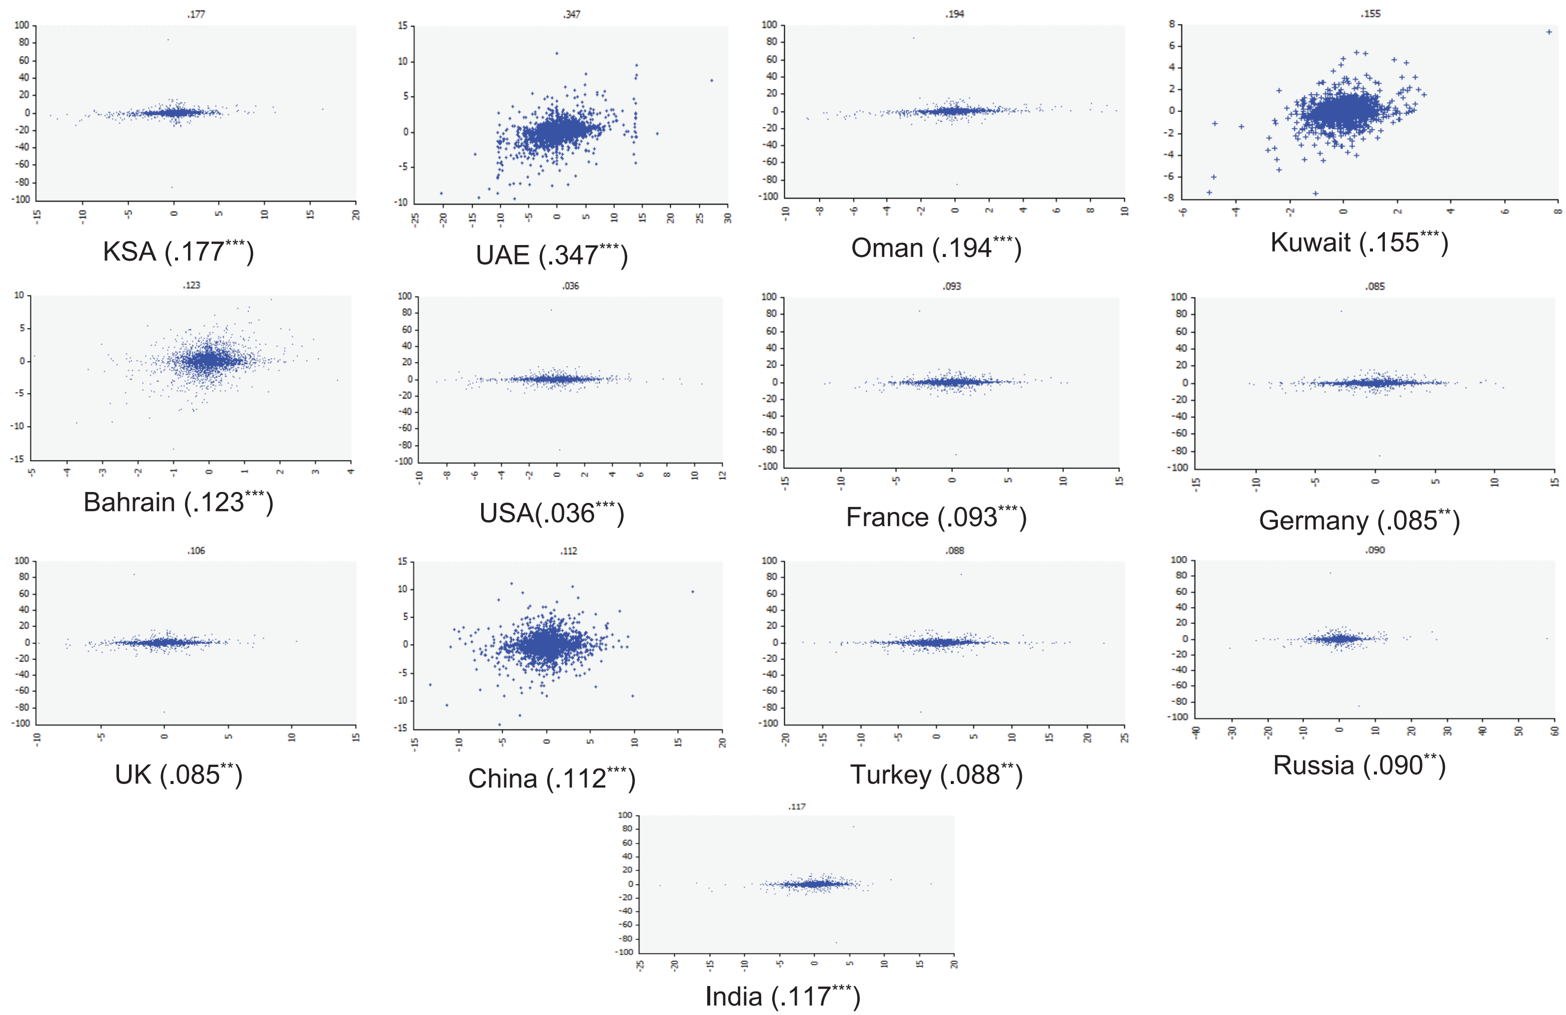
Notes: This table reports the main summary statistics for the return series for the 14 studied countries. The gives the p-value of the Jarque–Bera statistic test of normality and Q (10), Q^2 (10) which correspond to the Ljung–Box tests for 10th-order serial correlation in the returns and squared returns. The ADF and PP designate the Augmented Dickey and Fuller (1981) and Phillips and Perron (1988) unit root tests. *, **, and*** stand for 10%, 5% and 1% significance.

Figure 1: Scatter plots and correlation coefficients of market returns.



EMPIRICAL RESULTS

Marginal distribution estimations

Tables 2 and 3 report the maximum likelihood (ML) estimates for the conditional marginal distributions, ARMA-GARCH-*sk*t, of the daily returns for the GCC, emerging, and developed countries. The degrees of freedom (dof), ν, of the skt density is significantly small for almost all time series ranging between 3 and 6 for the GCC countries and between 6 and 9 for the emerging and developed countries. The low values of the dof suggest the index returns cannot be approximated by a normal distribution and that the developed countries' indices have fatter tails than the emerging and GCC countries' indices.

For the diagnostic checks of the marginal distributions, Panel B in Tables 2 and 3 show the result of the serial independence *Ljung–Box* (10) test on the first two moments of the estimated probability integral transformations, respectively: $(\hat{u}_t - \overline{u})^j$, $j \in \{1,2\}$, where $\hat{u}_t = F(\hat{x}_t)$, and $t = 1, \ldots, T$. Both the Q and the Q^2 statistics fail to reject the hypothesis of no serial correlation in the estimated residuals at conventional levels. Panel B in Tables 2 and 3 also reports the goodness-of-fit tests of Anderson-Darling and Cramer-von Mises for the null hypothesis that the transforms are $Uniform\ (0,1)$.

Tables 2 and 3 also show that the marginal models are well specified by the ARMA-GARCH-*sk*t specification and that the transforms are $Uniform\ (0,1)$. From the perspective of financial theory, the GCC, emerging, and developed countries' index returns display similar stylized facts as any other stock return series. Specifically, the investigated series show significant volatility clustering. Moreover, there is strong evidence of asymmetric behaviour among these returns. Finally, we see that the distribution of the stock returns fluctuates broadly according to the data series. Therefore, the standard GARCH specification under the highly flexible ARMA-GARCH-*sk*t model is appropriate to identify the true patterns of the studied index returns. Having well-specified marginal models is central to robust copula construction (Joe, 2005; Ning, 2010; So and Yeung, 2014).

Notes: See table 2

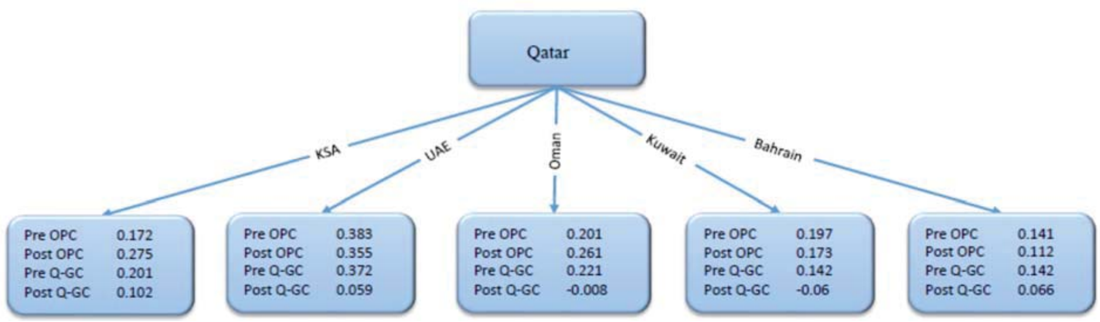
Static Student's-*t* copula results

Table 4 reports the results of the static Student's-*t* copula estimated parameters. Our analysis focuses on the discrepancy between the regional and international dependence structure.

Regional dependence

The results show that the order of the level of dependence for almost all the studied pairs is identical to that found by the linear coefficient of correlation examined previously. Specifically, for the GCC countries, the highest dependence is detected for the pair Qatar and UAE, followed by Oman and SA. However, a lower dependence is observed for the pair Qatar and Bahrain. These results reveal a strong integration of the Qatari stock market with the UAE and Oman stock markets and weaker integration of the former with the SA stock market. This low integration between the Qatari and Saudi markets is not specific to these two countries. Indeed, the Saudi market has the lowest levels of integration with each of the other GCC financial markets. Despite the fact that the Saudi stock market is the largest among the GCC members in terms of market capitalization, it remains inaccessible to foreign investors and risk managers (see, for instance, Alotaibi and Mishra, 2017).

Figure 2: The copula estimated dependence between Qatar and the other GCC stock markets



The results also show that the average of dependence significantly increases during the post-oil price shock period for the studied pairs in terms of the daily returns. In particular, in the GCC area, the increase in dependence is observed mainly for the following pairs: Qatar-SA, Qatar-UAE, and Qatar-Oman. However, the dependence with Kuwait and Bahrain, respectively, significantly drops after the oil shock.

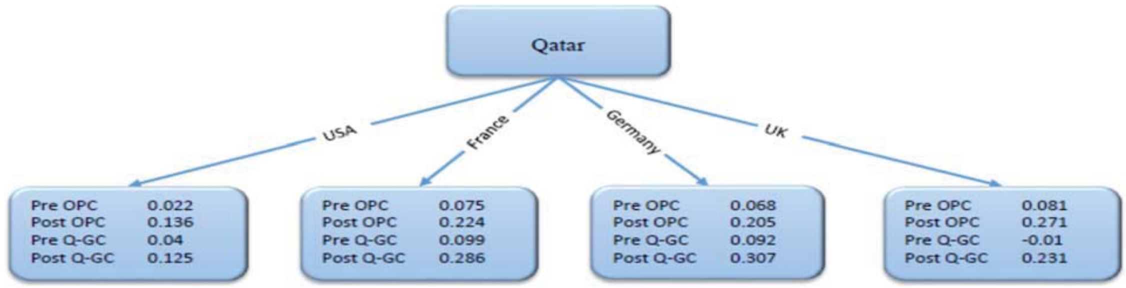
In the post-blockade period, the dependence between Qatari and each of the other GCC financial markets significantly diminishes, suggesting a decline in the level of regional integration. Interestingly, the dependence of the pairs of stock markets, Qatar-Oman and Qatar-Kuwait, becomes negative. Notably, these two countries are not among the blockade countries.

International dependence

Regarding the dependence between Qatari and each of the developed stock markets studied, the results indicate that the dependence between Qatar and US daily stock returns is the highest among the studied developed markets followed by the UK. The lowest level of dependence is between Qatar and Germany. In general, the dependence between the Qatar market and the developed financial markets is significantly weak. This implies that the Qatari financial market is isolated from most developed financial markets.

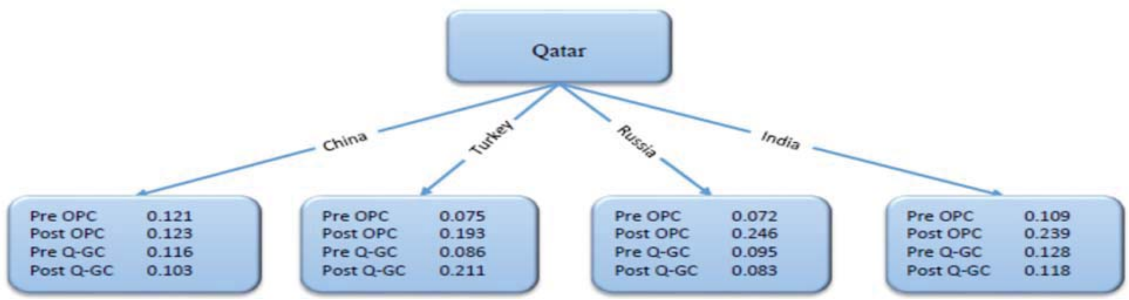
For the emerging markets, the highest level of dependence is between Qatar and China, followed by Qatar and India and Qatar and Turkey. Notably, there is a negative dependence between Qatar and Russia. According to the results, the Qatari financial market is integrated in the GCC area and is linked more closely to emerging markets than to developed ones.

Figure 3: The copula estimated dependence between Qatar and the developed stock markets



In the pre-oil price crash period, the increase in dependence is more significant with each of the developed countries (e.g. the dependence between Qatar and France increased from 0.075 before the oil price shock to 0.224 during the pre-crisis). Regarding the order, during the post-oil price shock, the Qatar financial market is linked more closely to the European countries (France, the UK, and Germany) than to the US market. The increase in dependence is also observed with all of the examined emerging countries.

Figure 4: The copula estimated dependence between Qatar and the emerging stock markets



As in the case of the developed markets, the order of dependence between Qatar and each of the emerging countries significantly changes after the oil price shock. After the shock, the highest level of dependence is between Qatar and Russia followed by Qatar and India and Qatar and Turkey. In contrast, the dependence between Qatari and China is the lowest among all the emerging markets studied.

Tail dependence

Tables 5a and 5b report the estimated tail dependence coefficients of the Student's-*t* distribution. The results indicate that for almost all the studied pairs of returns, the tail dependence parameters, $\tau_L and\ \tau_U$, of the Student's-*t* copulas are statistically significant, suggesting that the dependence at the lower and upper tails are symmetric.

The results also show that the pair Qatar and UAE has the highest tail dependence among the GCC countries followed by Qatar and SA. The lowest tail dependence is detected for the pair Qatar and Kuwait, and the tail dependence for the pair Qatar and Bahrain is statistically non-significant. The oil price shock does not affect the tail dependence parameter for all of the studied pairs. However, the blockade significantly affects the dependence structure in the GCC area. For all the pairs, except for Oman, the tail dependence parameter becomes non-significant, indicating that during the post blockade daily returns, the Gaussian copula is the most suitable to describe the dependence structure in the studied financial markets.

Table 5b shows that, except for Turkey, the tail dependence parameters between Qatar and the emerging countries' financial markets estimated for the full sample are statistically significant. The results also indicate that the tail dependence parameter between Qatar and the emerging financial markets significantly increases after the oil price shock. In contrast, the blockade significantly diminishes the dependence. More precisely, the tail dependence for the pairs Qatar and Turkey and Qatar and Russia becomes statistically insignificant.

Table 5b also indicates that for the developed countries, the tail dependence parameter estimated using the full sample is significant only for the pairs Qatar and the US and Qatar and the UK. It shows clearly that the oil price shock significantly increases the dependence at the tails between the daily returns of the Qatar market and the developed financial markets studied. Finally, the blockade event reduces remarkably the tail dependence between the Qatar market and the developed financial markets.

Overall, the static copula analysis provides two fundamental results. First, the oil price shock has a moderate impact on the dependence between Qatar and other GCC countries. Indeed, the strong integration between Qatar and the other GCC counties is not specific to Qatar. Actually, all the GCC member stock markets show the same integration patterns. This can be explained largely by the common GCC market status declared in 2008. The GCC common market status is aimed at forming a distinct location where the populations in the member countries have equal rights, including their engagement in several economic activities and services. It also calls for the unrestricted rights of property ownership and equity, movement of capital, and similar tax treatments. Hence, all these priorities, defined by the common GCC market status, are in favour of increasing the level of dependence and integration among the GCC members. Moreover, the different members of the GCC have taken similar actions to absorb the negative effects of the oil price crash.

The dependence of Qatar on both developed and emerging financial markets increased considerably after the blockade, indicating a growing level of international financial integration. This result is in contrast to that obtained previously on the integration between Qatar market and the other GCC stock market returns. The increase in the level of integration between Qatar and the emerging and developed financial markets after the blockade could relate to the government's support for the Qatari economy. Indeed, to deal with the undesirable effects of the GCC political crisis, the Qatari government has deposited billions of dollars into the local financial system, in particular, to prevent liquidity from drying up when Gulf residents started to withdraw their deposits. According to the central bank data, in August 2017, Qatar pumped 29.1 billion riyals into the financial market, growing public deposits from 273.5 billion riyals in July to 302.6 billion riyals. In August 2017, the central bank's international reserves and foreign currency liquidity increased to $38.3 billion, up from a low of $35.4 billion in July. In addition, the Qatar Investment Authority (QIA) has $300 billion in reserves that it could liquidate.

Further action has been to restructure supply chains in cooperation with new regional and international actors. In particular, Turkey's exports to Qatar grew by 42.3% in June and by 170.2% on an annual basis in July. Moreover, Qatar container lines have identified new shipping services via Oman, Kuwait, and the Indian subcontinent due to the blockade of Dubai as a trans-shipment port. Qatar is also looking to accelerate the effectiveness of its new Port with the objective of intensifying shipping routes to India, Oman, Turkey, and Pakistan. This would allow Qatar to import more food, construction materials, and other products. Securing food supplies is also one of the government's objective, as the country is dependent on imports for over 90% of its supplies.

These measures and the government's support have restored the trust of foreign investors in the Qatari financial system. New investors from several emerging and developed countries (e.g. Turkey, China, India) have replaced the GCC members. Consequently, the level of financial integration between Qatar and the international financial markets has increased. At the same time, the local integration (Qatar and the other GCC countries) has decreased significantly.

5.3 The time varying Student's-*t* copula results

In the static copula analysis, we compare the different regimes based on the fluctuation of oil prices since 2014 and the Q-GC crisis since June 2017. This first regime is based on the comparison between the pre- and post-events. The main technical finding in this first part sheds light on the fact that dependence between different markets is time varying. Moreover, the dependence between stock returns may be affected in various directions by economic and political events. Actually, the time varying copula analysis provides further information on the correlation patterns between the GCC members and the other stock markets during the period. The plots of the time varying parameters can provide interesting insights into the behaviour over time of the dependence between the Qatar stock market and the GCC, developed, and emerging stock market indices. The results of estimated time varying dependence parameters are reported in Tables 6a and 6b. These tables also report the estimated static Student's-t copula parameters for comparison.

The level of persistence is measured by the parameter Ψ_1, and the variation in the dependence process for the Student's-*t* copula is commonly captured by the parameter Ψ_2. As shown in Tables 6a and 6b, the persistence parameter Ψ_1 is significant at the 5% level in the time-varying student-*t* copula for almost all the stock return pairs. Moreover, this parameter is positive for all the pairs, except for Russia and the UK, in the post-blockade period. This result suggests a high level of persistence over time in the dependence behaviour between the Qatar market and the other international financial markets. This result is consistent with findings from previous studies (Chang and Hsueh, 2013; Wu and Liang, 2011; Wu and Lin, 2014).

The parameter Ψ_1 is also significant at the 5% level for practically all the pairs, showing considerable variations over time in the dependence between Qatar market and the other international stock markets. The positive values of this parameter for all countries suggest that the latest information on stock returns is a significant indicator for modelling the dynamic dependence between international stock markets.

Notes. See notes in Table. 6.a

Figure 5 illustrates the time path and average of the dependence structure between the Qatar market and the GCC, developed, and emerging stock markets, respectively. The area presented in grey corresponds to the post-oil price crash and the post-blockade periods. A third grey area corresponds to a period of high dependence between the studied stock returns. The average dependence is mostly weak (values near to zero) with uncommon exceptions. In the full dataset, the highest mean dependence (in absolute value) is found with the UAE with a value close to 0.4, followed by Oman, SA, and the other GCC stock markets. The lowest values are for Turkey and China. After the oil price crash, the average dependence increases for all the studied pairs, except for Bahrain. The increase of the average of dependence with the Qatari index is particularly substantial for the developed and emerging stock markets. For example, for the pair Qatar and the UK, the average dependence increases from 0.1 to 0.31 and for the pair Qatar and Russia, it increases from 0.089 to 0.247.

In the post blockade period, the average dependence decreases significantly for all the studied pairs. The mean of the dependence values in this period equals the values obtained for the full data.

Notably, Figure 5 shows a high dependence in the period 2007-2009 for all the studied pairs. This period corresponds to the recent global financial crisis. In this specific period, the dependence between the Qatar market and other stock markets peaks. In particular, the average dependence exceeds 0.6 between Qatar and the other GCC countries; reaches 0.3 between Qatar and the developed countries; exceeds 0.25 between Qatar and the emerging markets; and reaches 0.634 between Qatar and China. Thus, we provide evidence of an increasing level of market integration for all the markets in our sample due to the global financial crisis. This result is consistent with the existing literature on the impact of the recent global financial crisis on market integration (see, for instance, Frijns et al., 2012; Kumar and Okimoto, 2011; Alotaibi and Mishra, 2017).

This last result highlights the greater effectiveness of time-varying copula modelling. This implies that the static copula approach does not support the detection of hidden information related to the presence of regimes in the dependence between time series due to the impacts of several bad or good events.

Overall, our results show that the dependence between the Qatar market and the other international financial markets is time varying and significantly sensitive to political, economic, and financial crises.

24

CONCLUSION

This paper sets out to examine to what extent economic and political events affect stock market dependence. Empirically, we employ static and time varying copula approaches, which prove to be a convenient way to express multivariate distributions and take into consideration movement dependency, especially tail dependency between variables in the case of infrequent risk events. Broadly, the empirical findings report a time varying dependence between the Qatar stock market and the group of selected emerging and developed country stock markets. While previous studies have tried to investigate the impact of bad news on the dependence between financial markets by considering only one break (economic or political bad news), our study provides a more realistic exploration by considering more than one unique event. Indeed, the results of our empirical study show that the time varying behaviour of dependence is due to three major events.

Specifically, the oil price shock significantly affects the dependence structure between the Qatar stock market and the other stock markets. An increase in the international dependence does not significantly impact the local dependence (intra-GCC). The results also show that the oil price shock does not affect the tail dependence parameter for all the studied daily return pairs. In addition, our findings show that the blockade significantly affects the dependence structure in the GCC area. The blockade also affects the levels of dependence between Qatar and the rest of the developed and emerging countries. Finally, the empirical results show that the impact of the global financial crisis on the dependence structure is significantly stronger than the impact of either the oil price crash or the blockade.

In general, our results show that the dependence between the Qatar stock market and the other international financial markets is time varying and significantly sensitive to political, economic, and financial crises. Our results align in part with those of Charles and Darné (2006) and Dungey and Martin (2007), who point to market liberalization and financial crises as the main determinants of instability in the patterns of stock market links.

From a financial perspective, the increasing dependence between the Qatar stock market and other market returns during the post-oil price shock, the post-blockade, and the global financial crisis, corroborates the ‘contagion hypothesis’ during these periods. In recent financial literature (Forbes and Rigobon, 2002), ‘contagion effects’ are perceived as the significant increase in cross-market linkages after a shock to an individual country. Forbes and Rigobon (2002) explain the difference between ‘stock market interdependence’ and ‘the contagion effect’. The ‘contagion effect’ occurs if the stock market exhibits a significant increase in co-movement during the crisis compared to other periods of stability. However, ‘interdependence’ is viewed as a relatively constant correlation between stock markets and the absence of a significant interaction between stock markets and crises. Our results are similar to some previous studies including Garham and Kiviaho (2012), and Kiviaho et al. (2012), and Aloui and Hkiri (2014).

It is also important to note that the increasing level of dependence between stock market returns depends on the type of event considered. In fact, the results show that the global financial crisis has the largest impact on the increase in the dependence between the studied stock markets. However, the dependence between the Qatar stock market and each of the other GCC country markets is more sensitive to the oil price crash. This result suggests there is dissimilarity between the effects of the oil price shock and the blockade at the regional and international integration levels. This difference may be explained by the nature of the two events (economic versus geopolitical). These findings are important for portfolio diversification and asset management, risk management and international asset pricing. Future research should consider how financial dependence relates to financial and political crises, why these events have slowed dependence for some countries and increased it for others, and whether these effects are likely to be long lasting or temporary.

ABSTRACT

Maharatna companies are top most PSUs contributing greatly to the development of our nation. These companies have existed for a long time and became self-sustained without depending on government for funds. In recent past some of the companies have started reporting losses continuously and are on the verge of bankruptcy. The government has been infusing funds to safeguard them, but is not able to improve their performance to the desired level. This paper attempts to study the reasons for the current situation of these companies by applying the famous Altman Z-Score model to verify whether these companies really suffer financially. The sample for the study comprises of Maharatna companies, and the results reveal that not all the Maharatna companies are performing as expected.

KEYWORDS: Altman Z-Score, Maharatna, Navaratna, PSUs, Bankruptcy

INTRODUCTION

In the present world of globalization, the business environment is very much turbulent, and the manner in which the business operates is changing over time. With increasing competition and rising costs, many companies are on the verge of bankruptcy or becoming bankrupt. In light of this, it is very much important to measure the financial soundness of the enterprises, so as to safeguard the interest of the stakeholders associated with them. We can estimate the financial soundness of the companies by establishing the relationship between various financial variables. There are various studies, which attempted to study the nature of bankruptcies in various industries, and one of the most prominent among them was done by E.I. Altman, who developed the model named after him as the Altman’s Z score model.

The Altman Z-score is the output of a credit-strength test that gauges a publicly traded manufacturing company's likelihood of bankruptcy. The Altman’s Z-score is based on five financial ratios calculated from data found in a company's annual report. It uses profitability, leverage, liquidity, solvency and activity to predict whether a company has high probability of becoming Insolvent.

Maharatna companies are the top most PSUs contributing greatly to the development of our nation. These companies have existed for a long time and became self-sustained without depending on government for funds. In recent past some of them started reporting losses continuously and are on the verge of bankruptcy. The government has been infusing funds to safeguard them, but is not able to improve their performance to the desired level.

OBJECTIVES OF THE PAPER

1. To investigate the financial performance of Maharatna Companies with respect to selected ratios.
2. To study the relevance of ratios used in Altman's Z score model to predict the probability of a company becoming bankrupt.
3. To predict the possibility of bankruptcy of Maharatna Companies using Altman's Z score model.

METHODOLOGY

Collection of data: The study is based on secondary data analysis, and the data was collected from Bloomberg database. The supporting data was collected from various other sources.

Tools used: The Altman's Z score model was used to predict the bankruptcy of the companies considered for the present study.

Altman's Z score model: The model is one of the most important models used for predicting the possibility of bankruptcy of the companies. The Z-score is a set of financial ratios in a multivariate context, based on multiple discriminant model, which is a statistical technique used to classify and/or make predictions in problems where the dependent variable appears in qualitative form (Altman, 1968).

The formula for the standard Z-Score in case of manufacturing firms is:

Z-Score = $1.2T_1 + 1.4T_2 + 3.3T_3 + 0.6T_4 + 0.999T_5$

T_1 = Working Capital / Total Assets
T_2 = Retained Earnings / Total Assets
T_3 = Operating Earnings / Total Assets
T_4 = Market Capitalization / Total Liabilities
T_5 = Sales / Total Assets

A score below 1.8 means it's likely the company is headed for bankruptcy, while companies with scores above 2.99 are not likely to go bankrupt. Investors can use Altman Z-scores to determine whether they should buy or sell a stock if they're concerned about the company's underlying financial strength. Altman's Z-Score determines how likely a company is to fail, by evaluating seven simple pieces of data, all of which should be available in the company's public disclosure.

Altman originally developed the Z-Score for manufacturing firms primarily because those were the companies in his original sample. However, the emergence of large, public service companies prompted him to develop a second Z-Score model for non-manufacturing companies. The formula is essentially the same as before; it just excludes the last component (sales / total assets) because Altman wanted to minimize the effects of manufacturing-intensive asset turnover.

The formula for the Z-Score in case of service firms is:
Z-Score = $1.2T_1 + 1.4T_2 + 3.3T_3 + 0.6T_4$

Interpretation of the variables

1. The first ratio (working capital / total assets) is an indicator of a firm's ability to make good on what it owes in the next few months.

2. The second ratio is a good indicator of how in debt the company is and whether it has a history of profitability.
3. The third ratio is a measure of efficiency in that it indicates how much the company generates in earnings by efficiently using its assets.
4. The fourth ratio is a fluid measure of the market's confidence in the company.
5. The fifth ratio is similar to the third ratio in that it measures the company's efficiency in generating sales from its assets.

Altman Z Score			
Weight	**Factor**	**Ratio**	**Significance**
1.2	A	Working Capital / Total Assets	It measures the net liquid asset of a company relative to the total assets.
1.4	B	Retained Earnings / Total Assets	It measures the financial leverage level of a company.
3.3	C	EBIT / Total Assets	It measures productivity of a company’s total assets.
0.6	D	Equity / Total Liabilities	It measures what portion of a company’s assets can decline in value before the liabilities exceed the assets.
0.999	E	Sales / Total Assets	It measures revenue-generating ability of a company’s assets.

Altman’s Z Score	Zone	Interpretation
Z>2.99	Safe Zone	There is low probability of bankruptcy and the company is healthy
1.81<Z<2.99	Grey Zone	These firms are considered as cases which should be watched with attention
Z<1.81	Distress Zone	There is high probability of bankruptcy

The Z-Score is a commonly used metric with wide appeal, though it is just one of many credit scoring models in use today, that essentially combine quantifiable financial indicators with a small number of variables in an attempt to predict whether a firm will fail. Over time, however, the Z-Score has proved to be one of the most reliable predictors of bankruptcy, so much so that analysts often equate certain Z-Scores with corresponding bond ratings. When Altman re-evaluated his methods by examining 86 distressed companies from 1969 to 1975 and then 110 bankrupt companies from 1976 to 1995 and later 120 bankrupt companies from 1996 to 1999, the Z-Score gave accurate results between 82% and 94%. However, if the company’s financials are misleading or incorrect, the Z-Score will be, too.

MAHARATNA COMPANIES

A state-owned enterprise in India is called a public sector undertaking (PSU) or a public sector enterprise, owned by the union government of India, or one of the many state or territorial governments, or both. PSUs are further classified as central public sector enterprises (CPSEs) and state level public enterprises (SLPEs). In 1951, there were just five enterprises in the public sector in India, which increased to 246 by March 1991. CPSEs are companies in which the direct holding of the Central Government or other CPSEs is 51% or more. The Ministry of Heavy Industries and Public Enterprises administer them. Certain public sector undertakings have been awarded additional financial autonomy, which have comparative advantages, giving them greater autonomy to compete in the global market to support them in their drive to become global giants.

Financial autonomy was initially awarded to nine PSUs and given Navaratna status in 1997. In 2010, the government established the higher Maharatna category, which raises a company's investment ceiling from Rs. 1,000 crore to Rs. 5,000 crore. The Maharatna firms can decide on investments of up to 15 per cent of their net worth in a project while the Navaratna companies could invest up to Rs 1,000 crore without explicit government approval.

The country has witnessed the introduction of a new industrial policy in the 1990s that emphasized delicensing, greater independence for profitable PSUs and restructuring of loss-making firms through the Bureau of Industrial Financing and Restructuring (BIFR). Other elements of the liberalization involved free entry to private sector firms in industries reserved exclusively for PSUs, and disinvestment of a small part of the government's shareholding (while still holding majority stocks) and listing PSUs on the stock exchanges.

Eligibility Criteria for grant of Maharatna status
CPSEs fulfilling the following criteria are eligible to be considered for grant of Maharatna status:

1. Having Navratna status
2. Listed on the Indian stock exchange, with a minimum prescribed public shareholding under SEBI regulations
3. An average annual turnover of more than Rs. 20,000 crore during the last three years
4. An average annual net worth of more than Rs.10,000 crore during the last three years
5. An average annual net profit of more than Rs. 2,500 crore during the last 3 years
6. Significant global presence or international operations

<u>The list of Maharatna CPSEs is given below</u>
1. Bharat Heavy Electricals Limited (BHEL)
2. Coal India Limited (CIL)
3. Gas authority of India Limited (GAIL)
4. Indian Oil Corporation Limited (IOCL)
5. National Thermal Power Corporation Limited (NTPC Limited)
6. Oil & Natural Gas Corporation Limited (ONGC)
7. Steel Authority of India Limited (SAIL)
8. Bharat Petroleum Corporation Limited (BPCL)

REVIEW OF LITERATURE

Altman (1968) tried to assess the quality of ratio analysis as an analytical technique. He took a sample of sixty-six firms in two mutually exclusive groups, namely, thirty-three bankrupt firms and thirty-three non-bankrupt firms, and developed the multiple discriminant analysis for manufacturing corporations. The author explained that since ratio analysis is susceptible to faulty interpretation and can be analyzed subjectively, there is a need to develop a model that suitably removes the possible ambiguities observed in traditional studies. He developed a model known as the Altman's Z score model, which has been used extensively in various research studies.

Altman, Haldeman, and Narayanan (1977) developed a new model to identify bankruptcy risks of the corporations, named as the Zeta model, which considered the developments related to recent business failures. The new model was effective in classifying bankrupt companies up to 5 years prior to failure on a sample of corporations consisting of manufacturers and retailers.

Altman (2002) reviewed two important credit scoring techniques, the Z-score (developed by the author himself in 1968) and KMV's Expected Default Frequency (EDF) model with respect to default probabilities in general. He explained that the relevance of these credit scoring models are in accordance to the changes brought about by the Basel II norms and the increasing bankruptcy filings by large corporates.

Samarakoon and Hasan (2003) investigated the ability of three versions of Altman's Z score model (Z, Z', and Z”) to predict bankruptcy in listed companies in Sri Lanka, and the results revealed that these models have a very high degree of accuracy in predicting corporate distress.

Jayadev (2006) provided empirical evidence on the acceptability of the Z-score model. The author used three forms of the Z score model and estimated the coefficients in all the 3 equations by using a sample of 112 companies. The results of the study revealed that Altman's model was capable of predicting default possibilities in most of the sample companies.

Gerantonis, Vergos, and Christopoulos (2009) took a sample of all listed companies on the Athens exchange for a period of 2002-2008 and concluded that Altman's Z score model can predict failures.

Hayes, Hodge, and Hughes (2010) attempted to construct and interpret Z score and apply it to the retail industry in the study period during 2007 and 2008. Their sample constituted the public retail companies which had assets greater than $1,000,000 and had declared bankruptcy during 2007-2008. The results of the period under study accurately classified eight out of nine firms under investigation as bankrupt.

Ramaratnam and Jayaraman (2011) used Altman's Z score model to predict, analyze, and compare the financial health of the major steel companies in India during 2006-2010. The Z score was further tested using the ANOVA to analyze the consistency and stability on the different ratios used in Altman's Z score.

Raiyani and Bhatasna (2011) studied the financial health of the textile industry in India by considering four major players during 2002-2009 and applied the Altman’s Z Score model to these companies to predict, analyze, and compare the financial health of these companies.

Ray (2011) made an attempt to apply Altman's Z Score model on the Indian automobile industry and tested whether the model can accurately predict the cases of bankruptcy in the Indian automobile industry for the study period from 2003-04 to 2009-10. The author considered a sample of 62 publicly traded companies listed on the Bombay Stock Exchange.

Reddy (2012) made an attempt to study the association between liquidity, profitability, and risk factors by employing Altman's Z Score model on Dr. Reddy's Laboratories Ltd. during the time period 2005 -2011, and the study revealed that the company was not suffering from financial distress.

Ahuja and Singhal (2014) have applied Altman's Z score model to investigate the financial position of the companies operating I the Indian textile industry, with a sample of fifteen companies and concluded that the model can be used by banks to predict the signs of bankruptcy of firms and devise various strategies to overcome it.

ANALYSIS AND RESULTS OF ALTMAN'S Z SCORE

Table-1(a): Altman's Z score of Maharatna Companies

Name of the Company	2018	2017	2016	2015	2014	Mean
CIL	2.423	3.656	3.612	3.439	3.246	3.275
BPCL	2.757	2.918	3.65	3.468	3.383	3.235
GAIL	2.119	2.161	2.156	1.947	2.053	2.087
IOCL	2.214	2.324	2.038	1.858	1.88	2.063
ONGC	0.614	0.876	0.91	0.941	1.071	0.882
SAIL	0.791	0.533	0.572	1.118	1.285	0.86
NTPC	0.652	0.676	0.733	0.859	1.05	0.794
BHEL	0.493	0.537	0.48	0.466	0.619	0.519
Mean	1.508	1.71	1.769	1.762	1.823	1.714

Table-1(b): Altman's Z score Model of the companies

Z Score	Name of the Company
Z>2.99	Coal India Limited, Bharat Petroleum Corporation Limited
1.81<Z<2.99	Gas Authority of India Limited, Indian Oil Corporation Limited
Z<1.81	Oil and Natural Gas Corporation, Steel Authority of India Limited, National Thermal Power Corporation, Bharat Heavy Electricals Limited

Analysis and Results
The data of eight Maharatna companies are analyzed and the Z score was obtained for the period 2014-2018 using the Altman's Z score model. Table-1(b) shows the consolidated results of the Z score using Altman's Z score model. Table-1(a) shows the mean Z score value of the companies during the last five years. As per the mean score, only two companies, namely Coal India Limited, Bharat Petroleum Corporation Limited had a score of Z>2.99, which suggests that these companies are financially safe. However, the companies, namely Oil and Natural Gas Corporation, Steel Authority of India Limited, National Thermal Power Corporation, Bharat Heavy Electricals Limited had an average Z score of less than 1.81, which indicates that these companies are not performing well and are in the bankruptcy zone.

Detailed analysis of various variables of Altman's Z score

From Table-1(a), we can observe that Coal India Limited has the highest average Z score of 3.275, which is due to the market capitalization, which was the highest during 2017, but has decreased during 2018. Also, its EBIT is higher compared to other companies, but is showing a declining trend during 2018. Bharat Petroleum Corporation Limited has the second highest Z score of 3.235, which is due to its EBIT and Sales.

Tables 2 to 6 provides the detailed analysis of the variables used for Altman's Z score model. Table-2 shows the working capital to total assets ratio, which reflects the operational efficiency of the company. The ratio of all the companies have shown a declining trend, most of them being negative, which indicates the company's inability to meet its current obligations.

Table-3 provides the ratio of retained earnings to total assets, which is an indicator of the extent to which the assets of the company has been financed by retained earnings. The results indicate that for most of the companies, the ratio is showing an increasing trend, which is good for the companies. However, for BHEL, the ratio is negative, which indicates that the company has borrowed debt in excess of retained earnings to finance its assets.

Table-4 shows the analysis of EBIT to total assets, which indicates how efficiently a company is using its assets to generate earnings before interest and taxes. The results indicate that the ratio for all the companies is showing a decreasing trend, which is an alarming situation, and needs to be taken care of.

Table-5 indicates the detailed analysis of equity to total liabilities, which indicates whether the company has sufficient net worth to meet the total debt obligations. This ratio is directly related to the market capitalization of the companies, which in turn depend upon the trends in the stock market, which are affected by the macro economic factors. The results reveal that the ratio for most of the companies shows an increasing trend, which is a good sign, but for few of them, it has decreased, which needs to be analyzed in light of the macro economic factors.

Table-6 shows the analysis of sales to total assets, which measures the effectiveness with which the firm uses its total assets to generate sales revenue. Except for SAIL and CIL, the ratio for other companies has shown a decreasing trend. It indicates that these companies are not able to utilize their assets to generate sales revenue.

Table-2: Working Capital / Total Assets

Name of the Company	2018	2017	2016	2015	2014	Mean
BHEL	0.328	0.372	0.374	0.385	0.364	0.365

CONCLUSION

Sound financial health is an important requirement for the survival and growth of a business. Since crucial business decisions are taken keeping in mind the financial capability of the firm, it is important to select and use optimal tools to analyze and predict financial strength of the firms. Altman's Z Score is one of the effective models which helps in judging the financial position of the firm and predicting bankruptcy.

A bolder roadmap for gradually getting the government out of the business must be prepared with a hard look at the real economic benefits from some of the profit-making state-owned firms as well. For now, India could leave the Mahartana's which hold about one-third of total assets of all PSUs in state hands, but with a plan to make them world class companies.

ABSTRACT

This study describes a numerical taxonomy of stroke patients, which was developed with *k-means* cluster analysis methods, using 22 medical history variables. The patient sample comes from a stroke dataset of a tertiary referral hospital that houses an award-winning comprehensive stroke center. The data contain the patient-level data of 8,531 patients for a time period from January 2009 to March 2017. We provide insights for the operations management issues of stroke patient care processes and discuss the necessity to develop specific operating procedures and resource management policies for different patient groups.

KEYWORDS: Taxonomy, Patient Classification, Healthcare Operations, Stroke

INTRODUCTION

Organizations attempt to reduce process variations by standardizing their processes, which in turn improves the quality of products or services provided to their customers. However, standardizing hospital processes has proven to be challenging. One reason for this is due to inherently heterogeneous patient populations (Tucker et al., 2007). This study aims to provide an in-depth understanding of a patient population from a set of medical history variables involving a stroke patient sample by developing a numerical taxonomy. A numerical taxonomy is an effective method to determine distinct groups within which common characteristics are presented (Miller and Roth, 1994). As such, a numerical taxonomy using cluster analysis methods is useful in classifying patient populations.

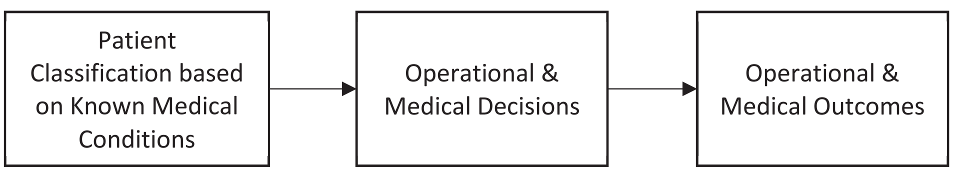
We reviewed two streams of literature on patient classification: i) the medical literature and ii) the operations management literature. First, in the medical research community, cluster analysis methods have been widely used to classify patients and compare patient clusters on medical outcomes. For example, Vanfleteren et al. (2013) use a self-organizing map cluster analysis method to classify chronic obstructive pulmonary disease (COPD) patients. They find 5 distinct patient groups based on the 13 comorbidities and conduct a further comparison analysis among patient groups on the patients' medical conditions. Also, Vu et al. (2011) use an agglomerative hierarchical clustering method to classify fall injury patients. They find 5 distinct patient groups based on the 22 comorbidities. Each study addresses a specific morbidity, and its related comorbidities are different from those of other studies based on different morbidities.

As such, each patient classification study generates a unique set of patient clusters. Studies on patient classification in the medical literature do not address how patient classification triggers medical or operational decisions, which in turn affects patient care outcomes. Rather, they heavily focus on medical outcomes or physician conditions among the different patient groups.

Second, patient classification in the operations management literature has been primarily applied to appointment scheduling (AS) methods. These studies utilize patient classification for sequencing and determining appointment intervals to examine the efficiency of the scheduling system based on outcome variables such as patient wait time, physician idle time, and overtime. Patient classification in this stream of literature could be as simple as new-return patients (Cayirli et al., 2008), outpatient-inpatient-emergency patients (Kolisch & Sickinger, 2008), or based on more patient characteristics such as self-reported health conditions, medication, etc. (Salzarulo et al., 2016). Although these studies for AS show how different patient classes or groups lead to different operational decisions, the use of medical information (e.g., comorbidities) is substantially lacking. Research that addresses both the link between patient classification and operational or medical decisions, and patient classification based on patients' medical conditions are scant. Hu et al. (2018) present a similar notion to what we are trying to achieve. Instead of patient classification, they use patient risk scores based on vital signs, lab results, diagnoses, and patient demographics to make informed decisions on the transfer of patients to the intensive care unit (ICU).

We attempt to answer the following research question with this study: Does a numerical taxonomy for patient classification trigger more informed medical and operational decisions for stroke patient care? Figure 1 describes the conceptual framework of how patient classification could help improve operational and medical outcomes. We first present how we classify patient groups using a numerical taxonomy and then discuss how such a classification could lead to informed medical and operational decisions for better outcomes.

Figure 1: Conceptual Framework



MEDICAL CONTEXT OF STROKE

Stroke is one of the leading causes of deaths, accounting for 5.2% of the total number of deaths in the United States, according to the 2015 National Center for Health Statistics (2017). Stroke care is highly time dependent because a typical stroke patient loses 1.9 million neurons every minute (Saver, 2006). Due to its severity and prevalence, stroke care has received national attention. The American Heart Association initiated "*Get With The Guidelines-Stroke (GWTG-Stroke)*" in order to provide hospitals with standardized patient data collection methods so that participating hospitals could measure their performance and compare their own performance with that of other hospitals. The ultimate goal of *GWTG-Stroke* is to improve stroke care processes, which essentially means faster treatment delivery to patients. Of the key performance measures from *GWTG-Stroke*, Door-to-Needle (DTN) time is considered one of the most important stroke care performance measures. The DTN time refers to the time elapsed between the arrival of a stroke patient at the hospital and the infusion of a thrombolytic medication called TPA (Tissue Plasminogen Activator) to the patient. The national target for the

DTN time recommended by the *Target:Stroke* initiative (which is part of *GWTG-Stroke*) is 60 minutes. Rewards (e.g., *Target:Stroke* Honor Roll) are given to participating hospitals who meet the target. *Target:Stroke* also provides 10 best practices for hospitals to follow in order to achieve or exceed the national target for the DTN time. Thus far, however, the *GWTG-Stroke* and *Target:Stroke* initiatives have not addressed the necessity of prompt gathering or access to patient medical history information, nor have they addressed information transfer from emergency medical service (EMS) providers to emergency department (ED) clinicians. Also, the national target and rewards system of *Target:Stroke* are not based on different patient medical conditions that hospitals receive.

METHODS

Research Setting and Data Collection

This study is based on a patient-level stroke dataset from a tertiary referral hospital that houses a comprehensive stroke center (CSC), the highest level of certification based on patient care capability. The hospital has over 800 certified beds, was certified as a primary stroke center (PSC) in 2009, and has been certified as a CSC since November 2017 by the *Joint Commission*. This hospital has actively participated in *Get With the Guidelines-Stroke (GWTG-Stroke)* since 2006 and the *Target:Stroke* initiative since 2011. Both programs are governed nationally by the American Heart Association. The hospital has won performance-based awards in stroke care (i.e., *GWTG-Stroke Gold-Plus* and *Target:Stroke Honor Roll Elite Plus*), and has been recognized by the American Heart Association.
The stroke dataset includes 8,531 patient visit episodes from January 2009 to March 2017. The dataset includes patient-level variables, such as patient demographic information, patient medical history, stroke type, arrival mode, time stamps of process milestones, insurance information, doctor information, etc. Patient demographics are summarized in Table 1. Approximately 45% of the patients in this sample were 70 years of age or older. There were about 3% more female patients than male patients. 78% of the patients were white, 21% were black, and less than 2% of the patients were Hispanic.

Table 1: Descriptive Statistics of Patient Demographics

Characteristics	**Sample (Total=8531)**	**Proportion**
Age Group		
< 50 years old (1)	1127	13.2%
50-59 years old (2)	1603	18.8%
60-69 years old (3)	1993	23.4%
70-79 years old (4)	1907	22.4%
80+ years old (5)	1901	22.3%
Gender		
Male (0)	4134	48.5%
Female (1)	4397	51.5%
Race		
White (0)	6635	77.8%
Black (1)	1791	21.0%
Asian (2)	52	0.6%
Native (3)	5	0.1%
Not Documented (4)	48	0.6%
Ethnicity		
Non-Hispanic (0)	8387	98.3%
Hispanic (1)	144	1.7%

Taxon Variables

In order to identify different groups of patients based on their medical conditions, we chose medical history variables as taxon variables, which were available from the stroke dataset. Such variables are standard patient medical history variables from *GWTG-Stroke* by the American Heart Association and include 22 comorbidity and stroke risk factor variables (American Heart Association, 2018 - *Get With The Guidelines®-Stroke Overview*). All of them are binary variables (= 1 for a condition present, = 0 for a condition not present). Table 2 describes the medical history variables. Approximately 4% of the patients in the sample did not have any of the medical conditions.

Table 2: Descriptions of Taxon Variables

Medical History Variable (Taxon)	Percent of Total Patients
Atrial Fibrillation or Atrial Flutter	15.4%
Coronary Artery Disease / Prior Myocardial Infarction	29.3%
Carotid Stenosis	5.5%
Current pregnancy	0.1%
Depression	11.4%
Diabetes Mellitus	33.2%
Drugs/Alcohol Abuse	5.8%
Dyslipidemia	48.4%
Family History of Stroke	7.8%
Heart Failure	10.2%
Hormone Replacement Therapy	1.3%
Hypertension	77.1%
Migraine	2.3%
Obesity/Overweight	37.4%
Previous Stroke	24.9%
Previous TIA	8.9%
Prosthetic Heart Valve	1.1%
Peripheral Vascular Disease	7.1%
Renal Insufficiency - Chronic	7.2%
Sickle Cell	0.1%
Sleep Apnea	2.8%
Smoker	26.8%

Cluster Analysis Procedures

We employed a cluster analysis to identify patient groups based on the medical history variables. The SAS ACECLUS (Approximate Covariance Estimation for CLUStering) procedure and the FASTCLUS procedure were used (Miller and Roth, 1994; Rosenzweig et al., 2011; and Lee et al., 2015). The ACECLUS procedure enabled us to "obtain approximate estimates of the pooled within-cluster covariance matrix," using the 22 medical history variables (SAS/STAT® 13.2 User's Guide: The ACECLUS Procedure 2018). The FASTCLUS procedure was subsequently employed to conduct a disjoint cluster analysis. According to the SAS/STAT® 13.2 User's Guide: The FASTCLUS Procedure (2018), “the FASTCLUS procedure uses Euclidean distances, so the cluster centers are based on least squares estimation. This kind of clustering method is often called a *k-means* model, since the cluster centers are the means of the observations assigned to each cluster when the algorithm is run to complete convergence. Each iteration reduces the least squares criterion until convergence is achieved.” Since all of the 22 medical history variables are coded in 0/1 binary codes and the units are consistent across all variables, standardization of the variables is not necessary.

To ascertain a suitable number of clusters, we contemplated using the R^2 and pseudo-F statistic. These statistics show notable increases with respect to the homogeneous nature of the clusters and the practical interpretability of the patient clusters based on ANOVA, Chi-square test, and Tukey (for continuous variables) or Dunn (for binary variables) pairwise comparison tests involving cluster mean or proportion differences. The four-cluster model best fulfills these two criteria. According to Wilk’s Lambda criterion and the F-statistic, the null hypothesis (four clusters are equal across all taxon variables) may be rejected (F-statistic= 562.95, $p <.0001$).

RESULTS

In this section, we report on the stroke patient groups based on patients’ prior medical history before arrival at the hospital for the treatment of stroke symptoms. We also report the differences among the patient groups on demographic, time performance, and other process-related variables.

Patient Groups based on Medical History

The four resultant patient groups are described in Table 3 in cluster centroid (mean) scores. Since we use binary codes, the scores essentially represent the percentage of patients in a cluster who had a particular medical history prior to the occurrence of stroke symptoms. We labeled these four clusters of patients as “Metabolic,” “Cardiovascular,” “Behavior,” and “Low Risk.”

Cluster 1: Metabolic. We label cluster 1 as “metabolic” because the patients in this group had a relatively higher likelihood of having conditions related to metabolic syndrome: diabetes, dyslipidemia, hypertension, and obesity (American Heart Association, 2018 - What is Metabolic Syndrome?). The 2,148 patients of cluster 1 represent 25 percent of the entire stroke patients in our sample.

Cluster 2: Cardiovascular. We label cluster 2 as “cardiovascular” because the patients in this group had a relatively higher likelihood of having cardiovascular diseases, such as atrial fibrillation or flutter, coronary artery disease, carotid stenosis, heart failure, previous stroke, previous TIA, a prosthetic heart valve, peripheral vascular disease, and renal insufficiency (American Heart Association, 2018 - What is Cardiovascular Disease?). Although patients in this group did not have the highest cluster means for previous stroke and renal insufficiency, they had the highest cluster means on all other cardiovascular disease histories. The 1,702 patients of cluster 2 represent 18 percent of the entire stroke patients in our sample.

Cluster 3: Behavior. Because this group of patients had the highest cluster means on both of the behavioral risk factors - drug and alcohol abuse and smoking among the four clusters, this group is labeled as “behavior.” The 2,001 patients of cluster 3 represent 24 percent of the entire stroke patients in our sample.

Cluster 4: Low Risk. The patients in this group had the highest cluster means on only two out of the 22 medical history variables (i.e., pregnancy and hormone replacement therapy) among the four clusters. We label cluster 4 as “low risk” patients. For all other medical history variables, this group had relatively low cluster means among the four clusters. The 2,680 patients of cluster 4 represent 31 percent of the entire stroke patients in our sample.

Table 3: Cluster Results - Patient Groups by Medical History

Medical History Variable	**1. Metabolic (n=2148)**	**2. Cardio-vascular (n=1702)**	**3. Behavior (n=2001)**	**4. Low Risk (n=2680)**	**Chi-square Statistic (p-value)**

Notes. The cluster means indicate the percentage of patients in the patient group that had the medical condition. The numbers in parentheses represent the groups that are significantly different from the particular group at the 0.05 significance level, based on the pairwise post-hoc Dunn test with Bonferroni adjustments. The bolded numbers indicate the highest group centroid for that variable.

Underlying Dimensions

A multiple group discriminant analysis was conducted to validate our model. We performed the SAS canonical discriminant analysis (i.e., SAS CANDISC) as a component of the SAS FASTCLUS procedure. We used four clusters as the dependent variables and the 22 medical history variables as the independent variables. Table 4 shows the discriminant analysis findings. The canonical loadings signify the correlations between the 22 medical history variables and the three discriminant functions. This is the result of N-1 dimensions, where N indicates the number of clusters (4 clusters). The measure of the multivariate association (γ_6), which is the average of the squared canonical correlations, is .583. Thus, 58.3% of the variance in patient group membership is explained by the set of the 22 medical history taxon variables (Cramer & Nicewander, 1979).

Table 4: Results of Canonical Discriminant Analysis

Canonical Correlation Function	Eigenvalue	Canonical Correlation (R_c)	Squared Canonical Correlation	p-value
1	2.312	0.835	0.698	<.0001
2	1.214	0.741	0.548	<.0001
3	1.012	0.709	0.503	<.0001

Notes. The high loadings in canonical functions ±|0.40| are bold numbers. Wilk's Lambda = 0.07 (F value = 562.95, df = 66, p <.0001) indicates a significant overall multivariate relationship for the 22 medical history taxon variables. The three canonical correlations (R_{c1} = 2.312, R_{c2} = 1.214, R_{c3} = 1.012) are statistically significant.

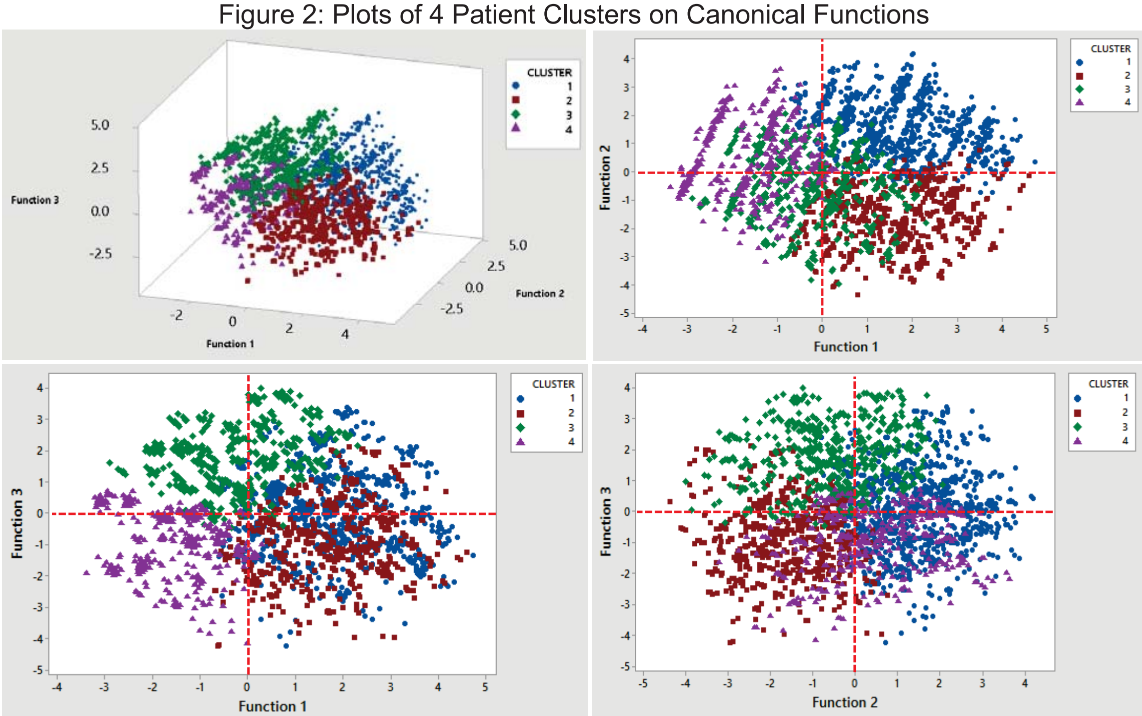
We interpret the underlying stroke patient dimensions based on the standardized canonical loadings. As indicated on the "function 1" column of canonical loadings in Table 4, the first canonical function has high loadings on some of the cardiovascular diseases and metabolic syndrome, such as coronary artery disease, diabetes mellitus, dyslipidemia, and hypertension. The second canonical function has a high loading on obesity. The third canonical function has a high loading on smoker.

However, labeling the dimensions using the canonical loadings is still not trivial. As an alternative approach, a graphical analysis is conducted in order to properly label the three dimensions. Derived from the canonical coefficients, the 4 clusters of the patients are depicted on a 3-dimensional coordinate, as shown in Figure 2. Patients in each cluster are located within distinct spaces in the 3-dimensional coordinate.

Based on the 3-D and 2-D plots of Figure 2 and the averages of the canonical coefficients for all patients, the locations of the patient clusters are summarized, as indicated in Table 5. Along with the first dimension (i.e., function 1), the metabolic and cardiovascular patient clusters have a high-level average canonical coefficient, whereas behavior and low risk patients have a low- level average canonical coefficient. This pattern is similar to the average ages of the patient clusters. Considering this similar pattern, we interpret the first dimension as being "age related," where a high canonical coefficient represents an older patient, and a low coefficient represents a younger patient.

Along with the second dimension (i.e., function 2), the average canonical coefficient is high for the metabolic patient cluster and low for the cardiovascular patient cluster. The average canonical coefficients for the behavior and low risk clusters are between high and low. With the exception of the low risk patient cluster, this pattern is similar to the proportion of female patients in each patient cluster. Accordingly, we interpret the second dimension as being "gender related," where a high canonical coefficient tends to be female, and a low coefficient tends to be male.

Figure 2: Plots of 4 Patient Clusters on Canonical Functions



Cluster Key: 1 = Metabolic; 2 = Cardiovascular; 3 = Behavior; 4 = Low Risk

Lastly, along with the third dimension (i.e., function 3), the average canonical coefficient is high for the behavior patient cluster and low for the cardiovascular and low risk patient clusters. The average canonical coefficient for the metabolic cluster is between high and low. This pattern is similar to the proportion of black patients in each patient cluster. The pattern is the opposite of the proportion of white patients. Accordingly, we interpret the third dimension as being "race related," where a high canonical coefficient tends to be black, and a low coefficient tends to be white. The black-white race dimension is plausible with our patient sample, as the two race categories account for 98.8% of all patients (i.e., 21.0% black and 77.8% white).

Table 5: Pattern Comparison between Canonical Functions and Demographics

Function or Demographic Characteristic	**1. Metabolic (n=2148)**	**2. Cardio-vascular (n=1702)**	**3. Behavior (n=2001)**	**4. Low Risk (n=2680)**
Function 1	High (1.58)	High (1.58)	Middle (-0.50)	Low (-1.90)
Function 2	High (1.51)	Low (-1.62)	Middle (-0.61)	Middle (0.27)

Function or Demographic Characteristic	1. Metabolic (n=2148)	2. Cardio-vascular (n=1702)	3. Behavior (n=2001)	4. Low Risk (n=2680)
Function 3	Middle (0.06)	Low (-0.88)	High (1.70)	Low (-0.76)
Age (years)	67.6	74.2	62.9	63.6
Female (%)	53.1%	47.5%	48.8%	54.9%
Black (%)	23.6%	15.2%	26.5%	18.5%
White (%)	75.3%	83.9%	72.6%	79.7%

Notes. The numbers in parentheses for the canonical functions represent the averages of the canonical coefficients for each cluster.

Statistical Cross-validation

A cross-loading analysis was performed to ensure that the estimates were stable. Table 6 presents the results of the cross-validation using a Jackknifing method in the SAS DISCRIM procedure. The total error rate (i.e., the percentage of misclassified cases) from the statistical cross-validation is 0.029, indicating that the 22 medical history taxon variables aptly classified the stroke patients.

Table 6: Cross-validation of the Number of Observations and Percentages

	1	2	3	4	
From/To	**Metabolic**	**Cardiovascular**	**Behavior**	**Low Risk**	**Total**
1	**2052 (95.53%)**	67 (3.12%)	12 (0.56%)	17 (0.79%)	2148 (100%)
2	17 (1%)	**1662 (97.65%)**	20 (1.18%)	3 (0.18%)	1702 (100%)
3	6 (0.3%)	29 (1.45%)	**1937 (96.8%)**	29 (1.45%)	2001 (100%)
4	2 (0.07%)	39 (1.46%)	4 (0.15%)	**2635 (98.32%)**	2680 (100%)
Error Rates from Cross-validation	0.045	0.024	0.032	0.017	**0.029**

Cluster Comparisons based on Associated Variables

Based on the clusters, we systematically examined the variables associated with patient group membership. The following sub-sections present the differences among the four patient clusters in terms of demographic variables, time performance variables, and other system variables.

<u>Demographic Variables</u>

Table 7 presents the comparisons among the four patient groups, based on each of the demographic variables. The “metabolic” patient group has the highest BMI (Body Mass Index) among the four groups. The “cardiovascular” patient group is the oldest group, has the highest proportion of white patients, and has the highest percent of individuals with Medicare and private insurance. Such differences are statistically significant from each of the other three patient groups. The “behavior” patient group has the highest proportion of black patients. Finally, the “low risk” patient group has the highest proportion of female patients.

Table 7: Demographic Variables Associated with Patient Groups

Variable	**1. Metabolic (n=2148)**	**2. Cardio-vascular (n=1702)**	**3. Behavior (n=2001)**	**4. Low Risk (n=2680)**	**F or Chi-square Statistic (p-value)**

* The cluster mean indicates the averages of the specified variable by each patient group. The numbers in parentheses represent the groups that are significantly different from the particular group at the 0.05 significance level, based on the Tukey pairwise tests.
** The cluster means indicate the percentage of patients in the patient group that met the specified variable condition. The numbers in parentheses represent the groups that are significantly different from the particular group at the 0.05 significance level, based on the pairwise post-hoc Dunn test with Bonferroni adjustments.
Note. The bolded numbers indicate the highest group centroid for that variable.

Time Performance Variables

Figure 3 visually describes the steps of the stroke patient care process and the time intervals that are used as performance measures for stroke patient care. Once a stroke patient arrives at the hospital, the patient receives a brain imaging in the CT (computer tomography) scan room in order to determine the type of stroke that the patient has. Then, the eligible patient receives a thrombolytic medication called TPA (Tissue Plasminogen Activator) (Davis et al., 2009). Once emergency care after TPA infusion is complete, the patient is admitted either to the regular floor or the ICU (Intensive Care Unit). Then, the patient is discharged from the hospital as his or her condition improves. The most critical in-hospital time interval is the door-to-needle (DTN) time. DTN is broken down into two sub-time intervals: Door-to-CT (DTC) and CT-to-Needle (CTN).

Figure 3: Stroke Patient Care Process Flow

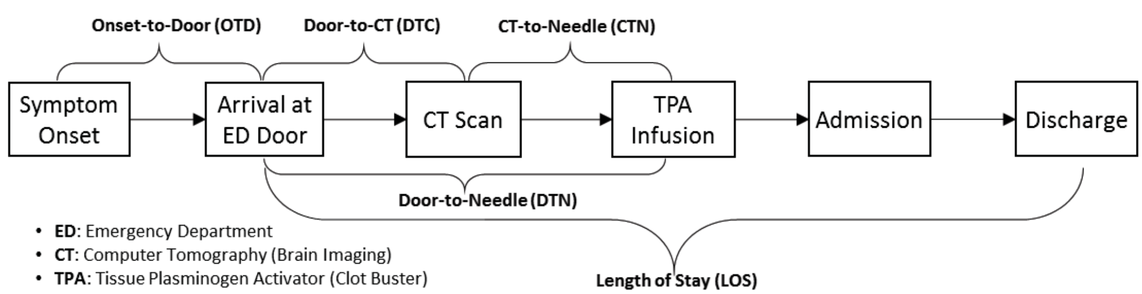

Table 8 presents comparisons among the four patient groups, based on each of the time performance variables. Interestingly, there is no significant difference in the DTN time among the four patient groups. However, among those who received TPA, the “metabolic” patient group took the longest DTC time (i.e., the front-end of the care process), while the “low risk” patient group took the shortest DTC time. Due to patients being overweight, it is possible that additional time may have been spent for a metabolic patient prior to the CT scan, e.g., transfer from the EMS stretcher to the CT bed. For the low risk patient group, the diagnosis time may have been shorter prior to the CT scan due to the smaller number of comorbidities that a patient had.

On the other hand, the “cardiovascular” patient group took the longest CTN time (i.e., the back-end of the care process), and the “metabolic” patient group took the shortest time. The TPA treatment decision by the neurologist may have been longer for the cardiovascular patient group because the patients in that group may have already been treated with anti-coagulant (blood-thinning) medications. Because using TPA treatment on such patients may cause certain complications, additional steps may have been taken to make a TPA treatment decision.

The differences in DTC and CTN among the different patient groups provide important information to stroke care teams regarding the prompt and proper use of the patient’s medical history. Obtaining the medical history information prior to the patient’s arrival or immediately after the patient’s arrival could be a critical factor in allocating the right resources, both in terms of clinicians and diagnostic/treatment equipment.

Table 8: Time Performance Variables Associated with Patient Groups

Variable	**1. Metabolic (n=2148)**	**2. Cardiovascular (n=1702)**	**3. Behavior (n=2001)**	**4. Low Risk (n=2680)**	**F-Statistic (p-value)**

Notes. The cluster mean indicates the average time spent for the specified time interval by each patient cluster. The numbers in parentheses represent the groups that are significantly different from the particular group at the 0.05 significance level, based on the Tukey pairwise test with Bonferroni adjustments. The bolded numbers indicate the highest group centroid for that variable.

Other System and Outcome Variables

Table 9 presents the comparisons among the four patient groups, based on other system and outcome variables. As for the type of stroke, the "metabolic" patient group had the highest proportion of ischemic and TIA (transient ischemic attack) patients among the four groups, whereas the "low risk" group had the highest proportion of hemorrhagic patients. Also, the "cardiovascular" patient group had the highest usage of EMS (emergency medical services). This could be partly because the cardiovascular patient group is the oldest group that has already experienced the benefit of using EMS over private transportation. Also, the cardiovascular patient group had strokes in healthcare settings, compared to the other patient groups. In line with the highest EMS usage, the cardiovascular group had the highest percentage of pre-notifying the hospital of the pending patient's arrival and the highest percentage of stroke alert activations. However, the cardiovascular group still had the highest percentage regarding the in-hospital mortality rate, which is due to the high severity of medical conditions prior to having a stroke.

Table 9: Other Variables Associated with Patient Groups

Variable	1. Metabolic (n=2148)	2. Cardio-vascular (n=1702)	3. Behavior (n=2001)	4. Low Risk (n=2680)	Chi-square Statistic (p-value)

Notes. The cluster means indicate the percentage of patients in the patient group that met the specified variable condition. The numbers in parentheses represent the groups that are significantly different from the particular group at the 0.05 significance level, based on the pairwise post-hoc Dunn test with Bonferroni adjustments. The bolded numbers indicate the highest group centroid for that variable.

DISCUSSION

Theoretical Contributions

We developed a numerical taxonomy of stroke patient medical histories by performing a cluster analysis. This taxonomy contributes to the medical literature by extending patient classification based on comorbidities and risk factors to the realm of stroke patient care and relating such patient classification with the operational variables. This study also contributes to the operations management literature by extensively using medical history variables to classify stroke patients and by relating such patient classification with the medically relevant operational issues. That is, we go beyond extant operations literature on patient classification, which is primarily focused on issues like patient appointment scheduling. Such literature only addresses time performances but does not address the operational issues that can influence medical outcomes. Results of our study suggest that patients in different patient groups may require different levels of resources, both human resources and physical resources such as diagnostic and treatment devices and medications. A hospital can improve time performances by allocating appropriate resources. For example, because the “metabolic” patient group takes a longer DTC time (i.e., the front-end process) potentially due to a longer time for patient bed change, more crew members may be assigned for the bed change. Also, because the “cardiovascular” patient group takes a longer CTN time (i.e., the back-end process), the key decision makers for TPA treatment such as radiologists and neurologists should start getting involved in the care process as early as possible. Moreover, because patients in the “metabolic” and “cardiovascular” groups are more likely to have an ischemic stroke or TIA (Transient Ischemic Attack), stroke care clinicians can begin preparing for ischemic stroke treatments including TPA treatment as soon as they identify the patient classification group. Our study can be an important platform for future research on how such patient classification affects operational outcomes that are associated with medical outcomes.

Our study contributes to the service operations literature, as it provides insights on how understanding customer (i.e., patients) groups might improve operational performance and customer satisfaction in a service setting where there is an inherently heterogeneous customer population.

Managerial Contributions

Our analysis results indicate that understanding patient groups based on medical history information can be critical in treating stroke patients in a timely manner. Hospital organizations must ensure the fast compilation of the patient’s medical history or timely access to the patient’s medical records. Two issues should be considered. First, the role of EMS providers is important for obtaining the patient’s medical history. If the EMS provider can make available the important medical history of a patient when he/she gives advanced notification of the pending stroke patient to the destination hospital, the hospital’s stroke team can be more appropriately organized, and the relevant equipment or medication can be prepared in advance. Our taxonomy suggests that a hospital may benefit from developing specific care procedures (i.e., resource allocations) for each of the stroke patient groups. That way, the in-hospital diagnosis and treatment time can be minimized. Currently, the *GWTG-Stroke* and *Target:Stroke* initiatives by the American Heart Association do not address ways of obtaining a patient’s medical history. Coordination between EMS and ED is certainly important, and developing a standard operating procedure on obtaining a patient’s medical history can improve such coordination. Second, the electronic medical records (EMRs) of patients should be readily available to the stroke team and shared between hospitals and between EMS providers and hospitals. That way, the stroke team does not have to rely on verbal information from the patient or the patient’s family members about his or her medical history. Moreover, from the physician’s point-of-view, many aspects of the patients need to be considered for the treatment plan in a short time period. Having 4 patient groups instead of 22 medical history variables would certainly reduce the information overload for the physician.

Currently, our research site hospital uses a universal target and reward criterion, regardless of the patient’s condition. As our analysis shows, there might be inherent differences in the realistically required time to treat stroke patients among the different patient groups. The hospital might have to consider a differentiated reward system for different patient groups in order to ensure fairness.

CONCLUSIONS

For a rich understanding of patient classification, we developed a numerical taxonomy using 22 medical history variables, including comorbidities and risk factors associated with stroke. We performed a *k-means* cluster analysis method, which resulted in 4 distinct patient groups. We labeled the 4 patient groups as "metabolic," "cardiovascular," "behavior," and "low risk," based on the holistic judgments from the cluster means. These 4 patient groups were located within distinct spaces in a 3-dimensional space, where the dimensions were developed based on canonical functions. The patient groups are different in terms of several demographic variables, such as age, gender, race, and the type of insurance that the patient has. More interestingly, they are different in terms of the operational aspects of stroke care, such as in-hospital time performance, mode of hospital arrival, stroke occurrence location, EMS pre-notification, stroke alert, etc. This suggests that the hospital could benefit from standardizing the patient care procedures for each of the patient groups and standardizing the way that the stroke team obtains the patient's medical history. Future research should investigate the casual relationship between patient classification and operational/medical outcomes.

ABSTRACT

In this study, we explored the factors that encourage or discourage healthcare organizations to adopt Cloud ERP, and whether organizational contingencies (e.g., organizational size) affect this adoption. Based on literature review, we proposed a research model of Cloud ERP adoption. Our model and findings can guide healthcare IT manager and support future research on this topic.

KEYWORDS: Cloud, ERP, Healthcare, Technology adoption

INTRODUCTION

Enterprise resource planning (ERP) systems support effective decision making in organizations by integrating various business functions (e.g., accounting, finance, human resources and operations) through extensive data processing (i.e., collecting, analyzing and sharing of data). Recently, there has been an accelerated transition from on-premise ERP systems to Cloud ERP systems in a variety of service and manufacturing industries. On-premise ERP systems (including data, software, and database servers) are internally hosted, and maintained by user organizations; while Cloud ERP systems are externally hosted, and related data are maintained by a third party vendor (Peng and Gala, 2014). To investigate this transition, a significant body of literature has recently been made available.

This literature primarily identified three issues: (1) the factors that encourage or discourage organizations adopt Cloud ERP, (2) whether the organizational contingencies (primarily organization size) influences Cloud ERP adoption, and (3) whether the industry type influences on Cloud ERP adoption. Regarding the first issue, Peng and Gala (2014) building on compressive literature review identified the factors that promote Cloud ERP adoption, these are: (1) reduced cost, (2) improved system speed and performance, (3) improved system upgrade, and (4) improved mobility and accessibility. They also identified factors that obstruct Cloud ERP adopting, these are: (1) lack of data privacy and control, (2) lack of data security, (3) vendor lock-in, (4) integration difficulties, and (5) organizational challenges.

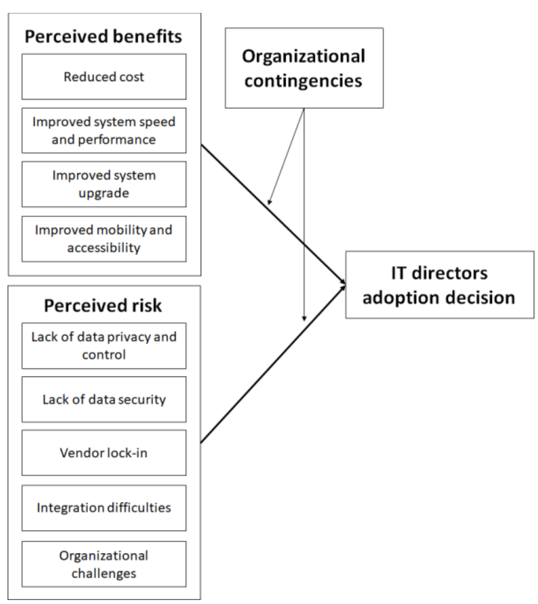
Regarding the second and third issue, this literature found evidence that the rate of the Cloud ERP adoption was dependent on organizational contingencies, specifically organizational size. This literature found that small and medium sized organizations were more likely to adopt Cloud ERP compared to large sized organizations. Also, they found out that Cloud ERP adoption has been successful in a wide variety of service and manufacturing industries. However, to the best of our knowledge, there are only a few number of studies on Cloud ERP adoption focused on the healthcare industry.

To address this gap, we investigate the following research question: *what factors influence Cloud ERP adoption in healthcare industry, and what organizational contingencies affects the adoption rate?* Healthcare is one of the major industries in the US (17 % of the GDP). There has been a significant effort in this industry to reduce costs and improve quality. One of these efforts that has become increasingly important is the adoption of Cloud technologies. However, the rate of adoption, particularly Cloud ERP, has been relatively slow compared to other industries. We believe our research findings can guide healthcare IT managers for the Cloud ERP adoption decisions.

LITERATURE REVIEW AND RESEARCH MODEL

The fundamental difference between on-premise ERP and Cloud ERP is where the ERP system is located and maintained. On-premise ERP is maintained by the organization internally, while a Cloud ERP system is maintained by the ERP vendor externally (Peng and Gala, 2014). This difference between on-premises ERP and Cloud ERP is associated with factors that enhance or obstruct Cloud ERP adoption. In this section, we summarize the literature on these factors, based on Peng and Gala's (2014) model, and proposed a research model for Cloud ERP adoption in healthcare (Figure 1). We built the model primarily considering Peng and Gala's (2014), because their model adequately covers the domain of research problem.

Figure 1. Cloud ERP adoption model



Factors that enhance cloud ERP adoption

Peng and Gala (2014) discusses the following four factors to enhance Cloud ERP adoption: (1) reduced cost, (2) improved system speed and performance, (3) improved system upgrade, and (4) improved mobility and accessibility.

Reduced costs

One of the benefits of Cloud ERP systems is its cost advantage over on-premises ERP systems. The literature discusses five different topics under cost advantage. Cloud ERP requires (1) less hardware investment; (2) less human resources for system operation and maintenance; (3) less start-up cost; (4) less total cost of ownership; and (5) have better cost transparency. Regarding the first topic, the research identified that on-premise ERP systems require a facility to run servers and hardware; while Cloud ERP systems do not require servers at the organization, significantly reducing these costs (Peng and Gala, 2014; Purohit et al., 2012; Castellina, 2011). Regarding the second topic, the research identified that organizations need to have costly IT professionals to operate and maintain an on-premise ERP system; while organizations reduces the need for these professionals with Cloud ERP systems (Peng and Gala, 2014; Johansson et al., 2015; Elmonem et al., 2016). Regarding the third topic, the research identified that any ERP system has certain upfront costs such as initial subscription fees and employee training. These costs are less for Cloud ERP systems (Peng and Gala, 2014; Johansson et al., 2015; Purohit et al., 2012; Elmonem et al., 2016; Castellina, 2011). Regarding the fourth topic, several research considered that the overall cost (i.e., hardware, human resources and upfront) associated with on-premise and Cloud ERP systems and found that Cloud ERP has a lower total cost of ownership (Castellina, 2011; Johansson et al., 2015). Regarding the fifth topic, the research found that the predictability of the cost is an important factor for adopting an ERP system. Relative to the on-premise ERP systems, Cloud ERP allows costs to be more transparent and predictable making it more desirable for organizations (Johansson et al., 2015; Elmonem et al., 2016). However there is research that suggest the opposite, such as there are many hidden costs of Cloud ERP (Elmonem et al., 2016; Gupta et al., 2017).

Improved system speed and performance

Another benefits of Cloud ERP systems is the improved system speed and performance. Three different topics are discussed under this factor. Cloud ERP (1) is faster to implement; (2) allows access to leading technologies and software; (3) enhances user satisfaction, efficiency, and multi-tasking. Regarding the first topic, the research provided extensive amount of evidence that on-premises ERP systems require significantly longer time to implement than Cloud ERP implementation, because Cloud ERP requires less hardware/software and employee at the focal organization (Johansson et al., 2015, Purohit et al., 2012; Elmonem et al., 2016; Elragal and El Kommos, 2012; Castellina, 2011). The faster, perhaps seamless, implementation allows organizations to achieve ERP benefits quickly. Regarding the second topic, the research reported that Cloud ERP systems allow access to the most advanced technology that fits the complex needs of customers and can be integrated with the other systems of the customers, supporting to achieve higher speed and performance (Johansson et al., 2015; Castellina, 2011). However, there are opposite claims, stating the integration can be problematic for Cloud ERP (Peng and Gala, 2014; Elmonem et al., 2016; Gupta et al., 2017). Regarding the third topic, the research explained that Cloud ERP results in higher level of satisfaction, efficiency and multi-tasking. Since the vendors use hundreds of servers and large data storage capacity, an ongoing operation (such as MRP calculation) would not slow down another ERP functionality, such as searching or printing specific products or customers. This high performance system would eventually lead to increased client satisfaction and efficiency (Peng and Gala, 2014).

Improved system upgrade

Another benefits of Cloud ERP is the improved system upgrade over on-premises ERP systems. Three different topics are discussed under this factor. Cloud ERP allows (1) centralized, automated and seamless upgrades by the vendor; (2) higher scalability and flexibility; and (3) access to the latest software and upgrades. Regarding the first topic, the research explained that Cloud ERP upgrades is centralized, meaning all the upgrades needed is managed by one party (i.e., ERP vendor), and upgrades are automated and seamless because this is vendors' core competency (Peng and Gala, 2014; Castellina, 2011). Regarding the second topic, the research found that Cloud EPR is more flexible and scalable (Peng and Gala, 2014; Johansson et al., 2015; Purohit et al., 2012; Elmonem et al., 2016; Elragal and El Kommos, 2012). Flexibility (i.e., ability to customize the ERP system) and scalability (i.e., ability to change capacity in a cost efficient manner) enables organizations to adapt rapidly and with minimal cost to the changing needs of the market and thus to compete more efficiently with other organizations (Johansson et al., 2015). Regarding the third topic, the research found that ERP vendors usually has the most advanced IT infrastructure and expertise, so they can offer the latest upgrades more frequently (Johansson et al., 2015; Elmonem et al., 2016). Further, this research explains that improved upgrading capability is particularly important for small and medium size organizations. These organizations need flexibility and scalability because of significant uncertainty in their operations. In addition, they do not have enough IT resources to constantly upgrade their systems and access to the most advanced technologies and software (Johansson et al., 2015).

Improved mobility and accessibility

Another benefit of Cloud ERP is the improved mobility and accessibility. Accessibility and mobility means that system can be accessed from anywhere through a web browser and a mobile device (Peng and Gala, 2014; Johansson et al., 2015; Purohit et al., 2012; Elmonem et al., 2016). Peng and Gala (2014) stated that accessibility and mobility is particularly important for sales personnel who may require access to the ERP system outside the organization. In addition, they stated that accessibility and mobility is important for organizations with multiple branches. Multi-site on-premise ERP installations may require additional hardware and on-site IT personnel, significantly increasing the cost. Cloud ERP systems are already mobile by design. In most cases, all it takes is a standard browser to reach company's Cloud ERP system. With Cloud ERP, the system is used by more people, more frequently in wider functional areas of business (Purohit et al., 2012; Johansson et al., 2015; Elmonem et al., 2016).

Factors that hinder Cloud ERP adoption

The literature discusses the following five factors frequently as hindering Cloud ERP adoption: (1) lack of data privacy and control, (2) lack of data security, (3) vendor lock-in, (4) integration difficulties, and (5) organizational challenges.

Lack of data privacy and control

One of the hindering factors of Cloud ERP adoption is the lack of data privacy and lack of control compared to on-premises ERP systems. Data privacy and control is about user's concerns over the vendor's not properly and cautiously handling of data and not being transparency of the data handling processes. Specifically, the literature discusses three different topics under this factor. These are: (1) lack of control in system and data storage; (2) losing technical capabilities; and (3) lack of trust in the vendor. Regarding the first issue, the research reported that lack of control can be a major issue because of inconsistent data protection laws and policies. In addition, some vendors may not be transparency of their data storage processes, such as the data being stored in different locations around the globe (Peng and Gala, 2014). Also, client concerns are reported that data in the Cloud can be exposed to the competition, get corrupt or lost, causing significant damages (Castellina, 2011; Gupta et., 2017). In addition, these concerns increased when the data is sensitive, such as patient information (Elmonem et al., 2016). Further, the research reported that the lack of control is not only about data, but also other processes such as upgrading process (Castellina, 2011), which is another concern for the organization. Regarding the second issue, Cloud ERP may result in organizations to lose technical competencies, since they become dependent on the technical capabilities of the vendor. This creates strategic risks in the long-term, since the organization may not properly evaluate the risks and take the mitigating actions related to information technology (Elmonem et al., 2016; Saa et al., 2017). Regarding the third issue, storing organization's private data in a cloud ERP system requires trust in the vendor. Lack of integrity, consistency, transparency and reliability in data processing and storage practices may lead to lack of trust by the client which may hinder Cloud ERP adoption (Gupta et al., 2017; Saa et al., 2017).

Lack of data security

Another hindering factor of Cloud ERP systems is lack of data security over on-premises ERP systems. Data security prevents unauthorized access to computers, databases and websites. The research frequently reported that lack of data security is a major concern for organizations to adopt Cloud ERP (Peng and Gala, 2014; Johansson et al., 2015; Elmonem et al., 2016; Gupta et al., 2017; Saa et al., 2017; Elragal and El Kommos, 2012; Castellina, 2011). Specifically, Peng and Gala (2014) reported that poor data protection practices may result in unauthorized data access. Further, Saa et al. (2017) stated that vendor organization can leak the information and Cloud user may not have control or security protocols and standards to prevent it. Also, smaller Cloud ERP vendors may have poor data protection measures, network monitoring and lower data management standards (Peng and Gala, 2014; Gupta et al., 2017). However, today many third party Cloud technology providers are large companies such as Amazon, Google, Microsoft and IBM, which provide extensive data security measures. Also it should be noted that the majority of data security issues are caused by human errors/actions rather than technologic weakness (Peng and Gala, 2014).

Vendor lock-in

Another risks of Cloud ERP systems is the vendor lock-in, which creates customer dependency on a vendor for the ERP services, and incurs high switching costs. There are five different topics discussed under this factor. These are: (1) high cost of ERP migration; (2) High long-term cost; (3) legal and contractual restrictions; (4) vendor's network dependence; and (5) variance and uncertainty in service quality of different vendors. Regarding the first topic, the research identified that organizations may not implement Cloud ERP because of high switching costs. Cloud ERP adoption requires a high level of commitment, time and effort for the client, leading to high switching cost. Although this is a common situation with any large software/hardware system, Cloud ERP may introduce additional difficulties to switch vendors due to distributed nature of servers, database systems, and software platforms used in the Cloud ERP systems (Peng and Gala, 2014; Johansson et al. 2015; Elmonem et al., 2016; Gupta et al., 2017). Regarding the second topic, the research identified that organizations may not implement Cloud ERP because of high long-term cost. Although start-up costs with Cloud ERP could be lower than on-premises ERP installation, annual subscription fees, and fee based upgrades could add up to significant cost figures. (Elmonem et al., 2016; Gupta et al., 2017). Regarding the third topic, the research identified that organizations may not implement Cloud ERP because of legal and contractual restrictions. The Service Level Agreement (SLA) may give the Cloud vendor additional rights to make the switch more difficult (Peng and Gala, 2014; Saa et al., 2017). Regarding the fourth topic, the research identified that organizations may not implement Cloud ERP because Cloud ERP can make the organization dependent on not only to the vendor but also vendor's network. Many Cloud ERP vendors partner with IT services providers (e.g. Amazon, IBM, Google, Microsoft) in terms of IT infrastructure and software platforms. This supply chain network may introduce additional dependencies on third parties for the client (Gupta et al., 2017; Saa et al., 2017). Regarding the fifth topic, the research identified that organizations may not implement Cloud ERP because of the variance and uncertainty in service quality of different cloud vendors. Cloud ERP is a relatively new technology compared to on-premise ERP systems, which may create uncertainties and concerns about the Cloud ERP service quality. Also, vendor-to-vendor service quality differences may be difficult to assess when selecting the right vendor, or hesitate to change the vendor (Peng and Gala, 2014).

Integration difficulties

Another risks of Cloud ERP systems is the integration difficulties. There are two topics discussed under this factor; these are: (1) customization and integration difficulties; and (2) functionality limitations. Regarding the first topic, the research identified that organizations may not implement Cloud ERP because of customization and integration difficulties (Peng and Gala, 2014; Johansson et al., 2015; Elmonem et al., 2016; Gupta et al., 2017; Castellina, 2011). Integration difficulties mostly stem from the fact that Cloud ERP systems could be incompatible with existing legacy systems at the client. Also, vendors may prohibit or limit third party software access needed for seamless integration and impose it in their service contracts. (Peng and Gala, 2014). On the other hand, in terms of functionality limitations, Cloud ERP modules offered by the vendor may not be as comprehensive or functional as the on-premises counterpart, which could lead to the use of more legacy and complementary software systems along with Cloud ERP, imposing more need for integration (Elmonem et al., 2016; Gupta et al., 2017).

Organizational challenges

Another risks of Cloud ERP systems is the organizational challenges. There are three main organizational challenges: (1) lack of top management support; (2) resistance to change; (3) inadequate understanding of Cloud ERP technology and business processes. Regarding the first topic, the literature emphasized the importance of upper level management support for Cloud ERP adoption. There are several reasons the top management may not support Cloud ERP, including financial risks, and strategic mismatch (Peng and Gala, 2014; Elmonem et al., 2016). Regarding the second topic, the research found that some organizations may be reluctant to change from a traditional system to a Cloud based system, primarily due to unwillingness for making process and cultural changes. This research mentioned that the change management could be difficult and organization may not know how to communicate the change and implications resulting from the Cloud ERP adoption (Peng and Gala, 2014; Johansson et al., 2015). Regarding the third topic, managerial lack of adequate technical knowledge on Cloud technology, its capabilities and limitations, inability to assess its benefits, costs and risks, unfamiliarity with legal, jurisdictional and compliance issues of Cloud ERP are cited by the researchers as hindrance for Cloud ERP adoption. The research also found that the organization may have difficulty understanding how to implement Cloud ERP in their internal business processes, resulting not to choose Cloud ERP (Peng and Gala, 2014; Elmonem et al., 2016; Gupta et al., 2017).

Organizational contingencies

Typical organizational contingencies, such as organizational size, industry and organizational structure (decentralized vs. centralized) could be significant factors for Cloud ERP adoption and success. The literature specifically reports that the *size* of the organization moderates the impact of motivating and hindering factors on the adoption decision (Johansson et al., 2015; Purohit et al., 2012; Elmonem et al., 2016; Gupta et al., 2017; Saa et al., 2017; Elragal and El Kommos, 2012). As shown earlier, the research explains that improved upgrading capability and scalability are particularly important for small and medium sized organizations. Since these organizations may grow fast and receive volatile demand, need for flexibility, scalability and upgradability are important features expected from an ERP system. As an additional challenge, they may not have enough IT resources to upgrade on a continuous basis, and access to the latest technologies and software. Therefore, Cloud ERP could be the most viable option for them to have the state of the art technology (Johansson et al., 2015). Also, while small and medium sized organizations could be more lenient on Cloud ERP adoption due to lower upfront costs and faster implementation times, a larger organization with a better financial standing could approach Cloud ERP with less enthusiasm (Castellina, 2011;Saa et al., 2017; Elragal and El Kommos, 2012).

Open Source Software Communities (OSSPCs) as a Good Solution for the Productivity Dilemma: An Empirical Research Proposal

Zhengzhong Shi
University of Massachusetts at Dartmouth
Email: zshi@umassd.edu

ABSTRACT

Productivity dilemma is about the contradiction between pursuing efficiency and driving innovations and it is about the inconsistent requirements in terms of organizational systems, structures, behaviors by exploitation and exploration activities. Organizational ambidexterity as the balance between exploitation and exploration activities has been proposed as the solution to resolve this dilemma. Both structural and contextual factors impacting ambidexterity have been identified and ambidexterity's impacts on organizational performance has been tested. This rich stream of research on productivity dilemma and ambidexterity in organizations can be applied to explain why OSSPCs could resolve the productivity dilemma and consequently become very successful.

KEYWORDS: OSS Project Community, Productivity Dilemma, Ambidexterity, and Research Proposal

INTRODUCTION

Based on data in the automobile industry, Abernathy (1978) found that a firm's decline is highly related to its efficiency and productivity efforts and raised the issue of productivity dilemma. He argued that for firms to gain sustained competitive advantages overtime, it is imperative to be both efficient/productive and innovative/flexible. While to improve the efficiency of a production system is to exploit existing capabilities, to be innovative and flexible is to explore new capabilities. March (1991) proposed that there is a need for the balance between exploitation and exploration for firms to be successful both in the short term and in the long run. This argument is further developed in the research stream of dynamic capabilities by Teece, Pisano, and Shuen 1997). In addition, Benner and Tushman (2003) proposed that ambidextrous organizations can help with meeting this requirement for the balance between exploitation and exploration activities. In their reflection of the 2003 paper, Benner and Tushman (2015) further specified the need for the combination of both the structural ambidexterity and contextual ambidexterity to better manage this balance between exploitation and exploration. Structural ambidexterity can be produced by firms to have both organic and mechanic units that are integrated at the senior manager level. Contextual ambidexterity can be produced by firms through encouraging employees making their own decisions regarding time and efforts dedicated to efficiency or innovation activities (Gibson and Birkinshaw, 2004).

Open source software project communities (OSSPCs) have been playing a critical role in software development for several decades and good examples are such as the Linux community, open source enterprise systems communities, and many communities supporting Apache foundation's open source software projects (e.g., Spark, Kafka, Hadoop, etc.). In this paper, we propose that the structure of the OSSPC management and the flexibility of community members in terms of freely deciding the tasks they would like to work on and the tools they may use demonstrate an almost perfect integration of the structural ambidexterity and contextual ambidexterity. And this integration,, in addition to other factors such as community trust dynamics, may very well help explain the underlying reasons why OSSPCs can be very successful in software development, facilitating both incremental innovations such as bug fixes and discontinuous innovations such as new feature development and change of technology trajectories for software development. In this paper, we will propose a research plan to empirically test the open source software community ambidexterity hypothesis.

THE CONCEPT OF AMBIDEXTERITY

The concept of ambidexterity is initially developed in the context of organizations, which means that while firms exploit existing competences, knowledge, and assets for efficiency, refinement, cost leadership, and continuous improvement, they also explore new fields through discovery, global search, disruptive innovations, and new competence building. While the purpose of exploitation is to make full use of existing knowledge and assets for the short-term oriented profit maximization, the goal of exploration is to ensure their long-term viability and sustained performance, especially during the period of industry revolution when existing dominant product designs are overthrown and new emerging designs are competing to dominate in the industry.

In early studies of ambidexterity, scholars proposed that it is very challenging for organizations to simultaneously maintain effective exploration and efficient exploitation due to the competition for scarce firm resources and the embedded conflicts between exploration and exploitation in terms of their demands for different organizational structures, processes, systems, and cultures (March, 1991; Sidhu, Commandeur, and Volberda. 2007). While to exploit existing routines, assets, and knowledge requires discipline, tight coupling, and continuous process improvement, to explore new fields effectively requires flexibility, loose coupling, and process transformation. Consequently, without establishing appropriate organizational contexts and structural designs, exploitation and exploration may both suffer.

Later studies demonstrate that while simultaneous implementation of exploitation and exploration strategies is indeed very challenging and replete with barriers, it is possible for firms to be ambidextrous through balancing exploitation and exploration and some empirical evidences show that firms properly matching exploitation with exploration perform better in the long run and have a high probability to survive disruptive technological innovations (Gibson and Birkinshaw, 2004). Cao, Gedajlovic, and Zhang (2009) further developed measurements of ambidexterity (including both the balanced and combined dimensions) and provided empirical evidence proving the positive impact on organizational performance of the balanced and combined dimensions of ambidexterity and their interactions.

Further, Porter’s (1996) development of the concept of productivity frontier also provides the theoretical foundation for the feasibility of simultaneous exploitation and exploration. In his theory, he argued that before companies reach the productivity frontier, “they can often improve on multiple dimensions of performance at the same time. … What were once believed to be real trade-offs—between defects and costs, for example—turned out to be illusions created by poor operational effectiveness” (Page 62, Porter, 1996). Exploration is risky and costly, but it is the foundation for the long-term viability in case of industry discontinuous innovations. Exploitation is to generate continuous adjustments for incremental innovations with low risk and investments and it is good for benefiting from existing capabilities. Before companies reach their productivity frontiers, based on Porter’s theory, they can move forward along both the exploitative and explorative paths within the constraints of resource limitation. With today’s dramatic technology advancement (especially in Internet and cloud computing supported technologies such as AI and machine learning), the productivity frontier is pushed further outward. Thus, companies may be able to better simultaneously handle resource competition and structural challenges raised by exploitation and exploration activities with well nurtured ambidexterity.

THE AMBIDEXTERITY OF OSSPCS

The concept of ambidexterity could be especially useful in the context of open source software project communities (OSSPCs). For example, Temizkan and Kumar (2015) applied social network and organizational ambidexterity theories to the field of OSS development and found that while exploitation oriented teams (such as patch development teams) consist of a smaller number of densely connected subgroups and emphasize close collaborations, exploration oriented teams (such as feature request and development teams) consist of a larger number of sparsely connected subgroups and emphasize the need to access new ideas. They further proposed that the identification of ambidextrous developers in an open source software community helps develop the concept of OSSPC ambidexterity. While it is true that an OSSPC cannot be treated as an organization with strict employer-employee relationships, community members can be viewed as forming a virtual organization through sharing common values and beliefs (Stewart and Gosain, 2006), participating community activities by following joining scripts (von Krogh, Spaeth, and Lakhani, 2003), and establishing appropriate structural conditions (Lee and Cole, 2003). For example, in the study by Lee and Cole (2003) about the OSSPC for the Linux development, they identified two tiers of community members (core vs. periphery) and parallel code branches (development branch vs. stable branch) as community organizing structures resulting in structural ambidexterity.

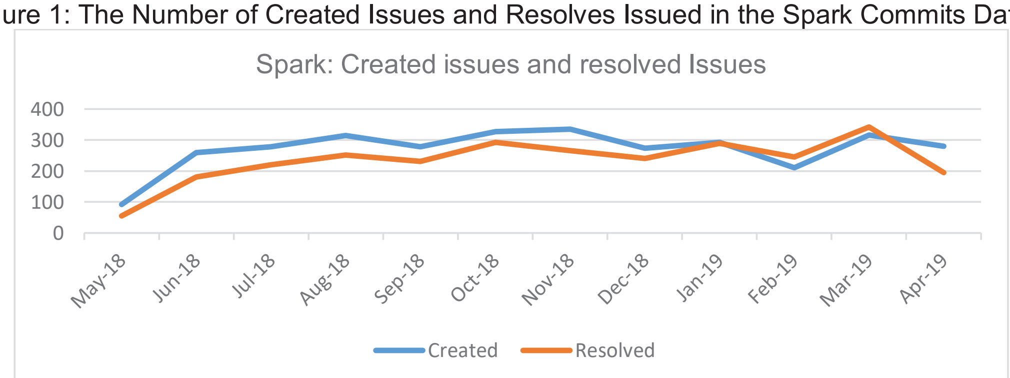
These community structures are not separate entities like mechanic and organic business units in a company, which are integrated at the senior managers' level. While employees in organizations can change their positions, they are not as flexible in switching their focus between exploitative and explorative activities beyond assignments from managers as community members who can switch between exploitation and exploration activities freely without consultation with any other members. In addition, members themselves decide the problems they want to solve, choose the tools to solve those problems, and control the pace of problem solving. Indeed, it is our belief that this behavior pattern of freely switching between exploitative and explorative activities is the key factor resulting in the contextual ambidexterity proposed by Gibson and Birkinshaw (2004) in the context of OSSPCs. Gibson and Birkinshaw believe that contextual ambidexterity differs from structural ambidexterity remarkably in that the former is achieved by building a set of systems and processes enabling individuals make decisions about their time and energy allocation for alignment and adaptability. Their empirical testing further demonstrated the critical role contextual ambidexterity plays in enhancing firm performance. For the four groups of firms in their data, they found that the highly ambidextrous firms perform the best and the moderately ambidextrous firms have the second-best performance. Following their conceptual development and empirical findings, it is our belief that the OSSPC contexts encourage simultaneous exploitation and exploration, which results in the OSSPC contextual ambidexterity.

As Benner and Tushman (2015, page 12) proposed, "that structural and contextual ambidexterity are complementary". The goal of this paper is to apply the rich findings from the research stream in organization ambidexterity to the field of OSSPC and empirically demonstrate that the OSSPCs are indeed a good solution for the productivity dilemma raised by Abernathy (1978) through the integration of structural and contextual ambidexterity.

A RESEARCH PROPOSAL FOR THE EMPIRICAL STUDY

In this section, we will sketch out an outline for the future empirical study on whether OSSPCs could be a good solution for the productivity dilemma from the community ambidexterity perspective. First, we plan to use the open source software project commits as the source of data for the empirical study. One example OSSPC is Apache Spark™ community. Spark "is a unified analytics engine for large-scale data processing. Apache Spark achieves high performance for both batch and streaming data, using a state-of-the-art DAG scheduler, a query optimizer, and a physical execution engine" [https://spark.apache.org/, accessed on May 22, 2019]. The Spark's commits data are hosted in the Jira site [https://issues.apache.org/jira/projects/SPARK/, accessed on May 22, 2019] and the Spark community is very active. As indicated in the following figure, for the past year from May 2018 to April 2019, the Spark community created 3256 issues and resolved 2807 issues (Figure 1).

Figure 1: The Number of Created Issues and Resolves Issued in the Spark Commits Data



In terms of the different types of tasks facing the Spark community, the following list shows the details.

1. Epic - Created by JIRA Software - do not edit or delete. Issue type for a big user story that needs to be broken down.
2. Bug - A problem which impairs or prevents the functions of the product.
3. Dependency upgrade - Upgrading a dependency to a newer version
4. Improvement - An improvement or enhancement to an existing feature or task.
5. New Feature - A new feature of the product, which has yet to be developed.
6. Story - Created by JIRA Software - do not edit or delete. Issue type for a user story
7. Task - A task that needs to be done.
8. Sub-task - The sub-task of the issue

For the purpose of investigating the OSSPC ambidexterity in our research, we are interested in the bug, improvement, and new feature tasks. Bugs and improvement tasks represent incremental innovations with the focus on exploitation of existing software capabilities. New features represent the efforts of exploring new capabilities for the software.

Structurally, for the Spark community, besides the master branch of the source codes, there are two active source code branches (2.3 and 2.4) [https://github.com/apache/spark/branches, accessed on May 22, 2019]. These different branches are to store the source codes for different versions, some of which are stable for the production use with focus on exploiting existing software capabilities and some of which are for the explorative purpose with experimented features and no or few production-based tests. Contextually, community members can freely make their own decisions in terms of which branch of source codes they would like to work on and which type of tasks they would like to complete. The aggregated member behaviors of the whole community represent the organic distribution of efforts and time dedicated to exploitative and explorative activities respectively, forming the OSSPC ambidexterity resulting from both the contextual and structural factors embedded in the Spark community.

Second, we would like to divide the available bug, improvement, and new feature commit data into different periods. Each period could be two or four or six months as the community may have its own developmental cycles. Then we will count the exploitative activities and the explorative activities in each period. Further, based on Cao, Gedajlovic and Zhang (2009), we will also calculate the balanced and combined dimensions of the ambidexterity for each period and examine the evolution of the Spark's community ambidexterity. In addition, we plan to collect the web exposure data of the Spark project (primarily using google search) and its downloads for each period to examine the impact of community ambidexterity on its popularity and downloads over time. We assume that the web popularity and downloads for each period can be used to approximate the market share of the Spark project in the big data analytics and AI market.

Third, we will collect more commits data from other OSSPCs and do a comparison study in terms of the evolution of the community ambidexterity and their impacts on web popularity and the number of downloads per period. Other potential OSSPCs we may include in the future empirical research are such as the Dolibarr ERP/CRM community and the Vtiger CRM community, both of which have very active members.

CONCLUSION

In this paper, we review the concept of productivity dilemma and the proposed ambidexterity as the solution to this dilemma in the context of organizations. We notice that over time, researchers agree that structural and contextual ambidexterity are complementary, and both are needed to better resolve the challenge of the productivity dilemma. We conjecture that the structural design and the contextual factors embedded in OSSPCs may result in community ambidexterity resolving the productivity dilemma. On the one hand, there are multiple source code branches with the stable branches for the production purpose and other unstable branches for the development purpose. These different branches automatically organize the community members into groups working on commits for exploitative and explorative activities and this structural design is the driver for the structural ambidexterity in the OSSPCs. On the other hand, the freedom of the community members in deciding the problems and tasks in different source code branches they would like to work on over time is the key contextual factor enabling contextual ambidexterity. Lastly, we sketch out an outline for the empirical study in terms of commits data collection and analysis. We believe that this paper, through drafting a research proposal on the OSSPCs as a good solution to the productivity dilemma from the community ambidexterity perspective, will lead to fruitful research studies.

ABSTRACT

This paper evaluates the relationships between support networks (social capital) and skills (human capital) on both employees' job satisfaction and companies' expansion of their supply chain (SC). A structural equation model (SEM) is tested based on four constructs: relationship orientation, job skills, job satisfaction, and supply chain expansion. To do this, we conducted a survey of Colombian supply chain professionals and managers. The results reaffirm the literature's previous findings of a strong relationship between employees' social capital and their job skills. We also found a significant relationship among SC members' skills and job satisfaction. SC expansion determinants were not conclusive, probably because other factors affected the expansion of companies; however, the research overall highlights the indirect importance of human resources management on supply chain performance.

KEYWORDS: Human Resource Management; Skills; Satisfaction; Latin America; Performance

INTRODUCTION

As the importance and influence of supply chain functions grow in all businesses, the importance of the supply chain's human resources is becoming evident (Barnes and Liao, 2013). Long-term, high-performance supply chain management (SCM) depends, in part, on human capital and data-driven decision-making processes (Barnes and Liao, 2012; Waller and Fawcett, 2013). However, scant research is available to characterize the influence of multiple factors on organizational performance and only a handful of papers link Human Resource management (HRM) to overall supply chain performance (Gunasekaran et al. 2004; Ou et al. 2010; Smith–Doerflein et al. 2011; Swart et al. 2012; Lengnick-Hall et al. 2013; Gómez-Cedeño et al. 2015).

The available HRM studies in SCM have either focused on deepening the understanding of diverse job skills or on mapping social relationships to see their effects on human and organizational performance (Barnes and Liao, 2012). Yet only a couple of these studies propose metrics related to this overall performance. Furthermore, little research has examined the impact of the job satisfaction of SCM professionals on SC performance (Antoncic and Antoncic, 2012).

To address this gap in the literature, this paper evaluates the (somewhat obvious) hypothesis that in order to deliver high-quality organizational SC performance, supply chain employees must possess a sufficient level of skills, an adequate network supporting them, and satisfaction with their jobs. Even though this research does not establish causality, its aim is to contribute to setting the foundations of how to develop future talent in SCM in order to respond to challenges in the discipline, such as rapidly changing environments, fragmented logistics operations, growing urbanization rates and dynamic data-driven decision-making processes (Rivera at al., 2019). These contextual features are present in emerging regions such as Latin America and countries such as Colombia. Thus, our contribution targets a better understanding of the role that high-skilled SCM professionals should have in transferring skills, to make SCM a more active member of the talent development process via social relationships and employees' job satisfaction, and to promote organizational and SC growth.

Therefore, some unique aspects that distinguish our study from the existing body of similar works in the literature involve the inclusion of employee's skills, satisfaction, and social networking in order to model, analyze, and derive conclusions about their performance in SCM. Hence, this paper contributes to the literature 1) empirically, by providing new insights about the aforementioned constructs of HRM in a Latin American country through primary data collected via surveys, and 2) methodologically, by explicitly modeling the relationships among these constructs and their effect on overall supply chain performance. Our model differs from (and builds onto) the existing body of traditional structural equation models (SEM) in that it enables us to first evaluate the relationships that have a significant effect on skills development and how these skills influence employee's satisfaction and supply chain performance.

Section 2 reviews the theoretical background, explains the relationship between HRM and SCM, and provides some context for the HRM in Latin America. Section 3 presents the research model and hypotheses. Section 4 depicts the methodology, questionnaire design and data collection. Section 5 presents the results, including Confirmatory Factor Analysis (CFA), SEM and cluster analysis. Finally, Section 6 discusses the results and Section 7 concludes with final observations.

LITERATURE REVIEW

Supply chain management and logistics are topics that have gained traction in the academic and practitioner communities in the last two to three decades. In fact, SCM has shifted from having a secondary role in organizations, to becoming a core strategic function that builds a competitive advantage among diverse stakeholders (i.e., suppliers, manufacturers, retailers, distributors and end customers) (Mentzer 2001; Gunasekaran et al. 2004; Hult et al. 2007). In consequence, the characteristics required of supply chain personnel have also evolved dramatically (Slone et al. 2007; Flöthmann and Hoberg, 2017). This evolution has also affected the way in which companies perform HRM for the purpose of recruiting, training, and retaining superior SCM professionals to improve the performance of organizations and grow their productivity and profitability (Swart et al. 2012).

Human resources have proven to be a key factor for the undertaking of successful supply chain activities, ensuring greater customer satisfaction and enhanced organizational performance (Menon, 2012). In addition, the role played by individuals is critical for the execution of SCM and its complex web of relationships. Hence, HR practices in firms must be aligned with SCM in order to promote the integration of the chain and safeguard better business outcomes. (Gómez-Cedaño et al. 2015). However, few studies in the literature describe the relationship between human resource activities or organization variables and supply chain success. This omission may be due to the emphasis on technical or “hard” determinants of supply chain performance (Shub and Stonebraker, 2009).

On the other hand, there is an ongoing shortage of SC managers who have the broad range of competencies and managerial skills needed to promote operational innovation (Jordan and Bak, 2016). Moreover, SCM personnel may not be sufficiently aligned with the objective of developing the “soft” side of SC managers. Perhaps the reason behind it all is that organizational development (OD) is often left to organizational leaders and managers who are tasked with such responsibilities but may not be trained to execute them. (Ellinger and Ellinger, 2014). Regarding the lack of research that examines the so-called “soft side” of SCM, more research in this area would help organizations to better manage strategically significant supply chain processes with the adequate connection between the needs of the chain, the SCM personnel and the responsibilities asked of them (Ellinger and Ellinger, 2014; Othman and Ghani, 2008).

HRM in Latin America

Despite the noted progress of Latin America in terms of access to education and healthcare, as well as increased prosperity and decreasing poverty rates during the last decade, the region still needs further improvement (UNDP, 2017). There is still a remarkable lack of high-quality human capital, which hinders regional economic growth and obliges firms to work with a large base of low-skilled workers in various productive sectors (Santos, 2016). Even worse, rapid technological pace threatens to broaden the existing gap between the skills required by regional labor markets and those available from regional human talent. This further polarizes the socioeconomic situation in developing countries, where most of the labor is trained for mechanical and manual tasks to develop a low-cost workforce, at the same time limiting the professionalization in technology, data-driven decision-making processes, critical thinking, and non-routine cognitive skills (Elvira and Davila, 2005; Perez-Arrau et al. 2012). Further trends, such as growing urbanization and poor policymaking, shape labor markets and in some cases are likely to be even more important than technology (Santos, 2016).

Elvira and Davila (2005) is, to our knowledge, the first study to describe the state-of-the-art of HRM in Latin America. Since that pioneering work, solid constructs related to HRM in SCM such as social relationships, job satisfaction, and personal contact were identified to be important manifestations of the Latin American working environment. Later, Perez-Arrau et al. (2012) showed that HRM depends on cultural and country-related characteristics that affect human and organizational performance. Despite the authors' focus on Chile, their study updates the state-of-the-art of HRM in Latin America, without analyzing particularities and implications of SCM professionals. Therefore, even with the growing efforts to address HRM in Latin America, there are still several research opportunities available.

HRM and SCM: which relationships?

It is clear that HRM has a deep impact in configuration of SCM professionals and workforce, which in turn has a significant consequence for organizational and company performance (Gómez-Cedeño et al. 2015). But there is scarce research connecting HR skills and SCM performance, especially in Latin America. By looking at recent literature (e.g., Mangan and Christopher, 2005; Murphy and Poist, 2007; Derwik and Hellström, 2017; Flöthmann et al. 2018), four important constructs that allow for mapping and building a detailed model of how SCM professionals and logistics managers might affect organizational and supply chain performance emerge. Thus, it is important to investigate the effects of multiple HR factors from a twofold perspective: 1) from a typical HRM perspective, by analyzing *relationship orientation* (i.e., social connections and networking), employees' satisfaction and their work skills; and, 2) from a SCM perspective, by linking employee features (e.g., experience, technical training) to supply chain expansion and organizational growth (Brauner et al. 2013).

Relationship orientation. Social relationships reflect the connective power of networking for the employee. Such relationships can be in the form of organizational collaboration, camaraderie, professional networking, and friendship that facilitate personal communications, knowledge co-creation, knowledge sharing, and empathy among organizational members (Elvira and Davila, 2005; Hitt and Ireland, 2007; McCallum and O'Connell, 2009, Wood et al. 2016). This idea relies on systems where the party and the state are intertwined and let individuals facilitate access to broader and better sources of information; develop influence, control and power to achieve goals; increase solidarity; and reduce the need for formal controls (Adler and Kwon, 2002). In particular, it measures the extent to which individuals have established connections to potentially influential people, such as leaders, policy makers, and decision makers (Barnes and Liao, 2012).

Employee-related features. Hohenstein et al.'s (2014) recent extensive literature review on human capital management in SCM and Flöthmann et al.'s (2018) study of the key competencies of SCM personnel can be considered as a benchmark when dealing with the level of job *skills*. In particular, their framework suggests the inclusion of four categories of skills: 1) technical expertise; 2) general management skills; 3) interpersonal skills; and 4) analytical and problem-solving abilities. These categories are defined by the employee's socioeconomic profile, education, experience, skills, values and abilities that increase their value in the workplace (Elvira and Davila, 2005; Forret, 2006; Murphy and Poist, 2007; Derwik and Hellström, 2017).

Employee's satisfaction. In line with several past (Wanous et al. 1997) and more recent (Dobrow and Ganzach, 2018) studies, employees will more effectively contribute to organizational (and SCM) success when they are satisfied with their work status, both in terms of its economic and non-economic aspects. The factors contributing to job satisfaction include working environment, flexible job descriptions, team work, and rewards that lead to the well-being and high performance of the personnel (Menon, 2012; Goffnett et al. 2012). Humphrey et al. (2007) used a large meta-analytical review to show that job satisfaction depends heavily on motivational-human capital characteristics. Moreover, Antoncic and Antoncic (2011) found that job satisfaction characteristics significantly influence a firm's growth.

Organizational/supply chain expansion. Finally, the growth potential expresses the traditional dimension to measure supply chain coverage (van Hoek, 2001), and it is linked to the characteristics of people (Fawcett and Waller, 2013). Since the diffusion of the SCM culture, authors have debated the need for SCM and whether supply chain evolution is strictly related to the people operating in it (Chapman et al., 2000); in this regard, Gunasekaran et al. (2004) proposed a set of performance metrics to measure SCM activities' growth. The authors linked SCM activities – plan, source, make/assemble and deliver – at different levels with the aim to create flexibility, effectiveness, accuracy and speed in the flow of goods/services, information, cash, and knowledge along the supply chain. Besides this focus, the current literature has little evidence on the connection between the SC expansion and the characteristics of SC professionals.

The next section proposes a research model that is grounded in the above theoretical considerations. Three constructs are considered and three related hypotheses are proposed for the relationships among them. This model may serve to increase the understanding of the relationships among HRM-related activities and SCM performance.

THEORETICAL DEVELOPMENT/MODEL

The need to select highly competent supply chain employees is grounded in the knowledge-based view (KBV) of the company (Grant, 1996). This theory proposes the idea that knowledge and capabilities may become a source of competitive advantage that supply chain management can exploit (Handfield et al. 2105). Strategic knowledge, in particular, can be rooted both in the individuals and in the organizations (McCallum and O'Connell, 2009; Wood et al. 2016).

Personal knowledge can be seen as the combination of individual skills and abilities possessed by an employee and applied in day-to-day job activities (Fossum and Arvey, 1986). As cited in the HRM literature (Wright et al. 2001; Kang and Snell, 2009), highly skilled employees can be a strategic resource that facilitates competitive advantage to a firm. Furthermore, these skills and the expertise accumulated by employees over time become a source of sustained differentiation, especially, if the skills are valuable, rare, inimitable, and non-substitutable (Barney, 1991).

This is particularly true in the context of SCM. SCM has become a profession that requires a mixed of technical and managerial skills. These skills need to be cultivated by adopting a multidisciplinary and cross-functional perspective, in order to link numerous functions within and across companies that manage an integrated value flow (Flöthman et al. 2018).

Therefore, this paper is grounded in the idea that in order to deliver high-quality performance and help companies expand and grow, supply chain employees need to possess a sufficient level of skills, a broad network supporting them, and be satisfied with their jobs. To analyze these linkages, the theoretical model illustrated in *Figure 1* has been tested.

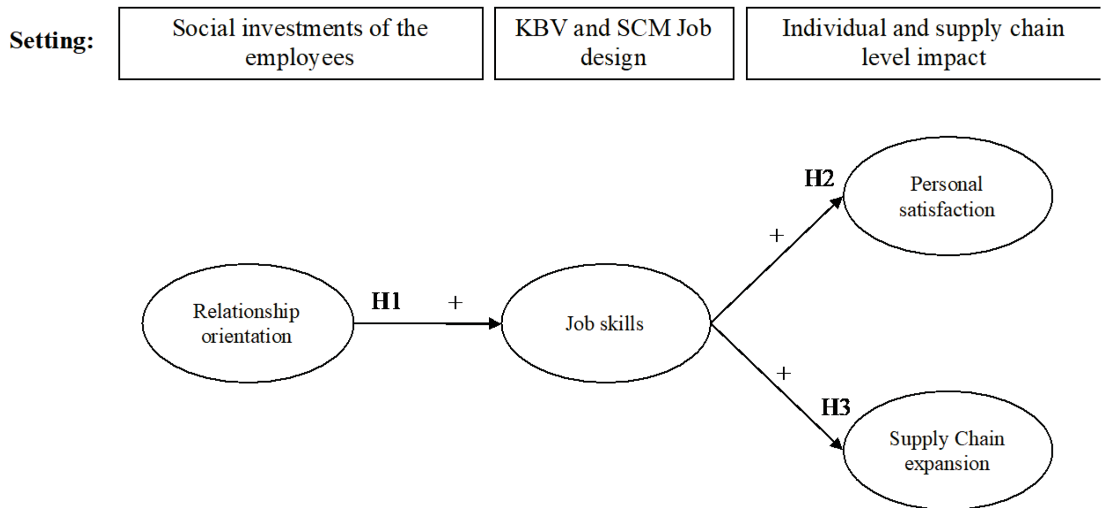

Figure 1. Research model

When we talk about competence and skills, we adopt the perspectives provided by McCormick (1976) as well as Fossum and Arvey (1986), who define skills as *developed abilities that facilitate learning or the more rapid acquisition of knowledge*. These skills influence performance and they are not subject to a big change.

An important property of skills is that they can be trained or acquired "on the job" and that several elements can contribute to enhancing them (Mumford et al., 1999). Under social exchange relationships theory, the establishment of an extensive network of relationships promotes interpersonal exchange and individual growth, which may affect skills and knowledge improvement (Möller and Halinen, 1999; Baron and Markman, 2000).

Among the different possible external relationships for an employee – those involving people who have a relevant role and/or qualifications for the employee's context (i.e., managers, executives, policy makers) – are recognized as being the most valuable in fostering individual skills development (Barnes and Liao, 2012; Dowell et al. 2015; Schermuly and Meyer, 2016). This is even more important in supply chain management, where the possibility to build relationships and grow networking (i.e., connection power) is amplified by the complexity of the unit of analysis. This puts employees in contact with several supply chain actors such as suppliers, distributors, and retailers at diverse levels (Wright and Kaine, 2015).

Based on these reasons, we can thus formulate the following hypothesis:

H1: In SCM, a greater orientation toward employees having external business relationships is associated with a greater level of job skills

By developing skilled workers and investing in human resources, companies can obtain payback on two levels: employee satisfaction and organizational performance. If we examine the HRM literature, there is a broad set of scholars (Messersmith et al. 2011; Kehoe and Wright, 2013; Kianto et al. 2016) who discussed that, in companies pushing for development of employee competencies – in line with job requirements and the organizational environment – the employee's personal job satisfaction is higher.

SCM jobs require multifaceted skills to manage flexibility, change, risk, complex decision-making processes, creative thinking, and technical knowledge. SCM positions give employees the

opportunity to express their capabilities in a more extensive way, as well as to improve and demonstrate their abilities. Companies also reward workers for the complex tasks and challenges they have to face by providing them higher benefits in terms of salary, non-economic privileges, work-life balance, and better work environment (Lai Wan, 2007). Altogether, this results in higher satisfaction of the employees in their jobs, maximizing the company's ability to retain the best performers and develop high-potential employees to become the next generation of decision makers (Myers et al. 2004).
We can thus formulate the following hypothesis:

H2: In SCM, a higher level of job skills is associated with a higher level of employee satisfaction

Finally, the human resources department at any organization should focus on recruiting, investing in, and developing talented supply chain professionals to maximize their satisfaction and the company's talent retention. The latter creates a crucial, long-term competitive advantage because relying on a high-skilled employee base has been linked positively to overall improvement of organizational performance (Chowhan, 2016).
Specifically focusing on the SCM literature instead, several authors have promoted the idea of a linkage between the skills of SCM employees and the growth of the supply chain (Fisher et al. 2010; Mendes and Machado, 2015; Huo et al. 2016; Flöthman et al. 2018). Therefore, skilled SCM professionals might enable improvement of supply chains, in terms of the market served and the global reach of supply and distribution networks (Hohenstein et al. 2014; Jordan and Bak, 2016). We can thus formulate the following hypothesis:

H3: In SCM, a greater level of job skills is associated with a greater level of supply chain expansion

METHODOLOGY

To investigate the research model, a survey-based methodology was used, being suitable for testing purposes (Choi et al. 2016). The hypotheses were tested through a questionnaire that collected information about human resources management, employee and SC characteristics, in multiple main cities of Colombia during 2018 and 2019.

Questionnaire design and scale development

The questionnaire collected data from SC professionals pertaining to the four areas included in the model (i.e. the extent of networks of relationships, types of job skills and capabilities, job satisfaction, and company growth). We also collected socioeconomic data and years of experience from the surveyed professionals. In addition, we asked respondents for values and principles followed at their positions, as well as the employee trainings and course offerings at their organizations.
The survey items used to measure the theoretical constructs were derived from an extensive literature review about HRM, according to which the questionnaire was designed. Based on these constructs, we formulated diverse questions to form a large pool of items. Also, we compared these constructs in order to fill the two identified literature gaps (i.e., the existing link between the skills required by regional labor markets and those available from regional human talent; and the relationship between human capital characteristics and SC performance), and we added questions to the survey to fill these gaps. We piloted a preliminary version of the survey that contained 35 questions, which was reduced to 21 items for the sake of respondent time,

uniqueness, and significance of the results. The pre-test allowed us to improve the items of each dimension, alter the five-point Likert scale, and design a better survey. Following the suggestions in literature to reduce non-response, we carefully designed the survey instrument, established the research significance, and balanced survey length (Rogelberg and Stanton, 2007). The final version of the questionnaire in Spanish is presented in Appendix 1.
Table 1 summarizes the main items adopted for each construct and their operationalization in the survey.

Table 1. Operationalization of constructs

First-order construct	Indicators	Label	Scale
Relationship orientation	I have relationships with entrepreneurs in successful start-ups	REL 1	1 = “no relationships” 5 = “with more than 15 people”
	I have relationships with executive managers in medium companies	REL 2	
	I have relationships with decision makers in large firms	REL 3	
Job skills	I have leadership capabilities	SKILL 1	1 = “not at all” 5 = to a large extent
	I have goal orientation	SKILL 2	
	I can manage efficient decision-making and problem-solving processes	SKILL 3	
	I have quantitative skills	SKILL 4	
Personal satisfaction	I am satisfied with my current salary	SAT 1	
	I am satisfied with my non-economic incentives	SAT 2	
	I am satisfied with my work-life balance	SAT 3	
Supply chain expansion	In the last 10 years, my company has changed the number of employees	EXP 1	1 = “0%” 5 = “more than 15%”
	In the last 10 years, my company has changed the number of products or production lines	EXP 2	
	In the last 10 years, my company has changed the number of suppliers	EXP 3	

Data collection and sample characteristics

Logistics professionals face a double challenge because their role encompasses both the diverse functional departments of their company as well as coordinating similar tasks with logistics roles at external supply chain stakeholders (e.g., suppliers, customers, and carriers). Therefore, there are strong interdependencies between SCM and human resources (HR) that require an integrative, cross-functional, multi-company vision and a developed HR ability to create levers to avoid imposing activities and hindering the growth of certain actors of the supply chain (Jurčević et al. 2009).
However, there is still a lack of knowledge and research in this complex topic (Jurčević et al. 2009). Moreover, a few authors (Brauner et al. 2013) argue that incorrect decisions in HR-related

realms lead to lower performance not only for the company, but also for other actors of the supply chain. Furthermore, Latin America faces multiple difficult challenges, such as poor infrastructure, ineffective logistics operations, income inequality, and social and political instability (Velazquez-Martinez et al. 2018). Moreover, Latin America lacks a strong educational system that instills the required abilities in its population that logistics job positions nowadays require.

Developing countries display labor market polarization in which a large number of workers perform manual labor, while in developed regions these tasks are largely handled more efficiently by automated processes and technology. This pattern prevails in most of Latin America as well, due to the low skill levels of workers that makes their jobs lower-paying and non-technologically dependent (Perez-Arrau et al. 2012; Santos, 2016). Unfortunately, this hinders the (macro- and micro-) economic growth of the companies and the country in the long term. Our research picks a Latin American country as a case study and investigates how multiple skill profiles foster the growth of supply chains and the development of companies. This research is relevant to closing the existing research gap in whether SCM professionals might enable supply chain expansion of a company through a better skillset and the relationship network they develop through their jobs.

We conducted the survey at six events organized by LOGYCA, a Colombian organization that administers several international standards, such as barcode, and offers products and services in logistics for over 650,000 different companies across Latin America. These events were in five main cities of Colombia, including the largest metropolitan areas, and were attended by a total of 180 people. The profile of attendees to these events were primarily professionals in logistics, transportation, and supply chain management from service and manufacturing industries. We did not select specific industries because we wanted to guarantee heterogeneity in the results, but we did concentrate on medium and large firms to understand the effect of constructs such as the relationship orientation, as it is in these type of organization where HRM practices are more consolidated and employees have the opportunity to create stronger network of relationships (Blanco-Alcántara et al., 2018). Also, larger firms have the opportunity to employ a larger number and variety of people and to represent a less fragmented, more formal labor market.

At each event, we delivered the survey to the registration table and asked attendees to fill out the survey during the event. Clear instructions were written in the printed version of the survey, and staff from LOGYCA answered questions that the respondents had about the survey. To increase the validity of findings, we opted for a multi-city sample in Colombia. Naturally, larger cities are more oriented to SC activities because urban logistics are more complex and because they are nuclei of economic activities for Colombia. Therefore, this heterogeneity in profile also benefited the results of the survey.

In light of this, we performed the survey in 2018 and 2019, collecting data from 144 questionnaires. After removing responses with missing values on critical items, we obtained a final sample of 131 usable responses, which corresponds to a raw response rate of 73%.

Table 2 reports the relevant descriptive statistics of the sample.

Table 2*.* Sample descriptive

Descriptive	Freq.	%	Descriptive	Freq.	%
Organization Size			*Respondent sex*		
> 250	91	69.5	Male	77	58.8
100-250	11	8.4	Female	46	35.1
50-100	11	8.4	Missing	8	6.1
< 50	18	13.7			
			Respondent position		

Supply Chain Sector			Country and International executive (VP, chief)	28	21.4
Logistic provider	4	3.1	Regional and local executive managers (DCs, Plants, Cross-docking platforms)	28	21.4
Manufacturing	31	23.7	Indoor Firm coordinators (Warehousing, transportation, operations, finance, logistics)	17	13
Retailer	77	58.8	Outdoor Firm coordinators (Procurement, purchases, Customer service, supplier engagement)	23	17.6
Service (Bank, ICT, Finance, Consulting)	9	6.9	Supervisor	28	21.4
Other	10	7.6	Technician	4	3.1

			Missing	39	29.8
Total	131	100		131	100

Bias control

Potential biases were considered in survey and protocol design and in the data analysis. To check non-response bias, we adopted the “continuum of resistance” model (Kypri et al. 2004), thus comparing early and late respondents – where a late respondent is then used as a proxy for a non-respondent. Student's t-tests were performed on early and late waves on all variables, and these tests indicated no statistically significant differences between the groups in both groups.
Further, social desirability in the entire survey bias was reduced through assurance of confidentiality and through questions mixing both the behavior of the organization and its members in general and direct personal behaviors. The institutional items themselves do not relate to personal behaviors or performance and are thus less likely to be affected by a social desirability bias.

Finally, the procedure of the study was the first way to control common method bias (Podsakoff et al. 2003). First, even though the research project was labeled as a comprehensive study to understand human capital management in Latin American supply chains, no reference to the model in *Figure 1* was provided. Second, questions were organized in order to separate the different sections, to prevent respondents from developing theories about possible cause-effect relationships.

Statistical approaches for model testing

Because the objective of our research is theory testing and confirmation, the presented hypotheses were tested using covariance-based structural equation modeling (CB-SEM), which is a common method employed for this type of research (Perols et al. 2013; Hair et al. 2017).

First, to check the reliability of the hypothesized constructs, Confirmatory Factor Analysis was performed (Schreiber et al., 2006). Following indications by Byrne (2013), we also used Average Variance Explained (AVE), Composite Reliability (CR), and Cronbach alpha (CA) to assess construct validity (detailed in section 5.2 below). Acceptable values of CR and CA are above 0.7, while the AVE should be higher than 50%.

The model was then tested using the maximum likelihood (ML) estimation method (White, 1982), because ML provides more realistic indexes of overall fit and less biased parameter values for paths that overlap with the true model, compared to other methods such as generalized least squares and weighted least squares (Olsson et al. 1999; Gómez-Cedeño et al. 2015). The ML estimation assumes that the variables in the model are *conditionally* multivariate normal, which is true for our dataset according to the Doornik-Hansen (χ^2= 104.207; p > χ^2 = 0.000) and Henze-Zirkler (χ^2= 224.383; p > χ^2 = 0.000) tests.

To evaluate the model fit, we use a combination of the chi-square goodness-of-fit statistic and the use of other absolute or relative fit indices (Hu and Bentler, 1999). Regarding the chi-square, there is the need to check for the ratio between the chi-square value and the degrees of freedom in the model, where cut-off values range from <3 to <5, depending on the type of study (i.e., exploratory or explanatory SEM).

With regard to fit indices, they can range from 0 to 1, with values closer to 1 indicating a good fit. Some authors (e.g., Hair et al., 2017) suggest various indices presentation strategies including, among others, the comparative fit index (CFI), the Tucker Lewis index (TLI) and root mean square error of approximation (RMSEA). A satisfactory threshold for CFI and TLI is >0.90 (with a value >0.95 showing excellent fit), whereas RMSEA is supposed to be < 0.05 (Hooper et al., 2008).

Finally, to better explain the results coming from the model tested, we also performed a cluster analysis, a technique that has been largely adopted in HRM research (e.g., Lengnick-Hall et al. 2009). In order to perform the cluster analysis, a two-step clustering algorithm was selected, because it was able to determine the optimal number of clusters by minimizing the variance within each cluster (Punj and Stewart, 1983).

To perform the data analysis, we used Stata v. 15.0. We estimated the measurements, factor analyses, structural models, and cluster analyses. The main conclusion about the statistical experiments is shown below.

Descriptive statistics

Table 3 presents descriptive statistics for the construct indicators.

Table 3. Descriptive statistics for questionnaire items

Items	Mean	St. Dev.
REL 1	2.64	0.938
REL 2	3.29	1.024
REL 3	3.53	0.965
SKILL 1	4.52	0.614
SKILL 2	4.26	0.7
SKILL 3	4.48	0.601
SKILL 4	4.35	0.635
EXP 1	3.47	1.474
EXP 2	3.13	1.358
EXP 3	2.95	1.34
SAT 1	3.66	1.161
SAT 2	4.19	1.001
SAT 3	4.24	0.696

Confirmatory factor analysis

Table 4 presents the results of the confirmatory factor analysis (CFA). All the measurement model fit indicators show a good fit (χ^2/d.f. = 1.12; CFI = 0.987; TLI = 0.982; RMSEA = 0.032). In addition, convergent validity was assessed through significant loadings from all scale items on the hypothesized constructs as well as through the AVE, CR and CA.
AVE ranges were between 49% and 66% (higher or near the 0.5 threshold), and both CR and CA were higher than 0.7 for all the constructs.

Table 4. Confirmatory Factor Analysis

Construct	Factor Loadings	Average Variance Explained	Composite Reliability	Cronbach Alpha
Relationship orientation		66.09%	0.852	0.807
REL 1	0.699			
REL 2	0.914			
REL 3	0.812			
Job skills		49.15%	0.794	0.801
SKILL 1	0.656			
SKILL 2	0.672			
SKILL 3	0.752			
SKILL 4	0.720			

Personal satisfaction		51.84%	0.761	0.812
SAT 1	0.750			
SAT 2	0.789			
SAT 3	0.608			
Supply chain expansion		61.99%	0.827	0.794
EXP 1	0.611			
EXP 2	0.876			
EXP 3	0.848			

As an additional test for discriminant validity, in *Table 5* we report the squared correlation between two latent constructs to their AVE estimates (Fornell and Larcker, 1981). According to this test, the AVE for each construct should be higher than the correlation between each pair of constructs, a condition that is valid for all the constructs.

Table 5*.* Correlation matrix

Variables	*Mean*	*St. dev.*	1	2	3	4
1.Relationship orientation	*3.15*	*0.82*	1			
2. Job skills	*4.40*	*0.49*	0.033	1		
3. Personal satisfaction	*4.03*	*0.81*	0.009	0.089	1	
4. Supply chain expansion	*3.18*	*1.20*	0.007	0.004	-0.002	1

Finally, the common latent factor technique was applied as a further way to address common method bias (Craighead et al. 2011). We found that the common latent variable has a linear estimate of 0.598. This value indicates a variance of 0.357, which is below the threshold of 0.50. Thus, this indicates that common variance does not represent a problem in our study.

Model testing

The postulated path model produced a good fit to the data (χ^2/d.f. = 1.97; CFI = 0.979; TLI = 0.973 RMSEA = 0.039). *Figure 2* reports the results of the hypotheses testing. The structural equation model shows a highly positive and significant relationship between "*Relationship orientation*" and "*Job skills*", thus we can reject the null hypothesis in favor of H1. In turn, higher "*Job skills*" demonstrates having an impact on "*Personal satisfaction*" – thus we can reject the null hypothesis in favor of H2. However, no statistical significance is found for the relationship with "*Supply chain expansion*" – thereby failing to reject the null hypothesis in favor of H3.

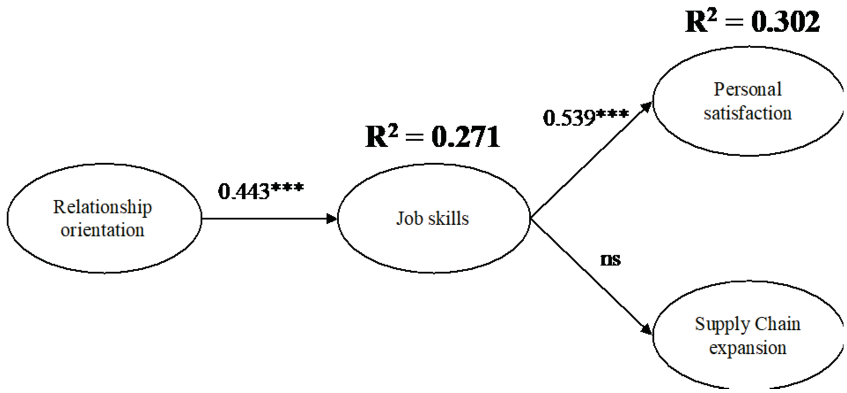

Figure 2. Resultant structural model (**p<0.05; **p<0.01; ***p<0.001)*

Cluster analysis

In performing the cluster analysis we used, as classification variables, the "*Relationship orientation*" and "*Job skills*" factors. The cluster analysis results are reported in *Table 6*.

Table 6. Cluster centroids characteristics (Silhouette coefficient: 0.502; Clusters distance: 1.652)

	Cluster 1		**Cluster 2**		*F*	*P value*
	Mean	*St.dev.*	*Mean*	*St.dev.*		
Relationship orientation	2.41	0.50	3.51	0.71	241.5	0***
Job skills	3.93	0.43	4.62	0.33	3.43	0***
Number of cases	*41*	*32.1%*	*89*	*67.9%*		

The results of the iterative procedure shown at *Table 6* show two different and significant clusters, which can be both differentiated according to the input variables. Cluster reliability was considered acceptable considering the value of the silhouette coefficient – which should be higher than 0.5 – and the cluster distance.
Results show that in cluster 1: *individual – based group*, supply chain professionals tend to have a lower orientation toward having external relationships (below the median, on a 1-5 Likert scale), being characterized by a medium level of skills. In contrast, in cluster 2: *network – based group*, supply chain workers have a higher orientation toward external relationships and an associated higher average level of skills.

After cluster determination, we also ran a one-way analysis of variance (ANOVA) in order to verify if there were statistically significant differences between clusters for "*Personal satisfaction*" and "*Supply chain expansion.*" *Table 7* reports the results below.

Table 7. ANOVA results

	Cluster 1		**Cluster 2**		*F*	*P value*
	Mean	*St.dev.*	*Mean*	*St.dev.*		
Personal satisfaction	3.76	0.8	4.15	0.77	7.34	0***

Supply chain expansion	2.98	1.05	3.26	1.26	1.62	ns

ANOVA at *Table 7* shows, on one hand, that the level of "*Personal satisfaction*" is significantly higher among the network-based group. On the other hand, although the "*Supply chain expansion*" value is higher for the network-based group, it is not statistically significantly greater.

DISCUSSION OF RESULTS

This research analyzes the impact of HRM practices on SCM performance at the individual and organizational levels and confirms the importance, both theoretical and practical, that SCM professionals must establish a powerful network through a relationship orientation in order to enhance their skills. In today's market, where success depends on multiple and complex activities, it is essential for employees to contribute to the competitiveness of their companies and of their supply chains. SCM positions allow employees to interact with talented people inside and outside the company, as well as to access people with multiple hard and soft skills such as leadership and managerial responsibilities (Kiessling et al., 2014). This contact allows individuals and companies to create, through social interactions, a knowledge exchange process contributing to the individual's growth through their daily jobs (Guzzo and Noonan, 1994; Wang-Cowham, 2011).

Finding a strong link between external social relationships and job skills has important implications. At an individual level, SC professionals and managers need to be aware of the opportunities that derive from their social networking in order to boost their skills, and vice versa. Having a large, diverse network of contacts with supplementary, multidisciplinary job profiles will enhance the decision-making processes of the SCM professionals and leverage their learning processes. Thus, at a firm level, giving incentives to SCM employees to build a stronger network could become a valuable organizational practice. In fact, this is already a widespread practice in knowledge-intensive companies operating in complex and turbulent environments such as the computer software, pharmaceuticals, chemicals, and aerospace industries (Wilhelm, 2011; Huggins et al. 2012).

The results support the importance of organizational knowledge exchange as a core concept in KBV. Individuals represent a source of competitive advantage for companies when the employees possess knowledge and skills (representing human capital) that are rare, inimitable and non-substitutable (Kang et al., 2007; Hitt and Ireland, 2002). In addition, these characteristics can be gained not simply through self-development, but also by access to other professionals who already have these skills and play this role for their organization and supply chains through social interaction (i.e., social capital) (Lewin et al. 2011). Therefore, social and human capital should not be treated in isolation (Lepak and Snell, 1999). This is particularly vital for people working in supply chain positions, given the level of complexity that affects both outbound and inbound supply chains. A radical improvement of personal knowledge and skills is possible through continuous interaction with people who have already managed this complexity, and who are able to transfer this experience to other individuals and teams (Mangan and Christopher, 2005; Lengnick-Hall et al. 2013). The aforementioned evidence is also supported by our clustering analysis.

The model's results also support the idea that SCM professionals who have higher skills are also more satisfied with their jobs. Humphrey et al. (2007) found through a large meta-analytical review that motivational and social characteristics (which are closely tied with human capital and social capital characteristics) can explain 34% and 9% of the job satisfaction outcomes of employees, respectively. That is, job satisfaction depends heavily on motivational-human capital characteristics. This evidence is also reinforced through our clustering results' analysis. If we step from the individual-based to the network-based cluster profile, we can see an increment of the level of personal satisfaction with an increase of the average level of employees' job skills.

This justifies investing in the development of skills of supply chain workers, not only to exploit their talent for a more effective SC, but also to maximize potential retention through higher job satisfaction. In the long term, this becomes a sustainable strategy for companies and supply chains that build a baseline of SCM talents that will educate new SCM professionals by training them with the right skills and assuring the transference of acquired lessons and know-how to subsequent generations (Swart et al. 2012; Wood et al. 2016).

Finally, our data was not able to confirm the existence of a positive relationship between the level of job skills and the supply chain expansion, despite the evidence provided by Antoncic and Antoncic (2011). From a theoretical point of view, it is true that some scholars have debated how skilled SCM professionals contribute to company's growth, but it is also true that, according to our definition of supply chain expansion (measured as the increase in the number of employees, products, or suppliers) that relationship is not expected to be linear.

Thus, having skilled employees on its own may not be sufficient to explain company growth, given that the growth may depend largely on the specific characteristics of the company, such as sector, products, location, and size, among others, or on other internal and external variables that arise from the complexity of current businesses practice. For example, scanning the external environment in regard to both competitors and customers from a strategic SCM perspective may serve as a source of competitive advantage (Kiessling et al., 2014). Nevertheless, we hypothesize that using a larger database may dissipate the doubts to conclude with certainty about job satisfaction influence on company growth. For this reason, we are currently running this survey to obtain more observations (at least 100 more in the next couple of months) that will shed light on this issue and determine whether the results are going to change or not.

From an empirical perspective instead, a further scrutiny of our data might better explain this trend. *Table 1, in section 5.1, reports* the descriptive statistics of the items used to measure "*Job skills*" and "*Supply Chain expansion.*" The data show that the relationship is not significant because, on average, the respondents consider the level of skills used for their jobs higher than the growth results. However, we realize that, for each item, the average rate is near or higher than three, which, according to the scale used, still means an expansion between 6-10%. Overall, this indicates that companies and their supply chains still benefit from growth in the case of higher employees' skills; even though, on a 1-5 scale, this outcome is not commeasured to the level of skills in the input.

Therefore, further research is required in that domain by creating a better metric that relates the quality of SCM professionals and their skills to the growth of their company and their supply chains. Lastly, some evidence emerges from cluster analysis: the *network-based group*, characterized by SCM workers with broader external relationships and higher skills, also have a higher average level of growth compared to the *individual-based group* (3.26 vs. 2.96, respectively), suggesting a link may exist overall, even if it is not statistically significant with the sample size of this data set.

Consequently, current research results help to broaden the understanding between HRM-related issues and supply chain outcomes. In short, individuals with higher social capital are more likely to have higher human capital, particularly their in terms of their skills. Meanwhile, job skills are strongly related with employees’ satisfaction. Further research is needed, however, to evaluate the impact of external relations, skills, and satisfaction on supply chain expansion.

CONCLUSIONS AND FUTURE DEVELOPMENTS

This paper´s theoretical contribution helps to clarify the links between HRM constructs in the context of SCM. First, the results provide empirical evidence of the important link between relationship orientation (i.e., social capital) and job skills (i.e., human capital) for SC professionals and managers. The empirical findings also contribute to the existing knowledge base in multiple ways. We find that low- and high-skilled SCM professionals show a different dependence on social relationships. Actually, the individual-based group shows a lower orientation toward building external relationships and is characterized by a medium level of skills; while the network-based group heavily depend on social relationships to improve, train and diffuse knowledge.

Second, it evaluates the impact of job skills on SC outcomes at both the individual (i.e., job satisfaction) and firm level (i.e., supply chain expansion) units of analysis. In this regard, job skills were strongly associated with employees’ job satisfaction but not significantly associated with supply chain expansion. By modeling job skills and satisfaction, our results suggest that SCM professionals having higher skills are also those more satisfied about their jobs. In contrast, variation in job skills was not sufficient to explain variation in supply chain expansion. This may be due to other internal and external variables that arise from the complexity of businesses practice or the need for other supply chain expansion metrics.

Our results suggest that SC managers and professionals should be increasingly aware of the impact of developing significant and positive social relationships with SC members (inside and outside the firm) on their skills and career. Furthermore, higher skills may help them access better job profiles that properly fit their expectations and increase their satisfaction. These findings are relevant because roles of supply managers have changed dramatically (and are currently changing) due to several factors such as new business opportunities, cultural and economic contexts, and a rapidly-evolving data-driven business environment (Kiessling et al., 2014; Waller and Fawcett, 2013). Adaptative capacity then becomes a requirement to update skills that are necessary to succeed in complex and constantly evolving SCM environments.

Moreover, SCM and logistics education decision makers should also be aware of these results. Despite the importance of technical knowledge and skills, soft skills (e.g., managing social relationships, leadership, goal orientation, etc.) are also essential for a satisfying career in SCM. Therefore, education programs in SCM and logistics should include material on these soft skills, which are necessary to succeed in an increasingly complex SC environment. Further research would be valuable on how education should change to promote softer skills, in addition to technical skills, in order to achieve productivity alongside professional satisfaction.

The model’s results also indicate that firms must actively manage their social and human capital in order to have skilled and satisfied employees, which could support SC goals. In fact, HRM activities in SCM should reinforce the evidenced link between Relationships – Skills – Job Satisfaction to drive SCM’s sustainable competitive advantage dimensions. However, further research is needed to broaden the understanding about the impact of employees’ job satisfaction on supply chain expansion and firm performance. This will require novel metrics and methodologies that properly characterize SC outcomes.

Finally, in order to offset the limitations of this study, future research may consider the evaluation of other countries, longitudinal data, broader data on each of the construct elements, and larger sample sizes. Acknowledging the implication of the model's results, the proper analysis extension might minimize cultural differences as biases and illuminate the relationship between social capital and skills level on employees' job satisfaction and companies' expansion in a supply chain context.

ABSTRACT

Under the globalization and the multi-level complications of supply chains (SCs), SC disruptions increasingly occur to the detriment of SC performance (SCP). Here, we explore the ability of dynamic capability (DC) and SC resilience (SCRES) to support SCP with disruption considerations. The research results show that SC agility (SCA) is the determinant of SCP with disruption considerations. Both SC Collaboration and SCA mediate between knowledge-based DC and SCP with disruption considerations and between resource-based DC and SCP with disruption considerations, and their mediating roles are sequential and interdependent.

KEYWORDS: Dynamic capability, Supply chain resilience, Supply chain performance, Supply chain disruption

INTRODUCTION

With increasing environmental uncertainty and globalization, organizations must now more than ever obtain competitive advantages to achieve success. Competition no longer exists merely among organizations but among SCs (Wu et al., 2014) so organizations must factor in the capacities of upstream suppliers and the needs of downstream customers to rapidly respond to external volatility. In this process, SCs have the key role. Moreover, SCs are more complex as they include multilevel suppliers or customers, increasing their vulnerability. Dynamics of the external environment, such as technical progress, changing customer needs, political considerations and economic factors, increase the possibility of SC disruption. When SC disruption emerges, it is crucial to understand which capabilities a focal firm or a SC must have to remedy this disruption. This study focuses on SCP with disruption considerations, rather than SC disruption alone so its key target is SCP during or following SC disruption, and the antecedents of SCP with disruption considerations are the main focus.

Based on a literature review, two capabilities are proposed. First, SCRES demonstrates its importance in the disruptive situation. Second, from dynamics view, DC is a solution of environmental volatility. When SC disruption occurs, resilience is the most important factor for survival, so SCRES is closer to SCP with disruption considerations than DC. Rojo et al. (2018) note that a hierarchy of firm capabilities is composed of operational routines and DCs. The former is operational functions of the organization, and the latter is modifications of operational routines. They are related in that operational capabilities are the visible outcome of DCs (Liu et al., 2013). DC is a value-creating strategy that can improve operational capability; and over the long-term, it is an evolutionary process supporting an organization’s growth. Juttner and Maklan (2011) note that SCRES consists of four capabilities: SC flexibility, SC velocity, SC visibility and SC collaboration (SCC); and of these flexibility, velocity and visibility are included under “agility”. Therefore, SCRES include SC agility (SCA) and SCC. Liu et al. (2013) consider SCA as an operational capability. Likewise, SCRES is assumed to be an operational capability. Accordingly, we reasonably assume that the DC of a focal firm would be the most influential factor of its SCRES.

Several studies find that SCA significantly affects a firm’s financial or operational performance (Tse et al., 2016; Chan et al., 2017; Martinez-Sanchez & Lahoz-Leo, 2018; Liu et al., 2013; Al-Shboul, 2017; Gligor & Holcomb, 2012). Similarly, Wu et al. (2014), Panahifar et al. (2018) and Pradabwong et al. (2017) demonstrate that collaboration supports a firm’s performance. DC is a factor widely applied to explain variances in performance across competing firms (Liu et al., 2013). To date, given the sparseness of literature on how DC affects SCRES, only Lee and Rha (2016), who regards SC ambidexterity as resiliency of SC, examine the effect of DC on the resiliency of SC. In fact, Lee and Rha (2016) do not focus on the effect of DC on SCRES, but on SC ambidexterity. Moreover, it is unclear whether DCs can directly improve organizational performance. Wilden et al. (2013) find that DCs can directly influence organizational performance only when organizational structure is more decentralized, self-managed, and has local autonomy, or under a more competitive environment. In other words, the performance effects of DCs are contingent on organizational structure and competitiveness of the market.

According to resource-based theory and knowledge-based theory, DCs are divided into resource-based dynamic capability (RBDC) and knowledge-based dynamic capability (KBDC). In this study, RBDC, KBDC and SCA contain complex concepts. According to Teece (2007), RBDC is represented by a framework, consisting of sensing, seizing and transforming capability. In addition, a literature review shows that absorptive capability (AC) (Zahra and George, 2002; Liu et al., 2013), knowledge management process capability (KMPC) (Cantor et al., 2014) and organizational learning capability (Wu & Chen, 2014; Rojo et al., 2018) can represent KBDC. Because agility includes flexibility, velocity and visibility according to Juttner and Maklan (2011), agility is extended to the SC context as SCA. We assume that SC flexibility, SC visibility and SC velocity can represent SCA.

In this study, we explore the roles of two DCs of the focal firm, including RBDC and KBDC, as well as SCRES, comprising SCA and SCC, to see how they enable SCP with disruption considerations, combining SCP and SC disruption, to fill the research gap among these three. Furthermore, KBDC, SC velocity and SCP with disruption considerations are all first proposed as newly conceptualized constructs, and SCA is re-conceptualized, showing the uniqueness of this research model.

LITERATURE REVIEW AND HYPOTHESES

We develop the research model by combining the three research streams of SCRES, DC and SCP with disruption considerations. In this section, we propose our research model, literature review and research hypotheses.

Research Model Development

In this study, we explore the capabilities of successful SC in a dynamic environment. A competitive SC must have resilience to disruptions or vulnerabilities and the focal firm must have sufficient DC to deal with environmental uncertainty. Thus, we combine RBDC with KBDC and SCRES to reduce the impact of SC vulnerability and SC disruption. This can enable an effective model of SC risk management that achieves better SCP with disruption considerations. In this research model, DCs of the focal firm, including RBDC and KBDC, are drivers; SCRES, consisting of SCA and SCC, are mediators; SCP with disruption considerations of the focal firm is a dependent variable and industrial type is the control variable.

Development of Hypotheses

Supply Chain Resilience and Supply Chain Performance with Disruption Considerations

Some SCs recover from risk events more effectively than other SCs, which leads to concern about SCRES (Juttner & Maklan, 2011) though there are few empirical studies of SCRES.

Juttner and Maklan (2011) note that “SCRES addresses the SC’s ability to cope with the consequences of unavoidable risk events in order to return to its original operations or move to a new, more desirable state.”

Chan et al. (2017) note that agility helps deliver value to customers, face changes readily, value human knowledge and skills, and form virtual partnerships. To survive in a volatile business environment, firms should not only be agile themselves but should also be agile within their SC relationships (Tse et al., 2016). Chan et al. (2017) contended that a firm’s level of SCA represents the strength of the interface between the firm and its markets. Swafford et al. (2006) define SCA as the capability of the SC to adapt or respond quickly to a dynamic and unpredictable business environment. An agile supply chain enables its member firms to be more market-sensitive, more capable of synchronizing supply with demand, and better able to achieve shorter cycle times so SCA is widely considered to be the most critical success factor in today’s competitive marketplace (Chan et al., 2017). Tse et al. (2016) regard SCA as a firm’s ability to transform the threats of market uncertainty and SC disruption into competitive opportunities by increasing visibility in inventory and demand levels, and satisfying customer needs with speed and flexibility. This is in line with the view of Juttner and Maklan (2011). Accordingly, we consider SCA to reflect the three dimensions of flexibility, visibility and velocity.

Upton (1997) defines flexibility as “the ability to change or adapt with little penalty in time, effort, cost or performance.” Swafford et al. (2006) posit that flexibility in a firm’s SC process derives from co-alignment of its range and adaptability dimensions. Swafford et al. (2006) propose that SC process flexibilities include procurement/sourcing flexibility, manufacturing flexibility and distribution/logistics flexibility in a firm’s internal SC. Rojo et al. (2018) note that SC flexibility refers to the ability of a SC to react to changes in the environment. Researchers have suggested which dimensions SC flexibility should include, and we here adopt the model of SC flexibility proposed by Moon et al. (2012). A flexible SC can be not only a reactive capability, but also perform a strategic role (Rojo et al., 2018). In uncertain environments, firms can develop a competitive advantage by using flexibility to handle uncertainty and dynamics better than their rivals (Rojo et al., 2018).

Williams et al. (2013) define SC visibility as the access to high quality information that describes various factors of demand and supply. Scholars assume that the critical factors accelerating SC visibility are an automatic system and closer relationships between the SC partners. There is agreement that the resulting SC visibility is useful for high quality of information sharing (Papert et al., 2016; Wei & Wang, 2010; Williams et al., 2013).

Though speed is critical in SCs to sustain competitive advantage, there is currently little consensus over a definition of SC speed. Chan et al. (2017) note that the speed of a firm’s response to key SC outcome measures reduces manufacturing lead-times, increases new product introductions, and improves customer service. Speeds pertinent to SC management

(SCM) include customer response speed (Chiang et al., 2015), purchasing decision-making speed (Kaufmann & Gaeckler, 2015) and product launch speed. Here we combine the SC velocity concept suggested by Chan et al. (2017) and two specific SC speed constructs proposed by Chiang et al. (2015) and Kaufmann and Gaeckler (2015) in our SC velocity construct.

The SC Operations Reference (SCOR) model measures SCP by monitoring and diagnosing overall SC health using APICS (2017). To improve SCP measurement, Beamon (1999) proposes a new framework for SCP measurement including three key elements of strategic goals: resource, output and flexibility. Wu and Chang (2012) using the balanced scorecard propose SCP measurement in the e-SCM context. Wu et al. (2014) further categorize organizational SCP measurement into finance and non-finance in a complementary manner. Here we adopt the financial measures of SCP from Wu et al. (2014) because the research model focuses on evaluating disruption.

SCA reflects the complex coordination and integration among different channel members, which enable firms to change SC practices in response to market changes (Liu et al., 2013). Due to the growing need for timely and cost-effective means of product and service delivery, SCA is necessary for superior firm performance (Liu et al., 2013). SCA mediation between drivers and firm performance is evidenced with significant impact by Chan et al. (2017), Liu et al. (2013), and Gligor and Holcomb, (2012). Even focusing on the effects of disruption, we still argue that SCA is a determinant of SCP. Accordingly, we propose the following hypothesis:

H1, SCA has positive impact on firm’s SCP with disruption considerations.

There are several important reasons for inter-firm collaborations, for example, sharing the cost of large investments, spreading risk, and accessing complementary resources (Wu et al., 2014). Firms may collaborate to access resource combinations or improve capabilities (Pradabwong et al, 2017). Liao, Hu and Ding (2017) note that collaboration is a significant process that leads to value-creation opportunities in SCM. SCC targets mutual benefits and profit maximization for the SC members through a well-coordinated plan and delivery of offerings (Pradabwong et al, 2017). Prior research has identified SCC in various ways, generally concerned with the relationship, the process and mutual benefits gained from collaborating with SC partners (Pradabwong et al, 2017). Angerhofer and Angelides (2006) propose “a collaborative supply chain model” that includes stakeholders, business strategy, processes, enabling technology, topology and levels of collaboration.

In a collaborative SCM, transacting partners (e.g. suppliers and their customers) exchange and integrate information to make strategic or tactical joint decisions (e.g. supply and demand forecasts) (Panahifar et al., 2018). Trading partners with a higher level of collaboration can achieve better operational performance (Panahifar et al., 2018). That collaboration supports a firm’s performance is found by Wu et al. (2014), Panahifar et al. (2018) and Pradabwong et al.

(2017). We also assume that SCC is a precursor of SCP despite SC disruptions. Therefore, we postulate:

H2, SCC has positive impact on firm's SCP with disruption considerations.

Most SCC approaches encourage sharing information (Panahifar et al., 2018). The results of improved information sharing include improved coordination for faster response, increased agility and greater flexibility (Panahifar et al., 2018). SCA requires a firm to closely supervise the legally separate but operationally interdependent partners to maintain a close and coordinated relationship (Liu et al., 2013). This means that SCA refers to how well a firm collaborates with its channel partners in executing SC practice (Liu et al., 2013). Thus, better SCC leads to higher SCA. Gligor and Holcomb (2012) find that SC coordination, cooperation and communication are the determinants of SCA. Accordingly, we propose the following hypothesis:

H3, SCC supports SCA.

<u>Dynamic Capability of the Focal Firm and Supply Chain Resilience</u>

Liu et al. (2013) note that "DCs are defined as the firm's ability to integrate, build, and reconfigure internal and external competences to address rapidly changing environments and achieve new and innovative forms of competitive advantage." The DC perspective is a widely applied paradigm to explain how performance varies across competing firms (Liu et al., 2013). DCs emphasize the importance of change in the capabilities that support firm-specific resources, and they focus particularly on the development of these resources. Because DCs include both tangible and intangible resources of a firm, we refer to them as resource-based dynamic capabilities (RBDCs). RBDCs include three clusters of activities: sensing, seizing and transforming capabilities (Teece, 2007). Sensing refers to scanning, perceiving, absorbing, and interpretive activities of organization. Seizing refers to the ability of organization to make timely decisions in order to develop new opportunities. Transforming is the ability of organization to reconfigure organizational resources timely and efficiently for matching the changed environment. RBDCs are generated and based only on the combination of these three capabilities, so we can consider RBDCs as a strategic integrating capability.

However, SCA is one type of operational capability (Liu et al., 2013), and in the firm capability hierarchy proposed by Rojo et al. (2018), DC is higher than operational capability. Thus, after a focal firm makes a strategic decision, this strategy would modify operational process. Vanpoucke et al. (2014) reveal that supplier integrative capability (i.e. RBDC) significantly influences process flexibility. Moreover, Dubey et al. (2018) show that SC connectivity is a predictor of SC visibility, while Zhang and Cao (2018) find that inter-organizational systems are a predictor of SCC. Hence we regard SC connectivity and inter-organizational systems as one type of assets within SC and propose the following hypotheses:

H4, A firm's RBDC supports SCA.

H5, A firm's RBDC supports SCC.

A DC with intangible resources such as knowledge is also a source of competitive advantage. From the organizational learning perspective, recognizing the new external knowledge from SC partners is a very important process within knowledge acquisition. Furthermore, an organization utilizes the knowledge management (KM) system to organize and disseminate useful knowledge among its employees. And the organization continues to learn through external challenges. In this study, we formulate KBDC with AC, KMPC and organizational learning.

Zahra and George (2002) consider AC as "a DC pertaining to knowledge creation and utilization that enhances a firm's ability to gain and sustain a competitive advantage". KMPC is the ability of an organization to acquire, create, transfer, integrate, share and apply knowledge related resources and activities across functional boundaries to generate new knowledge. It should be recognized that organizational learning as a group-based learning approach originates from individual learning (Wu & Chen, 2014).

An organization with knowledge-based dynamic learning capability will generate collective memory that is embedded in the processes and culture of the organization. Therefore, an organization with KBDC would make better strategic decisions in response to a changing environment than its competitors. These effective strategies will in turn support their SC operations and executive factors such as SC flexibility, SCA and SCC. Liu et al. (2013) find that AC has a significant effect on SCA, while Rojo et al. (2018) show that both operational AC and organizational learning are the determinants of SC flexibility. Cantor et al. (2014) show that the KM process is a predictor of joint planning with suppliers. Accordingly, we propose the following hypothesis:

H6, A firm's KBDC facilitates SCA.

H7, A firm's KBDC facilitates SCC.

Mediating Effects

According to the hierarchy of firm capabilities proposed by Rojo et al. (2018), because DC pertains to the high-level strategic capability of a firm, SCA and SCC are the ordinary operational capability of a firm. When SC disruption occurs, DC can affect SCP only through SCRES because a system without the element of resilience cannot prevent or cope with the results of a disruption (Ponomarov & Holcomb, 2009). In contrast, SCA and SCC are both elements of SC resilience. Therefore, we postulate the following:

H8a, SCA mediates the association between RBDC and SCP with disruption considerations.

H8b, SCA mediates the relatedness between KBDC and SCP with disruption considerations.
H9a, SCC mediates the association between RBDC and SCP with disruption considerations.
H9b, SCC mediates the relatedness between KBDC and SCP with disruption considerations.

Control Variable

Firms in highly dynamic industries, such as high-tech industries, have shorter product lifecycles, in which time-to-market is critical (Wu et al., 2014). These firms show higher revenue change and customer turnover compared to those in less dynamic industries (Wu et al., 2014). Some studies suggest that industry type is an important variable to control the performance of SC practice (Wu et al., 2014). Thus, a firm's SCP under disruption should also consider industrial type.

METHODOLOGY

We collected research data through a survey, and used PLS-SEM for data analysis. The analysis unit is focal firm. As described below, the questionnaire was mostly adopted from previous studies apart from two items of SC velocity and one item of seizing capability, which were developed by the authors.

Measurement

The questionnaire has two parts. The first part is the basic data for firms and respondents; the second part uses a 7-point Likert scale (ranging from 1 = strongly disagree to 7 = strongly agree) to analyze five constructs: RBDC, KBDC, SCA, SCC and SCP with disruption considerations. We considered their sub-constructs and the indicators of these constructs and selected the unambiguous constructs without overlapping sub-constructs as our constructs.

SC flexibility uses the scale from Rojo et al. (2018). SC visibility uses the scale from Dubey et al. (2018). SC velocity adapts the scales from Chiang et al. (2015), and Kaufmann and Gaeckler (2015), together with the supply chain speed construct self-developed from Kaipia (2008) and adapted from Lee and Rha (2016). SCC uses the scale from Wu et al. (2014). RBDC uses the scale from Lee and Rha (2016). AC adapts the scale from Garcia-Morales et al. (2007). KMPC uses the scale from Wu and Chen (2014). Organizational learning capability uses the scale from Rojo et al. (2018). SCP with disruption considerations adapts scales from the financial measures of Wu et al. (2014).

The questionnaire design considered the problem of common method bias to elicit subjective responses from the informants. Podsakoff et al. (2003) notes that common method bias is due to measurement methods rather than the construct of interest. We thus separated the items of the questionnaire into four sections, according to the content and the length of each section. Each section was preceded by a brief introduction to transfer the informants' attention and avoid fatigue. In the questionnaire preface, we assured informants of their anonymity and that response data was only for analysis. Informants did not need to record their email address to answer this online questionnaire.

Subject

Many industries in Taiwan are transforming into multinational corporations with increasingly international contacts and thus face increasing risk of SC disruption. For the context of this study, B2B manufacturing firms are more appropriate to be the subject. We investigated B2B focal firms from the 2018 list of manufacturing firms published by the Taiwan Stock Exchange Corporation and OTC Corporation. For the pilot phase, we obtained the 2018 list of public companies published by the Taiwan Stock Exchange Corporation (TSEC) available online and extracted manufacturing firms. A total of 630 manufacturing public companies received emails with an online questionnaire hyperlink. There are thus a total of 30 respondents for analysis in the pilot phase. In the formal investigative phase, the same invitation emails were followed up with three follow-up emails. Next, over-the-counter-listed (OTC-listed) companies were searched from the OTC Exchange website and 1,115 manufacturing listed companies were accessed. These companies also received this invitation email with an online questionnaire hyperlink and two follow-up emails were sent when there was no response. The investigation period of these two phases was from March 12th to April 19th of 2019. There were 72 responses from the two phases and the initial analysis was based on these 72 samples. The samples in the pilot phase were put into the initial analysis. The respondent firms are mostly high-tech and middle and small corporations but have high annual revenue. The informants are mostly upper-managers, especially vice general managers over one-fourth, and their service years are mostly over 20 years.

Survey Procedures

The survey had three stages, including the pretest and pilot test of the questionnaire and the formal survey. In the pretest stage, the questionnaire was evaluated by five professors from four universities of Taiwan and the upper managers of three manufacturing firms to confirm its surface validity. In the pilot survey procedure, 30 samples were used to assess the questionnaire. The item with the highest factor loading from every first-order sub-construct of three original second-order constructs (i.e. KMPC, SC flexibility and SC velocity) was selected to reflect these three first-order sub-constructs. This completed the formal questionnaire, as shown in the Appendix. In the formal survey procedure, the final questionnaire was our measurement instrument.

Measurement Model

This study uses structural equation modeling with Smart PLS 2.0 M3 to estimate the research model. PLS-SEM is appropriate for this study for the following reasons (Ali & Park, 2016; Hair et al., 2017):

1. This is an exploratory study. The hypothesis associations between dynamic capabilities (i.e. RBDC and KBDC) and SC resilience (i.e. SCA and SCC) are in the early stage of theory development.
2. The structural model is complex, including both first-order and second-order reflective constructs.
3. The sample size (n=72) is relatively small and the data are not all normally distributed.

This study follows a two-step approach to analyze and interpret the PLS-SEM results: (1) assess measurement model, and (2) test the structural model. We implement PLS algorithms in the first stage.

Scale Refinement and Reliability

In these results, the meanings of the items of the three sub-constructs of RBDC and KBDC seem partially redundant or duplicated. Thus, we deleted the fourth item from sensing, the third item from seizing and the fifth item from transforming in the RBDC construct. The second and third items from absorptive capability, the third and fourth items from knowledge management process capability, and the first and third items from organizational learning in the KBDC construct were all eliminated to increase validity.
Cronbach's alpha is the most generally accepted criteria for internal consistency reliability. Cronbach's alpha values of all second-order sub-constructs and first-order constructs range from 0.852 to 0.978 which is satisfactory for a threshold value 0.7.

Validation

Scale validation proceeds in the two phases of convergent validity and discriminant validity analyses.
Convergent validity is assessed by three criteria (Wu & Chen, 2014) as following:
1) All item loadings should be larger than 0.7;

2) Composite reliability (CR) for each construct should be greater than 0.8;
3) Average variance extracted (AVE) for each construct should be larger than 0.5.

The factor loadings of all items range from 0.753 to 0.981, the CR for all constructs from 0.9 to 0.983, and AVE from 0.694 to 0.955. These three criteria are all satisfactory. Discriminant validity between constructs is assessed according to the recommendation of Fornell and Larcker (1981) that the square root of AVE for each construct should be larger than its correlations with all other constructs. The lowest square root of AVE 0.833 (corresponding to SC flexibility) is higher than the highest correlation between any pair of constructs 0.829 (between seizing and transforming). Hence, the discriminant validity meets the criterion.

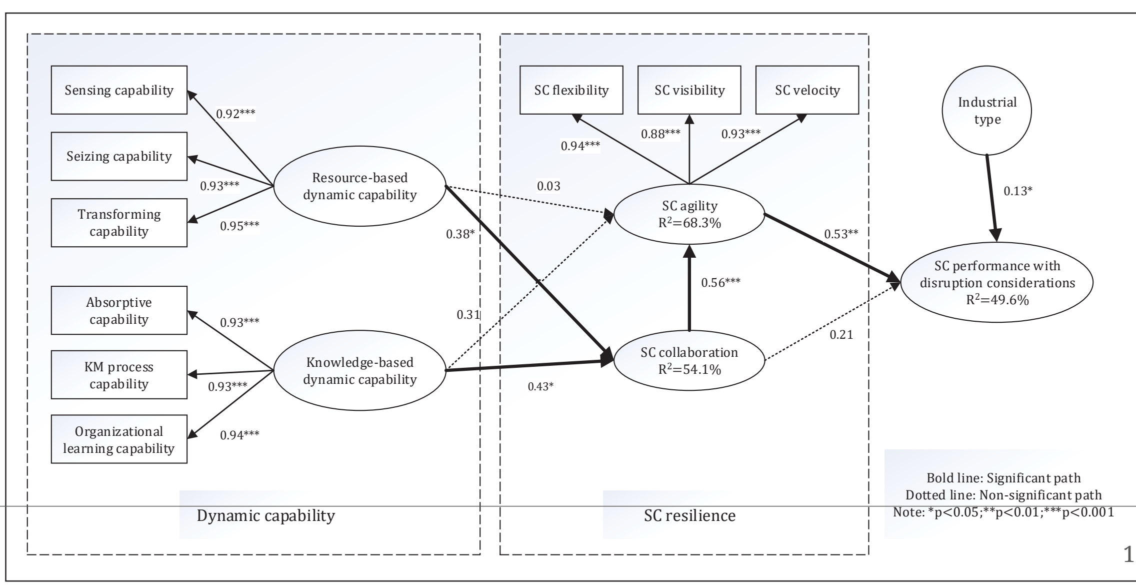
DATA ANALYSIS AND RESULTS

In this stage, we analyze hypothesized relationships in our research model and the mediating effects of SC resilience, and then discuss the findings of this research.

Structural Model: Path Analysis or Direct Effects

We verify causal relationships of the hypotheses in our research model using PLS for our data to estimate the standardized path coefficients and their statistical significance for the hypothesized paths and compare relative effect sizes for common dependent variables. It is also necessary to examine the relative importance of the first-order sub-constructs in reflecting the second-order construct, namely the sub-construct factor loadings of RBDC, KBDC and SCA. We ran the bootstrapping algorithm with 1,000 resamplings (Hair et al., 2017, p.97, 195). The results of the analysis, including path coefficients, path significances, sub-construct factor loadings, and variance explained (R^2 values) for each dependent variable, are shown in Figure 1.

Figure 1 Structural Model



For the path between sub-construct and construct, sensing capability, seizing capability and transforming capability all show high predominant loadings, reflecting RBDC (factor loadings = 0.92, 0.93 and 0.954). And they all have high variances (R^2= 84.6%, 86.5% and 91%) explained. Transforming capability is the highest, followed by seizing capability and then sensing capability. Of these, transforming capability is the key factor of RBDC. Similarly, AC, KMPC and organizational learning capability all represent high notable loadings, reflecting KBDC (factor loadings = 0.926, 0.934 and 0.939). In addition, they all have high variances (R^2= 85.8%, 87.3% and 88.1%) explained. Organizational learning capability is the highest, followed by KMPC and then AC. Of these, organizational learning capability is the key factor of KBDC. Likewise, SC flexibility, SC visibility and SC velocity all indicate highly significant loadings, reflecting SCA (factor loadings = 0.94, 0.881 and 0.93). They also all have high variances (R^2= 88.3%, 77.6% and 86.5%) explained. SC flexibility is the highest, followed by SC velocity and then SC visibility. Of these, SC flexibility is the key factor of SCA.

For dependent variables, only SCA (β=0.53, path coefficient) has significant and positive impact on SCP with disruption considerations, so H1 is supported. SCC (β=0.21) does not have significant and positive effect on a firm's SCP with disruption considerations, so H2 is not supported. SCP with disruption considerations has 49.6% of its variance explained. However, SCC (β=0.56) has significant and positive effect on SCA, thus supporting H3. SCA has 68.3% of its variance explained. But RBDC (β=0.03) and KBDC (β=0.31) do not have significantly positive impacts on SCA, thus not supporting H4 and H6. RBDC (β=0.36) and KBDC (β=0.43) are both the prominent determinants of SCC, so H5 and H7 are supported. They jointly explain 54.1% of the variance in SCC. Industry type (β=0.13) has significant impact on SCP with disruption considerations.

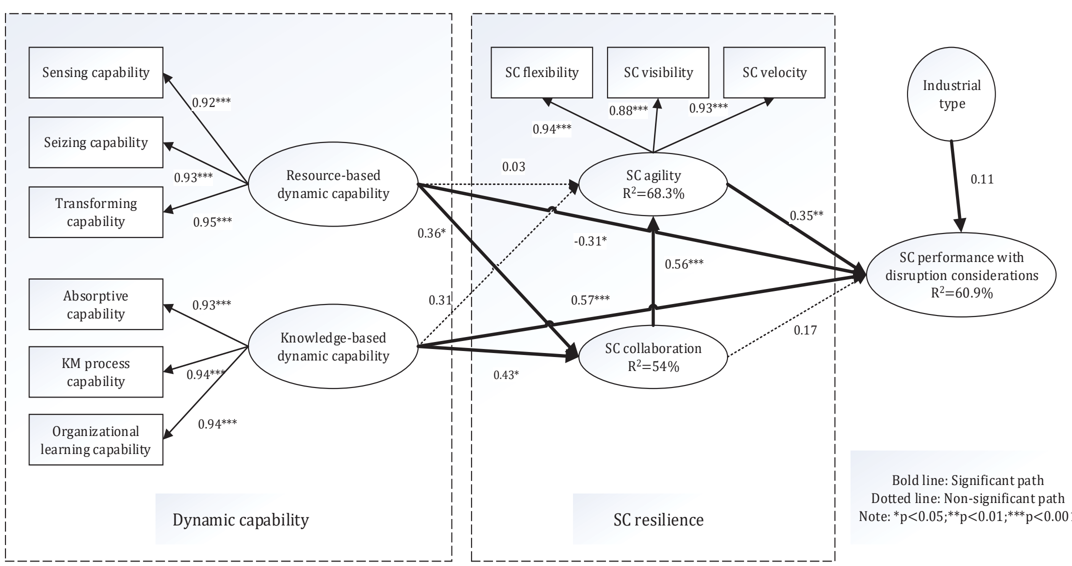
Mediating Effects

The mediating effect is supported when the path from independent variable to the mediator and the path from mediator to the dependent variable are both significant. In this case, the condition on the direct path from the independent variable to the dependent variable will be considered (Hair et al., 2017: p.228-235). Since the association from RBDC to SCA is not significant, and even though the effect of SCA on SCP with disruption considerations is prominent, the direct relationship between RBDC and SCP with disruption considerations is not considered, thus not supporting H8a. Similarly, because the link from KBDC to SCA is not significant, and although the effect of SCA on SCP with disruption considerations is significant, the direct relationship between KBDC and SCP with disruption considerations is not considered, so not supporting H8b. Likewise, since the relationship between SCC and SCP with disruption considerations is not significant, H9a and H9b are not supported.

Three mediating effects are found, including the mediating effect of SCA from SCC to SCP with disruption considerations, the two SCC from RBDC to SCA and from KBDC to SCA. Since the effect of SCC on SCP with disruption considerations is not significant, SCA has full mediating effect for the link from SCC to SCP with disruption considerations. Similarly, since the effect of RBDC on SCA is not significant, SCC has full mediating effect for the association from RBDC to SCA. Likewise, because the effect of KBDC on SCA is not significant, SCC has full mediating effect for the relationship between KBDC and SCA.

Even though H8a, H8b, H9a and H9b are not supported, we still examine the two relationships between RBDC and SCP with disruption considerations and between KBDC and SCP with disruption considerations. The alternative model is proposed as shown in Figure 2. In Figure 2, RBDC (β=-0.31) and KBDC (β=0.57) are both the important predictors of SCP with disruption considerations but the effect of RBDC on SCP with disruption considerations is negative. Both of them and SCA jointly explain 60.9% variance of SCP with disruption considerations. The explained variance of SCP with disruption considerations in the alternative model is 11.3% much more than that in the original model. There is a partial mediating role of SCC and SCA in enabling SCP with disruption considerations.

Figure 2 Alternative Model



Findings and Discussions

In this research model, the first important finding is that the effect of KBDC on SCP with disruption considerations has the highest direct significance. This accounts for the fact that

KBDC is the most important determinant of SCP with disruption considerations. In other words, DC underlying knowledge is superior to SCA. This indicates that through AC, KMPC and organizational learning, organizations can recover from SC disruption more than through SCA. In this study, we integrate AC, KMPC and organizational learning into KBDC from the previous works. It especially stresses the importance of KBDC on SCP in the situation of SC disruption. The second important finding is that the better RBDC, the worse SCP with disruption considerations. Namely, RBDC is the suppressor of SCP with disruption considerations rather than an enabler. These two findings show that KBDC as the source of competitive advantage, integrating AC, KMPC and organizational learning, is a more sophisticated capability for addressing the situation of SC disruption than RBDC. It indicates that learning is imperative for organization, which always needs more time before the success of transforming organization. That a focal firm can succeed in addressing SC disruption must learn to generate effective DC which intangible resource like knowledge is particularly essential.

For SCP with disruption considerations, apart from KBDC, the second important predictor is SCA consistent with the results of the previous researches. In this model, SCC is the only precursor of SCA. Because SCA reflects the connective capability among SC partner network, the success of SCC would drive SCA to response market change and to address SC disruption. Only focal firm's DC cannot trigger SCA no matter which DC is, but through SCC, RBDC and KBDC are the predictors of SCA, thus RBDC and KBDC are the indirect predictors of SCA. This is the third important finding. Only SCC cannot enable SCP with disruption considerations. SCC can improve SCP with disruption considerations only through SCA, so SCC is the indirect determinant of SCP with disruption considerations. KBDC and RBDC are both determinants of SCC and KBDC is more important than RBDC for SCC. This stresses the importance of KBDC once more for SCC. This is the fourth important finding.

In our initial hypotheses, H8 presume that SCA mediates the associations between RBDC or KBDC and SCP with disruption considerations. H9 presume that SCC mediates the associations between RBDC or KBDC and SCP with disruption considerations. In these four hypotheses, SCA and SCC are independent and not related. After the data analysis, we find that the mediating roles of SCC and SCA between RBDC or KBDC and SCP with disruption considerations are sequential and dependent rather than respective and independent. In other words, the effects of RBDC and KBDC on SCP with disruption considerations can be through SCC first and then SCA. This is the fifth important finding of this research.

Accordingly, there are three strong associations in this research model. The strongest path lies in the link from KBDC to SCP with disruption considerations. The second strongest connection is the association from KBDC through SCRES, i.e. SCC first and then SCA, to SCP with disruption considerations. The third strong relationship is from RBDC through SCRES, i.e. SCC first and then SCA, to SCP with disruption considerations.

CONCLUSION

We combine the perspectives of three research streams, including DC, SCRES and SCP with disruption considerations in research framework. In this framework, DCs are drivers, composed of KBDC and RBDC; SCRES is mediator, composed of SCA and SCC; and SCP with disruption considerations is a dependent variable. The initial research findings demonstrate moderately explained variance in SCP with disruption considerations, showing that the mediating role of SCRES and the drivers of DC are almost consistent with our original formulation, apart from three direct linkages from SCC to SCP with disruption considerations, from RBDC to SCA and from KBDC to SCA. The reasons are inferred as following:
(1) Dependent variable contains two concepts, i.e. SCP and SC disruption, thus the effect of SCC on SCP with disruption considerations is not significant: Given scarce extant literature regarding the effect of SCC on SC disruption, most of them are about the effect of SCC on SCP. Because SC disruption is a negative concept, only SCC cannot trigger SCP with disruption considerations.
(2) SCA is one type of dynamic capability, thus the effects of RBDC and KBDC on it are not significant: Rojo et al. (2018) noted that a flexible SC can be not only a reactive capability, but also perform a strategic role. Thus, we can infer that SCA reflected by SC flexibility could not only operational capability but also strategic capability, i.e. dynamic capability. The reason that DCs are not the predictors of SCA is clear.
There are also some limitations in this study. First, this is cross-sectional investigation with a self-reported questionnaire which includes all independent variables and dependent variables, so common method bias is possible. Especially, the dependent variable considers the risk of disruption in SCP. If there is the above case, future researchers can separate independent variables and dependent variable into two investigative phases for the same respondent to complement the cross-sectional investigative method. Second, there are potential endogenity in RBDC. It could avoid this problem to add time-series review into transforming capability items (e.g. the items of organizational learning capability have three years review).

ACKNOWLEDGMENT

The authors are grateful to the Ministry of Science and Technology, R.O.C., for the partial financial support to this work under the grant MOST 108-2410-H-004-205.

APPENDIX

Formal Questionnaire

Part 1: Basic information
Firm characteristics
1. Industry type
2. Annual revenue (NT$ millions) Last year
3. Number of employees (persons)
4. Number of suppliers

Respondent's characteristics
1. Working experience (years)
2. Education level
3. Gender
4. Position
Part 2: Constructs and item measures
Resource-based Dynamic Capability
Sensing capability
SEN1: We can perceive demand shifts and changes in customer preference before competitors do.
SEN2: We can feel major potential opportunities and threats.
SEN3: We have good observation and judgment ability.
SEN4: We have frequent interactions with other partners to acquire new knowledge related to product development, process innovation, or logistics and distribution practices.#
Seizing capability
SEI1: We can quickly deal with conflicts in the strategic decision-making process.
SEI2: Under any circumstance we can make timely decisions to deal with environmental change.
SEI3: We can reconfigure resources in time to address environmental change.#
SEI4: We can quickly decide our technological innovation and development.+
Transforming capability
REC1: We can successfully realign or reinvent organization in response to (or in anticipation of) market change.
REC2: We can successfully reconfigure organizational resources to come up with new productive assets.
REC3: We are able to engage in resource re-combinations to better match the product-market areas.
REC4: We are able to align skills to meet the current customer's needs.
REC5: We can effectively integrate and combine existing resources into novel combinations.#
Knowledge-based Dynamic Capability
Absorptive capability
AC1: We have a clear division of roles and responsibilities to acquire, analyze, interpret, understand and utilize new external knowledge into its operations.
AC2: We have the necessary skills to implement new acquired knowledge better than its rivals.#

AC3: We have considerable competences for knowledge development.#
AC4: We can recognize new external knowledge and has the competences to absorb, adapt and use this knowledge.
Knowledge management process capability
KC2: We can codify acquired knowledge into accessible and applicable formats.
KT2: We can distribute relevant knowledge throughout the organization.
KI2: We can integrate different sources and types of knowledge.#
KA2: We can apply knowledge to solve new problems.#
Organizational learning capability
OL1: We have acquired and used much new and relevant knowledge that provided competitive advantage over the last three years.#
OL2: We have acquired important capacities and skills that provided competitive advantage over the last three years.
OL3: The improvements of my firm have been influenced fundamentally by new knowledge entering the organization over the last three years.#
OL4: My firm is an organization that fosters learning.
Supply Chain Agility
Supply chain flexibility
SF3: There are multiple suppliers that provide major materials/components/products in our SC.
OSF4: Our SC can adjust manufacturing facilities and processes.
DF2: Our SC can change delivery modes.
ISF1: The information systems of our SC can support the transportation and distribution management.
Supply Chain Visibility
VIS1: Inventory levels are visible throughout the SC.
VIS2: Demand levels are visible throughout the SC.
Supply Chain Velocity
PDS2: Our SC reacts faster to purchasing changes than our competitors.
CRS1: Our SC can quickly modify products to meet customers' requirements.
SCS2: Our SC can quickly deliver products to customers before the due date.+
Supply Chain Collaboration
COL1: My firm and SC partners set up a communication plan for action.
COL2: My firm and SC partners collaborate in developing new market and customer response.
COL3: My firm and SC partners collaborate in designing their processes or products.

COL4: My firm and SC partners collaborate in implementing their operational activities.
COL5: My firm and SC partners have frequent interaction when problems occur.
Supply Chain Performance with Disruption Considerations
FM1: Our supply chain can improve return on investment under the risk of supply chain disruption.
FM2: Our supply chain can improve return on assets under the risk of supply chain disruption.
FM3: Our supply chain can improve sales growth under the risk of supply chain disruption.
FM4: Our supply chain can improve market share under the risk of supply chain disruption.
FM5: Our supply chain can improve production and inventory cost under the risk of supply chain disruption.

ABSTRACT

Automotive recalls have impacted the companies and the customers involved. To this account, we examine the antecedents of the speed to recall—assessed via National Highway Traffic Safety Administration (NHTSA) investigation time and manufacturers' time to recall— and, subsequently, examine the impact of the speed to recall on recall completion ratio, a measure that captures the effectiveness of the recall process. Our study contributes to the literature and practice, alike, by highlighting factors that affect the speed and effectiveness of recall process while demonstrating the significance of reducing NHTSA investigation time and time to recall in improving recall completion ratio.

KEYWORDS: Automotive recalls, Recall completion ratio, Time to recall, Investigation time, Secondary data

INTRODUCTION

The National Highway Traffic Safety Administration (NHTSA) reports an increasing trend in automotive recalls. In the past few years, the number of vehicles recalled have exceeded the number of vehicles sold (Gorzelany, 2018), and the cost of recalls in 2016 amounted to $22.1 billion dollars (Jibrell, 2018). However, despite the recalls issued, there are approximately 70 million cars on the road that have open recalls (Gillis, 2018). Vehicles with open recalls not only can have safety concerns to their drivers and passengers, but also may pose a real threat to other vehicles on the road. In addition, automotive recalls have drawn the attention of lawmakers. On December 4th, 2015 the US government signed into law Fixing America's Surface Transportation Act (FAST Act), under which automakers must report recalls and their completion rates to U.S. Congress. And, despite the significance of recall completion rates, we have limited understanding about the speed of the recall process that might influence recall completion rates.

Recalls can have a significant impact on affected firms' performance and threaten their very survival (Eilert et al., 2017). For instance, Takata had to file for bankruptcy due to the recalls involving their airbags and the costs incurred in the process (Tajitsu, 2017). Hence, NHTSA and auto manufacturers involved have the motivation to undertake a comprehensive investigation prior to issuing a recall. Besides, auto manufacturers might want to strategically time their recalls to minimize the negative consequences of issuing a recall. In one instance, it is documented that Toyota saved $100 million by delaying a full recall (McCurry, 2010). There is also significant variability in the NHTSA investigation times and auto manufacturers' time to recall (*source* NHTSA), which could influence the effectiveness of recalls completion.

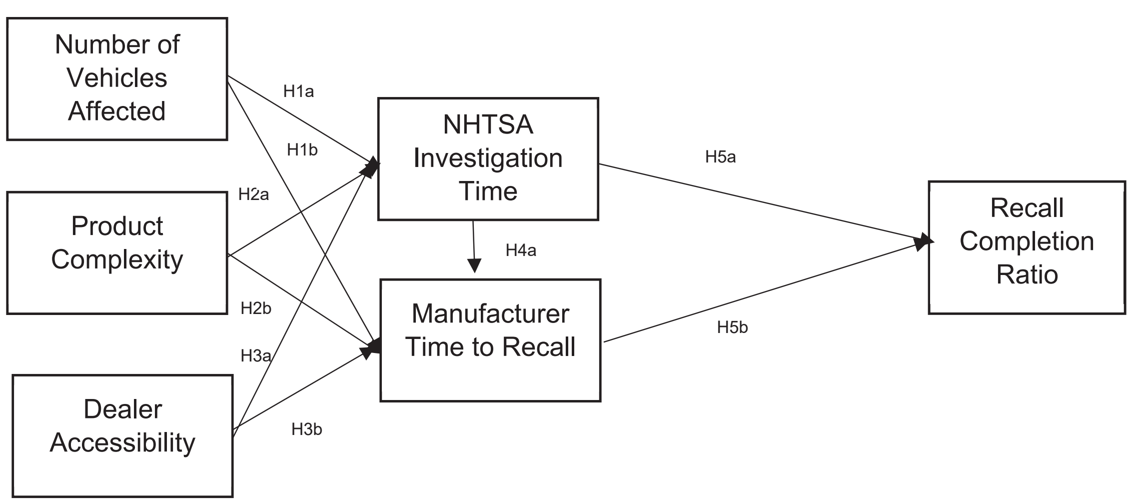
In this study, we examine two distinct components of the speed to recall— NHTSA investigation time and auto manufacturers' time to recall— as factors that might influence recall completion ratio. Besides, we utilize the behavioral theory of the firm to examine the antecedents to NHTSA investigation time and auto manufacturer time to recall. The behavioral theory of the firm suggests that "firms selectively attend to market information, conduct limited search, and find satisficing solutions" (Eilert et al., 2017, p.113). In this regard, we examine the number of vehicles affected, product complexity, and dealership accessibility as factors that can influence the time to recall.

RELEVANT LITERATURE REVIEW

The studies on automotive recalls can be broadly classified into two categories, one examining the effects of recall and the other examining the drivers of recall. Studies that examine the effects of recall largely examine its impact on variables such as firms' financial performance and brand sales. For instance, Liu and Shankar (2015) examine the impact of recalls on brand sales and advertising effectiveness while Borah and Tellis (2016) examine the effect of online negative chatter associated with recalls across other models of the same brand and across brands within same segments and their impact on sales and stock market performance. More recently, Topaloglu and Gokalp (2018) examined how brand concept moderates the relationship between recalls and product sales.

Among studies that examine the drivers of recall, Shah, Ball, and Netessine (2018) examine the plant level drivers of automotive recall. Specifically, they examine the impact of plant variety, product variety, and capacity utilization as the drivers of automotive recalls. Eilert et al. (2017) examine the effect of severity of problem on time to recall contingent of brand reliability. They also examine the effect of time to recall on stock market performance. And, Ni and Huang (2018) examine the effect of the source of defect (i.e., design or manufacturing), parties responsible for defect, types of defect, the number of models involved, and the number of prior recalls on time to recall. None of these studies look at NHSTA or dealer accessibility in relation to time to recall, it must be noted that mandatory recalls are initiated by NHSTA and the relevant customer information and recall service process are completed by the dealers. These two organization are important entities in the automotive recall process.

Figure-1: Proposed Model



Although the extant literature has informed us on the implications of recalls and some factors that can influence recalls. To the best of our knowledge, there is no extant study that has examined the impact of the speed of recall on recall completion ratio, which is significant from a legal, a financial, and a customer perspective. This study also contributes to extant literature by examining two distinct components to the speed of recall that has been largely overlooked, and their antecedents (see Figure-1).

HYPOTHESES DEVELOPMENT

Number of Vehicles Affected → Investigation Time; Time to Recall

As customers submit complaints, NHTSA screens the complaints for safety issues, if deemed serious then it would result in a formal investigation. However, if the number of vehicles affected is large, there is likely to be greater public pressure towards speeding up the formal investigation. Similarly, if the number of vehicles involved is large the manufacturer is likely to issue the recall quickly to salvage brand reputation. Besides, as the number of vehicles involved increases, the chance of injury or a crash related to the recall issue at hand increases, which can then cause legal and financial problems to the organizations involved. Therefore, we propose, the following hypotheses.

H1a: The number of vehicles affected negatively influences NHTSA investigation time.
H1b: The number of vehicles affected negatively influences manufacturers' time to recall.

Product Complexity → Investigation Time; Time to Recall

An engine in car can be strategic product while a windshield wiper can be a commodity product. Strategic products are typically more complex in nature than commodity products, and, hence, it is likely to take longer for both, NHTSA and the manufacturer to determine the root-cause of the problem associated with strategic products vis-à-vis commodity products. As the complexity of the product increases, it requires greater skill, time, and effort to determine the root-cause of the associated problem. Moreover, determining accountability associated with a complex product is going to be relatively more difficult. Hence, we propose the following hypotheses.

H2a: Product complexity positively influences NHTSA investigation time.
H2b: Product complexity positively influences manufacturers' time to recall.

Dealer Accessibility → Investigation Time; Time to Recall

Dealers serve as the primary source of data regarding customer reported problems during an investigation for NHTSA and to the manufacturer. Since, dealers deal directly with customers, they are often very knowledgeable regarding customer reported problems, which can then further help with formal investigations and the manufacturers' recall process in a timely manner. Moreover, since dealer interact with customers on a regular basis, they have access to timely information regarding customer contact details, which can be instrumental while the manufacturer contemplates to issue a recall. Thus, we propose the following hypotheses:

H3a: Dealer accessibility negatively influences NHTSA investigation time.
H3b: Dealer accessibility negatively influences manufacturers' time to recall.

Investigation Time → Time to Recall

With the NHTSA investigation time becoming longer, it is more likely that the manufacturer will have less flexibility to delay issuing the recall, which can be due to the need to preserve brand reputation. Moreover, as NHTSA investigation time increases, it gives the manufacturer greater time to gather relevant information regarding the potential recall and effectively plan resource deployment, which can then help quicken its decision to issue a recall if needed. Thus, we propose the following hypothesis:

H4: Investigation time negatively influences manufacturers' time to recall.

Investigation Time & Time to Recall → Recall Completion Ratio

As the NHTSA investigation time and manufacturers' time to recall increases, the eventual recall notices might not reach the correct customer due to inaccurate databases regarding customers. Moreover, increased investigation time and manufacturers' time to recall are likely to convey a lack of seriousness regarding the recall to the customer. With increased time to recall, customers are likely to have experienced the problems attributed to the recall and might make a self-determination not to expend resources such as their time and effort towards addressing the issue. Therefore, we propose the following hypotheses:

H5a: NHTSA investigation time can negatively influence recall completion ratio.
H5b: Manufacturers' time to recall can negatively influence recall completion ratio.

DATA AND ANALYSIS

Data Collection and Analysis Software

The recall data are obtained from NHTSA while the data regarding dealerships are obtained from a third-party vendor. The data collected involved recall investigations during the period of 2012-2018. Besides, we only focused on mandatory recalls to examine the effect of NHTSA investigation times. The data was compiled using Microsoft Access and analyzed employing the path analysis structural equations modeling (SEM) technique in STATA 13 as the variables use in our study were observed and not latent. A total of 176 unique mandatory recalls were considered in this study.

Measures Used

In this study, our primary dependent variable is captured as the ratio of the number of vehicles remedied to total number of vehicles involved. NHTSA investigation time is recorded as the time since a formal investigation began related to the recall to when the manufacturer was notified, and the manufacturer time to recall is the duration since the manufacturer was notified to when the customer was intimated regarding the recall by the manufacturer. The measure for number of vehicles affected by the recall was obtained from the NHTSA website, and product complexity was coded as either a 'zero' or 'one' depending upon whether it was a commodity type product or a strategic product respectively. And as noted earlier, an engine in car can be strategic product while a windshield wiper can be a commodity product. We use the dealership count for each brand at the time of investigation being opened as a proxy measure for dealership accessibility. All variables were standardized prior to our SEM analysis in STATA.

Controls

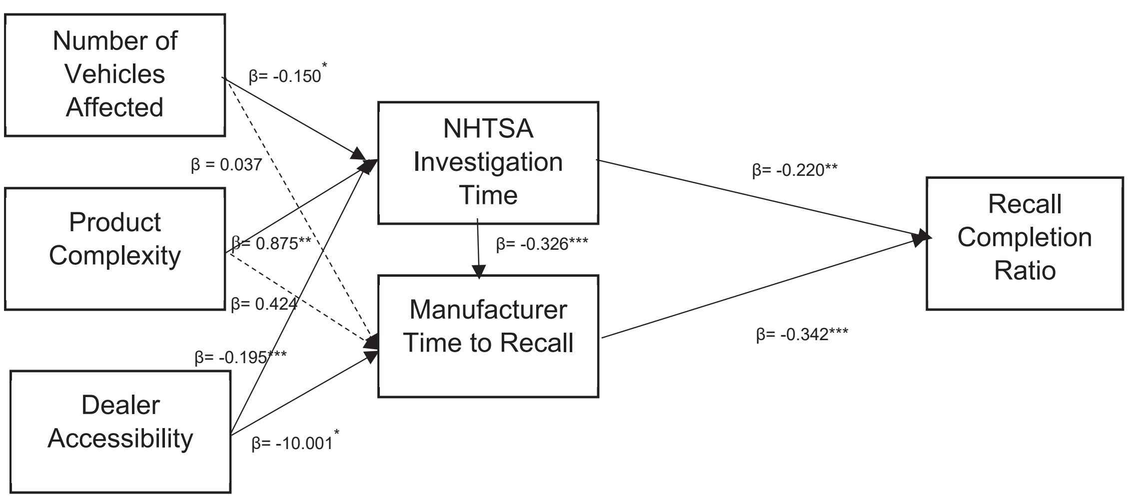
In this study, we control for brand, time fixed effects, the severity of the problem, and the source of the problem (Ni and Huang, 2018). The brand variable was dummy coded, and so were the severity variable and the source variable. Severity dummy variable received either a value zero or a one depending upon whether a fire or a crash was reported related to the recall. If no fire or crash was reported the severity dummy variable received a zero else one. The source of the problem variable received either a value zero or one depending upon if the problem was due to the supplier or the parent company respectively.

Table-1: SEM Path Analysis Results

	Hypothesized Effects	Std. Coefficient
H1a	Number of vehicles affected → Investigation time	-0.150 *
H1b	Number of vehicles affected → Time to recall	0.037
H2a	Product Complexity → Investigation time	0.875**
H2b	Product Complexity → Time to recall	0.424
H3a	Dealer Accessibility → Investigation time	-0.195**
H3b	Dealer Accessibility → Time to recall	-10.001*
H4	Investigation time → Time to recall	-0.326***
H5a	Investigation time → Recall Completion Ratio	-0.220**
H5b	Time to recall → Recall Completion Ration	-0.342***

Notes:
Fit indices (overall): CFI= 0.94; RMSEA= 0.06; R^2 = 0.74
*p<0.05; **p<0.01; ***p<0.001
Control Variables: Brand, time, severity of the problem, source of problem

Figure-2: Model Results



*p<0.05; **p<0.01; ***p<0.001

RESULTS

The results of our analysis are presented in Table-1 and Figure-2. The model fit indices suggest that the model has a satisfactory fit (*CFI = 0.94*, *RMSEA = 0.06; SRMR=0.01; Coefficient of*

Determination= 0.74). H1a and b predict that the number of vehicles affected will negatively influence the investigation time and time to recall (i.e., higher the number of vehicles affected, the investigation time and time to recall will be shorter). We find statistical support for H1a (β= -0.150*) while H1b is not supported (β= 0.037). Similarly, H2 a and b posit that the product complexity will positively influence investigation time and time to recall. We find strong statistical evidence to support H2a (β= 0.875**) while H2b (β= 0.424) is not supported. H3 a and b pertain to the negative relationship between dealer accessibility and investigation time, and time to recall respectively. We find evidence to support both, H3a and b (β= -0.195**; β= -10.001*). In addition, H4 that negatively relates investigation time to time to recall (β= -0.326**) is statistically supported. Moreover, our relationships as proposed in H5 a and b are statistically significant (β= -0.220**; β= -0.342***), which suggests that greater investigation times and time to recall can negatively impact recall completion ratio.

DISCUSSION AND LIMITATIONS

In this research we find the number of vehicles affected in the recall is associated with shorter the investigation time at NHSTA but does not affect the manufacturers' time to recall. This finding suggests two things, first when there is a greater number of vehicles involved NHTSA is more likely to deploy greater amounts of resources towards completing the formal investigation process more quickly, and second, larger or smaller recalls are both treated in the same way by manufacturer as they affect brand image alike. For example, Volkswagen had a highly publicized emissions recall related to its diesel vehicles in US, however the number of diesel vehicles sales was only a fraction of its total sales in US (Ewing, 2015). Also, the complexity of the product positively affects the investigation time at NHSTA, however has no effect on the ability of the manufacturers' time to recall. Specifically, longer investigation times with NHTSA for concerns with strategic parts can be attributed to greater difficulty in identifying the root cause of the problem or need for communication with other stakeholders to accurately determine accountability. We also find that having a higher number of dealers in the network significantly reduces the time to recall and investigation time. This is a significant finding, since having access to customers' current up to date information is essential in completing the recall process and the dealers are the source of such information.

As expected, the NHTSA investigation time does affect the manufacturers' time to recall; the longer the time to investigate, the shorter is the time to recall. Moreover, the investigation time and the time to recall negatively affect the recall completion ratio. Our analysis based on secondary data shows that NHSTA can be a significant bottleneck in the mandatory recall process in automotive industry. Therefore, the resources (staffing and others) and the processes at the NHSTA are significant determinants in the recall process.

There are some limitations in this research, as with any research which uses secondary data. First, this study is limited to the mandatory recall process. Second, the research is based on the automotive industry in US, and the process and practice could be different in other nations, for example the role of entities such as NHSTA. Third, this study does not explicitly control for customer behavior.

ABSTRACT

Based on 187 survey responses, this paper examines the relationship between absorptive capacity and ambidexterity and the relationships between these concepts and Supply Chain Innovation (SCI). A positive relationship between absorptive capacity and ambidexterity and between absorptive capacity and SCI is found. Data reveal no relationship between ambidexterity and SCI.

KEYWORDS: Absorptive capacity, Ambidexterity, Innovation, Survey research, Structural equation modeling

INTRODUCTION

Supply chain innovation (SCI) has become imperative for any firm to survive in today's dynamic and competitive marketplace (Zimmermann et al., 2016). It is widely acknowledged that supply chains provide vital resources for creating competitive advantages (Narasimhan & Narayanan, 2013). Innovation processes are important both from a single company perspective and from a network perspective with a focus on shared processes (Arlbjørn & Paulraj, 2013; Ojha et al., 2016; Wagner, 2012). Supply chain innovation, over the last decade, has received increased academic attention in extant literature (Arlbjørn et al., 2011; Zimmermann et al., 2016, Wong & Ngai); however, with varied perspectives as to its conceptualization and operationalization. Although extant literature on SCI has grown considerably with respect to its content and processes (Gao et al, 2017; Wong & Ngai, 2019), empirical research on SCI is still sparse and additional work is needed (Grawe, 2009). Researchers have also called for development of measurement scales for operationalizing SCI (Wong & Ngai, 2019).

In this paper, we rely on an understanding of SCI as being comprised of the three components: *business processes, network structure, and technology* (Arlbjørn et al., 2011). SCI may lead to transformations in terms of engagement in a number of actions or projects that might lead to changes in a firm's supply chain, e.g. restructuring of customer and/or supplier portfolios, planning and distribution of goods (Arlbjørn & Paulraj, 2013; Hong & Roh, 2015).

Literature on supply chain innovation acknowledges two factors that are essential for successful outcome in innovation efforts. First absorptive capacity – which is the ability to acquire, disseminate and explicit knowledge – is a requirement for innovation (Cohen & Levinthal, 1990; Kavin & Narasimhan, 2018; Narasimhan & Narayanan, 2013; Zahra & George, 2002). Absorptive capacity is deemed important within a supply chain context because the most relevant information for the firm is often found outside the firm; however, information acquisition may be difficult. Such external information requires effective dissemination and application (Hong & Roh, 2015; Narasimhan & Narayanan, 2013; Preston et al, 2017). Second, the success of any innovation effort depends on the firms' ability to be ambidextrous (i.e. simultaneously conduct operational and development tasks) (Gibson & Birkinshaw, 2004; Im et al, 2019; Narasimhan & Narayanan, 2013). The underlying premise of ambidexterity is that companies that effectively manage both exploratory and exploitive activities will achieve a higher level of supply chain innovations (Fernhaber & Patel, 2012; Kristal et al, 2010). According to Gibson & Birkinshaw (2004) and Jansen et al (2006), ambidextrous companies are more innovative. Research has found a positive relationship between firms having a high level of absorptive capacity and ambidexterity (Solís-Molina et al, 2018).

This research offers two main contributions. First, a theoretical framework for supply chain innovation is presented. Although, other researchers have studied the relationship between absorptive capacity and ambidexterity, there is a paucity of literature linking absorptive capacity, ambidexterity and SCI. Our study fills this gap in current literature. Second, empirical data about the relationship between absorptive capacity and ambidexterity and SCI is analyzed. The paper is organized as follows. First, the theoretical foundation of the paper (research model) and research hypotheses are discussed. The next section describes the sampling frame and empirical data that were collected. The findings from statistical analysis are presented next. Finally, the conclusions drawn from this research along with its limitations, implications, and directions for future research are discussed.

LITERATURE REVIEW AND HYPOTHESIS DEVELOPMENT

Absorptive Capacity and Ambidexterity

The concept of absorptive capacity was introduced by Kedia & Bhagat (1988) and further explored by Cohen & Levinthal (1990). These authors argue that the ability to exploit external knowledge is a critical component of internal innovative capabilities. The ability to evaluate and utilize knowledge outside the company is a function of the level of prior related knowledge such as basic skills, shared language, and scientific or technological developments in a given field. Based on this, Cohen & Levinthal (1990, p. 128) define absorptive capacity as an "ability to recognize the value of new information, assimilate it, and apply it to commercial ends". Absorptive capacity is concerned about how much knowledge can be absorbed in the company. It can be viewed as a measure of an organization's ability to learn. According to Lane et al (2006), it can be divided into three phases: 1) acquire or search for knowledge, 2) store and share knowledge and 3) analyze and use knowledge.

Ambidexterity refers to the tension induced by the capability to concurrently exploit and explore (March, 1991); it is introduced as a central management task to secure long term survival. Duncan (1976) was the first to introduce the management dilemma of ambidexterity in a discussion on the need for a management structure between the first phases of innovation (i.e. exploration) and the implementation (i.e. exploitation) phases. Extant literature on ambidexterity discusses different forms of ambidexterity (i.e. sequential, simultaneous and contextual) (Gibson & Birkinshaw, 2004; O'Reilly & Tushman, 2008; 2013). Sequential ambidexterity treats operation and development tasks are separated in time. Simultaneous ambidexterity (also named structural ambidexterity) means that the company works on operations and development tasks at the same time. Contextual ambidexterity is focused on individuals or groups that make prioritizations between operations and development tasks (Gibson & Birkinshaw, 2004). In this paper, we don't adopt a specific perspective of ambidexterity but approach the concept as a general dilemma pertaining to prioritization of operational and development tasks in the supply chain.

While absorptive capacity reflects the ability of a company to value and integrate external knowledge for pursuing SCIs, ambidexterity addresses how the knowledge is to be used (Fernhaber & Patel, 2012). Both absorptive capacity and ambidexterity are deemed critical for the success of SCIs. Several studies have found that being ambidextrous requires a firm to expand on their capacity to acquire and process knowledge, i.e. to master absorptive capacity (Datta, 2011; Enkel et al, 2017; Rothaermel & Alexandre, 2009). Accordingly, we posit the following hypothesis:

H1: Absorptive capacity is positively associated with ambidexterity

Supply Chain Innovation
Supply chain innovation, in this paper, is viewed as a higher-order factor covering business processes, network structure and supply chain technology (Arlbjørn et al, 2011; Arlbjørn & Paulraj, 2013). Thus, it is a multi–dimensional construct that also encompasses technology and process innovations (Gao et al, 2017; Hazen et al, 2012; Kwak et al, 2018). Supply chain innovation can be incremental or radical and it can take place within the company or in collaboration with external supply chain partners. We briefly discuss each of these aspects of SCI.

Business Processes
The first component in the supply chain innovation framework proposed by Arlbjørn et al. (2011) is business processes which incorporate activities that generate a distinct output (product/process/service) of value to the customers (Davenport, 1993). In extant SCM literature, it is well-recognized that process thinking constitutes one of the backbones of supply chain management (Ellram & Cooper, 2014; Lambert & Cooper, 2000; Mentzer et al, 2001). The driving force for employing customer-oriented business processes within the firm as well as among partners of the supply chain is to both practice business more effectively and efficiently, and to organize inter-firm relationships (Arlbjørn et al, 2011). This paper uses the eight business processes developed by the Global Supply Chain Forum (Lambert & Cooper, 2000; Lambert & Enz, 2017).

Network Structure
The network structure aspect includes supply chain partners, variety of process networks, and structural dimensions. The structural component deals with both horizontal and vertical structure along with the horizontal position of the firm (Arlbjørn et al, 2011; Lambert & Enz, 2017). Process networks focus on different degrees of resources used toward integrating and managing

processes within and among supply chain partners (Arlbjørn et al., 2011; Arlbjørn & Paulraj, 2013; Munksgaard et al, 2014). In addition, network structure refers to effective networks in which new value creation depends on knowledge resources and core competences that could enhance the capability of the firm to sustain long-term relationship with supply chain partners (Bellamy et al, 2014; Cao & Zhang, 2011; Narasimhan & Narayanan, 2013).

Technology

Munksgaard et al (2014) state that supply chain technologies might be practiced separately or together with other technologies or with the other components of the framework to realize supply chain innovations. The technology component does not relate to the relevant technology in particular; instead it also includes the innovative use of technology within the context of supply chain (Arlbjørn et al, 2011; Gao et al, 2017; Hazen et al, 2012; Kwak et al, 2018). It is important to stress that SCI is not about the relevant technology itself (e.g. big data, automation and additive manufacturing, and other disruptive technologies) (Tan et al, 2015; Vyas, 2016). But it is in the novel use of technology within a supply chain context (Stentoft et al, 2016). Technology enables firms in engaging their customers more instantaneously online and adding more product variety (Arlbjørn et al, 2011).

Extant research has found a positive relationship between absorptive capacity and innovation (Albort-Morant et al, 2018; Berghman et al, 2012; Kostopoulos et al, 2011). Other studies that relate absorptive capacity to innovations within supply chains are Autry & Griffs (2008), Chapman et al, (2003), Gao et al, (2017), Grawe (2009); Narasimhan & Narayanan (2013), and Preston et al, (2017). Furthermore, extant research has also posited the positive relationships between ambidexterity and an innovation outcome (e.g. Im et al, 2019; Narasimhan & Narayanan, 2013; Wong et al, 2013). While most of these research relate absorptive capacity and ambidexterity to product innovations, we believe that both absorptive capacity and ambidexterity are strong proponents of developing an innovation culture within firms as well as supply chains. Accordingly, in line with extant research, we forward the following two hypotheses for formal testing:

H2: Absorptive capacity is positively associated with supply chain innovation (SCI)
H3: Ambidexterity is positively associated with supply chain innovation (SCI)

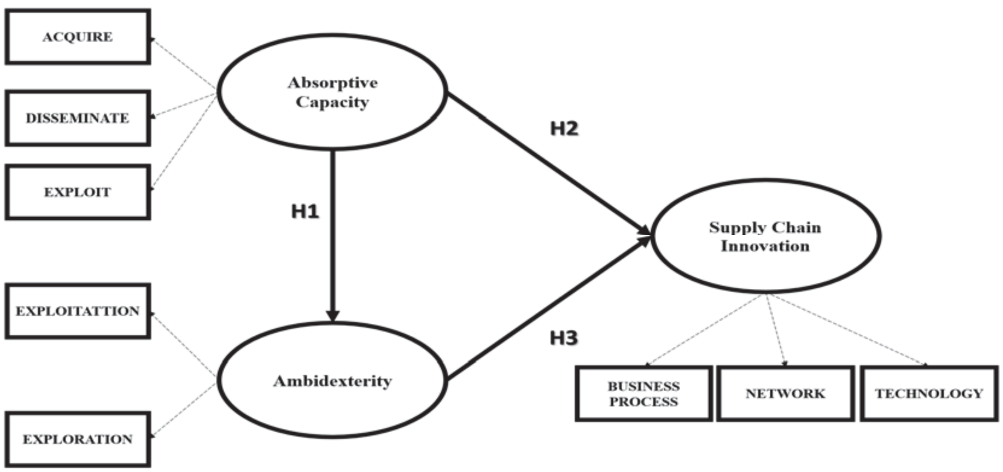
METHOD

This paper examines the relationship between ambidexterity, absorptive capacity, and supply chain innovation. Figure 1 shows the research framework of this paper.

Data Collection

This paper uses a questionnaire–survey that was distributed among Danish manufacturing firms with at least 50 employees in autumn 2016. The population of the companies was identified using the Danish company database “Names and numbers, business” (NN Markedsdata, 2016). The database allowed searching for these companies in a structured manner and the process resulted in an initial sample of 1,580 companies. The selected companies were then contacted and asked to identify the person with the overall responsibility for supply chain management. This process provided us with a net population of 879 companies that agreed to participate in the study. The email link to the electronic questionnaire (SurveyXact, 2016) was sent to all the participating companies. Reminder e–mails were also sent to increase the response rate and allow comparison of early and late responses (before and after the initial deadline). This process finally resulted in 187 companies that provided valid responses with a response rate of approximately 21.3%. The questions included in the survey questionnaire are grounded in literature and was further pretested using industry representatives. The questionnaire included questions related to company profile, supply chain innovation, learning practices, ambidexterity, and performance. The questions were of two types: 1) yes or no questions and 2) statements on a 5–point Likert Scale.

Figure 1: Research framework



Measures

<u>Dependent Variable</u>

Supply chain innovation construct was measured using the scales adapted from Arlbjørn et al (2011) and Cooper et al (1997); this construct included twenty-six 5-point Likert scale questionnaire items (see Appendix A). This construct includes three factors: business processes, network structure, and technologies. Business process (BP) factor includes indicators such as customer relationship management (BPCRM), supplier relationship management (BPSRM), customer service management (BPCSM), demand management (BPDEM), order fulfilment (BPORF), manufacturing flow management (BPMFM), product development and commercialization (BPPDC), and returns management (BPREM). Network structure (NS) factor includes indicators such as internal functions (NSINT), customers (NSCUS), suppliers (NSSUP), third party providers (e.g. logistics providers) (NS3PL), competitors (NSCOM), consultants (NSCON), universities (NSUNI), and public agencies (NSPUB). These represented the diverse sources of external information. Technology (TE) factor includes indicators such as planning and execution systems (TEPLA), identification systems (TEIDF), communication systems (TECOM), analytics technology (TEANA), electronic marketplaces (TEELM), advanced manufacturing technologies (TEAMT), advanced materials (TEADM), big data (TEBIG), and drones (TEDRO).

<u>Independent Variables</u>

The factors exploitation and exploration related to the construct ambidexterity were adapted from Kristal et al (2010); this construct included eight 5-point Likert scale questionnaire items (see Appendix A). The construct ambidexterity–exploitation includes indicators such as “improving our existing supply chain technologies (SCOIT1)”, “reducing waste in our existing supply chain processes (SCOIT2)”, “developing stronger competencies in our existing supply chain processes (SCOIT3)”, “making minor improvements in our existing supply chain processes (SCOIT4)”; and ambidexterity–exploration includes indicators such as “experiment with new supply chain technologies (SCORE1)”, “develop new supply chain processes (SCORE2)”, “developing new competencies in our supply chain processes (SCORE3)”, “implementing large scale improvements (SCORE4)”.

Absorptive capacity was measured using scale adapted from Ho & Lu (2015), Patel et al (2012), Setia & Patel (2013) Tu et al (2006), and Zacharia et al (2011); this construct included seventeen 5-point Likert scale questionnaire items (see Appendix A). This construct includes three factors: acquire, disseminate, and exploit. Acquire (ACQR) includes indicators such as “committed to looking for and developing new ideas in our supply chain (ACQR1)”, “created an environment that encourages identification and development of new and useful ideas (ACQR2)”, “frequently look for external sources of new knowledge and skills (ACQR3)”, “’seek to learn from tracking new market trends in our industry (ACQR4)”, “seek to learn from trying out new technologies (ACQR5)”, “seek to learn from other supply chain actors (ACQR6)””, and collect frequently operations related information in our supply chain (ACQR7)”. Disseminate (DISM) factor includes indicators such as “record and store newly acquired supply chain knowledge for future reference (DISM1)”, “share practical experiences with each other (DISM2)”, “periodically meet to discuss consequences of new products and processes (DISM3)”, “common language regarding our products and processes in our company (DISM4)”, “frequent interactions between departments in the firm to acquire new knowledge (DISM5)”, “employees are engaged in cross-functional work (DISM6)”, “clear division of roles regarding sharing newly acquired supply chain ideas and knowledge (DISM7)”. Exploit (EXPL) factor includes indicators such as “constantly consider how to exploit newly acquired knowledge, skills, and technologies in our supply chain (EXPL1)”, “quickly recognize the usefulness of new external operational knowledge to existing operational knowledge (EXPL2)”, “proficient in integrating newly acquired knowledge into current ways of doing things (EXPL3)”.

Descriptive Statistics

For statistical testing of the hypotheses, we utilized factor analysis and structural equation modeling. Given that the data were collected from a single respondent within each company, common method bias might be a concern. This could be tested using Harman’s single factor test (Podsakoff et al, 2003) which suggests entering all measurement items into a single factor analysis. Common method bias occurs when only a single factor emerges while carrying out factor analysis or if a single factor explains most of the variance in the data. An unrotated factor analysis using the eigen value greater than one criterion revealed eight different factors explaining 64% of the variance and the first factor accounted for only 27% of the variance. Since a single factor did not emerge and the first factor did not explain most of the variance, we could conclude that common method variance might not be an issue in the data. Next, the validity and reliability of the measurement instrument was assessed. The content validity was established by grounding the survey instrument in literature and was further confirmed by pre–testing the survey instrument with the help of scholars and practitioners. Based on their suggestions, the survey instrument was revised with minor changes to the questionnaire.

A confirmatory factor analysis (CFA) was performed to check the model fit, reliability, and construct validity. Model fit was assessed for reliability and validity by using a series of fit measures, where each measure provides different information for evaluating the model (Hair et al, 2006). Table 1 summarizes the overall fit statistics of the measurement model which includes higher–order constructs such as supply chain innovation and ambidexterity.

Table 1: Statistical fit of the overall measurement model	
RMSEA	0.088
90% confidence interval of RMSEA	(0.071;0.10)
χ^2	179.67
CFI	0.98
NNFI	0.97
Standard RMR	0.049
Goodness of Fit Index	0.88

The overall model fit can be tested using the comparative fit index (CFI), non–normed fit index (NNFI), root mean square error of approximation (RMSEA), and normed chi–square (i.e., χ^2 per degree of freedom) (Hair et al, 2006). In general, if the values of CFI and NNFI are higher than 0.90, then it represents good fit and if the value of RMSEA is typically less than 0.10 then it is an acceptable model. The normed chi–square (χ^2 divided by degrees of freedom) estimates the relative efficiency of competing models. In our case, the value of normed chi–square is 2.43, which indicates that it is a reasonable fit (Papke-Shields et al, 2002).

Table 2 presents the coefficients of the items on the higher–order constructs and Cronbach alpha value (reliability). The coefficients of the retained items were higher than the cut off value of 0.50 (Hair et al, 2006). The analysis also confirmed that the items do not cross-load indicating a good fit to the measurement model. In other words, the items were loading high only on their underlying factors. Reliability was tested using Cronbach alpha (α) (Nunnally & Bernstein, 1994) and the value of reliability coefficient need to be 0.70 or higher (Fornell & Larcker, 1981; Nunnally & Bernstein, 1994). The result indicates that Cronbach's alpha values (α) of the factors are greater than 0.70 and therefore, the theoretical constructs are reliable.

RESULTS

The results of the confirmatory factor analysis (CFA) are presented in Table 2. CFA results also indicate a strong evidence of convergent validity since the t–value ranges from 5.69 to 12.96 at the significant level of 0.01 (in general, t–values should exceed the threshold value of 1.96 at the significant level of 0.05). Moreover, the first indicator of all the constructs will not have a t–value because we intentionally made the constructs scale–invariant by fixing the first indicator to 1 (e.g. Kim, 2014).

Structural equation modeling was performed to test the proposed hypotheses and the results of the regression are presented in Table 3.

Table 3: Research model results

			Estimate	S.E.	C.R.	P
AMBIDEXTERITY (ABX)	<---	ABSORPTIVE CAPACITY (ABS)	.968	.118	8.176	***
SUPPLY CHAIN INNOVATION (SCI)	<---	ABSORPTIVE CAPACITY (ABS)	.486	.127	3.831	***

The results indicate that hypotheses H1and H2 are statistically significant and the significance level is at 99.9% (p–value < 0.001). Therefore, it can be concluded that the proposed hypotheses are supported. In other words, it could be suggested that there is a positive relationship between absorptive capacity and ambidexterity, and absorptive capacity and supply chain innovation. However, the analysis does not indicate a relationship between ambidexterity and supply chain innovation, failing to provide support for hypothesis H3.

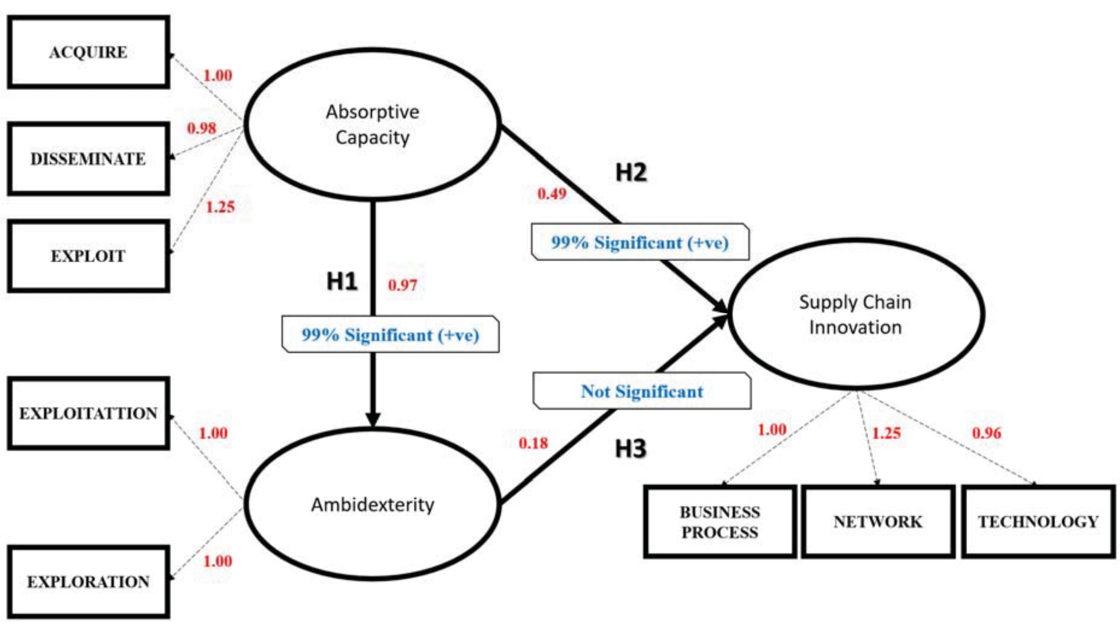
DISCUSSION

The purpose of this research is to investigate the association between absorptive capacity, ambidexterity, and supply chain innovation. Prior research observes the influence of absorptive capacity and ambidexterity on innovation efforts (e.g. Narasimhan & Narayanan, 2013) and underlines that the perception of several innovation is pursued in daily operations as continuous innovation. Bearing in mind, our research extends this understanding toward supply chain innovation. Supply chain innovation is much more complex than product innovation and manages the processes involved in the whole supply chain (Arlbjørn et al., 2011). Supply chain business processes, supply chain networks, and supply chain technologies can be also continuously improved or incorporated in daily operations.

On the whole, our findings show that absorptive capacity positively affects both ambidexterity and supply chain innovation, and ambidexterity does not affect supply chain innovation. First, focusing on the link between absorptive capacity and ambidexterity, the result suggests that absorptive capacity positively affect ambidexterity. Therefore, it could be suggested that firms being ambidextrous can significantly develop their ability to acquire, disseminate, and exploit knowledge to realizing absorptive capacity (e.g. Enkel et al, 2017). In other words, firms that are better able to balance activities pertaining to absorptive capacity are more likely to continuously explore new opportunities/knowledge and increase their firms' learning competencies. Second, the result reveals that there is a positive link between absorptive capacity and supply chain innovation. Extant literature has recognized the link between absorptive capacity and innovation (e.g. product innovation) (Albort-Morant et al, 2018; Berghman et al, 2012). However, it has not explored the link between absorptive capacity and supply chain innovation. Therefore, our research investigates this unexplored relationship and reveals that firms' capability of acquiring, disseminating, and exploiting knowledge increases the practice of supply chain innovation. Supply chain innovation, as mentioned earlier, is a complex process and requires firms to not only acquire new knowledge, but also disseminate and exploit the acquired knowledge to explore new opportunities for supply chain innovation. Borrowing literature on the association between absorptive capacity and innovations in supply chain (Gao et al, 2017; Narasimhan & Narayanan, 2013; Preston et al, 2017), this research confirms that firms' absorptive capacity increases the practice of supply chain business processes, supply chain networks, and supply chain technology. Third, with reference to the link between ambidexterity and supply chain innovation, interestingly, the result indicate that ambidexterity does not affect supply chain innovation. It is believed that being able to innovate in supply chain innovation is determined through the firm's ability to balance processes pertaining to daily operations and development (Slone et al., 2010; Stank et al., 2011). Moreover, extant literature has always focused on the link between ambidexterity and innovation (e.g. Blome et al., 2013; Kortmann et al., 2014; Markides, 2013). For this reason, our research made an attempt to explore the link between ambidexterity and supply chain innovation and found that firms being ambidextrous does not impact supply chain innovation practices. One of the reasons for this result could be that innovation (e.g. product innovation) can be seen explicitly while supply chain innovation includes innovations (e.g. process innovation) that can be realized only through different processes.

The overall result of the research model is presented in Figure 2. This result could be groundwork for further exploration of the proposed model with different dimensions.

Figure 2: Result of the research model



CONCLUSION

This paper has set out to analyze and discuss the relationship between absorptive capacity, ambidexterity and SCI. The paper presents novel data to a research area that lacks empirical data in the context of SCI. Data from the presented survey reveals a positive relationship between absorptive capacity and ambidexterity and thus, a support for hypothesis 1. The companies that acquire, disseminate and exploit supply chain relevant knowledge fully, perceived their ambidexterity to be higher compared to firms that were not as adept in enhancing their absorptive capacity. Furthermore, hypothesis 2 is also supported, i.e. that the firms that perceived their absorptive capacity to be high tended to pursue SCIs. However, the analysis does not find support for a relationship between ambidexterity and companies' efforts with SCIs. This result is surprising and may indicate that SCIs also are being carried out as part of daily operations and not only in development-oriented projects. These results are important for companies to consider if, and when, they are planning transformation processes towards more digitized processes. The results have implications for theory and practice. For theory, this study confirms the positive relationship between absorptive capacity and ambidexterity but not that SCIs are dependent on companies' ambidextrousness. Companies are pursuing SCIs regardless of their perceived ability to balance operational and development-oriented activities in their supply chains. It indicates that such innovations become a reality through development-oriented operations. For practice, these results indicate the importance for companies to search for relevant SCM knowledge and disseminate and exploit this knowledge to implement SCI that assists companies in fulfilling strategic objectives and in maintaining or even improving competitiveness.

The paper is not without limitations. First, the paper is based on perceptions from a single respondent from each company. Future research should include multiple respondents from each company. Second, data are from Danish companies. Future research should include respondents from other countries to make cross country comparisons. Finally, this paper analyzes SCI as one construct consisting of the three components; business processes, network structure and technology. Future research can decompose the construct to analyze the innovations more specific within each of the components.

APPENDIX A

Supply Chain Innovation (scale developed from Arlbjørn, 2011)

Business Processes
To what extent is your company pursuing innovations in the following supply chain management business processes? (Five-point Likert scale)

- Customer Relationship Management (CRM)
- Supplier Relationship Management (SRM)
- Customer Service Management (CSM)
- Demand Management (DeM)
- Order Fulfilment (OrF)
- Manufacturing Flow Management (MFM)
- Product Development and Commercialization (PDC)
- Returns Management (ReM)

Network Structure
To what extent does your company innovate together with the following supply chain network actors? (Five-point Likert scale)

- Internal functions
- Customers
- Suppliers
- Third party providers (e.g. logistics providers)
- Competitors
- Consultants
- Universities
- Public agencies

Technology

- To what extent does your company work with the following technologies in your supply chain?
- Planning and execution systems (e.g. enterprise resource planning systems, advanced planning systems, material requirements systems)
- Identification systems (e.g. barcodes, radio frequency identification)
- Communication systems (e.g. electronic data interchange, web-based communication tools, mobile communication solutions, cloud technology)
- Analytics technology (e.g. business intelligence, statistics and analytics software, algorithms)
- Electronic marketplaces (e.g. e-portals, e-auctions, supplier collaboration tools)
- Advanced manufacturing technologies (e.g. advanced robotics, 3D printing)
- Advanced materials (e.g. ultra-light or high-strength materials)
- Big data
- Drones

Ambidexterity (representative references Kristal et al., 2010; Levinthal & March, 1993; March, 1991)

Exploitation

- We continuously focus on improving our existing supply chain technologies processes
- We are focusing on reducing operational redundancies in our existing supply chain processes
- We are focusing on developing stronger competencies in our existing supply chain processes
- We have a constant focus on making improvements in our existing supply chain processes

Exploration

- We continually experiment with new supply chain solutions
- We continually develop new supply chain processes
- We are focusing on exploring new competencies in our supply chain processes
- We have a constant focus on novel approaches to make improvements

Absorptive capacity (based on Ho & Lu, 2015; Patel et al., 2012; Setia & Patel, 2013; Tu et al., 2006; Zacharia et al., 2011).

Acquire

- We are committed to look for and develop new ideas in our supply chain
- We have created an environment that encourages identification and development of new and useful ideas
- We frequently look for external sources of new knowledge and skills
- We seek to learn from tracking new market trends in our industry
- We seek to learn from trying out new technologies
- We seek to learn from other supply chain actors (e.g. customers and suppliers)
- We collect frequently operations related information in our supply chain

Disseminate

- We record and store newly acquired supply chain knowledge for future reference
- We share practical experiences with each other
- We periodically meet to discuss consequences of new products and processes
- We have a common language regarding our products and processes in our company
- We have frequent interactions between departments in the firm to acquire new knowledge
- Employees are engaged in cross-functional work
- We have a clear division of roles regarding sharing newly acquired supply chain ideas and knowledge

Exploit

- We constantly consider how to exploit newly acquired knowledge, skills, and technologies in our supply chain
- We quickly recognize the usefulness of new external operational knowledge to existing operational knowledge
- We are proficient in integrating newly acquired knowledge into current ways of doing things

DECISION SCIENCES INSTITUTE

Supply Chain Relationship Building and Knowledge Sharing, Big Data Capability, and Product Improvement

ABSTRACT

To extend big data research, this study examines Big Data capability's impact on product improvement and explores supply chain relationship building and knowledge sharing as two antecedents of Big Data capability. The model is tested with survey data. Findings of this study provide empirical support to the proposed theoretical model.

KEYWORDS: Supply chain relationship building, Knowledge sharing, Big Data capability, Product improvement

INTRODUCTION

Big data as a hot topic has attracted an increased amount of attention from industry practitioners as well as scholars. Recent research has noted its impact on market and financial performance (Gupta & George, 2016; Wamba et al., 2017). It can be easily understood that market performance contributes to financial performance. But market performance depends on product performance, as it is usually operationalized as how fast new products are introduced to and how well current products sell in the market (Wamba et al., 2017). However, prior and current research has rarely explored how big data contributes to product performance, especially existing product performance. Yet, incremental product improvement is critical to firm performance, as it helps cost reduction and repositioning (Holahan, Sullivan, & Markham, 2014). Further, because of brand commitment, customers prefer incremental upgrade to an existing product to a radical new product (Kirshner, Levin, & Nediak, 2017). Given these benefits, it is imperative to explore how big data enhances incremental product improvement.

Besides capturing big data's impact on firm performance, prior and current research has also offered another insight that organizational practices surrounding big data should be conceptualized as dynamic capabilities, which helps to explicate why there are cases of success as well as failure in big data practices (Braganza et al., 2017; Chen, Preston, & Swink, 2015; Gupta & George, 2016; Wamba et al., 2017). However, it is less known what factors contribute to the development of such big data related dynamic capabilities in firms.

Further, related to that gap is a question of whether such contributing factors exist outside the firm. Firms are embedded in supply chains. There are reported cases of how big data enhances supply chain performance in the literature such as forecasting cycle time (Wang & Zhang, 2016), production or service scheduling (Barton & Court, 2012), and demand forecasting and inventory management (McAfee & Brynjolfsson, 2012; Waller & Fawcett, 2013b). Yet few studies have examined whether supply chains might be an important source of resources that can facilitate the development of big data dynamic capabilities.

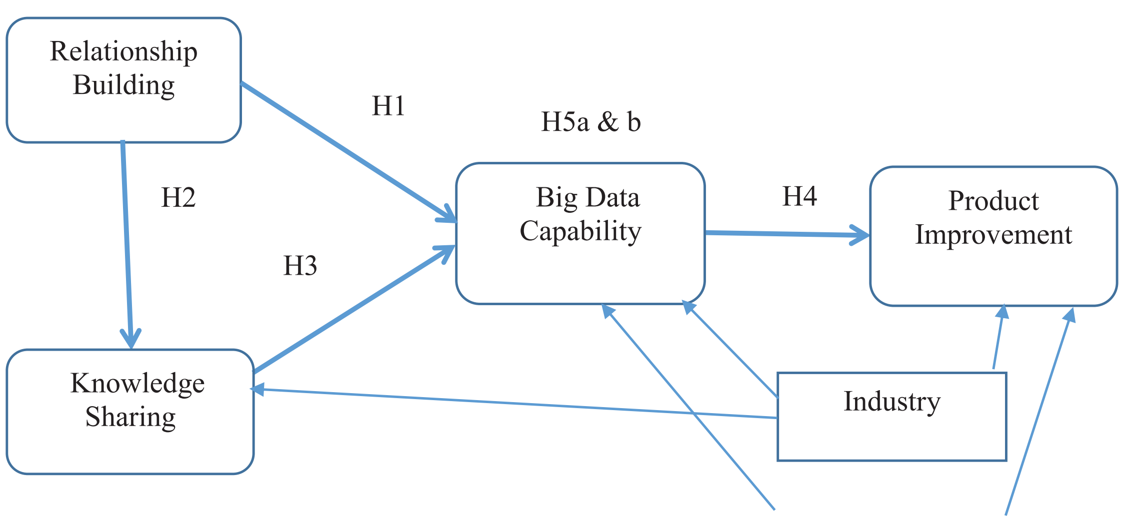
To fill these research gaps, this study attempts to empirically investigate big data's role in a firm's incremental product improvement performance and the influence of supply chain dynamics on this role. Supply chain dynamics in this study refers to two concepts: supply chain relationship building (RB) and knowledge sharing (KS) in the supply chains. Consistent with the literature, this study conceptualizes big data initiatives or practices in organizations as a dynamic organizational capability, which is named as Big Data capability (BDC). Based on the organizational capabilities perspective, we first argue that BDC contributes to a firm's performance in product improvement. Then drawing on the theories of dynamic capabilities, resource dependence, and social capital, we articulate an argument that supply chain dynamics (RB and KS) contributes to the development of BDC. We further show that BDC mediates the effects of supply chain dynamics on product improvement.

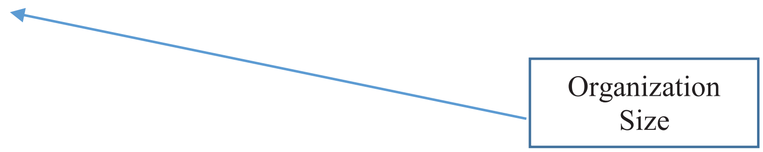
While accomplishing the above-mentioned objectives, this study contributes to the literature in three ways. First, it will show that when big data's initiatives and practices in firms develop into a BDC, it will enhance firms' product improvement performance. Second, this study will extend the literature by demonstrating that RB and KS contribute to the development of BDC. Our third contribution lies in revealing that BDC mediates the effects of RB and KS on product improvement. Findings from this study will help to renew our understanding of dynamic capabilities, especially BDC, as they will show that they are developed not in a vacuum but with external assistance despite that they are conceptualized as firm specific and path-dependent (Teece, Pisano, & Shuen, 1997; Teece, 2007).

LITERATURE REVIEW

The theoretical framework of this study is built on a strong rationale. To address environmental changes and keep their competitive advantage sustainable, firms have to develop dynamic capabilities (Girod & Whittington, 2017; Peteraf, Di Stefano, & Verona, 2013; Schilke, 2014), which help them to manage evolutionary changes and make incremental improvements in their products (Tushman & O'Reilly, 1996). But to develop dynamic capabilities needs resources including knowledge, which often times resides in buyer-supplier relationships (Villena, Revilla, & Choi, 2011). Thus, our research model is constructed as follows: supply chain relationship building and knowledge sharing contribute to Big Data capability, which, then enhances product improvement (see Figure 1).

Figure 1: Conceptual Model





Big Data Capability

According to the dynamic capabilities perspective, to develop and maintain their competitive advantage, firms should develop dynamic capabilities (Collins, 1994; Teece et al., 1997; Teece, 2007). Besides helping to perform the basic functions of the firm (Collins, 1994; Winter, 2003), dynamic capabilities are managerial (Kor & Mesko, 2013), concerned with change, and more importantly, of strategic insight (Collins, 1994; Teece et al, 1997, Teece, 2007). Further, dynamic capabilities are unique to each firm and strongly path-dependent in firms (Teece et al., 1997; Teece, 2007). A dynamic capability involves three components: sensing, seizing, and reconfiguring (Teece, 2007). Accordingly, sensing means to identify and shape opportunities and threats, seizing is to deploy and utilize resources and assets to address those opportunities, and reconfiguring is to transform, redeploy, and redevelop organizational competencies for continuous renewal. Reviewing some case studies, Lin, Kunnathur, and Li (in press) showed that all these three components are identifiable in big data practices.

More importantly, development of a dynamic capability dealing with information technology issues, is an emergent process: employees acquire skills, knowledge, and competencies in their interactions with material resources, which are further integrated, organized, and utilized through organizational processes governed by structural rules; these integrated and synergized skills, knowledge, and competencies, aligned with firms' strategy, then grow into dynamic capabilities (Peppard & Ward, 2004). Viewed from this perspective, a big data related dynamic capability can be developed in firms, which consists of skills, knowledge, and behavioral resources and competencies regarding big data practices, developed in processes of dealing with big data by using material resources such as IT hardware and software, to accomplish strategic objectives (Chen et al., 2015; Gupta & George, 2016; Lin, Kunnathur, & Li, in press; Wamba et al., 2017).

Big data material resources include raw data and technological tools that are used to collect, store, and analyze data, and present analysis results to a right audience. Big data as raw data exists in multiple formats such as numerical, text, visual, and audio. Big data is also carried in structured as well as unstructured formats (Chen, Chiang, & Storey, 2012). Moreover, big data is produced rapidly in multiple sources. Further, big data flows out in big volumes. These constitute the three basic characteristics of big data: volume, velocity, and variety (McAfee & Brynjolfsson, 2012). Technological tools include both hardware and software, including but not limited to IT infrastructure, computing equipment, and all software used for collection, storage, and analysis of big data such as Hadoop, NoDQL and SAS (Chang, Kauffman, & Kwon, 2014). Some of these material resources are possessions of a firm, while others may only be acquired externally. The non-material resources are individual employees' experiences, skills, knowledge of using and handling the material resources, and behaviors such as managing information security, and policy compliance. These non-material resources can also be acquired both internally and externally. Some typical big data non-material resources include data analytics, text analytics, web analytics, and mobile analytics (Chen et al., 2012).

In the spirit of the dynamic capabilities theory (Teece et al., 1997; Teece, 2007; Teece, Peteraf, & Leih, 2016), development of a big data capability is an emergent process. Non-material resources are then turned into big data competencies when they are used in organizational processes where the technical skills, experiences, and knowledge of big data interact with firm-based skills, knowledge, and behaviors such as communication, relationship building, and rule compliance. These big data competencies are shown in multiple areas such as enhancement of big data or IT infrastructure, development of an IT and specifically big data management capability, and employee acquisition of soft skills to handle big data related tasks (Wamba et al., 2017). As these skills, knowledge, and behaviors are firm specific, the big data competencies are therefore firm specific. Finally, when big data competencies are aligned with the firm's business strategy, and shaped by the firm's big data related investments, they grow into its Big Data capability. Thus, *Big Data capability* is defined as a bundle of socially complex routines and processes in which a firm's accomplishment of integrating its material and non-material resources to develop socially complex routines and processes of identifying, collecting, storing, and analyzing big data for achieving its strategic as well as operational objectives. It involves an integration of a firm's dataset, toolset, skillset, and mindset (Pigni,Piccoli, & Watson, 2016). While the dataset and toolset are material resources, skillset non-material resources (skills, experiences, and competencies), mindset indicates its strategic positioning and maneuvering of all these resources.

Product Improvement

Product improvement is a construct of firm performance in this research model. It includes overall product cost reduction, capital investment reduction, lowering of overall business risks (Lemon, 1991), and enhanced product functionality and customer acceptance (Pisano & Wheelwright, 1995). Further, according to McGinnis and Mele Vallopra (1996), established products can benefit from the cumulative effect of gradual process improvement over time. Thus, *product improvement* in this study refers to making changes to a current or existing product for the purpose of meeting customers' needs and creating more business value. Current or existing product performance, unlike new product development, represents a firm's competence-enhancing innovation capability (Tushman & Anderson, 1986), and reflects, to some extent, incremental innovation performance (Christensen, 1997), both pivotal to firms.

Supply Chain Relationship Building

In the process of developing Big Data capability, firms must practice organizational learning, which is performed both internally and externally (Argote et al., 2003; Salomon & Martin, 2008). Supply chains are a good site for external organizational learning. There is strong evidence showing that learning from supply chain partners benefits firms (Azadegan & Dooley, 2010). But effectiveness of organizational learning among supply chain partners depends on the quality and strength of their relationships (Cheung, Myers, & Mentzer, 2010). This calls for relationship building among these partners.

Another driving force behind supply chain relationship building is search for or acquisition of resources. Firms rarely possess all kinds of resources and can rarely develop new resources in an isolated vacuum in their process of developing their Big Data capability. Thus, to get access to resources, firms have to develop relationships with other firms. A supply chain is a candidate site for doing so. This idea has been well elaborated and strongly supported in the supply chain management, especially supply chain relationship building research literature. For example, Ireland et al. (2002) showed that inter-firm relationships mainly serve as a means to acquire external resources. These relationships are especially helpful for facilitating acquisition of resources necessary for filling a particular ‘resource gap’ (Grant, 1991), i.e., the gap between a firm’s strategic goals and its current resource endowments (Mathews, 2003). According to Leonard-Barton (1992), firms enter into business relationships with their supply chain partners mainly for strengthening functions beyond their own capabilities and/or core competencies. Given such economic benefits of buyer-supplier relationships, firms are motivated to enhance inter-organizational communication, and develop relational competency (Paulraj, Lado, & Chen, 2008), which are active means of relationship building.

Not just constituting resources, buyer-supplier relationships are also an important source of competitive advantage (Autry & Golicic, 2010; Krause, Handfield, & Tyler, 2007). This is consistent with the goal of Big Data capability, which, as a dynamic capability, is to develop and maintain a competitive advantage (Teece et al., 1997; Teece, 2007). Although definitions of inter-firm relationship vary across fields of research and studies even within supply chain management research, past studies do point to some common attributes of a positive relationship. These include: trust, commitment, collaboration, and long-term orientation (Griffith, Harvey, & Lusch, 2006; Johnston, McCutcheon, Stuart, & Kerwood, 2004; Monczka, Petersen, Handfield, & Ragatz, 1998; Tangpong, Michalisin, & Melcher, 2008). Thus, *supply chain relationship building* in this study is defined as SC partners’ mutual engagement to develop a relational tie that is characterized by trust, commitment, collaboration, and long-term orientation.

Knowledge Sharing in Supply Chains

As data analysis, a core part of BDC, is an integral part of knowledge creation (Davenport & Prusak, 1998), Big Data capability must be closely related to knowledge management. Knowledge management refers to a conceptual framework that treats an organization or a network of organizations as a system where people, processes, resources are integrated to achieve sustainable results by improving performance through learning and innovation (Seleim & Khalil, 2011; Wang, 2011). Knowledge management as a broad concept covers multiple processes such as knowledge acquisition, creation, retention, and transfer (Argote, McEvily, & Reagans, 2003). In this study, we focus on one element of knowledge management: knowledge sharing, as it is critical to product improvement (Su, Ahlstrom, Li, & Cheng, 2013). We treat knowledge sharing as a process in which both a focal firm and its supply chain partners rely on each other closely to share knowledge together. Big Data capability needs knowledge as its input in its process of producing new knowledge. Just as supply chains are a site where resources reside, they are also important sources of knowledge as well. For this reason, this study treats knowledge sharing as another contributor to the development of Big Data capability in the overall research model.

Once knowledge is produced or imported in supply chains, it must be transferred to where it is needed. In prior research, knowledge sharing, especially, conceptualized along the knowledge-based view (Grant, 1996), mostly refers to an internal integration mechanism facilitating the dissemination and synthesis of knowledge scattered in individuals as well as organizational units through organizational processes and routines (Kale & Singh, 2007; Verona, 1999). Yet, this study examines knowledge sharing in the supply chain context. Thus, *knowledge sharing in supply chains* is defined as the intensity of supply chain partners’ exchange of their knowledge (about customers, market, products, manufacturing, and technologies, etc.) with each other (Ho & Ganesan, 2013).

THEORETICAL DEVELOPMENT: HYPOTHESES

Linkage between SC Relationship Building, Knowledge Sharing, and Big Data Capability

Potentially useful knowledge and expertise always reside outside the firm (Bercovitz & Feldman, 2007). We argue that supply chain RB and KS facilitate the development of BDC because it lubricates acquisition of resources such as knowledge, an important input for developing a dynamic capability. This argument is made based on the following theories: dynamic capabilities, resources dependence, and social capital theories. First, according to Teece (2007), to develop dynamic capabilities, firms must do sensing, which is to identify and shape opportunities. More specifically, firms must invest in research activity, investigate customer needs and technological possibilities, and closely watch and monitor possible changes in the environment, which include, for example, changes in industry structure, instability of market demand (Schilke, 2014), and possible supplier and competitor responses (Teece, 2007). Information and knowledge is critical to effective analysis of these changes in the environment and more importantly, detection of opportunities. Firms can certainly rely on their own research and learning to create knowledge and opportunities. But exogenous knowledge can also open up opportunities (Teece, 2007). This suggests that firms, when developing their dynamic capabilities, even though unique and firm specific, must have an external orientation, a mindset of opening themselves to the outside, without which sensing is impossible to complete. Thus, the dynamic capabilities theory suggests that in their process of developing their own dynamic capabilities, firms are motivated to interact with other firms to gain external knowledge for opening up business opportunities. Such interactions happen in their supply chains. Thus, supply chain RB would enhance knowledge sharing and acquisition that is critical to the development of dynamic capabilities.

Second, in a similar fashion, the theory of resources dependence implies that firms must connect with other firms for resources such as knowledge when developing their dynamic capabilities. This theory is rooted in the open system theoretical tradition that maintains that firms must engage in exchanges with their environment to gain resources (Scott, 1987). To survive and prosper, firms must have critical resources. This is especially so when competition is strong. A firm may want to gain enough market power to deter its competitors from moving in or hope to create a skill or resource gap between the firm and its competitors. In doing either of these two, the firm does not perceive that it has all necessary resources to keep it in a competitive position. Thus, to gain and then enhance their competitive advantage, firms must acquire critical resources, or, using the theory's terms, make themselves in a state of resource dependence (Barringer & Harrison, 2000). To reduce such a resource dependence, firms can form an alliance or participate in interorganizational relationships with other firms (Mitchell & Singh, 1996). Firms enter into partnership relationships because they can take advantage of their complementary resources (Barringer & Harrison, 2000). This explication of why firms participate in interorganizational relationships from the resource dependence perspective can certainly apply to the case of BDC. When developing their BDC, firms need critical resources, which can be acquired by forming an alliance with their suppliers and customers.

A third theory that can be used to explain a perceived relationship between RB and BDC is the social capital theory. Based on this theory, social relationships help to build and gain social capital, which refers to a valuable asset that helps to gain access to resources made available through the relationships (Coleman, 1990). Social capital has three dimensions: cognitive, relational, and structural (Nahapiet & Ghoshal, 1998). The cognitive dimension represents shared meaning and understanding between actors in a relationship (Nahapiet & Ghoshal, 1998). It also helps to diminish misunderstandings, open discussion, and promote frequent communication among them (Tsai & Ghoshal, 1998). Subsequently, a shared vision and congruent goals will develop, which then help different actors in the relationship to integrate knowledge (Inkpen & Tsand, 2005). Additionally, these shared meaning, understanding, vision, and congruent goals would foster information sharing and resource exchange (Atuahene-Gima & Murray, 2007).

Next, the relational dimension refers to trust, friendship, goodwill, respect, and reciprocity developed in the interactions of the actors that help to sustain the relationships (Nahapiet & Ghoshal, 1998). This dimension entails the foundation of the relationship built over time (Villena, Revilla, & Choi, 2011). These ingredients of relational social capital allow actors to reliably expect to obtain and use the information and resources made available in the relationships (Nahapiet & Ghoshal, 1998). Lastly, the structural dimension refers to the embeddedness of actors in a social system or relationships, or the tie strength that positively relate to accessibility to information, knowledge, and other types of resources (Kemper, Schilke, & Brettel, 2013). As an integration of these three dimensions, social capital in general bring in information and resource benefits to organizations that would enhance their dynamic capabilities (Kemper, Schilke, & Brettel, 2013). This is done through employee behaviors.

Previous research (e.g., Lopez-Cabrales, Valle, & Herrero, 2006) shows that core employees play an important role in developing dynamic capabilities. More specifically, one group of such core employees, top managers, bring in social capital to their firms, which then facilitates effective access to the knowledge and resources necessary for developing superior organizational dynamic capabilities such as marketing and R&D capabilities (Kemper, Schilke, & Brettel, 2013). The literature provides evidence supporting the relationship between cognitive social capital and dynamic capabilities. For example, Tripsas and Gavetti (2000) showed that managerial cognitive representations may play a central role in terms of constraining organizational behavior, and ultimately, the development of a firm’s capabilities.

Similarly, relational social capital would facilitate the development of dynamic capabilities as well. Gibbons and Henderson (2012) show that how well top managers help to develop or diffuse organizational capabilities depends on their capability to build and refine relational contracts, which is a managerial practice aiming to seek collaboration with informal communication characterized by credibility and clarity. As agents representing their firms, top managers build and gain social capital in their interactions with external entities. Thus, relational contracts also work in their external communication, especially in interorganizational relationships. For example, Gulati and Nickerson (2008) found that high levels of interorganizational trust, an attribute of relational contracts or social capital, lead to choice of an informal but less costly governance mode for the interorganizational network and more importantly, tend to enhance the network’s exchange performance. As social capital is built in collaborative buyer-supplier relationships (Autry & Griffis, 2008; Cousins, Handfield, Lawson, & Petersen, 2006; Cousins & Menguc, 2006; Krause, Handfield, & Tyler, 2007; Lawson, Tyler, & Cousins, 2008; Min, Stephen, & Chen, 2008), the social capital theory suggests a strong link between supply chain RB and BDC.

H1: Supply chain relationship building is positively related to the development of Big Data capability.

Linkage between Supply Chain Relationship Building and Knowledge Sharing in Supply Chains

Most of the theories earlier reviewed share a central proposition that investment in relationship building, knowledge exchange, and combining resources lead to supernormal profit (Krause, Handfield, & Tyler, 2007). This suggests that RN and KS are inherently related. We argue that among those theories, the social capital theory, is most relevant to our proposition that there is a connection between supply chain RB and KS among supply chain partners. As the cognitive dimension of social capital contributes to diminishing misunderstanding and enhancing shared meaning, vision, and congruent goals (Nahapiet & Ghoshal, 1998; Tsai & Ghoshal, 1998), it facilitates information sharing, and knowledge exchange (Atuahene-Gima & Murray, 2007) and integration (Inkpen & Tsand, 2005). Similarly, the relational dimension, i.e., goodwill, friendship, and trust developed between actors of the relationship, makes it more likely for them to share information and knowledge (Nahapiet & Ghoshal, 1998). Likewise, the structural dimension suggests that the great number of ties and their strength enable actors with social capital to expand their access to information and knowledge (Kemper, Schilke, & Brettel, 2013).

Empirical research in the area of buyer-supplier relationships tends to support these theoretical implications. An extensively cited example is the case of Toyota, where information exchange and knowledge sharing are highly promoted in buyer-supplier relationships (Dyer & Nobeoka, 2000). Further, supplier trust leads to shared planning activities (in which both buyers and suppliers are involved) such as joint decision making (Johnston, McCutcheon, Stuart, & Kerwood, 2004). Joint decision making entails information sharing and knowledge exchange. Similarly, Cheung, Myers, and Mentzer (2010) showed that interorganizational factors such as trust, complementarity, and compatibility, ingredients of social capital, contribute to relationship learning, which involves information sharing, joint sense making, and knowledge integration. Corsten, Gruen, and Peyinghaus (2011) even suggested that to build relationships, and more specifically, to foster mutual trust, which in return nurtures information exchange and knowledge sharing between SC partners, mutual identification should be encouraged. These research findings give us support to articulate the following hypothesis:

H2: Supply chain relationship building is positively related to knowledge sharing in supply chains.

As shown above, all the three theories of dynamic capabilities, source dependence, and social capital suggest that positive supply chain relationships contribute to the development of dynamic capabilities. Further, the above review shows that both the dynamic capabilities and source dependence theories suggest that resources are integral to the development of dynamic capabilities. Knowledge is an important resource. Moreover, the review of the social capital literature indicates that social capital facilitates information and knowledge sharing among supply chain partners. Combining all these findings, we propose the following hypotheses:

H3: Knowledge sharing in supply chains is positively related to the development of Big Data capability.

Linkage between Big Data Capability and Product Improvement

Distinct capabilities can be developed in different areas of business activities that enable firms to generate competitive advantage (Eisenhardt & Martin, 2000; Schilke & Goerzen, 2010). This observation certainly applies to the big data area. Organizational capabilities in general positively impact performance. After a meta-analysis of 115 studies, Karna, Richter, and Riesenkampff (2015) found that both ordinary and dynamic capabilities influence financial performance in both stable and changing environments. Further, dynamic capabilities such as marketing and R&D capabilities differentiate firms in organizational performance (Kemper, Schilke, & Brettel, 2013). Big Data capability inherently involves both such capabilities as it deals with analyzing the market as well as developing tools, technologies, and competencies to analyze big data, similar functions of R&D. Most importantly, as it is revealed in previous reviews of case studies, Big Data practice helped to improve functional performance, enhance service quality, and reduce cost, etc (Ylijoki & Porras, 2016). These are important instances of product improvement based on our definition. Thus, to extend such observations from case studies, we propose the following hypothesis:

H4: Big Data capability is positively related to product improvement.

Mediation Effect of Big Data Capability

As it is shown early, supply chain relationships can bring firms social capital, which constitutes resources. These resources are critical to firm performance such as product improvement. However, according to the resource-based view (Barney, 1991) and the dynamic capabilities theory (Teece, 2007; Teece et al., 1997), when resources turn into organic elements of a dynamic capability, they help to boost firm performance. This suggests that dynamic capabilities tend to enhance the effect of resources stemming from social capital on firm performance. As demonstrated above as well, knowledge, like social capital, is also a resource. Thus it can be reasoned that dynamic capabilities also enhance the effect of knowledge sharing on firm performance. Empirical research has already shown that a path of social capital-dynamic capabilities-performance exists. More specifically, dynamic capabilities, i.e., marketing and R&D capabilities, fully mediate the relationship between social capital and performance (Kemper, Schilke, & Brettel, 2013). This leads us to pose the following two hypotheses:

H5a: Big Data capability mediates the relationship between supply chain relationship building and product improvement.

H5b: Big Data capability mediates the relationship between knowledge sharing in supply chains and product improvement.

METHODS

Questionnaire Development and Measures

The measurement scale for the constructs of knowledge sharing is adapted from existing scales used in previous studies, whereas the scales measuring Big Data capability, relationship building, and product improvement were developed in this study. The process for developing the three scales measuring Big Data capability, relationship building, and product improvement involved four phases: 1) item generation, 2) pre-pilot study, 3) pilot study, and 4) large-scale data analysis and instrument validation. Churchill's (1979) approach for developing and testing new scales was followed in the development of these scales. The first phase was a thorough review of past studies from which the content domain of the constructs was determined for this current research project.

The pre-pilot study was conducted with ten academicians who published work on the topic and eight industry experts with experience in Big Data. Feedback and comments from the academicians were used to check face validity of the newly drafted measurement items and improve the items. Using an adapted version of the Q-sort approach (Churchill, 1979), we asked the eight industry experts to read the construct and its dimensions, their definitions, and the items measuring them, and then match the scale items with the construct dimensions that they think the items measure well. This is to assess substantive validity of the scale items. Items with a 0.5 or higher value of substantive validity were retained. Some items were reworded based on comments and feedback from both the academicians and industry experts.

After the pre-pilot study, a small-scale pilot study was conducted to further improve the newly developed measurement scales. The pilot study questionnaire was posted on a research website (www.qualtrics.com). A list of potential participants was created using the LexisNexis database, with the following information: position title, specialty, mail address, telephone number, email address, firm size, SIC code, business description, and sales/revenue information. In the process of creating the list, a variety of job titles were used as key words such as: “Chief Operations Officer”, “VP Manufacturing”, “Manufacturing Manager”, “Plant Manager”, “Manufacturing Director”, “Production Manager”, and “Plant Operations Manager”. “Manufacturing” was used as the limiter in the search of the firm representatives to form the entries on the list. A total of 45 responses were obtained in this pilot study, of which only 42 were complete and usable. The 42 complete responses were analyzed using SPSS. Further deleting items was based on the results of this pilot study (Cronbach’s alpha, Corrected Item-Total Correlation (CITC), and factor loading values). The scales were then further refined based on the pilot study results. The fourth phase was a large-scale survey questionnaire administration.

The items measuring the construct of Big Data capability were generated based on the results of a thematic analysis of qualitative interviews which are reported in another paper, recent discussions of Big Data in the popular press, business journals for practitioners, and academic business literature, especially the works of Chen et al. (2012), McAfee and Brynjolfsson (2012), Chang et al. (2014), Peppard and Ward (2004), and Teece et al. (1997). The final version of the Big Data capability scale has a total of 16 items measuring Big Data operations, updating IT infrastructure, advanced analytics, and strategic uses of Big Data. However, the confirmatory factor analysis of the large-scale survey data used in this study yielded a single dimension structure for the Big Data capability construct. But the results also supported retaining all the 16 items in the scale. The relationship building (RB) construct has eight original items, measuring the four dimensions of trust, commitment, collaboration, and long-term orientation of the relationships with buyers and suppliers. The items developed for this study are based on previous studies that measured these dimensions, including Griffith et al. (2006) for long-term orientation, Johnston et al. (2004) for trust (they measured trust with two variables (dependability and benevolence)), Monczka et al. (1998) for trust, collaboration (coordination), and commitment. Each of these previous studies focused only on one or two of these four dimensions of relationship building, not the entire construct. They used multiple items to measure each of these four dimensions. If these items are all included in our measure for the relationship building construct, it would be an excessively long list of items. Further, the names and meanings of these four dimensions each are already familiar to respondents. Thus, we chose to use the exact words of these dimensions (trust, commitment, collaboration, and long-term orientation) in the items to measure their levels in the relationships with both buyers and suppliers. The product improvement (PI) construct originally has three measurement items. The scale measuring knowledge sharing is adapted from Ho and Ganesan (2013). The measurement items for all the constructs are listed in the Appendix.

In addition, consistent with previous studies on Big Data capabilities (see, e.g., Gupta & George, 2016), we treat industry and organization size as two control variables in this study. Industry is a nominal variable. Based on the responses from survey participants, the following industries were identified: manufacturing, IT, finance, automotive, telecommunications, construction, logistics, retail, media, healthcare, aerospace, utilities, chemical, consulting, and consumer products. Organization size, which is measured by the number of employees, ranges from 10 to 100,000, with a mean of 4603.

Respondents and Data Collection Procedure

Before the large-scale data collection process began, attention and efforts were directed on determining respondents for this study. It was decided that respondents for this study must be employees with enough knowledge about the phenomenon under study, i.e., Big Data practices in their organizations. Thus, the key informant approach was followed in the data-collection process (Phillips & Bagozzi, 1986). Based on interviews with industry experts in the instrument development and initial validation stage of this study, we learned that employees with high-level managerial positions in information technology, operations, and business analytics were potential key informants for this study. Thus, employees with the following positions were contacted for an invitation of participating in this study as survey respondents: CEO, COO, CIO, CTO, VP of Manufacturing, Operations Manager, IT Manager, Supply Chain Manager, Manufacturing Manager, Manufacturing Director, Plant Manager, Production Manager, and Analytics Manager.

Given the difficulties of locating and gaining access to enough key informants, we outsourced data collection to Qualtrics.com, a commercial research firm, which has a large list of business panel members who represent different firms in different industries. Email invitations were sent to its panel members by Qualitrics.com with the statement of the purpose of the study. They were directed to an online survey posted on Qualtrics.com's website.
It becomes increasingly popular among academicians to outsource data collection to commercial research companies. Yet serious concerns and challenges associated with such a practice emerged. All such concerns and challenges point to data quality. To ensure data quality, we followed recommendations from Schoenherr, Ellram, and Tate (2015). More specifically, we took the following measures to ensure data quality. First, we informed Qualtrics.com representatives of the purpose of this research project, and the detailed requirements for potential respondents. These requirements helped Qualtrics.com to locate a sample of potential respondents. Second, following Schoenherr et al's (2015) practice, we did not provide an initial statement at the beginning of the survey showing the purpose of the project so as to avoid the possibility that respondents form a pattern in their responses that reflect what they think we want as shown in the purpose statement. Third, we used screening questions at the beginning of the survey to ensure that only the respondents with the required characteristics take the survey and all other potential respondents would be disqualified. One such screening question, for example, was whether their organization has Big Data practice. Fourth, Qualtrics.com implemented some attention filters throughout the survey questionnaire to help to ensure that respondents focus their attention on the questions. Also, Qualtrics.com set a mechanism that automatically removes responses that were done in less than 9 minutes. This technical add-in helped to avoid those "speeders" (Schoenherr et al., 2015). Fifth, locations of all respondents and the ip addresses were recorded so as to check whether there were repeat respondents. Sixth, a "Not Applicable" response option was provided to each questionnaire item except for the open-ended and screening questions.

A total of 2700 panel members that were identified as managers in the manufacturing, operations, and IT industry, were targeted as potential respondents for this survey. With members whose contact information was not clear removed, a new total of 2200 remained in the list and an email was sent to them to solicit their participation in this study. A total of 273 responses was obtained. After a careful examination, 22 problematic responses were deleted. Thus, the final sample for this study was 251 responses. The response rate for this study was 12%.

Measurement Model

The measurement model consists of a confirmatory factor analysis that covers four constructs: Big Data capability, relationship building, knowledge sharing, and product improvement. All these constructs were modeled with reflective measurement items. Items were examined based on loadings and the overall model fit indicators such as CFI, TLI, NFI, and RMSEA (Byrne, 2010). Final measurement items, including their mean, standard deviation, loading, critical ratio, standard error, and R^2 values are shown in Table 1.

Table 1: Confirmatory Factor Analysis: Construct Descriptive Statistics, Factor Loadings, and Cronbach α Values

Construct	Mean	Standard Deviation	Loading	CR	SE	R^2
Big Data Capability (α = .92)						
BDC1	5.38	0.66	0.57	8.09	0.08	0.32
BDC2	5.23	0.78	0.58	9.18	0.08	0.34
BDC3	4.32	0.81	0.51	7.44	0.09	0.26
BDC4	5.21	0.87	0.58	8.30	0.10	0.34
BDC5	4.20	0.83	0.66	9.14	0.10	0.44
BDC6	5.16	0.87	0.66	9.30	0.10	0.44
BDC7	5.13	0.95	0.67	9.27	0.11	0.45
BDC8	5.12	0.90	0.63	9.46	0.11	0.40
BDC9	5.12	0.92	0.67	8.96	0.11	0.45
BDC10	4.99	1.01	0.61	8.63	0.13	0.37

BDC14	5.09	1.02	0.71	10.00	0.12	0.50
BDC15	5.19	0.94	0.65	10.16	0.10	0.42
BDC16	5.05	0.90	0.67	10.10	0.10	0.45
Relationship Building (α = .93)						
RB1	5.34	1.01	0.84	14.50	0.06	0.71
RB2	4.28	1.02	0.80	14.35	0.06	0.64
RB3	4.21	1.03	0.78	13.80	0.07	0.61
RB4	5.14	0.92	0.78	13.83	0.06	0.61
RB5	4.37	0.92	0.76	15.20	0.05	0.58
RB6	5.31	0.96	0.82	14.01	0.06	0.67
RB7	5.21	1.02	0.78	13.11	0.07	0.61
RB8	5.22	0.92	0.79	12.93	0.06	0.62
Knowledge Sharing (α = .78)						
KS1	4.98	0.97	0.58	7.83	0.12	0.34
KS2	5.19	0.81	0.65	7.40	0.13	0.43
KS3	4.21	0.86	0.69	7.89	0.14	0.48
KS4	4.28	0.90	0.58	6.35	0.14	0.34
KS5	4.32	0.82	0.65	7.39	0.13	0.42

KS6	4.24	0.74	0.54	6.63	0.11	0.29
Product Improvement (α = .73)						
PI1	5.15	0.93	0.67	10.14	0.10	0.45
PI2	5.12	0.89	0.70	10.00	0.10	0.49
PI3	5.11	0.90	0.71	10.14	0.10	0.50

Assessment of validity and reliability is based on recommendations by Anderson and Gerbing (1988). Reliability was assessed by looking at the Cronbach alpha value. The alpha values for these constructs range from 0.73 to 0.93, all above 0.70 (see Table 1). Furthermore, composite reliability serves a similar purpose but is considered a more rigorous reliability measure in structural equation modeling (Raykov, 1998). The composite reliability values of all the constructs are close to and even greater than the threshold value of 0.70 (See Table 2) (Bagozzi & Yi, 1988; Gefen, Straub, & Boudreau, 2000; Nunnally, 1978). These results indicate that items measuring the same construct are highly interconnected and that the constructs have good construct reliability.

Table 2: Composite Reliability, Correlations, and Average Variance Extracted

	Composite Reliability	BDC	KS	RB	PI
BDC	0.68	0.41			
KS	0.68	0.67**	0.38		
RB	0.66	0.43**	0.34**	0.61	
PI	0.73	0.68**	0.61**	0.37**	0.48

**: Correlation is significant at the 0.001 level (2-tailed).
Average variance extracted values are printed in diagonal.

Similarly, construct validity was assessed in several ways. First, content validity was ensured by designing, developing, and refining measurement items based on literature reviews, interviews of practitioners and academics knowledgeable in the content domain, and cross checking with these practitioners and academics. Next, convergent validity was assessed by looking at each indicator's loading. As seen from Table 1, loadings of all measurement items are higher than 0.5, the cutoff point traditionally used in the literature.

Traditionally, discriminant validity was assessed by examining the cross-loadings of the items measuring each construct, and whether the square roots of the average variance extracted (AVE) for each construct are greater than the corresponding correlation coefficients (Fornell & Larcker, 1981). Recently, Hensler, Ringle, and Sarstedt (2015) identified flaws of the Fornell and Larcker's (1981) method and proposed using a new criterion called the heterotrait-monotrait ratio (HTMT). This ratio is based on the average of the correlations of indicators across constructs measuring different concepts relative to the average of the correlations of indicators within the same construct. Based on this approach, the HTMT ratio below 0.85 demonstrates sufficient discriminant validity. We ran this test on all the four constructs, and the HTMT values were all below 0.85, suggesting that they all have sufficient discriminant validity.

Additionally, the uni-dimensionality of the constructs was established by confirmatory factor analysis, with all item loadings well above the suggested threshold of 0.50 (Byrne, 2010). Finally, construct validity was established by satisfactory content validity, uni-dimensionality, reliability, and convergent and discriminant validity (O'Leary-Kelly & Vokurka, 1998). Composite reliability, and correlations and the AVE values are all presented in Table 2.

The measurement model test results showed that the model overall has good fit. The CMIN/DF ratio (= 1.42) shows superior model fit. The CFI (= 0.95) and TLI (= 0.95) values indicate good fit, as these two values are close to the 0.95 cutoff line. The NFI value (= 0.86) suggests acceptable model fit. Lastly, the RMSEA (= 0.03) shows superior model fit.

Following prior studies (e.g., Swafford, Ghosh, & Murthy, 2006), we evaluated non-response bias, using a *t*-test. *T*-tests were performed comparing the responses of the first 30 and last 30 respondents with five items measured with an interval scale as dependent variables, which were randomly selected from the questionnaire. No significant difference was found between the two groups at the 0.05 level in all the five *t*-tests, suggesting no evidence of non-response bias in the data.

We addressed common-method bias in the questionnaire administration in several ways. First, we followed a rigorous approach for informant selection by ensuring that respondents are in the right positions in their companies, which indicate that they are fully informed of the subject matters investigated in the study. Second, while common-method bias is of greater importance in research related to issues of social desirability, this study focuses on topics that do not incur social desirability, further minimizing the potential for common-method bias. In addition, following recommendations provided in Podsakoff, MacKenzie, and Lee (2003), common-method bias was empirically assessed. More specifically, Harman's single-factor test was conducted. The single-factor model exhibited significantly worse fit than the measurement model, suggesting that common-method bias is not a serious concern in this study (Podsakoff & Organ, 1986).

Next, following the procedures of Schwarz et al. (2017) and Williams, Hartman, and Cavazotte (2010), we created three models: baseline, common latent factor, and marker variable, and then compared the models using chi-square difference test. As shown in Table 3, all the three models have good goodness of fit. The comparison test between baseline and common latent factor models shows that there is no significant difference between the two models, suggesting that common method is not a serious issue. However, the comparison between baseline and marker variable models indicates presence of common method bias in the dataset. But these tests did not show the extent to which common method bias exists in the dataset. Furthermore, the assumption underlying these model tests is that the difference between the two models in comparison is significantly different from zero. Therefore, following the approach recommended by Gaskin (2012), we noted that, from the marker variable model, the common factor unstandardized loading is -.042, with a square of .002, which is far less than 50%. Based on these two statistics, we can conclude that common method bias, is not a serious concern in the dataset.

Table 3: Chi-Square, Goodness-of-Fit Values, and Model Comparison Tests

Model	**$\chi 2$**	**df**	**CFI**	**RMSEA**
Baseline	376.33	246	.95	.04
Common Latent Factor	376.00	239	.95	.04
Marker Variable	474.60	314	.94	.04
Chi-Square Model Comparison Tests ΔModels	$\Delta\chi 2$	Δdf	P	
Baseline vs. Common Latent Factor	0.33	7	1.00	
Baseline vs. Marker Variable	98.28	68	.01	

Structural Model

In testing the structural model, all the constructs and their pre-specified relationships were entered in the model. All the following constructs with their measurement items still remain in the model: Big Data capability, relationship building, knowledge sharing, and product improvement. The final results show that the model has a good fit. The CMIN/DF ratio (= 1.46) shows superior model fit. Both the CFI (= 0.97) and TLI (0.97) values indicate strong goodness-of-fit. The NFI (= 0.88) value is a little bit lower, suggesting acceptable model fit. The RMSEA (= 0.04) suggests superior model fit. Thus, overall, these indicators show a good model fit.

RESULTS

The hypotheses covered in the structural model test are as follows: H1, H2, H3, H4, and H5a and H5b. Hypothesis 1 posits that supply chain relationship building is positively related to Big Data capability. The test results indicate that supply chain relationship building has a strong positive relationship with Big Data capability. Thus, H1 ($\beta = 0.19$, $p < 0.0001$) is supported. Further, hypothesis 2 posits that supply chain relationship building is positively related to knowledge sharing in supply chains. The test results ($\beta = 0.38$, $p < 0.0001$) show that H2 is also supported. Similarly, hypothesis 3 suggests that knowledge sharing is positively related to Big Data capability. The results ($\beta = 0.74$, $p < 0.0001$) show that H3 is supported. Hypothesis 4 indicates that Big Data capability positively contributes to product improvement. The results show support to this hypothesis ($\beta = 0.99$, $p < 0.0001$).

Finally, the two mediation hypotheses (H5a and H5b) were tested. Traditionally, the Baron and Kenny (1986) method has been used extensively to test mediation hypotheses in social science research. However, serious concerns were raised regarding its validity (Zhao, Lynch, & Chen, 2010). To overcome some of the key weaknesses of the Baron and Kenny (1986) method, a more advanced method, the bootstrapping method, which provides more accurate and powerful mediation testing, has been proposed (Shrout & Bolger, 2002). In addition to greater statistical power, the bootstrapping method provides two advantages. One is that indirect effect can be measured directly (Hayes, 2009). The other advantage is that it does not assume normality in the mediation effect. This adds to the validity of the mediation test results as indirect effects may not necessarily exhibit a normal distribution (MacKinnon et al., 2002).

In running the bootstrapping mediation tests, we followed the convention of setting confidence interval at the 95% level and the number of resamples at 5,000. The mediation test results are shown in Table 4. Hypotheses 5a states that Big Data capability mediates the effect of supply chain relationship building on product improvement. The results show that the mediation effect is significant, as 0 does not fall between the lower bound of 0.06 and upper bound of 0.22. Thus, hypothesis 5a is supported. Additionally, the results show that this is a full mediation effect, as supply chain relationship building does not have a significant direct effect on product improvement. Hypothesis 5b indicates that Big Data capability mediates the effect of knowledge sharing in supply chains on product improvement. The bootstrapping mediation test results indicate that this mediation effect is significant, as 0 does not fall between the lower bound of 0.22 and the upper bound of 0.40. Therefore, hypothesis 5b is supported. Further, the results show that this is a partial mediation effect. But, the direct effect of knowledge sharing in supply chains on product improvement is significant only at the 0.05 level with $\beta = 0.12$. The effect was smaller than that of the mediation effect. Based on these test results, the conceptual framework is adjusted (as shown in Figure 2).

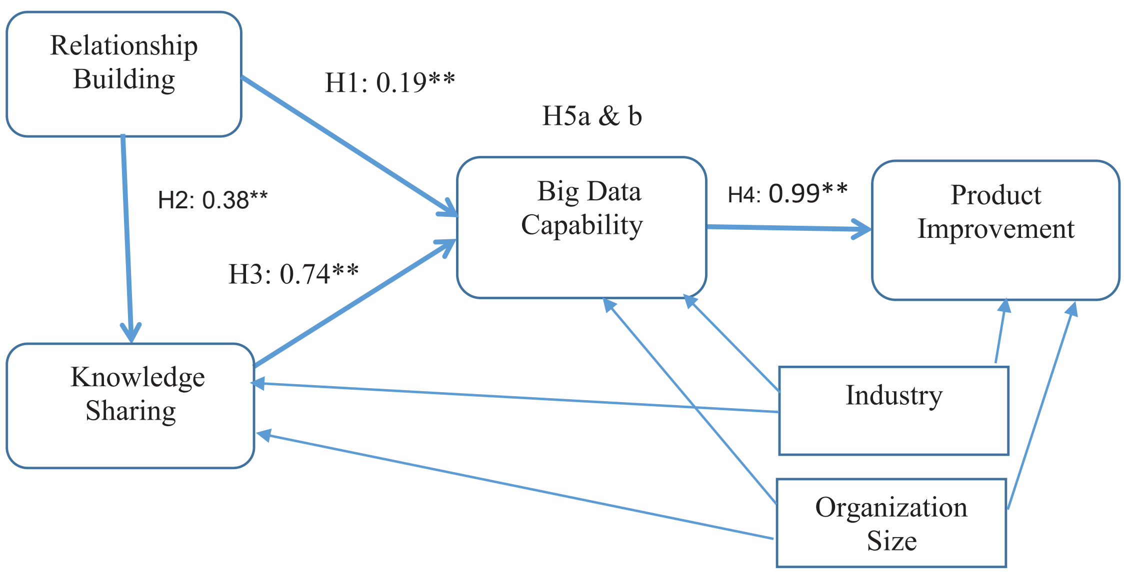
Table 4: Results of Bootstrapped CI Tests for Full and Partial Mediation Hypotheses:

			Mediation Test (*ab*)			Full/Partial Mediation Test (*c*)			
X variable	Mediator	Y variable	Lower bound	Upper bound	Zero included?	Lower bound	Upper bound	Zero included?	Type of mediation
RB	BDC	PI	0.06	0.22	No	0.21	0.49	No	Full
KS	BDC	PI	0.22	0.40	No	0.11	0.17	No	Partial

DISCUSSION AND CONCLUSIONS

In the emerging area of big data research, on the basis of numerous cases reporting how big data helps to enhance specific business functions including supply chains (for a review, see Ylijoki & Porras, 2016), academic research has pointed to the importance of conceptualizing big data initiatives and practices as dynamic capabilities and empirically verified the positive relationship between such capabilities and firms' market and financial performance (see Braganza et al., 2017; Chen, Preston, & Swink, 2015; Gupta & George, 2016; Wamba et al., 2017). To extend current big data research, this study draws on multiple theoretical perspectives to propose a framework where Big Data capability contributes to firm product improvement performance but its own development benefits from supply chain relationship

Figure 2: Adjusted Conceptual Model



building and knowledge sharing. Then it tests the validity and feasibility of this proposed framework with survey data collected from U.S. companies. We now present a discussion of the findings of this study with respect to theory and management practice.

First, the hypothesis testing results of this study show that Big Data capability directly enhances product improvement. Consistent with those from prior studies, this finding supports the view that only when Big Data initiatives and practices develop into Big Data capabilities can firms remain competitive in its performance (Braganza et al., 2017; Chen, Preston, & Swink, 2015; Gupta & George, 2016; Wamba et al., 2017), in this case, product improvement. Additionally, this finding contributes to the literature by offering us a more complete understanding of why or how big data enhances firm performance. It is that big data capabilities enhance product improvement, which then translates into market performance, and finally financial performance. The contribution lies in that it brings to light this step that connects big data capabilities and market and financial performance, which is missing in prior research.

Second, this study shows that supply chain relationship building and knowledge sharing are positively related to the development of Big Data capability. These findings suggest that supply chains supply nutrition to Big Data capability in its development. Additionally, they show that even though Big Data capability in nature is firm specific and path-dependent based on the dynamic capabilities perspective (Teece et al., 1997; Teece, 2007), its growth benefits from external resources, in this case, those available in supply chains. Further, these findings indicate that access to and even acquisition of such supply chain resources including knowledge is facilitated by firms' ability of building relationships with their supply chain partners. With these findings, this study contributes to the literature by identifying supply chain management activities, more specifically, supply chain relationship building and knowledge sharing, as antecedents to Big Data capability. This helps to extend this emergent enterprise of big data research to a new area and points to new directions for future research. Moreover, while previous research showed that big data contributes to supply chain performance, this study offers a new insight into supply chains that they constitute a site for nourishing the growth of big data dynamic capabilities with partners making efforts to build relationships and share knowledge with one another.

Third, the findings of this study indicate that Big Data capability strongly mediates the relationships between the two supply chain management activities, namely, relationship building and knowledge sharing, and product improvement. Our up-to-date knowledge about big data rests on the research finding that big data capabilities enhance firm performance. Thus, another contribution of this study is that it extends the literature by showing that big data capabilities not only contribute to firm performance but also facilitate and even aggrandize the effects of other contributors to product improvement, here in this case, supply chain relationship building and knowledge sharing.

In addition to the theoretical implications, this study offers several implications for managerial practices. First, the finding that Big Data capability enhances product improvement suggests that firms should integrate Big Data resources and competencies in alignment with their strategic directions to develop a Big Data capability. Second, the findings of this study inform firms that to increase Big Data capability's impact on product improvement performance, firms should learn to build positive relationships with their supply chain partners. These positive relationships also facilitate knowledge sharing among the partners. Knowledge from supply chain partners is a rewarding input to the development of Big Data capability.

Despite these contributions to both theory and practice, this study has some limitations that can be addressed in future research. First, in supply chain management, there are multiple factors, besides relationship building, that serve as conditioners to knowledge sharing's effect on product performance. We only examined the role of relationship building in this area. Future research can extend the examination to other factors such as supply chain integration, and organizational culture. Second, even though we took measures to ensure data validity and reliability in the data collection process, the endogeneity problem may still exist. Future research should consider different research designs, such as experiments, or use secondary data to establish the causal relationship between Big Data capability and product improvement.

Appendix

Codes	*Questionnaire Items*
	Big Data Capability (BDC)
BDC1	We are able to identify sources of big data that meet our needs.
BDC2	We are able to collect big data that meet our needs.
BDC3	We are able to store large volumes of data.
BDC4	We are able to process big data with a fast speed.
BDC5	We adopt state of the art technologies to process big data.
BDC6	We constantly update our computing equipment to process big data.
BDC7	We constantly update our IT architecture to process big data.
BDC8	We constantly update our IT infrastructure to process big data.
BDC9	We are good at data analytics which is mainly data mining and statistical analysis.
BDC10	We are good at text analytics that deals with unstructured textual format data.
BDC11	We are good at web analytics that deals with web sites.
BDC12	We are good at mobile analytics that deals with mobile computing.
BDC13	We rely on Big Data to identify new business opportunities.
BDC14	We rely on Big Data to develop new products.
BDC15	We rely on Big Data to enhance our innovativeness.
BDC16	We rely on Big Data to formulate our business strategy.
	Relationship Building (RB)
RB1	Trust level in the relationship with your buyers.
RB2	Commitment level in the relationship with your buyers.
RB3	Collaboration level in the relationship with your buyers.
RB4	Long-term orientation level in the relationship with your buyers.
RB5	Trust level in the relationship with your suppliers.
RB6	Commitment level in the relationship with your suppliers.
RB7	Collaboration level in the relationship with your suppliers.
RB8	Long-term orientation level in the relationship with your suppliers.
	Knowledge Sharing (KS)
KS1	My firm and our supply chain partners have shared a significant amount of knowledge with each other.
KS2	My firm has exchanged many ideas with our supply chain partners about how

	to improve each other's capabilities (in manufacturing, research and development, logistics, etc.).
	In general, the skills and knowledge that have been shared between my firm and our supply chain partners are
KS3	a. substantial amount.
KS4	b. advanced.
KS5	c. of significant value to both parties.
KS6	d. of significant use.
	Product Improvement (PI)
PI1	Big Data has enabled us to add new features that meet customers' needs to our current products.
PI2	Big Data has enabled us to add new functionalities that reflect customers' needs to our current products.
PI3	Big Data has made our current products more competitive in the market.

ABSTRACT

Grounded with paradox theory, we conduct a systematic literature review within the supply chain management context to extract interdependent elements which possess persistent contradictions. We embark on this study by casting a wide net and searching through four different databases over the last 20 years of peer-reviewed literature between 1998 and 2019. We found 63 articles as the basis of our literature review. Our findings shed light on the extent of usage for the paradox theory as well as elements perceived as paradoxical by supply chain management scholars in the extant literature.

Keywords: Paradox theory, Systematic literature review, Paradoxical elements, Supply chain management

INTRODUCTION

In the past 20 years, paradox perspective has evolved from ground of zero to a theory (Lewis, 2000; Smith and Lewis, 2011; Lewis and Smith, 2014; Smith et al., 2017). According to paradox theory (PT), paradox is defined as "persistent contradictions between interdependent elements" (Schad et al., 2016). Paradox is suggested as an effective "theoretical lens to understand and to lead contemporary organizations" (Smith and Lewis 2011, pp.398) where fierce competition in a globalized marketplace that is fueled by innovation and sustainability pressures creates a setting that is full of uncertainties. Paradox theorists offer future research agendas (Schad et al., 2016; Smith et al., 2017, Schad et al., 2019) that point to the potential of paradox lens across diverse streams of management science. In this study, we follow their lead and embark on an introductory search to examine how the PT relates to the extant supply chain management (SCM) literature. We conduct our investigation by extending an exploration for the use of PT and those elements that are perceived as paradoxical by scholars within SCM literature. Our study conducts a systematic literature review (SLR) for paradoxical elements (PEs) by implementing the methodology that Durach et al. (2017) propose in SCM. Prior studies have not delved into the systematical review of PEs, especially in the domain of supply chain. This study is a forerunner of reviewing these PEs in-depth and group them based on the paradox theory (Smith and Lewis, 2011; Smith et al., 2017).

Scanning the SCM literature, Adler et al. (1999) investigate the paradoxical dynamic between flexibility and efficiency. A decade later, Adler et al. (2009) further developed the discussion of productivity dilemma that Abernathy (1978) discovered in the automobile industry. Innate trade-off approach of SCM literature is also rich in plenty of other instances of paradoxical elements, though usually presented in dualities such as lean and agile, efficiency and flexibility, etc. (e.g. Naylor et al. 1999). Moreover, for instance, interactions created between an academic and a practitioner (Bartunek and Rynes, 2014) can be perceived as paradoxical at times. By investigating PEs in the SCM domain, our study makes several contributions.

We structured our paper as follows. We briefly introduce the PT in the following section. Then, we explain the SLR approach in the methodology section and continue with reporting the study findings in the results section. In the end, we reported the findings of the study and future discussions along with potential future research avenues were presented.

PARADOX THEORY (PT)

Lewis (2000) explores paradoxes and provides insights into the increasing organizational complexity and ambiguity. Lewis proposes a paradox framework that clarifies the nature of paradoxical tensions, reinforcing cycles, and their management by initially providing three paradox types – paradox of learning, paradox of organizing, and paradox of belonging. However, the study does not include the performing paradox which is added much later. Lewis' work serves as a lens for examining surprising findings and seemingly absurd aspects of organizational life. In Smith and Lewis (2011), the authors review the paradox literature ten years after the paradox framework is introduced. Our results reveal that the performing paradox has the largest number of PEs among the four paradoxes. Highlighting the debates in paradox literature, the article extends the paradox categories mentioned in Lewis (2000) and includes a fourth paradox category – performing paradox. In addition to the paradox categories, the two main challenges to paradox theory are also discussed. The first challenge of the paradox research stems from the lack of clarity of what paradox is, and the second challenge stems from the ontological debate that differentiates paradoxical tensions either as an inherent feature of a system or as social constructions. In their study, Smith and Lewis propose a model that seeks conceptual clarity, describes both the inherent and socially constructed features of organizational tensions and integrates management strategies of acceptance and resolution.

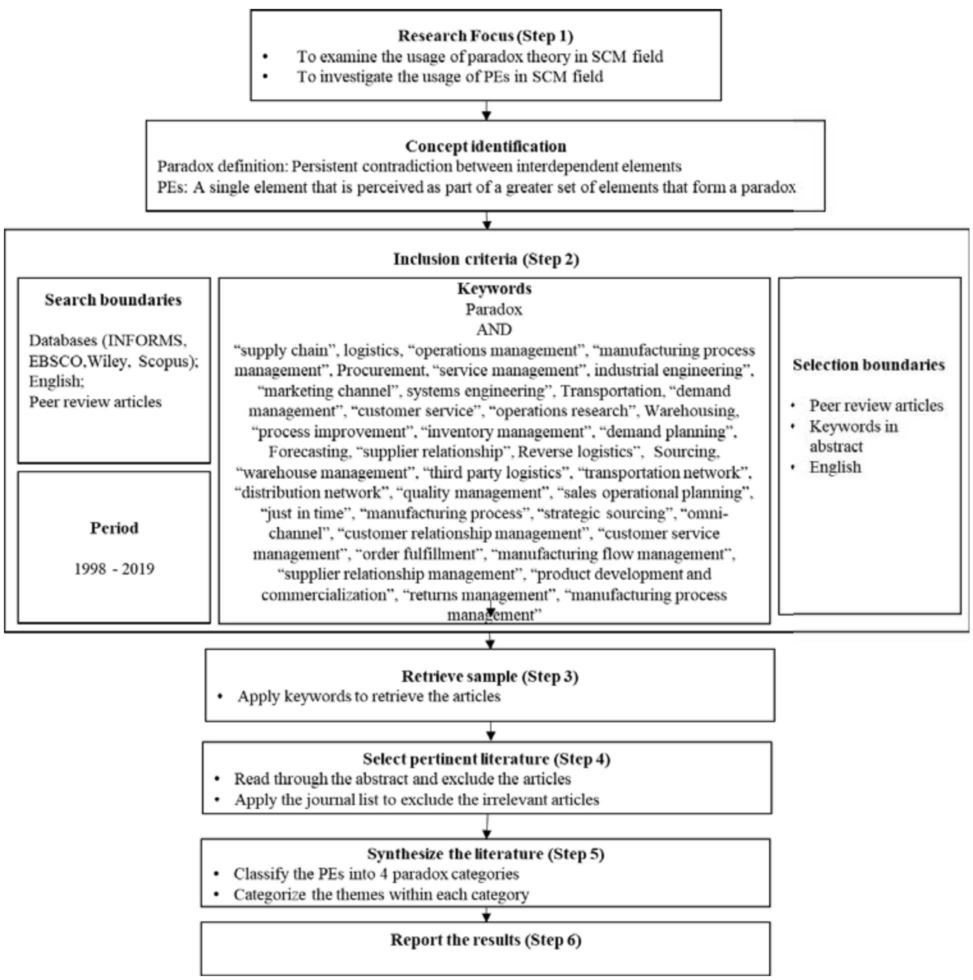
Smith et al. (2017) arguably pin phenomenon of paradox to ancient philosophy while citing that paradox research increased by ten percent per year between 1990 and 2014 after building on early research conducted in psychoanalysis, communications, and macro sociology disciplines. The authors also add a collection of studies that advance the PT that is rich in the explorative nature of paradox and posit that interdependent contradictions are inherent in human nature, its environment as well as the constructs that we humans build (e.g. life-death, knowledge-ignorance, self-other, expansion-constriction, independence-dependence, time-space, particles-waves, stability and change, empowerment and alienation, flexibility and control, diversity and inclusion, exploration and exploitation, social and commercial, competition and collaboration, learning and performing, profits and purposes, novelty and usefulness). In this literature review, we follow the appeal of the paradox scholars and intend to classify and summarize the PEs in the SCM domain.

Based on our SLR, we extract the PEs found in the SCM related articles and classify them into 10 paradox categories (Smiths and Lewis, 2011) and then group them under themes within each category. In Lewis (2000), the themes are specified within each paradox category except the performing paradox. By classifying the PEs from the SCM domain in the paradox categories and grouping them within different themes, we provide a foundation to import the PT into the SCM domain. In doing so, we hope to help spur more research on introducing the theory to the SCM field.

SYSTEMATIC LITERATURE REVIEW (SLR) METHODOLOGY

Durach et al. (2017) argue that while SLR has helped substantially to developing knowledge in fields such as medicine, it has made limited contributions to developing knowledge in the SCM domain. They suggest that an SLR needs to be adjusted to unique characteristics of SCM and thus further recommend six steps to achieve this. We adhered to these six steps of the SLR in this study (see Figure 1): step 1 define the research question, step 2 determine the required characteristics of the study, step 3 retrieve a sample of potentially relevant literature, step 4 select the pertinent literature, step 5 synthesize the literature, and step 6 report the results. Each step needs to be addressed carefully. Otherwise, several biases associated with each step will occur. The discussion of addressing the biases associated with each step will also be described in the following sections.

Figure 1: Systematic Literature Review (SLR) Process



Defining the Research Questions (Step 1)

This SLR intends to explore the PT in the SCM domain. Particularly, we want to explore the level that PT is employed in the SCM literature. Therefore, the first research question in the SLR is “What is the scale of usage of PT in the SCM literature.” Besides, the SLR also intends to extract the PEs used in the SCM domain where the PEs are defined as those elements that are *persistently contradictory and interdependent with one another.* Therefore, the second research question in the SLR is “What are the PEs used in the extant SCM literature.”

Determining the Required Characteristics of the Study (Step 2)

In this study, we included the previous studies that range from January 1998 to December 2019. We believe that the duration of two decades is long enough to keep track of the usage of the paradox related studies in the SCM field. This time frame is also in line with the emergence of the idea of organizational paradox. We include articles with both qualitative and/or quantitative methodologies because both methods benefit the SLR in SCM (Durach et al., 2017). The four databases that we employed are ABI/INFORM Complete (ProQuest), Academic Search Complete (EBSCO host), Scopus (Elsevier), and Wiley Online Library. ABI/INFORM Complete (ProQuest) is the largest database including full-text of scholarly and trade journal articles in business, management, and trade. Wiley Online Library covers a large number of supply chain management journals. Academic Search Complete (EBSCO) and Scopus are the interdisciplinary databases that also cover business and management journals. Initially, we searched by applying keywords “paradox” and “supply chain” to search the articles in the entire article texts. However, we found that including the entire text did not yield any added value to the search. Instead, it provided a large number of search results and increased time to read through all the articles and identify any relevant PEs. We assumed that if the PE that is mentioned in the article is a significant one, then the authors would mention it in the abstract. Therefore, we only included previous studies whose abstract includes synonyms of “supply chain” and “paradox” together. We limited the search process within abstracts of the selected peer-reviewed journal articles in the above databases and set the language of the articles in English only. Upon collecting all the articles, we created a finalized SCM journal list to exclude articles that are not tightly related to the SCM domain. We first selected three SLR papers (Fabbe-Costes and Jahre, 2008; Colicchia and Strozzi, 2012; Seuring and Gold, 2012) in SCM. Based on these three-literature review papers, we used the impact factor and citation centrality criteria to select the relevant journals in the SCM journal list. We also assumed that if a journal publishes a literature review in supply chain management, the journal can be considered related to the SCM domain. Therefore, we also search the databases for journals that have published SLR in the SCM domain.

We only focused on those articles that mention the word paradox and we excluded keywords such as ambidexterity, trade-off, and dilemma. The reason that we exclude these keywords is that even though they are similar to paradox, they do not fully satisfy the definition of paradox which suggests interdependence and persistent contradiction among the PEs.

Retrieving a Sample of Potentially Relevant Literature (Step 3)

The use of multiple databases can help us address the retrieval bias because it reduces the chance to miss any relevant articles. In addition to the multiple databases, we also finalized a list of 60 SCM journals to retain the articles (see Appendix). The use of the list of 60 SCM journals in lieu of any subjective preferred list of journals is instrumental in addressing the publication bias because we not only included the leading SCM journals but also all of the relevant SCM journals.

Durach et al. (2017) suggest that the search applies a combination of search strings, which are based on research purpose, research questions, and inclusion/exclusion criteria. We subjected the selection of our search strings to a series of processes. In the first step, we created a SCM domain keyword table which includes the phrases “Supply Chain”, “Logistics”, “Operations Management”, “Manufacturing Process Management”, “Service Management”, “Production Management”, “Industrial Engineering”, “Systems Engineering”, “Procurement”, “Marketing channel”.

In the second step, we formed an expert panel to help us refine the keywords list. We first thought that SCM scholars would have more knowledge on the supply chain synonyms, so we first consulted with 5 SCM scholars to refine our SCM keyword table. We also consulted with two SCM practitioners who have many years of industry experience in SCM practice. They helped us to include more relevant keywords that were not captured previously. In the end, we also consulted with subject librarians on the selection of keywords. After repeated discussions with the expert panel, we finally came up with a list of 40 synonyms for the key phrase “supply chain”. Table 1 lists the synonyms for the keyword “supply chain”. The key phrases are ranked according to the frequency mentioned. We opted to include all keywords/phrases in this study to cast a wide net for our search.

Table 1: Search keywords developed by the expert panel

	Supply chain management
10	Logistics
9	Operation Management
8	Manufacturing Process Management
8	Procurement
7	Service Management
6	Industrial Engineering
6	Production Management
5	Marketing channel
4	Systems engineering
2	Transportation
2	Demand Management
2	Customer Service
1	Operation Research
1	Warehousing
1	Process Improvement
1	Inventory Management
1	Demand Planning
1	Forecasting
1	Supplier Reltaionship
1	Reverse Logistics
1	Sourcing
1	Warehouse Management
1	Third party logistics
1	Transportation Network
1	Distribution Network
1	Quality Management
1	Sales Operational Planning
1	Just In Time/Lean Manufacturing
1	Manufacturing Processes
1	Strategic Soucring
1	Onni-Channel
1	Customer relationship management
1	Customer service management
1	Order fullfillment
1	Manufacturing flow management
1	Supplier relationship management
1	Product development and commercialization
1	Returns management
1	Manufactruring Process Management

With the combination of each of the 40 SCM field related keywords/phrases and the keyword “Paradox”, we performed the search within the abstracts of the target literature. The initial number of articles resulted in the databases were 540 in the ABI/INFORM Complete (ProQuest), 258 for in the Academic Search Complete (EBSCO host), 320 in the Scopus (Elsevier) and 699 in the Wiley Online Library is 740. After the initial search, the combined total number of articles in the four databases was 1,817.

Selecting the Pertinent Literature (Step 4)

In step 4, the inclusion and exclusion criteria are applied to select the articles. The authors first developed the inclusion and exclusion criteria independently and then compared with each other. To develop the inclusion and exclusion criteria individually help to address the inclusion bias, which might have led to the emergence of the incorrect results. The inclusion criteria are 4 databases, “1998-2019”, “English”, “Peer review”, “search strings”. As we mentioned earlier, we do not include the articles that focus dilemma, dialectic, and trade-off.

In each database, the authors read through the abstract of all the articles. If an article mentioned both the SCM field keywords and “paradox” in the abstract, the authors kept the article. Any articles that did not include both search strings in abstract were excluded. After this scanning process, the number of studies kept was 168 articles from ABI/INFORM Complete (ProQuest), 46 articles from Academic Search Complete (EBSCO host), 90 articles from Scopus (Elsevier), and 102 articles from Wiley Online Library. At this stage, the total number of articles was 423. In the final step, we applied the list of 60 journals to exclude the articles that are not published in the SCM related journals. Total of 63 articles are included in the literature review. The articles that were eliminated in this round were kept for gaining any possible insights from journals that are discussing paradoxes within the SCM context.

Synthesizing the Literature (Step 5)

In the beginning, two of the researchers in this study extracted the PEs individually. Having multiple researchers to extract the PEs individually can address the within-study bias, which would provide an incorrect outcome of review (Durach et al, 2017). Both coders further discussed and then agreed on correctly identifying less than ten percent of the PEs which ultimately yielded to full intercoder agreement rate. A total of 74 sets of PEs were coded through these two independent coders.

During the synthesis stage, the PE sets were coded based on the four core paradox categories (Learning Paradox, Belonging Paradox, Organizing Paradox, and Performing Paradox) and six combined paradox categories (Learning::Belonging, Learning::Organizing, Belonging::Organizing, Learning::Performing, Performing::Belonging, Performing::Organizing) proposed by Sandberg (2017) that is grounded in Smith and Lewis (2011). The authors strictly followed the category criteria in Sandberg (2017), and if there was disagreement on putting the sets of PEs into a category, the authors discussed until an agreement was reached. There were no stalemates that necessitated the involvement of the third researcher in this study. The PE sets were then grouped into 10 categories which are Learning Paradox, Belonging Paradox, Organizing Paradox, Performing Paradox, Learning-Organizing Paradox, Learning-Performing Paradox, Belonging-Organizing Paradox, Performing-Organizing Paradox, Belonging-Performing Paradox. We do not find any group to paradox category Learning-Belonging.

Within each category, we color-coded the themes of the PEs. The authors coded the themes after a detailed discussion and only classified the PEs into a theme until a full agreement was made. In the learning paradox category, the authors classified PEs under three themes: old, new, and present. In the organizing paradox category, the authors classified PEs under five themes: collaboration, efficiency and control, exploration, competition, and others. In the belonging paradox category, the authors classified PEs under two themes: single entity and multiple entities. And lastly, in the performing paradox category, the authors classified PEs under seven themes: specific, service, cost, forecast, sustainability, overall, and investment.

Reporting the Results (Step 6)

Figure 2 presents a histogram for the number of PE sets in each year. The usage of the PEs in SCM has increased from 1998 to 2019. More PE sets are perceived as paradoxical in recent years than two decades ago. This increase in numbers has also been steady over the years.

Figure 2: PE sets over the years of 1998 – 2019

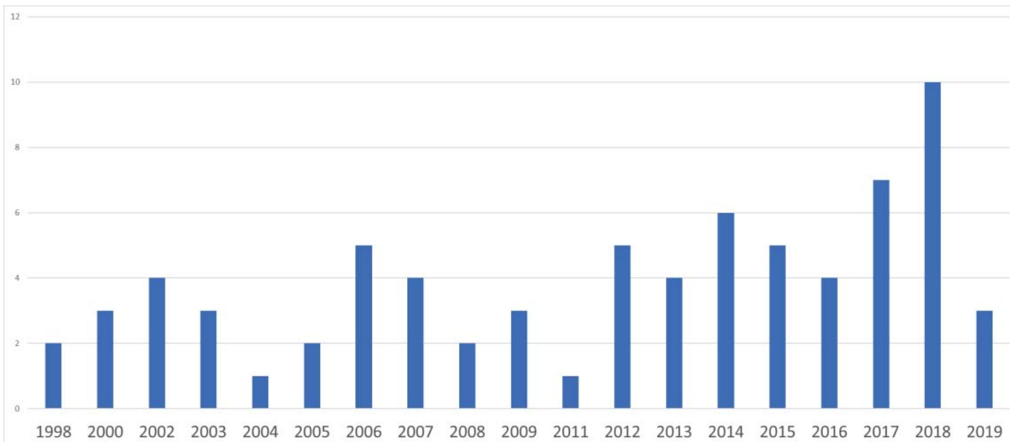


Table 2 shows the usage of PE sets in SCM journals. The Decision Science Journal has the greatest number of PE sets at 7. The second-ranking journals are the International Journal of Operations and Production Management, Journal of Supply Chain Management, and Production and Operations Management with 6 PE sets. Many journals seem to have published at least one or two articles that contain a PE set.

Table 2: The usage of PE sets in the SCM journals

Number of Journals	**Journal Name**	**Number of PE sets in each Journal**
9	Benchmarking Computers & Operation Research European Journal of Operational Research European Journal of Purchasing and Supply Management Journal of cleaner production Journal of the Operational Research Society Management Science Supply Chain Management Technological Forecasting & Social Change	1

3	International Journal of Operations & Production Management Journal of Supply Chain Management Production and Operations Management	6
1	Decision Science	7

Figure 3 shows the number of PE sets under each paradox category. The performing paradox category has the largest number of PE sets which is followed by the intersection of performing/organizing paradox category, and then by the organizing paradox category.

Figure 3: Number of PE sets under each paradox category

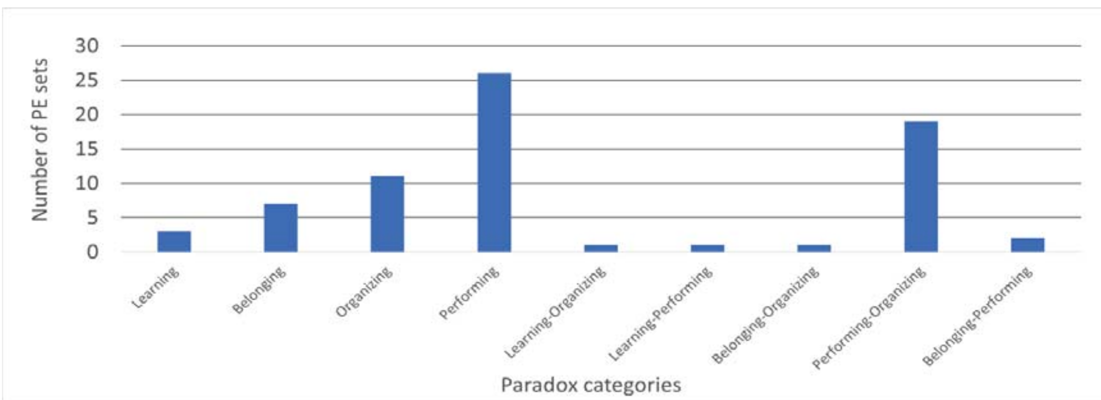

Table 3 summarizes the number of themes in each paradox category. The learning Paradox has three themes. The organizing paradox has 5 themes. The belonging paradox has 2 themes. The performing paradox has 7 themes.

Table 3: The number of themes under each paradox category

Learning Paradox (3 themes) Old; New; Present	Organizing Paradox (5 themes) Collaboration; efficiency and control; exploration; competition; and others.
Belonging Paradox (2 themes) Single entity; Multiple entities	Performing Paradox (7 themes) specific, service, cost, forecast, sustainability, overall, and investment.

Table 4 shows the paradox categories in each article. Overall, most of the articles only identify one paradox. Sandberg (2017) identifies four paradox categories. Looney et al (2016) and Kolk (2012) identify three paradox categories. Wacker and Lummus (2002) identify two paradox categories.

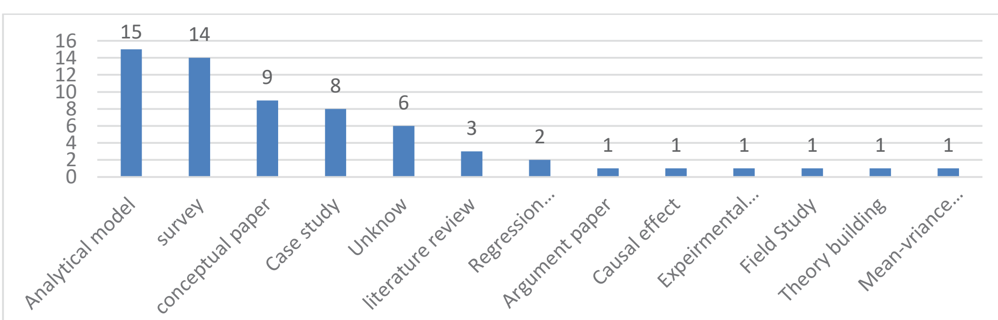
Figure 4 shows the usage of method in articles. The analytical model is the mostly used method in the literature. The survey method is the second mostly used method. Conceptual paper and case study are the third and fourth mostly used methods in the article.

Figure 4: The usage of method in articles



Our SLR also came across two studies that offered unique PE sets. PE set in Choi and Eboch (1998)'s Journal of Operations Management paper was formed via 3 PEs and this TQM study's results explicated paradoxical relations among TQM practices, plant performance, and customer satisfaction. On the other hand, a Journal of Supply Chain Management paper, Matthews et al. (2016) presented 4 PEs within a PE set by looking into paradoxical tensions among different levels of analysis: encompassing individuals, the organization, inter-organizational networks, and macroenvironmental levels.

DISCUSSION

Based on the results, we find that the trend of the occurrence of paradox sets is increasing. The increase of the use of PEs may be related to ever-increasing business complexity, globalized organization in the supply chain network. Especially as firms increasingly establish global and complex network structures, more tensions appear, and more PEs surface.

Addressing the first challenge raised by paradox theorists regarding what paradox is, we find that performing paradox is the dominant paradox category, where we have identified 7 themes. The seven themes in performing paradox are *specific, service, cost, forecast, sustainability, overall, and investment.* The *specific* theme is related to specific supply chain performance. The *service* theme is related to service elements in the supply chain, such as lead time variability and optimal safety inventory. The *cost* theme is related to the cost elements in the supply chain. These supply chain cost elements are summarized as the total cost of logistics and the amount of costs to ship. The *forecast* theme is related to forecast accuracy and error. The *sustainability* theme is related to sustainability issues in the supply chain, such as green supply chain management performance and sustainability. The *overall* theme is related to overall supply chain performance, such as plant performance. The *investment* theme is related to investment performance, such as IT investment. We thus provide new insights for the performing paradox. These 7 themes in the performing paradox reflect the characteristics of supply chain management, which focus on cost, performance, and efficiency. Some of the paradox sets under the performing category are closely related to supply chain outcomes, such as traffic flow performance, amount of goods shipped, and optimal safety inventory.

The five themes in organizing paradox are *collaboration, efficiency and control, exploration, competition, and others.* The *collaboration* and *competition* themes are similar to that in Smith and Lewis (2011), while the *efficiency and control*, *exploration*, and *others* themes are newly added. The *collaboration* theme consists of elements related to supply chain collaboration, such as supply chain coordination, supply chain integration, and global integration. These elements focus on the collaboration within the supply chain. The *efficiency and control* theme consist of elements such as TQM practices, standardization, and level of automation. The exploration theme investigates the exploratory activities in the supply chain. The elements consist of openness, supply chain transparency, and alternation to a road network to improve traffic flow, etc. The *competition* theme focuses on the competition element. The *others* theme consists of elements such as network distance to consumers and unsatisfied objectives.

We slightly modify the individual and collective tensions in belonging paradox (Smith and Lewis, 2011) and classify them into our newly created categories, the *single entity* and *multiple entities*. The themes reflect level of supply chain entities. The PE elements that are related to single level are grouped into single entity, while elements related to multiple levels are grouped into multiple entities.

The learning paradox has three themes, old, present, and new. The PE elements in the old theme are extant literature and historical experiences and know-how. The PE elements in the present theme are investor competence and level of analytics capabilities. The PE elements in the new theme are theory development, new ideas and knowledge, process innovation, and product innovation.

According to Smith (2000), the second challenge in the paradox literature stems from an ontological debate that differentiates paradoxical tensions either as an inherent feature of a system or as social constructions. Based on our findings, especially in the performing paradox, we find that the paradoxical elements can be classified into either as inherent features of the system or as social constructions. Take the widely used Braess's paradox as an example where the traffic performance decreases when an additional route is added to the network. When we talk about the traffic performance it can be classified as a social construction, and the additional route can be classified under the feature of the system. Our findings show that the paradoxical elements in supply chain management reflect this debate. Even though our findings do not help solve the debate, they provide a foundation to introduce the PT to the supply chain domain.

We also find that four methods, which are analytical paper, survey, conceptual model, and cast study, dominate the overall range of method used in the articles. It is not surprising that the analytical model is the most used method in the SCM domain (Wacker,1998). Therefore, even though our focus is on paradox research, the analytical approach still dominates the overall usage of methods. As for the qualitative approach, case study and conceptual model dominate. Because the PT is in its development stage, case study and conceptual model contribute to the development of the theory. It is interesting to notice that the 4 articles that apply paradox theory use either case study or conceptual model. Sandberg (2017), Xiao et al (2018), and Brix-Asala (2018), and Miriam and Jörg (2018) use case study. Matthews et al (2016) apply the conceptual model. Niesten and Stefan (2019) apply the paradox framework in the literature review.

In two of articles that were identified as containing more than two PEs within a PE set, Choi and Eboch (1998) and Matthews et al. (2016) are able to discuss paradoxical tensions 'among' the PEs. This is an interesting finding which positions SCM PEs outside the definition of paradox. The dualities, dilemmas, and dialectics which Smith and Lewis (2011, 387) suggest help us distinguish among organizational tensions, however, SCM PEs seem to protrude beyond, and perhaps due to the pressure emanating from the mindset that reside within performance paradox category.

From the results, we noticed repeatedly the perceived paradox between sustainability and business performance/economic goals. SCM scholars seemed to have combined the environmental and social issues under one PE while designating a standalone PE for the economic aspect. There are similarities between this perception and the one that is prevalent among layman which is tied to the expression 'time is money'. Whereas time is not money and it is well understood, for instance, the conventional management practices force many practitioners to fold time onto cost so a trade-off can be set up between cost and scope. Following a similar logic, when sustainability components are being considered, even in scholarly works, social and environmental dimensions seem to be lumped together so a duality is formed along with the use of economic dimension. This action might ultimately be reducing the complexity of decision-making process and therefore managers can perhaps constrain the cognitive workload under two PEs and then pursue trade-offs and perform optimization tasks.

A plausible argument can be made regarding the trade-offs. The analytical tools may not allow SCM scholars to obtain desired results when more assumptions are relaxed such that a strict trade-off is not warranted in a problem. Paradox theorists demonstrate over and over again that even if desired results may not be possible, meaningful results can be obtained and put into action by dealing with elements that form the trade-offs in PE sets. So, is it the PT that needs to navigate and find inroads into SCM domain, or should the SCM scholars entertain exploring the not-so-frequently explored territories beyond trade-offs?

CONCLUSIONS

This study summarizes and classifies the PEs in SCM via the help of SLR methodology. With the time span of 20 years and 4 databases, we cover a comprehensive list of PEs in SCM domain. According to the paradox categories (Smith and Lewis, 2011), we group the paradoxical elements into these categories and classify the themes within each category. By providing the paradox categories and groupings, we provide an inventory of paradox elements and themes to scholars and practitioners to the inventory of the paradox categories and themes. With the hope of providing paradox categories groups to the literature, we also provide insights to help address the debate in paradox research. The need for a SLR of PEs in SCM exists due to several reasons. First, there is a lack of a comprehensive list for PEs in the SCM domain. Based on PT, we identify and summarize the PEs in SCM in a list so an initial assessment of the state of PE usage can be offered for use by scholars and practitioners. The list also offers a path to further extend PT into SCM while informing back the PT for its refinement. In other words, we hope to contribute to both, centripetal forces that “buffer the existing boundaries” and the centrifugal forces that “foster boundary spanning” in PT’s development (Schad et al., 2019).

Second, recognizing PEs is the first step to handle these elements. Handling PEs simultaneously and successfully through the creation of “cyclical responses… enable sustainability – peak performance in the present that enables success in the future” (Smith and Lewis, 2011).

Paradox theory explores how organizations can attend to competing demands simultaneously (Smith and Lewis, 2011). Organizations who can handle the competing demands simultaneously can be more efficient and more successful. However, many researchers and practitioners claim that they find something contradicting but they did not notice that the findings can be analyzed under the paradoxical lens. With the use of PT, we can identify these elements and guide the practitioners to recognize and handle these elements simultaneously and effectively. This study applies PT to summarize and classify PEs in the SCM domain. The study intends to provide a list of paradoxical elements to SCM researchers and practitioners. The findings can help practitioners recognize and thus handle the PEs simultaneously.

The purpose of our research study was to search, collect, and then present the PEs in SCM literature. However, our SLR study is not without its limitations. First, we believe that the articles that were eliminated in Step 4 of our SLR that are ‘talking about paradoxes and supply chains’ will need to be included for gaining any possible supplementary insights in lieu of assuming them on the fringes. It will be interesting to compare and contrast the similarities and difference between PEs inside and outside SCM field. Second, even though mostly captured under the core elements of ‘exploitation and exploration’, including ambidextrous relationships that are examined in SCM research could further enrich our study. Third, the tradeoffs in SCM could be searched, collected, and then presented along with our findings in another study to draw a broader picture of the above arguments. Finally, we also introduce the paradox debate in the SCM domain, but our work is a first step toward bringing the debate to the SCM domain. We need more paradox studies in SCM.

The future study of paradox in the SCM filed is promising. Our results show that performing paradox and performing-organizing paradox has the most dominant paradox themes. Future studies can focus to investigate these two paradox categories where further insights can be obtained from these paradox categories. Our study also provides different themes of paradoxes within different categories which can be investigated for fitness in their contexts. This study also provides evidence for the ontological debate of paradox. We hope to spur interest and encouragement for the researchers to work on providing further evidence to inform the debate.

Email: ymatsui@ynu.ac.jp

ABSTRACT

Buyer-supplier collaboration is an important approach for successful supply chain management. Although it has been studied for a long time and some anecdotal evidences were introduced, study on typical causal patterns of supply chain orientation (SCO) between buyers and suppliers is not enough. Sandberg (2007) wrote “more research, especially empirical, is needed in order to verify existing literature.” We, based on the relational view, propose four hypotheses that explain buyer-supplier collaboration performance with a set of SCO aspects. We conducted an empirical study with data collected from manufacturing companies using SEM. Our study tries to narrow the gap and show a pattern of causal relationship.

KEYWORDS: SCM, Buyer-supplier collaboration, Information sharing, Relational view, and SEM

INTRODUCTION

Nowadays, any organizations do not operate alone. They are networked to many other partners and a member of one or more supply chains (Lofti et al., 2013). Christopher & Peck (2004) define “supply chain as the network of organizations that are involved, through upstream and downstream linkages, in the different processes and activities that produce value in the form of products and services in the hands of the ultimate consumer.” Buyer-supplier collaboration, which is also called as supplier relationship management (SRM) (Dubey et al., 2019), is claimed as an important approach for successful supply chain management (SCM). Rubber & Plastics News *(*2019) wrote “there's one general truth about the relationships between auto makers and their suppliers that doesn't change: The better the two sides work together, the more likely both sides will be successful.” Although it has been said for a long time and some anecdotal evidences were introduced, study on popular or typical causal patterns of supply chain orientation (SCO) between buyers and suppliers that are endorsed empirically is not still enough. Sandberg (2007) wrote “more research, especially empirical, is needed in order to verify existing literature.” Buyer-supplier collaboration “is an increasingly important unit of analysis and, therefore, deserves more study” (Dyer & Singh, 1998). Our study tries to narrow the gap with an empirical study and show a pattern of antecedent factors for successful buyer-supplier collaboration.

LITERATURE REVIEW

Collaboration

Collaboration is "a process where two or more companies formally undertake to share responsibility for sharing information, planning, and managing process execution to enable the formation of synergies between all supply chain members, thereby achieving greater mutual benefit than the firms would achieve individually" (Botes & Kotzé, 2017). Collaboration theory recommended cooperative transaction or inter-firm relation as a critical factor for corporate success (Frydlinger et al., 2013). According to the collaboration theory, successful collaboration should be based on embedded ties (Frydlinger et al., 2013). The embedded ties are "characterized by trust, fine-tuned information transfer, and joint problem-solving arrangements" (Uzzi, 1996). The collaboration theory claims that successful collaboration is a source of economic performance of organizations (Shekarian, 2018).

Relational View

The relational view is a stem of collaboration theory and claimed that idiosyncratic inter-firm linkage "is an important source of competitive advantage" (Dyer & Singh, 1998; Soosay & Hyland, 2015). The relationship is an economic rent. It reduces a variety of transaction costs through reduction of uncertainty, bounded rationality, and opportunistic behavior, and increases mutual learning and pooling of resources (Dyer & Singh, 1998；Frydlinger et al., 2013). Therefore, buyer and supplier need "relationship-specific investments" (Wagner & Krause, 2009) to realize these benefits.

The relationship is often based on self-enforcing mechanisms. It is "more effective than third-party enforcement mechanisms at minimizing transaction costs and maximizing value-creation initiatives both. Transaction costs are lower under self-enforcing agreements for four primary reasons" (Dyer & Singh, 1998).

Sandberg (2007) conducted a survey study of SCM logistics in Sweden, and found that supply chain orientation (SCO) between buyers and suppliers reduces cost and improves services not only of buyers and suppliers but also of buyers' customers. It concluded:

- There is a strong relationship among the process orientation, the degree of joint operational planning, and intensity of information sharing.
- The intensity of these aspects are positively related to the experienced effects of the collaboration.

However, Sandberg (2007) could not "make a strictly causal order of the aspects."

Transaction Cost Reduction

Dyer and Singh (1998) wrote "growing body of literature on transaction value is emphasizing the influence of governance on the value-creation initiatives of alliance partners. Effective governance can generate relational rents by either (1) lowering transaction costs or (2) providing incentives for value-creation initiatives, such as investing in relation-specific assets, sharing knowledge, or combining complementary strategic resources."

Transaction cost theory predicts that trust-based inter-firm linkage reduces transaction cost and expedites manufacturing process (Williamson, 1994).

HYPOTHESES DEVELOPMENT

In modern economy, companies play a role as a member in a supply chain network. Therefore, buyer-supplier relationship, and especially, buyer-supplier collaboration are important based on the collaboration theory and relational view. Supply chain collaboration (SCC) is critical to manage risk and realize supply chain resilience (SCR). Botes & Kotzé (2017) wrote “SCC aims to leverage the capabilities and knowledge of key suppliers under market uncertainty”, and to “improve operational flexibility by facilitating cooperation between (the) various supply chain members.” Rubber & Plastics News *(*2019) introduced that “the Toyota group vice president of purchasing cites the ‘three Cs’ as key. That's as in communication, collaboration and consistency.”

Resilience is defined as “the ability of a system to return to its original state or move to a new, more desirable state after being disturbed” (Christopher and Peck, 2004). Christopher and Peck (2004) distinguish it from robustness. Collaborative buyer-supplier relationship or creative working is a critical construct of SCR. SCR increases “supply chain’s ability to react to and absorb supply disruptions and return to the operational status quo” (Botes & Kotzé, 2017). The management philosophy is supply chain orientation (SCO), which includes soft factors such as trust, organizational compatibility, commitment, vision, and information sharing (Mentzer et al., 2001). They are requested to improve buyer-supplier collaboration performance. Companies cannot optimize their “supply chain operations until the constraints of suppliers and demands of customers are understood” (Botes & Kotzé, 2017).

Botes et al. (2017) wrote that one of three fundamental elements of vertical SCC was information sharing. Information sharing is to distribute “useful information for systems, people, or organizational units,” which “serves as an essential approach for the survival of enterprises and enabler of supply chain integration” (Lofti et al., 2013). Information sharing includes ‘knowledge sharing’ and ‘information integration’. Shared knowledge includes both explicit and implicit knowledge. Lofti et al. (2013) listed 14 benefits of supply chain information sharing based on the literature review. Supply chain information sharing by suppliers such as forecast (Sandberg, 2007) is critical to improve buyer-supplier collaboration performance.

Of course, supply chain information sharing by buyers is also critical. However, because this study views the problem not from supplier’s but from buyer’s point of view, supply chain information sharing by buyers is not considered. Cooperation and coordination of activities between buyers and suppliers include information sharing, joint planning, joint demand management, joint inventory management, and sharing of goals and objectives. They are critical for the creation of supply chain-wide velocity, visibility, and flexibility (Christopher & Peck, 2004; Botes et al., 2017).

Among some factors that affect buyer-supplier collaboration performance, we pick up information sharing, agreement on vision and goal, and SCM planning because they are popular activities as buyer-supplier collaboration. Sandberg (2007) wrote “typical collaborative logistics activities are joint planning and information sharing.” Christopher & Peck (2004) suggested collaborative planning and supply chain intelligence were two important sources for supply chain collaboration. Both buyer and supplier invest in relation-specific resources that include information sharing to realize the relational rent (Wagner & Krause, 2009). Therefore,

H1: Supply chain information sharing by suppliers affects buyer-supplier collaboration performance.

In reality, there are cooperative processes between information sharing and performance evaluation (Sandberg, 2007). However, as this study employs cross-sectional data analysis, the process view is neglected in our study (Figure 1). Agreement on supply chain vision and goals should be a base of supply chain information sharing by suppliers. Wagner & Krause (2009) wrote "When making investments in the buyer-supplier relationship, the buying firm should determine what goals it has for the relationship." Therefore,

H2: Agreement on supply chain vision and goals affects supply chain information sharing by suppliers.

Supply base reduction (SBR) is an important supplier management approach. De Toni and Nassimbeni (1999) found that SBR policies were positively related to the exclusive buyer-supplier relational exchange practice. Wagner & Krause (2009) suggests "the relationship between the goal to improve a supplier's capabilities and knowledge transfer from the buyer to the supplier firm is moderated by the degree of human interaction." However, supply base reduction is necessary in advance to manage human interaction and agree on supply chain vision and goals. SBR is a prerequisite to conduct "training and co-location of buyer and supplier employees to leverage the knowledge transfer to the supplier firm" (Wagner & Krause, 2009). Therefore,

H3: Supply base reduction affects agreement on supply chain vision and goals with suppliers.

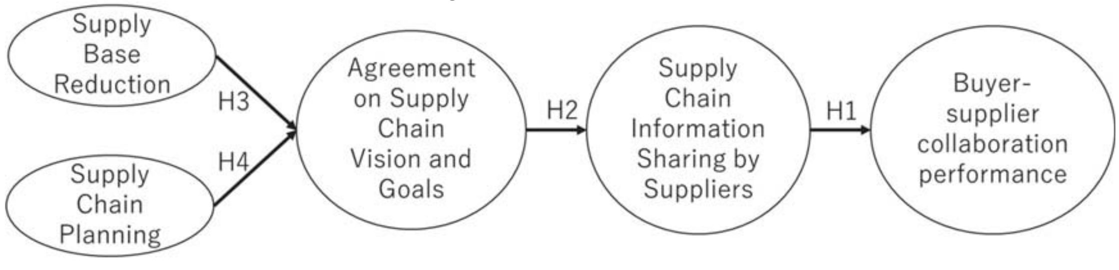
Visibility, velocity, and flexibility are typical SCR antecedents (Botes et al., 2017). Among them, upstream visibility requires collaborative planning (Christopher & Peck, 2004). Botes et al., (2017) wrote that collaborative supply chain planning "aims to balance supply and demand within a supply chain network through demand-driven processes." This balance is enabled through demand and supply information sharing, coordinated sales forecasts, efficient inventory management, effective materials management for production, and better performance management.

Supply chain planning is necessary as a base or antecedent for agreement on supply chain vision and goals with suppliers because it can improve visibility. Also, supply chain planning improves agreement on supply chain vision and goal by reducing uncertainty. Therefore,

H4: Supply chain planning affects agreement on supply chain vision and goals with suppliers.

Summing up, Figure 1 illustrates our research model.

Figure 1: Research model



RESEARCH DATA AND METHOD

Data

We employ the fourth round dataset of High Performance Manufacturing (HPM) project (Phan, 2014) because it is the latest version available. The fourth round of HPM project started in 2012-2013 and the data were collected in 2014-2015. Table 1 shows the distribution of sample size by country. The total sample size amounts to 306.

Table 1: Sample size by country

Country and Region	Count	%
Brazil	24	7.8
China	30	9.8
Spain	25	8.2
Finland	17	5.6
Germany	28	9.2
Israel	26	8.5
Italy	29	9.5
Japan	22	7.2
Korea	26	8.5
Sweden	9	2.9
Taiwan	30	9.8
United Kingdom	13	4.2
Vietnam	25	8.2
Missing	2	0.7
Total	306	100.0

Table 2 shows the sample size by industry. The data were collected from factories in electric & electronics, machinery, and transportation equipment. Transportation equipment factory includes automobile assemblers and their parts manufacturers.

Table 2: Data distribution by industry

Industry	Count	%
Electronics	114	37.3
Machinery	110	35.9
Transportation	80	26.1
Missing	2	0.7
Total	306	100.0

We picked up some relevant constructs in the dataset, set the research model in Figure 1 and hypotheses based on the above discussion, and tested it empirically.

Method

We employed Structural Equation Modeling (SEM, AMOS v.25) to study our research model in Figure 1. Each construct consisted of some question items. Table 3 shows these constructs and their questions items.

Table 3: Constructs and Question Items

Constructs and variables	Questions
RED	Supply base reduction
RED1	We rely on a small number of high quality suppliers. (Is this an item from an HPM scale?)
RED2	We maintain a close relationship with a limited pool of suppliers.
RED3	We try to keep our supply base small.
PLAN	Supply chain planning
PLAN1	We actively plan supply chain activities.
PLAN2	We consider our customers' forecasts in our supply chain planning.
PLAN3	We strive to manage each of our supply chains as a whole.
PLAN4	We monitor the performance of members of our supply chains, in order to adjust supply chain plans.
PLAN5	We gather indicators of supply chain performance.
VIS	Agreement on supply chain vision & goals
VIS1	Our supply chain members understand our goals for supply chain management.
VIS2	Our supply chain members understand that we expect them to continuously improve their supply chain practices and operations.
VIS3	Our supply chain members have clearly defined goals within our supply chain.
VIS4	We all know which supply chain members are responsible for particular goals with our supply chains.
BYS	Supply chain information sharing by suppliers: Our plant has access to the following information about our key suppliers
BYS1	Delivery information
BYS2	Demand change information
BYS3	Demand forecast information
BYS4	Inventory information
EVAL	Buyer-supplier collaboration performance: We are satisfied with the performance of our key suppliers on the following criteria:
EVAL1	On-time delivery
EVAL2	Product liability
EVAL3	Service level
EVAL4	Willingness to adapt processes to meet your changing needs

First, before employing SEM, we did explorative factor analysis (EFA, SPSS version 24) with a promax rotation based on principal axis factor analysis. Table 4 shows the result. We confirmed five constructs as expected. We believe it is a satisfactory result that allows us to use the data.

Table 4: EFA Pattern Matrix

RED1	0.028	-0.046	-0.020	-0.071	0.750
RED2	-0.003	-0.031	-0.016	-0.012	0.639
RED3	0.016	0.088	0.048	0.044	0.586
PLAN1	-0.004	0.808	-0.002	-0.065	-0.076
PLAN2	0.138	0.679	-0.021	-0.154	-0.005
PLAN3	-0.016	0.842	0.100	-0.062	-0.027
PLAN4	-0.034	0.753	-0.035	0.177	0.036
PLAN5	-0.072	0.678	-0.071	0.118	0.071
VIS1	0.020	-0.020	0.838	0.039	0.033
VIS2	-0.117	0.000	0.653	0.049	0.217
VIS3	0.086	0.043	0.741	0.034	-0.100
VIS4	0.018	-0.030	0.812	-0.074	-0.051
BYS1	0.657	-0.022	0.103	0.137	-0.135
BYS2	0.965	0.022	-0.009	-0.020	0.016
BYS3	0.976	0.006	0.009	-0.073	0.000
BYS4	0.711	0.007	-0.073	0.085	0.143
EVAL1	0.100	-0.086	0.007	0.700	0.029
EVAL2	-0.023	-0.001	-0.049	0.880	-0.124
EVAL3	0.029	0.014	0.070	0.673	0.018
EVAL4	0.036	0.047	0.016	0.510	0.116

Second, we conducted a confirmatory factor analysis (CFA) to confirm unidimensionality of each construct. “Unidimensionality is the existence of one latent trait or construct underlying a set of measures” (Anderson, et. al, 1988). “Assessing unidimensionality means determining whether indicators reflect one, as opposed to more than one construct” (Li et al., 2009). Table 3 shows the item factor loadings with average variance extracted (AVE), square root of AVE, composite reliability (CR), and Cronbach’s alpha. All item factor loadings are larger than 0.5 ($p<0.01$), above the suggested minimum of 0.30 (Schoenherr & Swink, 2012). AVE is used to indicate convergent validity. AVE should be greater than 0.50 (Dinger et al., 2015). All AVE are upper than the cut-off rate. All composite Reliability (CRs) exceed 0.7 (Gefen, Straub, & Boudreau, 2000). Cronbach’s alpha suggests reliability in terms of internal consistency. Its value for REDUC is less than 0.7. If it were 0.7 or higher, it could be considered acceptable, but with 0.6 being acceptable for new scales (Shin, 2000). Bhatnagar et al. (2016) wrote that Cronbach’s alpha between 0.6 and 0.7 was acceptable.

We checked common method bias (CMB) with Harman’s single-factor method (Dubey et al., 2019). We fixed the number of factors equal to one, and computed the un-rotated factor solution. Then, a single factor was obtained which explained 31.198 percent of the variance. It is less than 50 percent. Therefore, we can find that CMB is not a problem for this study and continue our analysis.

Table 5: CFA, Convergence Validity, and Reliability

Variable	Loading	AVE	CR	Sqrt (AVE)	Cronbach’s Alpha
RED1	0.654	0.528	0.770	0.726	0.672
RED2	0.588				
RED3	0.667				
PLAN1	0.687	0.567	0.930	0.753	0.852

PLAN2	0.614				
PLAN3	0.863				
PLAN4	0.820				
PLAN5	0.688				
VIS1	0.887	0.761	0.959	0.872	0.853
VIS2	0.708				
VIS3	0.773				
VIS4	0.724				
BYS1	0.740	0.838	0.975	0.916	0.906
BYS2	0.972				
BYS3	0.941				
BYS4	0.720				
EVAL1	0.748	0.672	0.940	0.820	0.814
EVAL2	0.723				
EVAL3	0.767				
EVAL4	0.652				

Table 6 shows the standardized correlations among constructs.

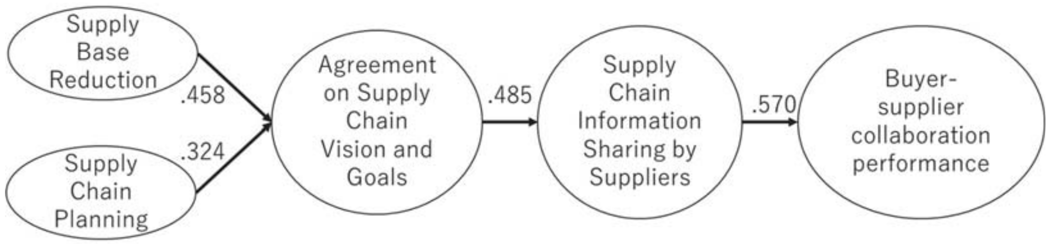
Table 6: Standardized Correlations Among Constructs			
PLAN	<-->	VIS	0.387
BYS	<-->	RED	0.212
PLAN	<-->	BYS	0.179
PLAN	<-->	EVAL	0.311
PLAN	<-->	REDUCN	0.137
EVAL	<-->	REDUCN	0.464
VIS	<-->	EVALSX	0.685
VIS	<-->	REDUCN	0.507
BYS	<-->	EVALSX	0.557
VIS	<-->	BYS	0.475

The minimum value of square-roots of AVE in Table 5 (0.726) is greater than the maximum of inter-construct correlations (0.685), which confirms discriminant validity (Fornell & Larcker, 1981). This suggests that the constructs of our model possess the discriminant validity.

RESEARCH RESULT

We apply SEM to the model in Figure 1 now. Figure 2 shows the result. All standardized coefficients are significant strongly ($p<0.000$). Model-fit is not perfect but satisfactory as below. CMIN/DF=2.424, NFI=.870, IFI=.919, CFI=.918, FMIN=1.311, RMSEA=.068.

Figure 2: SEM result



DISCUSSION AND CONCLUSIONS
\
Discussion

We proposed a research model of buyer-supplier collaboration and derived four hypotheses, which were tested for the dataset of 306 manufacturing companies. The performance (satisfaction level) of buyer-supplier collaboration from buyers' point of view was affected by supply chain information sharing by suppliers, which was in turn affected by agreement on supply chain vision and goals between suppliers and buyers. Buyers set purchasing policy to supply base reduction and supply chain planning in advance of the agreement on supply chain vision and goals with suppliers. Supply base reduction is necessary to establish intimate relationship with suppliers and agree on vision and goals. Then, on the base of agreement, suppliers share their information with buyers, which finally improves supply chain performance assessment by buyers.

Above network of cause-effect relationship is within natural inference and not new. However, our empirical study result is unique. Firstly, because there are many possible path from policy-setting to performance, there is no past research that is same as our research model as far as we know. Secondly, although there are some past studies that suggest above relationship, they are fragmented and suggesting a part of our model, and there is no research that tested our long cause-effect network empirically.

Our results are congruent with Sandberg (2007), who wrote

- There is a strong relationship between the process orientations, the degree of joint operational planning, and intensity of information sharing.
- The intensity of these aspects is positively related to the experienced effects of the collaboration.

Our research result suggests that the conclusion by Sandberg (2007) is applicable to industry not only in Swedish but also in other advanced countries in our dataset.

Although Sandberg (2007) was descriptive and not an article of hypotheses-testing type, it tried to find causal effects of related factors with correlation and ANOVA analysis. Correlation analysis is not suitable or enough to find a cause-effect relationship. Our study result not only endorses the relationship among above aspects but also suggests a causal sequence among those five constructs with SEM that Sandberg (2007) could not.

Limitations and Future Research

There are some research limitations in our study. First, although sample size in our dataset is enough for SEM analysis (Wang & Wang, 2012), our study rely solely on the fourth round HPM dataset. We need to repeat this study with different and hopefully more data to check the ubiquity. Second, we included some SCO factors such as vision, goals, and information sharing, but there are more factors that must affect performance evaluation by buyers such as trust, organizational compatibility, and top management support (Dubey et al., 2019). Although we have these data in our dataset, we did not include them for model simplicity. Future studies need to include these factors. Third, we studied only buyer-supplier relationship from buyers' point of view, and did not include seller-customer relationship. The relationship of these two factors that Sandberg (2007) suggested may need to be included in future study. Fourth, Wagner & Krause (2009) wrote "various goals for supplier development efforts might affect the relationship between the buying firm and the supplier firm" differently, but we neglected these differences for simplicity. These are left for future research.

ABSTRACT

Business owners operate their enterprises for profit and someday may harvest their accumulated capital. While many will transition their ownership through gifts and bequests, others will sell to unrelated, or potentially related, parties. This study attempts to explore the salient significant tax considerations to buyers and sellers in such transactions.

KEYWORDS: Sale of Business, Tax Reform, Tax Cuts and Jobs Act of 2017

INTRODUCTION

It is estimated that 9,919 sales of businesses closed in 2017, compared to 7,842 in 2016 (Small Biz). These numbers are from a survey of about 5,000 business brokers; however, considering that many sales occur without brokers, the actual number of business sales is likely much larger. Bob House, President of BizBuySell.com, reported that the small business market has been on the rise for years. Reflecting on 2017, House opined "(l)ast year, however, seems to represent a new tier of activity that brings a lot of momentum into 2018 . . . . It will be interesting to see how the recently passed GOP tax reform affects activity." This article examines the tax factors related to a sale of a business including the portions of the *Tax Cuts and Jobs Act of 2017* (TCJA 2017) that affect sales of business assets.

AN EXAMPLE FOR CONTEXT

Judith Pierce and her son, Paul Pierce, started a business that rents out heavy duty pick-ups to tradesmen who travel to Southern California. The business was an early entry into this growing market. In 2016, Big Trucks, LLC, purchased 24 Sierra 2500HD crew cabs from McClellan Buick-Pontiac-GMC for $800,000 to be used as rentals. The business operates through referrals from existing rental agencies at the airport and elsewhere. When a rental company has a renter for one of the units, it is rented by Big Trucks to the agency, which, in turn, rents it to the customers. This is a strong business model since it is unnecessary overhead for each rental agency to keep its own stock of large pickup trucks.

The Pierces have decided to go a different direction with a new business plan and have offered all the assets of Big Trucks for sale to a national equipment leasing company, LeBron Leasing Specialists, Inc. in 2019. The company balance sheet currently reflects assets having tax bases and estimated market values in Exhibit 1.

The tentative cash price for the assets is $850,000. Notice the value of the business exceeds the sum of the values of the identified assets by $165,000. This represents goodwill and other intangibles not identified in the balance sheet. The sellers are also paid $100,000 under a separate enforceable non-compete covenant.

Exhibit 1

Asset	Basis	Estimated Market Value
Equipment (Cost = $800,000)	$0	$475,000
Lease (the ground lease is transferable and the lease payments are below current market)	0	25,000
Leasehold improvements (building on the leased land, Cost = $90,000)	85,585	100,000
Solar panels (Cost $40,000, purchased 35 months before the sale)	0	35,000
Contracts	0	50,000
Total	$85,585	$685,000

STRUCTURE OF A SMALL BUSINESS SALE

Small business sales may be structured as a sale of the assets (including goodwill or going concern value), or as a sale of the stock or ownership interest. According a leading small business sale transaction database (DealStats), over 80% of small business sales are structured as a sale of assets. There are many pros and cons to each structure, but, from the buyer's standpoint, an asset sale is clearly advantageous. Not only does the buyer avoid liability exposure from the seller's operations, but the buyer gets to increase the tax bases of the acquired assets resulting in increased depreciation and amortization benefits.

ASSET VALUATION

In an asset sale, the identifiable assets of the business must be appraised to determine fair market value. U.S. Treasury Regulation §25.2512-1 provides the definition of fair market value for tax purposes: "The value of the property is the price at which such property would change hands between a willing buyer and a willing seller, neither being under any compulsion to buy or to sell, and both having reasonable knowledge of relevant facts." A discussion of items to be appraised and reasons for appraisals is available at firstbusiness.com. Internal Revenue Code § 1060 (IRC) provides guidance regarding allocation of purchase price to the acquired assets:

> **(a) General rule.** In the case of any applicable asset acquisition, for purposes of determining both—
> (1) the transferee's basis in such assets, and
> (2) the gain or loss of the transferor with respect to such acquisition, the consideration received for such assets shall be allocated among such assets acquired in such acquisition in the same manner as amounts are allocated to assets under section 338(b)(5). If in connection with an applicable asset acquisition, the transferee and transferor agree in writing as to the allocation of any consideration, or as to the fair market value of any of the assets, such agreement shall be binding

> on both the transferee and transferor unless the Secretary determines that such allocation (or fair market value) is not appropriate.

In most instances, the buyer and seller of a business must file Form 8594 (https://www.irs.gov/pub/irs-pdf/f8594.pdf), which includes details as to the values of various assets. The instructions to the form indicate that, in general, ". . . both the purchaser and seller must file Form 8594 and attach it to their income tax returns . . . when there is a transfer of a group of assets that make up a trade or business . . . and the purchaser's basis in such assets is determined wholly by the amount paid for the assets. This applies whether the group of assets constitutes a trade or business in the hands of the seller, the purchaser, or both" (https://www.irs.gov/pub/irs-pdf/i8594.pdf).

Valuations are based on market value, and the value assigned to an asset cannot exceed its fair market value. If a return is examined, the ". . . Internal Revenue Service may challenge the taxpayer's determination of the fair market value of any asset by any appropriate method and take into account all factors, including any lack of adverse tax interests between the parties" (https://www.law.cornell.edu/cfr/text/26/1.338-6).

The significance of the last part of this statement, and the reason why the IRS generally accepts the agreed to values, is that in almost every instance what is favorable for the buyer is unfavorable for the seller. For example, if more value is assigned to inventory and supplies, the seller has more ordinary income and the buyer enjoys a more immediate ordinary deduction.

BUSINESS VALUATION

Valuation of a business can be arrived at using any number of methods including industry related multipliers based on gross receipts, net cash flow analyses based on some definition of net income, and asset appraisals if there are no significant unidentified intangibles (First Business). One example of a multiplier deals with sales of CPA firms where the market value of the firm is typically around 1 to 1.35 times annual revenue (West). Since customer loyalty and sustaining goodwill are always an uncertainty, payouts may be based on sustained billing, i.e., a percentage based on actual future billings, or some uncertain future indicator (Sinkin).

Business brokers are available for owners who are not prepared to appraise the assets, the business as a whole, or who are not prepared to execute the transaction (Accounting Broker).

TAX CONSIDERATIONS: NEW AND OLD

The following paragraphs address the tax factors, particularly those affected by the Tax Cuts and Jobs Act of 2017 (TCJA 2017), involved in the sale and purchase. The treatment of various assets common to many business sales, including the sale of hypothetical Big Trucks, LLC, are addressed.

Tax Rates

The Tax Cuts and Jobs Act of 2017 (TCJA 2017) significantly altered tax rates and calculations. These individual rates, and most other non-corporate changes, are scheduled to be temporary for calendar years 2018–2025. The corporate tax rates are scheduled to be permanent.

Corporate Tax Rates

The corporate rate was reduced for years beginning in 2018 and beyond from a progressive structure, with rates from 15 to 35 percent, with even higher marginal rates over some ranges, to a flat 21 percent (IRC, § 11).

Individual and Estates and Trusts Rates

The rates for other entities, i.e., individuals, estates and trusts, were cut from a high of 39.6 to 37 percent. The brackets were altered somewhat, and the rates were lowered within most of the brackets (IRC § 1). Exhibit 2 summarizes the changes over approximate ranges:

Exhibit 2
Ordinary Tax Rates Before and After Tax Reform

Single Taxpayers	Before	After
Approximately $-0- to $9,525	10%	10%
Approximately $9,525 to $38,700	15%	12%
Approximately $38,700 - $82,500	25%	22%
Approximately $82,500 - $157,500 (beginning at $92,000 in 2017)	28%	24%
Approximately $157,500 - $200,000 (beginning at $192,000 in 2017)	33%	32%
Approximately $200,000 - $500,000 (beginning at $416,000 in 2017)	35%	35%
Over $500,000 (beginning at $418,000 in 2017)	39.6%	37%

Married Taxpayers	Before	After
Approximately $-0- to $19,050	10%	10%
Approximately $19,050 to $77,400	15%	12%
Approximately $77,400 - $165,000	25%	22%
Approximately $165,000 - $315,000 (beginning at $153,000 in 2017)	28%	24%
Approximately $315,000 - $400,000 (beginning at $233,000 in 2017)	33%	32%
Approximately $400,000 - $600,000 (beginning at $417,000 in 2017)	35%	35%
Over $600,000 (beginning at $471,000 in 2017)	39.6%	37%

The “ordinary” rates are presented here since not all sales of businesses result solely in capital gains and not all ordinary income gains are taxed at the highest rates. The brackets reflected are not precise but reflect the general positions. The shifts in the tax rates from 2017 to 2018 tend to represent an increased benefit to sellers of businesses where some of the gain is taxed at ordinary income rates.

Other structural changes for individual taxpayers that affected tax burdens were numerous. Large shifts in burden were caused by the repeal of the personal and dependency exemption deductions (still in existence but were set at $-0-), the doubling of the child tax credit, the approximately doubling of the standard deduction, and the cap on the itemized deduction for personal state and local taxes at $10,000. These structural items, other than the rate changes, affect tax burden, but they do not significantly affect the analyses in this study, so they will not be discussed further.

Capital Gains Rates for Individuals, Estates and Trusts

Capital gains rates remained essentially the same, with rates of 0 percent for lower income taxpayers, 20 percent for very high-income taxpayers, and 15 percent for most others. There are two additional capital gains rates. The maximum rate on dispositions of collectibles and § 1202 stock (IRC), which are not applicable in this study, remains at 28 percent. The maximum rate on “unrecaptured §1250 gain” (IRC), which could apply to sales of businesses that own real estate, is 25 percent. “Unrecaptured § 1250 gain,” is gain on the disposition of depreciable real property to the extent of depreciation allowed or allowable. Gain in excess of the 25 percent gain is subject to the 0 percent for lower income taxpayers, 20 percent for very high-income taxpayers, and 15 percent for most others.

Qualified Business Income Deduction

Congress created a large disparity between the tax rates for corporations and other taxpayers, creating a disadvantage for pass-through entities operating businesses, i.e. sole proprietorships, partnerships, and electing S corporations. Rather than causing a near mandatory shift for pass-through entities to switch to corporate status, Congress implemented what is called the qualified business income (QBI) deduction under new Code § 199A (IRC). This is an artificial deduction, not requiring any outlay of resources.

A detailed explanation of the QBI deduction is beyond the scope of this study, but since it could impact decision making, QBI is summarized here. This deduction cannot exceed 20 percent of QBI, or if smaller, 20 percent of taxable income before the QBI deduction. For taxpayers below established thresholds, i.e. taxable income before the QBI deduction of $321,400 for married filing jointly and $160,725 for others (2019 amounts), the deduction is simply 20 percent of QBI, or if smaller, 20 percent of taxable income before the QBI deduction.

Taxpayers whose taxable incomes exceed these thresholds are subject to a QBI deduction cutback over the next $100,000 for married and $50,000 for others. For example, married taxpayers with taxable income of $421,400 or more would get no QBI deduction because their deduction is fully cut back.

This cutback can obviously eliminate the benefit of the QBI deduction. Higher income taxpayers, other than taxpayers in service businesses, will enjoy a QBI deduction to the extent of a floor equal to 50 percent of W-2 wages or 25 percent of W-2 wages plus 2.5 percent of investments in depreciable assets, whichever is larger. If the married couple in the example above paid W-2 wages of $120,000, their QBI deduction would be $60,000, not to exceed 20 percent of QBI or 20 percent of taxable income before the QBI deduction.

QBI is generally just what it sounds like. It excludes investment type income, including capital gains and losses, and salaries and wages. For purposes of this study, a question arises as to what gains and losses upon the sale of a business for the seller and what deductions for the buyer, affect QBI. For example, gain on the sale of inventory and supplies should be QBI for the seller and reduce QBI for the buyer, assuming the buyer is not a regular corporation since corporations do not benefit from the QBI deduction. Capital gains are not QBI for the seller, but depreciation and amortization deductions for the buyer reduce QBI, again, assuming the buyer is not a regular corporation. These, and other determinations may change over time, as this deduction is new, and uncertainties still exist.

Inventory and Supplies

Any gain or loss from the sale of inventory and supplies is ordinary income or loss. A new twist was created by the Tax Cuts and Jobs Act of 2017(TCJA 2017), in that § 448 of the Internal Revenue Code (IRC, also see Revenue Procedure 2018-40) was amended to allow small businesses with gross receipts of $25 million or less to use the cash method of accounting and discontinue accounting for inventory as well as for the burdensome uniform capitalization procedure (IRC § 263A). Eligible businesses choosing to no longer account for inventory can simply treat purchases of goods similar to the treatment of supplies.

This really doesn't change the treatment of the sale of a business, but the gain attributable to the inventory to the seller will be greater since the basis will be zero. The buyer may be able to immediately expense the inventory if the buyer is eligible.

Equipment

Any gain attributable to equipment in a business sale will likely involve depreciation recapture under § 1245 (IRC). This recapture, of course, is ordinary income. On the buyer side, the taxpayer will be able to expense the entire cost since TCJA (TCJA 2017) allows 100 percent bonus depreciation for purchased property, including used property (IRC, § 168(k)). Prior to TCJA, used property was not subject to bonus depreciation.

Solar Panels

If the solar panels are sold along with the other assets of the business, part or all of the cost recovery deductions and the investment tax credit (ITC) will need to be recaptured. Specifically, the seller would have $35,000 of depreciation recapture, based on the $35,000 fair market value, and be required to pay back 60 percent of the ITC as recapture, resulting in a cash outflow of $7,200. ITC must be recaptured at a rate of 20% per year for each part or full year short of five years (i.e., three years in this case). The recapture of $7,200 is $40,000 x 30 percent credit x 60 percent.

The purchaser would not be entitled to a solar tax credit since the credit is only available to the original owner of the panels, so the panels could simply be expensed under bonus depreciation with no energy credit.

It is clear the panels could be removed from the structure and installed somewhere else. As a result, the seller should be able to sell the building and retain title to the panels. The seller could then retain title and sell energy to the buyer. After the credit is fully earned at the end of five years, a decision could be made as to whether to sell the panels, or not.

Real Estate Including Improvements on Ground Leases

Tax reform did not significantly affect the tax treatment for sale of real property.

Sale of Real Property

Depreciable property and land used in a trade or business that is held for more than one year is § 1231 property. Depreciable § 1231 property that is real property is not technically subject to depreciation recapture. But, as described previously, net gain is 25 percent capital gain to the extent of "unrecaptured § 1250 gain." Any remaining gain on improvements and land is 15 percent gain, or 0 percent for very low income taxpayers and 20 percent for very high income taxpayers.

Acquisition of Real Property

For a buyer, real property is classified as residential rental property or nonresidential real estate as before and depreciated using straight line and lives of 27.5 and 39 years, respectively (IRC, § 168). Real estate improvements constructed on rented land are depreciated the same as those on land that is owned by the taxpayer.

Leases and Contracts

If value is assigned to leases or similar contracts in which the owner has no basis, capital gain should be allowed. For example, if the seller entered into a favorable lease and the rent was lower than the prevailing market, the lease has value. The leases and contracts can be amortized over the life of the assets, however, they are not §197 assets (IRC).

Other Intangible Assets

Most other intangible assets will be §197 assets (IRC). Internally generated assets like goodwill generally qualify for capital gain treatment to the seller. Those that were purchased and amortized are §1231 assets (IRC) and any amortization deductions are subject to recapture under §1245 (IRC).

Section 197 property (IRC) can be amortized over a period of 15 years.

Covenants Not-to-Compete

A separate agreement not to compete adds another element to a business sale. The overall price is certainly affected by the potential future competition from the seller. One explanation, by Steven Thompson, follows:

> "When a business is sold, it is not uncommon for a portion of its sale price to be attributable to a noncompete agreement between the seller and the buyer. For tax purposes, a covenant not to compete is recognized when it is severable from goodwill, the agreement is separately bargained for, and the covenant can be shown to have economic substance. When this is the case, the portion of the sale price attributable to goodwill is generally treated as a capital asset, and the payment received for the noncompete agreement is taxable as ordinary income under Revenue Ruling 69-643, 1969-2 CB 10" (Thompson).

The buyer is entitled to an ordinary deduction as a business expense for periodic payments to the seller for the agreement not to compete.

EFFECT OF NEGOTIATIONS

For the seller, as has been indicated, sales of some assets result in capital gain or loss; others, ordinary income or loss. For the buyer, purchases of some assets result in immediate expensing; others, deferred deductions, or in the case of land, no deduction at all until the land is sold. Since § 1060 (IRC), and other authorities, respect allocations of value between the various assets, the buyer and seller can negotiate, not only the price for the business, but the reasonable fair value of the underlying assets.

Generally, in such negotiations, what is good for the buyer is not good for the seller, and vice versa. For example, with inventory, the seller has ordinary income (bad, but it might be QBI, which is good) and the seller has an ordinary deduction (good, but this might reduce QBI, which is bad). So, in negotiations, the buyer would favor a relatively high value for inventory, while the seller would prefer a lower value.

Another example is goodwill. For internally generated goodwill, the seller has capital gain and the buyer has a § 197 (IRC) asset that can be amortized over 15 years. In this case, the seller would prefer a higher value for goodwill, while the buyer would prefer a lower value since the buyer typically seeks current deductions.

As indicated, if it would be reasonable based on facts and circumstances, the buyer would negotiate for a higher value for inventory and a lower value for the goodwill. The seller has the opposite inclinations. These negotiations could, due to the give and take and varying tax rates between the buyer and seller (perhaps 21 percent for a corporation and 37 percent for an individual), result in renegotiating the overall price upward or downward. This is referred to as “tax arbitrage” (Investopedia).

It is important to realize that tax arbitrage could affect these negotiations. A corporate buyer might be willing to give up some ordinary deductions, rather than deferred deductions, for a slight increase in the overall price. A non-corporate seller might accommodate the change to get more capital gain.

STOCK OR OWNERSHIP INTEREST SALES

Our discussion so far has dealt with asset sales. If the business is operated as a partnership, including an LLC reporting as a partnership, limited liability company, or a corporation, including an S corporation, there is the option to sell the partnership interest, member interest, or stock. An elaborate discussion of the issues here will be left for another day. However, it is unlikely that the buyer of a partnership or an S corporation would gain from acquiring an ownership interest or stock over purchasing the assets.

<u>Sale of Corporate Stock</u>

The sale of stock in a regular corporation seems appealing, but an informed buyer would not pay as much for the stock of a corporation with appreciated assets, as they would for the appreciated assets because they would keep the low basis in the underlying assets resulting in less deductions. This is compared to the fair market value, as negotiated, basis in purchased assets that result in larger deductions.

Sale of Partnership Interest or S Corporation Stock

The sale of an interest in a partnership or S corporation might seem tempting, but in an asset sale, the gain or loss flows through to the owners and retains its character as capital gain or ordinary income. Since the owner's basis in the entity goes up by any gains and down by any losses, and since the buyer gets a basis equal to cost, there is no benefit to acquiring a partnership interest or stock in a corporation.

There are complex rules for the sale of a partnership interest that further complicate things. Even though a partnership interest is generally treated as a capital asset (IRC, § 741), ordinary income that would have been recognized had the underlying ordinary assets been sold will be recharacterized as ordinary income (IRC § 751(a)).

CONCLUSION

It is imperative that business buyers and sellers, and their advisers, be well versed in the advantages and disadvantages in structuring the transfer of a business. Understanding the effects of various elements allows a party involved in the transaction to seek advantages and avoid the risks of overlooking those advantages. A taxpayer can suffer economic consequences if the other party in the transaction is better informed and prepared. These taxpayers must involve their professional tax advisers and may benefit from engaging business brokers.

ABSTRACT

Marymount University is upgrading its analytics program for undergraduate business students, as the US workplace demands workers with stronger business analytics skills. Part of this is the implementation of an Advanced Business Statistics course. This course is based on several pedagogical “axioms,” uses real world cases, and uses a new textbook written by the professors. This permits updates of material in real time, provides fresh-graded material each semester, and is downloaded by the students without charge. This paper describes the “axioms,” the corresponding new textbook structure, the student literature review exercise, and the results achieved after the first semester’s presentation.

KEYWORDS: statistics, education, management science, undergraduate

INTRODUCTION

Marymount University is a comprehensive Catholic university offering a wide array of undergraduate and graduate degrees through the Schools of Design, Arts, and Humanities, Business and Technology, Sciences, Mathematics, and Education, and the Malek School of Health Professions. It is located in the Washington, DC metropolitan area in Arlington, VA, with a total enrollment of about 3400 graduate and undergraduate students.

The School of Business and Technology provides its Advanced Business Statistics courses in modern computer labs with maximum class sizes of 24 students per course section. Typical class sizes are about 20-22. Professors teach all of these courses.

The university upgraded its undergraduate business analytics (also called “operations research” or “O.R.”, or “Management Science”) program by the introduction of an Advanced Business Statistics course. This course is designed to help business students (BBA) become more competitive in the analytics marketplace upon graduation. According to the trade association “Institute for Operations Research and the Management Sciences” (INFORMS),

> O.R. and Analytics drive performance and change in organizations of all types – large and small, private and public, for-profit and not-for-profit.

> O.R. and Analytics are used in incredible ways, to inform high-level strategy, enhance day-to-day operations, design better public policies, and more.
>
> Using techniques such as mathematical modeling to analyze complex situations, O.R. and Analytics enable more effective decisions and more productive systems based on robust data, the fuller consideration of available options, and careful predictions of outcomes and estimates of risk. (INFORMS, 2018)

The following analytics-based jobs are considered among the best business jobs for 2017 by US News and World Report, October 6, 2017, Statistician (#1) and Mathematician (#3), and Operations Research Analyst (#5) (US News and World Report, 2017)

Our students previously took a basic statistics course in the business school from a Management Science professor. Now, these students take their first statistics course through the Mathematics department, and then take this Advanced Business Statistics course from Management Science professors. All business undergraduate students, therefore, take both the basic and advanced courses.

LITERATURE REVIEW

There are different approaches to setting goals for statistics courses. In the paper “Goals of Your Introductory Statistics Course,” Donald B. Macnaughton discusses “topic-based” course approaches, with goals of covering a set of topics such as probability, point and interval estimation, etc. He goes on further to state “Unfortunately, topic-based goals have a serious drawback: by emphasizing statistical topics, the goals usually *fail* to emphasize what is essential, which I believe is to help students appreciate the vital role of the field of statistics in empirical research.” (Macnaughton, 1997)

Jeffrey A Witmer, Oberln College, wrote the paper “A Second Course in Statistics.” In this paper he discusses his experience reviewing requests to transfer Statistics I courses to Oberlin from other institutions; he indicates that there is wide commonality in the US for this basic course. However, his experience is that there is not such commonality for Statistics II courses. He writes, “On some campuses Stat2 was, and still is, a regression course. For others it is an ANOVA course. Some statisticians prefer to follow Stat1 with a course on nonparametric methods, while others teach design of experiments.” “Our course is focused on how statisticians function as they work with clients and analyze data. … The Stat2 course that we have developed takes modeling as its theme.” (Witmer, n. d.)

Another approach is from Thomas E. Love. In his paper from the “Journal of Statistics Education,” he writes “In a single semester, students explore data using tools from EDA, multiple regression, analysis of variance, time series analysis, and categorical data analysis. The focus is on understanding and forecasting in a variety of data settings, learning how to summarize relationships and measure how well these relationships fit data, and how to make meaningful statistical inferences when the usual assumptions do not hold. The course emphasizes what the statistical process is all about: how to conduct studies, what the results mean, and what can be inferred about the whole from pieces of evidence.” (Love, 1998)

Our Advanced Business Statistics course goals were designed to show students how to use statistics in a business context to improve an organization’s return on investment, how to conduct business research, and how to evaluate business research done by others. It is designed to provide students with an environment very similar to that experienced by an entry-level analytics professional; the professor is both an "instructor" and a "supervisor." About 10% of Marymount students taking the analytics-based courses express strong interest in analytics as an eventual career field. This number is expected to grow as the workforce continues to grow for analytics. This course will give them first-hand experience in a professionally safe environment. The other students will get experience with what those analytics people will do, what to expect from them, and how to appraise analytics products at work. In particular:

- Students solve case-like exercises, not "homework problems," and explain their results in plain English. Their solutions must be sold to a "supervisor" or other "stakeholder/ customer" -- those roles played by the professor. Students are taught that an unsold analytics study is practically worthless – even if they achieved the correct answer. This is the primary component of the course grading.
- This focus includes using technology – tools that they will find in the workplace – primarily Microsoft Excel.
- The course also requires students to evaluate scholarly business research. Analytics professionals need to conduct literature reviews as part of their normal work and base their work on the findings of others.
- There is also a quiz, two midterms, and a final exam to access students' comprehension of the text material.

The course is basically conducted in three generic modules.

- Module 1: Excel Enrichment
    - One class period (75 minutes) of Excel graphics.
    - One class period of Advanced Excel (sorting, filtering, anchoring, pivot tables, logic formulas).
- Module 2: Advanced analytics.
- Module 3: Scholarly literature review.

The course was developed (and is currently being further developed) based on several "axioms." These are opinions of the professors from which the course is based. They certainly are arguable but they seem to work well for us – at least as of now. As this paper proceeds, those "axioms" will be introduced by italic font.

Axiom. Many collegiate advanced business statistics courses can be improved by formulating them as real world laboratories, where students take the roles of entry-level analytics professionals and are given a series of real-world case studies to solve which are from the experience of the professor. The professor is both their "instructor" and "supervisor." Because each case is from professor experience, the professor specifically knows why the case's business solution was chosen. This contrasts with the pre-published cases approach used by professors who may have had no personal involvement in the corresponding business solution. Students gain first-hand experience of what that profession is like, rather than reading textbooks and solving exercises in the back of the chapters.

Axiom. Business statistics textbooks are far too expensive. Costs can easily run about $250 for a traditional hardcover edition purchase and over $100 for softcover editions. Although many students will not keep the text as they are taking a “required” course and will choose to instead rent the book, about 10% of the students express sincere interest in analytics as a career field and may want to keep the text.

We wrote our own book. Students download the .pdf version from the university network.

- This presents a $0 cost to the students for the text, regardless of whether they decide to keep the text or not.
- This allows Marymount professors to update the gradable materials each semester with new materials to minimize cheating.
- This allows Marymount professors to change the text material as needed between semesters (or in real time if necessary).
- This is one less book for the student to carry if they select to review online but can be printed if student prefers.
- The book is also used in other analytics/management science courses at no charge to those students.

Axiom. Many of the current field of undergraduate business statistics books are far too lengthy. Most of the pages will go either unassigned or unread in a typical semester-length course. This is an undue burden to the student.

Today, many statistics books are full-sized and can be well over 850 pages. We place ourselves into the position of the general student who must buy a textbook of formulas, graphs, tables, new symbols, and new vocabulary. This can be quite daunting. It almost initiates the question “What will we ever use this for?” Also, a large number of those pages will not be in the curriculum and are therefore unneeded for the course. Our book has 292 pages, all used in the course.

Axiom. Some statistics courses are either taught or learned from the viewpoint of the “formalist” mathematical philosophical approach. This course is based on the “structuralist” approach.

In our experience, many statistics courses are taught from the approach of teaching formulas (“Here’s the formula.”) Many weaker students learn the formulas and manipulate them to achieve the solution. Examples of these are the numerous probability formulas and the z normal distribution formula. This student approach is a form of the philosophy of “formalism.” In this viewpoint, “The various philosophers that go by the name ‘formalism’ pursue a claim that the *essence* of mathematics is the manipulation of characters. A list of the characters and the allowed rules all but exhausts what there is to say about a given branch of mathematics.” (Shapiro, 2000)

Our book uses the philosophy from Stewart Shapiro that “mathematics is the study of patterns” (structuralism approach) (Shapiro, 2000).

“Mathematical structuralism is the view that, in some sense, mathematics is about structures and their relations, rather than about objects and their properties.” (Landry, 2016). For example, in this approach, the number “4010” refers to the room number location of a computer lab in the

Business School building. The number “5” refers to a location on the number line. The probability of rolling a die and getting a total of “4” is obtained by noticing the pattern that there are six possible outcomes, and one of those is a “4,” so a 6 is placed in the denominator and a 1 in the numerator: the pattern is “1/6.” Probability patterns showing all basic probability rules can be shown by using dice and playing a popular board game such as Monopoly®, as opposed to mathematical derivations.

By teaching the underlying patterns, students who learn them do not need to memorize or learn formulas. They merely learn how to quantify the patterns; the entire probability chapter can be taught without naming or algebraically deriving particular formulas per se.

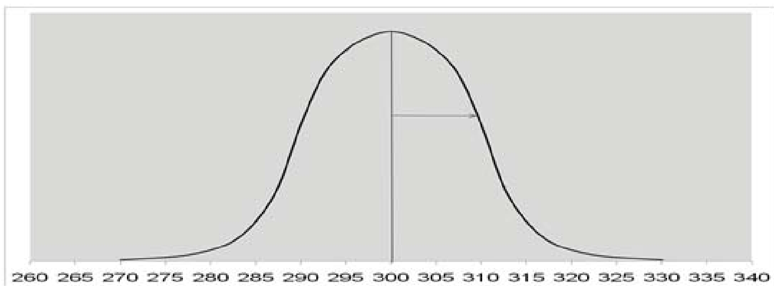

Figure 4-15

Figure 1

Figure 1 is from our book (book Figure 4-15) representing a hypothetical population of events with values normally distributed with a mean of 300, and a standard deviation of 10.

I was taught the relationships between z, x, μ, and σ by memorizing the following formula.

$$z = \frac{x - \mu}{\sigma} \qquad (1)$$

For example, Figure 2 is an extract from a presentation from a University of Wisconsin Statistics course (Lindstrom, 2004) which shows this approach. This approach consists of, basically, three steps: formulate the problem, convert the problem into a standard normal curve problem, and then solve the problem.

Standardization

If Y is a normally distributed Random Variable $Y \sim \mathcal{N}(\mu, \sigma^2)$

And we define

$$Z = \frac{Y - \mu}{\sigma}$$

Then Z is a standard normal random variable

$$Z \sim \mathcal{N}(0, 1)$$

Every problem that asks for an area under a normal curve is solved by first finding an equivalent problem for the standard normal curve.

Figure 2

For me, it was difficult to intuitively understand why normalizing the distance between x and μ by dividing by σ produced the value of z; or, why is it necessary to add a logical step to first convert the problem to a standard normal curve problem, and then solve. Instead, formulate the problem using this approach (i.e., one is allowed to multiply each side of Figure 2's formula by σ).

$$z\,\sigma = x - \mu \tag{2}$$

Then solve, eliminating the step of the standardized normal curve. Teach that the distance between x and μ is simply the corresponding number of σs. For example, if σ = 10, then distance between 310 and 300 is one σ (z = 1). The distance between 320 and 300 is two σs (z = 2). This pattern can now be taught and understood intuitively by most students in a few minutes without having to memorize the formula. Since it works for any shape normal curve, the additional step's discussion about the standard normal curve can be avoided.

Axiom. In the real world, analysts present the solutions to their work to their superiors, and often to groups of managers and analysts in business meetings. Critical thinkers in those meetings will appraise the work in terms of its accuracy, and also in terms of its usefulness. For the analyst who did the work, getting the right answer to a statistics problem is important, but it is no more than 49% of the requirement. One must sell the answer to the decision maker, and the sales part is worth at least 51% of the final product. Basically, an unsold correct answer is almost worthless.

Many statistics books and courses end an exercise upon "getting the correct answer." In the real world, there is an additional step: answers reached by analysts must be "sold" to decision makers before the decision makers will approve any subsequent action. Answers to the cases must be mathematically sound; but a manager, senior to the analyst, who may not be qualified in statistics, must also understand the process and solution. Case study answers therefore must be statistically/mathematically sound, and must be presented to the instructor in plain English who simulates a decision maker who may not be qualified in statistics.

THEORETICAL DEVELOPMENT/MODEL

Textbook Structure

Figure 3 shows part of the Table of Contents. For most chapters, there is a “chapter number,” and a “chapter number R.” The “R” denotes “review.” For example, Chapter 4 is the Normal Distribution case study with new material, and Chapter 4R is the basic normal distribution text material as a review from a typical introductory statistics course. This review chapter is optional for those who need it, and includes solved end of chapter problems; this provides guidance to students who cannot recall information from the introductory course.

Table of Contents

Figure 3

Axiom. In the real world, analysts present the solutions to their work to their superiors, and often to groups of managers and analysts in business meetings. Critical thinkers in those meetings will appraise the work in terms of its accuracy, and also in terms of its usefulness. For the analyst who did the work, getting the right answer to a statistics problem is important, but it is no more than 49% of the requirement. One must sell the answer to the decision maker, and the sales part is worth at least 51% of the final product. Basically, an unsold correct answer is almost worthless.

Many statistics books and courses end an exercise upon “getting the correct answer.” In the real world, there is an additional step: answers reached by analysts must be “sold” to decision makers before the decision makers will approve any subsequent action. Answers to the cases must be mathematically sound; but a manager, senior to the analyst, who may not be qualified in statistics, must also understand the process and solution. Case study answers therefore must be statistically/mathematically sound, and must be presented to the instructor in plain English who simulates a decision maker who may not be qualified in statistics.

Student Literature Review Assignment

Many times entry-level (and higher level) analysts will be tasked to somehow develop an analytic procedure that has never been done at their organization. We believe that students should be taught to perform a literature search early in their effort to be exposed to the lessons learned when other tried similar work (if they did). This part of the course simulates a serious literature review. This module of the course requires students to perform a scholarly review of an academic journal paper in the business field that contains a statistical analysis. During our first semester, some students indicated that this was the first time they performed such a serious literature review on a business paper. Figure 4 is an extract from the syllabus describing the literature review exercise.

> Choose any business-related paper from the recent (less than 5 years old) general business journal literature (accounting, sales, marketing, operations research/analytics, business medical services, business software development, IT, etc.) Suitable journals include Harvard Business Review, CrossTalk, Interfaces, University of Chicago Journal of Business, etc. Not acceptable publications are popular magazine articles, trade association magazine articles, or newspaper articles. Meet with the instructor if there are any questions about the suitability of the paper and source.

Figure 4

Figure 5 is the grading rubric. This is also from the syllabus.

_____ 1. Was the selected journal paper business-oriented. 5 pts.

_____ 2. Is there a copy of the selected journal paper attached to the back of the critique. Did it include a page showing the Cover and Table of Contents (or masthead "screenshot" if from an electronic format) from the journal chosen. 4 pts. (Zero points if not from an academic journal.)

______ 3. Was the journal paper a recap of the author's research that made a new contribution to the body of knowledge, as opposed to a "report" which accumulated already existing knowledge. The body of knowledge contribution may be either substantial or small. 8 pts.

_____ 4. Did the student's critique contain a statement and explanation of the author's null and alternative hypotheses in plain English and in the student's own words. 8 pts.

_____ 5. Was the student's critique of the author's research methods free from statistical jargon and symbols, and written in plain English easily understandable by a middle manager who does not have an analytics background. 5 pts.

_______6. Was the student's critique of the author's conclusions free from statistical jargon and symbols, and written in plain English easily understandable by a middle manager who does not have an analytics background. 5 pts.

_______7. Was the student's critique of the author's conclusions logical and based on data or other facts, and not based on opinions such as often found in editorials, social media postings, popular discussions, etc. Were the sources of the data/other facts references footnoted. 5 pts.

Figure 5

This rubric, including the weighting factors, reflects our professional experiences both performing such literature reviews and supervising junior analysts in their literature reviews.

RESULTS

Figure 6 shows the final grade distribution for two sections of the first 22 students taking the course. Minus and plus grades are included with their base grades (e.g., all B+, B, and B- grades are shown here as a "B").

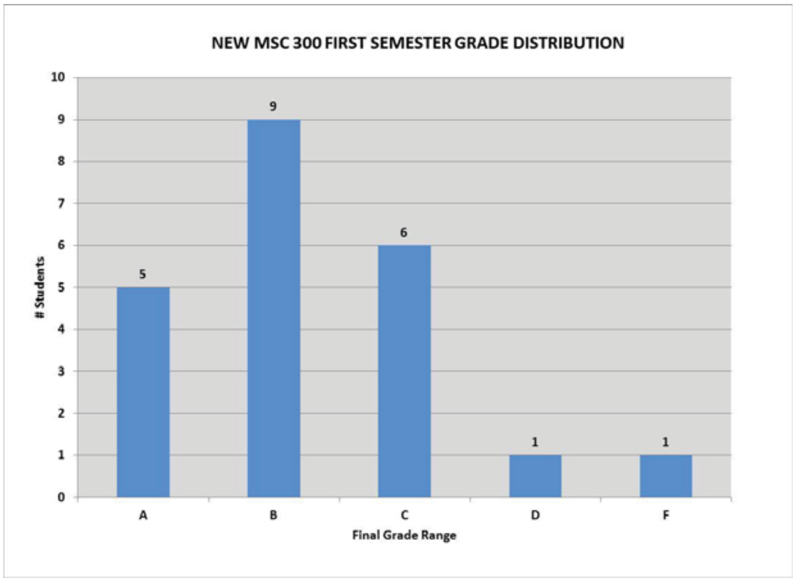

Figure 6

This shows the center of mass in the “B” range, and the overall distribution was consistent for both sections of the course. The course is designed so that most “A” and “B” range students should be fully academically qualified for an entry-level statistical analytics position, based on the professional experience of the instructors.

Figure 7 shows the student feedback scores for the first two sections of 22 students.

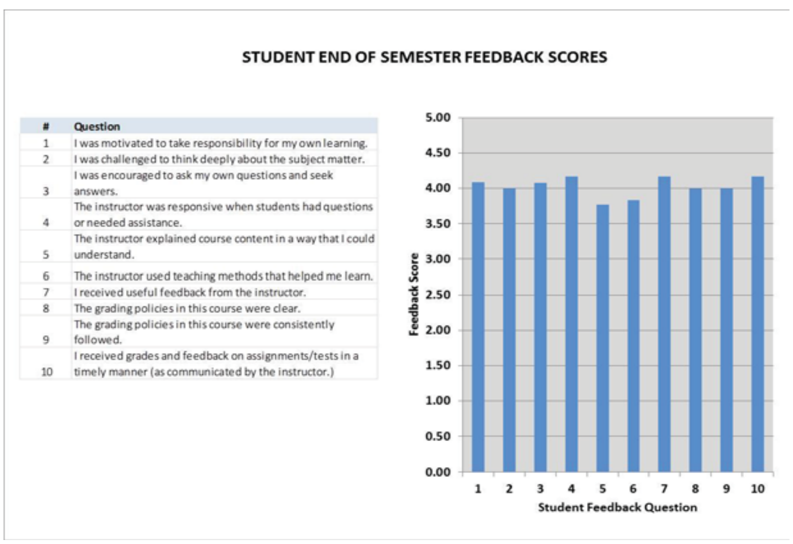

Figure 7

The center of mass on the student comment sheets was about a “4” out of “5” possible. These ratings were also consistent between the two sections. These scores were statistical averages; in the future, it might also be good to report medians to remove effects of possible insignificant outliers.

Finally, the 22 students avoided the list or rental prices of our previous textbook, representing a significant cost avoidance for them.

DISCUSSION AND CONCLUSIONS

One area for future development is to continue to solicit input from students for course improvements. This will include end of course student comment surveys, but will also include meetings with individual students for their confidential feedback after the course is over and their grades are turned in.

We will monitor how much time is needed for students to complete the case studies. Since the cases will be different, but similar, each semester, we will want to modify the time allotted for them so that the workload is cross-leveled more evenly in future semesters.

This course will be probably offered in two or three sections each semester. These professors will collaborate throughout the semester, and after the semester, to seek course improvement.

Another area for course improvement is to meet with professional analytics job recruiters. These meetings will result in a comparison of what they are seeking for their clients and what we are presenting in the course. This will help us keep the course calibrated for the job market.

Our results, both formally obtained through student feedback forms and by student interaction, indicate that we should continue with this approach as it reflects the real world as much as we can in the classroom and sparks many students to consider analytics as a career field.

ABSTRACT

Low college retention is a universal problem. This study lists the factors and causes identified by prior research on this issue and other non-academic factors that include family college history, family support, student self-knowledge, student preparation, a school's educational and health provisions, and faculty's role in students' development, among others. Based on the data collected from a university over a six-year period, this study attempts to predict retention as well as graduation rates and the categories of students at risk. This study uses statistical techniques of logistic regression and the binary choice decision model.

KEYWORDS: Data analytics, enrollment management, logistic regression, student retention rate, student graduation rate

INTRODUCTION

Low college retention is a national and international problem. The problem of low retention may suggest a declining trend at several colleges. Several studies have identified the factors and causes of this problem. This study will identify academic and non-academic factors that influence the success of college students. There should be an early identification and intervention strategy for at-risk first year undergraduate students. This study looks at various factors aiming to predict what affects retention rate and which categories of students are at risk. It uses 2008 – 2014 cumulative data from a university in southern United States. It includes the following variables: age, gender, ethnicity, start time, full/part-time status, admission status, classification upon entering, SAT and ACT scores, high school, high school rank, if a student considered to be a high achiever, first generation (first person to attend university in the family), college, major, athletic affiliation, and cumulative GPA. Several statistical techniques such as logistic regression, the binary choice decision model, and discriminate analysis will be used to study the relationship between the response variable and several independent variables.

Logistic regression is a very powerful statistical technique that is used to model the relationship between a categorical outcome, the dependent variable, and a set of independent variables, such as education level, age, gender (Hosmer and Lemeshow, 2000). It models the probability associated with each level of the independent variable by presenting a linear relationship between predictor variables and a link function of these probabilities. On the other hand, linear regression predicts the actual values of the dependent variable. Different link functions in the linear equation show different levels of goodness-of-fit for the given data. The logistic regression technique will be used to find a best fitting and most reasonable model that can justify the relationship between response and independent variables and other explanatory variables. Since the response variable was ordinal, the authors used ordinal logistic regression to analyze and ascertain if there were significant relationships between the response variable and the predictor variables.

The rest of the paper is organized as follows: Literature review, discussion of analysis and results, summary and conclusions.

LITERATURE REVIEW

The literature review presented here is very limited due to space limitations.

DISCUSSION OF ANALYSIS AND RESULTS

The results discussed in this section are based on the 2008-2014 data collected from a university in southern United States. Logistic regression is a very powerful method and used to analyze and determine if there are significant relationships between the response variables and set of independent variables such as gender, ethnicity, high school rank, financial aid, GPA, SAT, and age In contrast with linear regression that predicts the actual values of the response variables, logistic regression models the probability associated with each level of the response variable by finding a linear relationship between predictor variables and a link function of these probabilities. Different link functions offer different levels of “goodness of fit” for the data. The aim of the logistic regression model is to find the best fitting and most sound model to describe the relationship between the response variable and set of the explanatory variables. The multiple logistic regression model can be written as:

$$\ln(\text{odds ratio}) = \beta_0 + \beta_1 X_{1i} + \beta_2 X_{2i} + \ldots + \beta_k X_{ki} + \varepsilon_i \qquad (1)$$

In equation (1) *k* represents number of independent variables in the model, and ε_i represents the random error in observation *i*. A logistic regression is based on the odds ratio, which represents the probability of a success compared with the probability of failure. The maximum likelihood technique is used to obtain the estimates of the parameters in the logistic regression equation (1). The deviance can be used as a statistic to assess the model's goodness of fit. The model is generally considered reasonable if the deviance is not significantly large.

Test of All Slopes Equal to Zero

DF	G	P-Value
10	112.340	0.000

Based on the logistic regression results, we notice that there is a significant relationship between student retention and the following independent variables: high school rank, SAT, Gender, and financial aid.

P-value =0.000 for the G-statistic which indicates that there is sufficient evidence to conclude that at least one of the estimated coefficients for the independent variable is different from zero, and this helps the authors to conclude that the model with all variables is significant at α = 0.05.

Test of All Slopes Equal to Zero

DF	G	P-Value
10	62.676	0.000

Based on the logistic regression results, we conclude that there is a significant relationship between student retention and the following independent variables: high school rank, SAT, Gender, and financial aid.

SUMMARY AND CONCLUSIONS

Low college retention is a national and international problem. This paper listed the factors and causes identified by several authors for this problem. It also identified academic and non-academic factors that influence the success of college students.

Based on the logistic regression results, we notice that there is a significant relationship between student retention and the following independent variables: high school rank, SAT, Gender, and financial aid.

The limitations of this study include the results are based on a snapshot of the data from one university and so one should be cautious in generalizations. Further studies should include data from more periods of data, on more variables and from different universities. Further studies should also include data on intervention measures and their impact on retention and graduation rates.

ABSTRACT

Many institutions are challenged by the issue of student retention and persistence. In this study we used a text analytics method to summarize recent publications on student retention research. As demographics shift, new knowledge on student retention and practice should be consolidated and reviewed. Institutions can borrow from research to develop effective retention strategies.

KEYWORDS: Retention, Persistence, student success, online education, institution programming

INTRODUCTION

The National Student Clearinghouse Research Center (2016) reports that 30 percent of students who entered college in the fall of 2014 did not return in the second year. According to the National Center for Education Statistics, students enrolled in higher education in 2011-2012, only 11% of this cohort earned an associate degree and 7% earned a bachelor's degree within six years, 9% earned a certificate, and 12% were still working to complete a credential. Half of these students left their first two- or four-year college without earning a degree or certificate (Sparks, 2019).

Colleges and universities are challenged by multiple stakeholders such as state legislatures, the federal government, the broader public, and students to improve retention and graduation rates. To respond to the pressure of improving retention, many universities and institutions have created student success centers, student retention offices, etc. Programs and departments have been introduced across the country in an effort to increase the rates of retention in higher education. These initiatives are designed to improve student retention and support students with a variety of services (Fishman, Ludgate, & Tutak, 2017).

Universities and colleges are measured by graduation rates for their effectiveness. In order to improve graduation rates, institutions must improve retention rates as the institution's retention rate has a direct relationship with its graduation rate. The goal of retention programs is to reduce the number of students who leave the institution before completing a degree. Forty years ago, students who dropped out of college were viewed as lack of skills and motivations. Over the years, the dropout view has been changed. Institutions have to investigate their own internal processes, policies and procedures to understand a broad picture of students' dropout.

As colleges and universities are continually seeking ways to identify predictors of academic success and effective means to retain students, many institutions spend more money on recruiting students as opposed to retaining existing students (Fike & Fike, 2008). A prior study reports that retention of current students is far less expensive than the recruitment of new students (Lau, 2003). To help students complete college successfully, more resources should be invested in retention.

Though much retention research has been conducted (Robbins, 2004; Rendón, Jalomo, & Nora, 2000), retention and graduation statistics have remained relatively stable over the years (Sparks, 2019). Freshman attrition rates are commonly as high as 20-30% (Barclay, 2018) and 20% of all first-time, first-year students enrolled in a four-year institution were not returning to college in their second year (Feldman, 2017). Different generations have different characteristics and therefore their attitudes towards higher education and needs are different. Considering many years of research on the retention issue and the changing demographics of the student population, expectations of multiple stakeholders, we need to continuously understand retention dynamics. Summarizing recent findings could help us to better translate research into practice.

Given student retention is a persistent issue, understanding retention strategies and practices could shed some light on how to improve retention. This study intends to achieve the following: 1) review the literature on student retention; 2) perform a content analysis and a text mining analysis on the abstract of 30 recent publications on student retention; 3) summarize recent findings on student retention using a text analytic approach.

LITERATURE REVIEW

Predicting Retention

Tinto proposes a number of factors contribute to a student's decision to drop out: student characteristics, the extent of their academic, environmental, and social integration in an institution (Tinto 2006). Prior studies have identified many factors contributing to student retention. In general, the important predictors are socioeconomic status, high school GPA, college assessment entry scores when combined with institutional commitment, academic goals, social support, and academic self-confidence (Robbins, 2004). Fike & Fike (2008) report the developmental education programs and internet-based courses impact student persistence, financial aid, parents' education, the number of semester hours enrolled in the first fall semester, and participation in the Student Support Services program as strong predictors for first year persistence. (Droddy, Smith, & Guarino, 2009) conclude that school accountability status, ACT scores and first year GPA are strong predictors for first year college retention. Milea (2018) find students who were academically prepared, received grants or scholarships, and were in smaller classes have higher retention and graduation rates. Milea (2018) also suggests that universities could improve graduation and retention rates by investing in scholarships, smaller class sizes, and financial aid infrastructure.

Though many studies reported ACT/SAT scores and high school GPA are strong predictors for retention (Robins, 2014; Fike &Fike 2008), Saunder-scott et al. (2018) find that perceived stress and grit were good predictors for retention but ACT/SAT and high school GPA are strong predictors for college GPA but not for retention. Barclay and Barclay (Dewberry & Jackson, 2018) report psychological variables are important predictors for retention. Dewberry & Jackson (2018) find that theory of planned behavior variables predict student' voluntary dropout well.

These findings suggest effective retention strategies should be built upon understanding individual students, and their psychological factors.

Practices

Universities have designed a wide variety of programs including university wide, first year seminars, advising alteration, mentor/role model programs, and altering gateway courses to improve student retention. Traditionally, the most common method of retention focuses on study skills, time management, and habits. While study skill habits are effective in improving student's academic performance, retention rates have remained the same over the past decade (Scott et al., 2004). This begs for new programs to be developed. In general, retention programs fall into roughly four categories: academic, interpersonal skills, social situation, and financial situation. Nadeem, Abbas, & Javed (2015) find student orientation has a positively effect on satisfaction and retention. Cox (2005) states that enhancing first-year experience improves student retention. In addition, mentor/role model and advising programs contribute to retaining students. In a study of a two-year nursing program, effective practice in increasing retention includes adding a face to face meeting within the first two weeks of the semester as part of the advising duties plus maintaining and documenting contact at least once every 16 weeks, and responding to inquires within three days (Harrell & Reglin, 2018).

Students At-Risk

The literature produces fruitful results on how to improve retention for students at-risk. The typical risk factors are rural, low socio-economic background, minority, first-gen college, academic performance, gender etc. Chan (2015) finds that different types of interaction had different effects upon GPA. To retain low income and first-gen students, a structured first-year and learning community programs are effective when they are designed to meet the specific needs and characteristics of students from low income and first-generation backgrounds (Thayer, 2000). Peer tutors increase retention for low-income students and it is also important to realize that building self-confidence is essential for this group of students (Mangan, 2015). For rural students, three factors affect their college persistence: community's and family's values of education, the pull of family obligations, and the students' struggle to master college-level coursework (Hlinka, 2017). In the study of under-represented minority group, there is a positive impact on African-American male academics specifically to increased grade point averages with a mixed method (Brooks, Jones, & Burt, 2013). Black males have the highest dropout rate of any demographic (Strayhorn, 2014). In a study of black males attending a predominantly White institution, grit is positively related to college grades for Black males. Grit explains 24 % of the variance in Black male's college grades (Strayhorn, 2014). As the freshmen year is crucial to engage black males, universities should establish support structures such as a mentor program, same race peers, and faculty relationship to engage black males (Lucas, 2018). In order for retention strategies to be effective, the retention program should be specific and customized to the particular group at-risk (Hernandez, 2018; Brooks, 2012).

METHODS

We used a qualitative method to examine our research purposes; one is the content analysis of the title of the recent publications on retention, and the other is a text analytics approach to exact themes.

Data Collection

We performed a keyword search on student retention using ABI database. After reading the abstract of the publications, we've decided to use 30 papers published in the past four years on student retention as these papers cover a broad perspective of student retention and their findings are current. We plan in the future to include more papers for analysis.

Content Analysis

A content analysis of the title of the 30 papers was performed. We identified the themes as shown in Table 1 below. Recent research has investigated a wide variety of issues that are related to student retention: complex system, internal process, student satisfaction, macro influence, financial status, faculty personality, faculty employment status, strength based approach, professional staff, digital badges, peer mentoring, academic library, early alert systems, specialized courses etc.

Table 1: Topics
Complex system
Internal process
Student satisfaction
Macro influence
Online student success
Faculty and student perceptions
Student loans/financial stress
Faculty student lifestyle habits
Faculty employment status
Strength-based approach
Faculty personality
Professional staff

Learning analytics and digital badges
Expectations and experiences
Theory of planned behavior
Peer mentor characteristics
Specialized courses
Predictors of retention
Early alert systems
Academic library
Technology acceptance factor
STEM majors
Folk high school

Table 2 shows the number of papers published in the selected year window of study.

Table 2: Counts of Publication by Year	
Year	
2015	7
2016	10
2017	4
2018	7
2019	2

Text Analytics

After performing a content analysis of the title of the publications and identified themes, we then proceeded with a text analysis. Knime 3.7 was used to perform a text analysis on the abstract of the 30 papers. To analyze the text data, we must complete the data wrangling process. The data wrangling process includes tokenization and normalization. Tokenization is the process of breaking content into smaller pieces, words, or tokens. An important part of tokenization is the removal of “stop words.” Stop words include prepositions and conjunctions (after, for, of, but, nor) which will not improve our understanding of the overall sentiment of a paper. Normalization is the process of reducing a group of words to its base or stem. For example, retain, retentions, retention, retaining are all variations of the same stem, retain. We want to group variations like these into one stem; a normalization process is also called word stemming. We computed inverse document frequency (IDF) and term frequency (TF) and used the computed metric TFIDF to create a word cloud that visually represents the importance of retention studies in the past four years as TFIDF is one of the most popular term-weighting schemes (Beel, Gipp, Langer, & Breitinger, 2016)

Figure 1. Word Cloud of the Abstract

Figure 1 shows the word cloud. As shown in this word cloud, the highly occurred words are online, quality, recommendations, research, education etc. As more and more online programs and courses are offered, institutions now focus on how to retain students in the online environment. More research is needed in the online quality of education. To help students persist through college, universities must understand students’ profile, their issues/problems and take a student-centered approach to design course offerings, learning experiences, campus life, making college experience enjoyable and keeping students engaged.

CONCLUSION

To be financially healthy, universities and colleges should treat retention and recruitment as their top priorities. All institutions have implemented a variety of programming to retain students. In this study we performed text analytics on recent publications to better understand recent knowledge on retention strategies and practices. Our study shows that recent publications have examined internal and external processes, faculty personality/employment status, and a strength-based approach in the area of student intention. We can borrow knowledge and practice that are implemented in other institutions and adapt them to the specific education programs and student populations.

Limitations and Future Directions

This study is limited to the text analysis of the 30 abstracts. Student retention will continue to be of research interest as generation Z enters college. In the future we plan to expand the sample size and study the difference on retention research between 4-year universities vs 2-year colleges, and online programs vs traditional face-to-face programs. In addition, the method of text mining is limited to word clouds, where only the word count is taken into account. We will use the sentiment analyses, including the text network and the topic modeling for generating explanatory variables and statistical models to analyze significance of factors and explore the relationships between factors.

ABSTRACT

In this study, we consider an auxiliary variable to improve the estimation of the population mean of the primary variable, and propose another group of estimators for improved estimation of the average yield of peppermint oil. Also, we compare the proposed estimators with competing estimators theoretically and derive the conditions for the suggested class to be an improvement. Finally, original data collected from the Siddaur Block of Barabanki District at Uttar Pradesh State (India) are used to compare empirically the proposed class of estimators with the competing classes of estimators.

KEYWORDS: Study Variable, Auxiliary variable, Regression-cum-Ratio estimator, Bias, MSE, PRE.

INTRODUCTION

Auxiliary information enhances the efficiency of the sampling design. This information is achieved from the auxiliary variable which has a high degree of positive or negative correlation with the study variable. Many authors have utilized the auxiliary information for elevated estimation of the population mean. Some of the contributions in this direction is due to Sharma and Singh (2013), Subramani and Kumarapandiyan (2012, 2013), Yadav and Mishra (2015), Yadav et al. (2016), Subramani (2016), Abid et al. (2016), Gupta and Yadav (2017, 2018), Subramani and Ajith (2017), Subzar et al. (2017), Srija and Subramani (2018), Ijaz and Ali (2018) and Yadav et al.(2018**).**

In this study, we consider enhanced estimation of the population mean of the main variable utilizing known information acquired from an auxiliary variable. We introduce a new family of estimators for the elevated estimation of average production of peppermint oil at Siddaur Block of Barabanki District at Uttar Pradesh State in India. We study large sampling properties using Taylor series expansion up to the first order of approximation both theoretically and empirically.

LITERATURE REVIEW

A number of improved estimators of the population mean have been suggested by various authors. Some of the estimators under comparison are presented in Table 1.

Table 1: Different estimators of population mean by various authors

PROPOSED ESTIMATOR

Motivated by Subzar et al. (2017b) and Jerajuddin and Kishun (2016), we suggest the following family of estimators of the population mean using non-conventional parameters and the ninth decile of the secondary variable as,

$$t_{pi} = \frac{\bar{y} + b(\bar{X} - \bar{x})}{(\bar{x} + \xi_j)}(\bar{X} + \xi_j),\ i = 1,2,...,8 \text{ and } j = 1,2,...,8$$

$$t_{pi} = \frac{\bar{y} + b(\bar{X} - \bar{x})}{(\bar{x}\rho + \xi_j)}(\bar{X}\rho + \xi_j),\ i = 9,10,...,16 \text{ and } j = 1,2,...,8$$

$$t_{pi} = \frac{\bar{y} + b(\bar{X} - \bar{x})}{(\bar{x}C_x + \xi_j)}(\bar{X}C_x + \xi_j),\ i = 17,18,...,24 \text{ and } j = 1,2,...,8$$

The biases and the mean squared errors of the above estimators up to the first order of approximation are, respectively,

$$B(t_{pj}) \cong \frac{1-f}{n}\frac{S_x^2}{\bar{Y}}R_{pj}^2,\ j = 1,2,\ldots,24$$

$$MSE(t_{pj}) \cong \frac{1-f}{n}[(R_{pj}^2 S_x^2 - (1-\rho^2)S_y^2],\ j = 1,2,\ldots,24$$

Where,

$$R_{pi} = \frac{\bar{Y}}{\bar{X} + \xi_j},\ i = 1,2,...,8 \text{ and } j = 1,2,...,8$$

$$R_{pi} = \frac{\bar{Y}\rho}{\bar{X}\rho + \xi_j},\ i = 9,10,...,16 \text{ and } j = 1,2,...,8$$

$$R_{pi} = \frac{\bar{Y}C_x}{\bar{X}C_x + \xi_j}, \ i = 17, 18, ..., 24 \text{ and } j = 1, 2, ..., 8$$

and,

$\xi_1 = (QD \times D_9)$, $\xi_2 = (DM \times D_9)$, $\xi_3 = (TM \times D_9)$, $\xi_4 = (MR \times D_9)$, $\xi_5 = (HL \times D_9)$, $\xi_6 = (G \times D_9)$, $\xi_7 = (D \times D_9)$, $\xi_8 = (S_{pw} \times D_9)$

EFFICIENCY COMPARISON

In this section, the suggested class of estimators is compared with the competing families and the theoretical conditions for the suggested family to be more efficient are given in Table 2.

Table 2: Efficiency conditions of proposed estimator over the competing estimators

S. No.	Estimator by	Efficiency condition of suggested estimator to be more efficient than other if,
1.	Kadilar and Cingi (2004)	$MSE(t_{ai}) - MSE(t_{pj}) > 0$
2.	Subramani and Kumarapandiyan (2012a, 2012b)	$MSE(t_{ci}) - MSE(t_{pj}) > 0$
3.	Abid et al. (2016)	$MSE(t_{di}) - MSE(t_{pj}) > 0$
4.	Subzar et al. (2017)	$MSE(t_{ei}) - MSE(t_{pj}) > 0$
5.	Subzar et al. (2018)	$MSE(t_{hi}) - MSE(t_{pj}) > 0$

NUMERICAL STUDY

In this section a real population has been considered and the data has been collected from a block of the Barabanki district of Uttar Pradesh State of India.
The study and the auxiliary variables under considerations are as follows:
Y : The production (Yield) of peppermint oil in kilograms
X : The area of the field in Bigha (2529.3 Square Meter)

Table 3 represents the parameters of the population under consideration.

Table 3: Parameters of the population under consideration

$N = 150$, $n = 40$, $\gamma = 0.018333$, $\bar{Y} = 79.58$, $\bar{X} = 6.5833$, $\rho = 0.9363$, $C_y = 0.781333$, $C_x = 0.661726$, $S_y^2 = 3866.165$, $S_x^2 = 18.97791$, $\beta_1 = 1.4984$, $\beta_2 = 5.408$, $Q_1 = 4$, $M_d = 5$, $Q_3 = 10$, $D_1 = 2$, $D_2 = 3$, $D_3 = 4$, $D_4 = 5$, $D_5 = 5$, $D_6 = 6$, $D_7 = 8$, $D_8 = 10$, $D_9 = 13$, $QD = 3$, $DM = 6.22$, $TM = 6$, $MR = 11$, $HL = 7$, $G = 8.2298$, $D = 9.2542$, $S_{pw} = 9.3707$

The MSEs of some competing and suggested estimators (see Table 2) of the population mean for the mentioned natural population are presented in the following Table 4.

Table 4: MSE of competing and suggested estimators

Estimators	MSE	Estimators	MSE
t_{a1}	59.5772	t_{p1}	9.7970
t_{c1}	31.1269	t_{p6}	8.8734
t_{d1}	22.1784	t_{p7}	8.8702
t_{e1}	50.6571	t_{p12}	8.8234
t_{e18}	56.1919	t_{p16}	8.8545
t_{h1}	14.3495	t_{p21}	8.8427
t_{h18}	12.1847	t_{p24}	8.7972

CONCLUSION

In the present study, we investigated the enhanced estimation of the population mean using an auxiliary variable. We demonstrated that the suggested class of estimators may be used for improved estimation of the population mean. We derived the expressions for the bias and mean squared error of the suggested estimators up to an approximation of degree one. The suggested estimators are compared theoretically with the competing estimators using auxiliary variable and the efficiency conditions for the suggested estimators to be more efficient are also obtained. The theoretical conditions are verified through natural primary data on peppermint oil production collected from a block of the Barabanki District of Uttar Pradesh in India. The numerical study shows that the suggested estimators have the least MSEs among the class of competing estimators of the population mean. Thus the suggested family may be used for enhaced estimation of the population mean of similar products.

ABSTRACT

The aim of this paper is to assess the rationality of certified investment advisors employed as mutual fund managers operating on the Polish capital market by examining the decision biases to which they are subject. Investment fund managers are expected to make rational decisions while managing the capital of individuals and this hypothesis is verified in the paper. The method of tasks identifying the behavioural traps is used in the survey. As the result of the survey it is concluded that investment fund managers are rational basic on the answers they gave to the questions analyzing their decisions.

KEYWORDS: Rationality, Investment fund managers, Behavioural biases

INTRODUCTION

Investment fund managers make their decisions in the environment of continuous process related to the information coming from different local and international institutions. The information process is not coordinated and there are periods with more and less intensive news appearing on the market. That news affect rates of return and its volatility in a positive and negative way. There is a wide scope of evidence related to the overreaction and under reaction of the market on the available information indicating, that the model of making decision is not a simple project but more complicated process that can be described only in a small part. Decisions that investors make on the market are not only the result of the external information but also the internal motivations and preferences. In case of investment fund managers it can be related to the corporate governance, knowledge and experience all together with heuristics they are affected by. In this paper the behavioural biases are examined but it is only a small part of the rationality assessment.
The effects of certainty and reverse in a prospect theory, isolation (framing), disposition, overconfidence, illusion of control, ambiguity aversion, attribute substitution, sunk costs and fast thinking are analysed in the presented paper in the group of investment fund managers on the Polish capital market to verify the hypothesis that their decisions are rational. The survey is made on an emerging capital market but it can be expected, that there is a little difference between investment fund managers on other markets since the capital flow, information and knowledge is universal in a global financial world.

LITERATURE REVIEW

Rationality is a multidimensional issue that can be considered from different points of view. In case of papers in the area of finance authors stress on the economic approach to this issue. But the concept of rationality differs between psychology, philosophy, economics, and biology. For psychologists and philosophers, the emphasis is on the process by which decisions are made: rational beliefs are arrived at by reasoning and contrasted with beliefs arrived at by emotion, faith, authority or arbitrary choice. Economists emphasize consistency of choice, regardless of the process and the goal. Biologists use a concept that links both previous ideas. (Kacelnik, 2006). Moreover no such thing exists as a rationality that is not the rationality of some tradition. Each tradition is developed within a particular historical context and sought to resolve particular conflicts. Allegiance to one tradition can allow for meaningful contact with other traditions in a way that can lead to understanding, vindication, or revision of that tradition in its continuing form. Thus, only by being grounded in the history and opposing traditions we are able to restore rationality and intelligibility to our moral attitudes and commitments today (Macintyre, Macintyre,1988). Analysing the rationality is a complicated project, but every survey may add something to the general theory.

Rational behaviour refers to a decision-making process that is based on making choices that result in the optimal level of benefit or utility for an individual. Most conventional economic theories are based on the assumption that all individuals taking part in an action or activity are behaving rationally. Rationality is based on wisdom, logical reasoning and choice of means and methods of action, naturally within the scope of knowledge (Penc, 2007). Rational behaviour of managers on the market may be accompanied by negative externalities, described by microeconomics as market weaknesses (Fornalczyk, 2007).

There are as many types of rationality as codes of conduct. Analytical rationality includes every action based on the analysis of elements of a given situation. Holistic rationality is based on a multidimensional view of the problem. The limited rationality corresponds to the information available and the actual human calculating abilities: the decision-maker first determines the intervals of satisfactory grades, and then rests on the first option considered from such a range. When analysing decisions, one needs to be aware of what type of rationality we are dealing with (Szapiro, 1993).

Dean and Perlman (1998) point out that the one of the opponents of the traditional concept of homo oeconomicus was Leibenstein, the author of selective rationality, i.e. selective tendency and ability to calculate. Leibenstein pointed to the gradability of rationality (strict and loose) and assumed that people act as they please, or as they think they must act or choose a compromise solution between these two possibilities. Behaviours that do not maximize usability are by no means irrational. Sensible behaviour requires only marginal rationality, not total rationality at all times (Adamska, 2008).

By observing and describing the real behaviour of people in organizations, the researchers tried to find out what makes real decision-makers behave differently than the models of perfect rationality recommend them. There are many reasons for this state of affairs. They can be divided into two groups (Bolesta-Kukułka, 2003):

- psychological reasons, i.e. disturbances of rationality resulting from cognitive and emotional distortions that man's common thinking is subjected to;
- organizational reasons resulting from the very nature of the organization.

Bounded ethicality is based on the term bounded rationality, which explains how rationality is limited. Bounded rationality was first used by Simon (1986) who explained how people act rationally in their decision-making, their rationality is limited by the information they have, their own mental limitations and the limits on the time frame available for the decision-making. As such, Simon noted, people are more focused on reaching a satisfactory decision, rather than the optimal one.

Simon stressed that rationality have different meaning in economics and psychology and economy from the beginning was treating people as rational while psychology always concerned people as irrational. People make decisions on the purpose driven by motivations

and goals. In the investment process there are some goals that can be mentioned like to maximize the return, reduce the risk or look for a balance. The problem of achieving the goal is another fact since the behavioural biases may influence the decisions and affect the results of investment, therefore economic approach may emphasize irrationality while the psychological approach explain it in another way looking for the answer what constitute the rationality, not what it is in itself. The assessment of rationality should be in a context of situation, goals and the way they will be attended. In economics rationality is viewed in terms of choices it produces, in the other social sciences it is viewed in the process it employs.
Bounded rationality (Kahneman, 2003) was presented following Simon's ideas and states that decision makers are bounded rational and the utility maximization was replaced by satisfaction in this proposal. Kahneman and Tversky explored three programs of research: first heuristics that people use and the biases to which they are prone in tasks of judgement under uncertainty (Kahneman Tversky 1973, Tversky and Kahneman 1974, Kahneman et al. 1982). The second was concerned with prospect theory, a model of choice under risk (Kahneman and Tversky 1979, Tversky and Kahneman 1992) and loss aversion with riskless choice (Kahneman et al 1990, 1991, Tversky and Kahneman 1991). The third line was dealing with framing effect (Tversky and Kahneman 1981, 1986). Rational models are psychologically unrealistic and the previous areas are extended by unified treatment of intuitive judgements and choice based on the previous study of the relationship between preferences and attitudes (Kahneman et al 1999) and extends the model of judgement heuristics proposed by Kahneman and Frederic (2002). Kahneman (2003) claims that the most choices and judgments are made intuitively, rules that govern intuition are generally similar to the rules of perception. Cognitive approach and distinguishing the reasoning and intuition is one step toward understanding the decision process.In case of investment fund managers, who are professional and certified advisors, hard thinking may be the common behaviour that can affect the cognitive process of decision making. Intuition and reasoning can be joined in the systems of decision making in the cognitive process and one can be fast and intuitive, while the second is slower and effortful. Effort is the main difference and in case of investment fund managers it is common to use an effort. People who are occupied by demanding mental activity are much more likely to respond to another task by blurting out whatever comes to mind (Gilbert 1989). Accessibility is another issue that can be defined as ease with which mental contents come to mind (Higgins 1996). The acquisition of skills gradually increase the accessibility of useful responses to the effortless level. Intuitive decisions described by Klein (1998) show that experienced decisions makers working under pressure rarely need to choose between options because only one answer comes to their minds. Rational agent makes his choices in a comprehensively inclusive context with all relevant details of the present situation and expectations about all future opportunities and risks. People are characterized by narrow framing, mental accounting, decision bracketing but it can help in case of investment fund managers to make fast decision basing on hard thinking they are subject to.
Investors' decisions about a particular investment appear to be considered in isolation from the remainder of investors portfolio (Barberis, Thaler 2003). The time horizon investors evaluate their investment is very short and affects the equity premium puzzle (Benartzi, Thaler 1995). Narrow framing is far from risk neutrality than decision made in a more inclusive context. Tversky and Kahneman in 1974 stated that people rely on limited number of heuristic principles which reduce the complex tasks of assessing probabilities and predict the values to simpler judgemental operations. In general these heuristics are useful but sometimes they lead to severe and systematic errors. Heuristics such as representativeness, availability and anchoring were described to explain such bias in judgement under uncertainty. In 2002 Kahneman and Frederic proposed attribute substitution, changing the judgement under uncertainty.

There are many heuristics affecting the decisions of investors on the market. The group investment managers are in a specific situation since they do not make decisions over their money but behave as agents toward the owners of capital, providing rate of return in relation to their expectations. Even though they are professionals they decisions may be irrational but it can be expected, from the other hand, that the knowledge and experience may reduce the irrationality and influence the process of decision making in a positive way. Investment fund managers can be replaced by automatic systems and machines making decisions (Teixeira, De Oliveira, 2010) but we cannot be certain, that artificial intelligence built on the scheme of human brain will not suffer the behavioural traps.

In the literature there are many proposals describing and identifying the behavioural biases. It seems like this area of behavioural economics is trying to implement as much as possible from the science of psychology to explain the market inefficiency and investors irrationality. Loss aversion or prospects theory related to the individual's desire to avoid losses than comparable profits (Kahneman, Tversky 1979) is a trap that investors are a subject to when making decisions. The disposition effect is a behavioural trap that means a tendency to quickly getting rid of shares in upward trends and to excessively hold shares of companies whose prices are falling (Shefrin and Statman, 1985). Overconfidence is a bias that affects the decision of individual as well as corporate world. People have a propensity to overestimating their abilities and avoid taking the help of others in decision making process. These people are totally rely on their abilities and therefore they search less help and direction during the decision making process. According to Shefrin "pertains how well the people understand their own abilities and the limits of their knowledge". Excessive optimism' refers to the overconfident and overestimation of the favourable outputs rather than unfavourable outputs (Shefrin 2007). Confirmation bias is a cognitive trap or the ability of people to understand information in such a way that it confirms the previous ideas while avoiding explanation which disagrees with previously held beliefs (Shefrin, 2007). Illusion of control is defined as the propensity of people to believe that they can control or affects the outputs that in reality they have no affects over (Shefrin 2007). Illusion of control appears when people give wrong impression that their personal involvement influenced the outputs but the reality is quite different. Mental accounting is defined from the other hand as the process in which the people code, categorize and evaluate the economic outputs (Thaler, 1980). There are only examples of biases and the methods of recognizing them seems to be adequate for implementation in the presented survey.

The dominant paradigm regarding the response of asset prices to new information (first articulated by Fama, 1971) is that, since markets are efficient, asset prices should react immediately and in an unbiased manner to new information. Orphanides, Williams (2005) state that the learning process lead to different behaviour than in rational expectations equilibrium. A number of studies have considered the impact of the unexpected component of scheduled news released on individual markets (Balduzziet al. 1999). More information may induce not more but less clarity and common understanding among market participants, as there are limits to how much information can be digested effectively (Kahneman, 2003).

Every person has cognitive limits, i.e. a constraint to absorb and process information only up to a certain point. Such limits bind utility-maximising rationality, as conventionally conceived in economics. What is more, the investment-making process includes quasi-rational motives, which satisfy psychological needs . In the latter case, the paramount need is likely to be the desire to continue being able to decide at all, followed by the desire to control actions and to minimise cognitive dissonance, for example, with regard to previous decisions (Shefrin and Statman, 1985).

Efficiency of the market is based on the assumption that investors are rational, irrational investors behave chaotic and their decisions match and eliminate themselves, irrational investors decisions are eliminated by arbitrageurs (Shleifer, 2000). Brenner et al (2009) suggest that some of this evidence is consistent with existing theoretical arguments in the literature, e.g., those emphasizing the role of investors' trading activity.

Market sentiment is the overall attitude of investors toward a particular security or financial market. Market sentiment is the feeling or tone of a market, or its crowd psychology, as revealed through the activity and price movement of the securities traded in that market. In broadest terms, rising prices would indicate bullish market sentiment, while falling prices would indicate bearish market sentiment.

Abreu and Brunnermeier (2003) argue that noise traders are subject to animal spirits, fads and fashions, overconfidence and other psychological biases. Chung, Hung, and Yeh (2012) emphasize that sentiment-driven overpricing is more prevalent than underpricing due to the limits of arbitrage and short-sales constraints. All their evidence suggests that sentiment affects the stock price reaction to monetary policy news. Crucially measures that are orthogonalized to a set of macroeconomic variables, and thus, the state dependence is related to optimism or pessimism that is unwarranted by developments in economic fundamentals. It highlights the existence of a separate behavioural channel.

There is a wide scope of evidence related to the overreaction and under reaction of the market (Barberies, Shleifer, Vishny 1998) on the available information indicating, that the model of making decisions is not a simple project but more complicated process. Khan (2018) stated that behavioural approach is related to many aspects. Norms influence decisions of decisionmakers can be divided for social, market and legal. From their perspective there is a chance of simplifying the decision making process. Behaviour of other influence the decisions as well from the internalization, identification and conformity perspectives.

Investment fund managers may be subject to rules related to corporate governance. The theory of the agency was formulated by Alchian, Demsetz (1972), and it was developed by Jensen and Meckling (1976) who refer to it in the relationship between principals (shareholders) and agents (managers). According to the theory of the agency, the principals hire agents to accomplish their goals. Investors expect some actions of managers, who in turn may avoid implementing them (Ross 1973). Another proposal to explain the problem is corporate governance is the theory of stewards, which was presented by Davis et al. in 1997. Its authors stated that the steward aims to maximize and protect shareholders, because by doing so, it maximizes its own utility function. Fama (1980) and Shleifer and Vishny (1997), however, argue that managers' actions are motivated by building their own reputation on the market and questioning the assumptions of the steward theory at the same time. Both theories can be applied to the investment fund managers whose motivations can be related to the role they play in the relation to investors and their expectations.

Brzeszczynski et al (2015) stated that the role of institutional investors has grown substantially in emerging markets. Developed and developing countries policy-makers alike have promoted institutional investors as a pillar of their financial systems. Among many different objectives, they are expected to invest for the long term, follow market fundamentals, provide liquidity to countries and companies overlooked by other financial markets participants and reduce many of the shortcomings of the financial system. Although the significance of this group of investors is still relatively small in some emerging markets, they are nevertheless important players there and, therefore, they are subject of numerous research studies which document their positive role but sometimes also negative effects of their actions. Study presented in this paper extend the findings of Brzeszczynski et al. in the field of behavioural biases of managers on the emerging market.

HYPOTHESES/MODEL

The survey was conducted in 2017 and 2018, a total of 17 questionnaires were collected. The surveyed were managers of investment funds. The survey was divided into three parts. The first is a metric in which managers gave answers to questions about gender, the fund's time horizon and investment strategy. In the second part of the survey, the in-depth interview was conducted on the functioning of the fund. The questions concern both the fund's strategy and the basis for making decisions. In this part, the authors of the survey wanted to learn more about the nature of the fund and how it was managed. In total, 16 questions were asked. Both in the first and in the second part of the survey, there are closed questions, where the respondent has a choice of standardized answers as well as open questions. In the last part, the analysis of behavioural biases was conducted and 10 questions were asked in the form of tasks.
Task 1 measures the effect of certainty, or tendency to reevaluate certain events in relation to highly probable events. This task measures whether a person will choose a certain profit, but with a lower expected value (Option B - vulnerability) or choose an option more rational, potentially higher expected value (A) (Kahneman 2003).
Task 2 measures the reverse effect, which means that majority of people are characterized by risk aversion in the area of profits and risk in the area of losses. Selecting option A the tested person is susceptible to the reversal effect, especially when he chose answer B in Task 1 (Kahneman 2003).
Task 3 is a task for the effect of isolation (framing), that is related to different forms of presenting the same decision problem that may affect other decisions of the respondents (Kahneman 2003).
Task 4 is a task for the disposition effect measuring the tendency of investors to sell assets that have increased in value, while keeping assets that have dropped in value with the only rational option A, while others mean the effect of disposition. It may also examine the degree of "severity" of this disposition effect (Szyszka, 2009).
Task 5 is a task for overconfidence, the so-called effect of being better than average. Here, it is analyzed whether the respondents in various spheres will consistently indicate that they are above-average better in a given field (Czerwonka, 2017)
Task 6 is a task measuring the manifestation of overconfidence called "the illusion of control" which is based on the illusory conviction of many people that they can affect the course of future events of a random nature (Heath, Tversky 1991).
Task 7 is measuring the paradox of Ellsberg, analyzing the phenomenon of aversion to ambiguity (Segal, 1987).
Task 8 is a modified version of the Linda and attribute substitution problem assessing the representativeness heuristics (Tversky, Kahneman 1983).
Task 9 is a task for the sunk costs, managers often face (Kahneman, Lovallo, 1993, Szyszka 2009).
Task 10 is a task for fast and short thinking affecting the decisions (Kahneman, Egal 2011).
The essence of the survey was to determine the occurrence of behavioural heuristics in the group of people professionally associated with the management of investment fund portfolios. A research hypothesis has been put forward that these people with appropriate education and competences will be aware of the occurrence of specific behaviours and therefore will not be subject to behavioural heuristics. The study was aimed at examining the occurrence of the following effects: the effect of certainty, reversal, isolation (framing), disposition, overconfidence, ambiguity aversion - avoiding ambiguities, heuristics of representativeness, sunk costs and the effect of fast thinking.

METHODS

In the survey that is composed of two parts, in the first one the consistency of the questionnaire is analysed and in the second the statistical analysis of the answers to the questions that investment fund managers gave is made.
Cronbach's alpha is a measure of internal consistency, that is, how closely related a set of items are as a group. It is considered to be a measure of scale reliability. A "high" value for alpha does not imply that the measure is unidimensional. Cronbach's alpha is not a statistical test – it is a coefficient of reliability (or consistency). Cronbach's alpha can be written as a function of the number of test items and the average inter-correlation among the items. Below, for conceptual purposes, we show the formula for the Cronbach's alpha:

$$\alpha = \frac{N \cdot \bar{c}}{\bar{v} + (N-1) \cdot \bar{c}}$$

Here N is equal to the number of items, c-bar is the average inter-item covariance among the items and v-bar equals the average variance. [https://stats.idre.ucla.edu/spss/faq/what-does-cronbachs-alpha-mean/]

RESULTS

The first stage of work on the results of the research was to conduct a reliability analysis allowing to assess how many questions are actually able to identify the occurrence of certain behavioural effects. The analysis was carried out in three variants. For the sensitivity analysis, the output data should be presented in the form of a matrix presented in Table 1.

Table 1. Number of responses in subsequent variants of the analysis.

variant	task and number of answers																
I	**1**	**2**	**3a**	**3b**	**4**	**5a**	**5b**	**5c**	**5d**	**5e**	**5f**	**6**	**7a**	**7b**	**8**	**9**	**10**
A	11	8	9	5	5	15	12	8	9	10	1	6	13	12	10	10	16
B	5	9	2	5	1	2	5	9	8	7	16	9	1	3	7	7	1
C	0	0	5	5	2	0	0	0	0	0	0	0	0	0	0	0	0
D	0	0	0	0	7	0	0	0	0	0	0	0	0	0	0	0	0
II	**1**	**2**	**5a**	**5b**	**5c**	**5d**	**5e**	**5f**	**6**	**7a**	**7b**	**8**	**9**	**10**	**x**	**x**	**x**
A	11	8	15	12	8	9	10	1	6	13	12	10	10	16	x	x	x
B	5	9	2	5	9	8	7	16	9	1	3	7	7	1	x	x	x
III	**1**	**2**	**3a**	**3b**	**4**	**5**	**6**	**7a**	**7b**	**8**	**9**	**10**	**x**	**x**	**x**	**x**	**x**
A	11	8	9	10	5	55	6	13	12	10	10	16	x	x	x	x	x
B	5	9	7	5	10	47	9	1	3	7	7	1	x	x	x	x	x

Source: own study

The questionnaire contained 10 questions, but question 3 had two sub-tasks in which one could choose answers A, B and C. In addition, the fourth question had four possible answers. This led to the necessity of equating in the test the number of possible answers for all questions. In place of additional answers, it was always entered 0. The matrix prepared in this way was tested using the first variant of the study.

Table 2. Cornbach's alpha test results in option 1.

Avarage	69	Sum	275

Standard deviation	73,39	Variance	5386
Bias	0,59	Curtosis	-2,64
Minimum	7	Maximum	160
Cronbach's Alpha	0,96	Standardized alpha	0,96
Average correlation between positions	0,85		

source: own study in the Statistica package

In the first variant, the Cornbach alpha assumes a high value of 0.96. Confirmation of the correctness of Cornbach's alpha calculation is lower than the first alpha value calculated on standardized positions. Because the alpha is standardized at the same level, the test may not be fully reliable. The test was repeated in variant 2. In variant 2, the analysed questions with more than two possible answers were removed. This meant omitting questions 3 and 4.

Table 3. Cronbach's alpha test results in option 2			
Avarage	115	Sum	230
standard deviation	36,77	Variance	1352
Bias	0	Curtosis	0
Minimum	89	Maximum	141
Cronbach's Alpha	0,69	Standardized alpha	0,66
Average correlation between positions	1		

source: own study in the Statistica package

The estimated Cornbach alpha dropped significantly to 0.69. It is a value on the verge of recognition. The standardized alpha is lower, which makes the test more credible. The reasons for the drop in alpha value can be found in the construction of tasks. The fifth question consisted of six similar tasks, which always, according to the accepted research hypothesis, were expected to answer "no" marked as "B" in the matrix. A similar situation took place in question 7, where the same answer was also expected from respondents, this time in line with the adopted hypothesis was the answer "A". The similarity and the number of these questions may have resulted in lower reliability measured with alpha.

The third option assumed the answers in question 3 and 4 to the values "A" and "B". These questions checked the occurrence of the zero-one feature - that is, the bias occurs or does not. In question 3a, the trait occurred for the answer "A", while for the answer "B" and "C" the trait did not occur. The authors counted "B" and "C" answers to one category, adding them together. In question 3b, the trait existed for the answer "B", while for the answer "A" and "C" the trait did not exist. The answer number "C" was therefore added to the answer "A". Similarly in question 4. The trait did not occur for the "A" answer, the trait appeared for the "B", "C" and "D" responses. In this case, the "B", "C" and "D" links were added together and saved in the matrix as the "B" response. Thus, the number of rows of matrices was reduced to two, equalizing them for all questions. In addition, for question 5, all six variants were added to one case, together counting all the answers to "yes" - "A" in the matrix and "no" - "B" in the matrix. The results of the analysis for option 3 are presented in the table 4.

Table 4. Cronbach's alpha test results in option 3.			
Avarage	138	Sum	276
Standard deviation	38,18	Variance	1458

Bias	0	Curtosis	0
Minimum	111	Maximum	165
Cronbach's Alpha	0,85	Standardized alpha	0,73
Average correlation between positions	1		

source: own study in the Statistica package.

In the third variant, Cornbach alpha was obtained at 0.85 and standardized alpha at 0.73. On the basis of the tests carried out, it can be said that the questions allow to make correct inferences, hence a further interpretation of the collected data and generalization of results is possible. In the further part of the analysis, the data were aggregated in such a way as to check how many respondents answered the questions so that they confirmed the existence or not of the given effect. The results of such aggregation of data are presented in Table 5.

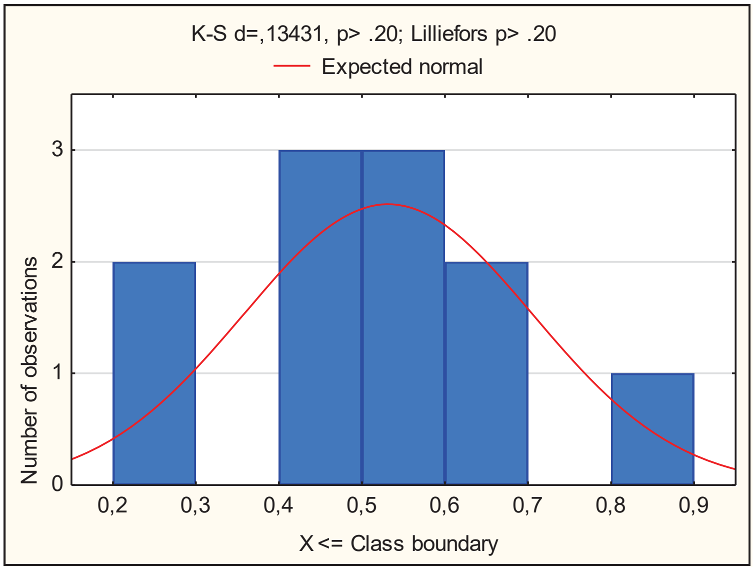
Table 5. Behavioural effects in subsequent questionnaires.

		Effect exists	Effect does not exists	Effect exists	Effect does not exists	Effect exists	Effect does not exists
Task1	Certainty effect	6	12	33,33%	66,67%	0	1
Task 2	Reverse effect	8	9	47,06%	52,94%	0	1
Task 3a	Isolation (framing) effect together with certainty and reverse	9	7	56,25%	43,75%	1	0
Task 3b	Isolation (framing) effect together with certainty and reverse	5	10	33,33%	66,67%	0	1
Task 4	Disposition effect	12	5	70,59%	29,41%	1	0
Task 5	Overconfidence effect	55	45	55,00%	45,00%	1	0
Task 6	Overconfidence effect	6	9	40,00%	60,00%	0	1
Task 7	Ambiguity aversion	12	5	70,59%	29,41%	1	0
Task 8	Represantivness heuristic	9	7	56,25%	43,75%	1	0
Task 9	Sunk cost	7	10	41,18%	58,82%	0	1
Task 10	Fast thinking	2	15	11,76%	88,24%	0	1
					Total	5	6

Źródło: opracowanie własne.

Although in 6 cases out of 11 it was confirmed that there is no selected behavioural effect, this analysis seems too vague to draw conclusions. Hence, a study was carried out on the distribution of the percentage of respondents responding in a way that negates the occurrence of subsequent effects. This distribution is shown in Figure 1.

Figure 1: The distribution of answers confirming the lack of successive effects.



source: own study in the Statistica package.

The study shows that the distribution of the percentage of responses negating the occurrence of a given effect has no normal distribution. Descriptive statistics are presented in table 6.

Table 6. Descriptive statistics of the percentage of respondents confirming the lack of successive effects.

N	11	Variance	3,05%
Avarage	53,15%	Standard deviation	17,45%
Median	52,94%	Bias	0,45
Minimum	29,41%	Curtosis	0,26
Maximum	88,24%		

source: own study in the Statistica package.

Skewness of 0.45 indicates a right-sided distribution, while positive kurtosis indicates a leptokurtic distribution. This information combined with information on the average of 53.15% and the median of 52.94% suggests that the majority of answers given by respondents show that they lack behavioural effects.

DISCUSSION AND CONCLUSIONS

Investment fund managers are expected to be rational and use their knowledge and experience to manage effectively the capital of individual investors, who trust their competences. The assumption of rationality is not under doubt and the knowledge and experience that the certified investment advisors must have seems to be sufficient to prove their rationality. In this survey the research toward verifying this hypothesis is presented.

The majority of answers given by respondents show that they lack behavioural effects. Thus, the hypothesis can be considered as positively verified. However, the results must be approached with a great deal of caution for at least several reasons. The first is a relatively small sample of respondents. In addition, the rightness of the distribution of response rates is not dominant, which is confirmed by the mean and median values. The Cronbah alfa was analysed to prove that the questionnaire that was used for the research is built properly. Investment advisors have all the information and are able to use them effectively because they are rational. Therefore, if there were only investment funds on the market, the market could be more effective. Direct comparison with investors operating on other markets could prove that there is no difference between rationality of investment fund managers on a global market.

ABSTRACT

This research explores the influence of personality types on ERP system learning performance. The four personality types are determined using cluster analysis based on Big Five personality traits: conscientiousness, neuroticism, extraversion, openness, and agreeableness. The results suggest that prior computer experience, learning motivation, demographic factors (gender, age, year in school), and social culture influence moderate relationships between personality types and ERP learning performance.

KEYWORDS: Personality traits, Information Systems, ERP, Learning Performance

INTRODUCTION

Enterprise Resource Planning (ERP) systems are large-scale, complex, heavily procedural-, process-, and detail-oriented computer systems (Kumar &Van Hillegersberg, 2000; Shtub, 2001; Tenhiala & Helkio, 2015). Due to their intricate nature, it can be challenging for beginners to familiarize themselves with and become adept at utilizing ERP systems. The lack of ERP-relevant technical, analytical, and business process management skills in IT professionals and end-users can hinder the adoption and successful use of such systems (Sumner, et al., 2006). As a result, the need for a skilled ERP workforce put pressure on universities to educate students with ERP knowledge (Charland, et. al., 2015).

Finding an efficient mechanism for universities to educate students with ERP knowledge and for various companies to recruit talented and qualified workers has presented itself as a difficult task. Although a multitude of factors contributes to the success of students learning ERP systems, the ability to identify factors with the highest correlation to success, or particular clusters of these factors could be a significant advancement. As personality traits are perceived to be correlated with job performance, companies often utilize personality assessment in their quest for skilled IT workers (Lui, et. al., 2008). This study aims to determine to determine if there is an ideal personality type (a combination of the Big Five personality traits) that correlate to the success of learning ERP systems.

LITERATURE REVIEW

Challenges in Complex Information System Education

ERP system is “an integrated system where a unique database provides flow for information continuously and consistently for the entire company” (Wadate, 2014; Klaus & Gable, 2000) and becomes a strategic tool that helps an organization to gain a competitive edge through integrating all business processes and optimizing the available resources available. As an ERP system integrates all information systems across an organization, it creates an interconnection between functions and various processes (Barki & Pinsonneault 2002) and that contributes to the complexity in learning and operating the system.

The widespread implementation of ERP systems over the last two decades has led to the challenge for companies to recruit a skilled ERP workforce and for universities to educate graduates with ERP knowledge (Charland, et al., 2015). As most IT failures stem from a lack of user acceptance rather than poor technical quality (Nelson and Cheney, 1987), the successful implementation of ERP systems requires effective, reinforced, and updated training of personnel (Markus et al., 2000; Gargeya and Brady, 2005). Because of the complexity of an ERP system, the learning curve is steep and has become a challenge for both educators and learners. Furthermore, the steep learning curve and heavy infrastructure investment needed by the educational institutes result in few academics who have intimate knowledge of the strengths and weaknesses of ERP (Becarra-Sanchez, et. al., 2002) and that had limited the ability of the U.S. universities in addressing this industry critical need. Such a shortage had led to IT outsourcing that hinders our nation’s competitiveness and economy.

Léger (2006) and Seethamraju (2011) believe that the challenge for students to learn the business process and ERP software in the classroom is the lack of knowledge and understanding about real-world business processes as well as the limited IT skills to operate an ERP software application. To be successful in learning an EPR system, Boyle and Strong (2006) report that a student needs to possess not only technical skills such as operating system, system analysis or data management, but also technology management knowledge, business functional knowledge, interpersonal skills and teamwork skills. Researchers have observed correlations between personality traits and one’s interpersonal skills and teamwork skills (Riggio, 1986; Wodarski, et al., 1988; Neuman & Wright, 1999). As a result, personality traits and assessment are often utilized by companies in their quest for skilled IT workers (Lui, et. al., 2008).

Personality Traits and Academic Learning Performance

Since the late twentieth century, psychologists have used the Big Five Trait model to assess and describe people's unique personality styles. The traits included are conscientiousness, neuroticism, extraversion, openness, and agreeableness. Each trait is presented as a spectrum, on which subjects can score moderately or to either extreme. Conscientiousness is a measure of how organized, disciplined, and achievement-oriented a person is (Komarraju, et. al., 2011). People who are highly conscientious have good self-control, determination, purposefulness, dependability, and the will to achieve (Grehan, et al., 2011). Neuroticism is known as the degree of emotional stability, anxiety, and impulse control a person has. Extraversion refers to a person's degree of sociability, talkativeness, and assertiveness (Komarraju, et. al., 2011). People who are highly extraverted will have a tendency to be cheerful, assertive, and social (Grehan, et al.,, 2011). Openness is the measure of a person's intellectual curiosity and preference for novelty and variety. When a person is highly open they are receptive to new ideas, attentive to inner feelings, and prefer varied sensations (Grehan, et al., 2011). The last trait, agreeableness, is characterized by how helpful, cooperative, and sympathetic a person is.

Meta-analyses have shown a connection between personality traits and academic success. For example, certain personality traits have been linked to learning styles such as deep and shallow processing. Individuals who are highly conscientiousness, open, extraverted, and emotionally stable tend to process information with the goal of mastery through deep understanding and long-term retention as opposed to the shallow goal of performing well on assessments. (Furnham, 1996; Komarraju et. al., 2011). Conscientiousness, openness, and agreeableness each show a positive relationship to academic success (Paunonen & Ashton, 2001; Laidra et. al., 2007) with conscientiousness having the highest relation and being the strongest predictor (Poropat, 2009). Meanwhile, neuroticism and extraversion were negatively related to success in academics (Chamorro-Premuzic & Furnham, 2003; Nguyen et. al., 2005; O'Connor & Paunonen, 2007; De Raad & Schouwenburg, 1996). Agreeableness and openness were also shown to have an impact on fostering collaborative learning (Komarraju et. al., 2011).

Although personality traits & academic performance are clearly linked, learning styles and academic environment may complicate how these connections manifest. When in specific academic settings, the impact of certain traits on academic success varies. In learning environments and contexts that require knowledge acquisition, conscientiousness was shown to be the best predictor of academic success. However, in graduate settings that tend to emphasize skill acquisition and application, neuroticism was shown to be linked to increased performance (Ferguson, 2014).

Researchers further classify Big Five personality traits into higher-order factors such as stability (Neuroticism, Agreeableness, Conscientiousness) and plasticity (Extraversion, Openness) (Buruk, et al., 2017; Davies, 2014; DeYoung, 2006; DeYoung, et al., 2002). As personality traits often exist as dynamic systems of several personality traits for an individual (Specht and Luhmann, 2014), personality types (or combinations of personality traits) can provide a more comprehensive and detailed picture of an individual's character than do the individual traits (Specht and Luhmann, 2014; Tyseen, et al., 2007). Cluster analysis is often used to derive personality types (Specht and Luhmann, 2014) and common personality types are resilients, overcontrollers, and undercontrollers (Gerlach, et al., 2014; Donnellan and Robins, 2010). Resilients are individuals with high scores on all of the Big Five personality traits and are comparatively emotionally stable, extraverted, open to experience, agreeable, and conscientious. Undercontrollers are individuals with particularly low on conscientiousness and agreeableness. Overcontrollers are those who with particularly introverted, neurotic, and less open (Donnellan and Robins, 2010).

Prior Computer Experience, Demographic factors, Motivation, and Culture/Social Influence

Academic motivation comes in different forms and scales and is one of important predictors that has significant impact on academic achievement (Fairchild, et al., 2005). Research has also provided empirical evidence that experience is a predictor of performance (Avolio, et. al., 1990; Schmidt & Hunter, 1998), but that the relationship between these two measures is moderated by length of experience and job complexity (Mcdaniel, et. al. 1998). Gender (Wawrzynski, 2003; Li, et. al., 2015), prior knowledge (Avolio, et. al., 1990; Mcdaniel, et. al, 1998), academic performance (e.g., GPA), academic experience (Cheung & Kan, 2002; Wawrzynski, 2003), and cultural and social influences (Wawrzynski, 2003; Fatemifar, et. al.,2015) have also shown influence in IT education.

RESEARCH QUESTIONS, HYPOTHESES, AND METHODOLOGY

The objective this research is explore if there is an ideal personality type (i.e., a combination of the Big Five personality traits) that predict success in learning ERP systems and concepts. Prior computer Experience, culture or social influence, learning motivation, age, gender, and year in school are included as moderating variables in this study. Prior computer experience is measured by three participant self-reported measures including (1) years of information system (IS) experience outside of classroom, (2) number of ERP classes completed previously, and (3) the computer savvy level. The degree of excitement on the selected course, on IT in general, and on using an ERP system are used to represent learning motivation with a reliability score of Cronbach's Alpha 0.838. Culture and social influence are represented by participants' school location, race, and English proficiency. Participant demographic characteristics are represented by age, gender, and year in school.

H1. Personality types have influence on ERP learning performance.

H2. Prior Computer Experience moderates the relationships between personality types and ERP learning performance

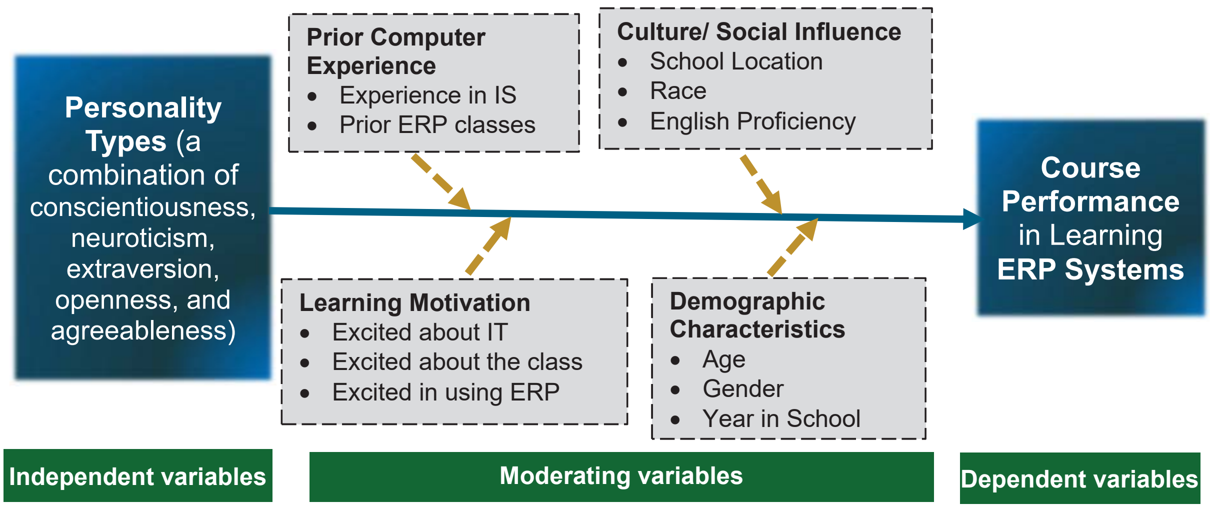
H3. Learning motivation moderates the relationships between personality types and ERP learning performance

H4. Culture and Social Influence moderates the relationships between personality types and ERP learning performance

H5. Demographic characteristics moderate the relationship between personality types and ERP learning performance

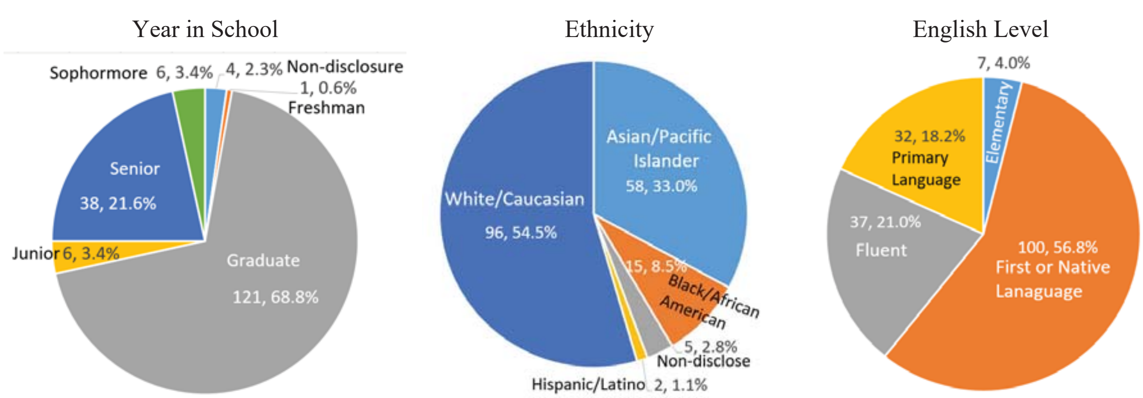
The success in learning ERP concepts and concepts is measured by course grade. The personality types are derived from cluster analysis based on the Big Five personality traits of conscientiousness, neuroticism, extraversion, openness, and agreeableness. The Mini-IPIP. This twenty-item assessment is an abbreviated version of the original International Personality Item Pool (IPIP) which contains only four questions to assess each trait. Studies conducted to test the reliability and validity of the Mini-IPIP have confirmed both; the Mini-IPIP is recommended as an efficient yet effective personality assessment tool (Donnellan, et al., 2006). Each item in the 20-item questionnaire were rated on a 5-point likert scale from 1 is Very Inaccurate to 5 is Very Accurate. The assessment also includes demographic questions about age, gender, year in school, self-reported technology level, ethnicity, and other relevant data. The research model is summarized in Figure 1.

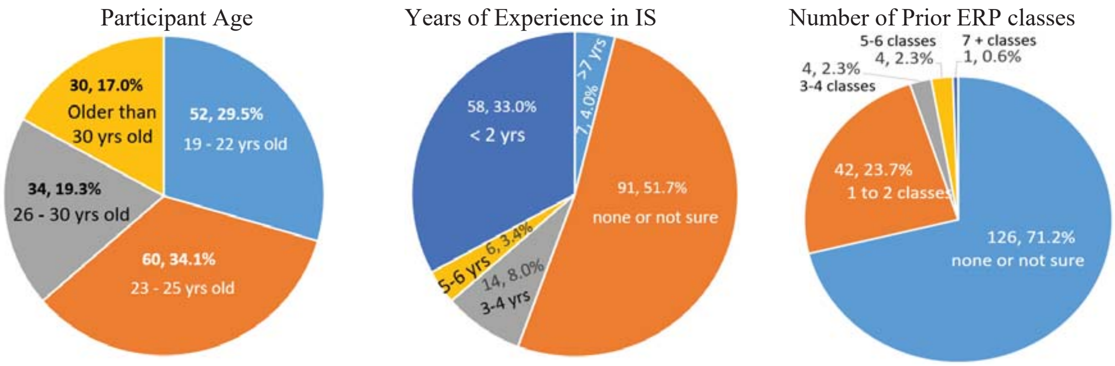
Figure 1 Research Model



Data were collected from two universities located in a rural university town and in a metropolitan area in the Midwest of the United States over three semesters: Fall 2016, Spring 2017 and Fall 2018. Among a total of 176 students with valid responses, female, male, and no disclosure students are 38.1%, 59.7%, and 2.3% respectively. Participants enrolled in the rural area university and the metropolitan area university accounts for 48.9% and 51.1% respectively. Graduate students, undergraduate, non-disclosure students are 68.8%, 28.9%, and 2.3% respectively. About 54.5% of participants are white or Caucasian, 33% are Asian or Pacific Islander, 8.5% are Black or African American, 1.1% is Hispanic or Latino, and about 2.9% are other or non-disclosure. Participants indicate that English is their first or native language and primary language is 56.8% and 18.2% respectively. About 21% of participants speak English fluently and about 4% speak at the elementary level. Figure 2 provides a summary of participant information.

Figure 2. Year in School, Ethnicity, and English Ability Information among Participants





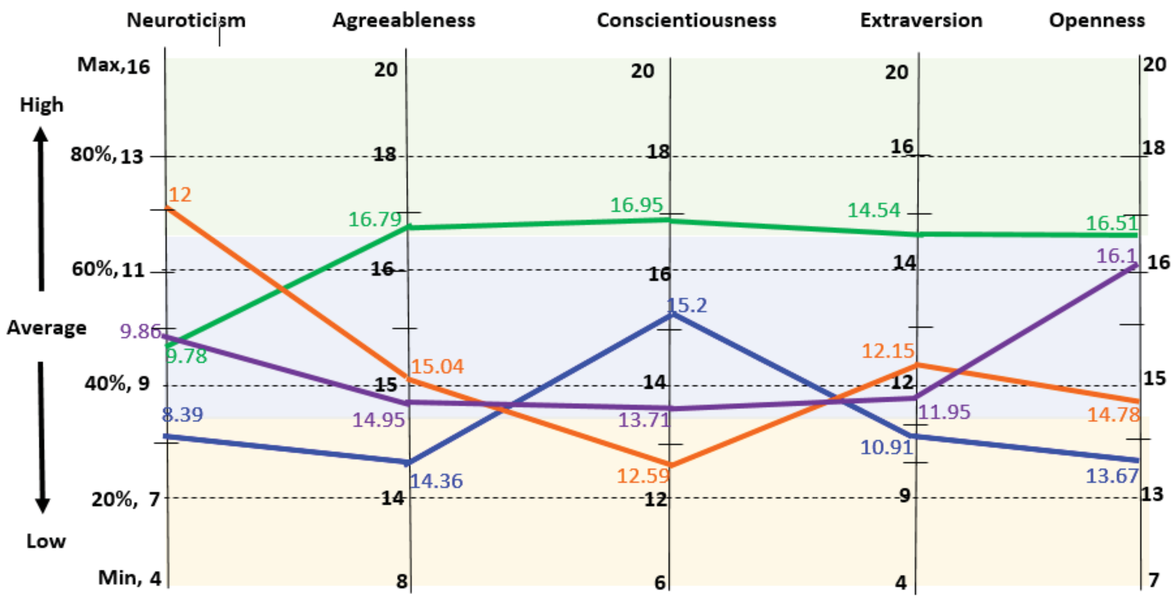
RESULTS AND OBSERVATIONS

Cluster analysis was conducted with the number of clusters ranged from three to ten. A four-cluster is selected based on the Elbow methods and the cluster centers, the distance between clusters, and the number of cases in each cluster. As shown in Figure 3, the following general description is derived for each personality type:

- Personality type one scores low on agreeableness, extraversion, openness, and neuroticism which means they are not cooperative, withdrawn, play it safe, and are emotionally stable. Their conscientiousness score is relatively high, meaning they are relatively disciplined and studious.
- Personality type two scores high on agreeableness, conscientiousness, extraversion, and openness which means that they are highly cooperative, organized, outgoing, and willing to take risks in trying new things. They score average on neuroticism which means their emotional stability is typical.
- Personality type three scores relatively low on agreeableness, conscientiousness, extraversion, and openness meaning they are not cooperative, studious, outgoing, or curious. Their neuroticism scores are comparatively high meaning they are very anxious and emotionally unstable.
- Personality type four scores relatively low on agreeableness, conscientiousness, and extraversion meaning they do not care much about group cohesion, are not very organized and are reserved. The relatively high score on openness indicates that they are imaginative and creative and the average score on neuroticism indicates that they have a typical level of emotional stability.

Generalized Linear Model analysis was conducted and results are summarized in Table 1. The influence of personality types (clusters) on ERP learning performance is significant at the α = 0.05 level. The moderating effects of English proficiency, race, years of IS Experience, degree of computer savvy, gender, age, school level, excited about the class, excited about using ERP system, and excited about IT on ERP learning performance are statistically significant at α = 0.05 level. The moderating effects of school location and number of prior ERP classes on relationships between personality types and ERP learning performance are not statistically significant at α = 0.10 level.

Figure 3 Parallel Diagram of Cluster Average



Personality Types (number of cases)	Neuroticism	Agreeableness	Conscientiousness	Extraversion	Openness

Prior Computer Experience and Personality Types on ERP learning performance

As shown in Table 1, prior computer experience represented by years of IS experience, number of prior ERP classes, and the self-reported level of computer savvy significantly moderate relationships between personality types and ERP learning performance. As shown in figure 4a, the learning performance decrease as participants' prior IS experience increase for type two personality participants. For participants with the other three personality types, participants with some level of prior experience in information system (IS) had better learning performance than those who do not have any experience. However, the impact of prior IS experience becomes negative for participants with more than seven years' experience. Although more analysis and research are needed to identify the root causes, it is possible that those participants with longer IS experience may have been to a management position and their IS experiences are more relevant to managerial and analytical and less relevant to the procedural and detailed oriented ERP tasks. This finding can also result from the complexity of ERP system as reported by McDaniel, et al. (1998) that that the length of experience and job complexity moderate experience and performance (McDaniel, et al., 1998)

As shown in Figure 4b, learning performance improve as the number of prior ERP classes increase regardless of personality types. However, the performance seems to not differ significantly after having three or more prior ERP classes. One interesting observations from Figure 4b is that participants who ranked themselves as least computer savvy (strongly disagree) had the strongest performance. Participants with personality type two and are not computer savvy (strongly disagree or disagree) performed better than those who ranked them as computer savvy (agree and strongly agree). On the other hand, participants ranked themselves as not computer savvy (disagree) had very different performance level. Participants are not computer savvy (disagree) with personality types one and four had the lowest performance level while those with personality types two and three had strong performance.

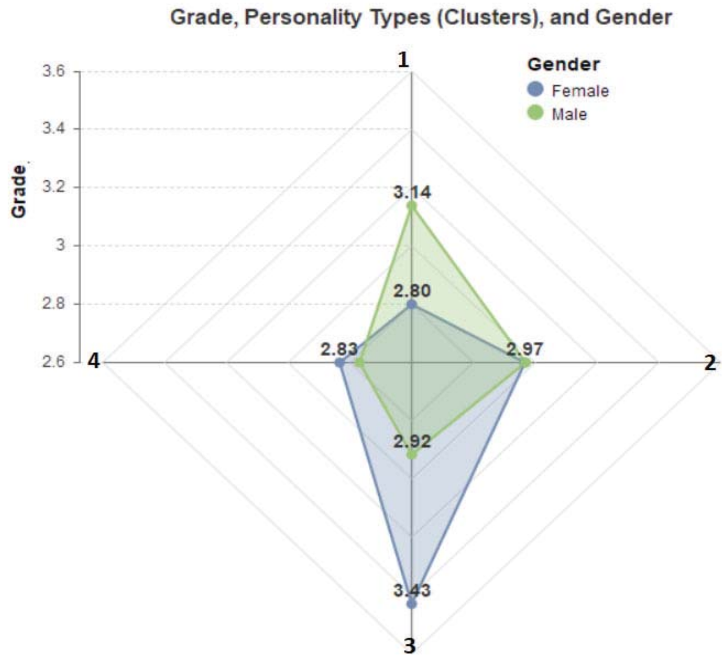
Demographic Characteristics and Personality Types on ERP Learning Performance

The results indicate that demographic characteristics of gender, year in school, and age moderate relationships between personality types and ERP learning performance. As shown in Figure 5, except personality type one participants, female participants typically performed better than male participants. An interesting observation is the performance between male and female participants are completely opposite. For type one participants, female participants performed significantly worse than male participants. On the other hand, female participants performed significantly better than male participants for those who with a personality type three. Although additional studies are needed to identify causes, it is observed that closely aligned personality type and gender characteristic result in better performance. Comparing with type three participants, personality type one participants have relatively low neuroticism, agreeableness, extraversion, and openness, but exhibit a higher level of conscientiousness, so they are more emotionally stable, more studious, more cooperative, less outgoing, and less open to new ideas and are more closely aligned with a typical male profile. As a result, male participants outperformed female participants. Type three participants are more emotionally unstable, more cooperative, more outgoing, more willing to try new things, and less studious, and those are more aligned with the characteristics of a female. As a result, female participants thrive more than male participants.

Figure 5 Gender, Personality Types, and ERP Learning Performance

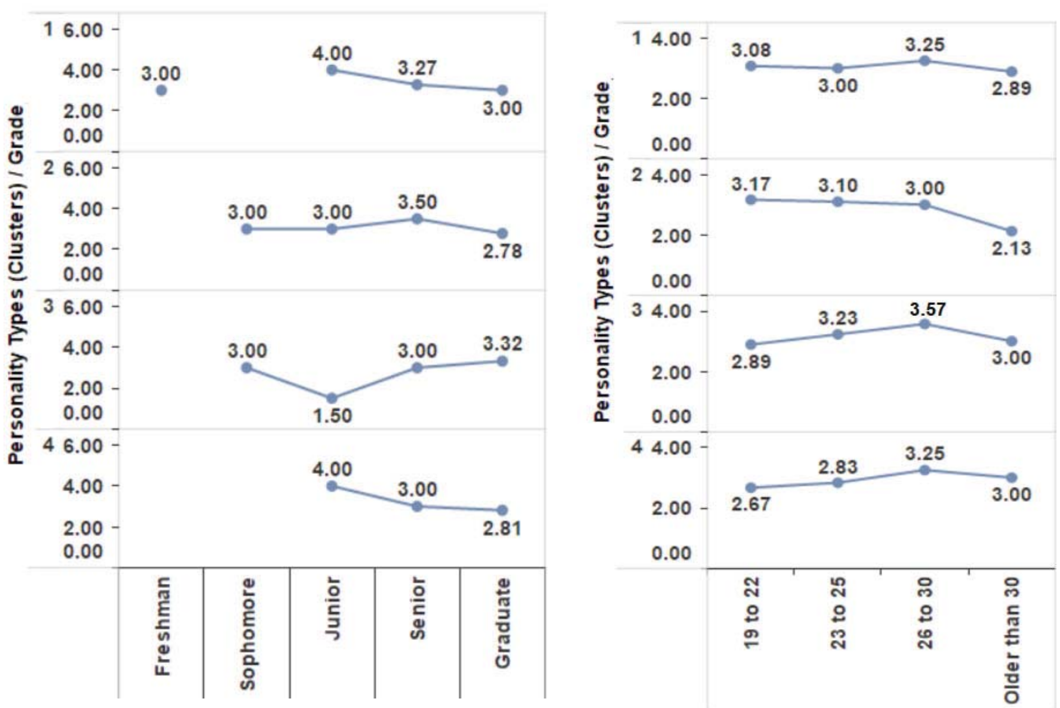


For personality type one and type four participants, results indicate that ERP learning performance decrease as participants advance through their academic majors and that senior students outperform graduate students, as shown in Figure 6a, For type two participants, it is also observed that senior students tend to outperform other groups of students. Other than personality type three, graduate students had lower performance than undergraduate students for the other three personality types. Boyle and Strong (2006) report that a student needs to possess not only technical skills such as operating system, system analysis or data management but also technology management knowledge, business knowledge, problem-solving, analytical and team skills to be successful in learning ERP systems. As the curriculum for the participating undergraduate students require both business core classes (accounting, finance, marketing, management, business capstone) and information technology core classes (two programming courses, Management Information System, digital media, ERP Introduction), undergraduate students are more likely to be successful in learning ERP than graduate students who specialized in either information technologies or business administration (MBA students).

For personality type two participants who exhibit high level of agreeableness, conscientiousness, extraversion, and openness, it is observed that younger participants had better ERP learning performance than older participants and the performance decrease as the age of participants increase, as shown in Figure 6b. For participants younger than 30 years old with a personality type of one, three, and four, learning performance seems to increase as participants' age increase. Participants who are older than 30 years old perform worse than other age groups for all four personality types.

Figure 6 Year in School, Age, Personality Types, and ERP Learning Performance

a. Year in School b. Age



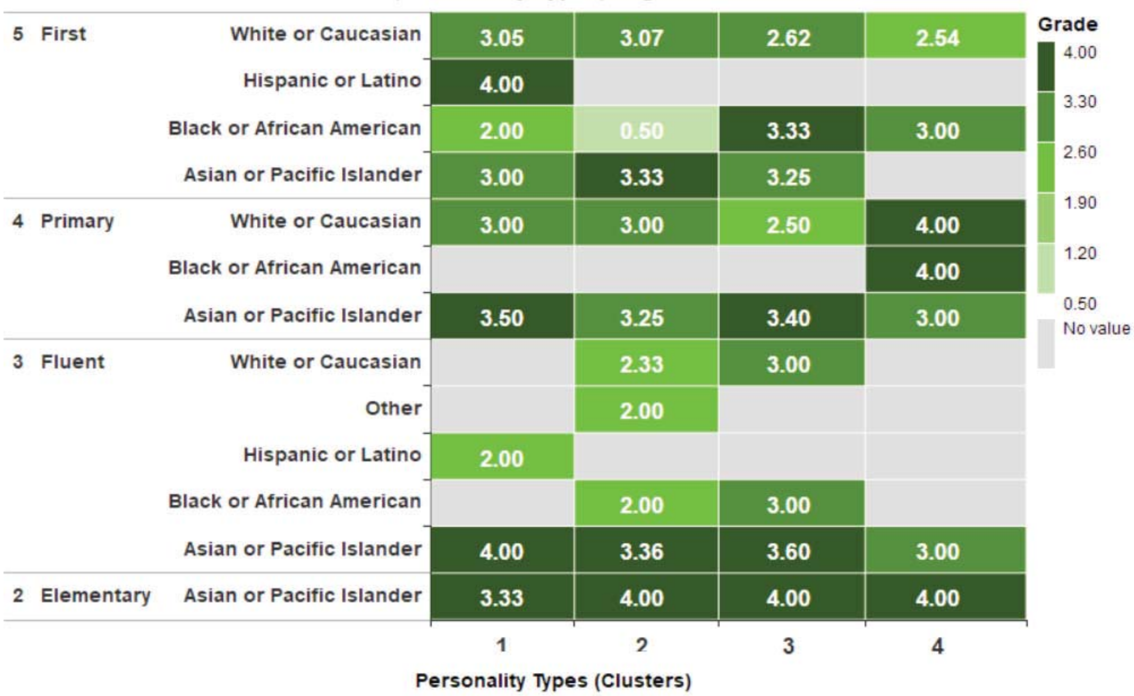
Culture and Social Influence and Personality Types on ERP Learning Performance

As shown in Figure 7, it is observed that participants who indicate English is their first or native language have lower ERP learning performance than those with lesser English proficiency. Participants with the least English proficiency (i.e., elementary level) outperform participants who have better English proficiency. In general, ERP learning performance decrease as English proficiency increase regardless of personality types and ethnicity.

Further analysis reveals that participants with Asian or Pacific Islander origin tend to self-report lower English proficiency, but their performance is significantly better than other ethnicities regardless of personality types, as shown in Figure 8. Although additional studies are needed to identify causes, Asian or Pacific Islander origin students tend to exhibit stronger mathematics, reasoning, and memorization skills. As an ERP system is complex and highly procedural, stronger mathematics, reasoning, and memorization skills often proof beneficial in operating or troubleshooting the system.

Figure 7 Influence of English Proficiency and Personality Types

Figure 8 Influence of Personality Types, English Proficiency, and Race on Course Grade



Learning Motivation and Personality Types on ERP Learning Performance

Participants who reported a positive excitement level (agree or strongly agree) perform better than participants who had a negative excitement level (disagree or strongly disagree), as shown in Figure 9. Furthermore, results indicate that learning performance improves as participants' level of excitement increase regardless of personality types. However, ERP learning performance of personality type 2 participants is not consistent. For the "excited about the class" measure, those who responded "strongly disagree" perform better than those who with other responses. For the "excited about IT in general" measure, those who responded "disagree" had the lowest performance than participants who had other responses.

SUMMARY, LIMITATIONS, AND FUTURE RESEARCH DIRECTIONS

As personality types can provide a more comprehensive and detailed picture of an individual's character than individual personality traits (Specht and Luhmann, 2014), this study identifies four different personality types derived from Big Five personality traits (i.e., conscientiousness, neuroticism, extraversion, openness, and agreeableness) through cluster analysis. The results suggest that participants' prior computer experience, demographic factors of age, gender, and year in school, culture and social influence, and learning motivation moderate the relationships between personality types and ERP learning performance.

Only college students were included in this study is one of limitations. Studies that include additional participant groups such industry employees or high school students are invaluable in generalize results. Although this study presented many interesting observations, additional studies need to be conducted to identify causes, to derive theories, and to create decision models to those observations are invaluable.

Pricing the Cloud: A QoS-based Optimal Design

Yang Lu
Old Dominion University
College of Charleston
Email: y1lu@odu.edu

ABSTRACT

Cloud computing has a major impact on the IT industry. How to price and allocate cloud resources to meet users' requirements is an important problem. This paper proposes a dynamic mechanism to price cloud services, which can work in complex environments such as distributed system and uncertain budget constraints. A directly relationship between QoS and price is established. The approach uses an optimization technique to estimate the potential transaction price in the distributed network. It can allocate cloud resources under uncertainties, where providers can optimize their revenues, and consumers can obtain the resources at a relatively low price.

KEYWORDS: QoS (quality of service), Reliability, Availability, Robust optimization auction, Optimal revenue, Budget constraint

INTRODUCTION

"Cloud computing: a model for enabling ubiquitous, convenient, on-demand network access to a shared pool of configurable computing resources (e.g., networks, servers, storage, applications, and services) that can be rapidly provisioned and released with minimal management effort or service provider interaction." (Mell & Grance, 2011) Cloud services include Software as a Service (SaaS), Infrastructure as a Service (IaaS), and Platform as a Service (PaaS) (Josep, et al., 2010). Cloud service can be treated as an ordinary commodity that has spread through the Internet. Currently, leading companies are gearing up to use cloud services for their businesses: Amazon's AWS (Amazon Web Services), Google's GAE (Google App Engine), Microsoft's Azure, and IBM's Cloud. For instance, Amazon Elastic Compute Cloud (Amazon EC2) offers seven instance purchasing options: On-demand Instances, Reserved Instances, Scheduled Instances, Spot Instances, Dedicated Hosts, Dedicated Instances, and Capacity Reservations. But they have not yet provided roust optimal design directly related to QoS metrics (reliability and availability). Based on the SLA (service level agreement), the overall performance of cloud service is guaranteed to some extent, but the relationship between price and QoS metrics still isn't clear. Usually, customers can purchase cloud service via various strategies, at certain prices which are determined by costs and by an economy proxy (supply and demand). As a special commodity, the cloud not only has costs that are similar to those of other goods, but it also has QoS-related costs that aren't easy to estimate. It is possible that customers bid on cloud services based on the QoS metrics that both provider and customer really care about.

Cloud computing provides us with on-demand and remote QoS-embedded services that are scalable, elastic, complex, and potentially decentralized (Zhang, Cheng, & Boutaba, 2010). Quality of service is crucial to the cloud industry. On the one hand, providers seek to improve the overall performance of cloud service to compete in the industry; on the other hand, customers expect cloud service to have high QoS standards, especially in its reliability and availability. The reliability is actually the probability that a system will be operational in a given time interval without any failures (Armbrust, et al., 2010). The availability is actually the probability that the system will be up and functional correctly in a certain time period (Armbrust, et al., 2010). High availability, with high costs and price, is essential to guarantee QoS, to maintain customer's confidence, and to attract more customers. More customers are involved in the use of cloud services, a lower price each customer needs to pay. In other words, it is the economies of scale. The percentile of multiple Nines and Fives is defined to express the different level of availability in general, e.g., 3 Nines is 99.90% and 4N5 is 99.995%. In our study, we will briefly illustrate the relationship between reliability and availability by MTBF (Mean Time between Failure) and MTTR (Mean Time to Repair). A function between availability and price then will be established as the reference for participants to estimate the price of cloud services.

One customer's requirement for a specific service is not independent of those of other customers. Indeed, a customer using a specific service has some connection with the needs of other customers. In an auction, cloud services are auctioned concurrently, and bidders can compete for services. Since QoS is important, both for the provider and the customer, there is the potential to add QoS metrics (availability) into the pricing algorithms. A mechanism allocates services, associated with the expected QoS, to customers.

Depending on the customer's different requirements for cloud services, suppliers need a viable and efficient pricing mechanism that is critical to the allocation and optimization of the available cloud resources. For suppliers, customers will bid for their own budget for better service, and the suppliers will select customers based on their bids, provide resources for higher-priced customers and guarantee the cloud's QoS. For customers, they can freely choose resources according to their own needs. However, due to the liquidity of marginal customers, whose bidding is uncertain, and it is difficult to estimate the demand based on existing bids. The cloud resource scheme based on uncertain bid auction has the potential to improve both economic efficiency and optimal profits.

Our design is a QoS-based robust optimization mechanism that includes multiple customers bidding for a variety of cloud services with QoS guarantees offered by different providers in a distributed network. The reasons why our pricing model combines QoS metrics with auction design are (1) cloud computing is a new and advanced computing technology. Cloud services are different from ordinary products or services, which can be evaluated relatively easily based on supply and demand. However, the cloud has unique QoS features, such as reliability and availability. An auction is a proper approach to evaluate not-easy-estimated parameters of cloud. (2) Cloud pricing is still in its early development stage (Zheng, et al., 2014). There is no direct reference to pricing cloud services based on QoS metrics. Hence, an auction algorithm is an appropriate way to estimate the valuation of certain cloud services and to allocate resources efficiently. (3) An auction design can sell services in a way that customers come to expect, specifically based upon Service Level Agreement (SLA) and Quality of Service (QoS). There are no obvious QoS-based pricing algorithms in the extant literature. The most likely exponential relationship expresses the intrinsic connection between price and QoS metrics and offers a straightforward pricing reference to both provider and customer.

In this paper, we address the issue of designing a robust optimal mechanism, through which cloud services are distributed between provider and customer, along with QoS. The goals are (1) to propose QoS-embedded availability to price and to allocate cloud services from providers to customers, and (2) to flexibly set up a dynamic pricing mechanism to enable budget constraint. Our contribution is to build a QoS-based dynamic auction model to effectively allocate cloud resources. Specifically, as a critical indicator of QoS, availability is used to estimate the value of cloud service in the pricing algorithms. Because of the unique features of the cloud, the relationship between price and QoS availability is not simply linear. We apply a robust optimal scheme to allocate resources and to optimize revenues among participants.

The paper has the following structure. A complete overview of the auction design for cloud computing (fixed pricing strategy, dynamic pricing strategy, and auction pricing strategy) and discussion of QoS-embedded optimal pricing strategy are addressed in Section 2. Section 3 depicts the relationship between QoS metrics (availability) and price. We describe and explain the detailed stages of functions and scheme in Section 4. Section 5 explores future directions. The final section summarizes the paper.

CLOUD PRICING MECHANISM

Cloud-related usage is become more and more popular in the daily life. Pricing is one of the important issues in the cloud industry. In this paper, we divided cloud pricing mechanisms into three categories: fixed pricing strategies, dynamic pricing strategies, and auction pricing strategies. Specifically, the three popular fixed pricing strategies are pay-as-you-go, subscription, and pay-for-use. Dynamic pricing strategies have many different algorithms, such as Genetic Model, Financial Optional Theory, Markov Decision Process, etc. Auction pricing strategies consist of various auction design, such as English auction, sealed-bid auction, double auction, and combinatorial auction. A summary of cloud pricing scheme is addressed in Table 1.

Fixed Pricing Strategy

Provider presents the price of cloud service, and customer pays the amount if the customer expects to use the service. The price is stable. Although the fixed pricing strategy is straightforward to both provider and customer, the mechanism is unfair to all potential customers who don't have the same needs (C. S. Yeoa, S. Venugopalb, X. Chua and R. Buyyaa, "Autonomic Metered Pricing for a Utility Computing Service", Future Generation Computer Syst., vol. 26, no. 8, (2010).). Even to provider, the mechanism is not an optimal strategy, especially when demand is higher than supply.
Pay-as-you-go, which charges customers based on their overall resource usage. The customers pay for the amount they consume of a product or the amount of time they use a certain service. Pay for resources, which charges customers based on the technical features of cloud services, such as the storage and bandwidth. Subscription, customers subscribes with certain service for a time period. Subscription is another type of fixed pricing, in which the customer pays a fixed amount of money to use the service for longer periods at any convenient time or amount. Provider presents the price of cloud service, and if a customer wishes to use the service, the customer pays the amount according to the agreement. In the cloud industry, three pricing mechanisms are widely employed, pay-as-you-go, subscription, and pay-for-use. Pay-as-you-go charges customers based on the overall resource usage for a certain time period. Subscription is another type of fixed pricing, in which a customer pays a fixed amount in advance to use the service for a longer period of time. Depending on the technical features of cloud services, such as storage and bandwidth, a customer is required to make pay-for-use fees. The common feature of these three pricing mechanisms is that price remains stable over the contact time. While fixed pricing strategies are straightforward to both provider and customer, the mechanism is inappropriate to all customers because not all customers have the same needs (Al-Roomi, et al., 2013; Luong, et al., 2017). Even for providers, the mechanism is not optimal, especially when demand is higher than supply in the real world. Our pricing design is embedded with an auction algorithm that can offer all customers with equal opportunities and competition associated with dynamically changing prices.
The most prevalent method of pricing in cloud is pay per use, which is based on Units with constant price. Another common pricing model is subscription, whereby users sign a contract (subscribe) based on constant price of service unit and a longer period of time, for example six months or a year. Obviously, customers and providers would like to use static and simple pricing model in order to ease payment prediction. Nevertheless, for high-value services dynamic pricing can be more efficient.

Dynamic Pricing Strategy

The final price is calculated by a dynamic pricing mechanism. In this pricing strategy, prices are changing with respect to market condition or status. An appropriate pricing algorithm is an effective way to estimate the value of cloud service and to allocate the available resources. Aiming at providing high QoS, Sharma et al. employed the financial option theory and the related economic model to capture the real value of cloud service within the lower and upper boundaries.

Macias and Guitart [16] proposed a genetic model for pricing in cloud computing markets. Choosing a good pricing model via their genetic algorithms involved three main steps: define a chromosome, evaluate it, and finally select the best pairs of chromosomes for reproduction and discarding those with the worst results. The results of the simulation illustrated that genetic pricing acquired the highest revenues in most of the scenarios. Service providers employing genetic pricing achieved revenues up to 100% greater than the other dynamic pricing strategies and up to 1000% greater than the fixed pricing strategy. The proposed genetic model with a flexible genome was proven to be more stable against noise and earned more money than the one with the rigid genome. The proposed genetic model is easy to implement, flexible, and easily adapted to a set of various parameters that influence pricing. The genetic pricing approach can be further explored by defining relations between the parameters that influence pricing.

Li et al., [27] proposed a pricing algorithm for cloud computing resources. This proposal used the cloud bank agent model as a resource agency because it could provide the proper analysis and assistance for all members. The authors used a price update iterative algorithm to determine the price. It analyzed the historical utilization ratio of the resources, iterated current prices constantly, assessed the availability of resources for the next round, and determined the final price. The model included a user request broker (GCA), cloud banking, a cloud service agent (CSA), and a cloud resource agent (GRA). The proposed pricing model was comparatively fixed because it could not adapt to the rapid changes that typically occur in the market. However, it could reduce the costs to providers and maximize their revenues, allowing resources to be used more effectively.

In particular, Xu and Li (2013) study practices of AWS spot instances—spot prices are changed dynamically by AWS based on real-time demand and idle capacity. Truong-Huu and Tham (2014) consider competition between service providers and formulate the competition through a Markov Decision Process. However, those studies have not examined and compared the pricing schemes that are considered in our study, and they have not studied the service providers' optimal choices of pricing schemes and the impact of the chosen pricing schemes on the customers' choices of service providers.

Another major recent research on cloud pricing is dynamic pricing algorithms. The market-clearing price is computed by a dynamic pricing mechanism. In this pricing strategy, prices are changing with respect to market condition or status. An appropriate pricing algorithm is an effective way to estimate the value of cloud service and to distribute the available resources. The dynamic pricing mechanism can accurately estimate the price based on market status and present a reasonable price for both provider and customer. For instance, Macias and Guitart (2011) proposed a Genetic Model for pricing in cloud computing markets. Sharma et al. (2012) employed the Financial Option Theory and the related economic model to capture the real value of cloud service within the lower and upper boundaries. Truong-Huu and Tham (2014) used a Markov Decision Process to illustrate the competition between providers and to compute the price. Dynamic pricing strategy mainly focuses on changing prices based on supply and demand, but the strategy ignores the important cloud feature, especially the QoS metrics. The value of cloud is directly affected by QoS metrics and operational process. Although dynamic pricing strategy can offer a reasonable price, it is difficult for practitioners to estimate the actual price of cloud, because there are no QoS-related parameters in the extant dynamic pricing designs. Our pricing design added the QoS availability into pricing models that clearly indicates how a customer can bid directly on the expected QoS level with the related price.

Auction Pricing Strategy

Theoretically, prices should be determined by the interaction between supply and demand; however, in practice, it seems like that the companies employ specific auction mechanisms in setting up the prices, in order to make optional profits and to attract more potential customers. From Amazon’s initial effort of using auction-based allocation, it is reasonable to expect that cloud providers will be interested in more efficient allocation and pricing schemes in the near future.

This is a market mechanism for service allocation that enables users and providers to deal through double-sided combinational auction. This mechanism is suitable for cases requiring various services and where many participants exist. Both users and service providers should be satisfied by the resource allocation mechanism. A double-sided auction model and K-pricing scheme were used in this mechanism.

Basically, all participants accurately know the nature of the available resources and the distribution of these possible resources. Each participant, whether the participant is a provider or a customer, needs a bidding strategy (Milgrom and Weber, 1982). Reasonable uncertainties from participants and markets make auction design more attractive and more desirable through some mathematical algorithms and bidding strategies.

Many classic auction designs were employed to price cloud services. When they were applied to pricing cloud services, the mechanism will be NP-hard. Wang, Wang, & Huang (2012) proposed an English auction. The mechanism focuses on how to maximize the seller’s revenue and shorten the execution time. Another study about dynamic auctions was conducted by Wang, Liang, & Li (2013) to cope with changes in cloud market. Asymptotic optimization, incentive compatibility, and computational complexity were pursued, through their capacity allocation scheme. A double auction model has been used to distribute cloud resources to multiple buyers and sellers (Shang, et al., 2010). A framework uses marginal bid to evaluate cloud capacity distribution and to generate reasonable revenue for the cloud provider (Lin, et al., 2010).

In practice, leading cloud service companies, such as Amazon AWS or Microsoft Azure, lack the adoption of a desirable auction mechanism to efficiently allocate resources. For instance, Amazon EC2 offers three categories of pricing schemes to sell its cloud services: Reserved Instances, On-Demand Instances (Fixed Price), and Spot Instances. Spot Instance is one type of auction-style pricing policy, through which bidders can periodically bid on offered resources dynamically. Successful bidders can use these instances until the auction price exceeds their bids at a later date. This design has attracted significant attention from practitioners and researchers, and it has prompted a number of studies on auction-based pricing design. Zaman and Grosu (2013) believed that an auction design is better than the current fixed-price mechanism. Depending on the experimental results, the Auction-Greedy is a better choice than the Auction-Linear Programming. The Auction-Greedy can generate higher revenue and resource utilization in a limited time. But these mechanisms are only applied to certain types of items. Extended from Zaman and Grosu (2013), Samimi, Teimouri & Mukhtar (2016) proposed the Combinatorial Double Auction Resource Allocation, focusing on the economic efficiency of the cloud computing environments. Providers are more concerned about what economic profits they can obtain. Thus, based on individual rationality and incentive compatibility, our study will address two other important issues, QoS-based pricing mechanisms and revenue approximation.

Table 1. Summary of Pricing Scheme for Cloud Allocation
Fixed Pricing Strategy Classification: Pay-as-you-go, Subscription, Pay for Resource Characteristics: Stable price for the time of usage. Easily implemented, without auctioneer. Example: Amazon EC2, Microsoft Azure
Dynamic Pricing Strategy (Macias and Guitart, 2011; Sharma et al., 2012; Du, Das and Ramesh, 2012; Truong-Huu and Tham, 2014) Classification: Genetic Model, Financial Option Model, Markov Decision Process Characteristics: Price is changed based on supply and demand. Multiple providers to multiple customers.
Auction Pricing Strategy
English Auction (Wang, Wang, & Huang, 2012) Characteristics: One-sided ascending auction. Winning buyer pays the bidding price. One single provider to multiple customers, with an auctioneer.
Double Auction (Zaman & Grosu, 2013; Samimi, Teimouri & Mukhtar, 2016) Characteristics: Both provider and customer propose bids. Multiple providers to multiple customers, with an auctioneer
Combinatorial Auction (Zaman & Grosu, 2013; Samimi, Teimouri & Mukhtar, 2016) Characteristics: Customer can bid for customized bundle cloud services. The auction design construct computation complexity. Multiple providers to multiple customers, with an auctioneer

In a cloud environment, practitioners are concerned about Quality of Service (QoS). The sharing of resources, software, and information makes up the basic functions of cloud computing. In an auction design, economic models can be used to reduce unnecessary costs, to regulate available resources, to provide incentives for providers, and to stimulate buyers to choose the preferred services that are associated with rational evaluation and QoS criteria. Due to the heterogeneity of cloud computing, a well-designed auction is a basic step toward allocating available resources to meet supply and demand, via the Internet. A QoS-based auction design is a good attempt at finding an efficient and effective way to benefit from cloud computing and to guarantee the performance of the cloud.

Quality of Service describes the requirements that a service provider should provide to its customers, such as service availability, reliability, security, privacy, scalability, and integrity (Zheng, Xu, & Chai, 2017). Our model allows bidders to submit their own valuations and QoS-based bidding strategies. The transaction price will be calculated based on the basis of each participant’s bid directly related to QoS availability, although the economic perspectives of supply and demand in the cloud market still impact participants' auctioning strategies. What we did was using an exponential function to price cloud services based on QoS metrics (availability) and bids from customers. In this way, available cloud services can be distributed to clients with heterogeneous QoS expectations and portfolio requirements. Only buyers submit bids and QoS preferences for a certain item. A QoS-based auction mechanism is a good pricing strategy that could enrich the classic auction design, especially for the bidding targets with unique or not-easy-to-estimate features, e.g., cloud service has QoS criteria.

THE MODEL OF QOS AND PRICE

Reliability and Availability

The reliability and availability of cloud computing are the crucial QoS parameters, but they are difficult to quantifiably analyze because cloud services are implemented through the entire serving process in a complicated network that integrates software, hardware, and the related techniques. Reliability focuses on the downtime of cloud service, while, availability represents the uptime of cloud services (Armbrust, et al., 2010; Mell & Grance, 2011). Reliability and availability are interrelated with each other. A better performance of reliability will lead a better performance of availability. A more stable system will decrease the number of failures and lessen the time of repairing. In the real world, reliability and availability are integrated with each other greatly impacting the overall performance of cloud services.
The relationship between reliability and availability is:

$$A = \frac{MTBF}{MTBF+MTTR} = \frac{Uptime}{Uptime+Downtime} \tag{1}$$

A is referred to availability. MTBF (Uptime) and MTTR (Downtime) are the two parameters of reliability. MTBF is the Mean Time between Failure, and MTTR is the Mean Time to Repair. Thus, based on the above function, the availability can be increased either by increasing the average time interval between repairs (MTBF) or by decreasing the repair time (MTTR). The intuitive way to represent availability is using the downtime associated with Nines and Fives. The following table is an example.

Table 2. Representation of Availability

Availability	Downtime
99% (2-nines)	3.65 days/year
99.5% (2N5)	1.825 days/year
99.9% (3-nines)	8.76 hours/year
99.95% (3N5)	4.38 hours/year
99.99% (4-nines)	52 minutes/year
99.995% (4N5)	26 minutes/year
99.999% (5-nines)	5 minutes/year

The Relationship between Availability and Price

The QoS metrics is the availability of cloud service ($A_{(x)}$), and the bidding price is the average price (y) of the same item from different customers' bids.
The function that expresses the availability is:

$$A_{(x)} = 1 - 10^{-x+g(x)} \tag{2}$$

Where *x* represents the level of availability as Nines and Fives, e.g., x=2, it means "2Nines" as 99%; x=3.5, it means "3N5" as 99.95%. x = {x/x=2, 2.5, 3, 3.5, 4, 4.5, …}. $g(x)$ is a function that is potential to calculate for the result of *x*. Since we know all possible (x, y): (2, 99%), (2.5, 99.5%), (3, 99.9%), …, the function can be addressed as:

$$A_{(x)} = 1 - 10^{-x+(0.5+\ln 0.5)sin^2(\pi x)} \quad (3)$$

Therefore, *x* is expressed by $A_{(x)}$ as:

$$x = \begin{cases} -\ln\left[1 - A_{(x)}\right], if\ x\ is\ an\ integer \\ (0.5 + \ln 0.5) - \ln\left[1 - A_{(x)}\right], if\ x\ is\ not\ an\ integer \end{cases}$$

One Example of The Relationship between Availability and Price

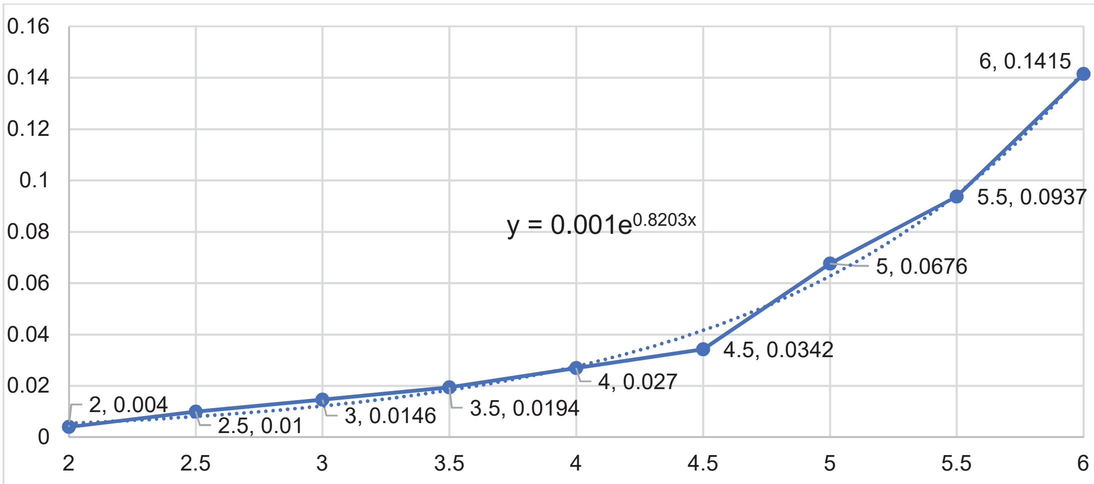
The exponential function that expresses price by the QoS availability is:

$$y = a + cb^{h_{(x)}} \quad (4)$$

Where, *a* is the constant and *c* is the slope. *b* is the base of the exponentiation, and $h_{(x)}$ is the exponent. Now, we can compute the exponential function based on *x* and *y*. In fact, there exist many different ways to establish the relationship between QoS metrics and cloud price. This relationship can be represented by a linear function that is easy to implement but not accurate. Because even with a slight increase in reliability and availability, the costs associated with cloud services increase significantly. Hence, an exponential algorithm is a better approach to describe the relationship between QoS metrics and cloud price. Figure 1 illustrates one example of the exponential relationship between price and availability. Based on the different levels of availability (*x*) that customers bid, such as 2 (99%), 2.5 (99.5%), 3 (99.9%), 3.5 (99.95%), 4 (99.99%), 4.5 (99.995%), 5 (99.999%), 5.5 (99.9995%), 6 (99.9999%), firstly the average price (*y*) of each level of cloud service is calculated accordingly: \$0.004, \$0.01, \$0.0146, \$0.0194, \$0.027, \$0.0342, \$0.0676, \$0.0937, \$0.1415. Then, based on function (4), the relationship between QoS availability and price is calculated as:

$$y = 0.001e^{0.8203x}$$

Figure 1: One Example of the Exponential Relation



ROBUST OPTIMIZATION SCHEME

Robust Auction Design

Symbols and Assumptions

This section addresses the related parameters and mathematical symbols used. Suppose there are *n* customers, *n* = {*1, 2, …, n*}, and *ith* represents the customer *i*. There are *m* providers, *m* = {*1, 2, …, m*}, and *jth* represents the resource *j*. $T_{m,j}$ represents the *mth* supplier offers the resource *j* or not. $T_{m,j}$ is a binary factor, $T_{m,j}$ (=1) means that the mth supplier is capable of offering the resource *j*, $T_{m,j}$ (=0) means that the *mth* supplier doesn't provide the resource *j*. $w_{i,j,m}$ illustrates that the customer *i* obtains the resource *j* provided by supplier *m*, and all the bidding resources are set in the matrix *W*.

In the system, the customer is the buyer, the provider is the seller. The buyer's bid is $b_{i,j,m}$, represented by vector B, and the final price is $p^b_{i,j,m}$. The customer *i*'s value is V_i, $v_{i,j,m}$ represents the valuation of the resource *j* provided by the seller *m*. The cost of the resource *j* is $c_{i,j}$. $D_{i,j}$ represents the demand of the buyer *i* on the resource *j*. The capability of the resource *j* from the seller *m* is $C_{j.m}$. The more the buyer bids, the utility (*μ*) is higher. Specifically, $\mu_{i,j}$ = $h_{i,j}v_i\ (b_{i,j}) - c_i\ (b_{i,j})$.

The customer's bid has two general constraints. (1) a customer needs to bid incrementally, (2) all customers are truthful bidders. The set (*U*) of all possible bids is: U_j = {($b_{1,j}$, $b_{2,j}$, …, $b_{n,j}$) | -Γ ≤ $\frac{\sum_{i=1}^{n} v_{i,j} - n\mu_j}{\sqrt{n}\,\sigma_j}$ ≤ Γ} . Where μ_j and σ_j are the bidding prices of two different time, respectively.

Optimal Auction Model

The overall auction model (*M1*) is:

$$max \sum_i \sum_j \sum_m x_{i,j,m} b_{i,j,m} \tag{5}$$

Subject to

$$\sum_m x_{i,j,m} = 1, \forall\, i, j \tag{6}$$

$$\sum_i x_{i,j,m} D_i T_{m,j} \leq C_{j,m}\,, \forall\, m, j \tag{7}$$

$$\sum_m \sum_j \overline{b_{i,j}} - \overline{p_i} \leq \sum_m \sum_j b_{i,j} x_{i,j,m} - p_i \quad (8)$$
$$c_{i,j,m} \leq b_{i,j,m} \leq v_{i,j,m}, \forall\, i,j,m \quad (9)$$
$$x_{i,j,m} \in \{0,1\}, \forall\, i,j,m \quad (10)$$

Function *M1* is the maximum revenue for all the bidding resources. Constraint (6) indicates that there must exists at least one seller (*m*) can provide the resource *j* as the buyer (*i*) expects. Constraint (7) indicates that the possible allocation of a seller's resources is less than the seller's capacity. Constraint (8) indicates that all buyers are trustworthiness. Constraint (9) indicates that the bid is between the cost and the value of the resource.
Function *M1* is an integer (0-1) programming problem. This problem belongs to NP-hardness (Karp, 1972). It is transformed to a solvable linear programming problem to find the optimal solution.

Solution to the Model

Algorithm 1

The *M1* model is based on the fact that $b_{i,j,m}$ can be estimated and controlled, but in reality, each user's pricing strategy and actual bid are dynamic and difficult to estimate. This study focuses on how to allocate resources to users based on their bidding strategies to meet the needs of users and resource providers. For the problem of uncertain optimization, a robust optimization method can be used to solve the problem. There are four criteria: optimal coordination based on probability, optimistic criteria, conservative criteria, and optimistic and conservative weighting (Beyer & Sendhoff, 2007; Bertsimas, Brown & Caramanis, 2011; Chaithanya & Dimitris, 2014). This study uses conservative criteria. It is seeking the worst result of the original problem and then finding the optimal case under the worst scenario.
Since $b_{i,j}$ is uncertain in model M1, $\widehat{b_{i,j,m}}$ is used to represent the conservative bid of user *i*, and the user *i* has to pay this amount to get the required resource *j*. Constraint (8) can be converted to its equivalent. In order to achieve a reasonable resource allocation, each customer first proposes a conservative bid, and then provider can obtain a higher return based on the bid. Using a conservative bid ($\widehat{b_{i,j,m}}$) converts the original 0/1 problem into a linear programming problem. *M1* is converted to *M2*:

$$max \sum_i \sum_j \sum_m x_{i,j,m} \widehat{b_{i,j,m}} \quad (11)$$

Subject to

$$\sum_m x_{i,j,m} = 1, \forall\, i,j$$
$$\sum_i x_{i,j,m} v_{m,j} \leq B_{i,m}\,, \forall\, m,j \quad (12)$$
$$\sum_i x_{i,j,m} D_i T_{m,j} \leq C_{j,m}\,, \forall\, m,j$$
$$\sum_m x_{i,j,m} \widehat{b_{i,j,m}} \leq \sum_m \sum_j x_{i,j,m} \mu_{i,j,m}\,, \forall\, i,j \quad (13)$$
$$c_{i,j,m} \leq \widehat{b_{i,j,m}} \leq v_{i,j,m}, \forall\, i,j,m \quad (14)$$
$$x_{i,j,m} \geq 0, \forall\, i,j,m \quad (15)$$

Now, *M2* is converted into *M3*, which is the dual problem of M2.

$$min \sum_i \sum_j \varepsilon_{i,j} + \sum_i \sum_m (\delta_{m,j} B_{i,m} + \theta_{m,j} \sum_j x^*_{i,j,m} U_{i,j}) \quad (16)$$

Subject to

$$\varepsilon_{i,j} + z_{i,j,m}\delta_{m,j} + z_{i,j,m}\theta_{m,j} \geq z_{i,j,m} \quad (17)$$
$$\varepsilon, \delta, \theta \geq 0 \quad (18)$$

$z_{i,j,m}$ is the bid of the worst scenario, $x^*_{i,j,m}$ is the solution. The user i's uncertain bid is $U_{i,j}$. Specifically,

$$U_i = argmin \sum_m \sum_j x^*_{i,j,m} \mu_{i,j} \quad (19)$$

The user's conservative bid ($\widehat{b_{i,j,m}}$) can be represented by $z_{i,j,m}$. Since $z_{i,j,m}$ is the bid under the worst scenario,

$$\widehat{b_{i,j,m}} = \varepsilon^*_{i,j} + z_{i,j,m}\delta^*_{m,j} + z_{i,j,m}\theta^*_{m,j} \quad (20)$$

ε^*, δ^*, and θ^* are the parameters of the dual problem, respectively. These parameters can be solved by the model M3. After the results of M3 are solved, the algorithm 1 can be employed to solve $\widehat{b_{i,j,m}}$.

Algorithm 1. Estimated Bidding Algorithm

Algorithm 1 Calculating the Estimated Bidding Price

Input: The Uncertain Price Set U

Output: $\widehat{b_{i,j,m}}$ and $x^*_{i,j,m}$

Based on model M2, calculate the bid of the worst scenario ($z_{i,j,m}$) and the associated allocation result ($x_{i,j,m}$);
Based on model M3, calculate the parameters ε^*, δ^*, and θ^*;

To each of the involved suppliers

Based on Function (20), calculate the estimated bidding price ($\widehat{b_{i,j,m}}$).

Algorithm 2

After we get $\widehat{b_{i,j,m}}$ and $x^*_{i,j,m}$, the Algorithm 2 will solve the allocation and the final price. The intermediary variable $y^b_{i,j,m}$ represents adopted allocation, and the final allocation result is $a^b_{i,j,m} = x^*_{i,j,m} + y^b_{i,j,m}$, $a^b_{i,j,m}$ is the final allocation results. Specifically, bidding vector is *B*, the final price is $p^b_{i,j,m}$. $y^{b-k}_{i,j,m}$ is the temporary intermediate allocation.

$$y^b_{i,j,m} = argmax \sum_i \sum_j \sum_m y_{i,j,m}(b - \widehat{b_{i,j,m}}) \quad (21)$$

$$y_{i,j,m}^{b-h} = argmax \sum_{i \neq k} \sum_{j} \sum_{m} y_{i,j,m} (b - \widehat{b_{\iota,J,m}}) \tag{22}$$

The user's flexible bidding policy:

$$P = arg \begin{Bmatrix} \sum_{i} \sum_{m} y_{i,j,m} \leq 1 - \sum_{i} \sum_{m} x_{i,j,m}^{*} \\ \sum_{j} y_{i,j,m} \mu_{i,j,m} \leq B_{i,m} - \sum_{j} x_{i,j,m}^{*} \widehat{b_{\iota,J,m}} + \sum_{j} x_{k,j,m}^{*} \theta^{*} U_{i,j,m} \end{Bmatrix} \tag{23}$$

Since the final price is determined by the user *i*'s bid and other users' bids, we define Q_k is the allocation of the user *k*.

$$Q_k = arg \begin{Bmatrix} \sum_{i \neq k} \sum_{m} y_{i,j,m} \leq 1 - \sum_{i} \sum_{m} x_{i,j,m}^{*} \\ \sum_{j} y_{i,j,m} \mu_{i,j,m} \leq B_{i,m} - \sum_{j} x_{i,j,m}^{*} \widehat{b_{\iota,J,m}} \end{Bmatrix} \tag{24}$$

Function (21)'s constraint is function (23), and function (22)'s constraint is function (24). The final allocation ($a_{i,j,m}^{b}$) is

$$a_{i,j,m}^{b} = x_{i,j,m}^{*} + y_{i,j,m}^{b} \tag{25}$$

The final price ($p_{k,m}^{b}$) is

$$\begin{aligned} p_{k,m}^{b} = & \sum_{j} y_{k,j,m}^{b} \widehat{b_{\iota,J,m}} + \sum_{j} x_{k,j,m}^{*} \widehat{b_{k,J,m}} - \sum_{j} x_{k,j,m}^{*} \theta^{*} U_{k,j,m} \\ & + \sum_{i \neq k} \sum_{j} \sum_{m} y_{i,j,m}^{b-k} (b - \widehat{b_{\iota,J,m}}) - \sum_{i \neq k} \sum_{j} \sum_{m} y_{i,j,m}^{b} (b - \widehat{b_{\iota,J,m}}) \end{aligned} \tag{26}$$

Algorithm 2. Resource Allocation Algorithm

Algorithm 2 Resource Allocation Algorithm

Input: The bidding vector b and the estimated prices $\widehat{b_{\iota,J,m}}$ and $x_{i,j,m}^{*}$

Output: The final allocation vector $a_{i,j,m}^{b}$ and the final price $p_{i,j,m}^{b}$

To each supplier m

 If $b_{i,j,m} \notin U_{i,j}$

  Won't provide any resource to the user I;

Based on function (21) and (22), calculate the allocation $y_{i,j,m}^{b}$ and the temporary variable $y_{i,j,m}^{b-k}$ that satisfies function (23) and (24);
Based on Function (25) and (26), calculate the final allocation vector $a_{i,j,m}^{b}$ and the final price $p_{i,j,m}^{b}$.

The solution to M2 is solved by Algorithm 1 and Algorithm 2. We get the final allocation $a^b_{i,j,m}$ and the final price $p^b_{i,j,m}$.

Theoretical Proof

In our study, the final price is similar to the transaction price in VCG (Vickrey, 1961; Varian & Harris, 2014). The transaction price is associated with each users' bids, which consist of the winning bids and unsuccessful bids. In this section, we will illustrate that the solutions to Algorithm 1 and Algorithm 2 are also the solution for the original model *M1*.
Lemma 1. The unknown variables (z, x^*, ε^*, δ^*, θ^*, $\hat{b}$) of Algorithm 1 and Algorithm 2 satisfy the following relations.

$$\sum_m \sum_i x^*_{i,j,m} \leq 1, \forall\, j \tag{27}$$
$$\sum_j x^*_{i,j,m} z_{i,j,m} \leq B_{i,m}\,, \forall\, i, m \tag{28}$$
$$\sum_m \sum_j x^*_{i,j,m} z_{i,j,m} \leq \sum_m \sum_j x^*_{i,j,m} z_{i,j,m}\,, \forall\, i \tag{29}$$
$$x^*_{i,j,m} \widehat{b_{i,j,m}} = x^*_{i,j,m} z_{i,j,m}, \forall\, i, j, m \tag{30}$$
$$\sum_j x^*_{i,j,m} \widehat{b_{i,j,m}} \leq B_{i,m}\,, \forall\, i, m \tag{31}$$
$$\sum_i \sum_j \sum_m x^*_{i,j,m} \widehat{b_{i,j,m}} = \sum_i \sum_j \varepsilon^*_{i,j} + \sum_i \sum_m (\delta^*_{m,j} B_{i,m} + \theta^*_{m,j} \sum_j x^*_{i,j,m} U_{i,j}) \tag{32}$$

According to Functions (27)-(29), $z_{i,j,m}$ is a fixed term. The optimal model *M2* can be converted to the followings:

$$max \sum_i \sum_j \sum_m x_{i,j,m} z_{i,j,m}$$

s.t.

$$\begin{gathered}\sum_m \sum_i x_{i,j,m} \leq 1, \forall\, i, j \\ \sum_j x_{i,j,m} z_{i,j,m} \leq B_{i,m}, \forall\, i, m \\ \sum_m \sum_j x_{i,j,m} z_{i,j,m} \leq \sum_m \sum_j x_{i,j,m} \mu_{i,j,m}\,, \forall\, i\end{gathered} \tag{33}$$

Since $x^*_{i,j,m}$ is one solution to the optimal problem, Function (33) can be transformed to another question of *M3*.

$$max \sum_i \sum_j \sum_m x_{i,j,m} z_{i,j,m}$$

s.t.

$$\sum_m \sum_i x_{i,j,m} \leq 1, \forall\, i, j$$

$$\sum_j x_{i,j,m} z_{i,j,m} \le B_{i,m}, \forall\, i, m$$
$$\sum_m \sum_j x_{i,j,m} z_{i,j,m} \le \sum_m \sum_j x^*_{i,j,m} \mu_{i,j,m}\,, \forall\, i \tag{34}$$

If $\bar{x}$ is the solution of function (34), and x^* is the solution of function (33), x^* is also one solution of function (34).

$$\sum_m \sum_i \sum_j \bar{x}_{i,j,m} z_{i,j,m} \ge \sum_m \sum_j \sum_i x^*{}_{i,j,m} z_{i,j,m} \tag{35}$$

And

$$\sum_m \sum_j \bar{x}_{i,j,m} z_{i,j,m} \le \sum_m \sum_j x^*{}_{i,j,m} \mu_{i,j,m}\,, \forall\, i \tag{36}$$

Based on function (35) and (36),

$$\sum_m \sum_j \sum_i x^*{}_{i,j,m} z_{i,j,m} \le \sum_m \sum_j x^*{}_{i,j,m} \mu_{i,j,m} \tag{37}$$

Thus, $x^*{}_{i,j,m}$ is the optimal solution to Function (21). Function (34) can be converted to the followings:

$$\sum_m \sum_j x^*{}_{i,j,m} z_{i,j,m} \le \sum_m \sum_j x^*{}_{i,j,m} \mu_{i,j,m} \tag{38}$$

Hence, $x^*{}_{i,j,m}$ is an optimal solution to Function (33). U_i is computed from Function (19). We have the following:

$$max \sum_i \sum_j \sum_m x_{i,j,m} z_{i,j,m}$$

s.t.

$$\sum_m \sum_i x_{i,j,m} \le 1, \forall\, i, j$$
$$\sum_j x_{i,j,m} z_{i,j,m} \le B_{i,m}, \forall\, i, m$$
$$\sum_m \sum_j x_{i,j,m} z_{i,j,m} \le \sum_m \sum_j x^*_{i,j,m} U_i\,, \forall\, i \tag{39}$$

Obviously, $x^*{}_{i,j,m}$ is the optimal solution to Function (39). The Dual Problem of Function (39) can be the followings:

$$min \sum_i \sum_j \varepsilon_{i,j} + \sum_i \sum_m (\delta_{m,j} B_{i,m} + \theta_{m,j} \sum_j x^*_{i,j,m} U_{i,j}) \tag{40}$$

s.t.

$$\varepsilon_{i,j} + z_{i,j,m}\delta_{m,j} + z_{i,j,m}\theta_{m,j} \geq z_{i,j,m}, \varepsilon, \delta, \theta \geq 0 \tag{41}$$

ε, η, and θ represent the parameters of three constraints. Define ε^*, δ^*, θ^* are the values corresponding to the three parameters, when $x^*_{i,j,m}$ is the optimal solution. According to Complementary Relaxation Theorem, we have the followings:

$$\begin{gathered}\varepsilon^* \sum_m \sum_i x_{i,j,m} = \varepsilon^*, \forall\, j \\ \delta^* \sum_j x_{i,j,m} z_{i,j,m} = \delta^* B_{i,m},\ \forall\, i, m \\ \theta^* \sum_m \sum_j x_{i,j,m} z_{i,j,m} \leq \theta^* \sum_m \sum_j x^*_{i,j,m} U_{i,j},\ \forall\, i \\ x^*_{i,j,m}\left(\varepsilon_{i,j} + z_{i,j,m}\delta_{m,j} + z_{i,j,m}\theta_{m,j}\right) = x^*_{i,j,m} z_{i,j,m}\end{gathered} \tag{42}$$

$x^*_{i,j,m}$ is the optimal solution to Function (34), according to the Strong Dual Theorem, we get,

$$\sum_i \sum_j \sum_m x^*_{i,j,m} z_{i,j,m} = \sum_i \sum_j \delta^* + \sum_i \sum_m \left(\delta^* B_{i,m} + \theta^* \sum_j x^*_{i,j,m} U_{i,j}\right) \tag{43}$$

Based on function (20), (42), and (43), Function (18) and (19) can be proofed. And **Lemma 1** can be proofed as well.

FUTURE DIRECTION

Based on conventional auction design, we added QoS metrics (availability) and established a robust optimal auction to price and allocate cloud resources. For the future research, there are two potential directions. An auction model could be converted to a combinatorial double auction design. In this way, customers will have the opportunity to bid for bundled (package) cloud services (Lu & Zheng, 2018). The major cloud trading platform is centralized and controlled by companies. A blockchain-based decentralized P2P cloud trading platform is potential to play important role to allocate cloud resources between customers without unnecessary third-party intervention (Lu, 2018 a & b; Lu, 2019 b). The decentralized P2P cloud trading system is a good complementary of the conventional trading system.

Providers will compete with each other and submit bids related to guaranteed QoS. The mathematical issue (NP-Hardness) and the computational complexity should be carefully considered as well (Nisan, et al., 2007). Another direction is to adjust the QoS metrics. We only employed the availability as the indicator of QoS in this study. Multiple indicators can be added to represent the exponential relationship between price and QoS. Such as security. More QoS metrics are added into the auction algorithm, more accurate and practical the estimates will be. The relationship between price and multiple QoS indicators will be worth investigating in real-world industries. Whereas, more QoS metrics involved may lead to the complexity of algorithms, deep learning method is a possible way to assess cloud price, according to the training layer (historical pricing records) and output layers (estimated results) (Lu, 2019 a).

CONCLUSION

In the cloud environment, QoS criteria is critical to the overall performance of cloud resources. The extant research seldom illustrates the relationship between QoS metrics and price; our design has the potential to achieve this. By a dynamic pricing mechanism, cloud resources can be traded between provider and customer with uncertainties, e.g., budget constraints. In our work, we address the robust optimal allocation of cloud services to users who are flexible in their bids for their preferred QoS metrics (availability). Our study presents us with one probable way of investigating the questions of how companies formulate prices for cloud services and how customers can utilize the pricing mechanism to bid for cloud services, based upon the QoS metrics (availability). We highlighted the QoS indicator that was employed in the auction mechanism to price cloud services among different participants. The robust optimal auction design is an appropriate pricing mechanism for cloud resources in a distributed trading system.

APPENDIX

Table 3. Main Variables and Explanations (Alphabetic Order)

Variable	Description	Variable	Description
a	the constant of the exponential function	$p_{i,j,m}^{b}$	the final price
$a_{i,j,m}^{b}$	the final allocation results	Q_k	the allocation of the user k
$A_{(x)}$	the QoS availability of cloud service	$v_{i,j,m}$	the valuation of the resource j provided by the seller m
b	the base of the exponential function	V_i	the valuation of customer i
$b_{i,j,m}$	the buyer's bid	$T_{m,j}$	the mth supplier offers the resource j or not
$\widehat{b_{i,j,m}}$	the conservative bid of user i	U	the set of all possible bids
c	the coefficient of the exponential function	$U_{i,j}$	user i's uncertain bid
$c_{i,j}$	The cost of resource j	x	the level of QoS availability
$C_{j.m}$	The capability of the resource j from the seller m	$x_{i,j,m}^{*}$	the decision variable, $x_{i,j,m} \in \{0,1\}$
$D_{i,j}$	the demand of the buyer i on the resource j	y	the average bidding price of cloud service
h(x)	the exponent of the exponential function	$y_{i,j,m}^{b}$	the intermediary variable
i	the ith bidder	$y_{i,j,m}^{b-k}$	the temporary intermediate allocation
j	the jth provider	$z_{i,j,m}$	the bid of the worst scenario

m	there are m sellers	μ	the utility
n	there are n buyers	ε^*, δ^*, θ^*	the parameters of the dual problem

DECISION SCIENCES INSTITUTE
The Development of an Exercise to Incorporate a Management Dashboard into the Beer Game

Brad C Meyer
Drake University

ABSTRACT

An exercise to demonstrate the utility of management dashboards was created. Students were asked to play an online version of the beer game, where supply chain information was available and could be organized and displayed in Tableau. We explain several iterations of the exercise and describe our experience and game development process.

KEYWORDS: Active learning, innovative education, supply chain management, analytics

INTRODUCTION

It is common in these annual DSI meetings to describe techniques and exercises that have been used in class with successful results. By the time the innovation is presented, the bugs have been worked out and it appears as a finished product. What may not be apparent to the hearers are all the trials and errors that have taken place to get the exercise to be effective. For those with a creative bent who find themselves driven to develop learning innovations, the story of the development of an exercise might be as useful as the description of the final exercise. With that in mind, this paper sets out to describe the development of an exercise that has students using a visualization tool, in this case Tableau, to support decision making in a digital version of the beer game. We begin by describing our history of using the beer game in an introductory operations management class, then describe the original objectives for our exercise. We then describe the development of the technology for the game, and then our first runs of the exercise and we detail what did not work as expected. We continue through revisions and retests and finally tie up with the exercise as we are conducting it at this time and our future plans.

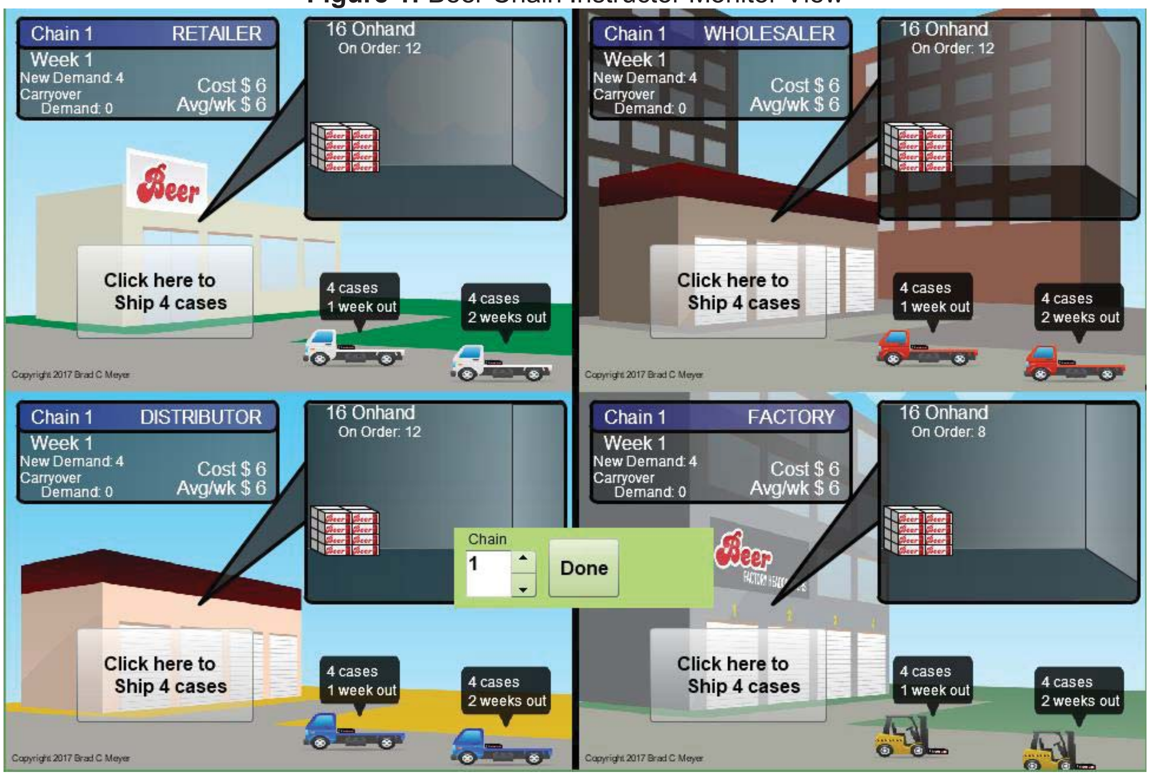
CONCEPTION OF THE EXERCISE

The beer game hardly needs an introduction, but for those unfamiliar with the exercise, we refer you to (Forrester, 1961; Sterman, 2000; and Senge, 1990). The game is a simulation of a supply chain with four echelons, not counting the end customer. The object for the players of the game is to minimize the sum of inventory and backorder costs by making order replenishment decisions. A simple demand stream with the doubling of demand consistently yields a pronounced bullwhip effect in the chain.

After playing the game with a physical board and small poker style chips for many years, one of the authors developed an online version of the game to reduce setup time and to facilitate collecting data from plays of the game. Figure 1 shows the screens for one chain from an instructor observation view.

The digital version of the game has proven to work well to illustrate the bullwhip effect and the results are comparable to the board version with typically higher levels of amplification, probably due to an interface that does not require physically sliding chips. Figure 2 shows an example of the graphs that are displayed at the end of the game. In debriefing the game, the class always concludes that performance would be better if 1) communication was allowed between the echelons and 2) they had a forecast of demand to know what to expect.

Figure 1: Beer Chain Instructor Monitor View



Student's commonly ask for another opportunity to play the game, mainly to redeem themselves from their poor performance in the first round. Using the same demand stream would be too easy, so we developed a version with a different demand stream. Demand begins around 4 per week and then ramps up by 1 every two periods till a peak and then ramps back down. To this underlying pattern is added a minor random component of plus or minus 0 to 3 units. This is a more difficult demand stream, but most teams perform better than the first round when they are given the ability to talk together as a group as the game is played.

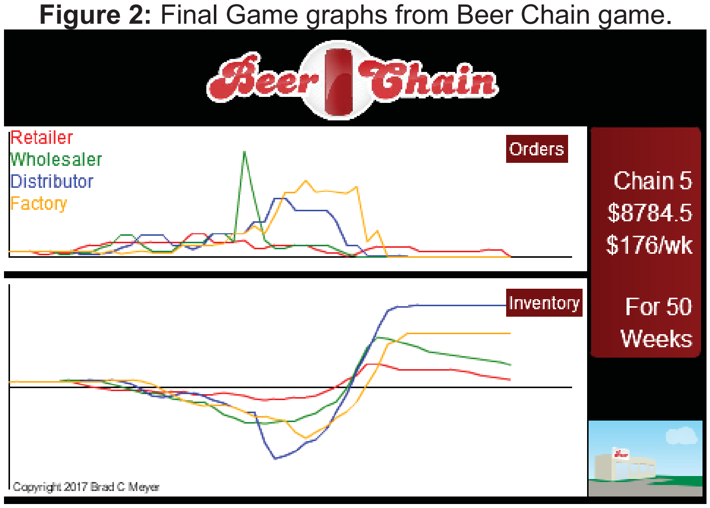
We were content with this approach: run first with no talking, then run a second time with communication but a harder demand stream, until the rise of data analytics. In fall of 2017 we began integrating Tableau into our core operations management class. We developed exercises to showcase the powers of Tableau and we introduced the idea of managing via a dashboard. It wasn't long until we hit on the idea of asking our students to create a dashboard in Tableau that could be used as the game is played. Thus began our development of this exercise.

INITIAL EXERCISE DESIGN

We began development with the following design objectives.

1. Reinforce Tableau skills
2. Give the students experience in creating a useful, albeit simple, dashboard
3. Demonstrate that managing with data yields better performance
4. Reinforce concepts of supply chain management
5. Engage students in activity that supports learning

Figure 2: Final Game graphs from Beer Chain game.



Our first technical step was to develop a way for Tableau to pull data from the database used in the game. Ideally a dashboard would show inventory at every echelon, orders at every echelon, end customer demand, and cost data. The database used by the game stored only order decision values, and they were stored in a compact way such that a direct connection to the database would require a lot of manipulation in Tableau, way above the level of our students. There would also be some permissions issues to overcome.

We settled on an approach that utilizes a Tableau Web Data Connector. This allows Tableau to access data through the internet by connecting to a web page. The web page provides data through .asp calls and a couple layers of additional coding. For those interested, code developed for the web connector is included in appendix A. This code was developed by us and is not seen or understood by the students undertaking the exercise. In the code, we use the order data and known initial values to compute the relevant inventory levels. Thus, the fields that are sent to Tableau are as shown in table 1.

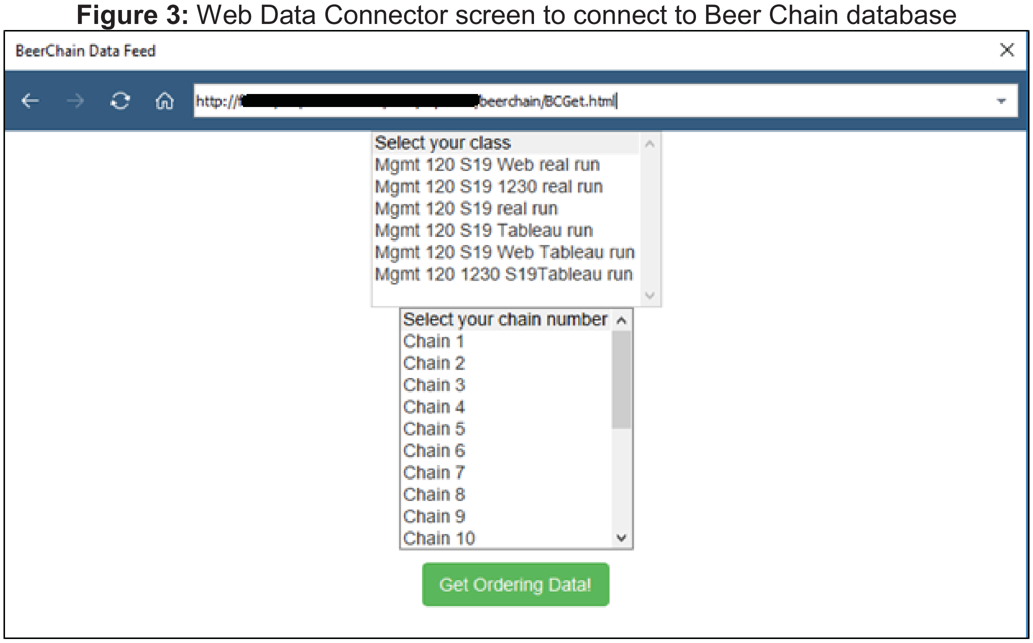
Table 1: Tableau Fields for the Beer Game Data

Field	**Description**
Period	week number, consecutive
Demand	orders from the end customer
Retailer	amount ordered by the retailer
RetailInv	current level of inventory held by retailer, positive or negative

RetailChange	the difference in inventory between current and previous period. (The sum of this column yields current inventory.)
Wholesaler	amount ordered by the wholesaler
WholesalerInv	current level of inventory held by wholesaler, positive or negative
WholesalerChange	the difference in inventory between current and previous period.
Distributor	amount ordered by the distributor
DistributorInv	current level of inventory held by distributor, positive or negative
DistributorChange	the difference in inventory between current and previous period.
Factory	amount ordered by the factory
FactoryInv	current level of inventory held by factory, positive or negative
FactoryChange	the difference in inventory between current and previous period.

From the student side, they are able to connect to the data by selecting *Web Data Connector* from the Source menu, entering in a url supplied by the instructor and then selecting their group and the chain number. Supply chain position is not entered, as each person in each chain has access to data for all the positions in that chain. Figure 3 shows the screen inside Tableau where the class and chain are selected.

Figure 3: Web Data Connector screen to connect to Beer Chain database



We wanted the students to design their own dashboard, but we demonstrated a few visualizations as starter ideas, a graph of demand, a graph of current inventory, and a chart that showed the current inventory at each echelon. Figure 4 shows a dashboard mockup with these visualizations. This figure comes from a handout given to the class for this exercise.

We designed the coding for the Web data connector so that it provides demand data from the past three years, but only has ordering and inventory data starting in year 4, the year for which they will be playing the game. We have students design their dashboard using the data from their first run of the game. The dashboard in figure 4 thus shows demand per week at 4 for the first three years and the first 4 weeks of the 4th year followed by a jump to 8 for the rest of the 4th year.

After they have designed their dashboard, we have them reconnect to the database and populate their dashboard with data from the game they are about to play. Since the database will not have any ordering data yet, all they will see on the dashboard is the demand from the past 3 years which they use to generate a forecast. Figure 5 shows this demand stream along with a forecast generated in Tableau.

Finally, we explained to the students how to refresh the data extract so they can keep their visualizations up to date as they play the game. With these design pieces in place, we began using the exercise.

Figure 4: Dashboard mockup shown to students to spur ideas

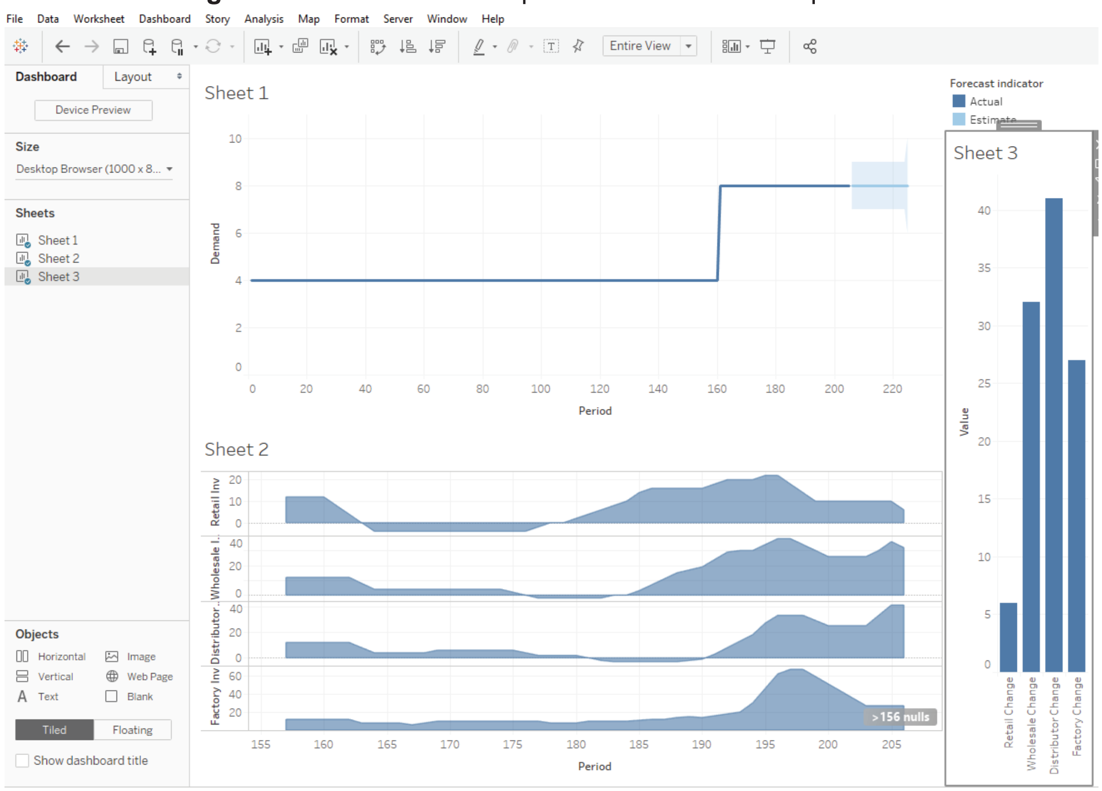


Figure 5: Historical demand for the Tableau Beer Chain exercise with forecast generated by Tableau.

GAME EXPERIENCE AND REVISIONS

The first times we used this exercise, we took 20 minutes at the beginning of a 90 minute class period to walk through the mechanics of connecting Tableau to the game database and demonstrated a few possible visualizations they could use. Then we gave the students 15 to 20 minutes to develop their dashboard and plan a strategy for playing the game. Then the game was started. We allowed the students to continue to communicate with each other while the game was being played.

The activity was engaging. The students typically reduced their costs to half that in the original 4/8 demand stream round. However, we noticed some things that were troubling with respect to our original intentions. The students relied heavily on talking to each other to make the ordering decisions. Often times a leader would arise in the group who had the major sway over the decision making across the entire chain. Most teams had one or two people who were looking at the dashboard, but there was little reliance on the dashboard. The students relied on communication, not on the analytics tool. For example, here are three responses to a debriefing question of whether their strategy to keep costs low worked.

> *"Our strategy seemed to help some. I think we kept confusing ourselves a little by talking through things too much, but for the most part, communicating helped. It was especially helpful that we could discuss our carryover demands & inventory levels (on hand) to help keep inventory levels steady and have a better balance between having too much on hand vs. too much carryover demand. Overall, the communication helped a lot. Looking at Tableau did not seem to help as much as we hoped, but it was slightly helpful to see the overall trend each of our inventory levels and demands."* (Final cost $96/wk)

> *"Our strategy did not work, as we more than doubled our cost from the last time we played. I think it was confusing for us to think ahead ten weeks, and we focused too much on the demand numbers on screen rather than talking to each other about what we needed. The graphs on our Tableau file were not very useful as they did not help us to look forward, they were simply a visualization of our errors."* (Final cost $113/wk)

Secondly, as is also apparent from the comments, many of the groups did not know how to make use of the forecast. That is, it helped them know the order quantity to expect from the end customer, but they didn't know how to plan for it down the chain, timing orders appropriately. The teams who understood the 4 week time delays built into the game and how to plan for a ramp up and ramp down of demand were able to achieve costs of $20 per week or less, total for the entire chain. The rest of the class had costs from $55 per week to $175 per week. We also realized that the students were primarily reacting in the game. They would start the game with some impressions of what should or shouldn't be done when demand started going up or when inventory started piling up, but they did not have cogent strategy going into the game.

The problem of not using the dashboards was the most troubling, given the objectives for the assignment, but we attacked the second problem first. We were using a pre-game questionnaire and we began to improve the questions to drive them to be more proactive and strategic in playing the game.

Our original questions were

- *What do you notice about historical demand?*
- *What will be your strategy to manage the chain to keep costs as low as possible?*

Answers to the strategy question were often vague, such as these examples.

> *"Be mindful of time delays. Since it costs half as much to hold inventory than it does to have backlog, err on the side of too much inventory rather than too little. In addition, obviously keep in mind the seasonality."*

> *"Try to keep inventory at zero."*

> *"We will communicate amongst ourselves to ensure that we are meeting demand and planning ahead with the information our supply chain is receiving."*

So, we tried adding a question to get them to think about timing of ordering. This questions was inserted between the two questions above.

- *How would your chain handle the case where demand was constant at 4 but you knew that in 16 periods, demand would increase to 8?*
-

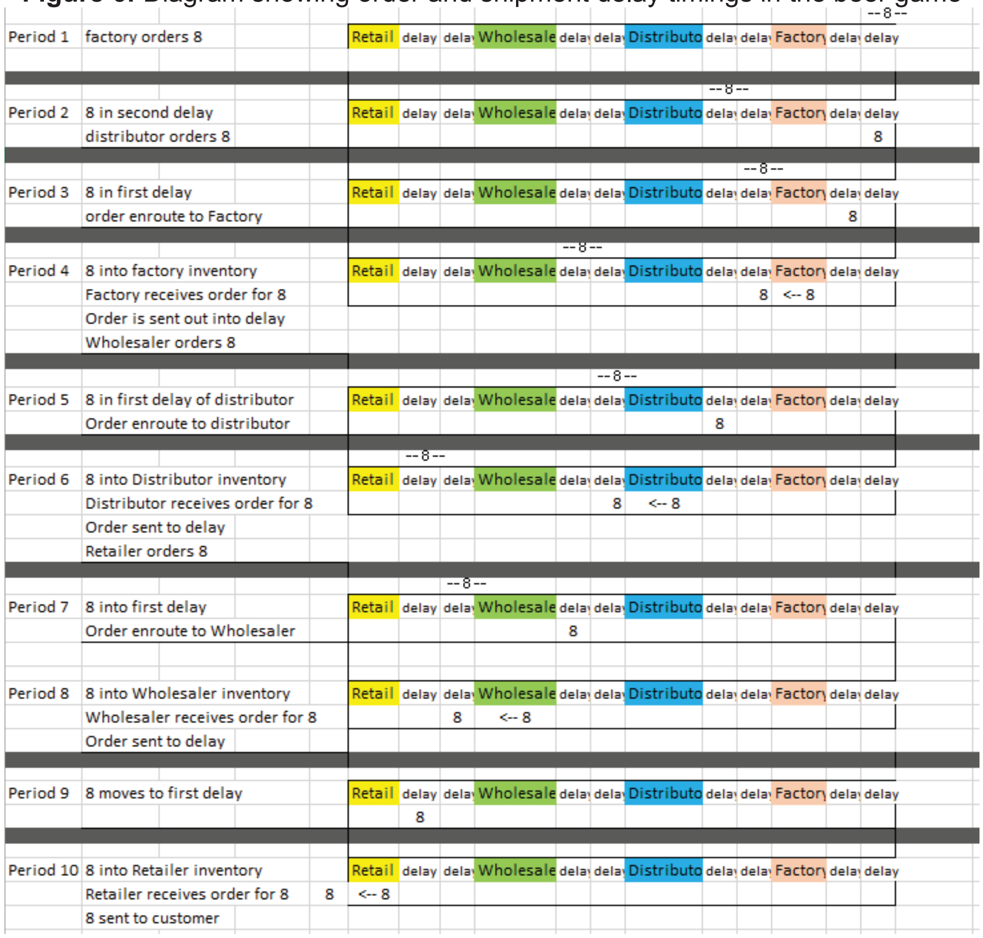
This was somewhat helpful, but we did more clarification in our next semester.

- *Look at the historical demand for the Tableau version of the game you are about to play. How would you describe the pattern of demand? How might this have an impact on how you play the game?*
- *How would your chain (the whole chain) handle the situation where end customer demand has been constant at 4 but you know that 16 periods from now, demand will jump to 8?*

- *Knowing what you know about historical demand, what is your plan for how you will determine order amounts during the Tableau round of the game? Be as specific as possible. For example, don't just say, "we will be careful not to order too much" instead describe what rules or thinking processes you will put in place so that you do not order too much. Or don't say "we will coordinate among the team members and communicate." Rather, tell what information will be communicated and how that will be used in the decision making process.*

We also hypothesized that giving the students only 20 minutes to create a dashboard and develop a strategy to play the game was not enough time to allow for deep thinking about strategy. So, we moved to briefing the exercise on one day and playing the game the following class period after giving teams time to finalize their strategy. Recently, we also added a short description of the impact of the time delays with a diagram, as shown in Figure 6.

Figure 6: Diagram showing order and shipment delay timings in the beer game



As we made these changes the answers to the strategy question improved, below are two examples.

> *"When we begin, the Factory and Distributor will order eight weeks ahead; the demand will be about 8. Wholesaler will order 6 weeks ahead, Retailer will order 4 weeks ahead. Every two weeks, we increases the order by 1 as demand increases by about half a case every week. After having ordered 16 twice, we will start decreasing our order amount by one every two weeks. So this follows the pattern of the demand so that we have the lowest inventory as possible to fulfilling all the orders."*

> *"We would order based off of the forecast. We changed the confidence interval to 90% and added a trend line so that while our data might not be quite as exact it will show some wider guidelines that we can follow and more methods to base our predictions off of. We also based our trend lines and intervals based off of what position we each had because retail would need to have a faster turn around than wholesaler. We decided as a team that we would rather over compensate for inventory so we are aiming to be towards the higher end of our confidence interval versus the lower end."*

While some of the strategies were not correct, they were at least detailed enough to guide the decision making process. In watching the game play, however, we realized that the students were still relying more on talking to each other than to looking at the dashboard, so in our next iteration, we did not allow them to talk to each other during the game. Instead, they would have to look at the dashboard to learn what was happening at the other echelons. Observing the teams playing this was revealed two main approaches. One portion of the students watch their dashboard carefully and try to make decisions based on the information displayed, another portion of students reverts to playing the game the way they played the first round where they simply watch the game screen and try to react in the best way, based on their strategy developed at the beginning of the game.

In the most recent iteration using this exercise (each iteration involves a new set of students, usually a new semester,) there was one team that achieved an average cost of $13 per week, which is about $3 per week at each of the 4 echelons. This is the group with the first of the two comments at the top of this page. This group figured out the pattern of demand and the staggered order timing necessary to maintain low costs. In fact, their strategy was good enough that they might not have even needed the dashboard. For this group that dashboard served as a status monitoring device and allowed them to make minor tweaks adapting to the randomness in demand.

At first, we were disappointed that the high achieving group was not leaning heavily on the dashboard during the game, but then we realized that this result provides us a platform to point out the difference between two primary uses of dashboards. First, a dashboard can be used for status monitoring. In fact, this is the primary use of a dashboard. In a car, the purpose for the dashboard is to notify the driver if there are any potential problems in the car system: oil level, engine temperature, battery charge, speed, etc. Adjustments can be made if some part of the system departs from normal functioning. In the beer game, the dashboard should do the same and alert the players if inventory is heading in a wrong direction, so adjustments can be made to order sizes.

The second use of a dashboard is to provide insight into a system. In our exercise, the dashboard was used *before starting the game* to display the historical demand pattern. That yielded the insight that demand was seasonal and ordering decisions should reflect that same seasonality. This insight had to be united with understanding of the time delays in the system. The delays were explained even before the first round of the game. We tried to help the students connect the dots by forcing them to think about how orders would have to be timed throughout the chain in order to get the necessary quantity to the retailer to match end customer demand. While it would be theoretically possible to determine the time delays in the system simply from historical data, that is not likely. The truth of the matter is that data driven decisions arise from a combination of system understanding and insights in the data. This exercise provides a good context to illustrate these concepts.

FUTURE DIRECTION

We are still modifying this exercise. We would like to see more advanced dashboards. For example, we have seen only a few teams display cost figures on the dashboard. The data provided allows for costs to be computed at each echelon and for the entire chain. We would also like to see triggers or warning zones on the dashboard that call attention to rising costs, to rising inventory levels, or dangerously low inventory levels. The way we plan to support these ideas is by extending the content we present when we first introduce management dashboards.

It is possible that students might use the dashboards more or in different ways if the game was played longer and customer order patterns were subject to other kinds of disturbances. We will consider options in this regards.

On the technical side, the current data feed provides a set of values for each week. Another approach that has some advantages for Tableau visualizations, is to provide a simpler data record. Each record would have 4 fields as show in Table 2. With this structure there are better options for drawing graphs that compare levels across the various roles.

Table 2: Revised Web Data Connector Structure

Field	Description
Period	week number, consecutive
Role	retailer, wholesaler, distributor, factor, or customer
Item	order, inventory, delay 1, delay 2, change in_inventory
Amount	applicable quantity

Finally, as we near the point where we are happy with the exercise itself, we will consider ways to make this assignment more easily available to instructors at other schools than our own.

APPENDIX

Below is the code for the 3 files that enabled the Tableau web data connection. These are not seen by the students. There is an html file, BCGet.html, a javascript file, BCGet.js, that defines the data fields and an .asp file, readChainTableuaMore.asp that connects to the Access database file and creates a table in JSON which is a coding format understood by Tableau.

BCGet.html - This is the file that the url in Tableau points to. Currently, this is not automatically created from the database, but has to be tweaked manually. A future version will develop the menu of classes and chain numbers from the database itself.

            };
        tableau.connectionData = JSON.stringify(callObj);
        tableau.connectionName = "BeerChain Data Feed";
        tableau.submit();
    });
});

})();
```

readChainTableauMore.asp – this is the file that accesses the database and creates a JSON file according to the format required by Tableau. The demand stream in the game is generated by a pseudo-random number generator, in such a way that the values are the same for every chain. In this file, that sequence of numbers is simply listed, rather than recreating the random number generator. There are other options of demand streams built here not discussed in this context.

```

ABSTRACT

Beer distribution simulation has served the purpose of understanding the bullwhip effect caused by communication lack among supply chain members. This paper proposes to extend the simulation with raw material and multiple products, with clarified butter (ghee), milk powder, and condensed milk as products using milk. Interestingly, the bullwhip intensifies for all three products as a result of limited raw material, which is supplied proportionately in response to the demand placed by respective product manufacturer.

KEYWORDS: Supply Chain, Beer Distribution Game, Extension of simulation, Simulation for teaching

INTRODUCTION

Beer-distribution game developed by professors at MIT has gained huge importance in supply chain and operations management classrooms. The simulation, crisply, demonstrates how the supply chain operates and thereby also helps in comprehending bullwhip effect occurring simultaneously in the supply chain. Here the over estimation of customer demand causes this bullwhip effect. Penalty for access or fewer inventories is charged. Even today, the beer game serves the purpose of demonstrating the inherent problems involved in supply chain management. However, the simulation has to adapt to changes to remain relevant and to display a better picture of the supply chain in other industries also. The proposed study asks the following changes to make the original model look more suitable to the current scenario:

a) The simulation focuses on the distribution of milk and milk products.
b) Dairy farm or association is the raw material provider, which serves to Milk Powder, Condensed Milk, and Clarified Butter industries.
c) Unlike the original version, manufacturers are not allowed to produce as per their wish, since there is limited raw material availability.

d) The raw material is supplied in the proportion of orders placed by three manufacturers, so the manufacturers have to compete with the other two industries to receive raw material.

LITERATURE REVIEW

Over the period of time, with the evolution of business environment; the understanding and definition of Supply Chain Management has evolved significantly. Thereby, its understanding and Implications have also broadened. Supply Chain Management (SCM) refers to overall management of the materials; from their procurement to the delivery. Hence, the process involves the functions of acquiring, processing, transporting and delivering the final product to the end user. Essentially, SCM studies the inter-relations and inter- linkages amongst the members involved, processes undertaken and functions performed within the Chain. The implications of the interactions that take place within the Supply Chain; have larger consequences on the profit maximization; due to value addition involved at each stage. New Dimensions such creating and nurturing long-term relationships amongst the members, strategic standpoint with respect to competitiveness, smooth flow of information, developing flexibility in the complex market and the element of e-procurement, have been added to the area of Supply Chain Management; besides its primary function of Cost Reduction. (Shilpa Parkhi, 2015)

Simulation Modeling is to create a model demonstrating the real-world situation, in order to analyse it and predict the results. The (Nance & Sargent, 2002) paper describes various categorizations of various simulation tools and technique that have evolved in around 50 years of simulation study. Out of this discrete event modeling has been greatly used by different areas of work. The method of Simulation has been used in various areas of work such as defence, communication, manufacturing, commerce; etc. (Walker, Giddings, & Armstrong, 2011)

With increasing scope of Supply Chain Management; Simulation is widely used by researchers to unveil complex problems present in the chain. Use of simulation tool helps to critically analyse the complexity involved SCM decisions and is also helpful in understanding the rationale of the decision makers in adopting a policy or a process. (Spagnoletti, D'Atri, & D'Atri, 2013)

Beer Distribution Game was developed by MIT Sloan System Dynamics Group; to illustrate all the hidden problems underlying the supply chain management system. The game demonstrates the ‘bullwhip effect”; commonly known as the over-estimation of demand from a consumer to the vendor. Beer Distribution Game aims at minimizing the cost at each level of the supply chain; by lowering the inventory held and timely delivery of orders.

Simulation modeling in the form of Beer Distribution Game is widely used for experiential learning in the dynamics of the supply chain management. (Jose Costas, 2015) The selfefficacy and Attitudes of the students studying supply chain management with BDG improved positively by role-play simulation. (Juthamas Choomlucksana, 2011).

The Beer Distribution Game - Variations and Extensions

The Beer Distribution Game has also been modified with different variations and extensions by researchers.

The strategies of providing access to Global Information and a shorter lead time, to all the members in the supply chain, reduced costs within the supply change and enabled greater control over inventory. (Muhammad Zeshan Rafique, 2014)

The traditional beer distribution game has certain shortcomings that do not reflect the realistic supply chain environment. Many problems that do arise in SCM can be resolved by shortening the delivery time and centralizing decision making. With this argument, the paper proposes a computerized beer distribution game with different policy options and settings. This new game has only a few exceptions to the traditional BDG; human player assumes only one of the roles of the BDG while the rest are managed by the computer. Three option settings in the game are: A short lead time, Centralize information and the Global Information option. Simulation of the new computerized BDG, offer an enhanced explanation of The Bullwhip Effect, The Centralization Effect and the Short Lead Time Effect. (Levi)

The (Hongliang Liu, 2009) simulates the Beer Distribution Game in four complex demand patterns namely, one step demand (demand changes only once in entire simulation), stationary demand (pattern follows normal distribution), uniform demand (random fluctuations in a specified range) and cyclical demand (seasonal variations). The variations proposed in the traditional game illustrate a more realistic picture of supply chain by the means of the improvised Beer Distribution Game. (Hongliang Liu, 2009)

The (Chen & Samroengraja, 2000) is an improvised version of the Beer Distribution game in terms of the proposed changes in the demand pattern. All the players within the system have prior information about the demand distribution, wherein the demand is independent and identical in different periods. The rationale of the improvisation is in-line with the real-world conditions. Also, the stationary game provides theoretical benchmark.i.e. optimal levels of inventory and costs that can be achieved in the game.

The paper (Sarkara, 2012) aims to enable the decision-making process and risk management wherein the inventory cost is not compromised. It also tries to avoid the bullwhip effect with a location independent model which is capable of acquiring the demand and the supply orders. The outcome of this study was that they were able to eliminate the bullwhip effect without any backlogs with help of the Petri Net Model that they used for their study.

The paper (Norina Szander, 2013) considers that the traditional efficiency method of evaluating the success of a supply chain by just using financial metrics is not complete. It thus takes into account four (financial, customer, internal, innovation and learning) perspectives of Balanced Scorecard performance measurement system. It accomplishes this by playing the beer distribution game. To conclude, while examining the performance of the supply chain, one should always consider the logistics trade-offs as well.

The Bullwhip Effect

The identification of the bullwhip effect helped in making improvements in the supply chain management. The Bullwhip effect has also been studied with different dimensions and measures have been suggested to control it. The bullwhip effect is not only the result of operational shortcomings in the supply chain instead it has also a lot to do with the decision maker’s tendency to undermine the supply chain. (Croson Rachel, 2006) The manager is unable to reduce the new orders considering the ones he has already placed but are yet not delivered. Also, (Croson Rachel, 2006) demonstrates that information sharing; a proposed solution to the bullwhip effect; though successful in doing so, benefits are skewed towards the upstream members of the supply chain.

A study carried out in (Shilpa Parkhi, 2015). presents an agent-based simulation which evaluates the bullwhip effect in SC through a series of numerical experiments in two scenarios. The first is two tiers SC and the other is four tier SC. The results of the experiments were compared with the analytical counterparts in literature. The results show that the assumption of non-negative demand or order quantities should be included for the accurate and realistic measurement of bullwhip effect. The four tier shows how bullwhip effect changes when we move upward in the supply chain.

Four causes of the Bullwhip effect have been identified by various research studies, namely, Demand signal processing (natural demand forecasting) , order batching (order frequency and evenness of order arrivals), price fluctuations (short-term changes in price as a part of sales promotions) and shortage gaming (order cancellation policy). (Hau L. Lee V. P., 2004) The paper (Hau L. Lee V. P., 2004), also suggests the need for more research in the area of “bullwhip effect” in order to develop practical solutions in terms of processes and policies by working with the practitioners.

Measures such as information sharing models, establishing strategic alliance, etc. would help in reducing the bullwhip effect. (Hongchun Wang, 2011) The (Frank Chen, 2000) proposes framework to quantify the bullwhip effect with different number channel members. With sharing demand information at each stage of the supply chain; can reduce the variability in orders placed but does not eliminate the bullwhip effect from the system. (Frank Chen, 2000)

The spreadsheet solution illustrates how the bullwhip effect in the supply chain can be minimized with greater inventory fluctuations and a reduced customer service. (Robert N. Boute,
2009)

In (S. Kamal Chaharsooghi, 2008) Bullwhip effect is studied by altering the forecasting methods used for demand forecast; the core factor to the bullwhip effect. Methods such as Time series forecast, moving average and Exponential Smoothening are used. The results suggest that the accurate the forecast; does not necessarily lower the bullwhip effect. (S. Kamal Chaharsooghi, 2008)

The bullwhip effect paralyzes the supply chain management and the penalties in terms of higher costs are borne by all its members. However, due to various incentives and promotional offers made by upstream members to downstream members (wholesaler’s discounting pricing to retailer, the option to return the unsold goods, etc.) the burden of penalty is borne more by the upstream players. Such outcomes do not provide any incentive to the downstream member (especially the retailer) to not exaggerate demand. (Hau L. Lee V. P., 2016)

The (Saitoh, 2014) uses a knowledge sharing simulation model (Elman Network) that aims to improve the decentralized information sharing and thereby controlling the bullwhip effect within the chain. The data about inventory volumes, demand forecast, etc. at each stage is provided as input, in the form of knowledge, to the model of the next stage. The study proposes a decrease in the magnitude of the bullwhip effect within the supply chain.

The (Wangphanich, Kara, & Kayis, 2007) proposes a model that illustrates The Bullwhip effect in a Supply chain network with three retailers to one manufacturer; three different products and assuming same forecasting technique. The model has been validated using ‘ROO Water’ and hence can be used by decision makers for real life SCM.

All these studies have introduced different dynamics to the problems arising in a supply chain and the corresponding bullwhip effect.

We aim to study the bullwhip effect arising out of introducing a new level in the supply chain and extending the game to multiple products.

SIMULATION DESIGN

The Milk Distribution Game developed during this study consists of 3 supply chains of three different products from the same industry i.e. Dairy, with a common raw material provider, who is the farmer. The three products are Ghee, Condensed milk and milk powder. It has thirteen players, Retailer, Wholesaler, Distributor and Manufacturer for the three supply chains and a farmer.

The participants are asked to sit in columns whereby each column represents a supply chain. There are 3 such columns with 4 levels in each supply chain. There is 1 farmer who caters to the demands of all the manufacturers of supply chains.

Of the total units of milk produced, 54% is used for these three-supply chain and the remaining 46% is utilized as fluid milk for domestic consumption.

The entire supply chain of ghee will have 9 units in their inventory, delay 1 and delay 2. Similarly, condensed milk's supply chain will have 2 units in their inventory, delay 1 and delay 2. Whereas, there will be 1 unit in the inventory, delay 1 and delay 2 of the milk powder's entire supply chain.

The retailer enters the order received manually according to the instructions given by the instructor of the game in the ratio of 9 or 2 or 1 unit(s), depending on the supply chain he/she is in. The demand is catered and the backlog is recorded automatically. According to the order received the participant places a relevant order which is then catered by the wholesaler.

The wholesaler, distributor and the manufacturer follow the suit. The demand is catered and the backlog is recorded automatically. According to the order received the participant places a relevant order to the next member of the supply chain.

The farmer on receiving orders from all the three suppliers; divides the limited supply of milk between them in the ratio of 9:2:1. The number of milk units a farmer can supply is 314 with a standard deviation of 10% (i.e. 31.4 units) in a normal distribution curve. These get converted into respective product units based on milk requirement in each product.

Demand at the retailer was determined on the basis of market share which are 1, 2, 9 for Milk powder, Condensed milk and Ghee respectively (Khamkar, 2014). In this simulation, the demand at the retailer level increases to double once during the 25 weeks' time, at this time the demand at retailer level increases to 2, 4, and 18 respectively. Though the percentage change is same, the impact on Ghee at the time of increase in demand will be higher because the change in absolute terms is very high.

Also, the conversion of 1 unit of product in terms of the milk units required is 8,3,16 for Milk powder, Condensed milk and Ghee respectively. So the milk required for production of Ghee is very high, this also contributes to the high bullwhip. Since the milk unit's requirement of Milk powder and Ghee is higher than that of condensed milk, condensed milk's supply chain suffers when the demand is high, and supply is limited and done in proportion to the demand received by the farmer.

FINAL ANALYSIS

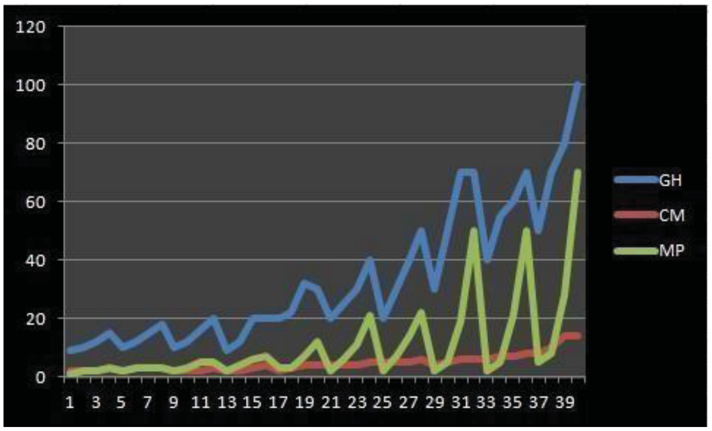
The objectives of the research are to analyze:

1. Observing the change that occurs in the bullwhip effect when a level is added.
2. Examining the cross-section impact on companies which depend on same raw material.

Bullwhip Graphs

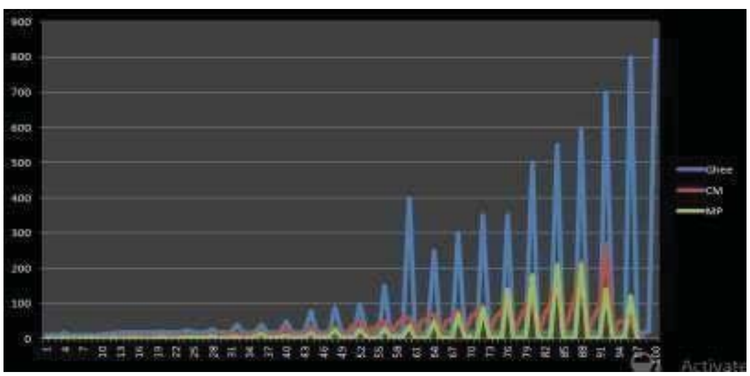
At first, we conducted the experiment with single supply chains of Ghee, Milk Powder and Condensed Milk by adding a raw material (limited supply) to the chain.

Figure 1: Single Product Bullwhip



Secondly, the experiment was conducted with all the three chains simultaneously working with milk as their common raw material. The following graphs show the same: -

Figure 2: Multiple Products Bullwhip Graph 1



Bhatt, Sharma, Kothari, Bhagchandani Is Milk as good as Beer?

Figure 3: Multiple Products Bullwhip Graph 2

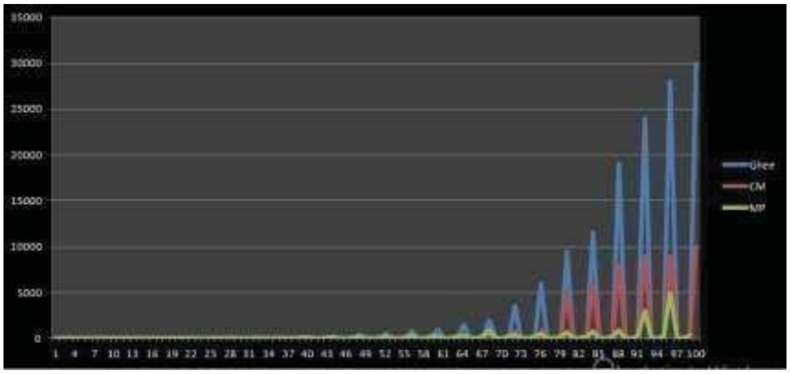


Figure 4: Multiple Products Bullwhip Graph 3

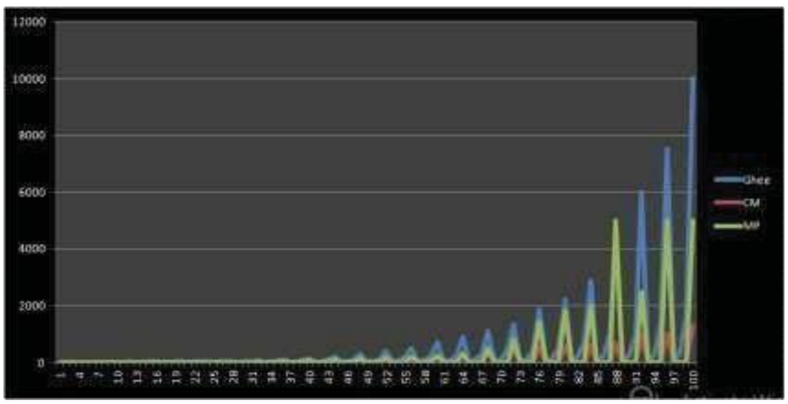

The bullwhip graphs suggest a significant rise in all the three supply chains when compared to the one wherein they were functioning independently. The intensity of the bullwhip significantly rises when there is more than on product in the market.

The demands' variation was tested for significance of difference with difference of variance test, and we found the following results, for three experiments.

The results of variance difference show that there occurs a significant impact on the orders placed by the agents of supply chain, when they know that there exist other products in the market and there is a common raw material provider with limited capacity. Raw material is supplied in proportion to the demand received by the farmer

The cross-sectional impact is exponentially high; participants were demanding more than what they require because they knew that the raw material supply is limited, and they will get the supplies proportionate to their demand.

CONCLUSION

The raw material supply is limited and supplied to all the three industries proportionate to the demand received by the farmer. Therefore, each industry demands greater quantities than required, in order to ensure that when divided proportionately; each gets a better share. Since this logic is followed by all the three supply chains, the resultant demand orders rise significantly each subsequent time.

The results of the experiment show a significant increase in the bullwhip effect of each of the supply chains operating within the industry with a limited raw material supply.

ABSTRACT

From a network perspective, this study conceptualized the role of social media in forming social networks among a focal company, customers, and suppliers. Data analysis based on samples from 117 U.S. companies demonstrated that social media usage had a significant impact on the operational efficiency of SRM and CRM systems.

KEYWORDS: Social media, Supplier relationship management, Customer relationship management, Empirical research, Social network theory

INTRODUCTION

Over the past few decades, the essence of inter-firm competition has shifted to supply chain management (Croom et al., 2000; Cousins et al., 2006; Gunasekaran et al., 2008). Previous research has shown that the supply base must be managed efficiently and carefully to avoid losing competitive advantage in the marketplace (Choi and Krause, 2006; Nam et al., 2011). Supply chain management is no longer regarded merely as a means of logistics and is seen as a key to improving the core results of customer satisfaction (Hult et al., 2007; Lyons et al., 2013). Today, companies are also faced with a new mission to improve organizational performance by combining existing management systems, processes, and capabilities with their social networking skills and technology (Trainor et al., 2014). Since the Internet revolution of the 1990s, the way we communicate has changed dramatically, and now social media has become an essential concept in most business models (Kaplan and Haenlein, 2010). According to the Nielsen Company's (2010) survey, US consumers spent nearly a quarter of their Internet time on social networking sites. As of January 2018, active social media users are estimated at 3.2 billion and 42% of the world's population (Shaw, 2018). Organizations now use social media platforms as tools to improve profitability, identify problems, promote innovation, interact with customers, respond quickly to what they want, and improve organizational performance (Gallaugher and Ransbotham, 2010; Rodriguez et al., 2012). Social media also enables employees to seamlessly communicate information and knowledge within an organization by facilitating customer interactions with external organizations, as well as providing job updates and best practices through improved business intelligence (Wu, 2013; Lam et al., 2016).

Although "social media" has received considerable attention in a number of academic communities, including Marketing (Fader and Winer, 2012) and Information Systems (Aral et al., 2013), it is still at an early stage in Operations and Supply Chain Management research. Further, it is reported that research on social media still remains incomplete and existing literature does not provide sufficient empirical evidence of the impact of social media on organizational performance (Parveen et al., 2015). Therefore, the purpose of this study is to explore how the use of social media impacts supplier and customer relationship management. In order to empirically investigate this research question, we collected data from 117 companies in the United States through surveys. CFA was performed to assess the validity of the measurement scales. Further, this study adopted the insomnia scale as “marker variable” to minimize the likelihood of a common method variance (CMV) in our data and also performed “common latent factor” analysis to diagnose the potential threat of CMV. Finally, the hypotheses developed in this study were examined using structural equation modeling. The results showed that social media platform was positively associated with social media capability and the usage of social media had a significant positive effect on both supplier relationship management (SRM) and customer relationship management (CRM). The results also indicated that CRM directly affected customer satisfaction, but the impact of SRM practices on organizational performance could be achieved positively when combined with the efficient operation of the CRM system.

This study contributes to the literature on social network perspective (Freeman, 2004; Choi and Kim, 2008; Borgatti et al., 2009) by conceptualizing the role of social media in forming social networks between a focal company, customers and suppliers. This study also contributes to the knowledge-based view of the firm (Grant, 1996; Spender, 1996) by demonstrating that the social media technology embedded in supply chain information systems (i.e., CRM and SRM) has become a strategic resource to maintain superior organizational performance.

THEORY AND HYPOTHESES

The Effect of Social Media on CRM

Customer relationship management (CRM) is described as “an information system that collects data from a number of customer-facing activities to help an organization better understand its customers so that it can better match its products and services to customer needs and thereby increase sales” (Hill, 2017, p. 104). CRM is also viewed as “a core organizational process that focuses on establishing, maintaining, and long-term enhancing associations with customers” (Jayachandran et al., 2005, p. 3). Namely, CRM can be understood as an integrated system of people, processes, technologies and all business activities to improve customer relationships (Anton, 1996; Anton and Hoeck, 2002; Feinberg and Kadam, 2002; Chen and Popovich, 2003; Jayachandran et al., 2005).

Social media is described as “an online resource that people use to share content: video, photos, images, text, ideas, insight, humor, opinion, gossip, news” (Drury, 2008, p. 274). Social media is used for information sharing and seeking, entertainment, and expressing an opinion about a product or an issue (Whiting and Williams, 2013). Examples of popular social media platforms in the industry include Blogger, Twitter, Facebook, LinkedIn, Flickr, YouTube, Ning, and Igloo. Previous research has shown that social media can be used to improve financial performance (Du and Jiang, 2014; Ainin et al., 2015), organizational learning (Vuori and Okkonen, 2012; Wu, 2016), employee performance (Cao et al., 2016; Cetinkaya and Rashid, 2018), and innovation (Lam et al., 2016; Dodokh and Al-Maaitah, 2019). Rodriguez et al. (2015) claimed that social media positively guided customer orientation activities and ultimately affected sales and business performance. Trainor et al. (2014) found that using social media could improve the efficiency of the company by promoting internal and external collaboration. Lam et al. (2016)

found that social media initiatives enhanced operational efficiency and promoted corporate innovativeness. Table 1 summarizes major findings on the impact of social media usage on various organizational performance over the past decade.

Social media has become an essential method for people to communicate with their customers (Sano and Sano, 2016). Corte et al. (2015) showed that companies use social media to track customer feedback and product loyalty. According to Lee et al. (2015), social media is also useful for information dissemination during product recalls. Trusov et al. (2009) showed that social media usage could enhance customer relationships by increasing opportunities for interactive conversations. In a similar vein, Parveen et al. (2015) reported that social media could improve customer relationships by increasing access to information. Acker et al. (2011) argue that if social media is effectively managed and used with CRM, it can contribute positively to customer satisfaction as well as financial rewards. Evidence from previous research also suggests that social media can help improve customer relationships by enhancing customer trust through information sharing (Maecker et al., 2016; Khan et al., 2017). Therefore, based on previous evidence, it is reasonably inferred that the use of social media will have a positive effect on customer relationship management:

H1. *The use of social media has a positive impact on customer relationship management.*

Table 1: Key findings on the effects of social media use on organizational performance over the past decade

Article	Purpose	Discipline	Sample	Findings
Luo *et al.*, 2013	Explore how social media affects firms' equity value.	Information System	9 hardware and software companies	Social media is a primary predictor of a company's equity value.
Abzari *et al.*, 2014	Investigate the effects of social media on consumers' attitude towards company brand.	Marketing	210 automaker customers	Social media has a positive influence on customers' buying intentions.
Du and Jiang, 2014	Examine the relationship between social media and firm performance.	Information System	S&P 1500 companies	Companies using social media achieve better financial results.
Parveen *et al.*, 2015	Investigate the impact of social media usage on organizational performance.	Marketing	Interviews with senior managers of 6 companies	Social media improves customer relationships, improves access to information, and reduces marketing costs.
Ainin *et al.*, 2015	Study the effects of social media on the performance of small and medium enterprises (SMEs).	Information System	259 SMEs owners in Malaysia	Social media has a positive effect on customer service, access to information, and financial performance.

Lam *et al.*, 2016	Explore how firms' social media initiatives affect operational improvement.	Operations Management	Longitudinal data between 2006 and 2012 from Compustat and Fortune; 281 firms' social media initiatives between 2006 and 2011.	Social media initiatives have a positive impact on operational efficiency and innovativeness by enhancing firms' knowledge-based advantages (e.g., information flow and knowledge sharing).
Wu, 2016	Study the role of social media strategies in organizational performance.	Marketing	327 chain and franchise stores in Taiwan.	Organizational culture, leadership, and social networks relate to social media strategies that have a positive impact on performance.

The Effect of Social Media on SRM

Strategic supply management has become a critical requirement in today's business environment, especially with multiple purchasing transactions with various suppliers (Wu and Choi, 2005; Moeller et al., 2006; Yeung, 2008). In particular, supplier relationship management (SRM) focuses on strengthening relationships with suppliers to improve collaboration, processes, quality and forecasting while reducing inventory, risk and costs (Hill, 2017). The primary goal of SRM is to ensure that information and materials flow smoothly throughout the supply chain in an effective manner (Feldmann and Müller, 2003; Childerhouse and Towill, 2003). The benefits of using SRM are tremendous. Prior research shows that through active collaboration with suppliers, SRM helps companies reduce unnecessary inventories and costs, enhance operational efficiency, minimize price volatility, and improve information flow (Jap, 1999; Shin et al., 2000; Swink et al., 2005; Li et al., 2006). As such, an effective SRM implementation is considered a prerequisite for optimizing the company's operations to maintain a competitive advantage (Song et al., 2014; Handfield, and Bozarth, 2015). According to the literature, in the early stages of product development, companies can benefit from using virtual communities by engaging users with similar interests in the development process and sharing experiences and knowledge (Hagel, 1999; Kozinets, 1999). Swain and Cao (2013) claim that partners in the supply chain can improve operational productivity and performance as they use more social media. Lam et al. (2016) also argue that social media enables companies to improve intelligence across their supply chain networks through a visual approach to external knowledge and information. In short, previous research points out the important role of social media in strengthening partnerships with suppliers through sharing knowledge and information. Previous research also argues that social media can improve customer relationships by enhancing customer confidence through information sharing (Munar and Jacobsen, 2013; Elena 2016).

This claim can be better understood by the lens of social network perspective (Freeman, 2004; Choi and Kim, 2008). In network analysis, network systems are represented by a set of nodes representing interrelated actors (such as individuals, organizations, and communities) and by lines representing exchange relationships (Borgatti et al., 2009; Kim et al., 2015). Thus, as shown in Figure 1, the structural relationships between a focal company, suppliers, and customers in CRM and SRM systems can be diagrammed from the networks perspective (Choi and Krause, 2006). Here, it is likely that social networking already exists between the focal firm and individual customers and suppliers through the operations of CRM and SRM systems. However, the relationship among individual suppliers as well as among individual customers is likely to still remain as two separate "clusters" based on similarities rather than social networks because there are no open channels for mutual information exchange and interaction. On the other hand, Figure 2 depicts social networks that have been expanded and enhanced due to social media effects on CRM and SRM systems. Here, customers and suppliers can share and interact with information and knowledge through the social media platform, which leads to form "social networks" based on "soft" ties (e.g., information sharing and favoritism) rather than "hard" ties (e.g., money and materials flow) (Borgatti and Li, 2009). As a result, enhanced social networks among the customers and the suppliers are expected to benefit to the focal company because the actor at the top of the network chain has the greatest information advantage when the type of tie is "soft" according to social network theory (Borgatti and Li, 2009). Therefore, from the network perspective, social media platforms enable customers and suppliers to form social networks, ultimately enhancing the efficiency of supply chain information systems such as SRM and CRM. Considering all the above arguments, the following hypothesis is proposed:

H2. *The use of social media has a positive impact on supplier relationship management.*

Figure 1: Social Networks in CRM and SRM Systems

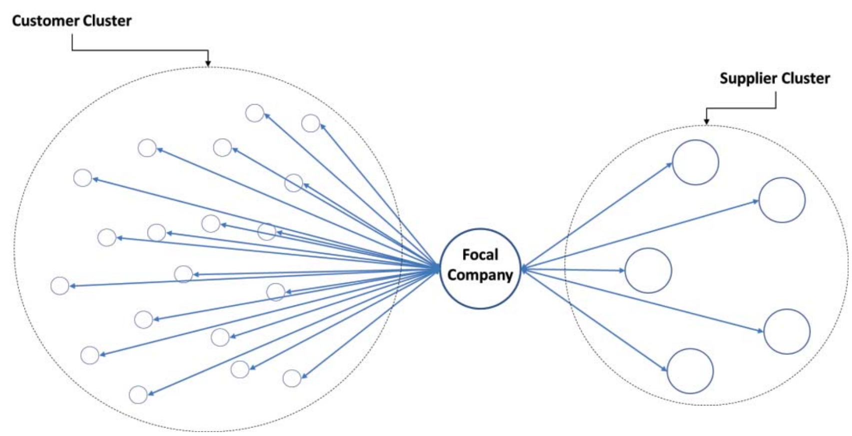

Figure 2: Adapted Social Networks based on Social Media Effects on CRM and SRM Systems

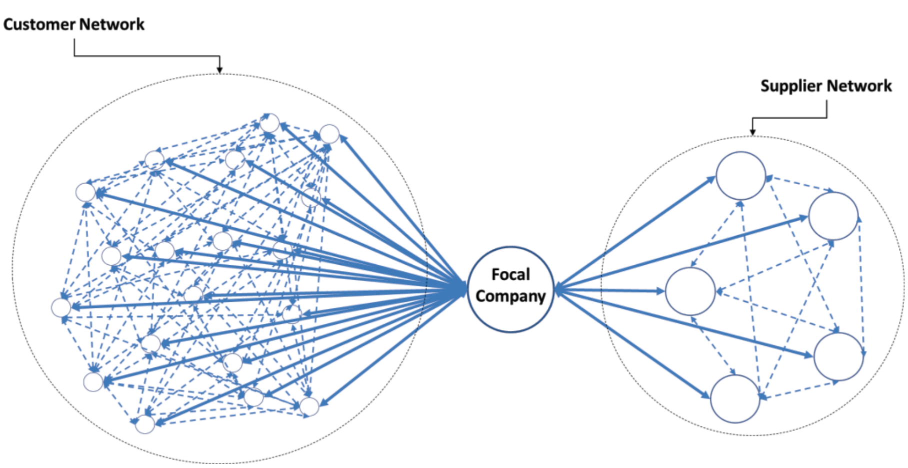

CRM, SRM, and Organizational Performance

Evidence supports that CRM motivates employees to remove functional barriers and encourage information sharing to enhance customer satisfaction (Chen and Popovich, 2003; Day, 2003; Cooper *et al*., 2008; Trainor *et al*., 2014). By implementing CRM, firms can create and maintain long-standing relationships with customers based on complete customer satisfaction (Reinartz *et al.*, 2004). This customer-centric approach is likely to improve customer interaction, increase the value of products and services, and ultimately improve customer satisfaction and business performance (Ryals, 2005; Kasim and Minai, 2009). Kuei *et al*. (2001) pointed out that improvements in organizational performance are related to improved supplier relationships. Previous research has also shown that SRM can help companies stay competitive and improve profitability (Swink *et al.*, 2005; Kosgei and Gitau, 2016**;** Kiarie, 2017). Table 2 summarizes key research on the relationship between CRM, SRM, and organizational performance over the past decade. In summary, considering the previous studies, a firm's CRM and SRM practices are expected to be positively associated with customer satisfaction, ultimately contributing to market performance. Therefore, the following hypotheses are suggested:

H3. *CRM is positively related to customer satisfaction.*
H4. *SRM is positively related to customer satisfaction.*
H5. *Customer satisfaction is positively related to market performance.*

Table 2: Major studies on CRM, SRM and organizational performance over the past decade

Study	Objective	Data	Results
Park *et al.*, 2010	Develop an integrated framework for SRM system.	Case study based on semiconductor manufacturing in South Korea	With SRM, companies can lower their purchasing costs, develop products on time, and maintain high quality.
Coltman *et al*., 2011	Study the effect of CRM on firm performance.	50 firms from industry sectors that use CRM	CRM capability is positively associated with human analytics and business architecture.
Shang and Lu, 2012	Explore the impact of CRM on financial performance in the context of freight forwarder services.	144 freight forwarding companies	CRM has a significant positive impact on financial performance
Bhat and Darzi, 2016	Investigate the effect of CRM on customer loyalty.	278 customers of a private bank	CRM has a positive impact on competitive advantage by improving customer loyalty.
Bashir, 2017	Explore how CRM impact on customer retention.	316 private bank customers	CRM positively impacts customer retention. CRM also helps build long term relationship with prospective customers.
Kiarie, 2017	Investigate the effect of SRM practices on operational performance.	60 large manufacturing firms with over 500 employees	SRM is significantly related to operational performance and productivity of manufacturing firms

Pozza *et al.,* 2018	Investigate the impact of CRM relative implementation time on performance.	142 European and 208 US top managers	Implementing a comprehensive CRM strategy can increase growth and loyalty.
Soltani *et al.,* 2018	Investigate how CRM affect organizational performance.	150 tax employees	The success of CRM is heavily influenced by information technology use and customer knowledge management.

RESEARCH METHODS

Measures

All of the measuring scales used in this study were prepared based on previous studies; however, scale items have been slightly modified to suit our study objectives. The survey items estimate the extent to which the respondent has agreed or disagreed with the given statement based on the 7-point Likert scale. Specifically, social media-related items were developed based on the studies of Jayachandran et al. (2005) and Trainor et al. (2014). Respondents are asked if they are using social media for customer and vendor management. The study of Reinartz et al. (2004) has been used to evaluate the company's CRM practices; the questionnaire measures how companies use CRM to initiate, acquire and maintain customer information to better respond to customer needs and expectations. The work of Swink et al. (2005) was used to assess the company's SRM practices. These measures capture cost, technology, and long-term relationships with suppliers. Various prior studies such as Das et al. (2000), Cho et al. (2017), Kaynak (2003), and Cho and Linderman (2019) were adopted to develop items that measure customer satisfaction and market performance.

In addition, this study adopted three control variables; (i) the number of full-time employees was used to measure company's size (ii) the length of time in business was used to measure the age of the company, and (iii) two-digit SIC codes were applied to categorize the company's industry groups (Cho and Linderman, 2019). Further, to minimize the likelihood of common method variance (CMV), this study used a "marker variable" that measures the severity of the respondent's insomnia problem (Bastien et al., 2001). Details of all measure items used in this study are shown in the Appendix.

Sample

Based on the work of Dillman et al. (2014), we designed our survey to collect primary data. In particular, the following criteria were established to obtain the appropriate sample data from eligible survey respondents; (i) companies participating in the survey must run at least one Social Media platform for their customer and vendor management, (ii) survey participants must have full-time positions in their companies, and (iii) If there are two or more respondents in the same organization, the highest ranked respondents are selected (Miller and Roth, 1994; Cho and Linderman, 2019). Survey invitations were sent out to 241 operations managers in the United States. Through three rounds of the survey, a total of 117 responses were collected, showing a response rate of 48.52%. The demographic profile of the sample is summarized in Table 3.

Table 3: Sample demographics

Category	Count

Company's Age (Length of Time in Business)	< 5 years	3	2.6%
	5 ~ 10 years	15	12.8%
	11 ~ 20 years	15	12.8%
	21 ~ 30 years	7	6.0%
	31 ~ 50 years	18	15.4%
	51 ~ 100 years	34	29.1%
	> 100 years	18	15.4%
	Missing responses	7	6.0%
Company's Size (Number of Employees)	< 10 employees	13	11.1%
	11 ~ 50 employees	9	7.7%
	51 ~ 100 employees	9	7.7%
	101 ~ 500 employees	17	14.5%
	501 ~ 1,000 employees	14	12.0%
	1,001 ~ 10,000 employees	24	20.5%
	> 10,000 employees	24	20.5%
	Missing responses	7	6.0%
Industry [2-digit SIC codes]	Agriculture, Forestry & Fishing [01-09]	2	1.7%
	Construction [15-17]	5	4.3%
	Apparel & Fabricated Textile Products [23]	1	0.9%
	Pharmaceuticals [28]	1	0.9%
	Transportation Services [47]	2	1.7%
	Communications Services [48]	7	6.0%
	Retail Trade [52-59]	11	9.4%
	Financial Services [60-64]	7	6.0%
	Hotels & Other Lodging Places [70]	2	1.7%
	Prepackaged Software [73]	3	2.6%
	Healthcare [80]	26	22.2%
	Education [82]	16	13.7%
	Accounting & Business Consulting Services [87]	2	1.7%
	Others	18	15.4%
	Missing responses	14	12.0%

ANALYSIS AND RESULTS

Testing of Scale Reliability and Validity

First, the scale reliability was examined by Cronbach's alpha. The alpha coefficients for all variables were between .710 and .901, which met the suggested threshold of .70 or higher (Cronbach, 1951; Hair et al., 2010). Next, Confirmatory Factor Analysis (CFA) was conducted to test the construct validity (Lee Park and Paiva, 2018). The CFA results (Chi-square = 381.183; *d.f.* = 215; Normed Chi-square = 1.773; CFI = .895; PNFI = .673; RMSEA = .082; RMSEA 90% confidence interval: .068 ~ .095) indicated that all measure items satisfied the suggested threshold of .50 or higher (Hair et al., 2010). The results of these measure assessments are summarized in Table 4. Descriptive statistics and correlations between variables are also reported in Table 5.

Table 4: Results of CFA

Factor and Items	Loading[a]	S.E.	t	Sig.	α
Social Media Platform					
Conversation support (e.g., Blogger, Twitter)	.616			***	.710
Relationship support (e.g., Facebook, LinkedIn)	.556	.183	4.533	***	

Sharing support (e.g., Flickr, YouTube)	.752	.236	5.285	***	
Groups and community support (e.g., NING, IGLOO)	.572	.202	4.621	***	
Social Media Capability					
Our company uses Social Media to detect changes in customers' product or service preferences.	.835			***	.833
Our company uses Social Media to collect customer complaints or supplier feedback.	.855	.127	8.088	***	
Customer Relationship Management					
We invest in technology to acquire and manage "real time" customer information and feedback.	.700				.893
We have a formal system to assess the value of our customers.	.818	.152	8.242	***	
We have a formal system to identify potential customers.	.783	.148	7.911	***	
We have a formal system to differentiate our communication objectives based on the value of our prospects.	.775	.136	7.833	***	
We continually update customer information to assess the true value of our customers.	.888	.146	8.866	***	
Supplier Relationship Management					
We provide technical support to our suppliers.	.650				.817
We share our cost information with our suppliers.	.744	.153	6.589	***	
We require cost information sharing by our suppliers.	.786	.148	6.852	***	
We make long-term contracts with our suppliers.	.575	.135	5.347	***	
We seek joint investments with our suppliers.	.740	.151	6.566	***	
Customer Satisfaction					
Customer satisfaction with our products/services has increased over the past 3 years.	.783			***	.901
Customer retention in our products/services has increased over the past 3 years.	.910	.089	11.050	***	
The best description of your company's customer satisfaction level.	.775	.110	9.029	***	
The best description of your company's customer retention level.	.892	.094	10.793	***	
Market Performance					
Sales growth	.948			***	.895
Market share growth	.821	.068	12.229	***	
Net profit margin	.824	.061	12.306	***	

Note: n = 117; [a] Standardized regression weights; [b] Standard error (not estimated when loading set to fixed value: i.e., 1.0); AVE = Average variances extracted; *** $p < 0.001$.

Table 5: Correlations and descriptive statistics

	Variables	1	2	3	4	5	6	7	8	9	Mean	S.D.
1.	Social media platform										3.906	1.420

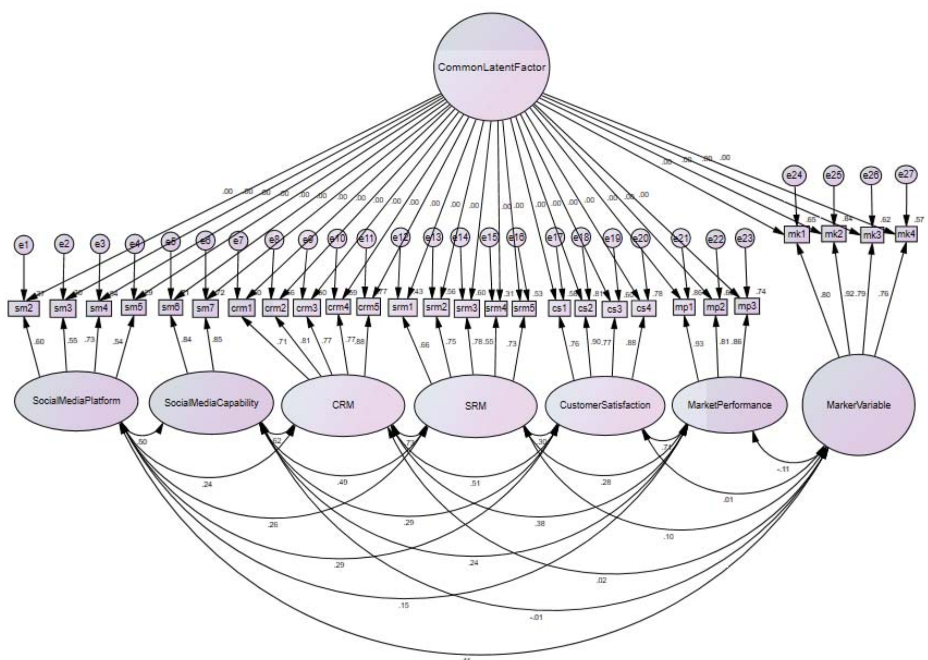
Note: *n* = 117; * significant at the .05 level (2-tailed). ** significant at the .01 level (2-tailed); [a] marker variable (to assess CMV); [b] length of time in business; [c] number of full-time employees.

Testing of Common Method Variance

Since the data of this study were obtained from a single source from each company, this study may not be free from common method variance (CMV) (Podsakoff et al., 2003). Hence, as an ex-ante remedy for minimizing the CMV threat, we included "marker variable" in our survey questionnaire (Podsakoff et al., 2003; Williams et al., 2010; Craighead et al., 2011). According to the guidelines of Simmering et al. (2015), "insomnia" was chosen as a marker variable for this study because the variable is not theoretically related to other variables in this study; the smallest correlation with other variables was also reported, as shown in Table 5. The insomnia measures used in this study are listed in the Appendix.

As an ex-post approach, we also investigated the potential threats of CMV in our data by performing a "common latent factor" analysis after completing data collection (Podsakoff et al., 2003; Richardson et al., 2009; Cho et al., 2017). Accordingly, we examined changes in the structural parameters when adding the common latent factor (CLF) to the measurement model. The test results demonstrated that the changes in parameters were minimal and CMV accounted for less than 1%, indicating that the CMV threat is not a pervasive problem in this study. Figure 4 shows the results of this CMV test performed by IBM AMOS 24.

Figure 4: Results of Common Latent Factor Analysis for CMV Assessment



Note: *n* = 108 (9 missing responses in the marker variable); standardized regression weights; Chi-square = 507.392; *d.f.* = 302; Normed Chi-square = 1.680; CFI = .879; PNFI = .647; RMSEA = .080 (90% confidence interval: .067 ~ .092).

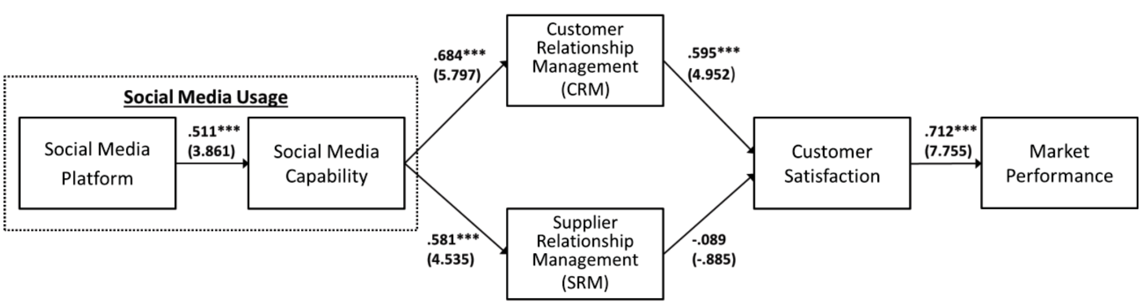
Results of SEM Analysis

To examine the hypotheses proposed in this study, we conducted a structural equaling modeling (SEM) analysis. The model fit was assessed by several different fit indices. The fit statistics reached or were very close to the desired threshold for each fit index (Chi-square = 415.688; *d.f.* = 224; Normed Chi-square = 1.856; CFI = .878; PNFI = .684; RMSEA = .086). Figure 5 illustrates the test results of the structural model hypothesized in this study. SEM test results demonstrate that social media platform is positively associated with social media capability (β = .511, t = 3.861, p < .001) and the usage of social media has a significant positive effect on both CRM (β = .684, t = 5.797, p < .001) and SRM (β = .581, t = 4.535, p < .001), supporting *H1* and *H2*. In addition, SEM test results indicate that CRM has a significant impact on customer satisfaction (β = .595, t = 4.952, p < .001) while there is no significant relationship between SRM and customer satisfaction (β = -.089, t = -.885, p = .376); therefore, *H3* is supported, but *H4* is rejected. Finally, the results also show that customer satisfaction significantly contributes to the company's market performance (β = .712, t = 7.755, p < .001), supporting *H5.*

Post Hoc Study

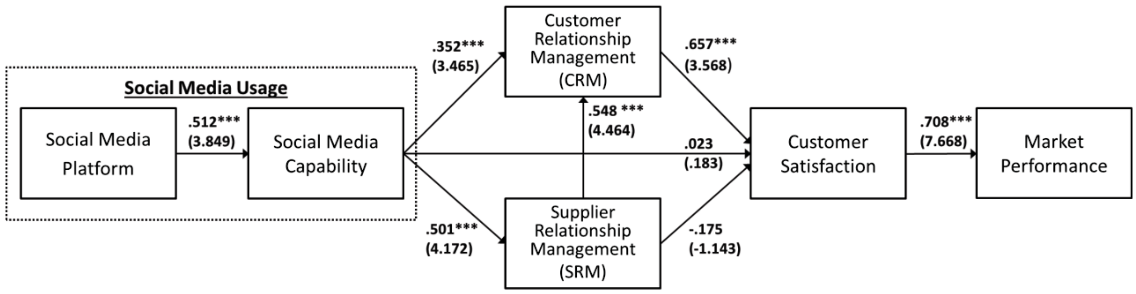
Although our sample did not support the direct effect of SRM on customer satisfaction (*H4*), SRM had a significant correlation with CRM and customer satisfaction as shown in Table V. Accordingly it is inferred that SRM indirectly affects customer satisfaction through CRM. We first tested this relationship with the modified SEM, as shown in Figure 6 (Chi-square = 387.551; *d.f.* = 222; Normed Chi-square = 1.746; CFI = .895; PNFI = .691; RMSEA = .080). Test results indicated that SRM had a significant positive impact on CRM (β = .548, t = 4.464, p < .001) while there was still no significant relationship between SRM and customer satisfaction (β = -.175, t = -1.143, p = .253). This implies that CRM is mediating the relationship between SRM and customer satisfaction. Therefore, we conducted an additional Sobel (1982) test to examine the significance of the mediation effect of CRM. Hence, z-value was computed by the following equation: $x*y/\mathrm{SQRT}(y^2*\mathrm{S.E.}_x^2 + x^2*\mathrm{S.E.}_y^2)$ where x is the unstandardized coefficient between SRM and customer satisfaction and y is the unstandardized coefficient between CRM and customer satisfaction; $\mathrm{S.E.}_x$ and $\mathrm{S.E.}_y$ are the standard errors. This result demonstrated that CRM had a significant mediation effect between SRM and customer satisfaction (z = 2.783, S.E. = 0.118, p = 0.005). Additionally, as shown in Figure 6, the SEM results of post hoc study also indicated that using social media did not directly affect customer satisfaction (β = .023, t = .183, p = .855).

Figure 5: Results of Hypothesized Structural Model



Note: n = 117; standardized path coefficients; numbers in parentheses indicate t-values; Chi-square = 415.688; *d.f.* = 224; Normed Chi-square = 1.856; CFI = .878; PNFI = .684; RMSEA = .086; *** p < .001.

Figure 6: Results of Post Hoc Analysis



Note: n = 117; standardized path coefficients; numbers in parentheses indicate t-values; Chi-square = 387.551; *d.f.* = 222; Normed Chi-square = 1.746; CFI = .895; PNFI = .691; RMSEA = .080; *** $p < .001$.

DISCUSSION

Implications for Practice and Research

The results of this study provide meaningful implications for practice and research in operational management. First, this study found that using social media has a significant impact on the company's CRM implementation, leading to customer satisfaction and competitive advantage in the marketplace. These results suggest that using social media can improve organizational performance by enhancing CRM capabilities. This finding is consistent with the earlier research by Trainor et al. (2014), which indicated that the use of social media could improve company's efficiency by facilitating internal and external collaboration that leads to internal solution improvements. The study findings also empirically support previous claims that effectively managing social media in conjunction with CRM would positively impact customer satisfaction and firm performances (Acker et al., 2011; Luo et al., 2013; Abzari et al., 2014). However, the post hoc study showed that using social media itself did not have a direct positive impact on organizational performance, indicating that technology alone is not sufficient to gain competitive advantage (Kotha, 1995). In short, the results of this study demonstrate that the combined operations of social media and CRM system enable companies to better respond to customer needs and gain feedback on products or services, thereby providing better products or services to customers. As such, it is advisable that operations managers consider increasing their investment in social media infrastructure and integrate their existing CRM systems with social media to improve operational efficiency and customer satisfaction.

Next, this study also showed that social media had a significant positive effect on firms' SRM implementation. This finding implies that the use of social media can improve SRM capability by allowing companies to quickly deliver their customers' real-time interests and changing needs to their suppliers, thereby reducing unnecessary inventories and improving lead times and operational efficiency. This study also revealed that the company's SRM practices did not directly affect customer satisfaction. However, the post hoc study has shown that the company's CRM system positively mediated the relationship between SRM and customer satisfaction. This finding implies that the impact of a firm's SRM practices on organizational performance can be achieved positively when combined with the efficient operation of the CRM system. Lam et al. (2016) argued that social media initiatives could improve knowledge-based benefits (e.g., information flow and knowledge sharing) within an organization and also enable organizations to access external knowledge and information outside their supply chain networks, ultimately driving operational efficiency and innovativeness. As such, instead of customer satisfaction and market performance used in this study, future research may adopt other criterion variables (e.g., new product development, product quality improvement, demand forecasting, and product and process innovation) in order to better understand how the combined operations of social media and the SRM system contributes to organizational performance.

Contributions to Theory

The present study also provides fundamental contributions to theory. First, by conceptualizing the critical role of social media in forming social networks among a focal firm, customers, and suppliers, this research contributes to the literature on social network perspective, integrating with the literature on operations management (Freeman, 2004; Borgatti et al., 2009; Kim et al., 2011). Second, this research also supports the knowledge-based view of the firm by showing that the combined framework of social media and supply chain information systems (i.e., CRM and SRM) can be a better strategic corporate resource to drive knowledge creation and superior organizational performance (Grant, 1996; Spender, 1996). Moreover, by adopting and validating the “insomnia” scale as a marker variable, this study also makes a methodological contribution to operations research in terms of how to defend against CMV threats arising from survey-based data collection.

Limitations and Future Research

Despite these meaningful contributions to practice and theory, there are some limitations to this study. All samples in this study came from U.S.-based companies operating under state-of-the-art social network infrastructure. However, given that many companies today are doing business globally in diverse social media infrastructure and regulatory environments, a fundamental question arises as to whether the results of this study will be useful for business operations in other countries. Further, previous studies have shown that cultural differences have a significant impact on information sharing practices (Li et al., 2014; Guo et al., 2017). Thus, future research should verify the social media effects on CRM and SRM implementations in various social media environments by using other country samples. Another limitation is that our study was conducted in the context of cross-sectional data. In the current study, we can not observe specific processes of how relationships with customers and suppliers are strengthened as social networks evolve through social media channels. Therefore, it seems particularly valuable to use longitudinal data to explore the evolution of social media effects on CRM and SRM implementations.

CONCLUSION

“To question the power of social media in society is to question the importance of sunlight on earth. It’s no longer a want, but a need," said Atanu Shaw, Vice President of Roosterly (2018 May 11, www.forbes.com). As discussed earlier, research on the role of social media has received a lot of attention in a variety of academic disciplines, but it is still in the early stages of operations and supply chain management. In particular, existing literature does not provide sufficient empirical evidence on how the use of social media affects the company's supplier and customer relationship management. Based on data from 117 US companies, we examined the impact of social media usage on the operational efficiency of CRM and SRM systems. The evidence in this study also supported that the social media technology embedded in the supply chain information systems could be a strategic resource for companies to create competitive advantage. We hope that this study will motivate future researchers to further study the role of social media use in operations and supplier chain management.

APPENDIX

Social Media Usage (Adapted from Jayachandran et al., 2005; Trainor et al., 2014)
Does your company use any forms of Social Media? YES □ NO □ If YES,
Social media platform
- Our company use Social Media for conversation support (e.g., Blogger, Twitter)
- Our company use Social Media for relationship support (e.g., Facebook, LinkedIn)
- Our company use Social Media for sharing support (e.g., Flickr, YouTube)
- Our company use Social Media for groups and community support (e.g., NING, IGLOO)

Social media capability
- Our company uses Social Media to detect changes in customers' product or service preferences.
- Our company uses Social Media to collect customer complaints / supplier feedback.

Customer Relationship Management (Adapted from Reinartz et al., 2004)
- We invest in technology to acquire and manage "real time" customer information and feedback.
- We have a formal system to assess the value of our customers.
- We have a formal system to identify potential customers.
- We have a formal system to differentiate our communication objectives based on the value of our prospects.
- We continually update customer information to assess the true value of our customers.

Supplier Relationship Management (Swink et al., 2005)
- We provide technical support to our suppliers.
- We share our cost information with our suppliers.
- We require cost information sharing by our suppliers.
- We make long-term contracts with our suppliers.
- We seek joint investments with our suppliers.

Customer Satisfaction (Adapted from Das et al., 2000; Cho et al., 2017)
- Customer satisfaction with our products/services has increased over the past 3 years.
- Customer retention in our products/services has increased over the past 3 years.
- The best description of your company’s customer satisfaction level on a scale of 1 to 7 (1 “low end of the industry,” 2 “much worse than average,” 3 “worse than average,” 4 “average,” 5 “better than average,” 6 “much better than average,” 7 “superior”)
- The best description of your company’s customer retention level on a scale of 1 to 7.

Market Performance (Kaynak, 2003; Cho and Linderman, 2019)
Evaluate your company’s market performance for competitive products or services in the industry on a scale of 1 to 7 (1 “low end of the industry,” 2 “much worse than average,” 3 “worse than average,” 4 “average,” 5 “better than average,” 6 “much better than average,” 7 “superior”).
- Sales growth
- Market share growth
- Net profit margin

Marker Variable (Bastien et al., 2001)
Please rate the current severity of your insomnia problem.
- Difficulty falling asleep: (1) None, (2) Mild, (3) Moderate, (4) Severe, (5) Very severe

- Difficulty staying asleep: (1) None, (2) Mild, (3) Moderate, (4) Severe, (5) Very severe
- How satisfied are you with your current sleep patterns? (1) Very satisfied, (2) Satisfied, (3) Moderately satisfied, (4) Dissatisfied, (5) Very dissatisfied
- To what extent do you think there is a sleep disorder that interferes with your daily life? (e.g. ability to function at work/daily chores, mood, concentration, memory)? (1) Not at all Interfering, (2) A little, (3) Somewhat, (4) Much, (5) Very much interfering.

ABSTRACT

Evaluating the organization's performance and communicating to shareholders are central roles of top management. This study extends the literature by investigating sentiment in the letters of shareholders as an indicator of top managers' interpretation of the firms' situation, which consequently influences the firms' post crisis profitability performance. Sentiment analysis was conducted to extract sentiment from the letters of shareholders. Overall, the results suggest that sentiment is a viable indicator of the top managers' reflections on upcoming performance, contingent on the degree of management discretion.

KEYWORDS: Sentiment analysis, Letter to shareholders, organizational performance, economic crisis

INTRODUCTION

Top management plays an important role in interpreting the current situation of the company and communicating the future direction and expectations to organizational stakeholders (Hambrick & Mason, 1984). In economic crisis, where tensions create anxiety and test the emotions of the organization's stakeholders, positive communication from top management can mitigate anxiety and positively affect performance (Lehmberg & Tangpong, 2018). Managerial communications from top management can take several forms and reflect various substances, including managerial sentiment. Sentiment – positive or negative – may indicate what will be coming for the company in the future.

Recently, developments in sentiment analysis have facilitated new research examining sentiment in managerial communications such as letters to shareholders and organizational performance (Boudt & Thewissen, 2019). However, these studies have yet to examine sentiment in crisis situations, where they arguably are particularly important.

To help explore these new areas, we ask the following research questions: (1) In the midst of economic crisis, are top management sentiments identified in letters to shareholders an effective indicator of the top management' interpretation of the firm's situation? And (2), does the degree of managerial discretion moderate the role of sentiment addressed in the first research question?

THEORETICAL BACKGROUND AND HYPOTHESES

Upper echelons theory posits that top managers make decisions based upon their personal interpretation of the situation they face, and that these decisions affect how the company acts, and ultimately performs (Hambrick, 2007; Hambrick & Mason, 1984). These interpretations are colored by the manager's experience, skills, values, and personalities (Hambrick, 2007).

In the management literature, it has been reported that both cognitive and affective factors influence CEO's strategic choices in particular situations and consequently could be reflected in the firms' performance (Delgado-García & De La Fuente-Sabaté, 2010; Staw & Barsade, 1993).

In this study, we aim to examine how sentiment, which is a belief that has emerged from emotions, influences top management's expectations of the firm's subsequent performance. Positive sentiment in letters to shareholders suggests that top management interprets the company's situation as offering potential for improvement and better performance. In other words, positive sentiment can be considered as an expression of top management's positive expectations of future performance. On an individual level, this suggests that top managers may be more active in identifying and investing in growth opportunities. At the organizational level, the positive atmosphere which is established and maintained through positive sentiment of the top managers may lead to a healthy morale and organizational climate which supports effective implementation of existing strategies as well as development of new ones. These positive actions and healthy climate enable the firm to improve subsequent performance. Based upon this logic, we hypothesize:

H1: The greater the positive sentiment from the letter to shareholders, the better the firms' subsequent performance.

Previous studies have suggested that the relationship between sentiment and managers' strategic decision making can be moderated by certain managers' characteristics, such as managerial discretion (Espedal, 2007). Hambrick (2007) notes that the degree of managerial discretion or "latitude of action" (p. 335) present affects the relationship between the top management's interpretations and subsequent performance. Where managerial discretion is high, top managers have discretion to select and implement a large variety of strategic actions, whereas where discretion is low, top management has access to a much narrower variety of actions, and is restricted in how they may implement these actions (Crossland & Hambrick, 2011). In this study, we hypothesize that the relationship between sentiment and subsequent performance may be moderated by the degree of managerial discretion present.

H2: Management discretion moderates the relationship between sentiment and performance.

When research investigates the characteristics of managers across different countries, home country appears to be a reasonable proxy for managerial discretion at the national cluster level. This is because the degree of managerial discretion is systematically influenced by national institutions of the organization's home country.

For this research, we study firms from the U.S. and Japan. This allows us to examine the effect of managerial discretion systematically at the national cluster level as the two countries are arguably the extreme cases at the opposite ends of the spectrum of managerial discretion. Managerial discretion is very high in the U.S. and very low in Japan (Crossland & Hambrick, 2007, 2011). Accordingly, we expect to find a strong relationship between sentiment and subsequent performance in U.S. based firms, and a weak (or no) relationship in the Japan based firms.

METHODOLOGY

Sentiment Analysis

This research employs sentiment analysis to extract sentiments from the letters of shareholders. Sentiment analysis is considered as a text mining technique that classifies the polarity of the text into positive, negative, or neutral (Pang & Lee, 2008). Sentiment analysis can be conducted at various levels of text (e.g., word, sentence, or document) and involve other concepts. In this study, sentiment analysis was conducted at the document level to extract the overall sentiment from letters to shareholders.

A sentiment analysis tool developed by IBM, Watson Natural Language Understanding (NLU), was used to extract sentiments in the letters to shareholders. Watson NLU is a cloud-based application that provides a set of services to analyze text information. In general, the sentiment classification feature in Watson NLU enables users to identify a given piece of text expresses positive or negative opinion. The sentiment classification relies a supervised machine learning technique to create a sentiment classifier that uses a lexicon-based approach to process text. It is considered as a domain independent application, which generate sentiment scores from the correlations between the embedding pre-trained sentiment words and the documents (Li, Zhang, & Sindhwani, 2009). Specifically, Watson NLU relies on the Matrix Factorization with Lexical (MFLK) approach developed based on a non-negative matrix factorization method to derive the sentiment scores (Li et al., 2009). Studies examining managerial communications have content analyzed the letters to shareholders (e.g., Cho & Hambrick, 2006; McClelland, Liang, & Barker, 2010; Patelli & Pedrini, 2013; Staw, McKechnie, & Puffer, 1983), including sentiment analysis (Boudt & Thewissen, 2019). The letter to shareholder is highly suited to such research because it is a concise, high profile, publicly available document which can readily be compared with those of previous years or other companies. Additionally, because unlike other parts of the annual reports, the letters themselves are not audited or required by the SEC, giving the CEO more freedom to put these together as they wish (Abrahamson & Amir, 1996; Boudt & Thewissen, 2019).

Sample Selection and Data Gathering

We used a sample consisting of U.S. and Japan based companies. As stated above, this allows us to examine the effect of managerial discretion on the relationship between sentiment and subsequent performance because the U.S. is very high in managerial discretion while the Japanese context is very low (e.g., Crossland & Hambrick, 2011). Additionally, this also allows us to maintain comparability with past studies of letters to shareholders, which have typically relied on U.S. samples.

Since crisis is a context where the role of sentiment may be particularly important, our study used a time frame in the midst of economic crisis, following Lehman Brothers' bankruptcy announcement in September 2008. This crisis became worldwide and had strong effects on Japanese as well as U.S. based firms.

To facilitate this research and mitigate several potential biases, we used a sampling strategy that involved both judgmental and stratified aspects (Babbie, 1995). We first identified a number of publicly traded firms in Japan and the U.S. in major, representative industries. We then screened out Japanese firms that did not provide letters to shareholders in English, and finally, we adjusted the makeup of the sample so that both Japan and U.S. sub-samples had similar representations in each of the industries.

Our final sample consisted of 100 firms: 50 from the U.S. and 50 from Japan. The set of industries represented was broad, ranging from heavy machinery to food. For each of the sample firms, we obtained the letters to shareholders published immediately following the Lehman Brothers bankruptcy announcement in September 2008.

Dependent, Independent, and Control Variables

The dependent variable in this study is post-crisis profitability performance (PCPP), which is a measure derived from the firms' return on assets (ROA) and return on sales (ROS) reported a year after the crisis. Both ROA and ROS are common measures used in the literature to assess business firms' performance (e.g., Daniel, Lohrke, Fornaciari, & Turner, 2004). Since ROA and ROS are highly correlated, a principal component analysis (PCA) was used on ROA and ROS to create a composite measure, PCPP, as an indicator of the firms' post-crisis profitability performance and the dependent variable in this study.

Two independent variables are included in the model—sentiment and interaction between sentiment and the level of management discretion. The sentiment score is a continuous variable obtained from the MFLK algorithm. An interaction term is created from the sentiment score and the country dummy variable to observe the moderating effect of management discretion on the relationship between sentiment and PCPP.

In addition, a set of control variables are included in the model to control major confounding effects related to the firms' pre-crisis conditions. These variables are commonly used in the previous studies related to firm performance (e.g., Lahiri & Narayanan, 2013; Tangpong, Abebe, & Li, 2015). These control variables are (a) the firms' profitability performance derived from the PCA factor score composed of ROA and ROS, (b) level of leverage measured by debt-to-asset ratio, (c) the firms' liquidity measured by current ratio, (d) the firm size measured by total sale, and (e) management discretion, a categorical variable represented by country (Japan = 0 and US = 1). Note that leverage, liquidity, and firm size were log transformed to correct the distribution skewness.

DATA ANALYSIS AND RESULTS

The results form a correlation analysis suggested that there was an issue with multicollinearity when the interaction term between sentiment score and country variables entered the model. Therefore, sentiment score was mean centered to remove the multicollinearity produced by interaction.

We used three regression models to test our proposed hypotheses in examining the effects of sentiment and management discretion on PCPP, controlling for the firms' pre-crisis conditions. The first model was developed as a baseline, which contained only the control variables. The results revealed that, among the pre-crisis attributes, the firms' pre-crisis profitability performance and the country appear to be significant variables that influence PCPP.

Consequently, the second model was created to test Hypothesis 1, which proposed that sentiment generates positive influence on PCPP. The results suggested that, while the effects of sentiment were in expected direction, the significant level does not reach the 0.05 level; therefore, Hypothesis 1 is partially supported.

Finally, the third regression model was developed to test Hypothesis 2, which hypothesized a positive relationship between the interaction between sentiment and management discretion and PCPP. The findings indicated that the effect of the interaction term on PCPP is statistically significant at the 0.05 level. Therefore, these results suggested that management discretion plays a significant role in moderating the relationship between sentiment and PCPP and Hypothesis 2 is supported. Note that the firms' profitability performance is the only control variable that produced statistically significant effect on PCPP across the three regression models.

DISCUSSION AND CONCLUSION

Overall, the results of this study indicate that sentiment found in letters to shareholders can be an indicator of management's interpretation of the firm's subsequent performance (Hypothesis 1), especially those with high degrees of management discretion (Hypothesis 2). Therefore, this study adds to the current literature and provide insights regarding how top managements interpret the firms' situation and communicate with their shareholders. In addition to the consistent direction of the main effect of sentiment on the firms' performance with previous studies (e.g., Boudt & Thewissen, 2019), our results also indicate that organizational contexts such as management discretion could moderate such effect.

After incorporating the control variables into the model, while the direction was as expected, the effect of sentiment on PCPP was only significant at the 0.1 level (Hypothesis 1). One possible explanation is that sentiment, as an affective aspect of the strategic decision making communicated in the letters to shareholders, may alone be a less effective indicator of subsequent performance. It is also possible that during certain situations (e.g., economic crisis), the cognitive features in the letters to shareholders tend to make more of a contribution than do the affective features for strategic decision (Swann, Griffin, Predmore, & Gaines, 1987). Therefore, in addition to the writing tone and mood overall, future studies should also investigate features related to the cognitive aspect in the letters to shareholders, such as specific goals and outcomes, expected cash flow and net income, and other major financial measures.

In addition, our results indicate that management discretion appears to be a significant moderator between sentiment and PCPP. It is possible that, where managerial discretion is high, top managers are more willing to disclose their sentiment that better reflects the forward-looking into what the companies may be facing in the near future. As such, under the high management discretion condition, the sentiment in the letters to shareholders becomes a more accurate indicator of the subsequent performance. Alternatively, the finding can also be interpreted that when the top management shares the positive sentiment 'publicly' to shareholders and stakeholders, they may become more committed to making the positive future results happen. With managerial discretion, they are more likely to take action and own up to what they have communicated to shareholders and stakeholders publicly.

Contributions

This study makes two important contributions to the literature. First, our study suggests that whether sentiment extracted from the letters to shareholders is a valid indicator of the top managers' reflections on upcoming performance is contingent to the degree of management discretion. This thus extends beyond the previous research focusing primarily on the sentiment-performance link. Second, our study broadens the scope of top management communication study or the research on letters to shareholders by investigating them at the sentiment level, which is a key departure from the mainstream research focusing the investigating efforts at the strategic and cognitive levels (e.g., Lehmberg & Tangpong, 2018).

In addition to the contributions to the literature, this study provides two practical insights. First, based on our findings, when the managerial discretion is high, firms' investors, partners, and other stakeholders can use the sentiment in top management communications to public to gauge whether the firms' situation would be improving in the near future. This foresight would allow those stakeholders to determine whether or how much they should commit their investment of time, effort, and money to the firms. If the situation is assessed as negative, some active interventions from stakeholders would soon be put in place to mitigate the potential adverse consequences. Second, from the perspective of the firms' top managers, if they plan to use their public communication via letters to shareholders as a mechanism to distribute the positive sentiments to shareholders or to use it as a reinforcing mechanism to compel them to strive for performance improvement, they should ensure that they would have adequate managerial discretion to deliver what they have publicly communicated.

Limitations and Future Research

Despite its contributions, there are important limitations of the study that warrant discussion. First, we restricted our investigation on top managers. In fact, lower-level managers and employers may also influence the development of strategic decisions of the firms. In this study, we speculate that while influence may emerge from numerous parts of the organization, the top managers and the CEO dominate the judgement and interpretation of the firm's situation addressed in the letters to shareholders. Second, our sample was restricted to large firms during a major economic crisis. Therefore, our findings may not be generalized broad base. Third, we used the U.S. and Japan as a proxy for high and low managerial discretion, respectively. While this practice is supported by the literature (e.g., Crossland & Hambrick, 2011), it is a crude proxy, thus limiting us to examine the phenomena at a finer-grained level. Finally, we used a proprietary sentiment analysis tool provided by IBM Watson's Natural Language Understanding (NLU) to generate the sentiment scores. While the algorithm used by Watson NLU is considered as a domain-independent technique that can effectively classify sentiments in text data, further studies may examine additional sentiment analysis techniques which may result in different conclusions.

A comparison of dispatching procedures to schedule jobs in a no-wait flow shop to minimize total earliness and tardiness with additional idle time allowed

Jeffrey Schaller

ABSTRACT

This paper considers the problem of scheduling jobs in a no-wait flow shop with the objective of minimizing total earliness and tardiness. Idle time may be needed on the first machine due to the no-wait restriction. Additional idle time can be used to improve the objective. A model is developed that shows additional idle can be inserted on the first machine to help reduce earliness. Several dispatching heuristics that have been in other environments were modified and tested. The LIN1 and Modified Due Date (MDD) procedures performed best.

KEYWORDS: Scheduling; Heuristics; No-Wait Flow Shop; Earliness and Tardiness

INTRODUCTION

The widespread adoption of lean production methods has caused early delivery of products as well as tardy delivery to be viewed as undesirable. Early deliveries result in unnecessary inventory that ties up cash as well as space and resources needed to maintain and manage inventory. Products that are delivered late can cause penalties such as lost sales and loss of customer good will. This paper addresses this trend by considering an objective that sums the penalties for earliness and tardiness for a set of jobs to be processed in a no-wait flow shop.

A flow shop is a production shop that consists of two or more machines. In a flow shop each of the jobs to be processed uses the machines in the same order. In a no-wait flow shop once a job starts processing it must continue through the flow shop without any intermediate waiting. In some cases, the nature of the product is such that the no-wait restriction is a requirement. In many cases, organizations are adopting a lean production philosophy and want to minimize waste by not having any waiting between the machines. When jobs do not have to wait between the machines there is no in-process inventory and space is not wasted.

Formally, suppose there is a set of n jobs to be processed in a flow shop with M machines. Let d_j be the due date of job j $(j = 1, \ldots, n)$. Let p_{jm} and C_{jm} represent the processing time and completion time of job j $(j = 1, \ldots, n)$ on machine m $(m = 1, \ldots, M)$. The earliness of job j, E_j, is defined as:

$$E_j = \max\{d_j - C_{jM}, 0\}, \text{ for } j = 1, \ldots, n \tag{1}$$

and the tardiness of job j, T_j, is defined as:

$T_j = max\ \{C_{jM} - d_j, 0\}$, for $j = 1, \ldots, n$. (2)

The objective function, Z, can be expressed as:

$$Z = \sum_{j=1}^{n} E_j + T_j. \tag{3}$$

In a traditional flow shop, there could be idle time on any of the machines but in a no-wait flow shop idle time may be needed before a job begins processing on the first machine to ensure that the job does not have wait on machines 2 through M. This is due to the no-wait restriction in which storage of jobs is not allowed in between the intermediate stages. The objective in this problem is non-regular, therefore the insertion of additional idle time on the first machine (beyond what is needed to ensure a job's continuous processing once started) could help to reduce the earliness of some jobs and thus improve the objective. However, to our knowledge, previous research has not considered additional idle time for this problem. In this research schedules with additional inserted idle time in a no-wait flow shop are considered.

LITERATURE REVIEW

Earliness and Tardiness Costs

Many papers have been published on scheduling models with earliness and tardiness costs. (Baker and Scudder, 1990) provide an excellent survey of the initial work on early/tardy scheduling. A more recent survey of multicriteria scheduling which includes problems with earliness and tardiness penalties is given in (Hoogeveen, 2005). Most of the research with an objective based on early and tardy job completion costs deals with single machine environments. Recent research for single machine environments with an early/tardy objective and no idle time is summarized in (Valente, 2009). Scheduling models with inserted idle time, on the other hand, are reviewed in (Kanet and Sridharan, 2000).

Earliness and Tardiness in Flow Shops

Ten papers considered earliness and tardiness costs for flow shop environments without the no-wait restriction. Two early papers that considered the objective were (Zegordi et al.,1995) and (Rajendran, 1999). (Moslehi et al., 2009) considered the objective of minimizing the sum of maximum earliness and tardiness in a two-machine flow shop. (Chandra et al., 2009) consider the flow shop problem with earliness and tardiness penalties when there is a common due date. (Madhushini et al., 2009) developed branch-and-bound algorithms by for a variety of objectives including minimizing earliness and tardiness. (Schaller and Valente, 2013b) developed a genetic algorithm, (M'Hallah, 2014) developed a variable neighborhood search heuristic, and a constructive heuristic, as well as local searches were developed by (Fernandez-Viagas et al., 2016) for the problem. Family setups were incorporated into the problem by (Schaller and Valente, 2013a). (Schaller and Valente, 2019) consider the problem of scheduling a permutation flow shop to minimize total earliness and tardiness when unforced idle time is allowed and develop several heuristics for the problem.

No-Wait Flow Shops

To the best of our knowledge there have been no papers that have addressed the problem of minimizing total earliness and tardiness in a no-wait flow shop with additional idle time allowed. However, there has been a great deal of research on scheduling problems in the no-wait flow shop environment. A review of early work was provided by (Hall and Sriskandarajah, 1996). Much of the research dealt with objectives that were measures of efficiency such as minimizing makespan or flowtime. Recent research with an objective of minimizing makespan includes (Pan et al., 2008) and (Laha and Chakraborty, 2009). For the flowtime objective, (Framinan et al., 2010) and (Gao et al., 2011) are recent examples. There has been increased research in recent years on objectives that measure the shop's ability to meet due dates and include tardiness in the objective. Minimizing total tardiness is similar to our objective but does not penalize the early completion of jobs. (Aldowaisan and Allahverdi, 2012), (Liu et al., 2013) and (Ding et al., 2015) are recent examples of research for minimizing total tardiness in no-wait flow shops.

PROBLEM DEFINITION

In this paper we only consider no-wait flow shops. A permutation flow shop is a flow shop in which the order the jobs are processed remains the same on each machine. Therefore no-wait flow shops are also permutation flow shops so a solution is defined by determining the order in which the jobs will be processed. Also, for each pair of jobs it can be determined how much idle time is needed on the first machine between the finish time of the job sequenced first and the start time of the job sequenced second. This time is the same regardless of where the pair of jobs appears in the sequence so it can be calculated before sequencing jobs. We refer to this time as the delay or offset time and use OS_{jk} to denote the offset time needed on the first machine if job j is sequenced immediately after job k for job j not to wait at any of the machines. A dummy job 0 is used to take into consideration that a job may be first in a sequence and $OS_{j0} = 0$ for $j = 1, \ldots, n$. Once a start time for a job is determined, its completion time on the final machine is easy to determine as we only need to add the sum of the job's processing times to its start time. Let $[j]$ represent the job that is in the jth position of a given sequence. The completion time of the job in position j of the sequence if no additional idle were inserted is:

$$C_{[j]M} = C_{[j-1]1} + OS_{[j][j-1]} + \sum_{m=1}^{M} p_{[j]m} \text{, where } C_{[0]1} = 0. \tag{4}$$

If a job was to be completed early, we may consider delaying the start of the job on the first machine to be greater than what would be needed to ensure it did not have to wait at any machine. We refer to this delay as additional idle time. We use $AI_{[j]}$ to denote the additional idle time inserted before the job sequenced in position j. Therefore the completion time of the job in position j of the sequence is:

$$C_{[j]M} = C_{[j-1]1} + AI_{[j]} + OS_{[j][j-1]} + \sum_{m=1}^{M} p_{[j]m} \text{, where } C_{[0]1} = 0. \tag{5}$$

To calculate the offset time between a pair of jobs j and k when job j is to immediately follow job k (OS_{jk}) we can use the following.

$$OS_{jk} = \max_{m=1,\ldots,M-1} \{ \sum_{l=1}^{m} p_{kl+1} - \sum_{l=1}^{m} p_{jl} \}. \tag{6}$$

The offset times between pairs of jobs can be thought of as a sequence-dependent setup time on the first machine. Using this concept, the problem can be transformed into a single-machine early/tardy problem with sequence-dependent setups. Let d_j' be a modified due date for job j by setting

$$d_j' = d_j - \sum_{m=2}^{M} p_{jm} \ . \qquad (7)$$

This is the time job j must finish on the first machine in order to finish on time on the last machine since the no-wait constraint means that the job is processed on all machines without any idle time between machines. The earliness of job j, E_j, can be equivalently defined as:

$$E_j = \max\{d_j' - C_{j1}, 0\}, \text{ for } j = 1,\ldots, n \qquad (8)$$

and the tardiness of job j, T_j, is defined as:

$$T_j = \max\{C_{j1} - d_j', 0\}, \text{ for } j = 1,\ldots, n. \qquad (9)$$

The problem then becomes:

$$\text{Min } Z = \sum_{j=1}^{n} E_{[j]} + T_{[j]} \qquad (10)$$

Subject to:

$$C_{[j]1} = C_{[j-1]1} + AI_{[j]} + OS_{[j][j-1]} + p_{[j]1}. \qquad \text{For } j = 1, \ldots, n \qquad (11)$$

If we have a specific sequence, then the insertion of additional idle on the first machine is an important element in optimizing the total earliness and tardiness for that sequence. A single-machine timetabling procedure for inserting idle time into a given sequence for minimizing total earliness and tardiness (Fry et al., 1987; Davis and Kanet, 1993; Kim and Yano, 1994) can be used with the modified due dates (dj's) to accomplish this task. In the next section we describe dispatching procedures that are used to develop sequences for the problem and once a sequence is generated a timetabling procedure is used to insert additional idle time on the first machine to obtain an objective value.

DISPATCHING HEURISTICS TESTED

Seven dispatching heuristics that have been used for minimizing total earliness and tardiness in permutation flow shops but without the no-wait restriction and considering additional idle time are tested in this research. These procedures were modified for the no-wait flow shop environment and to consider adding additional idle time on the first machine as described in the previous section.

We use the following notation in the heuristics. S is a current partial schedule. If job j ($j \notin S$) is the next job scheduled after S, $C_{jM}(S)$ is job j's the completion time. We use $s_j(S)$ to represent the slack of job j if job j is the next job scheduled after S, where $s_j(S) = d_j - C_{jM}(S)$. Additionally, let t be the current availability time of machine 1 under schedule S. This is the time the last job in schedule S completes its processing on the first machine. $P_j(S)$ ($P_j(S) = C_{jM}(S) - t$) is used to represent the time the shop is allocated to job j if job j is the next job scheduled after S, which includes the total processing time of job *j* plus the initial idle time on the first machine. Therefore, since the problem deals with a no-wait flow shop environment, *Pj(S)* includes both the job's cumulative processing time and its offset time. Suppose *k* jobs have been selected and we are now selecting the $k+1^{st}$ job. Let *[k]* represent the job in position *k*.

$$P_j\,(S) = OS_{j[k]} + \sum_{m=1}^{M} p_{jm} \quad . \tag{12}$$

Earliest Due Date (EDD)

The earliest due date (EDD) was first proposed by (Jackson, 1955). This rule schedules the jobs in non-decreasing order of their due dates d_j.

Modified Due Date (MDD)

In the modified due date (MDD) heuristic (Baker and Bertrand, 1982; Vepsalainen and Morton, 1987), at each iteration we select the job with the minimum value of the modified due date.

$$MDD_j\,(S) = \max\,\{d_j, C_j\,(S)\} = \max\,\{d_j, t + P_j\,(S)\} = \max\,\{d_j - t, P_j\,(S)\}. \tag{13}$$

Minimum Slack Rule (SLK) and Minimum Slack per Work Rule (SLK/P)

The minimum slack (SLK) rule (Panwalkar & Iskander, 1977; Vepsalainen & Morton, 1987) chooses, at each iteration, the job with the minimum slack

$$s_j\,(S) = d_j - C_j\,(S). \tag{14}$$

The minimum slack per required time (SLK/P) (Panwalkar & Iskander, 1977; Vepsalainen & Morton, 1987) selects, at each iteration, the job with the minimum value of the ratio

$$SLK/P_j\,(S) = s_j\,(S)/\,P_j\,(S). \tag{15}$$

LIN-ET Rules (LIN1 and LIN2)

The following two rules are based on the LIN–ET procedure proposed in (Ow & Morton, 1989) for the weighted single machine problem. These rules, which will be denoted by LIN1 and LIN2, choose, at each iteration, the job with the largest value of the following priority indexes:

$$LIN1_j(S) = \begin{cases} \frac{1}{P_j(S)} & if \quad s_j(S) \le 0 \\ \frac{1}{P_j(S)} - \frac{s_j(S)}{slk\_thr} \times \frac{2}{P_j(S)} & if \quad 0 < s_j(S) < slk\_thr \\ -\frac{1}{P_j(S)} & if \quad s_j(S) \ge slk\_thr \end{cases} \tag{16}$$

and

$$LIN2_j(S) = \begin{cases} \frac{1}{P_j(S)} & if \quad s_j(S) \le 0 \\ \frac{1}{P_j(S)} - s_j(S) \times \left(\frac{1}{slk\_thr \times P_j(S)} + \frac{1}{P_j(S)}\right) & if \quad 0 < s_j(S) < slk\_thr, \\ -\frac{s_j(S)}{P_j(S)} & if \quad s_j(S) \ge slk\_thr \end{cases} \tag{17}$$

where slk_thr, which stands for "slack threshold", is a parameter meant to represent a value such that slacks which are greater or equal to that value are considered large.

In the first branch of the priority index, identical in both heuristics, a job is late or on time if scheduled next. When one or more such jobs exist, LIN1 and LIN2 select the job using a shortest time rule, in line with various heuristics for (earliness and) tardiness problems (Baker, 1974; Ow & Morton, 1989; Smith, 1956).

In the third branch, the job has a large slack, and is quite early. If all jobs are quite early, LIN1 chooses the job using a longest time rule, again in line with several heuristics for early/tardy problems (Ow & Morton, 1989; Valente, 2007; Valente & Alves, 2005). LIN2, on the other hand, selects the job with the minimum slack per required time. Finally, the middle branch performs a linear interpolation between the priority values corresponding to $s_j(S) = 0$ and $s_j(S) = slk\_thr$. Such an interpolation was first performed in the LIN–ET procedure (Ow & Morton, 1989).

The *slk_thr* parameter is calculated as follows. At each iteration, representing a partial schedule *S* with *k* jobs, the slack threshold is set equal to

$$slk\_thr = w * (C_{\max}^{\mathrm{LB}}(S) - t), \tag{18}$$

where $C_{\max}^{\mathrm{LB}}(S)$ is a lower bound on the completion time of the last job on the final machine (makespan), given the current schedule *S*, and $0 \leq w \leq 1$ is a user-defined parameter. To calculate this lower bound we first obtain a lower bound on the completion of processing on the first machine of the unscheduled jobs and then add to this time the minimum cumulative processing time on machines two through *M*. To find the lower bound for completion on the first machine we sum the processing times on the first machine of the unscheduled jobs and add this to t ($t + \sum_{j \notin S} p_{[j]1}$). This lower bound is weak because the offset times of the unscheduled jobs is not included. To strengthen this lower bound we find the lowest offset time for each unscheduled job if it is not scheduled next (min{$\mathrm{OS}_{j \notin \mathrm{S}, \mathrm{l} \notin S}$} and sum the $n - k - 1$ of these times and add to this the minimum offset time among the unscheduled jobs if scheduled next. The lower bound on the offset times is then added to the lower bound above to obtain a lower bound on the completion time on the first machine. We then add the minimum among the unscheduled jobs of the cumulative processing time for machines two through *M* to obtain a lower bound on the makespan.

A Heuristic Based on (Fernadez-Viagas et al., 2016)'s Constructive Heuristic

A constructive heuristic for permutation flow shops when waiting is allowed between machines was developed by (Fernandez-Viagas et al., 2016). The heuristic adds one job at a time to a partial sequence based on an index. During each iteration of the procedure the problem is classified based on the due dates of the unselected jobs in order to determine the index to use to select the next job in the sequence. The index used is based on whether the due dates are relative tight, relatively loose or are neither relatively tight or loose. For details about the procedure see (Fernandez-Viagas et al., 2016).

In the original (Fernandez-Viagas et al., 2016) heuristic a variable is used to calculate the weighted idle time of the candidate jobs. The weighted idle variable in the (Fernandez-Viagas et al., 2016) heuristic is based on the idle time that occurs on all the machines if a job is to be scheduled next. Since in our problem the shop is a no-wait flow shop and idle time only occurs on the first machine, we modify this heuristic by using the idle time on the first machine for each unscheduled job if scheduled next. Let IT_{jk} be the idle time on the first machine of the candidate jobs if scheduled next (in the $k+1^{st}$ position): $IT_{jk} = OS_{j[k]}$. This redefined variable is then used in the (Fernandez-Viagas et al., 2016) indexes to select a job during each iteration. This procedure is referred to as FV in this paper.

COMPUTATIONAL TEST

The proposed algorithms are tested on randomly generated problems of various sizes in terms of the number of jobs and number of machines and under various conditions of due date range and tightness.

Data and Performance Measures

The dispatching heuristic procedures described in section three were tested on problems of various sizes in terms of the number of jobs and number of machines for nine sets of distributions of due date range and tightness. Each problem set consists of 10 problems. The problems within a problem set have the same number of jobs and machines, and the due dates for the jobs are generated using the same distribution. Eight levels of number of jobs (n) to be scheduled were tested: $n = 15, 20, 25, 30, 40, 50, 75$ and 100. Three levels of number of machines (M) were tested: $M = 5, 10$ and 20. The processing times of the jobs for each machine were generated using a uniform distribution over the integers 1 and 100. The due dates for the jobs were also randomly generated using a uniform distribution over the integers $MS\ (1 – r – R/2)$ and $MS\ (1 – r + R/2)$, where MS is an estimated makespan found for the problem using the makespan lower bound proposed in (Taillard, 1993), and R and r are two parameters called due date range and tardiness factors. Three levels of due date range (R) were tested: $R = 0.2, 0.6$ and 1.0 and three levels of due date tightness (r) were tested: $r = 0.0, 0.2$ and 0.4. These levels of R and r result in nine sets of due date parameters for each n and M combination.

The procedures were coded in Turbo Pascal and were tested on a Dell Inspiron 1525 GHz Lap Top computer. The measure of performance used to evaluate the dispatching procedures for the problems is percentage deviation ($\%\ Dev$) of the total earliness and tardiness of the solution generated by each procedure from the total earliness and tardiness generated by the EDD procedure.

$$\%\ Dev = [(Z_h - Z_{EDD})/ Z_h] * 100, \qquad (19)$$

where Z_{EDD} = the total earliness and tardiness of the solution generated by the EDD procedure, and Z_h = the total earliness and tardiness of the solutions generated by the dispatching heuristic procedures (MDD, LIN1, LIN2, SLK, SLKP). Since the EDD procedure would always have a $\%\ Dev$ = 0 it is omitted from the tables.

Results

Tables 1, 2 and 3 show the $\%\ Dev$ for each procedure for each level of number of jobs to be sequenced (n) as well as the averages across all the levels of jobs. Table 1 shows the results for $M = 5$, table 2, for $M = 10$ and table 3, for $M = 20$.

Table 3. % deviation from EDD solution among dispatching heuristics for $M = 20$.

	Procedure					
n	MDD	SLK	SLK/P	LIN1	LIN2	FV
15	-26.17	17.20	7.96	-23.46	-20.29	-15.86
20	-26.18	15.88	4.55	-22.83	-20.82	-16.29
25	-28.44	16.05	2.49	-26.47	-23.12	-21.29
30	-28.79	19.31	2.22	-26.22	-23.81	-20.77
40	-29.20	18.70	-2.38	-27.37	-25.65	-23.02
50	-30.81	19.48	-5.59	-28.80	-27.26	-24.91
75	-26.92	19.33	-10.31	-31.19	-28.78	-26.53
100	-18.40	19.79	-12.83	-32.69	-30.28	-28.57
Ave.	-26.86	18.22	-1.74	-27.38	-25.00	-22.16

The results show that the LIN1 procedure had the lowest average *% Dev* for each level of number of machines followed by the MDD procedure. The MDD procedure had *% Dev*s that were better than those of LIN1 when the number of jobs was lower. For $M = 5$ this was true for $n < 40$, for $M = 10$, $n < 75$, and for $M = 20$, $n < 75$. The LIN2 procedure was generally the third best performing procedure. The SLK and SLK/P performed the worst for all problem sizes. The SLK procedure generated solutions that were worse than the EDD procedure for all problem sizes and the SLK/P procedure had *% Dev*s that were greater than 0 for most of the combinations of *n* and *M*.

In order to show the effect of the due date range (*R*) and tardiness factor (*r*) on the results tables 4 and 5 are presented. Table 4 shows the *% Dev* by due date tardiness factor (*r*) for *n = 50* and *M = 10*.

Table 4. % deviation from EDD solution by *r* for *n = 50* and *M = 10*.

	Procedure					
r	MDD	SLK	SLK/P	LIN1	LIN2	FV
0.0	-22.32	20.25	-0.22	-21.11	-17.02	-13.84
0.2	-28.85	21.11	-4.82	-27.10	-23.42	-16.86
0.4	-31.86	17.24	-9.85	-31.76	-27.85	-21.89

The results by due date tardiness factor (r) show that the MDD procedure was best for for all three levels of *r* for this combination of *n* and *M*, followed by LIN1 and LIN2. The results also show that the performance of these procedures (MDD, LIN1 and LIN2), as well as the FV and SLK/P procedures, improves relative to the EDD procedure as the due dates become tighter.

Table 5 shows the *% Dev* by due date range factor (*R*) for *n = 50* and *M = 10*.

Table 5. % deviation from EDD solution by *R* for *n = 50* and *M = 10*.

	Procedure					
R	MDD	SLK	SLK/P	LIN1	LIN2	FV
0.2	-23.72	23.83	-9.01	-21.70	-19.65	-14.01
0.6	-28.21	15.45	-4.14	-27.21	-22.69	-19.06
1.0	-31.10	19.32	-1.74	-31.07	-25.95	-19.52

The results that the MDD procedure was the best for all three levels of this parameter for this combination of *n* and *M*, followed by the LIN1, LIN2, FV and SLK/P procedures. The SLK procedure was the worst performer for all three values of the parameter. The MDD, LIN1, LIN2 and FV procedures showed improved performance relative to the EDD procedure as due dates became more spread out. The performance of the SLK/P became worse relative to the EDD procedure as due dates became more spread out.

All of the procedures are very efficient and generated solutions quickly for all of the problem sizes tested.

CONCLUSION

In this paper seven dispatching heuristics were tested for minimizing total earliness and tardiness in no-wait flow shops when using additional inserted idle time on the first machine to reduce job earliness is considered. The procedures were tested on problems of various sizes in terms of the number of jobs and machines, and nine sets of distributions that determine the tightness and range of due dates. The procedures are very efficient and were able to generate solutions quickly for all the problem sizes tested.

The results showed that the Modified Due Date (MDD) and LIN1 consistently generated solutions with a lower total earliness and tardiness than the other procedures tested.

Areas of additional research would be the development of a branch-and-bound procedure or a lower bounding technique in order to gauge the accuracy of the tested procedures. Developing additional dispatching procedure that generate better solutions and finding improvement approaches that can be applied to the solutions generated by the dispatching procedures.

ABSTRACT

Dynamic Lot Sizing problem primarily decides on the production and inventory levels. This work studies the deterministic extensions of this problem by considering issues such as productions, inventories, capacities, bill of material, lead time, backorder, return and re-manufacturing, and transportation. The paper focuses on a brief review of different variations of the problem considering all mentioned issues and leaves the extensive literature review out of consideration. The solution methods are also disregarded in this study. The conclusion of paper hints on the possible directions to further explore variations of the dynamic lot sizing problem.

KEYWORDS: Dynamic lot sizing, Lead time, Backorder, Bill of material, Re-manufacturing

INTRODUCTION

Dynamic Lot Sizing (DLS) problem has variety applications in supply chain management. Since its first appearance in the work of (Wagner and Whitin, 1958), DLS problem has been extended and applied to a variety of industrial problems. DLS problem, as stated by (Wagner and Whitin, 1958), aims at finding the production and inventory levels at every period of planning horizon considering the total cost of production and inventory. There are two major streams to extend DLS problem which are the deterministic and stochastic streams. The stochastic demands and service level issues are studied in stochastic DLS problem and they are important for the producers and supply chain managers, for related works see (Bookbinder and Tan, 1988; Sox, 1997; Tarim and Kingsman, 2004; Helber and Sahling, 2010; Tempelmeier, 2013) among others. This paper considers the deterministic DLS and the related extensions.
The presented deterministic extensions are based on the inventory balance constraints. Our study exclude the formulations that are based on shortest path problem, transportation problem, and facility location problem. Interested readers may look at (Stadtler, 1997; Drexl and Kimms, 1996; Jayaraman and Pirkul, 2001; Brahimi et al., 2006; Denizel and Sural, 2006; Robinson et al., 2009; Helber and Sahling, 2010; Agrali, 2012; Schmid et al., 2013; Kian et al., 2014; Matta et al., 2015) for some examples of the alternative formulations. Using the inventory balance constraints, we focus on several areas such as DLS with multiple products, capacitated DLS, DLS and the assembly of sub-products (Bill of Material), DLS with backorder, DLS and lead time, DLS and multi-level productions, and DLS with a multi-level supply chain. Table 1 in the appendix summarizes a portion of the literature in these areas.

Table 1. DLS Extensions and related literature

Type of Extension	Related Literature
DLS	Wagner and Whitin (1958); Eppen and Martin (1987) Karmarkar et al. (1987); Wagelmans et al. (1992) Chang (2001); Karimi et al. (2003) Jaruphongsa et al. (2004); Li et al. (2004) Brahimi et al. The paper focuses on inventory and production issues commonly faced by firms. A company may produce several products and account for the capacity of inventory and the availability of time and resources. A manufacturer usually deals with the assembly of products and may consider the backlog and lead time in their manufacturing process, which are all the subject of this study. Furthermore, it is a general issue for the manufacturer to deal with the returned products and perform re-manufacturing processes which are another areas of consideration. Finally, producers manage several units of production and a network of supply chain that are the final subject of study.
This paper does not exhaust the complete literature of the DLS problems and their extensions. In addition, we do not cover the solution methods for the DLS problems. For reviews and surveys of the solution methods, we invite readers to look at (Bahl et al., 1987; Maes and Wassenhove, 1988; Karimi et al., 2003; Robinson et al., 2009; Buschkuhl et al., 2010) among others.

PROBLEM VARIATIONS

Dynamic Lot Sizing Problem

DLS problem decides on the inventory levels and production in each period of planning. This problem has been studied in the literature for decades and to present the basic formulation, we are committed to the notations similar to the ones that appear in the literature such as (Wagner and Whitin, 1958; Eppen and Martin, 1987; Wagelmans et al., 1992; Chang, 2001; Karimi et al., 2003). Let the set of periods be $T = \{1, 2, ..., |T|\}$, indexed by $t \in T$. We define inventory holding cost per unit per period as h^t, production cost per unit per period as p^t, and set up cost per unit per period as s^t. In addition, we have three sets of decision variables; x^t, q^t, and y^t. Variable x^t shows the amount of production during period t, variable q^t shows the inventory at the end of period t, and variable y^t is equal to 1 if $x^t > 0$, and 0 otherwise. Finally, demand during period t is shown by d^t and M^t is a big number (we set $M^t = d^t$). Then, the DLS problem can be formulated as follows:

$$\text{DLS:} \quad \min \sum_{t\in T} \left(h^t q^t + p^t x^t + s^t y^t\right) \tag{1}$$

$$\text{s.t.} \quad q^{t-1} + x^t = q^t + d^t \qquad \forall t \in T \tag{2}$$

$$x^t \leq M^t y^t \qquad \forall t \in T \tag{3}$$

$$x^t, q^t \geq 0,\ y^t \in \{0, 1\} \qquad \forall t \in T \tag{4}$$

Equation (1) aims at minimizing the total cost of inventories, productions, and set ups. Constraints (2) are inventory balance constraints. These constraints guarantee the conservation of the material flow within the production-inventory unit; the input to the unit (previous inventory and production) should be equal to the output inventory (demand and current inventory). These constraints are the core of DLS problems. Constraints (3) force the set up variables to be equal to one, if there is production. At last, constraints (4) define the variables.
This problem formulation, expressed in (1) - (4), appear in many works in the literature. Interested readers may look at the works of (Wagner and Whitin, 1958; Eppen and Martin, 1987; Wagelmans et al., 1992; Chang, 2001; Karimi et al., 2003; Jaruphongsa et al., 2004; Li et al., 2004; Brahimi et al., 2006; Parveen and Haque, 2007; Jans and Degraeve, 2008; Li and Meissner, 2011; Zhang et al., 2012; Dural-Selcuk et al., 2016). This formulation, however, does not consider the start up cost of the production unit. Assume the model returns a solution that forces

no production at some periods; once the production resume at some later periods, a start up cost may incur (Karmarkar et al., 1987). We use similar notation to (Karmarkar et al., 1987) to capture this cost. Let o^t be the start up cost during period t and z^t be equal to one, if the unit is off-line during period $t-1$ but operational during period t. Then, the following constraints will be added to the model (Karmarkar et al., 1987):

$$z^t \geq y^t - y^{t-1} \quad \forall t \in T \setminus \{1\} \tag{5}$$

the problem, then, can be stated as follows:

$$\begin{aligned}
\text{DLS:} \quad & \min \sum_{t \in T} \left(h^t q^t + p^t x^t + s^t y^t + o^t z^t \right) && && (6) \\
\text{s.t.} \quad & q^{t-1} + x^t = q^t + d^t && \forall t \in T && (7) \\
& x^t \leq M^t y^t && \forall t \in T && (8) \\
& z^t \geq y^t - y^{t-1} && \forall t \in T \setminus \{1\} && \\
& x^t, q^t \geq 0,\, y^t \in \{0,1\} && \forall t \in T && (9) \\
& z^t \in \{0,1\} && \forall t \in T \setminus \{1\} && (10)
\end{aligned}$$

where total cost is updated as (6); the rest of inequalities is the same as the previous version in (1) - (4). Constraints (7) are inventory balance constraints. These constraints guarantee the conservation of the material flow. Constraints (8) force the set up variables to be equal to one, if there is production. At last, constraints (9)-(10) are defining the variables.

Multi-Product DLS Problems

DLS problem formulated in (6) - (10) accounts only for one product. Extending this problem for multiple products is important as manufacturers may produce more than one product type practice. We refer to this extension as Multi-Product DLS problems or MPDLS problems in short. Let $I = \{1, ..., |I|\}$, indexed by i, be the set of products. Moreover, let the holding cost, set up cost, production cost, and start up cost of product i per unit per period be h_i^t, s_i^t, p_i^t, and o_i^t respectively. We also define four sets of variables x_i^t, q_i^t, y_i^t, and z_i^t. Variable x_i^t shows the production of product i during period t and variable q_i^t shows the inventory of product i at the end of period t. Variable $y_i^t = 1$, if there is a production of product i during period t and $y_i^t = 0$, otherwise. Variable $z_i^t = 1$, if there is a production for product i during period t and not during period $t-1$ and $z_i^t = 0$, otherwise. Finally, the demand of product i during period t is denoted by d_i^t and M^t is a big number (we set $M^t = \sum_{i \in I} d_i^t$). Given these definitions, a MPDLS problem can be formulated as follows:

$$\begin{aligned}
\text{MPDLS:} \quad & \min \sum_{t \in T} \sum_{i \in I} \left(h_i^t q_i^t + p_i^t x_i^t + s_i^t y_i^t + o_i^t z_i^t \right) && && (11) \\
\text{s.t.} \quad & q_i^{t-1} + x_i^t = q_i^t + d_i^t && \forall i \in I, \forall t \in T && (12) \\
& x_i^t \leq M^t y_i^t && \forall i \in I, \forall t \in T && (13) \\
& z_i^t \geq y_i^t - y_i^{t-1} && \forall i \in I, \forall t \in T \setminus \{1\} && (14) \\
& x_i^t, q_i^t \geq 0,\, y_i^t \in \{0,1\} && \forall i \in I, \forall t \in T && (15)
\end{aligned}$$

$$z_i^t \in \{0,1\} \qquad \forall i \in I, \forall t \in T \setminus \{1\} \tag{16}$$

Equation (11) minimizes the total cost of inventories, productions, set ups, and start ups. Constraints (12) are the inventory balance constraints, similar to (2). These constraints guarantee the flow conservation of material within production-inventory units for every product at each period. Similar to constraints (3), constraints (13) force set up variable to be equal to one, if there is production. Constraints (14) enforce start up, if there is a set up at the new period. At last, constraints (15)-(16) are defining the variables. Similar formulation appeared in the literature such as (Afentakis et al., 1984; Karimi et al., 2003; Jans and Degraeve, 2008; Agrali, 2012).
There are more issues to consider for MPDLS problems. For example, the production unit may not have enough machinery to produce more than one product at each period, e.g. they may only have one machine/worker. As the result, one product should be produced at each period, at most (Jans and Degraeve, 2008). This restriction may be shown in the model in the following constraints (Jans and Degraeve, 2008):

$$\sum_{i \in I} y_i^t \leq 1 \quad \forall t \in T \tag{17}$$

Another issue is the capacity of the production unit. For example, the amount of time available for the production may be limited as the production unit may not work continuously through all periods, the resources for the production may be limited, the inventory capacity may be limited, and etc. To formulate these issues, we first define appropriate parameters. Let b_i^t be the time required to produce one unit of product i during period t, r_i^t be the amount of resources required to produce one unit of product i during period t, and v_i^t be the volume of one unit of product i during period t. In addition, let τ^t, R^t, and V^t be the total available time, total available resources, and total available inventory space for products during period t. The capacity constraints can now be formulated as follows:

$$\sum_{i \in I} b_i^t x_i^t \leq \tau^t \quad \forall t \in T \tag{18}$$

$$\sum_{i \in I} r_i^t x_i^t \leq R^t \quad \forall t \in T \tag{19}$$

$$\sum_{i \in I} v_i^t q_i^t \leq V^t \quad \forall t \in T \tag{20}$$

Constraints (18) are time restriction constraints. These types of constraints appeared in the work of (Denizel and Sural, 2006; Helber and Sahling, 2010; Melega et al., 2018). Constraints (18) are the resource restriction constraints. These types of constraints are very common in the literature of DLS problems. Interested readers may look at the review papers such as (Maes and Wassenhove, 1988; Drexl and Kimms, 1996; Buschkuhl et al., 2010). Constraints (20) are the inventory capacity constraints.

Bill of Materials and DLS Problems

A production unit may produce several sub-products first and then assemble them to the final product through a complex assembly process. In the production process of such products, manufacturers use Bill of Material (BOM) to show the structure of assembly and manufacturing processes (Stevenson, 2018). Examples of BOMs can be seen in (Tempelmeier and Helber, 1994;

Tempelmeier and Derstroff, 1996; Stevenson, 2018). BOM shows the successor relation, as well as the quantity of product that is needed for the successor product. Let the parameter a_{ij} be the number of product i that is needed to produce one unit of its successor; product j (Tempelmeier and Helber, 1994; Kimms, 1996; Tempelmeier and Derstroff, 1996; Drexl and Kimms, 1996; Stadtler, 1997). Note that $a_{ij} = 0$ means there is no immediate relation between products and the corresponding matrix to a_{ij} values is not symmetric. Using the same variables and parameters introduced previously, we formulate the Capacitated Bill of Material DLS (CBMDLS) problem as follows:

$$
\begin{aligned}
\text{CBMDLS:}\quad \min\quad & \sum_{t\in T}\sum_{i\in I}\left(h_i^t q_i^t + p_i^t x_i^t + s_i^t y_i^t + o_i^t z_i^t\right) && && (21)\\
\text{s.t.}\quad & q_i^{t-1} + x_i^t = q_i^t + d_i^t + \sum_{j\in I} a_{ij} x_j^t && \forall i \in I, \forall t \in T && (22)\\
& x_i^t \le M^t y_i^t && \forall i \in I, \forall t \in T && (23)\\
& z_i^t \ge y_i^t - y_i^{t-1} && \forall i \in I, \forall t \in T \setminus \{1\} && (24)\\
& \sum_{i\in I} b_i^t x_i^t \le \tau^t && \forall t \in T && (25)\\
& \sum_{i\in I} r_i^t x_i^t \le R^t && \forall t \in T && (26)\\
& \sum_{i\in I} v_i^t q_i^t \le V^t && \forall t \in T && (27)\\
& x_i^t, q_i^t \ge 0,\ y_i^t \in \{0,1\} && \forall i \in I, \forall t \in T && (28)\\
& z_i^t \in \{0,1\} && \forall i \in I, \forall t \in T \setminus \{1\} && (29)
\end{aligned}
$$

The objective function, equation (21), and all the constraints of CBMDLS problem are similar to the MPDLS problem, except for constraints (22). Constraints (22) are inventory balance constraints and they appeared in the previous works, such as (Kimms, 1993; Tempelmeier and Helber, 1994; Kimms, 1996; Tempelmeier and Derstroff, 1996; Drexl and Kimms, 1996; Pitakaso et al., 2006; Sahling et al., 2009; Prakaiwichien and Rungreunganun, 2018). These constraints have an additional element, $\sum_{j\in I} a_{ij} x_j^t$, that shows the demand that is derived for the product i based on the quantity that its successors need for their own production (internal demand). The external demand, i.e. the demand coming from a external customer, is usually zero for the products with successors and only the final products are subject to external demand (Hung and Chien, 2000). As the result, for most products with successors, we have $d_i^t = 0$. Constraints (22) are inventory balance constraints. Constraints (23) force set up variable to be equal to one, if there is production. Constraints (24) enforce start up, if there is set up at the new period. Constraints (25) are time restriction constraints, constraints (26) are resource restriction constraints, and constraints (27) are inventory capacity constraints. At last, constraints (28)-(29) are defining the variables.

Backorder and DLS

Backorder happens in a production site when there is not enough production to satisfy the demand. As a consequence, the orders backlog to the next periods. In DLS problem, backorder is formulated by the additional variables and the updated inventory balance constraints. For example, the work of (Pochet and Wolsey, 1988; Lee et al., 2001; Staggemeier and Clark, 2001;

Brahimi et al., 2006; Absi et al., 2011) update the inventory balanced constraints as follows to reflect the backorder in the model, where u_i^t is the backorder amount of product i during period t:

$$q_i^{t-1} - u_i^{t-1} + x_i^t = q_i^t - u_i^t + d_i^t \quad \forall i \in I, \forall t \in T \tag{30}$$

By defining the backorder penalty cost g_i^t as the backorder cost of product i during period t and using the same notations and variables as before, we can update the CBMDLS problem as Backorder CBMDLS (BCBMDLS) problem reflected in the following:

$$\begin{aligned}
\text{BCBMDLS:} \quad \min \quad & \sum_{t\in T}\sum_{i\in I} \left(h_i^t q_i^t + p_i^t x_i^t + s_i^t y_i^t + o_i^t z_i^t + g_i^t u_i^t\right) && && (31)\\
\text{s.t.} \quad & q_i^{t-1} - u_i^{t-1} + x_i^t = q_i^t - u_i^t + d_i^t + \sum_{j\in I} a_{ij} x_j^t && \forall i \in I, \forall t \in T && (32)\\
& x_i^t \le M^t y_i^t && \forall i \in I, \forall t \in T && (33)\\
& z_i^t \ge y_i^t - y_i^{t-1} && \forall i \in I, \forall t \in T \setminus \{1\} && (34)\\
& \sum_{i\in I} b_i^t x_i^t \le \tau^t && \forall t \in T && (35)\\
& \sum_{i\in I} r_i^t x_i^t \le R^t && \forall t \in T && (36)\\
& \sum_{i\in I} v_i^t q_i^t \le V^t && \forall t \in T && (37)\\
& x_i^t, q_i^t, u_i^t \ge 0,\ y_i^t \in \{0,1\} && \forall i \in I, \forall t \in T && (38)\\
& z_i^t \in \{0,1\} && \forall i \in I, \forall t \in T \setminus \{1\} && (39)
\end{aligned}$$

The only updated parts in BCBMDLS compared to CBMDLS are constraints (32) and the objective function (31). Constraints (32) are the updated inventory balance constraints in the presence of BOM that are also appeared in (Hung and Chien, 2000; Almeder and Almada-Lobo, 2011). Constraints (33)-(39) are similar to constraints (23)-(29) considering the similar restrictions that they impose.

Lead Time and DLS Problem

DLS problems, as described before, assume a zero lead time. Zero lead time means the product is immediately available upon order. It also means that in an assembly line, the assembly operations and motion of the product takes zero time. Failing to incorporate lead time in the DLS problems results in unavailability of products that are needed for the production of their successors in the earlier periods of planning (Almeder et al., 2015). To prevent this issue, several researchers presented some solutions. One of the earliest solutions is to force the inventory at each period to be greater than the sum of what is needed in the future periods. Particularly, the work of (Kimms, 1993; Drexl and Kimms, 1996; Kimms, 1996) add the following constraints to the model to accompany the inventory balance constraints by defining l_i as the lead time of product i:

$$q_i^t \ge \sum_{j\in I} \sum_{r=t}^{\min\{t+l_i-1,|T|\}} a_{ij} x_j^t \quad \forall i \in I, \forall t \in T \tag{40}$$

Alternatively, one can update the inventory balance equation to reflect the lead time as follows (Hung and Chien, 2000):

$$q_i^{t-1} - u_i^{t-1} + x_i^t = q_i^t - u_i^t + d_i^t + \sum_{j \in I} a_{ij} x_j^{t+l_i} \quad \forall i \in I, \forall t \in T \tag{41}$$

As it can be seen, constraints (41) update the time index of the successive products; the demand of successive products of i should shift by l_i. We call these kind of problems Lead Time BCB-MDLS or LTBCBMDLS in short. A decision maker needs to either add constraints (40) to the model or replace inventory balance constraints by constraints (41). We name the problem in the first case as LTBCBMDLS1 and the problem in the second case as LTBCBMDLS2. The LTBCB-MDLS1 is formulated as follows:

$$
\begin{aligned}
\text{LTBCBMDLS1:} \quad \min \quad & \sum_{t \in T} \sum_{i \in I} \left(h_i^t q_i^t + p_i^t x_i^t + s_i^t y_i^t + o_i^t z_i^t + g_i^t u_i^t \right) && && (42)\\
\text{s.t.} \quad & q_i^{t-1} - u_i^{t-1} + x_i^t = q_i^t - u_i^t + d_i^t + \sum_{j \in I} a_{ij} x_j^t && \forall i \in I, \forall t \in T && (43)\\
& q_i^t \geq \sum_{j \in I} \sum_{r=t}^{\min\{t+l_i-1, |T|\}} a_{ij} x_j^t && \forall i \in I, \forall t \in T && (44)\\
& x_i^t \leq M^t y_i^t && \forall i \in I, \forall t \in T && (45)\\
& z_i^t \geq y_i^t - y_i^{t-1} && \forall i \in I, \forall t \in T \setminus \{1\} && (46)\\
& \sum_{i \in I} b_i^t x_i^t \leq \tau^t && \forall t \in T && (47)\\
& \sum_{i \in I} r_i^t x_i^t \leq R^t && \forall t \in T && (48)\\
& \sum_{i \in I} v_i^t q_i^t \leq V^t && \forall t \in T && (49)\\
& x_i^t, q_i^t, u_i^t \geq 0,\, y_i^t \in \{0,1\} && \forall i \in I, \forall t \in T && (50)\\
& z_i^t \in \{0,1\} && \forall i \in I, \forall t \in T \setminus \{1\} && (51)
\end{aligned}
$$

Constraints (44) impose the lead time to the model. The rest of constraints (42), (43), and (45)-(51) are the same as constraints (31) and (33)-(39). Alternatively, we can incorporate the lead time by defining LTBCBMDLS2 problem as the following:

$$
\begin{aligned}
\text{LTBCBMDLS2:} \quad \min \quad & \sum_{t \in T} \sum_{i \in I} \left(h_i^t q_i^t + p_i^t x_i^t + s_i^t y_i^t + o_i^t z_i^t + g_i^t u_i^t \right) && && (52)\\
\text{s.t.} \quad & q_i^{t-1} - u_i^{t-1} + x_i^t = q_i^t - u_i^t + d_i^t + \sum_{j \in I} a_{ij} x_j^{t+l_i} && \forall i \in I, \forall t \in T && (53)\\
& x_i^t \leq M^t y_i^t && \forall i \in I, \forall t \in T && (54)\\
& z_i^t \geq y_i^t - y_i^{t-1} && \forall i \in I, \forall t \in T \setminus \{1\} && (55)\\
& \sum_{i \in I} b_i^t x_i^t \leq \tau^t && \forall t \in T && (56)\\
& \sum_{i \in I} r_i^t x_i^t \leq R^t && \forall t \in T && (57)\\
& \sum_{i \in I} v_i^t q_i^t \leq V^t && \forall t \in T && (58)\\
& x_i^t, q_i^t, u_i^t \geq 0,\, y_i^t \in \{0,1\} && \forall i \in I, \forall t \in T && (59)\\
& z_i^t \in \{0,1\} && \forall i \in I, \forall t \in T \setminus \{1\} && (60)
\end{aligned}
$$

Constraints (52)-(60) are the same as (31)-(39). The only difference is the inventory balance constraints, (53), that is updated based on (41).
It is worth to note that in real life the lead times are not deterministic; rather, they are stochastic and stochastic methods should be used for formulating lead time in DLS problems. The work of (Huang and KucuKyavuz, 2008) is dedicated to the stochastic lead times, which we do not explore this case.

Re-Manufacturing and DLS Problem

We modify MPDLS problem to account for the returns and re-manufacturing activities. In most of works in the literature, only single item DLS problem, expressed in (1) - (4), is extended for re-manufacturing. For related works, interested readers may look at (Teunter et al., 2006; Schulz, 2011; Sifaleras et al., 2015). In addition to the parameters and variables introduced for MPDLS problem, we define holding cost of the returned product i during period t as Rh_i^t, set up cost of the returned product i during period t as Rs_i^t, re-manufacturing cost of the returned product i during period t as Rp_i^t, start up cost of the returned product i during period t as Ro_i^t, the number of the returned product i during period t as Rd_i^t, the required time to re-manufacture one unit of product i during period t as Rb_i^t, and the amount of resources for re-manufacturing one unit of product i during period t as Rr_i^t. In addition, let ω_i^t be the re-manufacturing quantity of product i during period t and μ_i^t be the inventory of the returned product i at the end of period t. We modify the variable y_i^t in MPDLS to $y_i^{1,t}$ and introduce the variable $y_i^{2,t}$ to show the set up for re-manufacturing: $y_i^{2,t} = 1$ if the machine sets up to re-manufacture product i during period t, $y_i^{2,t} = 0$ otherwise. Similarly, we modify the variable z_i^t in MPDLS to $z_i^{1,t}$ and introduce the variable $z_i^{2,t}$ to show the start up for re-manufacturing: $z_i^{2,t} = 1$ if the machine starts up to re-manufacture product i during period t and while it was not operational for product i in previous periods, $z_i^{2,t} = 0$ otherwise. Then the MPDLS can be reformulated for the Re-Manufacturing MPDLS (RMPDLS) as follows:

$$
\begin{aligned}
\text{RMPDLS:} \quad \min \quad & \sum_{t\in T}\sum_{i\in I}\left(h_i^t q_i^t + p_i^t x_i^t + s_i^t y_i^{1,t} + o_i^t z_i^{1,t} + Rh_i^t \mu_i^t + Rp_i^t \omega_i^t + Rs_i^t y_i^{2,t} + Ro_i^t z_i^{2,t}\right) && && (61)\\
\text{s.t.} \quad & q_i^{t-1} + x_i^t + \omega_i^t = q_i^t + d_i^t && \forall i \in I, \forall t \in T && (62)\\
& \mu_i^{t-1} + Rd_i^t = \mu_i^t + \omega_i^t && \forall i \in I, \forall t \in T && (63)\\
& x_i^t \le M_i^t y_i^{1,t} && \forall i \in I, \forall t \in T && (64)\\
& \omega_i^t \le M^t y_i^{2,t} && \forall i \in I, \forall t \in T && (65)\\
& y_i^{1,t} + y_i^{2,t} \le 1 && \forall i \in I, \forall t \in T && (66)\\
& z_i^{1,t} \ge y_i^{1,t} - y_i^{1,t-1} && \forall i \in I, \forall t \in T \setminus \{1\} && (67)\\
& z_i^{2,t} \ge y_i^{2,t} - y_i^{2,t-1} && \forall i \in I, \forall t \in T \setminus \{1\} && (68)\\
& \sum_{i\in I}(b_i^t x_i^t + Rb_i^t \omega_i^t) \le \tau^t && \forall t \in T && (69)\\
& \sum_{i\in I}(r_i^t x_i^t + Rr_i^t \omega_i^t) \le R^t && \forall t \in T && (70)\\
& \sum_{i\in I}(v_i^t q_i^t + v_i^t \mu_i^t) \le V^t && \forall t \in T && (71)\\
& x_i^t, q_i^t, \omega_i^t, \mu_i^t \ge 0,\ y_i^{1,t} \in \{0,1\},\ y_i^{2,t} \in \{0,1\} && \forall i \in I, \forall t \in T && (72)\\
& z_i^{1,t} \in \{0,1\},\ z_i^{2,t} \in \{0,1\} && \forall i \in I, \forall t \in T \setminus \{1\} && (73)
\end{aligned}
$$

Objective function (61) minimizes total cost of inventories, productions, set ups, and start ups costs for both manufactured products and re-manufactured products. Constraints (62) are the updated inventory balance constraints to reflect re-manufacturing. Constraints (63) are the inventory balanced constraints for the returned and re-manufactured products. Constraints (64) - (65) guarantee that at each period if we manufacture or re-manufacture we have to set up the process. Constraints (66) enforce that at each period we either manufacture or re-manufacture. Constraints (67) - (68) force a start up if we manufacture or re-manufacture at each period, but not in previous periods. Constraints (69) - (71) are capacity constraints. Constraints (72) - (73) define the problem variables.

Multi-Level Production and DLS Problem

Having multiple manufacturing units and warehouses requires modifications to the DLS problems. Multiple manufacturing units and warehouses/distribution centers coincide with transportation. Variety of publications in DLS problem account for these transportations by modifying DLS constraints and objective function. In (Staggemeier and Clark, 2001; Wu et al., 2018), authors consider multiple machines/units for production. In their case, every machine/unit can produce every item; hence, the extension of DLS problem only reflects on an update of the inventory balance equations. The work of (Sambasivan and Yahya, 2005; Brahimi et al., 2006) also consider the transportation of products between plants.
To formulate this problem, let $K = \{1, ..., |K|\}$, indexed by $k \in K$, be the set of production units/machines. Furthermore, Let the set up cost, production cost, and start up cost of product i in unit k per period be s_i^{kt}, p_i^{kt}, and o_i^{kt}, respectively. Moreover, let b_i^{kt} be the time required to produce one unit of product i in unit k per period t, r_i^{kt} be the amount of resources required to produce one unit of product i in unit k per period t, and v_i^t be the volume of one unit of product i during period t. In addition, let τ^{kt} and R^{kt} be the total available time and total available resources available for products in unit k per period t. Also we define variable x_i^{kt} as the production of product i by unit k during period t. Variable $y_i^{kt} = 1$, if there is a production of product i during period t by unit k and $y_i^{kt} = 0$, otherwise. Variable $z_i^{kt} = 1$, if there is a production of product i during period t by unit k and not during period $t-1$ and $z_i^{kt} = 0$, otherwise. The rest of parameters and variables are similar to MPDLS problem. If we assume there is no transportation between production units and all units use the same inventory space, the problem is Multi-Unit DLS (MUDLS) and it can be formulated as follows (Staggemeier and Clark, 2001; Wu et al., 2018):

$$\text{MUDLS:} \quad \min \sum_{t\in T}\sum_{i\in I}\sum_{k\in K}\left(h_i^t q_i^t + p_i^{kt}x_i^{kt} + s_i^{kt}y_i^{kt} + o_i^{kt}z_i^{kt}\right) \tag{74}$$

$$\text{s.t.} \quad q_i^{t-1} + \sum_{k\in K} x_i^{kt} = q_i^t + d_i^t \qquad \forall i \in I, \forall t \in T \tag{75}$$

$$\sum_{i\in I}\sum_{k\in K} b_i^t x_i^{kt} \le \tau^t \qquad \forall t \in T \tag{76}$$

$$\sum_{i\in I}\sum_{k\in K} r_i^t x_i^{kt} \le R^t \qquad \forall t \in T \tag{77}$$

$$\sum_{i\in I} v_i^t q_i^t \le V^t \qquad \forall t \in T \tag{78}$$

$$x_i^{kt} \le M^t y_i^{kt} \qquad \forall k \in K, \forall i \in I, \forall t \in T \tag{79}$$

$$z_i^{kt} \ge y_i^{kt} - y_i^{k,t-1} \qquad \forall k \in K, \forall i \in I, \forall t \in T \setminus \{1\} \tag{80}$$

$$x_i^{kt}, q_i^t \ge 0,\ y_i^{kt} \in \{0,1\} \qquad \forall k \in K, \forall i \in I, \forall t \in T \tag{81}$$

$$z_i^{kt} \in \{0,1\} \qquad \forall k \in K, \forall i \in I, \forall t \in T \setminus \{1\} \tag{82}$$

Equation (74) minimizes total cost of inventory, production, set up, and start up. Constraints (75) are the modified inventory balance constraints compared to constraints (12). These constraints guarantee the flow conservation of material within production-inventory units for every product at each period by all production units. Constraints (76) are time restriction constraints, constraints (77) are resource restriction constraints, and constraints (78) are inventory capacity constraints. Constraints (79) force set up variable to be equal to one, if there is a production by a unit. Constraints (80) force the start up variable for every production unit to be equal to 1, if we start production in a period after an idle period. At last, constraints (81) - (82) define the variables.

Multi-Level Supply Chain and DLS Problem

Problem MPDLS does not account for transportation and independent production units. In this section we formulate a multi-level Supply Chain DLS (SCDLS) problem to address multiple production units and transportation through a supply chain. For this purpose, we consider a graph that shows the production units, warehouses, distributions centers, and retailers as nodes. The transportation links between these nodes are the edges of the graph. The study of the DLS in a production/distribution network has a long history. For example, the works of (Jaruphongsa et al., 2004; Bard and Nananukul, 2009; Seyedhosseini and Ghoreyshi, 2014; Adulyasak et al., 2015) study a single production unit and multiple distribution centers. Moreover, the works of (Diaby and Martel, 1993; Barbarosoglu and Ozgur, 1999) present a model for multiple production units and multiple distribution centers. Furthermore, (Darvish, 2017; Darvish and Coelho, 2018) study multiple production units and multi-level of supply chain (distribution centers and retailers). The work of (Adulyasak, 2012) accounts for a supply chain that is presented as a complete graph. Also the graph approach has been used for the previous studies such as (Matta et al., 2015), this work accounts for any given supply chain network. We use similar notation to (Darvish, 2017; Darvish and Coelho, 2018) to formulate the problem.
Let $E = \{1, ..., |E|\}$, indexed by $e, f \in E$, be the set of nodes of the supply chain network. For the edges of this directed and connected graph, let $\gamma^t_{ef} = 1$ if node e is connected to node f, $\gamma^t_{ef} = 0$ otherwise ($\gamma^t_{ee} = 0, \forall t \in T$). In addition, let $E^p \subset E$ be the set of production units, $E^d \subset E$ be the set of distribution centers and warehouses, and $E^r \subset E$ be the set of retailers (customers). Note that $E^p \cup E^d \cup E^r \equiv E$. Furthermore, let c^t_{ef} be the transportation cost of the product i from node e to node f during period t, h^t_{ie} be the holding cost of the product i in node $e \in E$ during period t, s^t_{ie} be the set up cost of the product i in node $e \in E^p$ during period t, o^t_{ie} be the start up cost of the product i in node $e \in E^p$ during period t, p^t_{ie} be the production cost of the product i in node $e \in E^p$ during period t, and d^t_{ie} be the external demand of the product i in node $e \in E^r$ during period t. Moreover, let τ^t_e be the available time for production in $e \in E^p$ during period t, R^t_e be the available resources for production in $e \in E^p$ during period t, and V^t_e be the available inventory space in $e \in E$ during period t. Finally, we use five variables in the formulation; x^t_{ief}, q^t_{ie}, P^t_{ie}, y^t_{ie}, and z^t_{ie}. Variable x^t_{ief} shows the amount of transportation of product i from node e to f during period t, variable q^t_{ie} shows the amount of inventory of product i in node e at the end of period t, and variable P^t_{ie} shows the production of item i in node $e \in E^p$ during period t. The variable $y^t_{ie} = 1$ shows that there is a set up to produce i in node $e \in E^p$ during period t, $y^t_{ie} = 0$ otherwise. And, variable $z^t_{ie} = 1$, if there is a start up to produce i in node $e \in E^p$ during period t if there was no production of i during period $t-1$, $z^t_{ie} = 0$ otherwise. Now, we formulate SCDLS as follows:

SCDLS:

$$\begin{aligned}
\min \quad & \sum_{t\in T}\sum_{i\in I}\left(\sum_{e\in E} h_{ie}^t q_{ie}^t + \sum_{e\in E^p} s_{ie}^t y_{ie}^t + \sum_{e\in E^p} o_{ie}^t z_{ie}^t +\right) \\
& + \sum_{t\in T}\sum_{i\in I}\left(\sum_{e\in E^p}\sum_{f\in E^d\cup E^r} \gamma_{ef}^t p_{ie}^t x_{ief}^t + \sum_{e\in E}\sum_{f\in E} \gamma_{ef}^t c_{ef}^t x_{ief}^t\right) && (83)
\end{aligned}$$

$$\text{s.t.} \quad q_{ie}^{t-1} + P_{ie}^t = \sum_{f\in E^d\cup E^r} \gamma_{ef}^t x_{ief}^t + q_{ie}^t \qquad \forall e\in E^p, \forall i\in I, \forall t\in T \quad (84)$$

$$q_{ie}^{t-1} + \sum_{f\in E^p\cup E^d} \gamma_{fe}^t x_{ife}^t = q_{ie}^t + \sum_{f\in E^r\cup E^d} \gamma_{ef}^t x_{ief}^t \qquad \forall e\in E^d, \forall i\in I, \forall t\in T \quad (85)$$

$$q_{ie}^{t-1} + \sum_{f\in E^p\cup E^d} \gamma_{fe}^t x_{ife}^t = q_{ie}^t + d_{ie}^t \qquad \forall e\in E^r, \forall i\in I, \forall t\in T \quad (86)$$

$$q_{ie}^{t-1} + \sum_{f\in E^p\cup E^d} \gamma_{fe}^t x_{ife}^t = q_{ie}^t + \sum_{f\in E^r\cup E^d} \gamma_{ef}^t x_{ief}^t + d_{ie}^t \qquad \forall e\in E^r\cap E^d, \forall i\in I, \forall t\in T \quad (87)$$

$$\sum_{i\in I}\sum_{f\in E^d\cup E^r} b_i^t P_{ie}^t \le \tau_e^t \qquad \forall e\in E^p, \forall t\in T \quad (88)$$

$$\sum_{i\in I}\sum_{f\in E^d\cup E^r} r_i^t P_{ie}^t \le R_e^t \qquad \forall e\in E^p, \forall t\in T \quad (89)$$

$$\sum_{i\in I} v_i^t q_{ie}^t \le V_e^t \qquad \forall e\in E, \forall t\in T \quad (90)$$

$$P_{ie}^t \le M^t y_{ie}^t \qquad \forall e\in E^p, \forall i\in I, \forall t\in T \quad (91)$$

$$z_{ie}^t \ge y_{ie}^t - y_{ie}^{t-1} \qquad \forall e\in E^p, \forall i\in I, \forall t\in T\setminus\{1\} \quad (92)$$

$$x_{ief}^t, q_{ie}^t, P_{ie}^t \ge 0 \qquad \forall e,f\in E, \forall i\in I, \forall t\in T \quad (93)$$

$$y_{ie}^t \in \{0,1\} \qquad \forall e\in E^p, \forall i\in I, \forall t\in T \quad (94)$$

$$z_{ie}^t \in \{0,1\} \qquad \forall e\in E^p, \forall i\in I, \forall t\in T\setminus\{1\} \quad (95)$$

Equation (83) aims to minimize the sum of holding costs, set up costs, start up costs, production costs, and transportation costs. Constraints (84) are the inventory balance constraints for every production node. Constraints (85) are the inventory balance constraints for every distribution/warehouse node. Constraints (86) are the inventory balance constraints for every retailer node. Constraints (87) are the inventory balance constraints for every node that acts as both distributor and retailer. Constraints (88) - (90) are the capacity constraints. Constraints (91) guarantee that each production node should set up the production, if there is a production for products at each period. Constraints (92) force a production start up for the production nodes, if we produce at each period, but not in previous periods. Constraints (93) - (95) are defining variables. Problem SCDLS is multi-echelon and accounts for the inventory, set up, start up, capacity, multiple items, production, and transportation. This problem, however, does not account for the returned items, backorders, assembly procedures (Bill of materials), lead times, and re-manufacturing.

CONCLUSION AND FUTURE RESEARCH

In this paper some generic DLS problem formulations are presented. Variety of DLS problem extensions on multiple products, capacity, bill of materials, backorder, lead time, and multi levels of supply and productions are discussed. DLS problem can be further extended to combine assembly of components (bill of material) and the supply chain (multi-level). Alternative formulations of all these models along with the appropriate exact and approximation algorithms is another future direction for this research. In addition, incorporating the stochastic nature of demands, service levels, and lead times to the model is another future direction for the research in DLS problems.

APPENDIX 1: NOTATION

List of Sets and Indices	
T	: the set of time periods $T = \{1, 2, \ldots, \lvert T\rvert\}$
t, r	: indices used for time, $t, r \in T$
I	: the set of products $I = \{1, 2, \ldots, \lvert I\rvert\}$
i, j	: indices used for products, $i, j \in I$
K	: the set of production units $K = \{1, 2, \ldots, \lvert K\rvert\}$
k	: index used for production units, $k \in K$
E	: the set of network nodes $E = \{1, 2, \ldots, \lvert E\rvert\}$
E^p	: the set of production nodes
E^d	: the set of warehouses/distribution nodes
E^r	: the set of retailer nodes
e, f	: indices used for network nodes, $e, f \in E$

List of Parameters	
h^t	: holding cost per unit during period t
s^t	: set up cost of production during period t
p^t	: production cost during period t
o^t	: start up cost of production during period t
d^t	: demand during period t
h_i^t	: holding cost of product i per unit during period t
s_i^t	: set up cost to produce i during period t
p_i^t	: production cost of product i per unit during period t
o_i^t	: start up cost to produce i during period t
d_i^t	: demand of product i during period t
h_i^{kt}	: holding cost of product i per unit during period t by unit k
s_i^{kt}	: set up cost to produce i during period t by unit k
p_i^{kt}	: production cost of product i per unit during period t by unit k
o_i^{kt}	: start up cost to produce i during period t by unit k
Rh_i^t	: holding cost of returned product i per unit during period t
Rs_i^t	: set up cost to re-manufacture i during period t
Rp_i^t	: re-manufacture cost of i during period t
Ro_i^t	: start up cost to re-manufacture i during period t
h_{ie}^t	: holding cost of product i in node e during period t
s_{ie}^t	: set up cost to produce i in node e during period t

p_{ie}^t : production cost to produce i in node e during period t
o_{ie}^t : start up cost to produce i in node e during period t
c_{ef}^t : transportation cost from node e to f during period t
d_{ie}^t : demand of product i in node e during period t
b_i^t : required time to produce one unit of i during period t
r_i^t : required resources to produce one unit of i during period t
v_i^t : product i volume during period t
Rd_i^t : number of returned product i during period t
Rb_i^t : required time to re-manufacture one unit of i during period t
Rr_i^t : required resources to re-manufacture one unit of i during period t
b_i^{kt} : required time to produce one unit of i during period t by unit k
r_i^{kt} : required resources to produce one unit of i during period t by unit k
τ^t : available production time during period t
R^t : available resources during period t
V^t : inventory space during period t
τ^{kt} : available production time during period t in unit k
R^{kt} : available resources during period t in unit k
V^{kt} : inventory space during period t in unit k
τ_e^t : available production time during period t in node e
R_e^t : available resources during period t in node e
V_e^t : inventory space during period t in node e
a_{ij}^t : number of product i needed to produce a unit of product j during period t
γ_{ef}^t : $\gamma_{ef}^t = 1$ if node e is linked to f, $\gamma_{ef}^t = 0$ otherwise (directed graph parameter)
g_i^t : backorder cost of product i during period t
L_i : lead time of product i

List of Variables

x^t : production quantity during period t
q^t : inventory at the end of period t
y^t : $y^t = 1$ if there is production during period t, $y^t = 0$ otherwise
z^t : $z^t = 1$ if there is production at t and no production at $t-1$, $z^t = 0$ otherwise
x_i^t : production quantity of product i during period t
q_i^t : inventory of product i at the end of period t
y_i^t : $y_i^t = 1$ if we produce i during period t, $y_i^t = 0$ otherwise
z_i^t : $z_i^t = 1$ if we produce i at t and no production of i at $t-1$, $z_i^t = 0$ otherwise
x_i^{kt} : production quantity of product i during period t by unit k
q_i^{kt} : inventory of product i at the end of period t in unit k
y_i^{kt} : $y_i^{kt} = 1$ if we produce i during period t by unit k, $y_i^{kt} = 0$ otherwise
z_i^{kt} : $z_i^{kt} = 1$ if we produce i at t and no production of i at $t-1$ by unit k, $z_i^{kt} = 0$ otherwise
x_{ief}^t : amount of transported product i from e to f during period t
q_{ie}^t : inventory of product i in node e at the end of period t
y_{ie}^t : $y_{ie}^t = 1$ if we produce i during period t in node e, $y_{ie}^t = 0$ otherwise
z_{ie}^t : $z_{ie}^t = 1$ if we produce i at t and no production of i at $t-1$ in node e, $z_{ie}^t = 0$ otherwise
P_{ie}^t : Production of item i in node e at time t
u_i^t : backorder of product i during period t
ω_i^t : amount of re-manufactured product i during period t
μ_i^t : inventory of re-manufactured product i at the end of period t

ABSTRACT

Digitalization and Industry 4.0 require a holistic transformation process with focus on human-oriented aspects. This contribution identifies the central human-related barriers of digital transformation in logistics and supply chain management, describes the methodological gap of current personnel development approaches and explains innovative game-based concepts to master these challenges.

KEYWORDS: Managing Decisions, Digital Transformation, Management 4.0, Organizational Change, Competence Management

INTRODUCTION

Digitalization plays an important role in many sections of daily life and also companies are pursuing measures to integrate technologies into business processes (Roth 2016). A transformation of business processes is an important requirement to create transparency in supply chains (Kersten et al. 2016). Especially in German-speaking countries this digitalization is referred to as “Industry 4.0”, which describes a vision of economic production through stronger inter- and intra-company networking. Generally speaking, this is understood as the fourth industrial revolution, which represents a further development of the organization and control of the value chain (Plattform Industrie 4.0 2014). Industry 4.0 describes the vertical (within an enterprise) and the horizontal linkage of these Cyber-Physical Systems (both across multiple business units and across several companies along the supply chain) to the efficient, decentralized and flexible production of products or services.” In the course of this process, companies are increasingly formulating digitalization strategies to coordinate their initiatives and projects on digital transformation (Mertens et al. 2017). “Logistics and supply chain management coordinate and organize the physical and information exchange processes in internal and external processes” (Bischoff 2015) and thus bear a major responsibility for the changes in the Industry 4.0. The necessity to focus especially on changes in logistics and supply chain management in the context of Industry 4.0 results from its high relevance as one of the most important economic sectors in Germany. (Kübler et al. 2015) For instance, in 2015, logistics service providers and logistics services in industrial and commercial enterprises in Germany generated a logistics economic volume of 253 billion euros (Schwemmer 2016). In terms of turnover, the logistics sector is thus comparable with the automotive industry, mechanical engineering or the construction industry (Kübler et al. 2015). The importance of the logistics sector is also reflected in the number of employees. In 2015 there were around 2.97 million logistics employees, more than 8% of all employees subject to social insurance contributions in Germany (Schwemmer 2016).

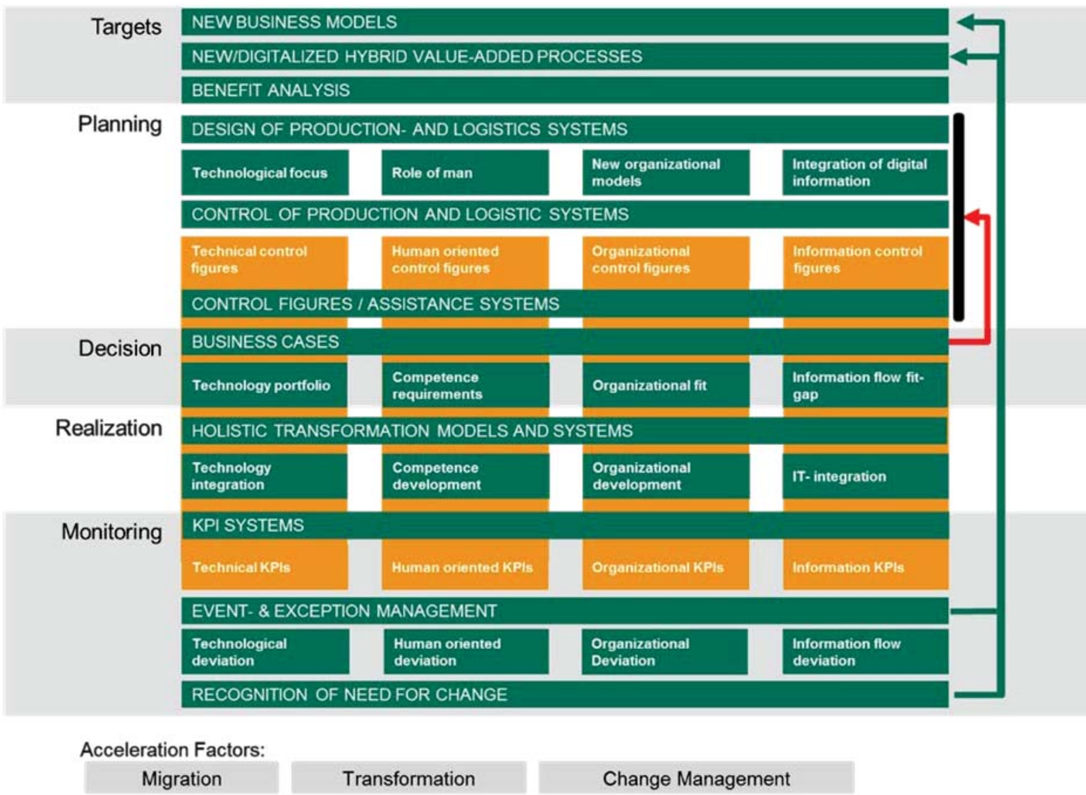
It is important to note that Industry 4.0 is not only the technological development of production but also a vision for the entire organization. The management of Industry 4.0 also has to consider the fact that in the near future new (digital) business models in logistics will emerge (Henke, Hegmanns 2017). As a result, two important key aspects of Industry 4.0 are the transformation of business process and the development of new business models according to company strategy. These developments make it necessary to rethink the entire company and its members in terms of a digital transformation. This involves a rethinking of corporate orientation in the sense of new business models and innovation processes as well as networking along the supply chain in the context of supply chain design and management and a rethinking of management as well as the strengthening and motivation of employees on their way to Industry 4.0. In logistics and SCM practice, companies face the greatest organizational challenges in implementing a digital transformation in the management of increasing complexity in collaboration and business processes as well as new forms of cooperation and networking and the necessary change in leadership culture (HR Report 2017).

This paper deals with the human-centered challenges of digital transformation in logistics and supply chain management. Based on the Dortmund Management Model, the digital transformation will be structured, changes in the working environment and the resulting competence requirements will be highlighted and a methodical gap in current qualification programs for industry 4.0 competences will be outlined. Finally, the paper discusses innovative game-based qualification approaches as a way to close this gap.

Dortmund Management Model

For this reason, the "Dortmund Management Model" (see figure 1) was developed. The Dortmund Management Model is a framework to support the management in the digital transformation of companies and is to be understood as a universal model. The challenge consists in an integrative management process that analyzes the corporate culture, the corporate organization and the value-added processes on the basis of the wealth of information and at the same time promotes process and technology innovations and has to be operationalized on a company-specific basis taking into account the individual needs of people.

Figure 1: Dortmund Management Model



In order to advance the transformation of a company to industry 4.0, the three acceleration factors change management, migration and transformation are integrated into the model as basic factors. Change management encompasses all activities aimed at bringing about far-reaching changes in the implementation of new strategies, structures, systems, processes or behaviors in a company across functions (Berger et al. 2013). Migration describes the step-by-step introduction of technologies in companies and their processes (Bildstein 2014). Transformation focuses on an agile organization, made possible by the use of suitable technologies and organizational learning to adapt to changed framework conditions (Schuh et al. 2017). Furthermore, the developed framework of the Dortmund Management Model structures the change process in two dimensions: a management dimension that describes the relevant (standard) tasks of management ('target', 'planning', 'decision', 'realization' and 'monitoring') (Ant 2018; Esser 2016), and an organizational design dimension in the form of four pillars.

The integrated view of the Dortmund Management Model is reflected in the four pillars 'Technology', 'People', 'Organization' and 'Information', which are equally included: This comprehensive organizational design approach is based on the MTO concept according to Ulich and includes the characteristics 'human', 'technology' and 'organization' (Ulich 2005). The increasing quality and quantity of digital data available in real time offers new opportunities for companies within the framework of Industry 4.0. By merging digital and real processes in the sense of digitization, companies have automatically or autonomously determined amounts of data at their disposal. By using appropriate analysis methods and artificial intelligence, these provide basic information about their own business processes, especially in the form of process, environmental and status data. Thus, on the one hand, increased transparency and valid forecasts can be achieved internally. On the other hand, data and the resulting information, for example from cross-company value creation networks, become a valuable asset for innovative data-supported business models and thus a central asset in industry 4.0. This leads to a self-optimizing organization that enables autonomous and timely adaptation to the changing conditions in the business environment (Schuh et al. 2017). Consequently, a fourth feature is added to the MTO model: Information (I) (MTO plus I).

The design requirements of the digital transformation of companies arise at the interfaces of these classic management tasks and pillars.

CASE STUDIES TO IDENTIFY THE HUMAN FACTORS IN MANAGING DIGITAL TRANSFORMATION

Based on eight concrete transfer- and implementation projects with SME, the special challenges during the transformation process were analyzed and integrated into the structure of the Dortmund management model (Henke et al. 2019). The integration of digital information and the corresponding information flows are identified as essential factors for the projects considered. For example, one metalworking company involved in the project aimed to develop an integrated information system, because the paper-based process that had previously been used increasingly led to intransparent material flows. Once these inefficient processes had been identified, an app was developed specifically for the company that could standardize, process and make available the recorded data via smart devices. In this way, the app ensures a transparent material flow that has a positive effect on delivery service levels, customer satisfaction and cost efficiency. Another company in the steel distribution manufacturing services sector saw the potential in digitizing its information flow. This measure enables the company to maintain its short order throughput time and high flexibility, as setup processes and throughput times can be better planned and integrated into production. In the context of identifying potentials with regard to new business models, the cross-company networking of data to expand the service portfolio was implemented in a pilot project for a wholesaler of technical supplies. (Henke et al. 2019)

The investigation of the cases showed that the central action dimension of most projects was to be located in the pillars of technology and information, since the objective of the digitization projects was usually a gain in information transparency through the use of new technologies in logistics. However, the challenges that arouse during the project can be classified into the pillars of people and organization.

This indicates that the successful digital transformation requires employees to be sensitized to innovations and to take them along on the path of organizational change. New technologies can only develop their full potential if the employees, as process experts and essential interfaces, are integrated into the design of the digitized processes. According to an empirical study by Ziemendorf, the causes of resistance are less to be found in rational decisions than in emotional aspects of "fear", "shyness", "helplessness", "inertia", "anger" and "power", which are increasingly attributable to insufficient participation of people in processes of change (Ziemendorf 2009).

This impairment for the transformation process exists first and foremost when resistance takes place undercover and no appropriate handling of barriers takes place because the causes are not clearly recognizable.
In this context, the emotional acceptance of transformation processes is described as the central problem. This usually leads to resistance on the part of the employees concerned during the transformation process.
The most frequently stated reasons for barriers to change relate both to the emotionality and attitude of the employees and to the type of internal project management, with the emphasis on aspects of a participative project approach and the communication structure.
In this respect, a participatory project approach is almost unanimously considered to promote change. Communication is a decisive factor in ensuring continuous transparency about concrete process changes. This primary importance of communication can also be found as a prerequisite for organisational learning. In theory, this results in optimal conditions for the implementation of change projects as well as the successful implementation of process change in organizations in a logistical environment. However, these theoretically optimal conditions are no guarantee for a smooth course of the project in operational practice. Rather, dealing with a multitude of possible resistances is part of the everyday practice of change projects. This once again shows that people are the central drivers of change.

The identified human factors in managing digital transformation include challenges such as the design of adapted organizational structures for the new digitalized business processes (Organization pillar), the active involvement of employees in the change process and the accompanying and forward-looking qualification for the new technologies (Human Resources pillar). The holistic character of the Dortmund Management Model makes clear that an integrative consideration of all pillars is necessary for a target-oriented and successful design of the change process within the scope of the digitization of companies, especially in the area of logistics.
The excerpt of the results of the case analysis emphasizes in particular the necessity to include human-oriented factors in the goal setting, planning, evaluation, realization and monitoring of digitization processes. On the one hand, it points out that an adaptive management strategy is needed, which regards the people working in the organization as the center of organizational transformation processes. This is supported with the help of the Dortmund Management Model. On the other hand, it becomes clear that the strategic qualification of employees is of particular importance and that companies must anticipate the future working requirements of their employees and proactively develop the necessary competencies.

NEW COMPETENCE REQUIREMENTS IN THE FIELD OF LOGISTICS

The present technological and organizational changes in logistics and SCM are going to transform the employees’ daily working routines. Especially in the field of operational logistics routine activities and manual work, such as the collection, documentation and inspection of incoming goods or the determination of fright weight and volume are going to decrease as part of growing options for automation. In addition, transportation and picking processes as well as packing and sorting orders can be largely automated (Kerner 2016; MHI & Deloitte 2018; Ten Hompel & Henke 2014; Ten Hompel & Kerner 2015). Furthermore, the usage of digital media, technology and mobile and assistance devices is going to increase rapidly as well as the collaborative work between humans and machines in the “Social networked industry”. (Taraj et al. 2007)

That leads to a fast development of new task fields especially in operational logistics and more and more complex processes. E.g. task extension by value creating activities (e.g. assembly activities or the operation of additive manufacturing processes) as well as by fault management related activities and maintenance. For that reasons the deployment of employees will become more flexible and new forms of work, such as collaborative group-work is going to increase, so that the daily tasks shift from manual work to more cognitive tasks (acatech 2016).
Against this background the understanding of processes and problem-solving abilities are going to become important key competences and information competence becomes a requirement for optimized decision making by means of assistance systems. (acatech 2016; Ahrens & Spöttl 2015; bayme vmb 2015; Hirsch-Kreinsen 2014; Ittermann et al. 2015) Moreover, the understanding of processes' interdependencies and the interaction between process, technology and organization will be necessary.
Hence, the development of these competences in the field of operational logistics is crucial to master the logistics system's complexity.

On a more management oriented level the field of logistics is more and more understood as an interdisciplinary field of activity that transcends organizational structures, which is currently increasingly motivating new responsibilities and thus completely new professions and designations, such as "Digital Transformation Manager", "Chief Digital Officer" or "Digital Transformation Architect".
Willingness to change, dealing with complexity, communication and, in particular, lifelong learning are the competencies in which the need for action with regard to digitalization is most significant for 99% of companies (Heise Online 2018, HR Report 2017). In particular, the necessary interdisciplinary cooperation and networking requires further training programs with new methods and approaches that enable interdisciplinary collaboration and communication as well as interpersonal transfer to be experienced and strengthened.

However, more than half of the companies in the field of logistics and SCM surveyed in the HR Report 2017 have no strategy for teaching these digital skills (HR Report 2017). At the same time, over 74% of employees want more training opportunities from their employers in relation to digital change (Heise Online 2018). According to this study, there is currently a gap between the efforts and the need for action on the one hand and the pressure on companies to act on the other. One of the main reasons given by companies for this discrepancy is that they have not found the right offer on the vocational training market.

OVERVIEW OF THE VOCATIONAL TRAINING MARKET

In the following, different types of vocational training programs on the topics of "Digital Transformation", "Digital Management" and "Management 4.0" will be outlined and subsequently examined. The scope of the analysis is initially limited to training courses offered in Germany and was then extended to international programs. For the search in Germany, "Deutsche Bildungsserver" (Bildungsserver für Weiterbildungssuche) provides a database of vocational training providers that was used to help identify suitable further training courses. The analysis of the programs offered by the leading providers of vocational training and management training in Germany revealed a total of almost 40 results for the search terms "Digital Transformation", "Digital Management" and "Management 4.0", which are summarizes in Table 1. These are mainly seminars and workshops. The measures extend over a period from one to five days. Online and certificate courses with a duration between 24 days and 18 months are also considered. The online courses are usually courses with flexible time

management. You can either register for a special course or a subscription and use the corresponding course platform. Additional learning materials are added at regular intervals so that the participant has sufficient resources at the end of the course. Some of these courses can be completed with an exam, while others already provide certificates for full participation.
In the international field, the search for vocational training programs is carried out using a structured Google search with the same search terms. In this way, additional 21 courses are identified that match the initial searches. Here, too, seminars and workshops are largely involved, although some conferences are also offered. The average duration of these measures is two days, but some are limited to two hours, while others last up to five days.

Tab. 1: Overview of the mentioned Methods

<table>
<tr><th colspan="2">Course-Format</th><th>Methods</th><th>Frequency of mentioning</th></tr>
<tr><td colspan="3">Online-Courses/MOOCS</td><td>3</td></tr>
<tr><td rowspan="10">Presence Workshops and Seminars</td><td rowspan="5">Trainer-Centre</td><td>Lectures and Presentations</td><td>12</td></tr>

<tr><td>Prototyping</td><td>1</td></tr>
</table>

While the courses advertise with a variety of methods, these are largely limited to classical training formats. They make use of lectures, individual and group work, group discussions and the exchange of experience. In addition, they work with practical reports and examples and provide qualified trainers. A classical seminar structure therefore always consists of several of the elements mentioned and usually alternates between lectures and interactive elements. For example, ESMT Berlin's seminar on "Digital Transformation: Change in Leadership and Culture" addresses the need for new didactic approaches. On the basis of the available course description, however, this remains on a purely theoretical level. Most international continuing education measures are also based on discussion rounds, case studies and lectures. Debates, question rounds and interviews can also be found here.
The integration of innovative learning environments, methods and approaches, which address the market-oriented competence requirements of a management of digital transformation in logistics and SCM under the necessary didactic approach of experiential learning in an interdisciplinary transfer- and competence-oriented manner, stay unconsidered in the existing offers.

OUTLOOK ON INNOVATIVE GAME-BASED APPROACHES

This demand, however, poses new challenges for current approaches and methods for competence development and for vocational training practice (Pfeiffer et al. 2016). Especially the mechanisms of entertainment games and virtual reality have the potential to interrelate competence development as well as the new requirements of knowledge-intensive technical work and progressive technology development. (Bundesministerium 2014, De Witt 2012, Härtel 2012). Serious Games offers management a tool to continuously improve the qualification of the workforce through new challenges in a protected environment. The didactic advantage lies in the close interlocking of game and learning process, which equates the game mechanics with the learning process.

This can be achieved through a variety of in-game elements, such as point systems, rewards, level ascents and badges. Especially competence-oriented level design, which considers individual user requirements and learning paths, has great potential to cause a state of positive excitement in the learner and thus to support the self-determined confrontation with the learning object for the development of the necessary action routine and the dismantling of empirical knowledge. (Henke et al. 2017) Through the game environment, the user is also able to receive direct feedback on his decisions and actions, which in addition to feedback learning also leads to further motivation through continuous curiosity. (Besenfelder et al. 2018) In addition to the great potential for developing the metacognitive competences necessary for the change of the logistic working world and the promotion of self-motivated learning, Serious Games continue to offer the possibility of automating competence diagnostics processes in the long term due to their structure. Both, the survey of the currently available competences and the comparison with the required competences in a corresponding competence profile are usually carried out subjectively using questionnaires for self-assessment and external assessment. However, the necessary and relevant data for competence measurement and evaluation are still based on personal experience and subjective assessments and cannot be collected autonomized at this point. In particular, a competence-dependent level design in serious games, which results in correspondingly defined key performance indicators for competence assessment, enables competence assessment in real time during the learning process and thus autonomizes the cycle of operational competence management via corresponding interfaces and cross-system data exchange. As a result, the management would always have transparent information available about the currently required competencies and their internal development as decision support. On this basis, management could continue to weigh different change scenarios against each other, anticipate human-oriented risks, and proactively shape the transformation process using risk management approaches and machine learning methods. Relevant topics for further research activities would be, for example, how competence measurement and diagnostic procedures can be autonomized by Big Data Analytics approaches, which data would have to be collected for this and how and which role game based applications can play in the generation of exactly this data. Moreover, a relevant research topic could be how the effect of competence oriented personnel requirements planning can be evaluated with regard to the quality of work and which economic conclusions can be drawn for the entire organization.

CONCLUSION: LIMITATIONS AND FUTURE REASEARCH

The Dortmund management model enables an integrated view of digitization in logistics and supply chain management. As a result, it enables management to merge isolated technological solutions into an integrated management model by using the design principles of supply chain management. For industrial companies, the most important fields of action for a targeted design of the digital transformation are identified and the necessary process steps are outlined. The

model does not favour specific technologies and can be used for various industries. The challenge of digital transformation, taking into account all fields of action, in particular all action dimensions, is addressed directly by the model. In addition to practical support, the management model also enables faster scientific progress. It supports the identification of white spots in science that can be addressed with specific work, leading to a research roadmap for the scientific community in industry. This paper identifies some research requirements related to human-centred factors and, in particular, innovative competence management. New approaches to staff qualification are needed. In particular, game-based Methden can be suitable approaches to address the requirements of the new world of work in logistics and SCM. In the integration of competence-based indicators into game-based qualification measures, the process of competence management and in particular competence diagnostics could be automated in the future and support more human-oriented management decisions.
Due to rapid changes and continuous developments, the Dortmund management model is regarded as a dynamic model that must be critically scrutinized and continuously further developed.

ABSTRACT

The central objective of this conceptual paper is the development of a transformation model for the implementation of additive manufacturing in existing corporate structures. Many companies see great advantages in the use of additive manufacturing, but cannot, or only with great effort, integrate the technology into their processes due to the associated complex decision-making structures. The work is based on the leading research question of how to design an appropriate process model taking into account the potentials and challenges of additive manufacturing, which can be seen as a subcategory of advanced manufacturing technologies.

KEYWORDS: Additive Manufacturing, Transformation Model, Advanced Manufacturing Technology (AMT), Production Technology, AMT Implementation

INTRODUCTION

The term additive manufacturing bundles a group of manufacturing technologies which, in contrast to subtractive methods, apply the material layer by layer. This type of manufacturing technology makes it possible to manufacture complex geometries and components with a negligible share of set-up costs, since tool changes are no longer necessary during the manufacturing process. (Möhrle and Emmelmann 2016)

By combining additive manufacturing with conventional manufacturing processes, various advantages can be achieved, especially for manufacturing company structures. For example, bionic designs based on natural models are easy to produce, component adaptations or improvements can be implemented quickly by adapting the data, and spare parts can be manufactured locally at the point of need. As a result, warehousing and capital commitment costs are reduced, as not all spare parts have to be kept in an indefinite quantity. (Zeyn 2017)

Many companies are aware of the advantages of additive manufacturing, especially in the area of customer-specific manufacturing of products and the flexible adaptability of the technology. Nevertheless, many companies have a certain inhibition threshold, since the location and above all the integration of additive manufacturing processes are associated with a high planning effort. The uncertainty as to whether the technology can really be used economically also prevents many companies from integrating it into their own production systems.

The manufacturing technology of Additive Manufacturing (AM) is allocated in this paper as an Advanced Manufacturing Technology.
Advanced Manufacturing Technologies (AMT) in particular are increasingly being used as strategic weapons in global competition (Singh et al. 2007). An important competitive advantage can be achieved by integrating additive manufacturing (Besenfelder et al. 2018) which is a subcategory of AMTs (Chen et al. 2017).
The implementation of AMTs is generally regarded as one of the longest, most expensive and most complex projects a company can undertake (Gunawardana 2006). Moreover, such projects to create efficient production structures are not supported by systematic measures, so that it is particularly necessary to introduce efficient management for process changes (Lerch et al. 2012).

This paper aims to answer the following research questions:

(1) What requirements does AM as an AMT demand from a structured integration into existing corporate structures?
(2) Which AM and AMT transformation models are already available and to what extent do they need to be adapted on the basis of the specific requirements?
(3) How can a holistic transformation model for additive manufacturing be described and structured?
In order to answer these questions, the integration requirements of AMTs will first be determined by a literature search, as well as in a next step the already existing models for the technology integration of AMT will be identified. In the next section, the specific requirements of additive manufacturing, especially in the area of direct manufacturing, will be examined and the most relevant models for the integration of AM will be shown. The final result of the paper is the development and explanation of a holistic transformation model for additive manufacturing processes based on literature research. This model will be finally summarized and future needs for further development and research will be identified.

LITERATURE REVIEW

Additive Manufacturing - an Advanced Manufacturing Technology

Additive manufacturing (AM) is a category of manufacturing technologies besides subtractive manufacturing and formative manufacturing. In contrast to the latter, AM technologies shape the workpiece by adding portions of material. If these portions of material are added in the form of layers, the term Additive Layer Manufacturing can also be used. Most AM processes are automated and feature layer technology, indicating that a workpiece is manufactured layer by layer. Therefore, the geometry of the workpiece is sliced virtually into layers and then built physically applying the virtual layer information. (Gebhardt and Hötter 2016)

The additive manufacturing process can be divided into the three applications Rapid Prototyping, Rapid Tooling and Direct Manufacturing (application level). Rapid prototyping is used to create models and prototypes to quickly implement first test applications and to make designs haptically perceptible. Direct Manufacturing (DM) describes the process by which saleable products are manufactured using AM. Tools and tool inserts are produced within rapid tooling. Rapid Repair is a fourth possible application that complements the process and describes the maintenance and repair of worn products. (Lachmayer et al. 2016)
If these applications of AM are located in the product development process, it becomes clear that rapid prototyping is used for product development phases. This is followed by rapid tooling

in the product development process, with which direct and indirect tools are manufactured. The DM is used for the production of small series or series. (VDI 2013) In principle, the term "series" must be viewed in a differentiated way in the AF sector, as the number of components can vary considerably between industries (Klemp and Pottebaum 2016). The Rapid Repair application can be assigned to the Service area after the actual product creation.

This results in a multitude of application possibilities for the technology and poses a challenge for many companies of identifying economically viable business models. A further challenge is the multitude of technical procedures, which are summarized under the heading of additive manufacturing. Many companies lack the appropriate know-how to select the right technology for the application.

In this section, DM is described in more detail, since the present paper focuses on the additive manufacturing of end products. Studies predict that DM, between 2030 and 2050, will even become the main application of AM (Fischer and Rommel 2018). DM originated from rapid prototyping and, according to Gebhardt and Hötter (2016), still uses the same machines (Gebhardt and Hötter 2016). Due to significant progress in quality, reliability and material selection as well as the increasing digitalisation of companies, DM is becoming increasingly relevant (Fischer and Rommel 2018, Grund 2015, Lutter-Günther et al. 2015b). DM is characterised by the fact that it is possible to produce individual pieces, small series and theoretically also mass goods (Grund 2015). The unit costs remain almost constant due to the tool-free and wear-free production with minimum material input, independent of the batch size. This type of production is therefore particularly interesting for small quantities and individual pieces (Grund 2015, Hague 2006, Hokinson and Dickens 2003, Ruffo and Hague 2007, Schmutzler et al. 2016)

DM as a specific application of the additive manufacturing process can be counted in the category of Advanced Manufacturing Technologies (AMT). (Chen et al. 2017)

AMT can be defined as a modern manufacturing technology and improvement in conventional manufacturing which represent excellent quality, cost efficiency and high productivity with a low environmental footprint (Gupta 2017). Further potential for AMTs comes from faster market access and faster response times to fluctuating customer needs (Small and Yasin 1997). In addition to the manufacturing operations, the overall competitiveness of the company is improved by AMTs (Pagell et al. 2000, Small and Yasin 1997).

Requirements of AMT Integration Projects

For the successful implementation of AMTs and the associated realization of potentials, the consideration of critical factors is elementary (Rahardjo and bin Yahya 2010, Singh et al. 2007) In the previous section it also became clear that differentiation into different phases during implementation is useful. Therefore, the study by Rahardjo & bin Yaha, which refers to individual phases of the implementation, is particularly relevant. The authors identify 15 decisive success factors and determine the five most important factors for each of four different implementation phases (cf.

Figure 1). Among other things, they orient themselves on the model presented by Frohlich (Frohlich 1998).

Figure 1: The five most important success factors of the respective implementation phase adapted from (Rahardjo and bin Yahya 2010)

Rank	Pre-Installation	Installation	Growth	Fully Developed
1	- Good Leadership	- Good Leadership	- Availability of Capital	- Support & Integration of Top Management
2	- Support & Integration of top management	- Availability of Capital	- Teamwork	- Cross-Departmental Coordination & Cooperation
3	- Availability of Capital	- Teamwork	- Availability of Expert Knowledge	- Enhancing Communications Technology
4	- Company Culture	- Support & Integration of top Management	- Control over the AMT process	- Collection and analysis of AMT data
5	- Training & Education of AMT	- Cross-departmental Coordination & Cooperation	- Good Leadership	- Communiction with Supplier

In the pre-installation phase and the installation phase, good management is the most important factor. In the growth phase, however, the availability of capital is the most important. In the final phase, the maturity phase, the support and involvement of top management is essential. (Rahardjo and bin Yahya 2010)

Further factors that are important for the implementation of AMTs are presented by the authors Saberi et al. and Darbanhosseiniamirkhiz & Wan Ismail. The two studies are very similar in their results.

In the area of technological factors, both studies describe that justification before installation is important (Darbanhosseiniamirkhiz and Wan Ismail 2012, Saberi et al. 2010) as many AMTs are associated with high costs for hardware and software, as well as complex organizational and operational problems. For a comprehensive view, which makes it possible to implement as many advantages of AMTs as possible, it is necessary to use an integrated approach that uses economic, strategic and analytical methods in parallel.

The degree of integration of AMTs into the company should also be considered, as a higher degree of integration requires more intensive planning. In the area of technological factors, the integration of a technology also offers more advantages than the automation of individual processes (Saberi et al. 2010) and the knowledge of potential advantages of AMT can positively influence the adoption of these (Darbanhosseiniamirkhiz and Wan Ismail 2012).

A key factor for a successful implementation is the structure of the organization. The factors of the two studies are very similar, especially in this area. For the corporate structure, as a factor, less hierarchical, bureaucratic structures are better suited (Darbanhosseiniamirkhiz and Wan Ismail 2012, Saberi et al. 2010).

In addition, employees should be prepared for new structures even before the implementation process, as in many industrial companies it takes several years until the structure and the technology match (Darbanhosseiniamirkhiz and Wan Ismail 2012). Furthermore, the corporate culture must also be taken into account when implementing AMTs. In principle, a flexible corporate culture is an advantage for the implementation of an AMT (Darbanhosseiniamirkhiz and Wan Ismail 2012, Saberi et al. 2010).

The third factor is the operational strategy or the manufacturing strategy. Within the framework of the manufacturing strategy, managers should see investments as an opportunity to gain lasting competitive advantages. A corresponding manufacturing strategy consists of the four

most important competitive factors: costs, quality, flexibility and reliability/delivery reliability. (Darbanhosseiniamirkhiz and Wan Ismail 2012, Saberi et al. 2010)
For a successful implementation of AMTs in the future, appropriate staff training is required (Darbanhosseiniamirkhiz and Wan Ismail 2012, Saberi et al. 2010).
At the same time, management practices must be adapted so that employees are intrinsically motivated and satisfied with their work. Successful implementation projects also benefit from "champions" who, as individuals, drive implementation efforts (Saberi et al. 2010). Top management plays a crucial role in motivating employees for the new technology and the associated challenges (Darbanhosseiniamirkhiz and Wan Ismail 2012).

Integration of Advanced Manufacturing Technologies
In principle, AMTs are seen as the key to improvement in many industries (Frohlich 1998). However, these expectations cannot be met in many implementation projects (Chen et al. 2017, Rahardjo and bin Yahya 2010). In U.S. companies, for example, implementation fails in 50-75% of cases (Chew et al. 1991).
A large part of the existing studies shows that above all, the organization of a company is relevant for the full potential exploitation of a technology and not exclusively the technological aspect (Friedli 2006, Rahardjo and bin Yahya 2010, Voss 1988). Traditional roles and responsibilities, work content, remuneration systems and teaching approaches in companies should be revised accordingly (Rahardjo and bin Yahya 2010).
On the one hand, the theory for the successful implementation of AMTs is therefore relevant in order to create a well thought-out implementation concept. On the other hand, the findings of AMT research can be used as a basis to introduce new industry 4.0 technologies, including AM (Maghazei and Netland 2017).

For the implementation of AMTs, some far-reaching procedural models already exist, the most important of which will be briefly summarized in the table below.

Table 1 Implementation Models for AMT

	Model Phases	Main emphasis
Voss 1988	Pre-Installation Installation and Commissioning After-Commissioning	Taking up special factors that influence the success and failure of the implementation.
Chen & Small 1994	Planning Phase Installation and evaluation phase	The focus of their work is on the pre-installation phase or the planning phase, as this phase is important for a successful implementation.
Small & Yasin 1997	Business Environment Corporate Response Company Goals Performance Indicators Technology Types Infrastructural Changes Legitimation Installation of Systems	Holistic framework, which also includes the dependencies between the individual elements or activities during implementation.

	Measurement of Performance	
Frohlich 1998	Unfreezing Changing Refreezing	Depending on the state of development of the technology (Degree of maturity), different actions are taken for implementation.

It should be emphasized that the Voss model was used as a basis for the Chen & Small and Small & Yasin models, but it was optimized by the continuation.

Requirements of DM Integration Projects

DM not only influences production but also the entire business logic and value chain of the company (Muita et al. 2015, Steinwender 2016). AM is therefore not a pure substitution technology for conventional manufacturing processes (Steinwender 2016). In order to utilize its full potential, various corporate divisions must be considered and their activities coordinated (Lutter-Günther et al. 2015b). For this purpose, a suitable business model should be chosen which is also the prerequisite for the successful implementation of additive manufacturing processes (Lutter-Günther et al. 2015a, 2015b).

Fischer et al. have dealt with the decision making for DM. DM is generally the most complex and demanding application (Fischer and Rommel 2018).

Due to the high complexity of the DM, it must be considered more precisely whether the advantages of the process can be exploited. For the corresponding determination, the authors specify influencing factors (product, material, human & environment, machine and method) which decide on success or failure. (Fischer and Rommel 2018)

For the product, at least one of the features should apply, such as small quantities, high degree of individualization desired, production on demand, high complexity of the component, and integration of functions or lightweight construction. With regard to the material, the following question must be clarified: "Can the material of which my product is made of be printed or can I replace the material sensibly and with added value with a printable one?. Well-trained employees who can handle a high degree of digitisation are necessary for the human and environmental factor. In addition, the introduction of AM is causing major restructuring, so that good change management up to the management level is necessary. (Fischer and Rommel 2018)

The following must be clarified: "Do I have the necessary personnel resources and the quality of employees or can I acquire them? Is my change management good enough for changes of this magnitude? (Fischer and Rommel 2018)

For the last success factor, the method, it is evaluated whether the surface quality and the quality of the mechanical properties of additively manufactured components are sufficient. Basically, the influencing factors must be considered before making a decision. (Fischer and Rommel 2018)

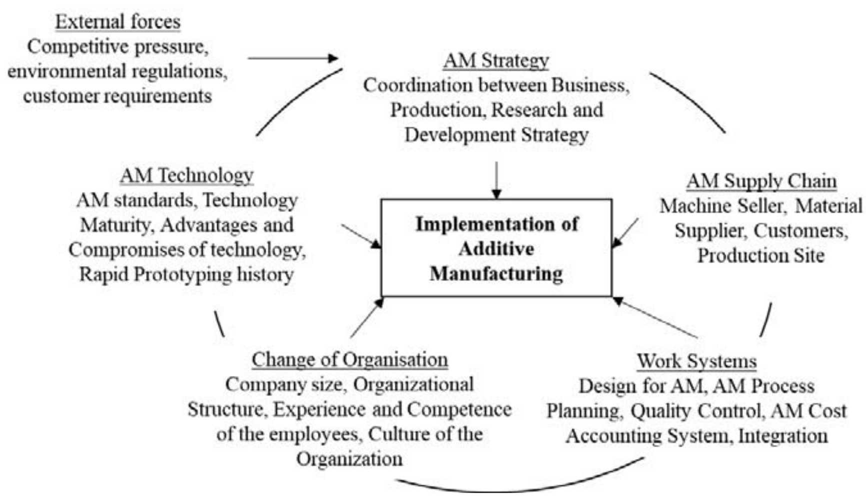
Integration of AM

This section presents research that has developed an approach for implementing AM in production structures, especially the DM. The most important models in this area are listed and illustrated below.

As part of Mellor's research, a framework for the implementation of additive manufacturing in production applications is being developed (cf.

Figure 2). The research is based on the theory of implementing new technologies or AMTs and builds on the findings of Voss. The presented framework considers external factors and the internal strategy as driver of AM as a production method. In the area of external factors, competitive pressure, environmental regulations and customer requirements must be considered. The approach to implementing AM is influenced by five overall constructs. (Mellor et al. 2014)

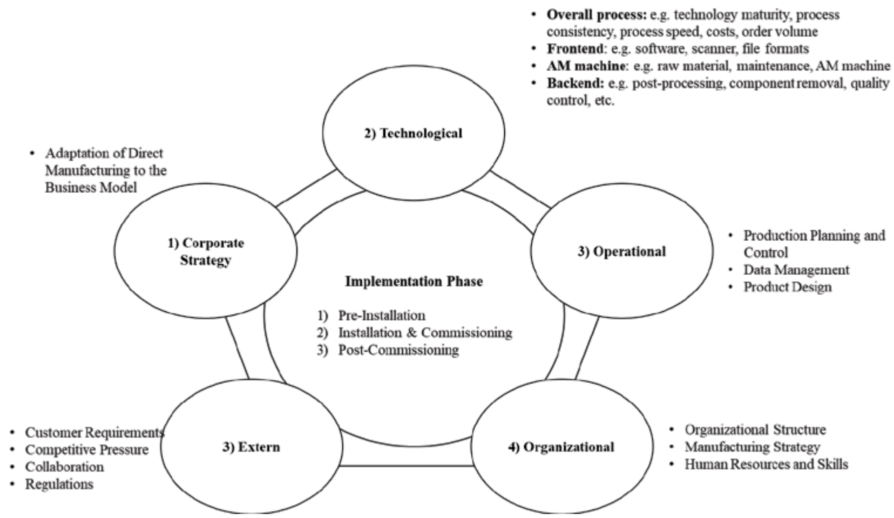
Figure 2: The proposed framework of AM implementation adapted from (Mellor et al. 2014)



As Deradjat & Minshall have already stated in their research, Mellor's model has decisive gaps, which can lead to the failure of the project in the event of implementation. Important technical factors such as necessary software components and necessary post-processing processes are not considered in the model. In addition, the changes to the framework parts during the implementation process are not further taken into account. The three steps along the implementation process (pre-installation, installation and commissioning, post-commissioning), which was already developed at Voss, are not considered in the existing framework. (Deradjat and Minshall 2017)

For this reason, Deradjat & Minshall have developed their own process model (cf.*Figure 3*), which takes the above mentioned aspects into account, but specializes in the field of mass customization.

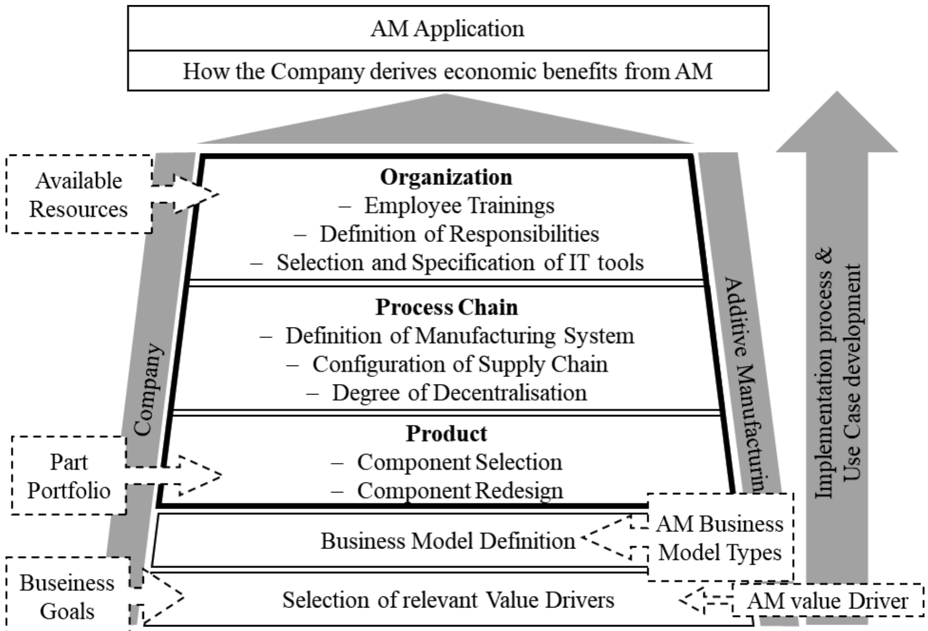
Figure 3: Framework of Rapid Manufacturing implementation for Mass Customization adapted from (Deradjat and Minshall 2017)



Their framework deals with technological, operational, organizational and internal and external factors with a focus on technological aspects. The implementation phase is based on the structure of the Voss model. (Deradjat and Minshall 2017)
The model focuses on the introduction of mass customization and is strongly tailored to the dental sector, and too little attention is paid to the necessary organizational changes. Only in the fourth step the employees and the necessary teams for implementation are taken into account.

The process model of Lutter-Günther et al. aims to provide a systematic support tool for the development of a company-specific AM application case (Lutter-Günther et al. 2015a).
The research is explained in more detail here, as the authors develop a process model that applies to all AF technologies. In addition, the process model has a special focus on business models that are important for the implementation of additive manufacturing processes.
The process model consists of three fields of action: product, process chain and organization (cf. Figure *4*). In addition, the typology of the AM business models is included in the model. The phases of the model are run through one after another. In the first step, the conceptual business model is defined, which in some cases can be a combination of different business models. Value drivers are selected on the basis of the business objectives and challenges using a pair comparison or a weighted multi-criteria evaluation. To gain knowledge about operational and strategic business goals and challenges, workshops can be conducted with AM experts and company representatives. (Lutter-Günther et al. 2015a)

Figure 4: Process model for AM implementation adapted from (Lutter-Günther et al. 2015a)

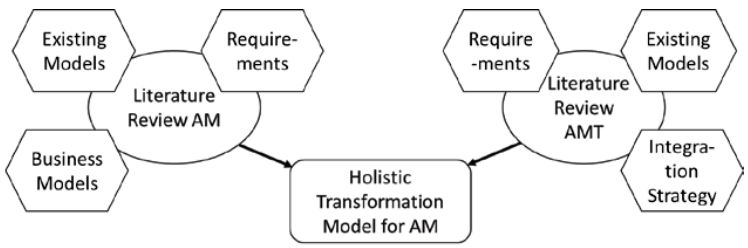


In the model of Lutter-Günther et al., the representation and description of the procedure in the text is partially inconsistent. However, the model is generally easy to understand and due to fewer elements, the model has a simple structure and, according to the author, is universally applicable. However, the procedure model does not have clear connections between individual elements and steps, since, for example, dependencies between individual elements are not described. Furthermore, the given process model has a roadmap character, but does not provide an optimal sequence for the introduction of AM. In addition, the process model answers only conditionally how the implementation takes place in concrete terms. It is not possible to make a statement on the practicability, since this has not yet been demonstrated. There is no concrete specification of the sequence of work steps and definition of responsibilities. Furthermore, there is no success control between the steps and the authors do not mention any feedback.

METHODOLOGICAL APPROACH

The previous chapters clearly show that none of the approaches presented for the development of a procedure model for the integration of additive manufacturing, especially DM, can be adopted. It is rather necessary to develop a procedure on the basis of the theory for the implementation of AMTs and to adapt this for the concrete case of the use of additive manufacturing processes. For the development of a corresponding procedure model it is necessary to make the resulting complexity controllable. The development of the process model therefore takes place step by step as shown in Figure 5. For this purpose, the facts are considered step by step "from rough to detailed".

Figure 5: Methodical approach for the procedure model

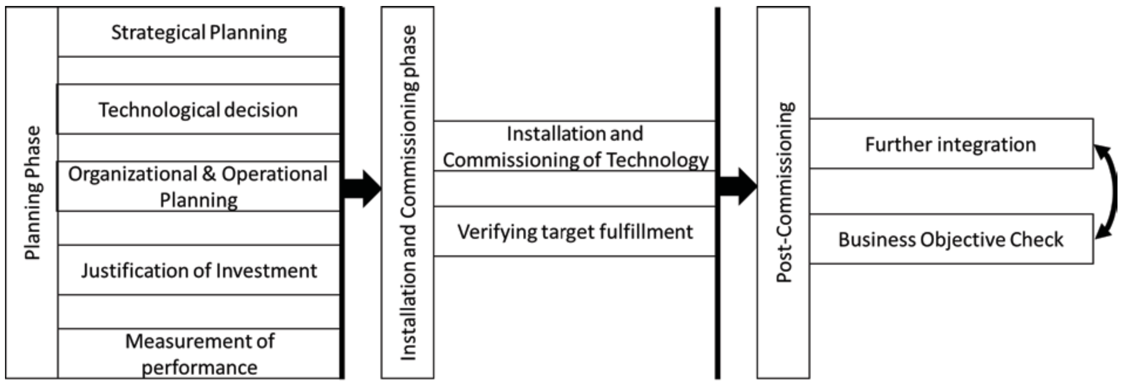


In order to develop the process model, a literature review on AM was first conducted. What are specific requirements during the introduction of the technology and which models were set up in this area? In addition to the technical components of the technology, possible business models were also identified in order to meet the aforementioned important step of the initial strategy.
In addition, a literature review was also conducted in the field of AMTs in order to derive the most important requirements for technology integration, but also to record existing integration models and their underlying integration strategy. Moreover, it became clear that an unstructured introduction of AMTs would lead to considerable blind processes and that therefore a guided process model is necessary for the introduction of AM.
In the next step, the developed process model is explained more closely.

HOLISTIC TRANSFORMATION MODEL FOR ADDITITVE MANUFACTURING

First of all, it must be clarified which structural requirements can be adapted to the model from the requirements of AMT and DM and the previous models introduced for AMTs and DM.
The process model is divided into a planning phase, an installation and commissioning phase and a post-commissioning phase. This structure has already been validated by Voss as suitable for AMTs, and is therefore valid for DM.

Figure 6: Holistic Transformation Model for AM



The planning phase is the most comprehensive phase and includes the determination of the company's objectives, technology monitoring, the planning of infrastructure adjustments, the justification of the investment, as well as the measurement of the current company performance. The installation and commissioning phase deals with the concrete installation of AM and the subsequent technical and operational fulfilment of the objectives. In the final phase, the post-commissioning phase, AM must be fully integrated and it must be checked whether the desired business benefit has been achieved. Each phase will be explained in more detail further on.

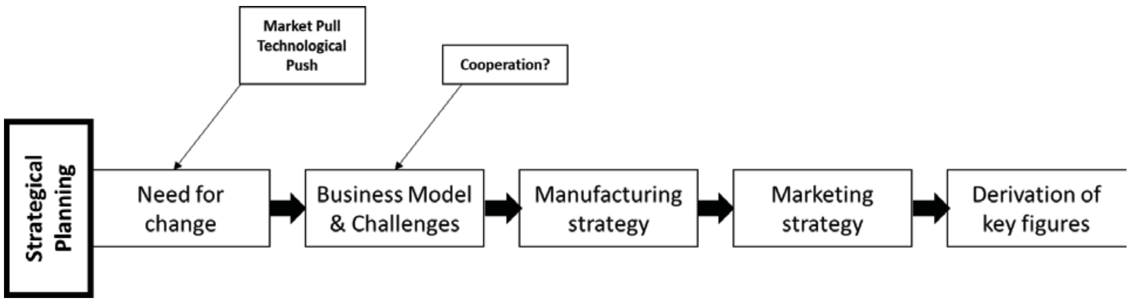
According to Voss and Chen & Small, a technical success measurement must be carried out after installation and commissioning. In addition, both studies provide for validation of the expected business benefits in the post-commissioning phase. Furthermore, the phases in the Voss model are only considered completed after successful testing. Reviews must therefore be integrated into the process model to be developed. A further feature of the Chen & Small and Small & Yasin models are dependencies between individual process steps. Due to these properties, the waterfall model with recesses will be used as the basic structure in the following. The model is characterized by a clear structure and subsequent steps are only carried out after successful verification. In addition, dependencies or feedback can be expressed by the regressions.

Planning Phase

<u>Strategical Planning</u>

The first step of the process begins with the company realizing that the current manufacturing process is no longer sufficient. On the one hand, this insight can result from a market pull in which the needs of the customer or the market have changed (Feldmann et al. 2019, Schallmo 2018). On the other hand, the investment in DM can arise as a technology push and thus for the proactive development of production capacities, as described in Mellor's approach.

Figure 7: Planning Phase

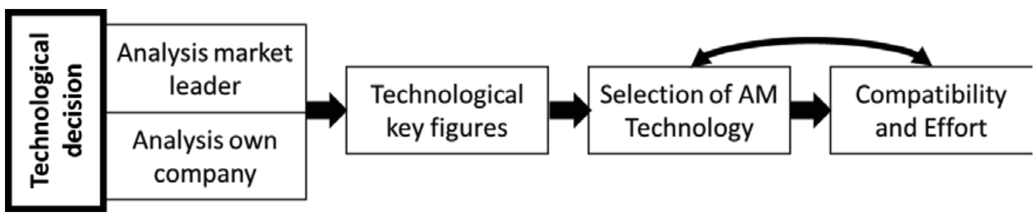


In the second step, the business objectives and challenges are identified.
Within the literature research, it becomes clear that business model development must be included in the framework. On the one hand, it becomes clear that a business model must be selected for the implementation of additive manufacturing processes for the use as DM. On the other hand, the approach of Lutter-Günther et al. also points to this activity as the first step to be carried out (Lutter-Günther et al. 2015a). The development of a business model basically offers the company the possibility to operationalize strategic goals.
Within the development of the model at least one of the following points should apply to the product: Small quantities, high degree of individualization desired, production on demand, high complexity of the component, integration of functions, lightweight construction (Fischer and Rommel 2018).
In principle, the strategic considerations must also determine whether collaborations are to be entered into and if challenges can be overwhelmed by these collaborations. In turn, the decision on this depends on the degree of technological maturity. First movers and early adopters, for example, have high initial costs, which are supported by collaborations. On the other hand, there is the protection of intellectual property. The consideration of partners for a collaboration is basically also a component of the development of the business model (Fueglistaller et al. 2016).
A further partial step of the strategic considerations is the planning of a manufacturing strategy. This strategy is divided into three elements: The manufacturing task, the production structure and the production process. For the manufacturing task, the type and quantity of the products to be produced, the technical specifications and market requirements are defined (Zahn 1988). When selecting a suitable manufacturing strategy for AM, the product is particularly the focus of consideration (Fischer and Rommel 2018). For the second element, the production structure, a differentiation must be made between the basic structure and the infrastructure. For the basic structure, capacity changes, locations and the design of the locations with production facilities are determined. The infrastructure in turn refers to information and communication systems, planning and control systems, organizational processes and personnel skills. The production process determines the vertical integration and handling of logistical processes (Zahn 1988). In principle, the four competitive factors cost, quality, flexibility and reliability/delivery reliability must be considered for a corresponding manufacturing strategy (Darbanhosseiniamirkhiz and Wan Ismail 2012, Saberi et al. 2010).
Subsequently, it is necessary to link the marketing strategy with the manufacturing strategy (Mellor et al. 2014). Focusing on additive manufacturing of products, it may be necessary to convince customers of the quality of the manufactured components (Deradjat and Minshall 2017).

A sub-step deals with the development of measurable variables or key figures, this is important to be able to determine the success of the implementation afterwards. Possible key figures can be found in the Framework of Small & Yasin (Small and Yasin 1997).
The performance review at the end of phase is particularly relevant. On the one hand, it is important to evaluate whether the DM has advantages over other manufacturing technologies. On the other hand, it must be checked whether the strategies are in line with the business objectives. If both questions are answered in the affirmative, the process model will continue to be run through. Otherwise, the implementation case under consideration is rejected.

Technological decision
Once the strategic considerations have been completed, an AM technology will be selected (cf. Figure 8).

Figure 8: Technological decision



First, the technological, organizational and operational profile of the market leaders and their own company are analyzed. The findings from the profile analyses are then brought together and, in the case of the proactive approach, supplemented by profile analyses in related sectors.

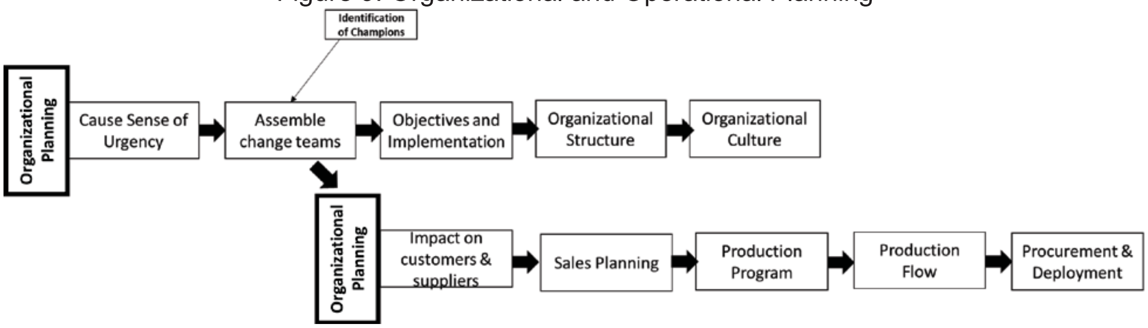
The findings can be used to evaluate the situations in which certain AM technologies can be used in the company itself. The next sub-step is the development of technical variables for the use of AM in the developed business case. The following variables can be used to select an AM technology: Component volume, material, component geometry, necessary quality and accuracy, production speed, costs, maintenance effort, production volume, the rate of introduction of new products, the software and possible software restrictions. (Besenfelder et al. 2019, Deradjat and Minshall 2017, Lutter-Günther et al. 2015b, Mellor et al. 2014)

In the last step, the AM technology is checked for compatibility with the existing production processes. In the special case of AM, the process chain is checked and evaluated to determine which processes are relevant before and after actual construction. This makes it possible to analyze which processes and competencies are available in the company or must be developed (Mellor et al. 2014). If processes and competencies have to be developed, the corresponding effort has to be determined. If the AM technology is not sufficiently compatible with the existing production processes, an accordingly higher expenditure for the integration must be considered (Deradjat and Minshall 2017).
As a result, more resources should be planned or collaborations should be considered. Alternatively, it is possible to select a different technology, as shown by the feedback loop in the figure. At this point, the analysis is less concrete, as concrete organizational and operational planning takes place in the following step. To successfully complete this step, an AM technology must be selected.

Organizational and Operational Planning

Organizational planning and operational planning are fundamentally highly interdependent (Sun and Riis 1994). In order to determine a structured procedure for the respective planning, however, the information in the studies on the implementation of AMTs and DMs is deficient. For this reason, research on operational planning as part of corporate planning, which serves to implement a previously defined strategy is used. (Welge and Al-Laham 1992)

Figure 9: Organizational and Operational Planning



First, organizational planning is described in more detail below. This begins before operative planning (cf.

Figure 9), since teams for cross-departmental planning, which are necessary for operative planning, are first determined in organizational planning.

The first sub-step in organizational planning is the creation of a sense of urgency. To this end, a plan is developed to convince the employees of the need for change, to achieve their active participation and to sharpen their awareness of opportunities and risks. (Rischar 2005, Steiger and Hug 2013)

The second sub-step serves to set up a committed, competent, trustworthy change management team willing to change (Rischar 2005, Steiger and Hug 2013). Implementation projects are particularly successful if "champions" are defined at this point who, as individuals, drive implementation forward to a particularly high degree.

In principle, employees from all affected company divisions must also be involved in the composition of the management team (Saberi et al. 2010). At the end of this sub-step, a team has also been appointed for operational planning, which will now be executed in parallel to the organizational planning

In the next step of organizational planning, top management and the management team derive a vision and goals for the organization depending on the strategic considerations previously made and the selected AM technology. The organizational success factors are processed in parallel in order to create corresponding plans. The organizational structure, as a success factor, must agree with the strategy. (Welge and Al-Laham 1992)

Furthermore, in the third sub-step, the organizational culture is revised. In preparation, the project structure is defined, resources are analyzed and decisions are made on external support. The actual culture is then recorded, whereby environmental factors and strengths and weaknesses of the organizational culture can be analyzed. Subsequently, a target culture is designed. (Homma and Bauschke 2015, Welge and Al-Laham 1992)

Less complex structures with the highest possible decentralization are particularly advantageous for the successful implementation of DM (Mellor et al. 2014).

A further element in the step of organizational culture is personnel. Basically, it is important to employ production staff with a wide range of qualifications and to plan training courses for project participants (Welge and Al-Laham 1992).
Especially for this element, there are strong links with operative planning, in which the planning of the technical components indicates the respective personnel requirements. First the qualitative and quantitative determination of the necessary personnel requirement is accomplished. Requirements profiles are created for this purpose. (Welge and Al-Laham 1992) If it is determined during the comparison of actual and target stock that qualification deficits exist, current employees must then be trained further or new employees with the appropriate knowledge must be hired. The planning for this takes place after the comparison.
The training is carried out before the actual implementation (Darbanhosseiniamirkhiz and Wan Ismail 2012). As a guideline, 25-40% of the project budget should be invested in appropriate continuing training measures (Saberi et al. 2010, Zhao and Co 1997). The training concept causes higher costs, but in some cases enables a faster gain of knowledge. On the one hand, knowledge can be created for larger groups of employees. On the other hand, special knowledge can be imparted. New employments as third possible concept make the fastest knowledge gain possible for the enterprise. This possibility is however most expensive and can lead to a rejecting attitude of the other coworkers. If only limited financial resources are available and the technology has a low degree of maturity, cooperation with machine vendors, material suppliers or research institutions is an option in order to reduce costs.

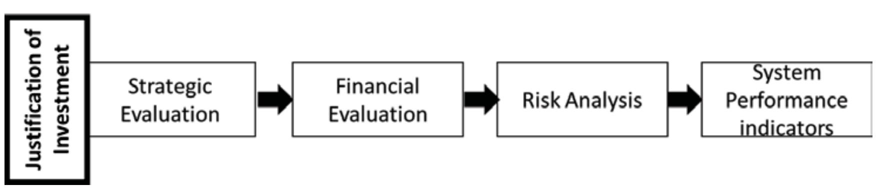
Operational planning transforms the specifications of the strategic planning level into area-related or department-related operational action programs. The responsibility for the operational planning lies in principle with the range and department managers. Besides, a high expenditure must be operated for a successful implementation, observing the consideration of probable effects on the customers and suppliers (Hammer 2015).
Good relationships with customers and AM machine vendors and material suppliers are particularly important when implementing additive manufacturing processes (Darbanhosseiniamirkhiz and Wan Ismail 2012).
Depending on the respective business model, different supply chain configurations must be considered (Lutter-Günther et al. 2015a).
The second step in operative planning is sales planning. Market conditions and the companies own sales are analyzed in order to create a sales forecast (Hammer 2015).
The sales forecast is also part of the approach of Lutter-Günther et al. (Lutter-Günther et al. 2015a) and therefore relevant for the AM. The production capacity from the later sub-step "procurement and supply planning" and the personnel from organizational planning have an influence on sales planning.
The next substep is production program planning, in which the assortment and quantity of products are determined (Hammer 2015).
In the third step, the production flow is planned. The production procedures, lot size, sequence, machine occupancy and production dates must be specified. (Hammer 2015)
The following properties should be taken into account during process planning: Component orientation, maximization of component volume, layer concept, generation of support structures, process speed, laser energy, hatching strategy, temperature control and quality control. (Mellor et al. 2014) Particularly in the context of additive manufacturing processes, it is also necessary to determine the production location (Lutter-Günther et al. 2015a). While a centralized production approach is initially pursued in an early phase of introduction, production can be decentralized at a later point in time (Mellor et al. 2014). The degree of decentralisation also depends on the type of business model (Lutter-Günther et al. 2015a).

As in the approaches for implementing AM, the process chain is also considered in this procedure model for determining the production process. It analyses how the AM can be optimally integrated into the existing production system in order to exploit all the advantages of the technology provided in the business model. For the front-end area it is evaluated under consideration of the available resources, which processes can be accomplished by the company themselves (Mellor et al. 2014). At this point, it must be checked, which resources and competencies are available in the design department in order to include clamping surfaces, reference points and tool paths in the design department that are necessary for possible reworking. If additive structures are to be generated on semi-finished products, resources for material testing and measurement of components must be planned in. It is also necessary to consider software that enables a high degree of automation of the necessary processes. (Manogharan et al. 2015, Möhrle and Emmelmann 2016, Yang et al. 2017)
If sufficient expertise is not available, partnerships can be entered into for the creation of CAD models, for the generation of support structures or for necessary scanners and software (Deradjat and Minshall 2017, Mellor et al. 2014). For the AM machine, it must be checked whether adjustments of the machine parameters are necessary for the respective application. These result, for example, from potential shrinkage and surface roughness (Manogharan et al. 2015).
Similar to the front-end area, the post-processing must also evaluate which processing steps are to be carried out for the specific application.

The last substep is procurement and material staging planning, in which the optimum order quantity is determined. Different methods and models exist to support this planning, which must be selected depending on the respective application. In addition, resource and personnel planning are carried out at this point.
In principle it is possible that strategic projects in the context of the operational planning turn out as unfeasible, so that a feedback is necessary, in order to revise the strategic plan. (Hammer 2015)

<u>Justification of Investment</u>
As part of the justification of the investment, the last review of the investment takes place before the actual implementation of the plans. The justification consists of four sub-steps (cf. *Figure 10*)

Figure 10: Jiustification of Investment



For the strategic evaluation it is necessary to put competition priorities and evaluation criteria in order. The competition priorities result from the classification of the competition factors time, costs, flexibility and quality and depend on the business model. Criteria for the evaluation of the technology are suitable as evaluation criteria. A priority must now be determined for the competitive factors and evaluation criteria. For this purpose, the competition priorities are coordinated with the technology selection criteria and an evaluation is carried out. (Iakymenko et al. 2016)

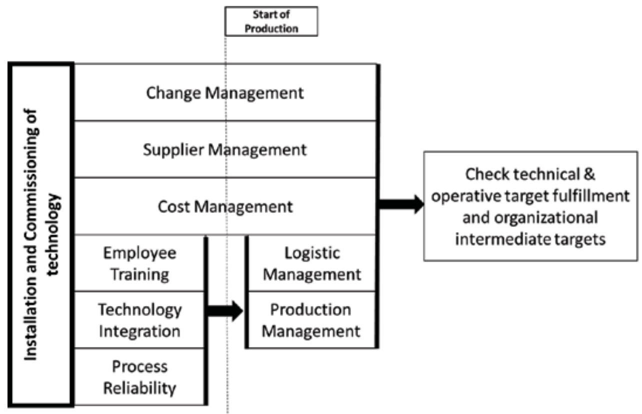
As part of this analysis, the company must commit itself to an AM machine. A feedback for the concretization of the organizational and operational plan, as in the procedure model for AMTs, is omitted, since with only one AM technology, specific planning has already been carried out.
This is followed by a financial evaluation of the integration of the AM technology. In this substep, the team members also define the evaluation requirement. (Iakymenko et al. 2016)
On the one hand, the costs for the technology are determined. Mellor uses in this context the following main factors: machine costs, material costs, personnel costs and the lifespan (Mellor et al. 2014). On the other hand, the organizational expenditure must additionally be calculated for a comprehensive overview of the costs of the integration of DM.
In the third step, a risk analysis is carried out. The decision on the method to be applied must also be made by the team members. Due to the high degree of integration of the DM, a probability and sensitivity analysis can be used. (Iakymenko et al. 2016)

If, after completing these sub-steps, it is determined that the selected AM technology does not yield a positive investment, the decision maker can jump back to the step of selecting the technology at this point to select another technology. However, if the reasons for a poor performance in this step are not due to AM technology, the investment is either discarded or rapid prototyping is introduced first. In case of a positive evaluation, the procedure can be continued.
The last sub-step is the further development of the system performance indicators that were already defined during the strategic considerations. However, the key figures mentioned in this step only allow an evaluation of the technical performance. In order to evaluate the system performance, additional organizational key figures are required that depend on the selected business model (Deradjat and Minshall 2017).

Measurement of performance
The last step of the planning phase is the evaluation of the current company performance on the basis of the previously developed key figures. This step is necessary in order to be able to track changes in company performance at a later point in time.

Installation and Commissioning of Technology
During the installation and commissioning phase, the organizational and operational plan is implemented and the progress is monitored. The existing implementation models for AMTs and the approaches for implementing DM, however, provide only little detail or no procedure for a structured installation and commissioning. Therefore, the procedure model in this paper is based on the AM start-up management model presented by Büsching & Koch, which is divided into two sections. (Büsching and Koch 2017)
Change management is located throughout start-up management and deals with organizational elements (cf.
Figure *11*).

Figure 11: Installation and Commissioning of Technology



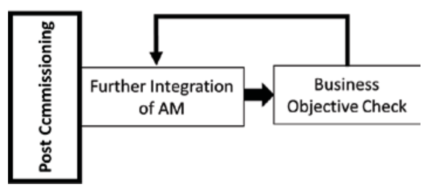
Supplier management, cost management and change management are sub-steps that will be continued in both sections, the phase before and the phase after the start of the actual production. Before the start of the production, change management aims to implement the goals defined in organizational planning for the organizational structure and culture and to adapt unfavorable processes and structures accordingly. Employees must be given room to manoeuvre. Intermediate goals should be celebrated as successes on the way to complete change in the sense of employee motivation. However, the overall goal must not be disregarded. (Schwarz 2019).
For the sub-step supplier management, cooperation with AM machine sellers and material suppliers must be achieved. The type of cooperation depends on how much effort the company has put into adapting the AM technology. The higher the effort for adaptation, the more the company must be involved. Also, for the cooperation with material suppliers, the less tested the material, the stronger the cooperation. Cost management has the task of monitoring the financial situation of the company, as high costs arise from employee training and investments, and only small revenues are generated from the sale of products at that time. The most important variables besides costs are time and quality. (Büsching and Koch 2017)
In the first section of process management, before the start of production, the sub-steps recruitment and/or further training of employees, technology integration and process stability are dealt with in parallel. In the case of employee training, the aspects determined during organizational planning are implemented for the personnel. For this purpose, either new employees are hired or an autodidactic concept or training concept is pursued for the selected employees.
Within the framework of technology integration, the necessary software and hardware are integrated (Chen and Small 1994).
The last partial step before the start of production is process reliability, in which the optimum settings for the AM machine are determined (Büsching and Koch 2017).
A higher degree of automation generally increases the process stability for further operation (Fischer and Rommel 2018).

In the section after the start of production, logistics and production management must take place. Logistics management organizes the flow of materials to and within the production facility. Standards for the use of additive manufacturing processes are established within the

framework of parallel production management in order to reduce complexity and start-up time. (Büsching and Koch 2017)
At the end of the installation and commissioning phase, the technology must work. In the second step of this phase, the technical and operational achievement of the objectives is therefore checked. The system performance indicators further developed when justifying the investment are suitable for this purpose. It is also important to achieve intermediate organizational goals. Here it is important that the employees have fully understood the technology.
Furthermore, progress must be made in the organizational culture and structure as well as in employee qualifications. If the technical and operational goals and the intermediate organizational goals have not been achieved, this phase has not been completed and the corresponding deficits must be improved.

Post-Commissioning
Post-commissioning is the final phase of the integration of additive manufacturing processes and begins with the start of series production. There is no information on this phase in the research on the implementation of DM.

Figure 12: Post-Commissioning



Only change management specifies that changes must be anchored in the last phase (Kostka 2016).
The aim of the post-commissioning phase is the complete development of the marketing and production interface, the further development of technical processes and the achievement of the expected business and marketing benefits.
In addition, organizational changes will be further developed (Sun and Riis 1994).
The phase basically consists of two steps: The further integration of DM and the review of whether the business benefits have been achieved. The steps are performed in a loop so that continuous improvements and the development of routines can be achieved. In theory this phase can last very long or forever (Voss 1988).
It should also be noted that strategic changes may occur over time, such as environmental changes (Sun and Riis 1994), which must be taken into account when integrating DM and adapting the organization. The phase is completed as soon as the desired business benefit has been achieved. If this is not done, at a certain point the company will need to consider whether to continue through the loop of the two steps or stop the implementation.

CONCLUSION AND FUTURE WORK

The procedure model now provides a concrete and clear procedure for the integration of additive manufacturing processes, especially DM, which is elementary for successful implementation. Furthermore, feedback is considered in the procedure model of this work in order to better reflect the real situation of the innovation process. The process model developed here also includes success controls on the respective phase closures and, if possible, specifies responsibilities and methods. Therefore, this paper contributes to the expansion of knowledge in the field of AM research. Another important point in which the process model developed generates an increase in knowledge is organizational and operative planning and implementation. Existing research on the integration of additive manufacturing processes and AMTs shows considerable deficits in the approach.

However, the research carried out also has limitations. Thus, the present work was developed purely theoretically and requires validation in practice. Here it must be specifically examined whether the phases and steps can be separated in each case as clearly as was assumed. Basically, the sharp separation simplifies the success controls. In reality however, a clear separation is difficult to achieve. A further limitation of the results of this work effects from the incomplete specification of responsibilities and methods.

These limitations in turn lead to research areas for future work. One area is the already mentioned validation of the procedure model in practice. The technology of additive manufacturing can be introduced in companies with different product structures with the help of the model, developed in this paper. Based on the results, the structure and the granularity of the model could be adapted and evaluated for its practical suitability. In practical application it would also be interesting to observe what influence a rapid prototyping history has on the integration of the DM and what conclusions can be drawn for a process model, since only a few details can be found in the literature.

Furthermore, there are new technical developments in software and hardware that can considerably facilitate integration. These could simplify the processes in the organizational and operative planning and implementation and make an adjustment of the procedure model necessary.

In addition, the business models can also change, since the profitability of the DM will also be ensured in large series production in the future through faster and hybrid manufacturing processes.

But it is above all the necessary integrated integration of AM that is currently deterring many companies, even with promising business models. So that structured procedure models have to be developed for different business models, for different company sizes and for different technology breakthroughs of companies.

The work on this paper was supported by grants from the Federal State of North Rhine-Westphalia using funds from the European Regional Development Fund (EFRE) 2014-2020, "Investments in Growth and Employment"

ABSTRACT

Through increasing digitization, classic Product Service Systems (PSS) are further developed into smart PSS. An early business model perspective is an important success factor of the development of smart PSS. Therefore, in this paper a procedure model for the lean design of business models for smart PSS is presented.

KEYWORDS: Lean Startup, Business Model Development, Smart Product Service Systems

BUSINESS MODEL DEVELOPMENT AS A KEY SUCCESS FACTOR FOR SMART PRODUCT SERVICE SYSTEMS

Increasing digitalization and the widespread availability of innovative technologies are leading to both product and service innovations. The development and use of new products and services for mastering complex processes and securing competitive advantages are essential, especially for industrial companies, which are characterized in many processes by a **combination of human competencies, skills and technologies** (cf. Gorldt et al. 2017, p. 355). Existing benefits in kind (products) are often combined with services to create **Product Service Systems (PSS)**. Through an additional combination with intelligent service modules, classic PSS are further developed into **smart PSS** (cf. Steven 2019, p. 190).

Due to the importance of smart PSS both for the competitiveness of companies and for the design of a future digital and integrative working environment, its development is being promoted within the framework of research programs. The **research project "Innovation Laboratory Hybrid Services in Logistics"** is a lighthouse project that focuses on a **human-centered design** of the future working environment, taking into account the dimensions of people, technology and organization. For such a **"Social Networked Industry"** it is necessary to enable new forms of cooperation and interaction between people and cyber physical systems (vertical networking) (cf. ten Hompel et al. 2017a, p. 3). In order to support and enable these **human-machine interfaces**, the aim of the innovation laboratory is to advance the development of smart PSS for production and logistics and to strengthen acceptance and, associated with this, the industrial introduction of these new technical solutions (cf. ten Hompel et al. 2017b, p. 1 f.).

The investment in appropriate resources for the development and implementation of smart PSS can only be carried out sensibly if, on the one hand, there is a market for corresponding solutions and, on the other hand, a perceptible (customer) benefit exists and can be communicated. Accordingly, an early **business model perspective** is an important success factor and an integral part of the development of smart PSS. For this purpose, a **procedure model for the design of business models** will be developed within the framework of the innovation laboratory in order to provide the smart PSS gained with timely business models. The use of the developed process model is illustrated in the context of an application example from **maintenance**.

SMART PRODUCT SERVICE SYSTEMS

First, the basics of PSS and smart PSS are explained. Following a definition, a thematic classification of smart PSS in the context of the research project "Innovation Laboratory Hybrid Services in Logistics" will follow, as well as an explanation of their significance for both a social networked industry and for the business-to-business application area.

Basics of Smart Product Service Systems

The term **Product Service Systems (PSS)**, also referred to as hybrid service packages or solutions (cf. Michalik et al. 2018a, p.310), was coined in particular in the context of the efforts of mechanical and plant engineering companies to differentiate themselves from increasing international competition. For this purpose, in addition to offering benefits in kind (production plants), greater emphasis is being placed on additional services (e.g. plant maintenance) (cf. Meier/Uhlmann 2012, p. 1 f; Steven 2016, p. 200).

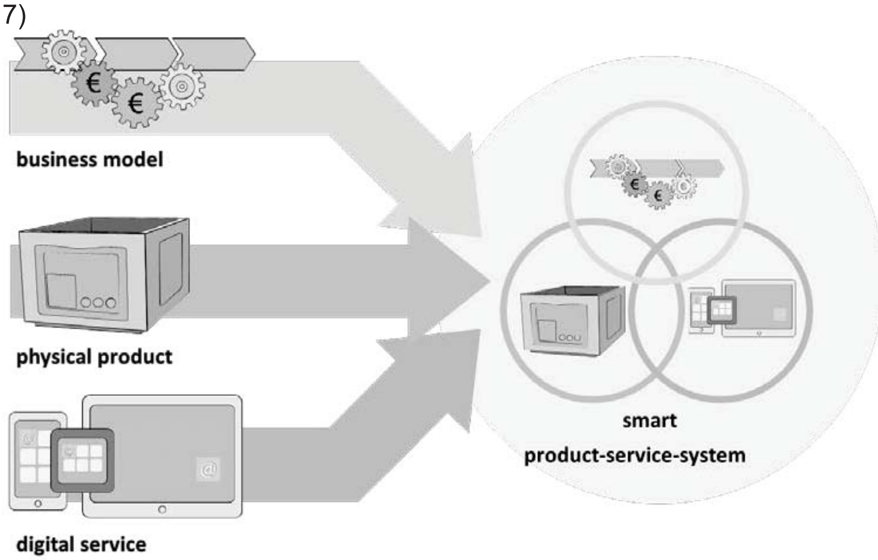
PSS is the term used to describe holistic and individual, customer-oriented problem solutions which are characterized above all by **systematic and integrated** planning, development and provision of the interlinked **material and service components** (cf. Meier et al. 2005, p. 529; Meier/Uhlmann 2012; p. 1 f; Grandjean et al. 2017, p. 18). This transformation from a pure producer of goods and services to a provider of customer-specific combinations of goods and services is also known as **servitization** and is not limited to mechanical engineering and plant construction, but can also be observed in other sectors (cf. Steven 2019, p. 133; Wiesner et al. 2014, p. 287).

Although many companies offer additional services, the competitiveness of purely product-oriented solutions seems to be no longer guaranteed in the digital age (cf. Chowdhury et al. 2018, p. 26). **Digitization** has a major influence on the provision of services and thus on the customer-specific benefit promise of PSS (cf. Grandjean et al. 2017, p. 8; Bruhn/Hadwich 2016, p. 11). In order to remain competitive, companies must therefore integrate digital technologies into the development and deployment of PSS. These PSS equipped with digital technologies are also referred to as **smart PSS** (cf. Grandjean et al. 2017, p. 8; Valencia et al. 2015, p. 11 f; Abramovici, 2018, p. 4). Smart PSS are essentially characterized by a high degree of (partial) autonomy, networking capability, and personalization capability as well as user friendliness and user centricity. Further characteristics are dynamic reconfigurability throughout the product life cycle, real-time reactivity to environmental changes and context sensitivity (cf. Abramovici et al. 2016, p. 18).

The Internet of Things and Services is regarded as an important technological basis for smart PSS. On the basis of the Internet of Things, **cyber-physical systems (CPS)** are used, which lead to the networking of the physical and the digital world through sensors and actuators (cf. Kagerman et al. 2013, p. 84; Abramovici 2018, p. 4). The exponentially increasing connectivity already enabled networking of 8.4 billion devices worldwide in 2017. The turnover with such devices and software services offered via them was estimated at almost two trillion USD. In 2020, the number of networked devices is expected to rise to 20.4 billion (see Gartner 2017). This high degree of networking represents an excellent **application prerequisite for smart PSS**, so that development and deployment activities must be intensified. The BMBF-funded project "Innovation Laboratory Hybrid Services in Logistics" focuses its activities in particular on the application-oriented development of smart PSS for production and logistics.

In order to develop smart PSS in a customer-oriented manner, the requirements for a solution must be derived from the respective customer needs (cf. Gorldt et al. 2017, p. 366). In addition to the technical requirements, this also requires an analysis and, if necessary, **adaptation of established or the development of completely new business models**. The use of CPS thus enables a PSS to provide new disruptive (digital) services (so-called smart services) and also requires the adaptation of existing and/or the development of new business models. Overall, **smart PSS** are thus formed by the interaction of **digital services** through the use of innovative hardware and software [in this context, hardware includes smart devices, cloud computing and augmented reality. Software includes service-oriented architectures, semantic and big data technologies (see Abramovici 2018, p. 3)], **physical products** and a **business model** tailored to them (cf. Figure 1).

Figure 1: Components of Smart Product Service Systems (based on ten Hompel et al. 2017b, p. 7)



Importance of Smart Product Service Systems

<u>Importance of smart PSS for a Social Networked Industry</u>
Interaction and communication between man and machine already play an important role in today's world of work, and this will increase significantly in the future (cf. ten Hompel et al. 2017b, p. 1). Therefore, it is of high relevance to develop and test technological solutions and to include them in the future digitalized world of work. This so-called **Social Networked Industry**

describes industrially oriented forms of social networks that enable a new kind of cooperation between people and cyber physical systems (cf. ten Hompel et al. 2017a, p. 3).

An **integrated view of CPS and PSS** is becoming more and more important for the design of this social networked industry and future working environments. The use of CPS enables an improvement of the human-machine interface and the combination of human performance, physical objects and virtual services provides for the emergence of new smart PSS. Autonomously interacting CPS ensure the functioning connectivity between humans and technology (cf. Drossel et al. 2018, p.199 f.), so that the **smart PSS** can come into contact with its environment and exchange information (cf. Steven 2019, p.191). The use of smart PSS thus enables the realization of the vision of **socially compatible human-machine communication** and interaction in the context of a social networked industry.

The **"Innovation Laboratory Hybrid Services in Logistics"** is currently the largest application-oriented research project for the investigation and design of an innovative human-technology interaction. This is accompanied by the development and prototypical use of smart PSS in production and logistics (cf. ten Hompel et al. 2017b, p. 4). In order to also do justice to financial and economic aspects in the context of application orientation, the smart PSS gained will be provided with timely **business models**.

<u>Importance of smart PSS in the B2B Sector</u>
After smart PSS (such as the iPod as a benefit in kind and iTunes as an associated digital service) have already been offered on the business-to-consumer (B2C) market for some time, smart solutions are also emerging in the **business-to-business (B2B) sector** that are oriented towards industrial users and their much more complex areas of application.

Increasing globalization and **highly competitive markets** in the field of high-quality machines and plants as well as **more individual customer requirements** require a differentiation beyond previous efforts in the field of servitization. The digital services offered complement the material product and thus represent added value both for the company (USP) and for its customers (value proposition) (cf. Steven 2019, pp. 131, 170f.).

In addition to maintaining a competitive position and opening up new markets, **customer loyalty** plays a key role in offering smart PSS in the B2B sector. By offering digital product-related services during the usage phase, the customer relationship can be strengthened and additional, continuous revenues generated.

The offer of such digital services requires an **adaptation or reorientation of the classic business models**, taking into account the individual benefit promise generated by the smart PSS.

Smart PSS therefore have a high significance both for the future vision of a social networked industry and for the B2B sector and will be an integral part of a digital and networked economy, or in some cases already are. This is accompanied by the need to develop new mechanisms and approaches for the way in which value can be created for the actors involved through the use of smart PSS (cf. Boßlau et al. 2017, p. 299f.). Based on this need, a **lean process model for the generation of business model approaches for smart PSS** will be developed in the following. The application will be initiated on the basis of a showcase from the innovation laboratory.

RESEARCH FRAMEWORK

The research methodology follows the principles of Design Science Research (DSR) utilizing a maintenance showcase stemming from the Innovation Laboratory. DSR is a proven methodology for the structured design of artifacts in information systems research. The authors utilize the Design Science Research Methodology, as proposed by Peffers et al., which provides the following steps**: Identify Problem, Define Objectives, Design and Build, Demonstration, Evaluation, and Communication** (Peffers et al. 2007, p. 45-77). Firstly, the authors gathered theoretical and practical insight from literature and experts of the innovation laboratory. Thus, they derive requirements for the targeted solution. For this, the authors chose to conduct multiple workshops with the responsible experts of the different showcases of the innovation laboratory. Workshops are an appropriate measure for collecting data in a domain-specific organizational context (Orngreen and Levinsen 2017, p. 70-81). The requirement is to develop business models in an early phase based on smart PSS. Secondly, the authors mark out the scope of this research, which is to develop a lean approach for sketching out business models for the showcase at hand. Thirdly, the authors present their findings concerning a lean development design of business models for smart PSS. Fourth, the authors present their procedure model for the lean business model design approach and further evaluate it based on a showcase in the field of maintenance.

DEVELOPMENT OF BUSINESS MODELS FOR SMART PRODUCT SERVICE SYSTEMS

It is necessary to integratively adapt, or renew business models in order to develop innovative, smart PSS. In addition to a definition and the dimensions of business models, their significance, especially in the context of digitization, will be discussed below. The procedure model used in the innovation laboratory to develop business models for smart PSS will then be presented.

Definition of Business Model

The concept of the business model was first discussed in the 1950s (cf. Osterwalder et al. 2005, p. 4) and was transferred to the business context with the 'New Economy' (cf. for this and in the following Becker et al. 2012, p. 8 ff.).

Basically, two types of business model can be distinguished: universal and partial business models. While **universal models** are generic business models that can be transferred to different companies and industries, **partial models** describe industry-specific business models. The **definition** of Osterwalder and Pigneur conveys an intuitive and **universal basic understanding** of a business model. They define a business model as "[...] the basic principle according to which an organization creates, imparts and captures value". (Osterwalder/Pigneur 2011, p. 18, for a definition overview see Schallmo 2014, p. 2-6).

Business models represent in an aggregated, conceptual way a considered operational unit or sales performance (cf. Grandjean et al. 2017, p. 70f.). In this context, necessary **value creation mechanisms** such as organizational, logistical and production-related processes for providing this sales performance are presented in simplified form (cf. Steven 2019, p. 187). The focus of business model development is on **customer benefit** as a unique service promise to the customer. The business model also takes into account the costs associated with the provision of services and the expected revenues (see Stähler 2001, p. 41ff; Wirtz 2010, p. 8 ff).

Importance of Business Model Development in the Context of Smart Product Service Systems

The business model is currently experiencing another major upswing in the context of ongoing digitization and Industry 4.0. The offer of digital PSS changes business relationships between companies, raises a new set of strategic choices about how value is created and captured, how companies work with traditional and new partners and how they secure their competitive advantage (cf. Porter/Heppelmann 2014, pp. 67). Hence, the development of smart PSS equally requires the development of new, valuable **business models** in order to tap new business potentials (cf. Gausemeier/Wieseke 2017, p. 23). **Business model development** offers a structured approach for this, fulfilling the following **functions** (cf. Grandjean et al. 2017, p. 70f, Wirtz 2010, p. 18; Osterwalder/Pigneur 2011, p. 19):

- One of the most important functions of a business model is **to better understand** one's own business and **customer benefits**. This aspect is essential for the company's success, so that it can be useful to think about a practicable business model not only after the completion of a product, but already during the development process.
- A further function is the **improvement of the current business and the development of new business segments**. This enables a differentiation from the competition and the development of new customer groups.
- Furthermore, the modelling of the value creation mechanisms of a company or business unit within the framework of business model analysis provides a basis for the **systematic analysis of the decision-making situation**.
- Furthermore, the **complexity is reduced** by the aggregated representation of the value creation processes in a business model.
- In addition, a business model can be used as a **strategic instrument** for the systematic development and design of an operational unit, e.g. in the context of the development of a sales performance.

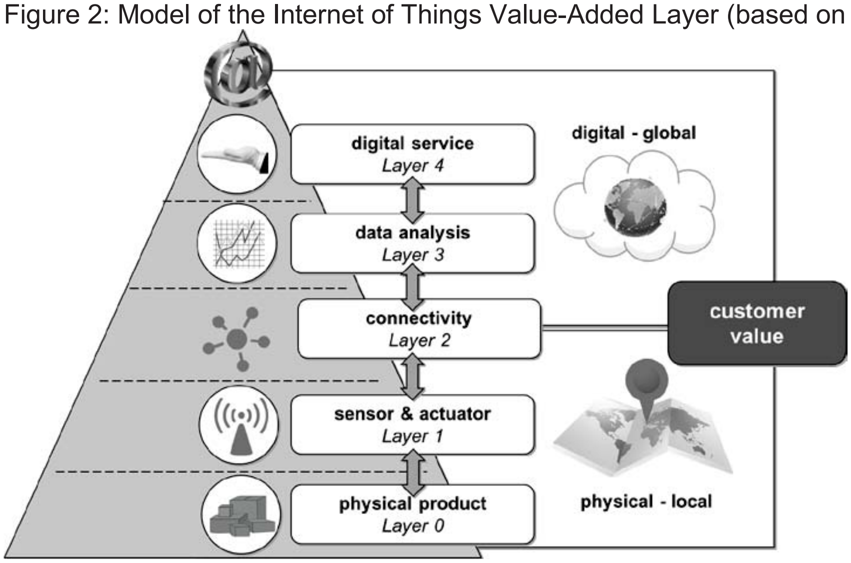
Digitalization in particular influences existing business models and leads to the development of new business model patterns (cf. Buhler/Maas 2017, p. 47 ff.). At present, however, it poses a challenge for companies to keep an overview of the opportunities and risks associated with digitization and industry 4.0 (cf. Geisberger/Broy 2012, p. 175) and to derive new, innovative business models (cf. Gausemeier/Klocke 2016, p. 14). According to a study by McKinsey, 80% of all companies **expect industry 4.0** and related technological innovations **to have an impact on their own business model**. A structured further development of business models rarely takes place in everyday business life, despite their high relevance for corporate success (cf. McKinsey 2015, p. 8; Gausemeier/Wieseke 2017, p. 7). The reason for the **failure** of many companies is therefore often a **failure to adapt the business model** to changing conditions and a lack of focus on the needs of customers. [A well-known example of this is Kodak, which has lost its market share for photography products to its competitor Fujifilm due to a lack of adaptation of its own business model to market changes (cf. Fujifilm; Schultz 2012).]

In order to meet these challenges, it is often necessary to take a holistic perspective from product and business model development, which is often lacking. In addition to the development of smart PSS, within the framework of the **Innovation Laboratory**, the possible exploitation of smart PSS through an initial **systematic and structured development of business model approaches** is also examined. Business model development is of particular importance because it is not sufficient to develop a product: For product success, it is also of great importance to examine marketability and **customer benefit**. Ideally, this test should be carried out **continuously and parallel to the solution development** in order to identify possible weak points or product characteristics that need to be added during the development process and to take them into account in the next development phases. In order to guarantee this integrative development and examination of the marketability, a **lean procedure model** is used in the context of the innovation laboratory, which already examines the fit between product characteristics and requirements of the target customers during the development process in close coordination cycles.

Thanks to very **successful business model developments**, companies have often succeeded in revolutionizing an entire industry **without a physical product** (cf. Gassmann, et al. 2013, p. 5; Gausemeier/Wieseke 2017, p. 24). Originally, physical products such as music CDs, books or video cassettes were replaced by digital products, which are always available on **platform markets** everywhere. However, the disruption potential of business model innovations is not limited to the B2C sector. In **B2B markets**, too, it can be assumed that business model innovations will be similarly revolutionary (cf. Gausemeier/Wieseke 2017, p. 24).

Integrated development of products, services and business models is also gaining in importance for **companies in mechanical and plant engineering**. They are increasingly moving along a product-service continuum, in which service-based value creation takes up an increasingly larger share of the revenue model. The benefit promise is generally based on a benefit in kind, a so-called "installed basis" (Braun 2013, p. 26), whereby the use of CPS in combination with intelligent, Internet-based services is expected to result in a steady decoupling of physical capital goods and thus increased scalability of smart PSS in the future (cf. Abramovici 2018, p. 4). The digitization of this installed base and the design of associated business opportunities have a decisive influence on the success of a company (cf. Henke/Hegmanns 2017, p. 339). Figure 2 shows the model of Bilgeri et al., which is used to generate **customer value** by **linking physical products with digital services (smart PSS)** (cf. Bilgeri et al. 2015, p. 14).

Figure 2: Model of the Internet of Things Value-Added Layer (based on Bilgeri et al. 2015, p. 14)



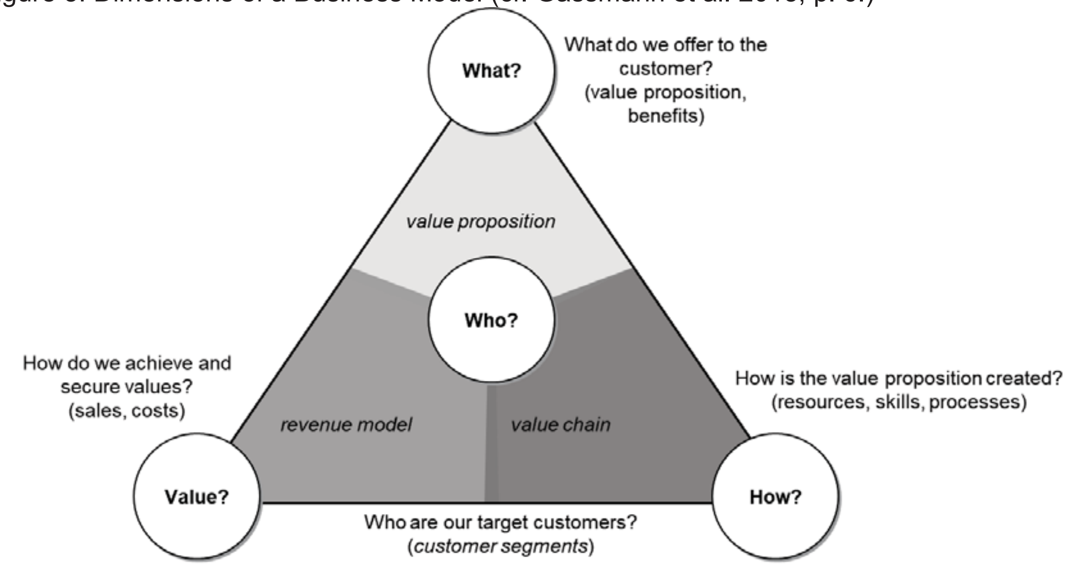
The so-called **model of the Internet of Things (IoT) value creation layer** represents the development from an analog, physical product to a digital service on the basis of successive layers. In the first step, a **purely physical product** is considered. In the second stage, sensors and actuators are added to this product so that data can be stored and shared. With the achievement of communication capability, the third IoT layer is reached and the product is on the boundary between the physical and digital worlds. Already at this point it is useful to initiate the **development of a business model** that goes beyond the mere sale of the physical product

and takes into account the data captured by the **digital component**. If the transmitted data is then transferred to an analysis unit or software, the fourth layer of the model is reached and the business model can be expanded and innovated (cf. Bilgeri et al. 2015, p. 13 ff.).
Current studies show, however, that companies that offer products in the context of industry 4.0 primarily market the **functional components** (cf. layers 0 and 1 in the model) of the product. For example, with intelligent, remote-controlled thermostats ("Smart Home"), the customer pays for the convenience of remotely controlling his heating system via app. At the same time, this results in large amounts of data that could be used in the course of further developing the business model. Other conceivable approaches for new business models include the sale of additional services or the customer's participation in cost savings (see Henke/Hegmanns 2017, p. 339).
The business model development within the framework of the innovation laboratory addresses these current challenges: In order to leverage the often untapped potential, an **early and continuous business model development** takes place here. On the one hand, this enables the early development of smart PSS product features to be evaluated and, on the other hand, potential marketing models to be identified, even beyond the pure sale of the non-cash component. The aim is to sharpen the service offering for the customer, identify customer segments and sales channels as well as the resources required. In addition, costs and potential revenue channels arising during the provision of services are to be identified.
Thus, the development of smart PSS takes a **holistic perspective consisting of physical product, digital service and business model** (see also Figure 1).

Dimensions of Business Model Development

A uniform **description pattern** is required for the analysis of existing business models and for the development of new ones (cf. Schallmo 2014, p. 21). Figure 3 illustrates the **four dimensions** of business model development that address key issues relating to the design of a business model. The four dimensions can be divided into internal and external dimensions. The **external dimensions** include the **customer segments** (**Who** are our target customers?) and the **benefit promise** (**What** do we offer our customers?). The **internal dimensions** address the **value-added processes** required to produce the service (**How** do we produce the service?) and the **earnings mechanisms** (**How** do we achieve and secure value?) (cf. Gassmann et al. 2013, p. 6; Schallmo 2014, p. 23).

Figure 3: Dimensions of a Business Model (cf. Gassmann et al. 2013, p. 6.)



These business model dimensions and associated key questions serve as **description patterns** for the analysis of existing and the design of new business models. The aim is to combine these dimensions in such a way that it is difficult for the competition to imitate a service that simultaneously represents a unique value proposition for the customer (cf. Schallmo, 2013, p. 23). These dimensions represent the fundamental frame of reference for business model development within the framework of the innovation laboratory.

If at least two of these four dimensions are subject to change, this is also referred to as **business model innovation** (cf. Gassmann et al. 2013, p. 6). In contrast to the pure further development of existing business models, a completely new composition and design of individual business model dimensions is aimed at, resulting in previously unavailable products and services (cf. Labbé/Mazet 2005, p. 897 f.; Lindgardth et al. 2009, p. 2; Mitchel/Coles 2003, p. 17).

Integration of the Lean Startup Approach into the Development of Business Models for smart PSS

The Internet of Things and smart PPS will not change business completely, as the rules of competition and competitive advantage remain the same. However companies need to understand these rules better than ever, as smart PSS open a new era of competition (cf. Porter/Heppelmann 2014, pp. 67-68). Due to this new competition and the importance of continuous review and (further) development of business activities, the design of business models must be an **integral part** of the product development of smart PSS. In the following, the **procedure model** used in the innovation laboratory **for the business model development of smart PSS** is presented.

In recent years, the number of approaches to developing business models has increased (cf. Schallmo 2013, p. 47). However, many of the approaches are at such a level of abstraction that no connections between the individual elements of the business model are explained and consequently there is **no procedural model** for developing business models (cf. Schallmo, 2013, p. 48). Other approaches, including those by Buchere (2010), Chesbrough (2007) and

Giesen et al. (2007), provide a process model for the development of business models and are generally applicable, but focus on the **analysis of existing business models**. A further development or business model innovation, as often required with smart PSS, is not achieved. The approaches of Mitchel/Coles (2004), Teece (2010) and Wirtz (2010) concentrate both on the analysis of existing and the development of new business models and propose techniques for the design of business models (cf. Schallmo 2013, pp. 47-113). However, none of the approaches takes into account the integrative customer-oriented **development of products** and **services** as well as an associated **business model** from a **holistic perspective**. A comprehensive overview and description of existing approaches to business model development can be found in Schallmo (2013).

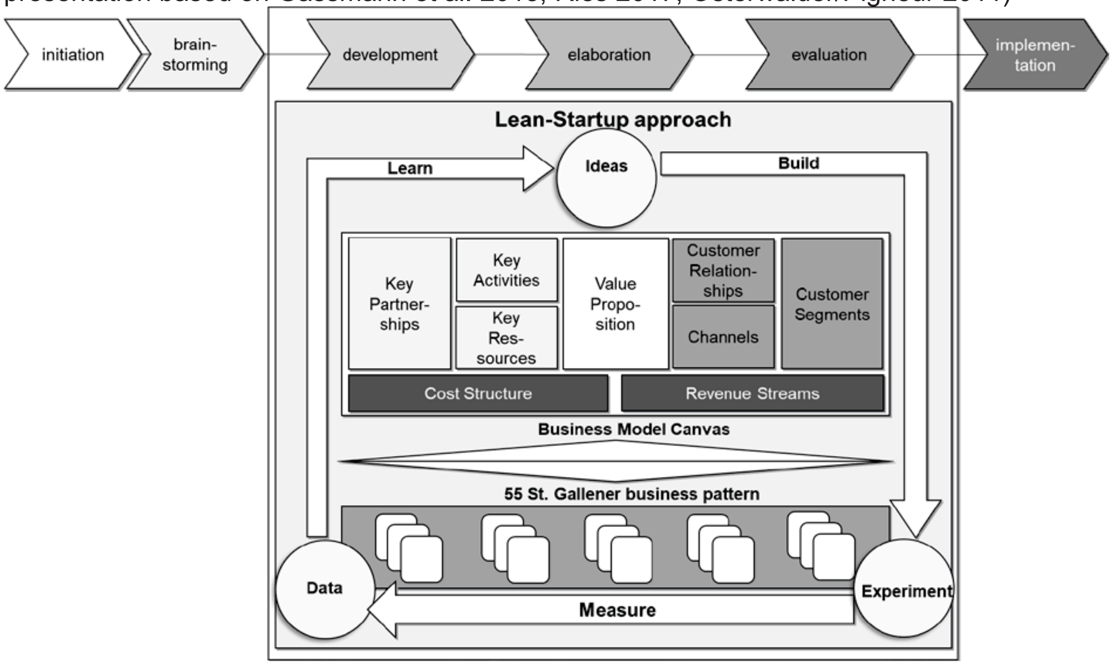
In addition to these classical approaches, the **lean approach**, originally a production philosophy to avoid waste, has recently been transferred to other areas, including business model development (cf. Ghezzi/Cavallo 2018, p. 7). Based on the general understanding of Lean, in the business model context this is understood as the attempt to streamline or even abolish all activities and processes that are not required by the **target customer**. This **customer orientation and centering** is increasingly becoming the focus of new lean approaches. In particular, the **lean startup approach** pursues high customer and market orientation in the development of products. The approach is characterized by short, iterative product development cycles and early marketing, so that customer feedback in the early development stage enables further learning and improvement of the product (cf. Ries 2017, p. 77 ff.).

This strong focus on customer needs is consistent with the understanding of **customer benefit** in business model development: both the lean startup approach and the business model dimensions (see Figure 3) focus on the value proposition to the customer (see Ghezzi/Cavallo 2018, p. 28).

Based on these parallels and first case studies, which classify an application of the approach in business model development as synergetic and promising (cf. Ghezzi/Cavallo 2018, p. 29), the **lean startup approach is applied** in the previous model for the development of business models. This enables a continuous **comparison between product development and customer benefit**. The comparison is achieved through a recurring loop of prototype construction, experimentation & measurement and continuous learning (**build, measure, learn principle**) (see Figure 4). The individual phases of the process model and the lean startup approach are explained below.

Gassmann et al.'s process model used here as a basis represents a proven construction methodology for business model development, which has been developed and applied over five years within the framework of action research and consulting projects with numerous internationally leading companies from a wide range of industries (cf. Gassmann et al. 2013, p. 15). The **six phases** of the model and the integration of the lean startup approach are shown in Figure 4 (cf. Gassmann et al. 2013, p. 16 ff.).

Figure 4: Procedure Model for the Business Model Development of smart PSS (own presentation based on Gassmann et al. 2013; Ries 2017, Osterwalder/Pigneur 2011)



The **initiation phase** lays the foundation for business model development and includes a holistic analysis of the current business model environment. In the first instance, different cause-effect relationships are uncovered, e.g. through the analysis of actors or possible influencing factors.

The second phase involves **finding ideas**. In this phase, business models that have already been successfully implemented are analyzed and supplemented with own ideas or adapted for a specific, individual application context.

Before the new business model idea can survive, it must be integrated into a holistic business model (see Figure 3: Who? - What? - How? - Value?). This is done integratively in the development, elaboration and evaluation phases. In the first instance, further **development and elaboration** of the generated business model idea will be carried out using different methods and workshop formats, before an **assessment** will be carried out in which consistency with the internal requirements as well as with the external corporate environment (influencing factors and actors) will be checked.

The business model development of the innovation laboratory is currently in these phases. The **lean start-up approach** of Eric Ries (cf. Ries 2017) is used to support and structure these phases. This approach can be used throughout the entire product development process, from **development** to **elaboration** and **implementation of the business model**. Individual prototypes in the form of so-called **Minimum Viable Products (MVP)** are used to test and evaluate hypotheses on customer requirements and business model approaches, and to take the findings gained directly into account in the next development stages.

An MVP is the first minimally functional iteration of a product that uncovers customer requirements with minimal effort and derives measures for future development work. MVPs are developed according to the **Build-Measure-Learn principle**, which focuses on fast testing, measuring and agile adaptation. In contrast to classical prototypes, MVPs focus on the validation of hypotheses regarding customer requirements (external), while classical prototypes are primarily used by the development team (internal) to carry out tests on product features (cf. Ries, 2017, p. 76 f.). As part of product development in the innovation laboratory, functionality and market potential are tested in the first **showcases** in the form of MVPs.

On the basis of the test results, there are **three options for action for the business model**: (i) **maintaining** the current business model if the hypotheses are correct; (ii) **adapting** the business model while maintaining the business model elements confirmed by the tests and adapting the others; (iii) **rejecting** the business idea. The process is repeated until all key hypotheses have been confirmed or validated by MVP testing, resulting in "product-market fitness" as the successful completion of the build measure learn loop. (cf. Ries 2017, p. 76 ff.; Ghezzi/Cavallo 2018, p. 7).

The **Business Model Canvas (BMC)** from Osterwalder/Pigneur is used for the structured development and documentation of the integratively developed business model approaches for the showcases. The BMC is a widely used and proven method in practice, which is also used for the development of business models for smart PSS due to its high application orientation and practical relevance (cf. Michalik et al. 2018a, p. 311). Figure 4 schematically shows the BMC at the center of the Build-Measure-Learn loop. The central positioning illustrates that the business model or individual business model dimensions must be reviewed after each MVP test cycle and maintained, adjusted or rejected depending on the test result.

The **BMC** focuses on a component-based view of a business model. **Nine partial models** are considered for the holistic description of business models (see Osterwalder/Pigneur 2011, p. 19). The central component is the **value proposition** to the customer in the middle of the BMC. The right-hand side of the BMC focuses on the **customer perspective**, examining the customer relationships, the sales and communication channels used and the customer groups (customer segments) to which the value proposition is to be submitted. A continuous comparison between the value offering and the target customer segment is important in order to ensure the best possible fit between customer needs and benefit promises. The left side looks at the **internal prerequisites** that must be created to generate the value proposition. It identifies key partnerships, activities and resources required to establish customer relationships, establish sales and communication channels and generate value. The lower part of the BMC shows the **cost structure and the revenue streams**. This includes the type and structure of the costs incurred in implementing the business model, as well as the revenues expected from the value proposition from the respective customer segments. Detailed information on the BMC can be found in Osterwalder/Pigneur 2011.

In addition to the BMC, the **St. Gallen Business Model Navigator** is used as part of the process model (see Figure 4). The basic idea of the Business Model Navigator is that a business model does not have to be completely redeveloped, but that by **recombining** and creatively adapting elements of **existing business models**, it can be transferred to other industries or branches of industry. Numerous studies and consulting projects have shown that 90% of all new business models are not really new, but are based on 55 existing patterns (cf. Gassmann et al. 2013, p. 17).

A **business model pattern** is a specific configuration of the four business model dimensions (see Figure 3) that has proven successful in different companies and industries. An analysis of existing business models shows that the innovation leap from one sector to another is relatively small, whereby it is not a question of pure imitation, but rather of a meaningful combination of business model patterns. Business model patterns thus help to integrate successful patterns into one's own business model. In the process model, these patterns serve as **reference patterns** that are used to generate ideas and sharpen one's own business idea. A detailed explanation of all 55 business model patterns can be found in Gassmann et al. 2013.

Once the development of the new business model has been completed, it is implemented in the sixth phase of the process model, the **implementation phase**. In this phase, a business model innovation should not be implemented in a roll-out on the market. Rather, prototypes must first be developed and tested in order to limit risk and thus create the opportunity for further learning and adaptation.

APPLICATION OF THE LEAN APPROACH MODEL FOR BUSINESS MODEL DEVELOPMENT FOR SMART PRODUCT SERVICE SYSTEMS

The application of the developed procedure model and the integrated methods Lean-Start-Up, BMC and St. Gallen business model pattern is exemplary for a maintenance showcase from the innovation laboratory. The subsequent validation of the process model is based on a comparison with a process model already used in practice. The results obtained are presented below.

Application of the Procedure Model within the Framework of the Innovation Laboratory

Germany is the world's leading exporter of machinery and equipment (see Wiechers 2018). In order to maintain this lead in the future, German industry must also develop into the leading **supplier of smart PSS in the field of maintenance**. The use of sensors in maintenance makes it possible to achieve greater transparency regarding the condition of the machines, to record their continuous maintenance requirements and to identify the triggers of malfunctions. Novel information and knowledge networks between operators, manufacturers and service providers are created, which contribute to increasing maintenance efficiency by exchanging knowledge.

The **maintenance showcase of the innovation laboratory** focuses on the integration of new technologies and the resulting development of smart PSS. The **objectives of the maintenance showcase** are to reduce downtime, shift from unplanned to planned downtime, and ultimately increase system availability with the help of remote services in the form of **smart PSS**.

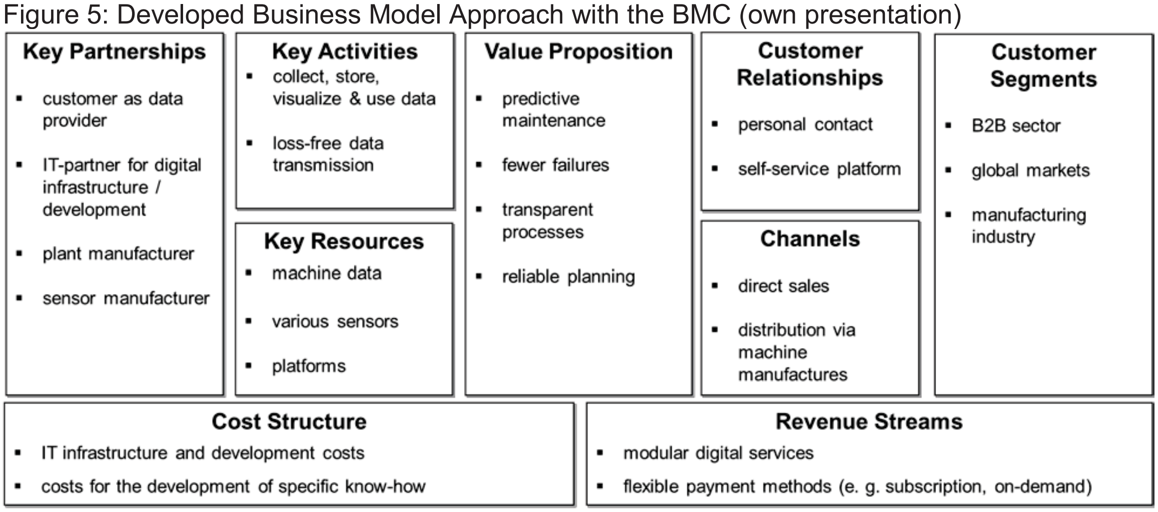
The following showcase is considered when **applying the Lean Procedure Model to business model development**: A fault message from an installed machine initiates the use case. The basis for the evaluation of the current state of the plant is a comprehensive sensor system. Based on the analysis of raw sensor data, a malfunction report is sent to the maintenance technician via a mobile terminal device, which at the same time supports fault identification by allowing fast and precise on-site analysis based on available information, e.g. from the social network. The repair and subsequent recommissioning of the affected machine is also supported and documented by mobile terminals, if necessary with the aid of augmented reality glasses.

On the **software side**, the analysis of sensor raw data with regard to potentially imminent machine faults is carried out on the basis of pattern recognition procedures. In terms of machine learning, algorithms must be trained in such a way that a deviation from the state of health is immediately detected. In addition to the software-based determination of fault messages, the augmented reality-based instructions for the maintenance engineer are based on an assistance system to be provided accordingly. As a **service**, the software used is designed, the data collected and processed and the necessary interfaces created. Smart PSS can thus make relevant information available in a context-sensitive manner, make a considerable contribution to the work design of sustainable maintenance and provide the hardware and software basis for **innovative business models**.

In order to develop the **business model for this maintenance showcase**, the smart PSS will be developed from the perspective of a **machine manufacturer** who wants to expand its target group, in particular by creating new value propositions, and differentiate itself on the market with the help of service-oriented approaches. To design an initial business model approach, the **BMC** is first used in the **development phase of the process model** (see Figure 4). The application of the BMC takes place within the framework of the innovation laboratory in the form of business model workshops. The aim of the workshops is to generate ideas and design the first business model, and at the same time to identify **deviations between value proposition and customer needs**. Identified gaps can be closed in the further product and service development process. In this phase, no implementable business model is generated. Rather, in the sense of **lean startup**, the current product development status is determined from the customer's perspective (*Does the product create benefits for the customer? Are product features still missing?*) and validated regarding internally required resources (*Am I in the position to produce and market it? Which resources and partners do I need for the next development steps?*).

The **value proposition** identified when applying the BMC is therefore based on the reduction of unplanned downtimes through knowledge of impending machine failures (predictive maintenance). This results in cost savings as well as the ability to plan necessary maintenance measures. The **key activities** essential for implementation are primarily based on data acquisition and analysis as well as subsequent reporting of potential anomalies. The basis for this is software and platform development on the one hand (**key resources**) and the establishment and maintenance of contacts to partners on the other, including the development of the necessary IT infrastructure and interfaces (**key partners**). A **predictive maintenance approach** can only be realized by ensuring an extensive and valid database. Figure 5 shows all elements of the business model approach developed in the workshop using the BMC.

Figure 5: Developed Business Model Approach with the BMC (own presentation)



In addition to the BMC, the **55 patterns of the St. Gallen Business Model Navigator are used as reference patterns**. Thus, following an initial design of the nine partial models of the BMC, intersections with existing business model patterns can be uncovered and suggestions for further design possibilities of the own business model can be generated. To this end, the 55 patterns were initially reduced by the workshop participants to five most appropriately rated patterns. The core of the business model, the value proposition and essential resources and skills were always taken into account in the selection process. The **patterns selected** during the workshops are (cf. Gass-mann et al. 2013, p. 72ff.): **Leverage customer data** with a focus on the acquisition and evaluation of machine data, **pay-per-use** as a billing model for each service used on the machine, **performance-based contracting**, which provides for a performance-based billing model (lower production and maintenance costs through predictive maintenance lead to improved machine performance), sales of additional services (predictive maintenance) as **add-on** to the machine, and the pattern of **self-service**, which is characterized by the transfer of maintenance work to the customer through the use of augmented reality-based instructions.

At its core, the business model of the use case thus represents a new combination of existing **business model patterns**. In particular, a multi-page use of customer data (**leverage customer data**) can be highlighted here. **Data as an economic good** can thus be of monetary value and can be prepared and used specifically for value-adding activities.

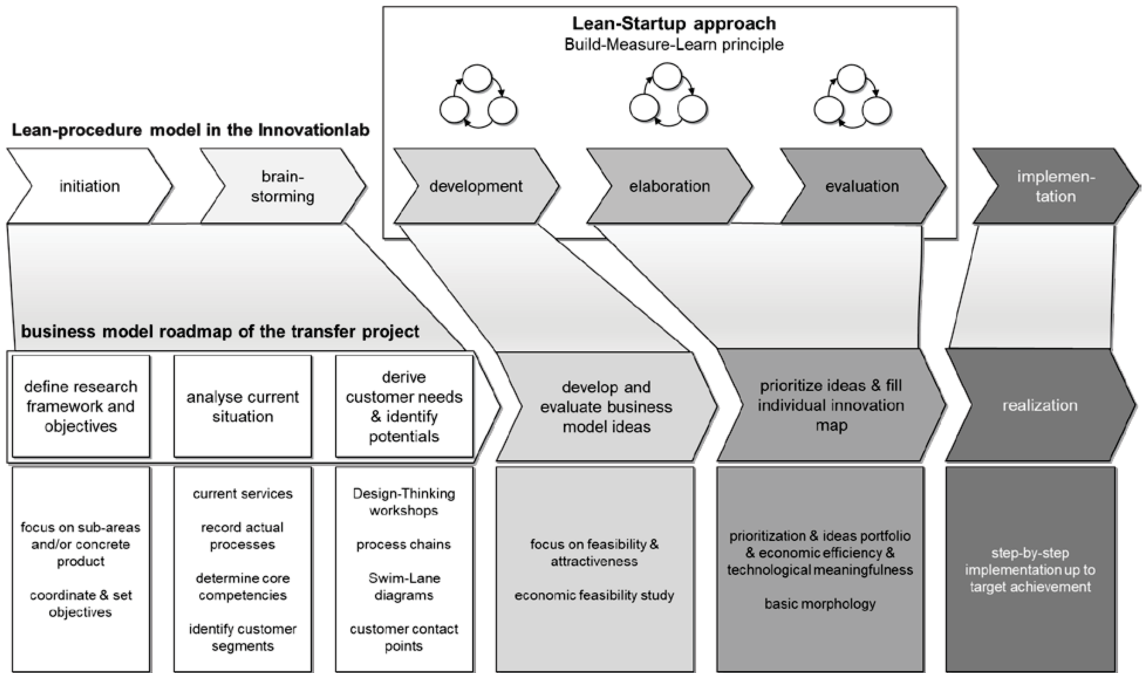
In contrast to other procedural models, the lean procedure model provides for a **continuous questioning and further development of the value proposition integratively to product development**. This is achieved on the one hand by a structured formulation of the business idea, here using the BMC, and on the other hand by comparison with existing business model patterns along the development, elaboration and evaluation phases. The lean startup approach ensures continuous development, measurement and learning through **build measure learn loops**, so that the focus is on market- and customer-oriented product development and business orientation.

Validation of the Procedure Model on the Basis of a Transfer Project

For the supplementary **validation of the lean procedure model**, this contribution uses the results of a transfer project, which was also carried out within the framework of the innovation laboratory in cooperation with a medium-sized plant manufacturer.

The goal of the six-month transfer project was the development of technologically validated, practical business model concepts for industrial services. The results led to a **roadmap** that supports the development of business models in **six phases** and proposes options for action and methods (cf. Michalik et al. 2018b, p. 325 ff.). The steps of this roadmap are comparable with the procedure model used in the innovation laboratory, based on Gassmann et al., in that both basically depict a six-phase process, which ranges from initiation to brainstorming and implementation (cf. Figure 6).

Figure 6: Lean approach compared to the roadmap of the transfer project



The roadmap was developed in cooperation with a medium-sized company from the machine and plant engineering sector. Different **methods** are used in the individual phases, for example creativity methods such as design thinking or business model sample cards, and workshop formats such as process workshops for the creation of swim lane diagrams. The **business model concepts** developed in the workshops were then evaluated and prioritized with regard to customer added value, available resources and competencies. The implementation as the last phase of the roadmap is still pending after the previous concrete elaboration and prototypical implementation. The business model roadmap developed in the transfer project thus offers a guideline for action, which in particular provides an approach for the first **design of a business model strategy for smart PSS**.

An essential **core result of the transfer project** is the realization that the current business model or the current development status of the business model must always be questioned in every phase of the roadmap. The options for maintaining, adapting or distorting the current business model (cf. section 3.4) are examined. The roadmap takes these into account and addresses them in design thinking workshops. However, there is a lack of an integrative perspective that integrates such a questioning into the product development process in a structured way. Without an integrative approach, there is a danger that information from product development will not flow into business model development or that business model development will only be initiated very late in the product development process or even after the development of an initial prototype. It can therefore be seen that iterative loops in the sense of the build measure learn principle are unavoidable for customer-oriented business model innovations.

The lean approach presented here focuses in particular on the creation of MVPs within the framework of the development and elaboration phases and contributes the iterative evaluation. A comparison of both approaches shows that Lean-Startup as well as the roadmap validated in practice use comparable phases with corresponding methods. A **fundamental applicability of the Lean Procedure Model** can thus be regarded as given. In particular, the use of the similarity principle, such as the 55 business model patterns of the St. Gallen Business Model Navigator, makes an important contribution in the early development phase.

Beyond the business model roadmap, the lean startup approach represents a meaningful further development at this point by focusing on **prototype implementation** and its constant comparison with customer needs. As soon as a business model concept has undergone the first development and evaluation steps, the actual market potential and feasibility are checked in the context of a prototype implementation in cooperation with a customer. In accordance with a lean open innovation principle, this enables companies to further develop business models in a structured and resource-efficient manner and to develop a sound basis for evaluation for potential market launches.

SUMMARY AND OUTLOOK

As part of the "Innovation Laboratory Hybrid Services in Logistics", various showcases are being developed to advance the design of smart PSS. The aim is to combine state-of-the-art hardware and software with innovative business models and thus generate **smart PSS for the B2B sector**. The process model presented in this article, which integrates the lean startup approach into business model development, makes a valuable contribution to this.

The results from the conducted business model workshops show the potential, which is opened by the meaningful combination of different methods to a lean procedure model. In this article, the approach is exemplified using a **showcase from maintenance** and validated by a comparison with a transfer project with a medium-sized company from the mechanical and plant engineering sector. When applying the approach in the form of workshops, the focus is on a continuous questioning of the value proposition through new value promises, a (new) combination of business model patterns as well as iterative build measure learn loops. Companies that use this approach not only to question their existing service portfolio, but also to identify and develop completely new service offerings and business models, are enabled to expand their target group and differentiate themselves on the market.

The "Innovation Laboratory Hybrid Services in Logistics" was extended for a further one and a half years until 2020 with the approval and support of the Federal Ministry of Education and Research. Within this framework, **further practical testing** of the lean procedure model is being promoted. Future research efforts will focus on the efficient **identification and evaluation** of (corporate) resources that are required for the market-ready development of business model ideas. On the other hand, **empirical studies** are aimed at that validate the effectiveness of the approach presented here and at the same time identify further research needs.

This publication was produced as part of the research project "Innovation Laboratory Hybrid Services in Logistics" in Dortmund, which is funded by the Federal Ministry of Education and Research (BMBF).

ABSTRACT

This study proposes a novel price fluctuation forecast model, Price Fluctuation Point Forecast Approach (PFPFA), to forecast the price fluctuation points and the degrees of price changes. PFPFA proposes four models predict the price fluctuation points and three models to predict the degrees of price changes. In consequence, for a single product, there would be twelve different forecast outcomes. PFPFA is applied on a real world case and compared with the Exponential Smoothing (ES). In the end, PFPFA predict acceptable result on the price fluctuation points and perform better on the degrees of price changes than ES.

KEYWORDS: Price Fluctuation Pattern, Non-uniform Time Series Data, Time Series Analysis, Short Product Life Cycle Product, Price Forecast

INTRODUCTION

For a manufacturer, the material procurement and product sales directly influence the cash flows. Buying material at a lower price and selling products at a higher price are the straightest way to obtain higher revenue. The life cycles of consumer products such as apparel, cosmetic and consumer electronics are getting shorter and shorter because of consumer preference shifts. The demands of these products usually resemble a diffusion process: rapid growth at the beginning and rapid decline at the end of a life cycle while stable in between (Li and Huh, 2012). If there is a way to predict the price fluctuation of material or products accurately, a company can maximize its profit by taking a right action at a right time. This study aims at modifying the existing price estimation models to develop new sourcing policies that can be used under the dynamic environment.

As the technology of producing a product getting mature, the cost of the product decreases, and the demand of the product may drop because a newer product with better functions may appear on the market. In order to eliminate the cost of obsolescence and attract more consumers, the prices of short life cycle products usually are highest when introduced to the market but are cascading down through the entire life cycle (Kurawarwala and Matsuo, 1996). Mostly, the time plot of prices falls in a series of cascades down towards the end of life cycle.

A company can benefit from forecast of price fluctuation either as roles of sellers or as roles of buyers. As a seller, it is crucial to decide when to cut the price and how large a discount to offer. The sensitivities of customers toward prices and demands are varying at different stages of a product's life cycle. Hence, it is crucial to charge different prices at different stages of a product's life cycle to maximize revenue (Li and Huh, 2012). In addition, providing a right discount at right time will increase customer satisfaction, avoid bargaining, and strengthen partnerships. Therefore, analyzing the price strategy from historical data can help managers to making right decisions about price cutting and discount offering for sellers.

On the other hand, as a buyer, it is very important to know the time epochs and the degrees of price fluctuations of a product in order to determine when is the best time to procure material and to review the performance of a supplier. When accumulated purchasing quantity of a material approaches a certain level, suppliers may offer price discount to boost up purchase while buyers can negotiate for discounts to reduce their purchase costs. Furthermore, when the number of products and materials increases and the patterns of price changes become complicated, it is essential to adopt data mining methods to automatically validate that material are purchased at reasonable prices and at the right times.

By analyzing the historical sales or purchase data, we can find the relationship between price change and sales/purchase quantity and build a forecast model to inspect the timing and degree to offer discount. In addition, if a supplier with relatively weak bargaining power fails to offer discounts when it should, buyers can and should initiate the process of negotiation with the supplier for a better price. Procurement at a lower price reduces the total cost, which leads to a higher profit, a better profit margin and a larger return-on-investment (ROI).

Previous researches have proposed many price forecast methods for electricity (Contreras et al., 2003), oil (Morana, 2001), gas (Buchanan et al., 2001) and stock (Baba and Kozaki, 1992). However, consumer products are very different from these commodity markets and stocks in terms of product life cycles and price fluctuation behaviors. Some products may change their prices only once or twice over their life cycles, while other change more times. Thus, time series analysis, a technology to discover the pattern from temporal data and to forecast the future, is a suitable tool to predict the price fluctuation points and the degrees of price changes (Esling and Agon, 2012). There are four components of a time series: the trend, the cyclical fluctuation, the seasonal fluctuation, and the irregular fluctuation (Bowerman and O'Connell, 1979). Based on the theory of product life cycle (Li and Huh, 2012), the demand of a product changes over time through its life cycle. Moreover, according to the law of demand, the price of a product should fluctuate to correspond with the demand for better profit. Therefore, in addition to those four components of a time series, demand variation must be considered when building the forecast model of price fluctuation.

To use demand quantity for price forecast, we need to understand the pattern of demand change through product life cycle. Although actual sales depend on both demand and supply, life cycles are widely used for modeling demand change (Polli and Cook, 1969). Product life cycle (PLC) theory is introduced to explain the different stages of a product from design to obsolescence. Researches showed that demand for most products follows a standard life cycle with five phases: introduction, growth, maturity, decline, and withdrawal (Polli and Cook, 1969).

Diffusion theory is an appropriate tool to model the PLC process (Qin and Nembhard, 2012) and are widely used for demand forecasting (Morrison, 1996). Diffusion Model assumes the demand quantity follows a non-linear logistics curve defined by three parameters: Long Run Saturation

Level, Inflection Point, and Delay Factor (Qin and Nembhard, 2012). If these three parameters are determined, Diffusion Model can be used to forecast the future demand. However, diffusion model represents only the demand of a product at growth and maturity stages and thus is inapplicable at introduction, decline and withdrawal stages. Every product has its own product life cycle curve and a company may have thousands of products. This study first classifies products into different groups whereas in group, the products have similar demand fluctuation behaviors. This study proposes to build a forecast model for each group rather than for each product.

To sum up, price fluctuation forecast is an urgent problem in many industries. Price fluctuation depends on the accumulation of sales/purchase volumes, which represents different stages of a product's life cycle. This study proposes a price fluctuation forecast model by adopting the time series analysis method based on the historic sales/purchase data and establish a classification model to automatically forecast the time and degree of price fluctuation when procuring material as buyers or offering price discount as sellers. The rest of this article is organized as follows: Section 2 describes the problem. In Section 3, we present our PFPFA to resolve the price fluctuation forecast problem efficiently. Section 4 compares the results obtained with our heuristic algorithm against other forecast methods to evaluate the PFPFA's efficiency and accuracy. Finally, in Section 5, we offer conclusions and suggestions for further research.

PROBLEM DESCRIPTION

In order to forecast the time and degree of price fluctuation when procuring material as a buyer or offering price discount as a seller, we first have to know how many times a product will change its prices during the life cycle. Normally, if a new material or product is expected to have similar behavior as the existing one, we can infer the result of a forecast model by using historical data of the existing one to this new material or product. Nevertheless, if there is no existing material or product for reference, managers must make a guess of the price trend based on experience and characteristic of the new material or product, which then lead to the most similar existing product as a role model for analysis and forecast.

After deciding the number of times for price changes, the next question is to determine the time of price fluctuation. Product price and demand quantity are both time series data. As mentioned above, price fluctuation depends on the accumulation of demand volumes at different stages of life cycle. Hence, we want to use the accumulating demand volume as a function of time, and apply time series analysis approaches to find the time of price fluctuation based on the corresponding accumulating demand quantity. For a seller, demand quantity is sales volume whereas for a buyer, demand quantity is purchase volume. Because we use demand as a function of time, the quantity will be accumulated through time.

For a large-scale manufacturer, buyers and sellers play important roles because their jobs influence the profitability of their company. A price fluctuation forecast model can advise sellers and buyers the right time to take appropriate action about product price change. Because the demand and price data are non-uniform time series, they need to be preprocessed before further analysis. Moreover, since the price and demand quantity are both time series data, we need to address and solve the issues related to the time series data. Finally, since this forecast model is novel, we need to propose an evaluation method to assess the forecast performance.

Most of the time series analyses focus on uniform sampled data that are regular recorded at uniform interval of time, e.g., weather records or sensory records. In real life, business transactions do not happen at uniform fixed interval of time, which poses a problem when applying time series analysis techniques. When data is non-uniform sampled, a time bucket is determined and used to convert the data into uniform time series data. Next, many time series analysis techniques, i.e., moving average or exponential smoothing, can be applied to these uniform time series data. These classical techniques focus on the using the historical data to forecast the future price or quantity. However, in real practice, transactions do not occur regularly and we cannot be sure the time when a transaction comes next. Furthermore, the price of a product usually drops consistently at the end of life cycle and time series analysis techniques, e.g., moving average or exponential smoothing, have the problem of delaying price change.

What managers really concern is the time and degree of price fluctuation and thus, using traditional time series analysis techniques cannot achieve this goal. As mentioned above, demand quantity differs at different stages of a product's life cycle. Therefore, using the demand quantity to analyze the price fluctuation points is more accurate rather than time. However, if the price or quantity of all products or material are used to forecast future demand, it will be very difficult to find the pattern of price fluctuation for each individual product or material. Consequently, we need to transform the price and quantity data into percentage to eliminate the effect of scale or unit, which helps us to group the items with similar behavior of price fluctuation.

After data pre-processing, we obtain two time series data. Define Q_{ij} as the demand quantity for transaction record j of product i and P_{ij} as the unit price for transaction record j of product i. Define OP_i as the original unite price for product i. For instance, assume that there are 50 transactions happened in the entire product life cycle of product A. The two time series data for product A, QA_j and PA_j, are listed as follows:

$$\text{Quantity of Product A} = \{Q_{A1}, Q_{A2}, \ldots, Q_{A50}\}$$

$$\text{Price of Product A} = \{P_{A1}, P_{A2}, \ldots, P_{A50}\}$$

This study uses quantity as a function of time to predict price change and thus a new forecast model is developed to predict the time of price fluctuation first followed by the degree of price fluctuation. To concentrate on the time of price fluctuates, we will remove those data points that the price does not change, and keep the data points with price fluctuations. Define the FQ_{ij} as the rate of accumulated demand quantity at price fluctuated data point j of product i and FP_{ij} as the price rate at data point j of product i. Define TQ_j as the total accumulated quantity at the end of price fluctuation of product i. Therefore, if a product changes prices five times in its entire product life cycle, the number of the time series data points to represent demand quantity and price will become 5.

$$\text{Rate of Accumulated Quantity of Product A} = \{FQ_{A1}, FQ_{A2}, \ldots, FQ_{A5}\}$$

$$\text{Rate of Fluctuation Price of Product A} = \{FP_{A1}, FP_{A2}, \ldots, FP_{A5}\}$$

To forecast price fluctuation points, we need know: (1) the number of price fluctuation points; (2) price fluctuation time; and (3) fluctuation price. Before forecasting price fluctuation points, we need to know the number of price fluctuation points from the historical data. As mentioned above, we forecast the demand quantity as the price fluctuation times. Define Num_F_i as the number of the price fluctuation points for product i. For example, we assume that product A has five price fluctuation points, which implies that $Num\_F_A = 5$. Traditional forecasting methods predict the times of these points (periods or dates). This study predicts the accumulated demand quantity level as the times of these points. Define $FARQ_{ik}$ as the fluctuation accumulated rate of quantity for product i and fluctuation record k. For instance, the first price fluctuation point of product A will occur when the demand quantity reached 15% of total demand quantity and thus, $FARQ_{A,1}$ = 15%.

After determining the time of price fluctuation, the degree of price fluctuation needs to be predicted. Define FPR_{ik} as the fluctuation price rate for product i and fluctuation record k. Thus, the price of product A drops to 95% of the original price at the first fluctuation point is noted as $FPR_{A,1}$ = 95%. That is, the price of product A will drop to 95% when the demand quantity reached 15% of total demand quantity.

To find the policy of ($FARQ_{ik}$, FPR_{ik}), we propose several forecasting methods for different kind of products to be chosen from. However, users need to find the best model for their products and employ the best model to forecast the new products. Hence this study constructs a classifier to divide products into different groups in which the products have similar demand fluctuation behaviors and build a forecasting model for each group.

The common error measurements are Mean Absolute Deviation (MAD), Mean Squared Error (MSE) and Mean absolute percentage error (MAPE). Mean absolute deviation (MAD) is the average of total errors from all time units. Mean Squared Error (MSE) is the average of total squared errors from all time units. Mean absolute percentage error (MAPE) is the average of total percentage errors from all time units. However, all these error measurements are for uniform time series data. To overcome this obstacle, we predict both the time and degree of price fluctuation and choose the same error measurement for both forecast results to evaluate the errors.

THE PFPFA

Negotiating lower price at the right time is very important for a manufacturer as well as reducing price at the right stages of a product life cycle is critical for a retailer. This study proposes a method called the Price Fluctuation Point Forecast Approach (PFPFA) to solve these problems effectively. We first introduce the process of PFPFA and transform the data to the format that is ready for forecasting. We then present the models for price fluctuation forecast. There are four models for time forecast and three models for price forecast. In consequence, for a single product, there would be twelve different forecast outcomes. Finally, to evaluate the forecast outcomes, we have to determine an assessment method. Hence, we could find the best combination of these forecasting models for each group.

The main process of PFPFA has four phases: (1) transforming data based on the number of fluctuation points; (2) calculating times with different forecast models; (3) calculating prices based on the results of phase 2 with different forecast models; and (4) evaluating and selecting the best forecast model combination for each group of products.

In phase 1, we transform the data into the format that can be used in phase 2 and phase 3. Because both the time and the degree that the price fluctuates are the main focus of this study, we propose to use demand quantity as the time to forecast the price fluctuation point. Thus, in phase 2, the accumulated rates of quantity are treated as time epochs of price fluctuation points and can be forecasted by four methods. PFPFA also proposes three methods to forecast the fluctuation price rate based on the accumulated rate of quantity derived before in phase 3. Therefore, for each product, there are totally 12 models to perform forecast. Finally, in phase 4, PFPFA chooses the best price forecast method with the smallest MAD for each group.

P1: Transform Data

We want to use the accumulated sales/purchase quantity to represent the time of price fluctuation. Thus, the original data of procurement, including the demand quantity and unit price of each order on different dates, need to be transformed to the accumulated quantities and price change percentages. The first step is to calculate the accumulated rate of quantity at data point j of product i (FQ_{ij}) which is computed as the accumulated quantity up to data point j of product i (AQ_{ij}) divided by the total quantity of product i (TQ_i).

Next, we need to calculate the price rate at data point j of product i, FP_{ij}, which is equal to the unit price (P_{ij}) divided by the original unit price (OP_i). By definition, OP_i is the unit price at first transaction. We also need to calculate the price change rate at data point j of product i (PC_{ij}) by subtracting P_{ij-1} from P_{ij}.

Since we only concern about the time that the price fluctuated, the final step is to filter out those transactions with price change equal to 0 or $PC_{ij} = 0$ and only keep the fluctuation with $PC_{ij} \neq 0$. Furthermore, to avoid confusing, we renamed the FQ_{ij} to $FARQ_{ik}$ and FP_{ij} to FPR_{ik}.

P2: Time Forecast

In this section, we introduce four time forecast models in PFPFA: (1) the linear fluctuation cycle model (LFC); (2) the exponential model (EXQ); (3) the logarithm model (LOGQ); and (4) the diffusion model (DFQ).

First, the linear fluctuation cycle model (LFC) assumes that the price of product i fluctuates every time when the accumulated quantity increased to a certain level. Therefore, the formula, $FARQ_{ik} = FF_i + FC_i \times FID_{ik}$, can be used to predict the fluctuation point k where FF_i is the first time of the price fluctuated and FC is the frequency of price fluctuation of product i. To find the best fit prediction model, we can use the simple regression technique. Assume that the relationship between $FARQ_{ik}$ and FID_{ik} is linear.

Second, the exponential model (EXQ) assumes that the prices of some products fluctuate more frequently at the beginning of their life cycles and getting less frequently toward the end of their life cycles. For this kind of products, we can use an exponential model to forecast the price fluctuation times, $FARQ_{ik} = b \times a^{FID_{ik}}$. To get the best fit prediction for these two parameters, b and a, we can use the simple regression technique. We can take logarithm of the equation and transform the equation to linear.

Third, opposite to the previous exponential model, the logarithm model (LOGQ) assumes that the prices of some products seldom change at the beginning of their life cycles and increase frequently at the end of their life cycles. Hence, we can use a logarithmic model to predict their fluctuation points as $FARQ_{ik} = b + a^* \ln FID_{ik}$. To get the best fit prediction for these two parameters, b and a, we can use the simple regression technique.

Finally, the diffusion model (DFQ) assumes that the prices of some products change frequently at the beginning and the end of their life cycles but keep steady in the middle period of their life cycles. In this case, we can use diffusion model to do the forecast.

$$FARQ_{ik} = \frac{1}{1 + e^{Di\,(Ii \times Num\_F_i - FID_{ik})}} - M_i$$

This model need three parameters, Inflection Point (I_i), Delay factor (D_i), and Middle Point (M_i). Ii is the inflection period when the price fluctuation frequency changes, Di controls the time when the frequency of price fluctuation starts to slow down, and M_i is the middle point or the average value of the accumulated quantity. To derive Ii, we calculate the slopes of $FARQ_{ik}$ every three points, find the most oblique period, and use the middle point of this oblique period divided by Num_F_i as I_i. We then use the deviation of 50% and the average of $FARQ_{ik}$, to calculate the value of M_i as $M_i = 50\% - (\Sigma \text{all } k FARQ_{ik}/Num\_F_i)$. To derive D_i, we set a range of 0.005 to 3, and use computer to automatically choose the value by selecting the one with the minimal sum of errors in absolute value.

P3: Calculating Prices based on Different Forecast Models

The models used to predict prices in this subsection are similar as the models for price fluctuation time proposed in the previous subsection. However, our forecast target is to achieve the minimum error of price forecast. Therefore, one product can use DFQ model for time forecast but use EXP model for price forecast as long as the final error of price forecast is minimized.

First, the fluctuation velocity model for price (FV) assumes that the prices of some products drop at a constant velocity. Therefore, we can predict the FPR_{ik} by the following formula: $FPR_{ik} = MPi + Vi \times FARQ_{ik}$. There are two parameters, Velocity (V_i) and Maximum Price (MP_i), needed in the FV model where MP_i is the price rate at first fluctuated point for product i and V_i is the velocity of price dropping for product i. To get the best fit prediction, we can use the simple linear regression technique by assuming that the relationship between FPR_{ik} and $FARQ_{ik}$ is linear where V is the slope and MP is the intercept.

Second, the exponential model for price (EXP) fits for those products whose prices drop fast at the beginning of their life cycles and become steady at the end of their life cycles. Assume that the relationship between FPR_{ik} and $FARQ_{ik}$ is exponential. We can predict the FPR_{ik} by the following formula: $FPR_{ik} = b \times a^{FARQ_{ik}}$. We then take logarithm of the equation and transform the equation to a linear equation.

Third, the logarithmic model for price (LOGP) is designed for those products whose prices drop slowly at the beginning of their life cycles and drop fast at the end of their life cycles. Assume the relationship between FPR_{ik} and $FARQ_{ik}$ is exponential. Therefore, we can predict the FPR_{ik} by the following logarithmic formula: $FPR_{ik} = b + a \times \ln(1.0001 - FARQ_{ik})$. To get the best fit prediction of these two parameters, b and a, we can use the simple regression technique.

P4: Evaluating and Selecting the Best Forecast Model

Our proposed forecast model involves four models for FARQ and three models for FPR for each product. In other words, when we want to perform a price fluctuation forecast for a single product, we have twelve different results. To evaluate these results, we have to choose an error assessment method. The most common error measurement methods are MAD, MSE and MAPE. Since the value of FPR is already in percentage, it would be inappropriate to use MAPE. In addition, using MSE will make the error become smaller if the data are in percentage. Consequently, we choose MAD as our evaluation method.

Because for each product i, the proposed forecast model not only predicts the future price rate by using model n but also predicts the time that the price fluctuates by using model m, two evaluation measurements are needed as follows:

$$Q\_MAD_{im} = \frac{\Sigma \text{all } k \, |\text{actual}(FARQ_{ik}) - \text{forecast}(FARQ_{ik})|}{Num\_F_i}$$

$$P\_MAD_{imn} = \frac{\Sigma \text{all } k \, |\text{actual}(FPR_{ik}) - \text{forecast}(FPR_{ik})|}{Num\_F_i}$$

For each product, we will run the 12 model combinations and choose the model combination which has the smallest P_MAD_{imn}, then use the parameters to forecast the price of new products. However, not all products have enough data points to perform 12 model combinations. Therefore, to train the system to select the best model for forecasting, all products are classified into several groups with similar price fluctuation patterns. Next, we randomly select 45% of the products in every group for training and the remaining 55% for testing. For each group of products, first we will run the 12 model combinations for each product. Second, we compute the average parameters needed for each model and the run these 12 model combinations again on the testing products in each group with these average parameters. Finally, choose the models with smallest P_MAD_{imn} and Q_MAD_{im} to forecast new products by using these average parameters.

COMPUTATIONAL ANALYSIS

In this section, we implement the PFPFA on a material purchase dataset from Company G, an international motherboard manufacturer in Taiwan, to demonstrate its feasibility. First, we introduce the dataset and divide it into a training set and a testing set. Second, we perform PFPFA on an example in the training dataset to show the result of each step. Third, we find the best forecast model for every group in the training dataset using PFPFA and then use these models to forecast the materials in the same group of the testing dataset. Finally, we interpret and analyze the testing results by comparing them with the models that Company G currently uses.

This dataset from Company G contains all the purchase transaction records within the five years from 2011 to 2015. There are 292,562 records for 17,511 different materials in the dataset. These materials are classified into 2,031 groups based on their price fluctuation patterns. Some materials have more than one supplier and therefore we mark the material numbers by adding their different supplier at the end. For example, MA5243 has two different suppliers, CVX and ASD, and hence is redefined by adding the supplier behind its material no as MA5243_CVX and MA5243_ASD. After we redefine the material numbers, there are 21,342 different materials in the dataset.

Because Company G has a weaker bargaining power than some suppliers do, the prices of 15,826 materials never change and the prices of 5,072 materials change less than 4 times, implying that there is no need to analyze these materials. Therefore, we filter out those materials and the remaining 444 materials in 55 groups are our target data for assessing PFPFA. To testing our PFPFA, we separate the remaining 444 materials into a training dataset and a testing dataset. We randomly select 45% of the materials in every group for training and the remaining 55% for testing.

For every group, PFPFA selects the model combination that best fits the training materials and uses the average of the parameters for the materials in the group in testing dataset. Next, PFPFA performs the forecast for the 55 groups in the testing dataset by the model selected for each group. This study also uses the Exponential Smoothing (ES), commonly used time series analysis and currently used by Company G, as the benchmark for comparisons. However, ES can only predict the degree of price change but not the time when price fluctuates. Therefore, the results of ES can be compared with the price of fluctuation points forecasted by PFPFA but for the time of fluctuation points, no comparison will be available. The smoothing index (α) of ES will be set as 0.9 after several trial and error testing. We use ES with $\alpha = 0.9$ to forecast for the materials in training set and then use the average of the forecast prices of every fluctuation points as the prediction to the materials in the testing set. We then calculate the average P_MAD of PFPFA and ES as 7.65% and 9.75%, respectively. Not only the price change, PFPFA can also predict the times of price change and the resulting average Q_MAD of all 55 groups is 13.45%. PFPFA works better than ES to predict the price changes in all 55 groups in terms of P_MAD.

To prove that PFPFA predict price change more accurate than ES, we first perform Chi-square normality tests on P_MAD of ES and P_MAD of PFPFA. Because p_values are 0.1227 and 0.0652, the null hypotheses are not rejected, both P_MAD of ES and P_MAD of PFPFA are normally distributed. We then perform the pair-t test on the difference between P_MAD of ES and P_MAD of PFPFA. Because t statistics = 6.5317 or p_value of the pair-t test is close to 0, the null hypothesis is rejected and the difference between P_MAD of ES and P_MAD is larger than 0. Based on the above results on the testing dataset, PFPFA performs better than ES. As to the time forecast of price change, since we have no other method to compare with, the result of PFPFA with an error of 13.45% is acceptable for the users to employ PFPFA in practice.

CONCLUSIONS

This study develops the Price Fluctuation Points Forecast Approach (PFPFA) by using the accumulated demand or sale quantity as the time of price fluctuation. PFPFA forecasts the quantity (time) by four quantity (time) forecast models, including a linear model, an exponential model, a logarithm model, and a diffusion model. These four models can represent different kind of relations between price fluctuation point and the accumulated demand or sale quantity. Based on the forecast result of quantity (time) forecast, PFPFA uses them to predict the product price at those fluctuation points by three price forecast models, including a linear model, an exponential model, and a logarithm model. These three models can represent different kind of relations between fluctuation price and the quantity. Therefore, PFPFA offers totally twelve model combinations for different types of products or material to fit. Once the model is selected and trained for a group of products or materials, PFPFA can predict the times and degrees of price fluctuation points for the existing or new products by using the average parameters of the selected best-fit model in the same group.

This study assumes that the number of price fluctuation points is known and can be used directly in training the model. However, in the real world dataset, the number of price fluctuation points is computed from the historical data. Hence, future works should be focused on the analysis of the number of price fluctuation points to enhance the forecast accuracy. Before PFPFA, there is no efficient way to forecast the price fluctuation points for Company G and some materials in the dataset from Company G may not reflect the real possible price. If Company G employs PFPFA for one or two years, they will push for better deals and thus, more price fluctuation points. Future works can observe the change and rebuild the models after applying PFPFA in practice for Company G.

ABSTRACT

Prediction models are an important part of financial research. In this paper, we review statistical prediction models, their application to finance, introduce Machine Learning methods for financial prediction, and investigate their use in banking research. By using stable statistical prediction, investors and regulators can hope to predict future bank failures and other variables of financial interest. In this paper, we report two successful machine-learning methods to predict the size of a bank one fiscal year ahead of the current date. We show that these models are successful.

KEYWORDS: Prediction, Bank failures, Machine learning, Financial research, Statistical predication, R programming language.

INTRODUCTION

Explanatory models (examples include regression models such as arise in experimental designs) assume a cause and effect relationship between the inputs to the system and its output. This allows one to examine such a potential cause and effect relationship. Predictive models on the other hand attempt to find independent predictor variables that in some sense “best predict” the dependent variable of interest (Shuemeli (2010)). As Shuemli(2010) points out variable selection models are most often the models of choice for identifying useful predictive models). In this paper, we build predictive models for bank size and show they are successful.

LITERATURE REVIEW

The data set that we use to illustrate the methods of machine learning based prediction in finance was first reported by Jin et al (2011). Our data set was collected and formed exactly as reported by Jin et al except that we did not use the audit quality variables, which were not available to us.. The variables used as predictors were those shown in Jin et al’s (2011) Table 2 except that the audit quality variables were not used. Further, we did not want to use the scheme proposed by Jin et al (2011) to attempt to predict bank failures because it requires knowledge of troubled banks, which is usually unavailable to most researchers. Since we did not have that information, we chose instead to predict CS or current status of the bank sample. CS is the values of the size variable for a bank one fiscal year ahead of the period where we are building our prediction model. The potential predictors we use are the ones Jin et al (2011) used in their Table 2. The definitions of these variables are given in our appendix. We do note that regulators and to some degree bank auditors have knowledge of some troubled banks which make the failed bank scheme reported by Jin et al (2011) more workable. However most researchers do not. Thus we follow Shumeli (2010) and use predictive models. We will show that two machine learning variable selection models are successful in predicting bank capital size one fiscal year ahead of the sample data. We note that all analysis programs (written in R) and data sets are available from the authors (DEB).

METHODS

An important tenet of modern statistics is that there are two types of statistical models: explanatory and predictive (Shamueli, 2010). Shamueli (2010) means that the objective of statistical modeling can be to explain or to predict. Explanatory models are the stuff of classical statistics. Their basic use is to test hypotheses and make estimates of model parameters. Predictive models on the other hand are models that are built with the primary goal of making predictions. Here we are most interested in, say, predicting values of a dependent variable from, say a regression model. In this case, variable selection is quite important. In the explanatory case choice of variables is largely driven by theory and the requirements of testing theories. Prediction on the other hand is different. Here our main goal is to get the most accurate possible estimates of the dependent variable in, say, a regression model. Prediction is quite different. In the predictive situation our goal is to get the most accurate possible prediction of the dependent variable or variables. This is what drives our variable selection efforts. It may come as a surprise to some that while theory may assist use in choosing independent variables, it is often not the only thing that is important. As Shumeli remarks (2010, p. 297) the choice of variables can be quite different in the two cases. Since the goals can be remarkably different in the two cases, we were lead to two important findings. First, a good set of explanatory variables is not necessarily a good set of predictor variables. In fact Shumeli, in an appendix (Shumeli, 2010) gives a mathematical proof that such is the case. Further she summarizes by quoting Hagerty and Sirinivasan (1991), “We note the practice in applied research of concluding that a model with a higher predictive validity is ‘truer’ is not a valid inference.” Thus we may conclude that the same set of independent variables may not be a good choice for models that are trying to achieve different goals. This brings us to the topic of variable selection.

In this paper we chose two modern machine learning variable selection methods (Booth et al, 2019), gradient boosting (R package GBM)) and adaptive lasso (Booth and Ozgur, 2019) using the least squares approximation(Boos, 2014). Full details can be found in: Booth et al (2019), Booth and Ozgur (2019), Zou (2006), Elith et al (2008). The R implementation was used in all cases.

In the Tables, the variable to be predicted was CS, which is, capsize in the predicted quarters.

In order to make the DVs and IVs as corresponding as possible, we tested the quarters:

Start		Stop
17	to	21
21	to	24
21	to	25

By this, we mean we use the data in quarter 17 to predict CS in quarter 21 in our forecasts as shown in Table 1-6. Stop is the quarter that was predicted and Start is the quarter that provided the predictors. The DV was always CS, capsize. The starting set of predictors were taken from Table 2 of Jin et al (2011). Under the gradient boosting Tables 1, 3, and 5, we list the IVs and the relative influence. The higher the relative influence the more important the predictor is. Under Adaptive Lasso, we list the predictors. Under OLS we list the OLS regression coefficients, under BIC we list the Bayesian Information Criterion values and similarly for the Akaike Information Criteria (AIC). The BIC was chosen as explained in Booth and Ozgur (2019), though some would use AIC. We finally cross validate the prediction error where PE=CS at the ending quarter minus CS from the starting quarter and then at the bottom of each table we list the mean, variance and standard deviation of the prediction errors from the gradient boosting estimates. The IVs chosen for the final prediction equations are chosen from the list of predictors in each Tables 1, 3, and 5 with BIC = 0 (Booth and Ozgur, 2019).

DISCUSSION AND CONCLUSIONS

Looking at Tables 1,3 and 5, the first thing we note is that the summary statistics of the cross validated predictions are small indicating that with prediction equations made up of the predictors chosen with this model, we get quite good predictions over the year-time span. Second, we note that all of our initial lasso predictors were the “best” predictors as used in Table 1 of Jin et al (2011). We note two things here:

1. Our equations contain fewer predictors and hence our gradient boosting prediction models are more parsimonious and
2. Jin et al claimed to have “good” prediction equations.

Two other things:

1. The authors do not give any cross validation information to show that their predictions are “good” and
2. They give no objective criteria for why the IVs they chose were in the model.

We do note that they used a longer time span so that their prediction errors are probably a bit larger than ours are (assuming the same DVs) because of this. We could not obtain the audit variables; therefore, we could not exactly check the prediction equations and the cross validation statistics.

We note the following facts from our estimates given in Tables 1-6:

1. Our gradient boosting and adaptive lasso models contain fewer predictors and hence our gradient boosting prediction models are more parsimonious with small prediction errors. These are the strengths of our models.
2. Jin et al’s models are not claimed to be in any sense “best” predictor models. This is a drawback for those models, as they do nothing at all to argue that they have produced models that are in any sense optimal.
3. We go on to consider our adaptive lasso models in comparison with the models produced by Jin et al. First, recall that we started with Jin et al’s ending selected predictor variables. If we can remove any of these predictors from our models than our models are more parsimonious using the BIC criterion of BIC=0 and looking at the adaptive lasso results in Tables 1-6 we see that is the case. Secondly, we know that (as shown by Zou, 2006) the adaptive lasso estimates satisfy an oracle property. This says that under our conditions that an adaptive lasso model is at least as good as any other model. Since we have a more parsimonious model with the same starting variables as Jin et al, we have models that are superior to what Jin et al would have gotten if the DVs were the same. Here, of course, we are comparing model building steps not regression coefficients. This is true

because of the way Jin et al built their prediction without considering the difference between prediction and explanation (Shamueli, 2010). This is of course a bit of an unfair comparison since Jin et al were trying to predict failure while we were predicting current status and failure is likely more difficult. We ,further, note two things:

1. Our models are more parsimonious and
2. Have either demonstrably small prediction errors (gradient boosting) or the models proven optimal (adaptive lasso).

Thus, we believe our conclusion is fair.

*Received from: (Dar-YehHwangCheng F.LeeK.Thomas Liaw)

We remark that we have shown several things in this paper:

1. We make successful predictions of capital size over a one fiscal year period.
2. The two machine learning algorithms were able to successfully predict capital size one fiscal year either ahead with small errors (gradient boosting) or with an optimal model (adaptive lasso).
3. Thus, machine-learning algorithms are valuable additions to the quantitative methods used in finance.
4. As Turak (2018) notes being able to predict capital size or even failure may be an advantage in dealing with or preparing for coming financial crises.

Considering the work that Jin et al (2011) did on failing banks, one might wonder why we chose to build models for the prediction of bank size. If we consider Table 7 in the paper we can see that there are banks that were quite large in the data set.. There is value in predicting things other than failure. We note that our models were able to predict the change in size in bank assets over the period of one fiscal year. Given the size of some of these banks, a major change in asset size could have a large impact on the US Economy even if the bank did not fail but was perhaps bailed out. We now know that we have models that can help us deal with effects such as these that may have large impact.

Exploring Forecasting Methodology With Switching Rule For Periods Of Slow And Fast Demand

Matthew Lindsey
Stephen F. Austin State University
lindseymd@sfasu.edu

Robert Pavur
The University of North Texas
pavur@unt.edu

ABSTRACT

Selecting the optimal forecasting methodology when demand patterns change from slow-moving demand to fast may benefit the inventory manager by reducing cost and increasing customer satisfaction. This research assesses an approach that uses the probability of demand and the size of the demand to determine the appropriate forecasting methodology. The proposed procedure outperforms either the Croston method or SES in this simulation.

KEYWORDS: Croston's Method, Forecasting, Intermittent Demand, Single Exponential Smoothing

INTRODUCTION

A large proportion of time periods with no demand characterizes intermittent demand. Instances of this research are plentiful, but many explore applications of Croston's method (1972) or Single Exponential Smoothing (SES). Croston (1972) exposed that SES was not optimum for cases of intermittent demand and introduced a new method. His method has become the foremost methodology for forecasting slow-moving demand. Willemain, Smart, Shockor, and DeSautels (1994), and Johnston and Boylan (1996) have provided evidence for the advantages of Croston's method when forecasting intermittent demand. Variations have been proposed, particularly by Syntetos and Boylan (2005) who provided a bias correction.

Many retail items or spare parts can be classified as having regular or high demand levels versus having intermittent or slow levels of demand. Seasonality, promotions, special events, trends and correlated demands can influence items with intermittent demand and research has begun to manage these effects (Altay, Litteral & Rudisill, 2012; Lindsey & Pavur, 2008). A situation that has only been addressed in a limited manner is how to handle shifts in mean demand. This is a common case in retail inventory management resulting in the item being categorized as slow moving and using forecasting methodology for intermittent demand to forecast demand during the slow period and then change forecasting methodology.
Leven and Segerstedt proposed a general method when demand is slow or regular, but introduces more bias than Croston's method (Teunter & Sani, 2009). Leven and Segerstedt' s (2004) provided a technique for all stocked items and can be utilized for all demand types but

not for an item with distinct demand rates during two different periods. Despite shortcomings, Croston's method (1972) has found widespread use and has been the benchmark for inventory models and forecasts (Syntetos & Boylan, 2005, 2006; Altay, Rudisill & Litteral, 2008; Teunter, Syntetos & Babai, 2010; Xu, Wang, & Shi, 2012; Ramaekers & Janssens, 2014).

The need for categorizing demand patterns to provide guidance in forecasting stock control is stated in the literature (Syntetos, Boylan, & Croston, 2005; Boylan, et al. 2006). By classifying demand, the optimal methodology for the forecast may be selected (Syntetos, et al 2005). An optimal methodology exists for a given demand level, however, no agreement exists on what the measure should be or what the cut off points should be within a measure for different demand levels. Williams (1984) used the coefficient of variation to describe the level of "lumpiness" in relation to the lead-time to define "intermittence" to select the best method. Shortcomings identified by Syntetos, et al (2005) were that it did not distinguish demand patterns sufficiently. Using Croston's method with the Syntetos and Boylan correction factor, Syntetos, et al (2005) proposed categorizing demand as erratic, lumpy, smooth and intermittent using the average number of periods between demands and the coefficient of variation.

This paper will examine a simulated series that shifts from "fast" demand to "slow" demand. It will use a ratio of Bernouli probabilities (likelihood functions) to determine whether the demand rate is at a historically established "fast" rate or a "slow" rate. Forecasts will be computed using SES, Croston's (1972) method and the Bias Corrected Croston's method by Syntetos and Boylan (2001). Additional forecasts will be computed using two switching rules and a combination of the switching rules. A rule of "no demand for two periods" and a "control chart" for the average demand mean will be used to indicate the need to switch methodologies. Finally, a combination of the two rules will be used. The Average Root Mean Square Error (RMSE) will be reported to compare forecasts.

LITERATURE REVIEW

Croston's method (1972) is a popular technique to forecast when demand is intermittent and is the standard for inventory models (Teunter, Syntetos & Babai, 2010; Xu, Wang, & Shi, 2012; Ramaekers & Janssens, 2014). Croston's method has documented benefits by Willemain, Smart, Shockor, & DeSautels (1994), Johnston and Boylan (1996) and others. Syntetos and Boylan (2001) corrected a bias in Croston's method. Many studies have compared the bias corrected method with the original without identifying a superior method in the evaluations (Eaves & Kingsman, 2004; Syntetos & Boylan, 2005; Teunter & Sani, 2009; & Teunter & Duncan, 2009). A generalized method when demand is slow or regular has been suggested, but it potentially introduces more bias than Croston (Teunter & Sani, 2009).

Categorization

Categorizing demand distributions to provide guidance in forecasting and stock control is suggested in the literature. (Syntetos, Boylan, & Croston, 2005; Boylan, et al. 2006). By correctly categorizing demand, the practitioner can select an optimal forecasting method (Syntetos, et al 2005). The literature suggests a proper course of action exists for a given demand level, but not what the measure should be or the cutoff point within a measure.

Aggregation Approaches

Aggregation provides an alternate approach to forecasting slow demand. It may eliminate slow periods altogether. An aggregate-disaggregate intermittent demand Approach (ADIDA) is proposed by Nikolopoulos, Syntetos, Boylan, Petropolulos and Assimakopoulos (2011). The ADIDA method eliminates intermittent data by condensing it into larger periods that can be forecasted and then redistributed. While the original ADIDA methodology was identified to have specific weaknesses (Petropoulos & Kourentzes, 2015; Rostami-Tabar, Babai, Syntetos, & Ducq, 2013; Spithourakis, Petropoulos, Nikolopoulos, & Assimakopoulos, 2012) several variations have been suggested for specific demand patterns and to address the problems with ADIDA (Petropoulos, Kourentzes, & Nikolopoulos, 2016; Kourentzes, Rostami-Tabar, & Barrow, 2017; Athanasopoulos, Hyndman, Kourentzes, & Petropoulos, 2017; and Li & Lim, 2018.) ADIDA could be applicable to shifts in demand.

Croston's Method

Willemain, et al. (1994) should be consulted for the methodology for implementing Croston's method used in this paper. Croston's technique is comparable to SES and assumes a constant demand mean of size of μ taking place every p periods, so the average demand is not μ/p but

$$y^* = (\mu/p)\ (p\alpha)/(1-(1-\alpha)^p) \tag{1}$$

Syntetos and Boylan's Bias Corrected Modification for Croston's Procedure

Syntetos and Boylan (2001) identified a bias in Croston's (1972) method. The paper should be consulted for the methodology. The bias increases as the value of the smoothing constant increases. It can be minimized by using a small alpha level. Boylan and Syntetos (2005) correct for the bias using Croston's method by multiplying the demand per period by $1-\alpha/2$. Teunter and Sani (2009) advocate that in some cases when only a limited periods have no demand, Croston's method excels. However, in the case when most periods have no demand, the use of the Syntetos and Boylan's correction is better. Syntetos and Boylan (2005) also remind us that Croston's assumptions apply to the new estimator.

Single Exponential Smoothing

SES is a weighted-moving average technique conventionally used to forecast demand for inventoried items. Any general statistics book will explain the method in detail. Trigg and Pitts (1962) provided guidelines for alpha selection. Later Ekern (1983) warns against "adaptive" methods that automatically adjust the constant in response to the forecast performance and identifies the case of the nonstationary demand rate as being especially difficult. Saygin (2005) considers the ability to maximize service level and minimize inventory cost in alpha selection.

Hybrid Approach: Adapting Croston's Method for Two Demand Levels

The conventional use of Croston's method is that it is based on exponential smoothing and will adapt to changing data patterns. Using the same notation as in Croston's method, the following approach is considered a modification of Croston's method. A superscript of S and F are used to distinguish between two modes of sales, slow and fast. For this study, the rule that if the last two time periods did not have a sale, then the current mode of sales is classified as “slow.”

If $X_{t-1} = 0$ and $X_{t-2} = 0$,

Then If $X_t = 0$, $Z^S_t = Z^S_{t-1}$
$P^S_t = P^S_{t-1}$
$q = q + 1$ (2)
Else $X_t = 1$ $Z^S_t = Z^S_{t-1} + \alpha(y_t - Z^S_{t-1})$
$P^S_t = P^S_{t-1} + \alpha (q - P^S_{t-1})$
$q = 1.$
Count_Slow = Count_Slow + 1 (3)

If $X_{t-1} = 1$ or $X_{t-2} = 1$,

Then If $X_t = 0$, $Z^F_t = Z^F_{t-1}$
$P^F_t = P^F_{t-1}$
$q = q + 1$ (4)
Else $X_t = 1$ $Z^F_t = Z^F_{t-1} + \alpha (y_t - Z^F_{t-1})$
$P^F_t = P^F_{t-1} + \alpha (q - P^F_{t-1})$
$q = 1.$
Count_Fast = Count_Fast + 1 (5)

The mean demand per period is then
(Count_Slow * Z^S_t / P^S_t + Count_Fast * Z^F_t / P^S_t)/(Count_Slow + Count_Fast) (6)

EXPERIMENTAL SIMULATION STUDY

To determine whether the data can be classified as fast moving or slow moving, a ratio of Bernoulli likelihood functions are used. If this ratio is greater than one than the data are slow moving, otherwise, the data are classified as fast moving.

Two rules and a combination of the two will be assessed in this simulation. One rule will be whether 2 previous periods have no demand. If true, it will signal to switch from SES. A second rule, “control chart”, based on the average demand per period will be used to signal to switch from SES when the average demand deviates from the mean. A combination of the two switching rules will also be used. Previous research by the authors compared forecasts using a switching rule of 1 period with no demand up to 6 periods with no demand for a variety of demand rates. To investigate the performance of different switching rules on a modification to Croston’s method in the presence of two distinct demand rates, a simulation was performed in which 1000 time periods are computed. Forecasts by SES, traditional Croston, and the bias corrected Croston approach are computed. The Average Root Mean Squared Error will be used to measure the accuracy of these methods.

A smoothing constant of 0.1 was used in this simulation. The length of slow moving periods was set at 300 and the length of the fast moving periods was set at 200 and then again 300 slow and 200 fast for a total number of time periods of 1000. The mean product demand for slow-moving periods was set at 200 and the mean demand for fast moving periods was fixed at 230. The standard deviation for the demand was fixed at 10. Each test situation consisted of 500 simulation repetitions to measure the root mean square error for each method forecasting the average demand over 1000 periods of time. Simulation parameters are provided in Table 1.

Table 1. Simulation Parameters

Simulation Periods :	1000
Number of Simulations:	500
Slow Periods	300
Fast Periods	200
Slow	**Fast**
Probability of Demand	
40% or 60%	80%
Mean Average Demand	
200	230
Demand Standard Deviation	
10	10

Forecasts were computed using SES, Croston method and the bias corrected Croston's method. To compare the methods, the reduction in forecast error in percent was computed for Croston's method and SES and between the modified Croston method and SES.

RESULTS

The forecast error using SES, Croston and the Bias Corrected Croston Method are given in Table 2. The average RMSE is then provided with a switching rule. The Hybrid Croston method percent improvement improved over forecasts using SES and Croston's method as the slow demand rate decreased and the number of periods of no demand required to switch methods decreased. The switching rule was one of three rules: 1.) Switch to Slow when no demand occurs in the last two periods. 2.) Switch to slow when the difference between the sample mean and the true value of the Mean Demand under the Fast Scenario is greater than 1.6 times the standard deviation of demand and dividing by the square root of 5. 3.) Switch to slow when both of the conditions in 1 and 2 occur.

DISCUSSION AND CONCLUSIONS

Knowing when to use the proper forecasting methodology improves the quality of the forecast. As shown in the table 2 above, one size does not fit all. Forecast error is decreased when the methodology is adapted for slower demand periods. These results suggest two things. First, utilizing more information in the forecasting procedure is beneficial and knowing when to reclassify a product based on demand is important. Second for slow moving inventory the sooner the slow-moving case can be identified, the better, for forecasting accuracy. It also appears that when the probability of demands are closer between the slow moving and fast demand rates, that is the rates are similar, the advantage from switching at the right time is less.

Table 2. Performance of SES and Croston's Method with and without Switching Rules

No Switching Rule - Probability for Slow is 0.4 & Probability for Fast is 0.8			
Forecasting Method	**Average Root Mean Square Error**		
SES (alpha= .1)	53.7		
Croston (1972)	49.9		
Croston Bias Corrected	50.2		
Croston Bias Correct (known P)	48.8		
Switching Rule			
Switching Rule Croston/SES	**Average Root Mean Square Error**	**% RMSE reduction over SES**	**Percent RMSE reduction over Croston**
No Demand for 2 periods	26.1	51.4%	47.7%
Control Chart for Mean Demand	31.8	40.8%	36.3%
Control Chart and no Demand	22.4	58.3%	55.1%
No Switching Rule - Probability for Slow is 0 .6 & Probability for Fast is 0.8			
Forecasting Method	**Average Root Mean Square Error**		
SES (alpha= .1)	37.3		
Croston (1972)	34.2		
Croston Bias Corrected	34.6		
Croston Bias Correct (known P)	34.0		
Switching Rule			
Switching Rule Croston/SES	**Average Root Mean Square Error**	**% RMSE reduction over SES**	**Percent RMSE reduction over Croston**
No Demand for 2 periods	24.8	33.5%	27.4%
Control Chart for Mean Demand	23.7	36.5%	30.7%
Control Chart and no Demand	21.2	43.2%	38.0%

ABSTRACT

In the paper, we utilized the given parameters of the auxiliary variable for improved estimation of population variance of the study variable. We proposed a Searls type estimator of population variance using known population tri-mean and third quartile of auxiliary variable. The natural properties of the proposed estimator are studied up to the approximation of degree one. The precision of the estimation of variance is tested using mean squared error (MSE) with the competing estimators of the population variance. The efficiency constraints are obtained for the proposed estimator and are justified through the numerical example. Finally, the improvement over the competing estimators is demonstrated by lower mean squared error (MSE).

KEYWORDS: Population Variance, Searls Type Estimator, Auxiliary Variable, Bias, MSE.

INTRODUCTION

One of the important measures of dispersion is the Population Variance. Variation is natural and it can be seen in our day-to-day life. However, precise estimation is crucial for planning, policy making and other business decisions. The most suitable estimator for population variance is the sample variance, but its sampling distribution is widely dispersed around the true population variance. Thus, we search even for a biased estimator to bridge the gap between sampling variance and true population variance. This is achieved through the use of auxiliary information. Many authors suggested various improved estimators of population variance using auxiliary variable. They used the known parameters of auxiliary variable like coefficient of variation, coefficient of skewness and kurtosis along with many conventional and non-conventional parameters of auxiliary variable. This study is motivated by Searls (1964) and Yadav et al. (2019). In this study, we propose a Searls type estimator of the population variance and apply the known population tri-mean and third quartile of the auxiliary variable for improving the estimation.

NOTATIONS USED

N - Size of Population

n - Size of Sample

$f = n/N$ - Fraction of Sampling

Y - Main Variable

X - Secondary variable

$\bar{Y}$ - Population Mean of Study Variable

$\bar{X}$ - Population Mean of Auxiliary Variable

S_y - Population Standard Deviation of Study Variable

S_x - Population Standard Deviation of Auxiliary Variable

ρ - Population Correlation Coefficient between Study and Auxiliary Variable

S_{yx} - Population Covariance between Study and Auxiliary Variable

C_y - Population Coefficient of Variation of Study Variable

C_x - Population Coefficient of Variation of Auxiliary Variable

Q_i - Population i^{th} Quartile of Auxiliary Variable

M_d - Population Median of Auxiliary Variable

β_1 - Population Coefficient of Skewness of Auxiliary Variable

β_2 - Population Coefficient of Kurtosis of Auxiliary Variable

$Q_r = Q_3 - Q_1$ - Population Quartile Range of Auxiliary Variable

$Q_d = \frac{Q_3 - Q_1}{2}$ - Population Quartile Deviation of Auxiliary Variable

$Q_a = \frac{Q_3 + Q_1}{2}$ - Population Quartile Average of Auxiliary Variable

$TM = \frac{Q_1 + 2Q_2 + Q_3}{4}$ - Population Tri-mean of Auxiliary Variable

LITERATURE REVIEW

Various modified estimators of population variance have been given by various authors till date. Different estimators of population variance by different authors are presented in Table 1.

Table 1: Various estimators of population variance in the literature

PROPOSED ESTIMATOR

Motivated from the literature, we suggest the following estimator as,

$$t_p = \kappa s_y^2 \left[\frac{S_x^2 + (TM + Q_3)}{s_x^2 + (TM + Q_3)} \right] \tag{1}$$

Where, κ is a characterizing scalar which is so obtained that the MSE of t_p is a minimum.

The bias and MSE of suggested estimator up to first order of approximation respectively are,

$$B(t_p) = \gamma \kappa S_y^2 [R_{17}^2 (\lambda_{04} - 1) - R_{17} (\lambda_{22} - 1)] + S_y^2 (\kappa - 1) \tag{2}$$

$$MSE(t_p) = S_y^4 [\kappa^2 \gamma (\lambda_{40} - 1) + (3\kappa^2 - 2\kappa) R_{17}^2 \gamma (\lambda_{04} - 1) - 2(2\kappa^2 - \kappa) R_{17} \gamma (\lambda_{22} - 1) + (\kappa - 1)^2] \tag{3}$$

The Minimum MSE for optimum κ is,
The MSE of the proposed estimator is obtained for the optimum value of κ as,

$$\kappa = \frac{A}{B} \tag{4}$$

Where,

$A = 1 + R_{17}^2 \gamma (\lambda_{04} - 1) - R_{17} \gamma (\lambda_{22} - 1)$ and

$B = 1 + \gamma (\lambda_{40} - 1) + 3R_{17}^2 \gamma (\lambda_{04} - 1) - 4R_{17} \gamma (\lambda_{22} - 1)$

$$MSE_{\min}(t_p) = S_y^4 \left[1 - \frac{A^2}{B} \right] \tag{5}$$

EFFICIENCY COMPARISON

Under this section, various competing estimators are compared with the suggested estimators and are presented in Table 2. The conditions under which proposed estimators performs better than the competing one are also given in Table 2.

Table 2: Theoretical comparison of suggested estimator with various competing estimators of population variance		
S. No.	Estimator	Efficiency condition
1.	Sample variance	$V(t_0) - MSE_{\min}(t_p) > 0$
2.	Isaki (1983) estimator	$MSE(t_R) - MSE_{\min}(t_p) > 0$
3.	Estimators in Table 1	$MSE(t_i) - MSE_{\min}(t_p) > 0$

NUMERICAL STUDY

For theoretical verification, we have used the population given in Yadav *et al.* (2019). The parameters of this population are presented in Table 3.

Table 3: Parameters of the population in Yadav *et al.* (2019)
$N = 80$, $n = 20$, $\bar{Y} = 51.8264$, $\bar{X} = 11.2646$, $\rho = 0.9413$, $S_y = 18.3549$, $C_y = 0.3542$, $S_x = 8.4563$, $C_x = 0.7507$, $\lambda_{04} = 2.8664$, $\lambda_{40} = 2.2667$, $\lambda_{22} = 2.2209$, $Q_1 = 5.1500$, $Q_3 = 16.975$, $Q_r = 11.825$, $Q_d = 5.9125$, $Q_a = 11.0625$, $T_m = 9.318$, $M_d = 7.575$

The biases and the mean squared errors and percentage relative efficiency (PRE) of some estimators along with the proposed estimators are presented in Table 4.

Table 4: Bias, MSE and PRE of suggested estimator over the competing estimators			
Estimator	Bias	MSE	PRE
Sample variance	0	5,393.89	271.57
Isaki (1983) estimator	10.87	3,925.16	197.62
Upadhyaya and Singh (1999) estimator	9.29	3,658.41	184.19
Kadilar and Cingi (2006) estimator	10.44	3,850.16	193.84

Yadav *et al.* (2019) estimator	1.33	2,040.12	102.71
Sharma and Yadav (Proposed) estimator	-5.90	1,986.22	100.00

CONCLUSION

In the present manuscript, we have suggested an improved estimator of population variance using known auxiliary variable. The biases and MSEs of suggested estimators are obtained up to the first order of approximation. The efficiency comparisons have been made with the competing estimators. The conditions have been defined for the suggested estimator under which it performs better than competing estimators of population variance under simple random sampling scheme. The study for the selected data set shows that the suggested estimator has least MSE among the competing estimators. We found that the proposed estimator is the best among the competing estimators of population variance under simple random sampling scheme.

The suggested estimator will be benefial in planning and making better business decisions for professionals.

When a Variable Is Not Perfectly Correlated with Itself:
Time to Retire Kendall's Tau_a Rank Correlation

John R. Dickinson
University of Windsor
Email: MExperiences@bell.net

ABSTRACT

Kendall's tau_a rank correlation coefficient is commonly presented in research methods texts and is readily available in statistical software packages. Tau_a is not defined to accommodate ties in the ranked data it analyzes. Kendall's tau_b correlation, though, is defined to accommodate ties in the ranked data. Where there are no ties in the ranked data, the tau_b formula is the same as tau_a, i.e., tau_b completely supplants tau_a. The present research suggests that tau_a not be presented in textbooks or statistical software packages.

KEYWORDS: Kendall's tau_a, Kendall's tau_b, rank correlation

INTRODUCTION

Kendall's (1938) tau_a rank correlation coefficient is commonly presented in research methods texts. Too, it is readily available in statistical software packages. Tau_a is not defined to accommodate ties in the ranked data it analyzes. While this limitation is not unknown, it is not always reported in texts and statistical software guides and is routinely produced by the latter. These conditions set the stage for the misapplication of tau_a. The present research suggests that tau_a be retired from textbooks and statistical software packages. Such retirement would not spell the end of Kendall's rank correlation for data without ties.

Kendall's tau_b correlation is defined to accommodate ties in the ranked data. Where there are no ties in the ranked data, the tau_b formula is the same as tau_a, i.e., tau_b completely supplants tau_a. Tau_a serves no purpose beyond tau_b and, again, its presence in texts and software packages facilitates its misapplication.

TEXTBOOK TREATMENTS

Though not presenting formulae or examples, Malhotra (2010) notes Spearman's rho and Kendall's tau (p. 536) without distinguishing between the two versions–not accounting and accounting for ties–of tau (or the two versions of rho). Stated without explanation, though, is that, "...when the data contain a large number of tied ranks, Kendall's τ seems more appropriate." p. 536) Malhotra's presentation does not include formulae or examples of nonmetric correlation. Stated, though, is that, "Both vary from -1.0 to 1.0.", again not apprising the student that this may not be the case in the presence of tied data.

Iacobucci & Churchill (2010) presents Spearman's rank correlation coefficient (pp. 385-386), but none of Kendall's coefficients. The possibility of tied ranks is not noted and the formula presented for Spearman's rho does not account for ties. Stated, though, is that, "The upper limit for the Spearman rank correlation coefficient is 1.0..." (p. 386) (Kendall is mentioned on page 388 in the context of the coefficient of concordance.)

Burns & Bush (2003) describes monotonic relationships (pp. 518-520, 542) but does not present any rank order correlation statistics: "...a rank order correlation's relationship falls between these two [chi-square and Pearson] with a monotonic relationship." (p. 542)

Zikmund (2003, pp. 571-572) presents the uncorrected formula for tau, noting only that, "Tied observations are treated in the same way as for the Spearman coefficient." (p. 571) That "same way" is to assign the average rank to tied observations and, "...a correction factor [unspecified] can be introduced to offset their effect..." (p. 570)

A textbook that does reflect the suggestion put forth here–that Kendall's tau_a be retired–is Cooper & Schindler (2006). Kendall's tau_b is presented (pp. 561-563), including the formula correcting for ties and notes, "Its compensation for ties.." (p. 561). Spearman's rho, too, is presented, though with the formula not correcting for ties and no mention of the treatment of tied data.

Cited here are instances where textbook treatments of rank correlation are incomplete. The implication of those instances is **not** that textbooks *should* include more complete presentations. The intended implication is that it can be easily understood why researchers may not appreciate the limitation of Kendall's tau_a.

OTHER PRESENCES OF TAU_a

In the context of the R statistical package Yao's (undated) online *R Tutorial eBook* presents "Kendall Rank Coefficient" and states the formula for the uncorrected-for-ties tau_a. (An endnote refers to a significance test for tau_b.) Wikipedia (2019) reports tau_a as well as tau_b and the Stuart-Kendall tau_c.

The "Nonpar Corr" procedure in SPSS Version 25 produces Kendall's tau_b and tau_a is not noted (p. 1301).

THE SUFFICIENCY OF KENDALL'S TAU_b RANK CORRELATION STATISTIC

Supporting the essential point of the present report, i.e., that Kendall's tau_a should be retired, is that his tau_b statistic completely supplants tau_a. That this is so is easily demonstrated. One formula for tau_b, the corrected statistic, is (Siegel 1956, p. 218, Equation 9.10):

$$\tau_b = \frac{S}{\sqrt{(1/2)N(N-1)-T_x}\,\sqrt{(1/2)N(N-1)-T_y}}$$

Excepting T_x and T_y, definitions of the other terms are not pertinent here. The "T" terms represent tied data. Where no ties are present they equal 0, leading to:

$$\tau_b = \frac{S}{\sqrt{(1/2)N(N-1)-0}\ \sqrt{(1/2)N(N-1)-0}}$$

$$\tau_b = \frac{S}{\sqrt{(1/2)N(N-1)}\ \sqrt{(1/2)N(N-1)}} = \frac{S}{(1/2)N(N-1)}$$

Siegel's formula for tau_a (p. 217, Equation 9.9) is:

$$\tau_a = \frac{S}{(1/2)N(N-1)}$$

In the absence of ties, tau_b equals tau_a. With this, it seems that there is no use for Kendall's tau_a that is not inherently present in tau_b.

AN INSTANCE

In research in the social sciences the correlation matrix is well-known. The square matrix comprises correlations between pairs of variables, the same variables comprising the rows and columns of the matrix. Entries on the matrix diagonal are correlations of a variable with itself, tautologically perfect correlation. That is, the entries on the diagonal of the correlation matrix must equal 1.0. Perhaps the most common type of correlation is the Pearson product moment correlation. However, for some applications, rank order correlation may be more appropriate.

For example, the Taxonomy Index (*TaxI*, Dickinson 2013) is a statistic describing the accuracy of published multiple-choice question difficulty taxonomies. *TaxI* commences with rank ordering questions according to their observed difficulty. A variety of measures of item difficulty exists, including the most common one, the percent of students answering the item correctly (Haladyna 2004, p. 207; Murphy & Davidshofer 1988, p. 131). A second measure of item difficulty divides examinees into the 27 percent of examinees receiving the highest score on an exam and the 27 percent receiving the lowest score. (Aiken (1991) The item difficulty index, then, is the percent of those combined subgroups answering the question correctly. Yet other measures are those of Horst (1933) and Guilford (1936) that correct for guessing.

Since the purpose of the specific measure employed is to rank order questions, that purpose is sufficiently met by any difficulty measure among those that are monotonically related. The measures need not be linearly (i.e., Pearson) correlated. Thus, a rank order correlation statistic might be employed to compare/contrast different measures of difficulty to determine which are substitutable for one another. Kendall's (1938) tau_a is one such rank correlation statistic.

Accordingly, using Kendall's tau_a rank correlation, for a random sample of 612 questions from the published bank of multiple-choice questions accompanying Levy, Weitz, and Grewal (2014) a correlation matrix was calculated (Table 1). As may be seen, the correlations on the diagonal do not equal 1.0. The reason that the entries on the diagonal in Table 1 do not equal 1.0 is, of course, that Kendall's tau_a is not defined to handle tied ranks.

Table 1: Difficulty Measure Intercorrelations (Kendall's Tau_a)

Difficulty Measure	Percent Correct	Percent Correct, Upper~Lower	Horst	Guilford
Percent Correct	0.9912	0.7952	0.9129	0.9887
Percent Correct, Upper~Lower 27%	0.7952	0.9725	0.7633	0.7821
Horst	0.9129	0.7633	0.9940	0.9149
Guilford	0.9887	0.7821	0.9149	0..9918

Correlations of four measures of item difficulty for a random sample of 612 questions

ERROR IN CALCULATED TAU_a VALUES AND THE PRESENCE OF TIED DATA MAY NOT BE OBVIOUS, BUT THAT SHOULD BE MOOT

The instance presented in Table 1 is unusual in that the incorrectness of the diagonal elements is readily apparent; it is known that they should equal 1.0. In most applications, though, no known value for the rank correlation exists. The example in Table 1 is of happenstance. Generally, the error in a calculated tau_a value is not known from the calculated value itself.

Textbook examples of rank order correlations typically use very small numbers of observations with the data exhaustively listed in a table: e.g., 15 observations (Iacobucci & Churchill 2010, Table 14A.4, p. 385), 10 observations (Cooper & Schindler 2006, Exhibit 19-24, p. 563), 11 observations (Gibbons 1993, Table 2.4, p. 10), 12 observations (Siegel 1956, Table 9.6, p. 209). With this, instances of tied ranks are easily identified and, of course, the authors explicitly point them out.

Real world applications, though, may involve hundreds or thousands of observations. (The numbers of observations in the multiple-choice question data that gave rise to this research range from 612 to 958 across six published question banks.) Accordingly, identifying tied observations is much more problematic.

With the retiring of Kendall's tau_a, happenstance or inspection of the data would be made moot. Kendall's tau_b formula, as has been shown above, accommodates both tied and not-tied ranks.

DISCUSSION

Per its title, the purpose of the present study is to suggest that Kendall's tau_a be retired; from textbooks, statistical computer packages, and applications. Kendall's tau_b inherently corrects for ties where they exist and subsumes tau_a thereby obviating the latter. That tau_a does not take into account tied data has been long known (Siegel 1956, pp. 217-219; Gibbons 1993, pp. 15-16). That noted, as cited above it is common for research methods textbooks to give but passing attention to this limitation if any attention at all is given. Also as cited above, popular statistical packages, e.g., R, produce Kendall's tau_a as well as Kendall's tau_b when taub is sufficient and producing tau_a sets the stage for its misapplication.

Mitigation

It might be maintained–with a degree of correctness–that the "limitation" of Kendall's tau_a highlighted here is more accurately positioned as a limitation of using that correlation in the first place. That is, the limitation is with the researcher who used an inappropriate statistical analysis. That granted as a normative prescription, several conditions mitigate that prescription.

Many, perhaps most, researchers are knowledgeable of the substance of their research, and not necessarily thoroughly knowledgeable of the statistical techniques they apply. *Should* researchers be expected to be thoroughly knowledgeable of the statistical methods they apply?

The standard deviation is a commonly applied measure of dispersion. Its calculation involves squaring of differences of observations from the mean of those observations. The effect of small deviations becomes enlarged with their being squared. But the effect of large deviations becomes much more enlarged with their being squared. It may be observed that this disproportionately increases the effect of large deviations. The less commonly applied mean absolute deviation (MAD) is a function of the absolute value of deviations, not their squared value; the deviations are taken as is.

Few researchers could explain the rationale for squaring the deviations. Nor should they be expected to be able to. The researchers sensibly apply what "everyone else" applies without belaboring its founding reasoning. A parallel situation exists in the least-squares method of estimation in linear regression. Why are the error terms squared, rather than using their absolute values?

There are, of course, tenable reasons for these statistical approaches. The issue, though, is whether researchers should be expected to pursue to their origins statistical methods already widely accepted.

Privacy, Awareness, and the Internet of Things

C. Bryan Foltz
University of Tennessee at Martin
Email: foltz@utm.edu

Laura Foltz
University of Tennessee at Martin
Email: lfoltz@utm.edu

ABSTRACT

This research examines the applicability of the Dinev and Hu (2007) awareness centric model of human behavior to the Internet of Things domain. This model is used to examine user intention to modify security settings on Internet of Things devices.

KEYWORDS: Privacy and Security, Consumer Choice and Judgement, Internet of Things

INTRODUCTION

Mason (1986) listed privacy as one of four primary ethical issues facing the information age. This early concern over privacy has only increased as technology has changed over time with modern technology posing a plethora of new privacy threats (Belanger & Crossler, 2011). Privacy models must, therefore, evolve to incorporate the technological changes.

The Internet of Things (IOT) is one such technological advancement. Despite rapid growth, the Internet of Things poses multiple security risks by collecting a variety of private data through smart devices such as watches, dish washers, and digital assistants. Many Internet of Things devices allow users to alter privacy settings to mitigate these risks. This research seeks to understand the degree to which users are aware of these configuration options and utilize these protective settings.

Zheng et at (2018) suggest that any solution to Internet of Things (IoT) privacy must consider user attitudes and awareness. This research examines user awareness of privacy settings in conjunction with privacy concerns in terms of IoT devices by utilizing the Dinev & Hu (2007) instrument.

LITERATURE REVIEW

Privacy

Although privacy has been a concern within the extant information systems literature for many years, interest in this topic extends across multiple disciplines (Mason, 1986; Belanger & Crossler, 2011; Dinev & Hart, 2004). Interest in privacy has increased as a result of the rapid growth of technology (Dinev & Hart, 2004; Belanger & Crossler, 2011). Belanger and Crossler (2011) note that many definitions of privacy incorporate the same basic concept: control over the use (especially the secondary use) of one’s information. Further, the authors suggest that

"Information privacy refers to the desire of individuals to control or have some influence over data about themselves." (Belanger & Crossler, 2011).

Information privacy concern is often used as a proxy for the idea of privacy within the Information Systems literature (Xu et al, 2008). Information privacy concern may be defined as "concerns about possible loss of privacy as a result of information disclosure to a specific external agent" (Xu et al, 2012, p2).

The Internet of Things

The Internet of Things (IoT) refers to a "dynamic global network infrastructure, where objects with unique identifications, wireless communication and computing capabilities are integrated into an information network" (Boos et al, 2013). The IoT acts as a bridge to connect physical and digital worlds by collecting data, largely without human interaction. IoT devices range from wearable devices to items created to automate cities (Weinberg et al, 2015). IoT devices are rapidly gaining acceptance, with some predictions of 50 billion IoT devices in use by 2020 (Weinberg et al, 2015).

Privacy and the Internet of Things

As the IoT grows, users voluntarily install sensor-equipped devices which often passively and aggressively collect data about daily activities (Lee & Kobsa, 2016). Since these devices are generally connected to the Internet, they also share data between multiple devices and services which leads to security and privacy issues (Sfar et al, 2018; Zheng et al, 2018). These issues include questions about what data is collected, where that data is stored, how the data is used, who owns the data, and who can access the data (Zheng et al, 2018).

Bannon (2016) notes that consumers often replace or upgrade home appliances with "smart" replacements but may be unaware of the data being collected and shared by these devices. Further, Bannon (2016) suggests many users fail to read privacy policies. Finally, each new IoT device installed provides yet another opening for attackers (Poudel, 2006).

METHOLODOGY

Information Privacy Concern Measurement

Within the Information Systems field, multiple instruments have been constructed to measure information privacy concern. Preibusch (2013) summarizes many of these.

Preibusch (2013) considers the Concern for Information Privacy (CFIP) instrument developed by Smith et al (1996) to be the "most influential" information privacy instrument. This instrument focuses on offline marketing and consists of four dimensions: "collection of personal information, unauthorized secondary use of personal information, errors in personal information, and improper access to personal information" (Xu et al, 2012). The CFIP scale contains a second-order factor structure (Stewart & Segars, 2002).

The CFIP instrument was modified by Malhotra et al (2004) to focus upon the information privacy concerns of Internet users. This new instrument, the Internet Users Information Privacy Concern (IUIPC) instrument, utilized three dimensions: "collection of personal information, control over personal information, and awareness of organizational privacy practices" (Xu et al 2012).

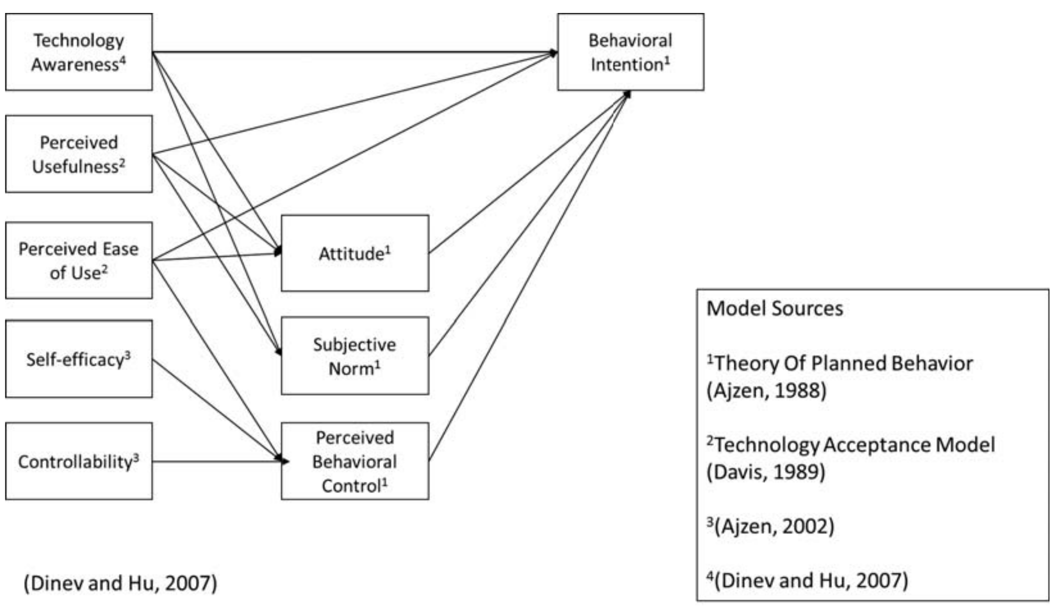
The IUIPC instrument itself was later modified to focus more upon mobile users. Xu et al (2012) based the Mobile Users' Information Privacy Concerns (MUIPC) instrument upon Communication Privacy Management theory. This instrument focuses on three dimensions: perceived surveillance, perceived intrusion, and secondary use of information (Xu et al, 2012). Other research suggests that solutions to IoT privacy concerns must consider both user attitudes and awareness (Zheng et al, 2018). A privacy instrument developed by Dinev and Hu (2007) specifically focuses upon these constructs.

The Dinev and Hu (2007) model focuses upon protective information technologies, which the authors define as "information technologies that protect data and systems from disturbances such as viruses, unauthorized access, disruptions, spyware, and others" (p. 386). The authors distinguish protective technologies from positive technologies, which "benefit their users in terms of productivity, efficiency, competitiveness, or entertainment" (Dinev & Hu, 2007, p. 387). Further, the authors suggest that awareness of threats strongly predicts user intention to use protective technologies.

Within the IoT domain, user awareness of threats appears to be low. Bannon (2016) observes that "the most dangerous part of IoT is that consumers are surrendering their privacy, bit by bit, without realizing it, because they are unaware of what data is being collected and how it is being used." This lack of awareness, coupled with user attitudes, is key to understanding the use of security and privacy settings within the IoT (Zheng et al, 2018).

The Dinev and Hu (2007) model (Figure 1) is based upon Ajzen's Theory of Planned Behavior (1988) but incorporates a number of other factors, including the Technology Acceptance Model (Davis, 1989).

Figure 1: The Dinev and Hu Model (2007)



The Theory of Planned Behavior

The Theory of Planned Behavior (TPB), which is based upon the Theory of Reasoned Action (TRA) (Ajzen & Fishbein, 1980), suggests that human behavior can be predicted by intention and that intention is formed from three factors: attitude toward the behavior, subjective norm, and perceived behavioral control. Attitude refers to individual evaluation about performing the behavior (good or bad), while subjective norm captures perceptions of how others feel about performing the behavior. Perceived behavioral control captures individual perceptions regarding the ease or difficulty of performing the behavior in question. Perceived behavioral control can also directly impact behavior (Ajzen, 1988).

Self-Efficacy and Controllability

Although the TPB has been widely used, perceived behavioral control has caused issues for many researchers. Ajzen (2002) suggests that self-efficacy and controllability are both components of perceived behavioral control, and that these may be measured separately. Self-efficacy refers to an individual's judgement of their ability to perform the behavior (Bandura, 1986), while controllability references the individual's judgement regarding the opportunity to perform the behavior and the availability of required resources (Ajzen, 2002).

Technology Acceptance Model

The Technology Acceptance Model (TAM) is also an extension of the TRA (Dinev & Hu, 2007). TAM suggests that two factors are key in understanding user acceptance of new technology. These determinants are perceived ease of use and perceived usefulness. Perceived ease of use captures user perceptions of the difficulty or ease of using the new technology, while perceived usefulness captures the degree to which the user believes the new technology will prove beneficial (Davis, 1989).

Technology Awareness

Technology awareness refers to "a user's raised consciousness of and interest in knowing about technological issues and strategies to deal them" (Dinev & Hu, 2007, p. 391). The authors also suggest that an individual cannot form attitudes toward protective technologies without being aware of those technologies in the first place (Dinev & Hu, 2007).

The Dinev and Hu Model

The Dinev and Hu Model encompasses the Theory of Planned Behavior, the Technology Acceptance Model and contains the attitude and awareness components that Zheng et al (2018) required for a model understanding IoT privacy. While the original model focused on spyware protection, the IoT technology aspect appears similar and suggests that the Dinev and Hu model might provide a methodology for thinking about IoT privacy. Since the current research setting differs from the initial 2007 article, all relationships and hypotheses will be examined.

Research Question: Does the 2007 Dinev and Hu awareness centric model of human behavior toward protective technologies apply to the Internet of Things?

Hypotheses

H1: Technology awareness is positively correlated with attitude toward the behavior.

H2: Technology awareness is positively correlated with subjective norm.

H3: Technology awareness is positively correlated with behavioral intention.

Users who are unaware of the privacy threats posed by IoT devices, or more specifically unaware of their ability to modify settings to enhance their own privacy will lack attitudes toward the behavior of changing those settings. These same users are also unlikely to be influenced by others regarding changing settings. On the other hand, informed users who are aware of their ability to modify settings are more likely to have a positive attitude toward doing so, are more likely to be influenced to do so by others, and are more likely to actually change those settings.

H4: Attitude is positively correlated with behavioral intention.

H5: Subjective norm is positively correlated with behavioral intention.

H6: Perceived behavioral control is positively correlated with behavioral intention.

H4, H5, and H6 are drawn directly from the TPB (Ajzen, 1988, Dinev & Hu 2007). Within the current study, individuals with positive attitudes toward modifying security settings should experience a stronger intention to do so. Also, pressure from important others should also encourage individuals to modify security settings. Finally, individuals who feel they are able to make these changes should be more inclined to do so.

H7: Self-efficacy is positively correlated with perceived behavioral control.

H8: Controllability is positively correlated with perceived behavioral control.

Ajzen (2002) suggests that both controllability and self-efficacy are components of perceived behavioral control. Individuals who feel they have the ability (self-efficacy) and resources and opportunities (controllability) to modify security settings should experience higher degrees of perceived behavioral control.

H9: Perceived usefulness is positively correlated with attitude.

H10: Perceived ease of use is positively correlated with attitude.

Although the TAM and later versions such as the Unified Theory of Acceptance and Use of Technology Model (Venkatesh et al, 2003) suggest a direct relationship between perceived usefulness and perceived ease of use and actual behavior (Dinev & Hu, 2007), the initial version of TAM (Davis et al, 1989; Dinev & Hu, 2007) incorporated attitude. H9 and H10 are drawn directly from the Dinev and Hu (2007) study. Essentially, individuals who perceive benefits associated with modifying IoT security settings should experience a positive attitude toward doing so. In addition, those who find changing these settings to be easy should also have a positive attitude toward doing so. Dinev and Hu (2007) did not find support for the relationship between perceived ease of use and attitude.

H11: Perceived usefulness is positively correlated with subjective norm.

Dinev and Hu (2007) suggest this relationship based upon work by Venkatesh and Davis (2000). Essentially this suggests that a protective technology that is perceived as being useful may lead referent others to feel the technology is beneficial.

H12: Perceived ease of use is positively correlated with perceived behavioral control.

Although these factors are quite similar, a user could consider changing security settings easy to do while feeling they lacked the ability to do so (Dinev & Hu, 2007). However, Pavlou and Fygenson (2006) noted a relationship between perceived ease of use and perceived behavioral control. Dinev and Hu (2007) confirmed this relationship.

H13: Perceived usefulness is positively correlated with behavioral intention.

H14. Perceived ease of use is positively correlated with behavioral intention.

H13 and H14 are duplicated from the TAM model (Davis, 1989) and suggest that individuals who perceive changing security settings to be useful and easy to do are more likely to change those settings. However, these were not supported in the Dinev and Hu (2007) study.

Survey Instrument

The original Dinev and Hu (2007) survey instrument was modified to focus upon the Internet of Things. Items that referenced spyware protection were reworded to address IoT.

<u>Survey Administration and Descriptive Statistics</u>

1257 students enrolled in undergraduate courses at a Carnegie Master's level university located in the mid-south were invited to complete the survey online. The survey itself was created as an Office 365 form. Students were asked to complete the survey by their normal instructors. Respondents were offered the opportunity to enter their email addresses into a separate survey form (administered by a faculty member not involved in the project) to enter a random drawing for three gift cards. 192 students completed the survey, for a response rate of roughly 15.3%.

The majority of respondents were females (60.5%) between the ages of 18 and 24 (81.1%). As expected, most respondents (68.6%) had completed some college, with almost half (47.8%) reporting business as their major. Further, most of the respondents (73.5%) reported over seven years of experience using the Internet; however, the majority (71.5%) reported less than 7 years of experience utilizing the IoT. The majority of respondents reported only infrequently being a privacy victim (24.3% responded very infrequently, while 59.4% selected the three least frequent categories). While only 13% of respondents reported having no IoT devices in their residence, 59.4% reported 1-4 such devices. Further, 57.4% of respondents utilize 1-2 mobile IoT devices, while 25.1% utilize no such mobile IoT devices. Descriptive statistics are presented in Appendix Tables 1-7.

RESULTS

SmartPLS, a structural equation modeling software, was used to validate the measurement model and test hypotheses. This software utilizes a variance-based approach to estimate parameters and a least-squares procedure to limit demands on measurement scales and sample size (Chin, 1998; Falk et al, 1992; Fornell & Bookstein, 1982). The analysis does not assume normally distributed data and utilizes a nonparametric bootstrap procedure (Davison & Hinkley, 1997; Efron & Tibshirani, 1986).

The measurement model was examined by comparing discriminant validity, convergent validity, and internal consistency reliability (ICR) to established heuristic values.

To establish discriminant validity, the average variance extracted (AVE) should exceed .707 and exceed the correlation between construct pairs (Fornell & Larcker, 1981). Also, the items should load more heavily upon their respective constructs than on others (Gefen & Straub, 2005). Within the current study, several criterion fail to meet the thresholds for discriminant validity. For example, the AVE for technology acceptance is .63, and the AVE for perceived usefulness is .70. In addition, several of the correlations between construct pairs exceeds the specified AVE values. Discriminant validity is not completely supported. Table 8 presents the ICR, AVE, AVE square root values, and correlations.

To establish convergent validity, the factor loadings should load upon the respective construct and should exceed .70 (Carmines & Zeller, 1979). In the current study, all loadings exceed .70 and load as expected. In addition, the Internal Consistency Reliability (ICR) values should exceed .70 (Fornell & Larcker, 1981) to establish convergent validity. In the current study, ICR values range from .87 to .94. Finally, the AVE values should exceed the accepted cutoff value of .50 to establish convergent validity. Within the current study, AVE values ranged from .63 to .87. As shown in Table 9, convergent validity is supported.

Next, all hypotheses were evaluated. Table 10 summaries the hypotheses, path coefficients, and t-statistics. H4, H6, H10, H12, and H13 are not significant.

Table 8: Internal Consistency Reliability, Convergent Validity, and Discriminant Validity

	ICR	AVE	A	SN	PBC	BI	SE	C	TA	PU	PEOU

A = Attitude toward the Behavior, SN = Subjective Norm, PBC = Perceived Behavioral Control, BI = Behavioral Intention, SE = Self Efficacy, C = Controllability, TA = Technology Awareness, PU = Perceived Usefulness, PEOU = Perceived Ease of Use

Discussion

Dinev and Hu (2007) found that perceived ease of use and self-efficacy were not significant within the model while examining the protective technology of anti-spyware. The authors suggest that ease of use and self-efficacy were not significant due to the differences in protective and positive technologies.

The current study focused upon altering security settings within IoT devices. As discussed earlier, the IoT presents numerous privacy concerns, and the only true method of alleviating many of these concerns (other than not using IoT devices) is altering the settings.

Of course, all results must be carefully considered, since discriminant validity was not completely supported. However, the first three hypotheses, which focused upon technology awareness, were supported. While expected, this suggests that awareness of an issue and the methods to prevent the issue are indeed important within the IoT arena. Since 87% of respondents reported having some form of IoT device within their home, these results are somewhat encouraging…awareness of issues does contribute to attitude, subjective norm, and (most importantly) to behavioral intention. Future research should explore this area more—for example, are IoT users concerned with the possibility of privacy intrusions?

Only one of the three TPB hypotheses (H4, was supported. The relationship between subjective norm and behavioral intention was significant, while the others were not. This is curious indeed, and simply raises more questions. Are users concerned with privacy in the IoT? If not, their attitudes toward protecting themselves by changing settings could reasonably be found insignificant.

Within the TPB, perceived behavioral control (PBC) has often been troublesome. In this study, no support was found for the anticipated relationship between perceived behavioral control and behavioral intention. However, both self-efficacy (H7) and controllability (H8) are indeed positively correlated with PBC. Further, perceived ease of use (H12) was not significantly correlated with perceived behavioral control.

Table 10: Hypotheses, Path Coefficients, and t-statistics

Hypotheses	Path Coeff.	t-statistic
*H1: Technology awareness is positively correlated with attitude toward the behavior.	0.1822	1.9791
*H2: Technology awareness is positively correlated with subjective norm.	0.4377	3.4523
*H3: Technology awareness is positively correlated with behavioral intention.	0.2615	1.9313
H4: Attitude is positively correlated with behavioral intention.	-0.0308	0.3276
*H5: Subjective norm is positively correlated with behavioral intention.	0.2981	2.594
H6: Perceived behavioral control is positively correlated with behavioral intention.	-0.0686	0.6305
*H7: Self-efficacy is positively correlated with perceived behavioral control.	0.2568	1.6717
*H8: Controllability is positively correlated with perceived behavioral control.	0.4059	3.4651
*H9: Perceived usefulness is positively correlated with attitude.	0.4821	3.7151
H10: Perceived ease of use is positively correlated with attitude.	0.102	0.9303
*H11: Perceived usefulness is positively correlated with subjective norm.	0.3924	2.9789
H12: Perceived ease of use is positively correlated with perceived behavioral control.	0.2143	1.3224
H13: Perceived usefulness is positively correlated with behavioral intention.	0.1989	1.172
*H14. Perceived ease of use is positively correlated with behavioral intention.	0.2444	1.8194

*These hypotheses are significant.

These results definitely cast doubt upon the applicability of the TPB within this setting. Of course, this could be a result of the specific survey instrument or the sample. However, the authors suspect this may simply represent the same underlying issue as mentioned above.

The remaining hypotheses (H9, H10, H11, and H12) examine two factors from the TAM model (Davis, 1989). The hypothesized relationship between perceived ease of use and attitude, (H10), PBC (H12) are not supported, although the relationship between perceived ease of use and behavioral intention is significant. The hypothesized relationship between perceived usefulness and attitude (H9), subjective norm (H11) are both supported; however, the relationship between perceived usefulness and behavioral intention is not significant. As Dinev and Hu (2007) suggested, these results may simply reflect the differences between positive and protective technologies. Respondents may simply feel that protective technologies are somewhat necessary even if less than convenient to utilize. This does not explain the unexpected results leading to intention however.

Limitations

As with any research, multiple limitations exist with this study. First, only students enrolled within a specific university were surveyed. This convenience sample may pose issues. Second, the survey instrument failed to achieve discriminant validity in a number of areas. This could be caused by refocusing the instrument on a somewhat different area. The respondents self-selected and there was a low, 15%, response rate. Thus, the study could suffer from self-selection bias and limited representativeness.

CONCLUSION

The results of this study are somewhat disappointing. The Dinev and Hu (2007) model did not perform well as used within this research. However, the results do suggest that technology awareness is critical to IoT privacy. Users who are unaware of (or unconcerned with) privacy may simply not realize that IoT devices jeopardize that privacy. Future research should explore this area.

In addition, other research could examine both the TPB and TAM within IoT to determine applicability of those instruments.

ABSTRACT

Fear Appeals are a common tool for encouraging individuals to adopt information security practices. A fear appeal describes a potential threat and suggests a course of action for avoiding the threat. Most fear appeals are static, generically worded messages designed for mass audiences. They lack personalization and are not sensitive to the interests, values, and preferences of individual recipients. As one of the primary tools for encouraging adoption of cyber security policies, fear appeals often have a modest effect on end user behavior. This research holds that fear appeals would be more effective change catalysts if their content was contextualized to the individual. Accordingly, this research describes a new framework for producing more relevant fear appeals. It uses machine learning to curate the most appropriate fear appeal for each individual. The efficacy of this framework is examined in an experiment involving mobile device security. Early results confirm the utility of the proposed framework. Implications and future research directions are also described.

KEYWORDS: Fear Appeal, Information Security, Machine Learning, Personalization, Context

INTRODUCTION

Convincing individuals to adopt new information security and privacy recommendations remains a hard problem within the information security field. A common approach for affecting behavioral change is to communicate via the fear appeal. Fear appeals are mechanisms for encouraging behavioral changes in the security practices of end users (Johnston et al. 2010). These messages are carefully designed to evoke fear among their recipients. Fear appeals also contain recommendations for minimizing information security and privacy risks. Many researchers have spent years experimenting with variations in the wording of the fear appeal in order to make them more persuasive (Ruiter et al. 2014). However, it appears that these efforts have had a relatively modest effect on the influence of fear appeals (Barlow et al. 2013). Individuals and organizations continue to eschew good security recommendations and leave themselves vulnerable to the malicious actions of outsiders.

The present study holds that fear appeals may be ineffective because they lack the personalization necessary to be relevant to individual recipients (Peters et al. 2012). People are increasingly deaf and blind to generic communications (Calder et al. 1980; Grass et al. 1969). As big data and mass customization continue to merge, people seek more tailored, thoughtful experiences. Enterprises which successfully curate their product recommendations to the tastes and preferences of individual shoppers are enjoying record sales growth (Peppers et al. 1997). Organizations which tailor each communication to the background and interests of each recipient are rewarded with increased awareness (Wind et al. 2001). Conversely, those who stick with the conventional one-size-fits-all approach are becoming irrelevant. Individuals have come to expect a high degree of personalization throughout their lives (Cöner 2003). Hence, should be of little surprise that a static, unitary fear appeal will have little effect on its recipients.

This research proposes a new framework for developing and delivering highly contextual fear appeals (see Figure 1). At the crux of this framework are processes for developing user insights and sending fear appeals which are personally relevant to each recipient. The proposed framework is conceptualized in terms of a front end which allows for data gathering, behavior observation, and fear appeal delivery, and a back end which performs analytics, machine learning, and message curation. The front end is implemented as a mobile device-based agent for the Android ecosystem. The back end is operationalized as a cloud-based platform which integrates a noSQL database for building user intelligence and Anaconda machine learning libraries for fear appeal curation. It uses textual analysis and machine learning to categorize individuals according to their profiles and then select the most relevant fear appeal. A data pipeline allows communication between the endpoints. The proposed framework is evaluated in a small-scale experiment in which it is pitted against the contemporary approach of the static fear appear.

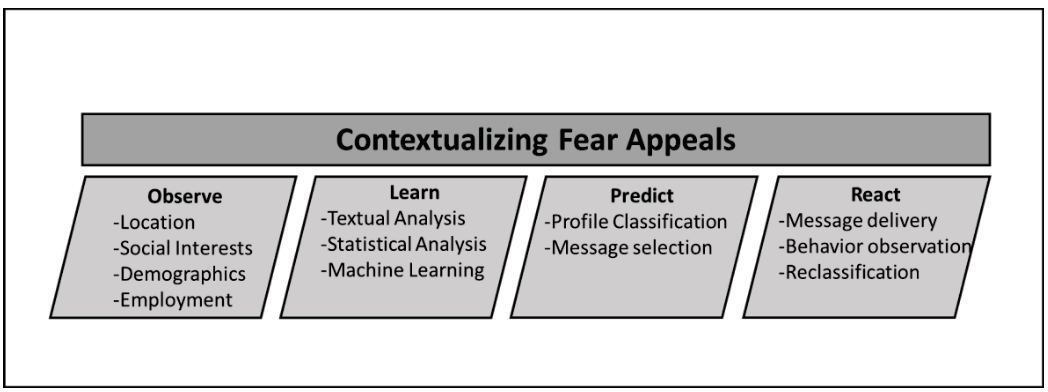

Figure 1. Creating Contextual Fear Appeals

The remainder of this paper is organized as follows. The next section contains the background. It describes the concept of message contextualization. The conceptual development section follows the background. It describes the proposed framework and explains the expected benefit. The process of testing and comparison described in the evaluation section. The results of the tests are described next. Implications for research and practice are then discussed. Finally, conclusions and future research directions are shared.

BACKGROUND

Until recently, it was widely assumed that the best way to reach a mass audience is to develop a single, clearly articulated message. Communicators sought to saturate as many channels as possible with that message in order to produce a desired effect (Belch 1982; Grass et al. 1969). This communication approach is widely seen in advertising campaigns for products and services, during election seasons, and for the promotion of social change. Indeed, change agents tasked with promoting the diffusion of new innovations are often ordered to adhere to a well-defined script for introducing the concept and persuading people to try it. This approach was widely regarded because it maximizes distribution of a consist message in a relatively short period of time. As the breadth of audience increases, the potential scope of impact also increases. Therefore, in a short period of time, it is possible to build awareness and effect change on a national or even international level (Calder et al. 1980). Hence, mass messaging is the preferred communication method for many industries and agencies.

Mass communication is very much a balancing act: the message must be broadly acceptable but it must also be vivid enough to trigger a desired response (Cho et al. 2007; Peters et al. 2012). A message which is too contextual will be misunderstood by vast swaths of the audience. Some percentage of the audience will not draw the correct conclusions. Their interpretation of the message could result in unexpected responses and undesirable behavior. Hence, mass messages should be standardized for broad interpretation (Jensen et al. 2014). However, a message which is too generic will be unmemorable and unpersuasive. People are unmoved by abstract information (Calder et al. 1980). A message must convey an individually meaningful consequence or benefit or else the recipient would have no cause to react. People respond to information which is relevant to their frame of reference. Hence, it is difficult to create a powerful message which is universally interpreted across a wide audience.

The solution lies in mass customization. This is the concept of modifying something for each member in a targeted group (Adomavicius et al. 2005; Wind et al. 2001). With mass customization of communications, it is no longer necessary to send a single message to everyone. A core message can be modified to create dozens or even hundreds of variants. This enables a finer-grained match between individual and message (Allen et al. 2001). Each person can receive the message which is most appropriate for their personal frame of reference (Peracchio et al. 1998). In the era of big data, it is now possible to rapidly develop in-depth profiles for scores of individuals and programmatically select the best message for each person (Peppers et al. 1997; Wind et al. 2001). Contextual factors, such as background, interests, goals, abilities, income, demographics, geographic location, social status, education, and career can be intelligently factored into message selection (Moon 1999). To sum, mass customization allows for massive distribution of information which is made contextually relevant for each recipient.

Business and communications professionals are aware of this capability and are employing it within their own enterprises with great success (Simonson 2005). For instance, E-commerce companies use this concept to tailor their storefront according to the tastes of each visitor (Kim et al. 1997). Some US government agencies modify the contents of their webpages according to the interests of each visitor. Even the advertising copy in postal marketing campaigns is increasingly adjusted according to the data that the sender has on each address. Message contextualization is effective because it increases the personal relevance of the information (Moon 1999). It raises the specter that a person will be persuaded to follow the recommended actions (Koch et al. 2013). To sum, organizations increasingly rely on mass customization of their communications in order to effectively reach their audiences.

CONCEPTUAL DEVELOPMENT

Given the demonstrated effectiveness of message customization in other fields, it makes sense to apply this concept to fear appeals (Ruiter et al. 2014). Fear appeals work on the principle that people will follow a recommended precaution in order to mitigate the risk of a potential threat (Rogers 1975). Fear appeals which are personally relevant are more apt to be persuasive (Roskos‐Ewoldsen et al. 2004). They draw a closer link between the threat and the personal impact of the loss. For instance, telling someone that they are susceptible to a potential risk is not as effective as telling someone what they personally stand to lose if something bad happens (Barlow et al. 2013). The increase in contextual relevance creates a more salient threat and loss. In turn, this amplifies the possibility that the individual will follow the recommendations associated with the fear appeal (Moore et al. 1996). Hence, it makes sense to send each person the most contextually relevant fear appeal as possible.

A framework for selecting and delivering contextualized fear appeals is herein proposed. The framework is comprised of two parts: a front-end host-based agent and a back-end cloud-based service. A data pipeline connects the endpoints. An outline of this arrangement is depicted in Figure 2 (below).

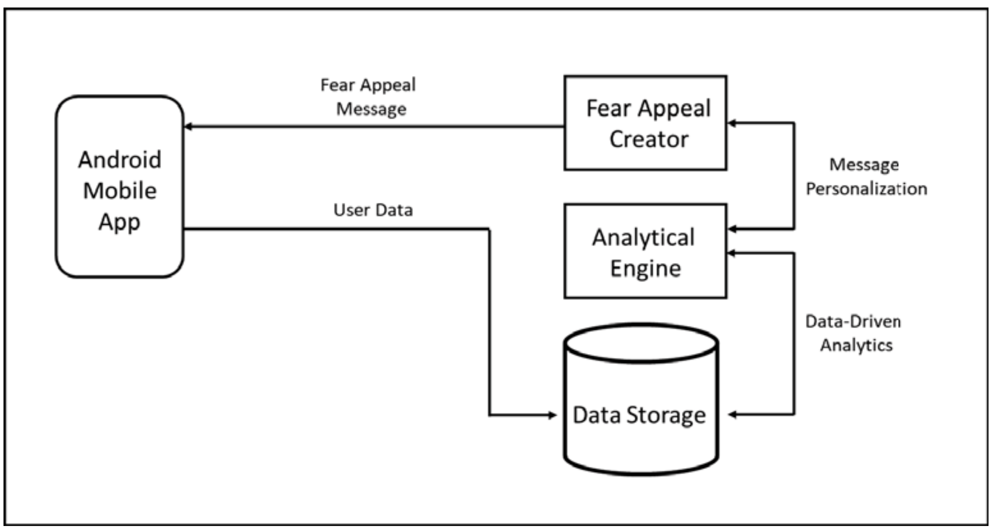

Figure 2. Proposed Framework

In general, the framework works as follows: the front-end collects data and sends it to the backend for analysis. The backend performs a number of analytical processes in order to gain insights into each individual. Individuals are sorted into one of many predetermined profiles using textual analysis, principal components analysis and Naïve Bayes classifiers. The pre-determined profiles are derived from marketing personas. Textual analysis is performed to transform string attributes into features which are amenable to quantitative analysis. Principal components analysis converts dozens of personal attributes into a smaller subset of independent features. The Naïve Bayes classifier assigns individuals to profiles based on the similarities between their principal components and the principal components associated with each profile. The front-end also observes the device's security and privacy posture. This information is also relayed to the backend. When it is time to deploy a new fear appeal the backend determines which users are susceptible to the potential security threat. Each individual in this subset is sent a fear appeal which is unique to the profile associated with their bin. The front-end displays the fear appeal and observes response behavior. The response is delivered to the backend for future analysis.

Based on the outcomes of studies in related fields, it is predicted that contextualizing the contents of fear appeals at the individual level will result in a higher rate of adoption of the associated recommendations (Adomavicius et al. 2005; Cöner 2003; Kim et al. 1997; Peppers et al. 1997). Further, it is expected that fear appeals contextualized for information security and privacy recommendations will be especially effective. It is assumed that individuals will be surprised to find out how much can be learned about them from a few pieces of unguarded information (Jensen et al. 2014). Thus, the following hypothesis is offered:

H_1: Individually contextualized fear appeals will be more effective than generic fear appeals.

EVALUATION

A small-scale experiment was performed in order to evaluate the efficacy of individually contextualized profiles. In general, the experiment was conducted as follows:

One hundred US-based subjects over the age of 18 were recruited via Amazon Mechanical Turk. An inducement of $2 US dollars was offered for fully participating in the experiment. Each subject was asked to install an app on their mobile phones. Those who complied with this requirement were randomly assigned to either a test group or a control group. A round-robin approach to group assignment was undertaken in order to assure equality of group size. Each subject entered a provided identification code into the mobile app. This identifier was relayed to the backend, which in turn linked the participant back to the tracking system within Mechanical Turk.

The proposed two-part framework was fully operationalized. The front-end consists of an Android Oreo-based application which performed the duties described in the previous section. The backend is instantiated as a series of micro-services within the Amazon AWS PaaS ecosystem. The service was built for the Ubuntu Linux operating system. In addition, a MongoDB NoSQL database was developed for data management. The front-end was coded in JAVA with Android libraries while the backend was constructed using python 3.7 and the Anaconda collection of machine learning libraries (e.g., Weka, pykit, scikit, pandas, etc.).

Once the experimental groups were fully formed, a notification was sent to each app to perform initial data collection. This data was pipelined to the back-end apparatus as WIFI permitted. From there a number of analytical processes were performed to assess device security and privacy settings, build user insights, and appropriately classify each individual. A security recommendation which would be applicable for all participants was then identified. The recommendation was to disable a feature in the Android Oreo operating system which defaulted to sharing user location when Bluetooth was also enabled. (Note: Following this experiment the principal investigator reported this bug to the Android team at Google, which subsequently issued a corrective patch.)

Those subjects in the control group received a standard fear appeal while those in the test group received a fear appeal which was contextualized to the profile they were associated with. A total of 25 a priori profiles were created. Accordingly, 25 different fear appeals were also created (one fear appeal was contextualized for each profile). The 46 subjects in the test group were binned into 18 profiles. Thus, 18 different fear appeals were used for the test group. The 45 members of the control group received a fear appeal which was designed to balance persuasiveness with broad applicability. The subjects received their fear appeals approximately 24 hours after they installed the mobile application.

After displaying the appropriate fear appeal, the front-end then polled the device settings and security settings every hour for 24 hours in order to determine if the subject complied with the recommendation. On success, the front-end sent a report to the backend to appraise it of the result. After 24 hours of polling the front-end released an alert message indicating that the experiment was over, and the subject could uninstall the app.

RESULTS

Following the experiment, the demographic data and test results were inputted into a spreadsheet for further analysis. The demographics indicate that the subjects skewed towards a younger age although gender was more evenly distributed. These data are illustrated in Table 1 (below). It should be noted that the previously developed profiles were defined in terms of 96 attributes. However, a principal components analysis was performed to transform the attributes into 7 principal components based on 40 significant features (Table 2). This preprocessing step is essential for ensuring the classifier's strong assumption of independence. The Naïve Bayesian classifier developed parameter estimates using a set of 111 training identities which were previously classified into 25 classes. The results of training indicated an 88.3% overall accuracy and a Kappa Statistic of .64. These results are further summarized in Table 3. The trained algorithm classified experimental subjects according to the probability that they belonged to a given profile. Subjects were sent the corresponding fear appeals and their behavior was noted. The effectiveness of the contextualized fear appeal is compared against the effectiveness of the standard fear appeal using a T-test of significant differences in adoption rate (Table 4). The results of the test support the hypothesis that contextualization provides a meaningful improvement in user response.

Table 4. t-Test of Significant Differences

IMPLICATIONS

This initial study was conducted on a small scale. Further, the proposed framework is limiting in that it is only considers one machine learning approach. A large-scale study would provide more definitive results while a variety of classification approaches would clarify the role of machine learning in message selection. These issues can be addressed in future research. Despite these issues, the present study clearly indicates that message contextualization provides a significant benefit over traditional, generalized messages. Fear appeals which are aligned with each individual's frame of reference present a more realistic threat than those which are crafted for a general audience. The next logical step in this research stream is to augment the proposed model by incorporating the role of behavioral response in follow-up messages. Continually refining user classification will allow for even closer matches between individuals and fear appeals.

CONCLUSIONS

Fear appeals are common tool for eliciting behavioral change. Within the information security research field, this topic has been well-explored. However, most of the research has centered on developing message for broad audiences. However, in the age of mass-customization people expect more relevant and tailored experiences. Hence, this study proposed a smarter framework for effecting behavioral change. It suggests a two-part approach to first building individual insights and then selecting and delivering the most relevant fear appeal to each individual. The proposed framework was evaluated using a small experiment. In this experiment the prevailing techniques were compared against the new framework in order to determine the relative effectiveness of contextualization. The results confirm that contextualized fear appeals are significantly more effective than generic fear appeals. This research represents an early first step in improving the effectiveness of fear appeals. Future research should build on this method by tailoring follow-up messages according to the responses of recipients.

How to Achieve a Seasoned Cybersecurity Workforce

Patricia A. McQuaid

ABSTRACT

Ransomware, phishing schemes, voting improprieties, and data breaches are increasingly challenging our infrastructure and privacy. We need to be positioned to fight off these cyberattacks and improve the quality of our security. But there is a severe shortage of cybersecurity workers in the United States that puts our digital privacy and infrastructure at risk. One of the big problems is in finding qualified people to fill these jobs. This paper discusses these issues and suggests a range of options to both attract new employees and keep those we have.

KEYWORDS: Cybersecurity, Workforce Development, National Initiative for Cybersecurity Education (NICE), Education, Training

INTRODUCTION

"Cybersecurity workers protect our most important and private information, from bank accounts to sensitive military communications" (Cyberseek, 2019). Cyberseek is a project that is supported by the National Initiative for Cybersecurity Education (NICE), a program of the National Institute of Standards and Technology (NIST) in the U.S. Department of Commerce. Among other important services, they have created an "interactive heat map" that provides a granular snapshot of demand and supply data for cybersecurity jobs at state and metro area levels, used to grasp the challenges and opportunities facing regional cybersecurity workforces (www.cyberseek.org/heatmap.html).

CYBERSECURITY SKILLS SHORTAGE

As of June 2019, in California Alone, there are more than 36,000 cybersecurity job openings, with more than 313,000 openings nationwide (Cyberseek, 2019). The data reflects the number of online job listings for cybersecurity-related positions from September 2017 through August 2018. We need to address the cybersecurity gaps identified by the current work shortage of cyber professionals, while preparing the public sector to defend itself against critical infrastructure attacks as identified by the Department of Homeland Security (DHS).

Mr. Jonas Prising, Chairman & CEO of ManpowerGroup emphasized the strategy of developing your own talent in an organization, in addition to hiring. He stated that, "With record talent shortages around the world, employers should shift their focus from just in time hiring strategies to becoming builders of talent for today and tomorrow. Developing the right blend of people, skills, processes and technology is the only way to execute your business strategy, create value and improve people's lives." (ManpowerGroup, 2018)

Reasons for the Shortage

So why is there such a shortage? There are several reasons for this problem, including that cybersecurity is a relatively new field. As a result, there is no current standardization on training or curriculum, although the NICE framework has done great work to address this issue (see below). Not only are there not enough programs to train people, there are not enough candidates applying. Part of the reason for that is that education is not started early enough.

Cyber awareness should begin in elementary school, not waiting for high school or college or trade school. There are a number of colleges that have cybersecurity programs, and many that are working with industry and government programs to give students practical experience before they graduate. There are also a number of cyber-related challenges and competitions for high-school students. One initiative that one of the authors is affiliated with is described in the reference, (McQuaid, et al, 2019)

<u>The Traditional Pathway Is Not Working</u>

Currently, women only make up 14% of the US cybersecurity workforce, so there needs to be an increased emphasis of training and hiring women. In the recent 2017 Global Information Security Workforce survey conducted by the Center for Cyber Safety and Education (Center, 2017), two thirds of the 20,000 respondents said they lack the number of cybersecurity personnel needed to combat today's threat. They also found that 30% of cybersecurity professionals have a background outside of IT, and that 33% of cybersecurity executives came from non-technical careers. So, we need to increase the number of cyber professionals and make people aware that they do not need to have a degree in computer science to be effective in the cybersecurity field.

<u>Other Reasons Why</u>

There is a shortage of qualified, seasoned professionals to teach or mentor. NICE stands for National Initiative for Cybersecurity Education, and the NICE Framework is "is a national focused resource that categorizes and describes cybersecurity work. The NICE Framework establishes a taxonomy and common lexicon that describes cybersecurity work and workers irrespective of where or for whom the work is performed. The NICE Framework is intended to be applied in the public, private, and academic sectors." Also, traditional computer science programs at postsecondary institutions align with only the Operate and Maintain category in the NICE Framework (NICE, 2019), while there are 6 other categories, as listed in Figure 1.

Figure 1: NICE Framework

Also, many traditional programs don't bring the soft skills (e.g., analysis, business knowledge, compliance & regulatory knowledge, ethics, some basic legal knowledge, troubleshooting, program management, general management, etc.) into their programs.

REASONS CYBERSECURITY WORKERS LEAVE THEIR JOBS

Using the David Letterman "Top 10" framework, below are the "Top 10" Reasons Cybersecurity Workers Leave Their Jobs (Figure 2). This list is based on an article written by Steve Morgan (Morgan, 2016), and also based on knowledge from the authors.

Figure 2: "Top 10"

#1 Reason for Leaving - They are Bored.

While there are numerous reasons for being bored, it is possible that they are mis-assigned for their Knowledge, Skills, and Abilities (KSAs) or they haven't received training, and/or they cannot stand doing their current job.

#2 Reason for Leaving - They feel Under Appreciated

We all know this one!

#3 Reason for Leaving - They feel Underpaid.

Oftentimes people think the grass is greener someplace else, so want to try something different. They may also be overestimating their own knowledge, skills, and abilities (KSAs). It could be that they really are underpaid, or think they are underpaid because they don't count their perks and retirement plans as their actual monthly compensation.

#4 Reason for Leaving - They Want to Switch Industries.

As Steve Morgan wrote, you might want more of a challenge in a different industry. He wrote, “If you're an experienced cyber pro working in a field that isn't a top hacker target, then maybe you should be.”

#5 Reason for Leaving - They Want Upward Mobility

Perhaps there is not room to progress upward in your organization, after all, there is only one CISO at a company. But you could create more of a career path for your employees.

#6 Reason for Leaving - Their Company has Lousy Security

Perhaps your current employer has their defenses down and they are practicing poor cybersecurity -- not allocating enough budget, not training employees on security awareness, not engaging senior management, and basically a sitting duck.

#7 Reason for Leaving - They Want to Master New Skills

Perhaps you are reading about IoT and mobile security, cyber forensics, automotive security, AI and other cutting-edge technologies that excite you -- but there's no clear path to get hands-on experience in those areas with your current employer.

#8 Reason for Leaving - They have a long commute

Perhaps your employees would like to work remotely, but policy prohibits it, or their work schedule is not flexible – making them commute at peak times.

#9 Reason for Leaving - They don't like or get along with their boss, co-workers, etc.

Enough said, there.

#10 Reason for Leaving - They won't say........

In conclusion, there are always a variety of factors that cause employees to want to change jobs, so if you want to retain your talent, be proactive and be sure to communicate with them and help them achieve their career goals.

So, How Do We Move Forward? Desire vs. Reality

Recognize that you already have people in your organization that want to move into cybersecurity and who have a talent for it. Be realistic about the talent in the marketplace and what your organization can acquire. Realize that you do not need the “perfect” cybersecurity person, and you might not find them nor be able to afford them. Instead, consider growing cybersecurity professionals and retain them.

“While cybersecurity education is maturing and improving at all levels, there is still work to do, including attracting young students to cybersecurity careers”, says David Shearer, CEO of

(ISC)[2] Inc., a global, not-for-profit that educates and certifies information security professionals throughout their careers (Collett-2, 2017).

Skills Needed Knowledge of Technology; Knowledge of Business

Cybersecurity is a hybrid of IT and business knowledge and skills. Someone can be good at Information Technology (IT) functions, but fail at cybersecurity. In terms of the knowledge of IT, it is best to have overall knowledge of all functions security touches, which is most areas of your business. It is important to learn how to work cooperatively within IT and which area to bring into security solutions or policy development sessions.

Having knowledge of how businesses operate is also a strength in a cyber-employee. For some job functions, it is good to have specific technical skill sets, but we also need people that have the breadth of knowledge. Having the ability to work well across the organization – not just within IT, is an asset. Knowing when to include parts of the organization and how to communicate across all realms in their own language can help improve overall security. Having basic business knowledge will give you an edge when talking to the program/business side of the organization. Let us not forget risk management, knowing how to identify and propose ways to mitigate risks.

Additional Factors

Using the full NICE Framework to align and standardize curriculum will help ensure students build the knowledge, skills and abilities needed.

It is very helpful to have a love for security. Do not select it just for the paycheck or because it pays more..., make it your passion!

Do you like puzzles and solving them? Good cybersecurity professionals have an “And then What?” inquisitive nature, and do not take things at face value. They have the ability to dig and piece the puzzle together – calling on things they may have seen weeks ago. You need ethics, along with some basic legal knowledge -to draw the line between White Hat vs Black Hat and what is Grey Hat.

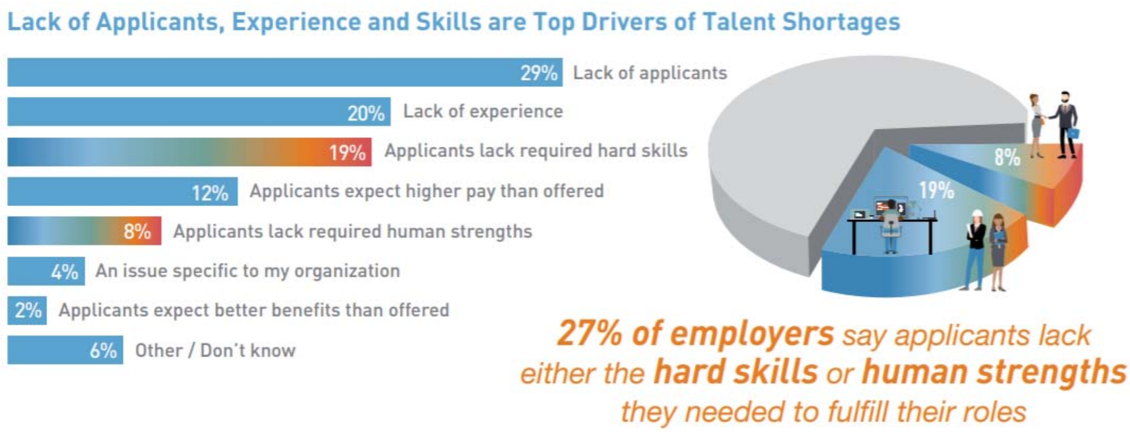
2018 MANPOWER REPORT, “SOLVING THE TALENT SHORTAGE”

In 2018, the Manpower Group issued a report entitled: “Manpower Report: Solving the Talent Shortage” (ManowerGroup, 2018). Below is are some of the key findings and a discussion of how we can apply the lessons learned to the cybersecurity industry. They found that the talent shortages have reached a 12-Year high and that the talent shortages are growing around the world.

Why Employers Can’t Find the Talent They Need

Nearly one-third of employers say the main reason they can't fill vacant positions is a lack of applicants. Another 20% say candidates lack the necessary experience. More reasons are detailed in Table 1 below.

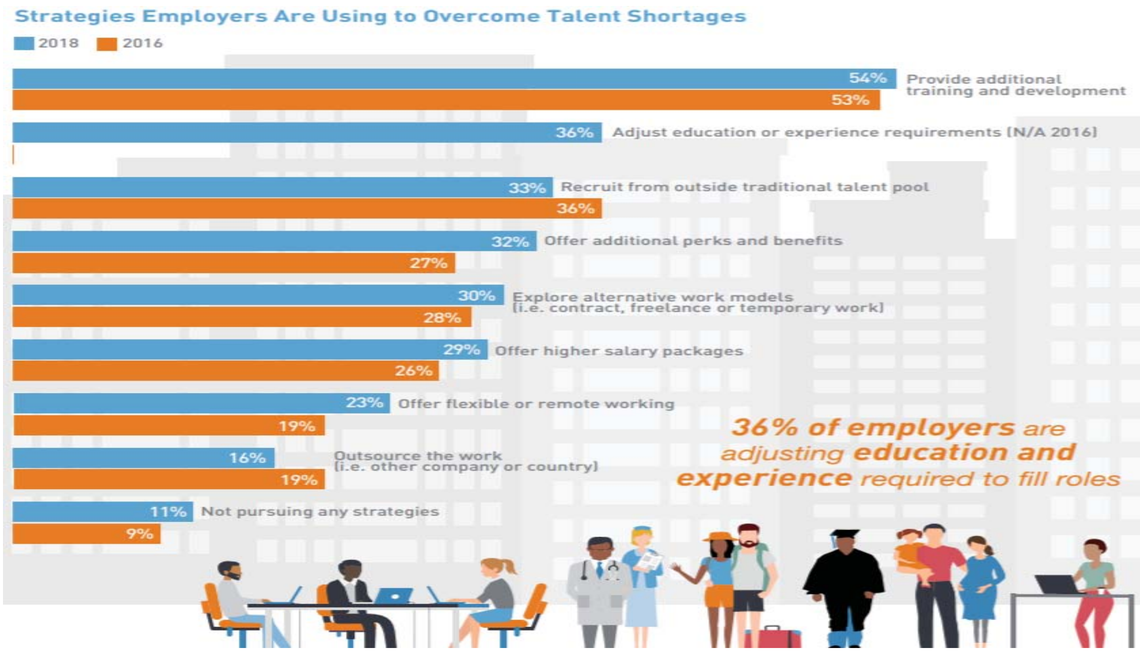
Table 1: Why Employers Can't Find the Talent They Need



The Talent Shortage Conundrum: What Employers Are Doing Today

Companies are beginning to tackle talent shortages by upskilling their own workforce: over half are investing in learning platforms and development tools to build their talent pipeline, up from just 20% in 2014. The data is listed in Table 2. This approach leads into the next section of this paper.

Table 2: Strategies Employers are Using to Overcome the Talent Shortage



Build, Buy, Borrow and Bridge: Overcoming Talent Shortages in the Future

The ManpowerGroup study emphasizes that employers are more active than ever in applying a mix of workforce strategies to address talent shortages. They have come up with a very interesting approach that can apply to many fields, suggesting that to win in the digital age an effective talent strategy should have four parts: build, buy, borrow and bridge. “Build your talent pipeline, buy skills where necessary, borrow from external talent sources and bridge people with adjacent skills from one role to another to complement existing skills.”

Build: Invest in learning and development to grow your talent pipeline.

There are several ways to build a cybersecurity team and deter them from leaving.
Put the Right Candidate in the Right Job. One way is to put the right candidate in the right job. Someone who has advanced skills will not be happy doing Account Provisioning, spending all day on Log Reviews or sitting in meetings – they will get bored and leave. Putting the wrong person in a job over their KSAs will make them frustrated, cause them to make errors, possibly create havoc or take down a network and put them on the Network Team’s and/or Management’s Most Hated or Useless List. And, instead of asking for help, they will find another job and leave.

Invest in them with training and create individual employee development plans. Do cross-training within the team with both hard and soft skilled members and mentor them. Include a budget for outside training and conferences, and allow time for webcasts and other video training during the workweek. Encourage staff to join professional organizations to find outside mentors and colleagues to learn from, and to always keep learning. Things change daily in cybersecurity; the day they quit learning is the day they should retire or move on.

Remember that you are building a workforce and not just a worker. Have senior team members or seasoned security pros (could be contractors) mentor others on the team and do knowledge transfers.

Michael Eisenberg, vice president in the Office of the CISO at Optiv Technologies, cautions that “You don’t want to bring somebody over [to a security role] if they don’t have an interest in security. It’s a different animal from IT”, he says (Collette-1, 2017).

<u>How to Find Cybersecurity Talent in Your Own Organization</u>

Ms. Stacy Collette has some suggestions for locating talent in your own organization (Collette-1, 2017). First, lower your expectations-look outside of traditional IT experience to fill cybersecurity roles. Also, be realistic of who your organization can actually attract; if you find the super qualified cybersecurity professional, you may not be able to afford them. Second, consider mid-and-later career-change employees. "There are many mid-and later-career IT pros who are not considered for redevelopment into cyber roles simply because they’ve been around too long”.

Mark Coleman, research director at Gartner indicates that organizations have become overly ambitious in their job descriptions that profile the ideal candidate, Coleman says. Companies must “free up your demands, talk to your HR department and unplug some of the requirements, such as [requiring] a degree in computer science or x number of years of information security experience,” Coleman says. Alternatively, “take a look at people in the process of achieving qualifications,” he says.

Another benefit -- “Those folks who want to make the jump can understand how their day-to-day responsibilities work right now, and how they can apply them to the security side”, says John Masserini, CISO at MIAX Options Exchange.

"There are many mid- and late-career IT pros who are not considered for redevelopment into cyber roles simply because they’ve been around too long,” Coleman says. In reality, their depth and breadth of experience could translate well into a security role.

You can also do mentoring or volunteering to grow your workforce. Yu can encourage and support coding clubs, youth hackathons and cyber challenges, and foster cybersecurity camps. A different building block could be to reach out to ex-military employment groups.

Buy: Acquire Talent.

Go to the external market to find the best talent that cannot be built in-house in the timeframe required. Consider hiring contractors to do the work or augment your staff. Be sure you require them to do knowledge transfer to your staff. You might also pay a little more to get seasoned talent. Additionally, you could invest in in-house and outside training. Be sure to choose appropriately to make sure it’s the right fit to keep an employee in place, and/or to grow them.

Borrow: Connect with Professional Groups.

Cultivate communities of talent outside of the organization, including part-time, freelance, contract and temporary workers to complement existing skills. There are numerous professional groups, such as (ISC)², ISACA, ISSA, WiCys, InfraGard, WITI, ASIS, and others...

Doing so allows your staff to connect with people who have other skill sets that can be called upon in a pinch or for mentorship. Professional groups are also a good way to remain current and to obtain Continuing Professional Education (CPEs) for their certifications.

Bridge: Create Professional Development Plans.

Help people move on and help them move up to new roles inside or outside of the organization. You can help to bridge the gap by creating professional development plans with your employee's input. You can set goals and training to grow them in their current jobs, and also for those roles they aspire to. You can utilize the NICE Framework to assist in making the plan step by step, and not an unrealistic leapfrog. You can encourage help them study and earn professional certifications.

CONCLUSIONS

It is imperative that we make some significant changes to our approach of training and hiring the cybersecurity workforce. We need to start cyber-awareness education much earlier in the lives of the upcoming workforce and cultivate an interest in cybersecurity among more than computer science students. Utilizing the NICE Framework to train, develop and hire cybersecurity professionals will most certainly help. And, we should all recognize that we may have more cyber-talent and resources in our organizations, than we might think!

ABSTRACT

Across business, Microsoft Excel has become an essential skill. For this reason, it is used in a variety of university courses. However, grading assignments in Excel can be tedious and time-consuming. Automation is a solution to this problem. This paper outlines a tool that automates the grading of these assignments.

KEYWORDS: Automation, Student Assessment, Microsoft Excel, Visual Basic for Applications (VBA), Macros

INTRODUCTION

According to a recent report by a labor market analysis firm, skills in Microsoft Excel are critical to accessing higher-paying jobs in the United States (Burning Glass Technologies, 2015). Employers are demanding these skills. In response, universities, and business schools in particular, are incorporating Excel into their courses and assignments. This is a positive change, but it requires unique, and sometimes more time-consuming grading methods. Automation can be a solution this problem.

Across business (not only manufacturing), automation has added value by removing humans from repetitive, mundane tasks and shifting them to more important, value-added activities. Automation can be used in academia to fulfill the same objectives. When automated grading is implemented, faculty members and teaching assistants can spend more time on improving the curriculum, coaching students, and conducting research.

With all of that being said, the main question that guides this work is as follows: *Can business departments at universities save time and resources by automating student grading of Microsoft Excel assignments while maintaining (or possibly improving) student satisfaction?* In order to make that determination, we developed an automated grading tool called EAGR, and data was collected from courses, where this tool was implemented, that includes (1) the time required to perform manual and automated grading, (2) the positive and negative effects of shifting to the automated method of grading, and (3) student satisfaction scores that were collected before and after the tool was implemented.

LITERATURE REVIEW

This experiment was not the first attempt to use automated tools to grade student assignments. Several studies have been documented on the topic. It is becoming increasingly popular as student-to-teacher ratios climb at universities across the world (Kovacic, 2012). Also, as online education becomes more popular, universities are looking to automation in order to scale their online programs (Geigle, 2016). Most of the tools and methodologies that have been developed and published were for classes in computer science or business management.

The objectives of previous studies varied. As an example, some sought to improve the quality and quantity of feedback that was provided to students (Matthews, 2012). Others sought to decrease the time required to grade assignments (Anglin, 2008). However, across those studies, several benefits were recognized: automation saves time (Anglin, 2008, Jones, 2001, Kovacic, 2012); automation allows grading to be consistent (Jones, 2001); automation enables fast feedback and more detailed feedback for the student (Kovacic, 2012, Matthews, 2012); and automation did not appear to negatively impact student satisfaction scores (Anglin, 2012). In general, it was noted that there is an upfront investment in migrating to automated grading methods, but that investment is paid off over several semesters (Jones, 2001). If class sizes are larger, the payback period is much shorter.

In our opinion, many of the solutions that have been developed are too technical and challenging to implement for an average user of Microsoft Excel. As an example, one solution requires the use several database tables in Microsoft Access in addition to worksheets in Microsoft Excel (Hill, 2003). The tool presented in this paper keeps everything in Microsoft Excel and does not require the transfer of data between software packages. Additionally, some of the solutions only automate a small number of grading steps or only reduce grading time by 50% (Anglin, 2008). Our solution is almost entirely automated, and when tested, it reduced grading time by more than 99%. Finally, with the solution documented in this paper, the upfront investment is minimal and can be paid back within the same semester in which the solution is implemented.

OVERVIEW OF THE MANUAL GRADING PROCESS

Before automation is discussed, we need a clear understanding of the steps required to manually grade assignments in Microsoft Excel. This will serve as a way to compare manual and automated methods. In a typical class, the process for manually grading an assignment that is submitted in Microsoft Excel might follow these steps:

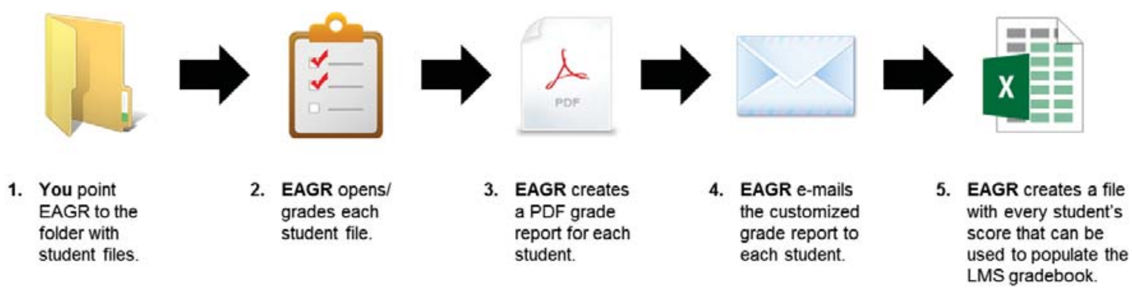
1. Download an individual student file.
2. Open the student file.
3. Evaluate each item in the rubric individually.
4. Compare student answers to the official answer key.
5. Capture feedback for the student about what was correct and incorrect.
6. Send that feedback to the student or upload it to the learning management system.
7. Add the student's grade to the learning management system.
8. Repeat steps 1-7 for each student file.

This is a time-consuming process with several mundane steps that are low-hanging fruit for automation. The solution discussed in this paper automates steps 2 through 6 above and eliminates step 8. Also, within the paper, in the “Results and Evidence” section, the time spent to manually grade assignments is compared to that of the automated method.

OVERVIEW OF THE AUTOMATED GRADING PROCESS

At Brigham Young University-Hawaii (BYUH), we programmed an automated grading tool in Microsoft Excel using the Visual Basic for Applications (VBA) programming language – called the *Excel Automated Grading Robot (EAGR)*. It automatically grades a batch of student assignments that are submitted in Microsoft Excel and e-mails students a customized grade report in a PDF format. EAGR also creates a spreadsheet for the professor that summarizes all student grades, which can be used to upload those grades to a learning management system. (At BYUH, we use Canvas.) Figure 1 below provides an overview of the solution. It has been used in the "Business Spreadsheets and Modeling Class" (BUSM 230), which is an online course required for all business students at Brigham Young University-Hawaii. Typically, there are about 175 students registered for the course in a given semester, and there are 8 assignments and 2 tests – all of which are completed by the student in Microsoft Excel. With EAGR, each of those assignments and tests can be graded in a matter of minutes. The data to demonstrate this is provided later in the paper. Even though EAGR was originally built for the BUSM 230 class, it is being tailored for other courses.

Figure 1: Overview of Automated Grading with EAGR



DETAIL BEHIND THE AUTOMATED SOLUTION

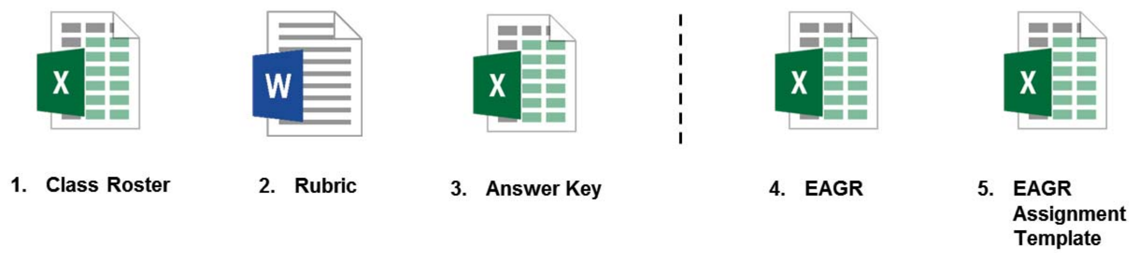
Technical Requirements

In order for EAGR to be used, the faculty member and/or teaching assistant must have a Windows PC, Microsoft Excel, Microsoft Outlook, and Adobe Acrobat. It may be possible to use other technical configurations, but that is outside of the scope of this paper.

Inputs

Additionally, several inputs are required before automated grading can be performed: (1) A class roster with student IDs, names, and e-mail addresses. This information should be gathered each semester from your learning management system. Then, (2) a rubric and (3) an answer key for the assignment. Finally, (4) the EAGR grading tool, which is a macro-enabled Microsoft Excel file and (5) the EAGR starter assignment template.

Figure 2: Inputs Required for Automated Grading with EAGR



Initial Setup

Prior to beginning the use of EAGR, the faculty member must complete the following steps: (1) Copy their rubric and paste it into the “GRADE” worksheet within the assignment template. (2) Create formulas to check whether each requirement from the rubric has been met. This can be done by comparing a student’s answer to the official answer key, which would be a hidden worksheet in the assignment template. (3) Enable restrictions within the learning management system, such as accepted file types, and the assignment template. The details of how to do so are in the “Implementation Tips” section later in this paper. These restrictions help to prevent grading errors. (4) Add student IDs, names, and e-mails to the “Student E-mails” worksheet.

Grading Process

Once the initial setup has been complete, you can begin using EAGR to grade assignments. To do so, the faculty member or teaching assistant performs the following steps: (1) Download all student files from the LMS; extract them, if they are compressed; and put them in an empty folder. (2) Open EAGR and click the “Grade Assignments” button. (3) When the first pop-up appears, select the folder where student files have been stored. On the second pop-up, enter the password used to protect the assignment file. At that point, EAGR will automatically grade the assignments and e-mail a customized grade report to each student. (4) After grading has completed, go to the folder where student files are stored and open the “Grade Spreadsheet” folder and select the “student_scores” file, which summarizes each student’s score. Use this data to update the LMS gradebook. (5) In the “student_scores” spreadsheet, address any errors that were identified in the “Errors” worksheet. (This usually occurs when students submit a different file type, such a Word document or PDF.)

Outputs

During the grading process, EAGR generates a few outputs: (1) a detailed grade report for each student in a PDF format (see Figure 2), (2) an e-mail to each student with their detailed grade report attached (see Figure 3), (3) a spreadsheet that summarizes all student grades and documents errors, if any occurred, and (4) folders that organize the student grade reports (PDFs) and the summary spreadsheet.

Figure 3: Student Grade Report (PDF)

GRADE REPORT

BUSM 230 - Module 2 - Intermediate Excel Skills

Problem Requirement	Score	
1. Correctly Sorted the "Sales" Column	0	out of 1.0 point
2. Correctly Calculated "Profit Margin"	0	out of 1.0 point
3. Added a Drop-Down Menu for "Order Method"	0	out of 1.0 point
4. Correctly Populated the "Region Manager" Column	0	out of 1.0 point
5. Formatted Appropriate Columns into Currency	0	out of 1.0 point
6. Correctly Created the "Orders Summary" Pivot	0	out of 1.5 points
7. Correctly Populated the "Returned?" Column	0	out of 1.5 points
Total	**0**	**out of 8.0 points**

Figure 4: Automated E-mail to Student

PDF [redacted].pdf

Aloha, Excel Ninja!

Attached is your grade report for a recent assignment. If you have questions about your grade, you can (1) review course lessons to identify where a mistake may have been made, (2) attend the lab and speak with the teaching assistant, or (3) visit me during office hours.

Assignment: 1 - Basic Excel Skills
Score: 5 out of 6.0 points

RESULTS AND EVIDENCE

Time Savings

The primary objective of automating grading was to save time and university resources. To assess the solution's ability to meet this objective, time tests were performed. For three assignments in the BUSM 230 class, we evaluated the time required to grade assignments using normal manual methods and the automated method (EAGR). The grading activities for which time was accounted include steps 2-6 in the "Overview of the Manual Grading Process" earlier in this paper.

Table 1: Grading Time – Manual vs Automated Methods

	# of Files	Manual Grading Time (MM:SS)	EAGR Grading Time (MM:SS)
Assignment 1 *("loans")*	30	04:01.0 per file	00:01.2 per file
Assignment 2 *("stocks")*	30	02:37.9 per file	00:01.5 per file

Assignment 3 *("goal seek")*	30	01:59.1 per file	00:01.1 per file
Average	--	02:52.3 per file	00:01.2 per file

These results show that EAGR can save considerable time and money, even with small class sizes. Those savings grow exponentially as class sizes increase. As an example, in our BUSM 230 class that had 175 students, given the average times above, manually grading an assignment would take 8 hours, 22 minutes, and 32 seconds. Using the automated grader (EAGR), it would take 3 minutes and 30 seconds

At this point, an important note should be made about the upfront investment to move an assignment to the automated grading method. It does take time and planning. However, manual methods have initial development and training time, too. For example, as teaching assistants leave the university, new resources need to be trained on grading methods and techniques. In our tests, the upfront investment with EAGR repaid itself many times over.

Student Outcomes

As part of our original research question, we wanted to determine if we could save time and resources by automating the grading of Microsoft Excel assignments, while still maintaining (or possibly improving) student satisfaction. After confirming time was saved, we evaluated student satisfaction scores before and after the semester in which EAGR was implemented in the BUSM 230 class. That data is available in Table 2 below. As context, during the Fall 2017 semester, manual grading was performed by the faculty member and teaching assistant. After that semester, EAGR was used to grade assignments. We included data for Winter 2018 and Spring 2018 as we assumed that some normalization was needed. Additionally, when students provide feedback on a course, they answer several questions using a scale from 0 to 7. Some of those questions deal with whether or not the students felt they were graded fairly and whether or not the feedback they received was timely and useful.

Table 2: Student Feedback Scores (BUSM 230)

Student Feedback Score	Fall 2017	Winter 2018	Spring 2018	Change
Overall Course Score	6.35	6.49	6.42	+0.07
"Fair in Grading"	6.34	6.39	6.61	+0.27
"Timely Feedback"	6.20	6.25	6.61	+0.41
"Useful Feedback"	6.22	6.08	6.56	+0.34

Based on these results, it is clear; student satisfaction was not negatively impacted by the shift to automated grading. Between Fall 2017 and Spring 2018, before and after the implementation of EAGR, each metric shown above improved, which was a promising sign.

ADDITIONAL BENEFITS

Beyond considerable savings of time and resources, EAGR provided additional benefits, which are documented below. In many cases, this confirmed outcomes from previous studies that were performed and are referenced in the literature review.

(1) More consistent grading. When manual grading is performed, especially by a teaching assistant, mistakes are inevitable. Two assignments that are exactly the same could be

assessed different scores. When automation is used, the grading operations are performed the same way each time. Everyone is treated fairly.

(2) More detailed grading. Sometimes, as faculty, we limit the items (or the scope of items) on our grading rubrics because we may not have time to conduct the necessary checks. This can be harmful to students. They may not have as much actionable information about how to address weaknesses in their skills. Based on our experience, students prefer detailed grade reports. They want to know exactly what they did wrong. Additionally, with more detailed information in their grade report, they tend to ask fewer clarifying questions about their score, which can be another source of time savings and increased student satisfaction.

(3) Shorter feedback cycles. When grading is automated, feedback can be given to students much quicker. We found that students appreciate this. Feedback on student performance is more valuable when the assignment is still fresh on their mind. If students have to wait days or weeks, they may not remember as much about the specifics of the assignment. Additionally, Matthews (2012) noted that feedback given to students – its quality, quantity, and speed – is an important key to unlocking student learning.

(4) Easier cheating detection. When using VBA in Microsoft Excel, several features about the file itself can be collected, such as the user and last update time. This metadata allows more cases of possible cheating to be identified, and when cheating is punished, students share this information with their classmates, which reduces instances of cheating.

RESULTS IN OTHER COURSES

In addition to being implemented in BUSM 230, EAGR was also tested in ACCT 312 (“Managerial Accounting”) at BYU-Hawaii. During this process, 30 student files were graded – using both manual and automated methods. Using manual grading, it took an average of 5 minutes and 22 seconds to grade each file. Using EAGR, it took an average of 1.2 seconds per file. As in other time trials in this experiment, those times included steps 2-6 in the “Overview of the Manual Grading Process” earlier in this paper.

As the tool was explored in other courses, it was found that the time and difficulty of transitioning to EAGR depends on the following: (1) the quality of your existing assignments, (2) the presence and quality of your rubrics, and (3) the types of grading checks you are performing. If you are only assessing students on whether or not they reached the correct answer – as opposed to validating all of their calculations – the transition will be faster and smoother.

IMPLEMENTATION TIPS

Based on experiences within the BUSM 230 class and other courses, the following implementation recommendations have been developed. Faculty members should consider these, if they seek to deploy the EAGR tool.

(1) Restrict file types. If possible, you should adjust the assignment settings within the learning management system to only allow Microsoft Excel files (i.e. the .xls or .xlsx file extensions). If not, over the course of time, you are likely to have Microsoft Word documents and PDF files

submitted -- whether intentional or not. Additionally, if possible, only allow one file to be submitted.

(2) Add data validation to the assignment template. To ensure proper grading and to avoid errors, when you are looking for a numeric answer, add data validation. For example, if "20" is the correct answer, you do not want the student to enter "20 widgets."

(3) Protect the workbook and each worksheet in the assignment template. Grading may fail, if a student alters the template, which inevitably occurs when students are given freedom to do so. For example, if you have a formula that looks for an answer in a certain cell and a student created a new worksheet to enter their answers, even if those answers are correct, they will not be given any points.

(4) Explain to students why it is important to use the assignment template and why there are protections in that file. At times, students get frustrated with limitations in the file. However, if you explain that, by doing so, you are able to give them more timely, more detailed, and more consistent feedback, most students understand and comply.

CONCLUSION & NEXT STEPS

This automated grading solution has already produced substantive results, but it is clear that it might not suit every course. Additionally, more work need to be done to improve the effectiveness of the solution. As such, next steps for this work include (1) improving the grading code and adding more capabilities to detect cheating and (2) incorporating feedback from other universities and faculty members to make their transition to the solution easier.

Business Process Redesign and the Learning Organization: Exploring Single and Double Loop Learning

Mary Helen Fagan
The University of Texas at Tyler
Email: mfagan@uttyler.edu

ABSTRACT

Business process redesign requires the reinvention of business processes to achieve transformational improvements. Individuals must re-examine their assumptions about how to best achieve the desired results in order to envision and implement innovative organizational processes. As a result, process design must include organizational learning in order to be effective. This study illustrates how single and double loop learning can occur by analyzing an example of business process redesign undertaken in a large retail organization. This organization's experience can provide useful insights for other organizations that are trying to do the same and for change agents who are facilitating such efforts.

KEYWORDS: Organizational learning, Learning organization, Business process redesign, Double loop learning

INTRODUCTION

There are many different ways that an organization can adapt and change. One of the most important approaches to bringing about organizational change involves viewing the organization from a process perspective, as opposed to taking a functional, divisional or product view (Davenport and Beer, 1995; Hammer, 2015). Both quality management and business process redesign take a process-oriented approach to organizational change. However, business process redesign differs from business process improvement in that it seeks to engage in a more radical rethinking of business processes in order to achieve transformational, not incremental, improvements (Davenport, 1993; Huang, Lee, Chiu, & Yen, 2015). Business process redesign involves individuals in a change program where they re-examine their assumptions about how to best achieve the desired results in order to envision and implement radically innovative organizational processes.

This article posits that business process design, in order to be effective, must include organizational learning. The objective of this article is to illustrate how single and double loop learning can occur by analyzing an example of business process redesign at FoodCo (a pseudonym). Lessons that were learned at FoodCo as they implemented and modified their version of business process redesign can provide useful insights for other organizations that are trying to do the same and for change agents who are facilitating such efforts.

This paper is organized as follows. First, conceptual background information is provided on business process redesign and organizational learning. Then the study's methodology is described. Next, the FoodCo case is presented, and its experience with business process design is analyzed in terms of the learning experiences it underwent. Finally, conclusions are drawn.

CONCEPTUAL BACKGROUND

Systems research documents the use of technology for the automation of existing functions. The traditional approach to systems development emphasizes a logical, structured problem-solving process and, in general, automates routine operations and does not seek to introduce radical changes to an organization:

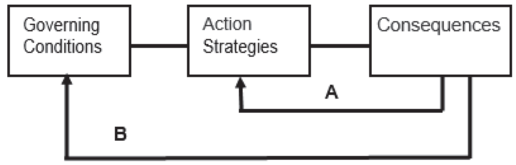
> "The organization is assumed to have a set of well-defined information processing problems which the MIS designer expertly analyzes. A rational decision-making process which examines alternative designs in terms of the goals of the system is followed to select the specific design. Implementation of this expert solution is then assumed to transform the organization immediately into a more effective state." (Bostrom and Heinen, 1977, p. 28).

The traditional systems development approach typically results in incremental improvements by speeding up processes through automation. Michael Hammer, one of the first proponents of business process reengineering, suggested that “heavy investments in information technology have delivered disappointing results - largely because companies tend to use technology to mechanize old ways of doing business. They leave the existing processes intact and use computers simply to speed them up" (Hammer, 1990, p. 104). In his work on business process redesign, Davenport (1993) contrasted the process improvement obtained by a traditional systems approach, which involves "performing work with slightly increased efficiency or effectiveness", with the objectives of process redesign, which involves "performing a work activity in a radically new way" (p. 10).

Some proponents of business process redesign suggest that organizations must radically change their business processes in order to survive in today's competitive environment (Vanwersch, Shahzad, Vanderfeesten, Vanhaecht, & Grefen, 2016). Setting aside the existing principles on which businesses processes are organized and endeavoring to “start from scratch” is one way organizations can work to achieve radical process redesign. When organizations seek to innovate in radically new ways, process redesign can be contrasted with traditional systems development approaches which have typically automated existing processes and resulted in incremental improvement. One author has called business process redesign "an organizational learning methodology that emphasizes a process view with its unique questioning: 'What do we do?' 'If we were doing it from scratch, how would we do it?'" (McGill and Slocum, 1994, p. 251). Organizational learning occurs, according to Argyris and Schon (1996), "when individuals within an organization experience a problematic situation and inquire into it on the organization's behalf. They experience a surprising mismatch between expected and actual results of action and respond to that mismatch through a process of thought and further action ... " (p. 16).

Argyris and Schon (1996) describe the two types of learning that can occur in organizations as single and double loop learning. Single loop learning is "instrumental learning that changes the strategies of action or assumptions underlying strategies in ways that leave the values of a theory of action unchanged" (Argyris and Schon, 1996, p. 20). In Figure 1, the loop labeled 'A' represents single loop learning. A double-loop learning process results in a "change in the values of the theory-in-use, as well as in its strategies and assumptions" (Argyris and Schon, 1996, p. 21). Together, the loops labeled 'A' and 'B' in Figure 1 represent the changes initiated by double loop learning.

Figure 1: Single and double loop learning



METHODS

This study takes a qualitative field study approach to studying a number of different business process management projects in one organization. The researcher was first involved as an observer and took a case study approach to studying the activities at FoodCo (Yin, 1994). Subsequently the researcher became a consultant to the business process redesign projects at FoodCo and eventually played the role of an active participant on a business process redesign team. The fact that the author participated in making decisions that would influence the success of the project and help to shape its direction meant any study coming from the author regarding these redesign activities could not consist of a typical case study where the author takes the role of a disinterested observer. Thus, an action research approach (Lau, 1999) the appropriate for the portion of the study involving process redesign. The data gathering process involved a combination of interviews, review of internal documentation and publicly available materials, and, when the researcher was involved as an active participant, materials gathered from internal project meetings and interactions with various vendors.

CASE DESCRIPTION

FoodCo is a vertically integrated food producer involved in the entire process of food production from growing the product to trucking the product to stores. FoodCo is a privately held firm with approximately 13,000 employees and $1.5 billion in revenue. The company has a culture that is highly focused on the key goals of efficiency and quality. FoodCo pursues their goal of increased efficiency through extensive measurement and management of details in all aspects of their operations. The slim profit margins in their segment of the industry mean that no wasted effort can be sustained in any area of the organization. This concern for costs is reflected in the fact that many individuals think of operational costs in terms of what percentage the costs constitute in terms of the cost per pound of the final product. For example, a manager might describe how his individual salary constitutes .xxx¾ of the cost per pound for the product. Their focus on measurement and efficiency is closely tied to the stress placed on quality. The commitment to quality starts with the chief executive and is mirrored throughout the organization. FoodCo has actively incorporated quality management into all of its operations through an intensive program of education, the articulation of the firm's Quality Improvement Process (QIP) and Error Cause Removal Process (ECR), and the cultivation of Corrective Action Teams (CAT's). The development of an organization that is focused on quality is a conscious, ongoing process at FoodCo.

The results of the twin focus on quality and efficiency can be readily seen in the changes that have taken place in the FoodCo Management Information Systems (MIS) department. The MIS department has shifted from a focus on application maintenance to a focus on determining the source of problems and redesigning processes to eliminate the root causes of ineffectiveness or inefficiency. A new relationship was developed with each functional area of the organization such that each group is treated as a customer of the MIS group, setting their own priorities and managing the development hours which they have been allocated and for which they are charged monthly. A set of critical success factors (CSFs) was defined for the MIS department which guide the activities of MIS associates and their organizational customers.

Business Process Redesign Activities

The MIS department took on the critical responsibility of introducing the concepts of business process redesign into the FoodCo organization. Characteristically, the introduction of process redesign at FoodCo was not the result of a top-down push from management. Instead, the initial introduction of process redesign concepts was in response to a dilemma that arose in the course of a typical MIS system development effort. This initial application of the process redesign approach was therefore appropriate to the problem, and, over time, the project was able to successfully demonstrate the utility of redesigning business processes in order to gain significant improvement at FoodCo.

The FoodCo Logistics organization was facing a changing business environment. To achieve their stated mission of providing quality transportation services that meet or exceed customer's requirements, they defined specific strategies that included reducing costs and providing a well-organized paperless environment. Key results areas and associated performance measures were defined for these strategies (e.g., improve tracking of trailers, reduce price of non-conformance, etc.). Analysis of the transportation area and dispatching, in particular, had identified a number of areas of potential improvement. Dispatch had three different tracking systems (board, paper, and computer) that made it difficult for areas within transportation to communicate with each other. Furthermore, the steep learning curve for dispatchers created a serious problem when there was staff turnover. A traditional systems analysis and design project had identified a number of ways in which technology could be used to improve and speed up the existing work flows. Data flow diagrams that depicted the existing system had been developed and 50% of the user requirements had been defined for a new system.

However, a number of serious questions arose in the process of completing the process of this traditional systems design effort. One key concern in the dispatch area was the potential for the current work load to double, creating an estimated 10,000 incoming phone calls per week. Even with a new automated system for dispatching, it was unclear how the proposed system design would deal with this increase in call volume without a corresponding increase in personnel. Furthermore, the proposed system design had a number of features designed to improve the ability to track trucks and trailers. However, in order to gather the needed data for the system, even more phone calls would be generated and a heavy data entry burden would be imposed on dispatchers. After the team reviewed these issues in light of their proposed design, the team determined that automation alone would not solve these problems and that a business process redesign effort was required.

Business process redesign would entail radically rethinking the dispatching and transportation business processes in order to achieve dramatic performance improvements. As a result of the redesign project, unnecessary activities would be eliminated and the remaining value-added activities would be simplified prior to the application of enabling information technologies. By communicating the vision for where the Logistics organization wanted to go in the future, the Logistics area's five-year strategic plan provided a context for the redesign effort. A consulting firm was engaged to help provide the needed expertise. The following steps were then undertaken.

Documenting the Current Process

As a result of prior system analysis, the dispatching employees were already expecting to get personal computers with planning software. The dispatching staff were very disappointed when this purchase was put on hold until the new business process redesign project was completed in an estimated four months. The participants' concern about this change in approach, combined with some frustration stemming from prior automation efforts, resulted in strong emotions as the project team began to document the current process. As one participant related, "it took almost an hour to decide where the load for a truck came from and to get the first symbol on the page". However, the team, which consisted of MIS staff and dispatching employees, started out with the understanding that the dispatching staff had to agree with each item or it would not be put down on the current process model. The full commitment of the Logistics organization and the development of a close-knit team enabled them to complete the task of understanding and documenting the dispatching process in detail. When the current process model was complete, the team identified non-value added activities such as inspection and rework, and began to identify and prioritize opportunities for improvement.

Conducting an Envisioning Workshop

With the organizational requirements from the Logistics strategic plan, the current process model analysis, and the knowledge of state-of-the-art techniques provided by external consultants, the team proceeded with the next step: to envision a world class transportation system. Three separate cross-functional teams met to develop ideas for the new process. The experience demonstrated how difficult it can be to think "out of the box", especially when one is concerned with obtaining management approval to proceed. As one participant related, "going into the visioning process, I thought radio frequency tags were the best solution we could achieve. Previously, the idea of using satellites had come up, but I thought there was no way it could be cost justified and approved. So, when we left the meeting with a decision to use satellites, I was very upset". The experience also pointed up the value of bringing in "outsiders" who provide a unique perspective on the problem.

Building a New Process Model

Although the costs seemed high, satellite tracking seemed to be the only approach that could address all the issues that had made process redesign necessary in the first place. Without the ability to address issues such as the increasing number of phone calls that would require the hiring of additional dispatchers, the project team would not be able to identify sufficient benefits to justify the system development effort. With the direction provided by the envisioning meeting, the team rapidly developed a future process model. Overall, the new process model was designed to: a) streamline the process, b) build in flexibility to adapt to a changing environment, c) incorporate an equipment tracking system, d) give the process the ability to grow and change as needed, and e) enable FoodCo to meet the needs of the marketplace.

Buy-in was generated as the system analysts discussed with each dispatcher how the future process design specifically addressed the items on their original issue list. The team identified nine projects and did a cost/benefit analysis for each. In a meeting with top management, their plan was approved. The team was directed to carry out an equipment tracking pilot project using satellite transponders to handle all tracking and check calls. The pilot was designed so that if there were any serious problems, they would surface in the pilot.

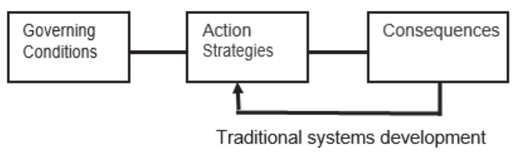
Institutionalizing Business Process Redesign

When the pilot equipment tracking project was completed, many of the desired benefits were realized. For example, dispatcher phone calls were reduced by approximately 30% and the ability to track and better utilize trailers resulted in a 7% reduction in trailer purchases. Dispatchers now have a better ability to make on-the-spot decisions with knowledge of the different trade-offs so that customer and organizational performance goals can be achieved. Changes to the transportation organization's work culture, organization and policy and procedures have been well-received. Approval to proceed with the full implementation of the new business processes in dispatching was given. Additional system development projects identified through the process redesign effort were initiated in the transportation organization.

DISCUSSION AND ANALYSIS

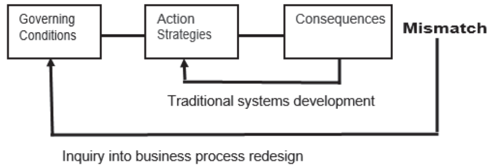
FoodCo used a traditional systems implementation process to identify and resolve problems in functional areas of the business. As shown in Figure 2, this activity, which is focused on a business problem, could be termed single loop learning since "the process enables the organization to carry on its present policies or achieve its objectives" (Argyris, 1977, p. 116).

Figure 2: Traditional systems development



However, in the case the dispatching organization at FoodCo, the MIS group found that the traditional systems analysis approach that they had used would not solve the problem situation that they encountered. Their analysis found that even if they installed an automated dispatching system, the anticipated increase in calls to dispatchers would not make the proposed systems solution approach cost effective. As shown in Figure 3, the fact that the normal systems analysis and design process would not result in an effective dispatching solution surprised the FoodCo employees, and the mismatch triggered a search for a new workable strategy. At this point, the organization was undertaking an inquiry, the type that occurs when a surprise/mismatch blocks the flow of spontaneous activity and gives rise to thought and further action aimed at re-establishing that flow" (Argyris and Schon, 1996, p. 11).

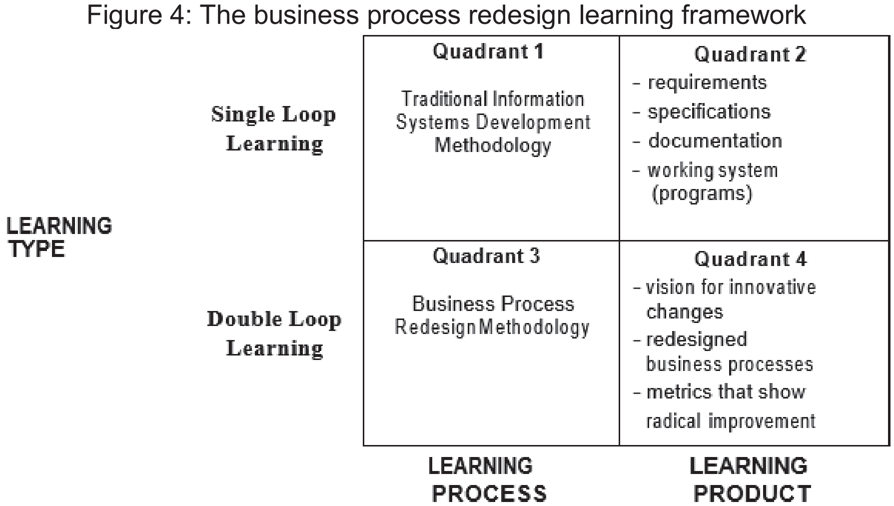
Figure 3: Inquiry into business process redesign



Until the team began to wrestle with the question - which had been unthinkable before - of whether their traditional systems implementation approach could resolve the dispatching problem, it was engaged in single loop learning. If FoodCo had uncovered a strategy for action that would have enabled it to resolve dispatching's systems dilemma within the framework of their established systems development methodology, that would have constituted single loop learning. However, since the governing values of the FoodCo organization favored incremental change (as evinced by their TQM program), the dispatching design team was initially at a loss as to how to proceed with a solution that would fit within the existing values and norms. When the inquiry led the dispatching design team to look to an external consultant to train them on business process redesign in order to achieve radical change, they were striving to change the governing values of the theory-in-use regarding systems change at FoodCo. This effort resulted in a double-loop learning process since the result was eventually a "change in the values of the theory-in-use, as well as in its strategies and assumptions" (Argyris and Schon, 1996, p. 21). When management agreed to the use of business processes redesign, they were espousing new values - an endorsement of intentional, radical, and risky organizational change.

A framework for analysis, derived from the work of Argyris and Schon (1996), can help further understanding of the organizational learning that occurred at FoodCo as they engaged in business process redesign. As discussed previously, Argyris and Schon define types of learning to be either single loop learning ("instrumental learning within a constant frame of values") or double loop learning ("learning to change the values that define 'improvement'") (1996, p. 4). Argyris and Schon (1996) also defined a generic schema of organizational learning that includes these items: "some information content, a learning product, a learning process which consists in acquiring, processing and storing information, and a learner" (p. 3). Combining the two types of learning (single and double loop) with two aspects of the generic schema of organizational learning (learning process and product) produces the framework for analysis shown in Figure 4.

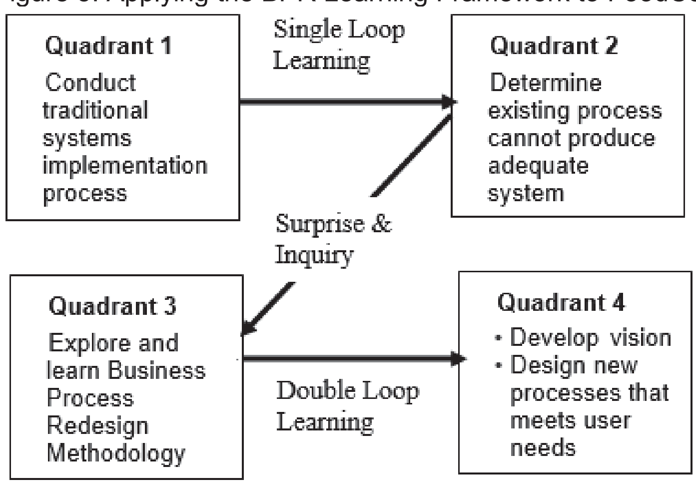
Figure 4: The business process redesign learning framework



From an overall perspective, the traditional systems development methodology can be seen as a learning process (quadrant 1) that produces a variety of information content/learning products (quadrant 2). At FoodCo the traditional systems development methodology was a well-understood process routinely used to automate existing operations. Within this framework, a business process redesign methodology/approach represents a learning process that should bring about double loop learning, a change in the values that define improvement from the incremental change associated with the traditional systems methodology to a new emphasis on innovative, radical improvements. Thus, quadrant 3 shows business process redesign methodology as a double loop learning process that produces a number of learning products (quadrant 4).

The following diagram (Figure 5) shows the process that took place at FoodCo in terms of the framework introduced in Figure 4. FoodCo was conducting a traditional systems implementation process (quadrant I) that could be termed single loop learning. When they determined that their existing methodology could not design a solution that would meet the users' requirements they could not produce the learning products associated with quadrant 2 (e.g., requirement documents leading to a working system). The surprise they encountered led to an inquiry process whereby they explored a new systems development approach, business process redesign.

Figure 5: Applying the BPR Learning Framework to FoodCo



The adoption of business process redesign constituted double loop learning since they were learning to change the values that defined improvement to include the risky, radical change called for by this new approach (quadrant 3). Business process redesign became the espoused theory-in-use for FoodCo for problems that appeared to require novel, innovative solutions outside the scope of the traditional systems development approach. These new values (e.g., of the importance of quantum, radical change) required a new way of carrying out the system analysis and design process. For example, employees who were exhorted to "think out of the box" in the dispatching envisioning workshop were engaging in a new strategy for problem solving. They were engaged in double loop learning related to instrumental business problem solving (quadrant 4). Indeed, without the urging of the consultant, some of the envisioning workshop participants would likely have selected a solution that they thought management would endorse (radio frequency networking) as opposed to the solution that was selected (satellite connections). When management accepted the risky and controversial satellite solution recommended by the dispatching team, it reinforced the espoused theory-in-use that it was OK to go for radical (and more risky) solutions. Thus, the teams search for dispatching solutions led them to rethink and adjust the governing conditions that affected system solutions at FoodCo. Business process redesign will require the ability to engage in double loop learning on an ongoing basis if teams are going to be able to challenge existing solutions and design innovative new processes, as opposed to falling back on tried and true traditional approaches to system development that simply automate existing processes.

FoodCo was able to engage in double loop learning and rethink the governing conditions that had guided systems/process change activities. Research in other organizations has indicated that activating double loop learning can lead to performance improvement (Jaaron & Backhouse, 2017). For FoodCo, which placed high value on efficiency and continuous, incremental change, it meant they had to be willing to experiment and learn a new radical and risky way of doing things. However, in order to successfully diffuse the new approach throughout the organization, teams engaged in actual business process redesign projects had to be able to continue to engage in double loop learning related to instrumental, functional business process issues. Argyris notes an organization is rarely "able to use double loop learning for its instrumental and policy issues if it cannot do so for the games and norms" (Argyris, 1977, p. 117). FoodCo was able to take the first steps toward this capability when it used double loop learning to adjust its norms (governing conditions) and then proceeded to engage in double loop learning in the dispatching business process redesign project itself. However, it remains to be seen if the development of FoodCo's own business process redesign methodology and the use of it in other projects will be sufficient to maintain this change and accommodate instrumental double loop learning on projects on an ongoing basis. Business process redesign requires identification of problems and a willingness to uncover unpleasant truths about how processes operate in order to envision a novel solution. If individual theories-in-use are geared toward avoiding embarrassment and blame, then it is unlikely that business process redesign will thrive even if it becomes an espoused organizational theory of action.

CONCLUSION

In the future, FoodCo must adapt to rapidly changing market conditions. Business processes will be continually examined in order to identify areas for improvement, and business process management is seen as key to FoodCo's future success. In some cases, process analysis will result in selected improvements in the existing work flows and incremental improvement in their efficiency and effectiveness (e.g., single loop learning). In other cases, business process redesign will be called for in order to implement a novel solution involving transformational learning on the part of process participants (e.g., double loop learning). Now, both adaptive learning from total quality management and transformative learning from business process redesign are part of the FoodCo culture, and the appropriate approach can be employed as needed. By incorporating process redesign tools and techniques along with the total quality management philosophy that pervaded the company, FoodCo positioned itself to undergo the continual learning that will be required for its ongoing success.

ABSTRACT

Blockchain, well-known as the Distributed Ledger Technology (DLT) behind cryptocurrencies such as Bitcoin, has attracted plenty of attention from both practitioners and academics and has begun to revolutionize the way businesses handle their day-to-day operations. In this study, we applied the systematic mapping method to review existing articles related to blockchain applications and research in different business areas (accounting, finance and banking, information systems, marketing, and supply chain). Following the recommended steps of the systematic mapping method, we extracted fifty primary papers from several scientific databases. Research gaps and future research directions are discussed.

KEYWORDS: Blockchain, Systematic Mapping Methods, Business Applications, Literature Review, Distributed Ledger Technology

INTRODUCTION

Blockchain is revolutionizing the way businesses handle their day-to-day operations. Most businesses rely on centralized transaction systems where the information is controlled by third-party organizations, instead of the specific entities involved in the transaction. Blockchain provides a decentralized platform where transactions can take place without the control and involvement of third parties. It is an open, distributed database where different participating computers (or nodes) validate the transaction which then gets added to a continuously growing list of the ledger (Iansiti & Karim, 2017). The validated information is available to every node, which adds to the transparency of the transactions conducted.

A main application of blockchain is cryptocurrency which eliminates the problem of double spending the same currency and increases the transaction security with the use of hash numbers, timestamp, and append-only decentralized system (Miraz & Ali, 2018). However, blockchain can be applied to different business sectors due to its security, reliability, transparency, traceability, inherent data provenance and immutability. Blockchain also creates new possibilities and applications in business.

Like other emerging technology in its nascent stage, blockchain has limitations that need to be addressed before having a major impact on business. For example, since nodes in the blockchain network can be anywhere in the world, complex jurisdictional issues may arise. In addition, every transaction requires peer-to-peer verification, which can become time-consuming with more data added. As a result, blockchain might be unsuitable for transactions where speed is of the essence.

Blockchain has received and is likely to continue receiving attention from researchers and practitioners. It is important to synthesize existing progress related to blockchain applications and research in business, in order to identify areas needed future attention. Specifically, this paper seeks to understand the following research questions: *What is the current status of blockchain research in business?*

Understanding the above research question helps researchers and practitioners develop an overall understanding of existing blockchain applications and research done by different disciplines and points out gaps that require more future attention. To address the research question, a systematic mapping study is conducted in which 50 articles about blockchain are extracted from scientific databases. Several research gaps are identified, and future research directions are pointed out.

The remaining of the paper is organized as follows. The research methodology used for literature review is introduced first. After that, figures showing the status of existing blockchain research in business are presented. The last section of the paper discusses the research gaps identified from our review and point out several future research directions.

RESEARCH METHODOLOGY

The systematic mapping method

The systematic mapping study as described by Petersen et al. (2008) was adopted to identify, review, and summarize relevant research papers. The systematic mapping method is appropriate for this paper because our goal is to identify and map existing research and application of blockchain in different business areas (i.e., accounting, finance and banking, information systems, marketing and supply chain) and to identify possible research gaps. The systematic mapping method as well as our application in this paper is summarized in Table 1.

Table 1 Summary of systematic mapping steps used in this paper

Steps	**The application in this study**
Defining research questions	Defined the research protocol and narrowed research questions down to the two research questions mentioned earlier.
Searching for relevant papers	Used search strings related to blockchain and business areas to search scientific databases including Springer Link, EBSCO, JSTOR, and ScienceDirect. The papers chosen mainly focused on peer-reviewed, high quality research that was published in books, journals, conferences, workshop, and symposium. 97 papers were initially identified.
Screening of papers	• The first stage of inclusion and exclusion was based on the relevance of the titles of the selected papers to our research questions; the following types of papers were excluded: papers in a language other than English, duplicate papers, and posters. After first stage screening, 60 papers were kept.

	• In the second stage of screening, abstracts were screened to see if they focused on blockchain in business areas to decide whether the papers could made to the next step. 10 papers were excluded because they focused mostly on the technical workings behind blockchain or did not provide any actual or clear research findings or evidence. This resulted in the selection of 50 paper, which were included in this study as primary papers.
Keywording	Read all 50 papers and identified the keywords and concepts related to different business areas to develop a higher-level understanding of the papers. After that, clusters and categories were formed for each of the business area based on the year of publication, publication type, source, and field.
Data extraction and mapping process	A data extraction form was created (Table 2) to collect the information needed to address our research questions. The extracted data were in excel to make it easy to organize and analyze the retrieved information.

Table 2. Data Extraction Items

Title	Title of the paper
Authors' name	Name of the author(s)
Publication information	Name of the publication place
Publication type	Conference, book, journal, working papers, thesis/dissertation, industry article/ magazines
Publication source	Industry or Academia
Abstract	Abstract of the selected paper
Study aim	Aim of the selected paper
Field	Business area(s) focused in the paper
Study findings	Major findings of the selected paper

RESEARCH FINDINGS AND DISCUSSION

RQ2: What is the current status of existing blockchain research in business?

In this section, we will first provide an overview of the selected papers, with a focus on publication date, publication source, publication types and the related business fields. We will elaborate on the current research status, research gaps and future research directions in the discussion section.

Figure 1 shows the distribution of selected papers by publication year. All selected papers were published after the year 2015. This reflects that Blockchain is a fairly new concept for research in Business. However, the papers that focused mainly on Bitcoin and technical working of blockchain date (which were excluded from this study) was published as early as 2012. When we pay closer attention to the publication year, we can see that out of all the selected papers, only 3 papers (6%) were published in 2015, 8 papers (16%) in 2016, 12 papers (24%) in 2017, 23 papers (46%) in 2018, and so far 4 papers (8%) in 2019 [The data for 2019 is only for the first 4 months and it is likely that more papers will be published before the end of the year]. This shows an upward trend with an increasing number of papers each year, which suggests that there is a growing interest in blockchain technology in different business areas.

Figure 1. Publication Year of Selected Papers

	2015	2016	2017	2018	2019
Total	3	8	12	23	4

Figure 2 provides a summary of the publication sources (academia or industry). Academic sources are the ones written by experts in the field for the audience who are familiar with the topic in order to make the research available to the scholarly world. Industry sources are the ones written by free-lance or scholars for the general population with little to no familiarity with the topic in order to provide general/ informative information about the topic. Our result showed that 40 papers (80%) were published by academic sources, 10 papers (20%) were published by industry sources. Please note that the results might be due to the tendency for scientific databases to not include industry papers.

Figure 2. Publication Source of Selected Papers

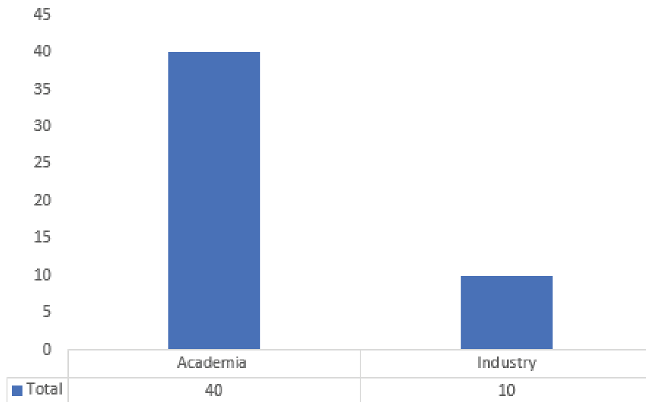

Figure 3 shows the different publication types (i.e., the channel where the paper is published, as listed in Table 2). Most of the papers were published in journals (52%) or industry article/magazine (20%). The other types include working paper (10%), book (6%), thesis/dissertation (6%), and conference proceedings (6%).

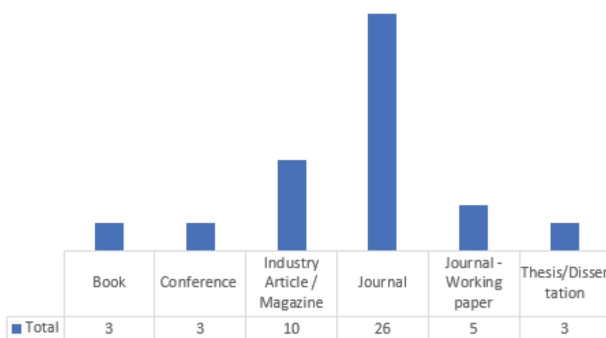
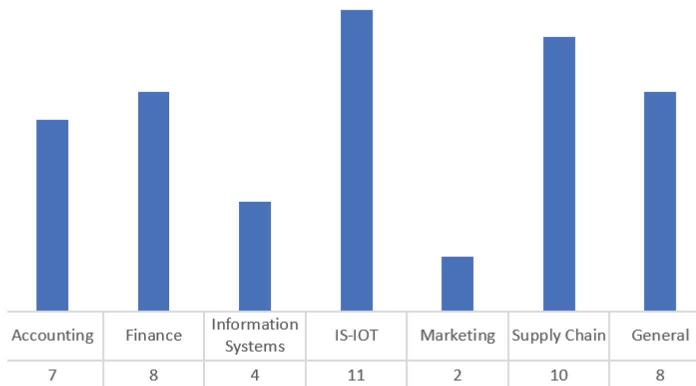
Figure 3. Publications Types of Selected Papers



The distribution of business fields related to selected papers is shown in Figure 4. The largest number of papers were published with the IS filed 15 papers (30%) with 11 papers focused on Internet of Thing (IoT), and supply chain with 10 papers (20%). The accounting field had 7 papers (14%), the finance field had 8 papers (16%), marketing had 2 papers (4%), and there were 8 papers (16%) that talked about the use of blockchain in general business setting.

Figure 4. Publications by Different Business Fields



DISCUSSION

Using the systematic mapping method, this paper seeks to understand the applications and existing research status related to blockchain in business areas (i.e., accounting, finance and banking, information systems, marketing and supply chain). Our study shows, first, that there are a number of journal articles on blockchain; in addition, there are quite a few industry articles and thesis/dissertation articles that focus on the application of blockchain in business areas. Most of these publications are made by academic (rather than industry) sources.

As to the distribution of papers across displaces in business, many research papers focuses on the application of blockchain in information systems (mainly IoT), followed by the application in the supply chain area. There are fewer research papers focusing on blockchain applications in accounting and finance and even fewer papers focusing on the marketing field.

As to the topics examined, supply chain research mainly focused on topics regarding the use of blockchain for supply chain sustainability, risk management, resilience, distributed data-driven application systems, and excipient supply chain. Information systems research, on the other hand, focused on topics of collaborative blockchain, operation management interface, proof of work, machine economy, and IoT dataset. Finance research mainly focused on topics such as financial blockchain technology, fintech, virtual currency, sustainable development, and banking industry transformation. Marketing research focused on the use of blockchain for programmatic marketing, data veracity, data-driven marketing, and consumer satisfaction. Finally, accounting research focused on blockchain accounting, triple-entry accounting, request network, real-time accounting, automated audit future accounting and assurance, and credit risk modeling.

RESEARCH GAPS AND FUTURE RESEARCH DIRECTIONS

One of the research gaps that we identify when conducting the review is the abundance of research papers on bitcoin and the relative lack of research focusing on the business areas, especially in the fields of marketing and accounting. Since both fields are likely to be heavily impacted by the implementation of blockchain, further research needs to be conducted. In addition, due to the complexity and fundamental changes that may be introduced by blockchain to different business fields, future research directions for blockchain in different business areas may be varied and it would be interesting to see where each business area is heading. Since the 2018 cryptocurrency crash, bitcoin's popularity has significantly declined. Academic and industry researchers are more interested in understanding the application of the fundamental technology behind blockchain from both business and technical perspectives. We believe that as more businesses start using blockchain in their day-to-day functioning, it will generate a significant amount of new research regarding the adoption of blockchain technology in different contexts. As the blockchain scope and user base increases, more attention needs to be paid to overcoming implementation limitations and challenges (e.g., the scalability issues) discussed earlier. The security and privacy issues would be especially important, as more and advanced attacks are likely to target the blockchain network with its increasing popularity.

The second research gap we identify is that most research focuses on blockchain application by companies (especially large companies). If the adopters were small-medium sized companies or teams or even individuals, would our existing understandings about blockchain hold or not? Accumulated knowledge in information systems indicate that factors affecting individual versus team versus organizational attitudes and behaviors (e.g., adoption) towards an innovation are likely to vary (e.g., Hwang 2005; Park, Lee, & Yi, 2011; Venkatesh et al 2013). Hence, future research should examine attitudes and behaviors towards blockchain at different levels of analysis.

The third research gap identified is that most of the current studies focused on the technical aspect of blockchain. The behavioral and regulatory aspects related to blockchain need more attention. For the behavioral aspects, researchers could study, for example, what factors (e.g., individual or organization or industry or cultural characteristics, blockchain characteristics, network externality) (e.g., Venkatesh et al 2003; Venkatesh and Zhang, 2010; Veiga et al 2001) influence the (initial and continued) (e.g., Bhattacherjee & Premkumar, 2004) adoption and implementation of blockchain? How the different concerns mentioned earlier (e.g., concerns for privacy) affect adopters' attitudes and behaviors towards blockchain? Does the blockchain technology exhibit the same bandwagon pattern as we have seen with other popular innovations (e.g., Abrahamson & Rosenkopf, 1993)?

In addition to the behavioral aspect, the regulatory aspect (i.e., industry or national regulations) also deserves more attention. For example, Chinese government imposes restrictions on the amount of money that individuals and companies could transfer to overseas. What kind of challenges would blockchain bring to such regulation? In addition, when disputes arise regarding transactions that happened on blockchain platform, what kind of authority (if any) could help to settle the dispute?

Finally, we noticed that the majority of blockchain applications in different business areas are still in the experimental or pilot phase. There is limited data published related to the success or failure of blockchain in different business fields. Future research should continue looking for such data. Also, researchers may examine market responses (e.g., stock market price change) to companies announcing the adoption and implementation of blockchain (e.g., Wang, 2010).

CONCLUSIONS

As an emerging and in-fashion technology, blockchain, a decentralized distributed ledger, where transactions are validated by the participating nodes and are visible to everyone on the network, has received quite some attention in academia and industry. Using the systematic mapping method and extracting 50 primary papers from various scientific databases, this paper conducts a systematic review to understand the applications and current research status related to blockchain in different business areas. Research gaps are identified, and future research directions are pointed out.

DECISION SCIENCES INSTITUTE

Supply Chain Workforce Training: Addressing the Digital Skills Gap

Abbas Foroughi
University of Southern Indiana
8600 University Blvd., Evansville, Indiana 47712
(812) 465-1667 | aforough@usi.edu

ABSTRACT

New digital technologies are transforming supply chains, enabling end-to-end transparency, precision in planning and forecasting, enhanced customer relationships, and efficiency and cost savings. However, many employees lack the skills needed to use these technologies. This paper addresses the need for supply chain employee training and identifies currently available sources of training, including non-profit supply chain organizations, supply chain consultant companies, MOOC providers, and Micromasters degrees offered by colleges and universities.

KEYWORDS: Supply Chain Management, Digitalization, Corporate Training

INTRODUCTION

In the global economy, in which companies around the world have far-flung supply chain suppliers and widely diverse customers with demands for highly customized, rapidly delivered products, supply chain management has become front and center in efforts to cut costs and provide excellent customer service (MHI and Deloitte, 2018, 2019). From its beginnings as a mere operational function that focused on production lines and delivery to customers, the supply chain has evolved into a management function of its own that focuses on sophisticated planning processes like analytical demand planning and integrated sales and operations planning and is a crucial part of modern digital business (McKinsey & Company, 2018). The stature of supply chain management has risen, and supply chain leaders are now included in corporate strategic decision making (Mussomelli, Gish, & Laaper, 2016).

As supply chains begin to exploit digital technologies, more and more supply chain leaders are realizing the benefits—and the necessity--of transforming their supply chains for the digital business world (MHI & Deloitte, 2019). Firms now use a wide variety of technologies in their supply chains to increase visibility and efficiency, analyze data, and maximize the strategic nature of decision making (MHI & Deloitte, 2018; McKinsey & Company, 2018; Alicke, Rachor & Seyfert, 2016; Deloitte Development, 2017; Ellis & Santagate, 2018; EYGM, Limited, 2016; Gezgin et al., 2017; Hansen & Malone, 2019; Stank, Scott & Hazen, 2018). To keep abreast of new technology advances, workforce development is needed to update employee skills (Berry & Mok, 2018).

Ed Miller, CEO of NovoEd, an online corporate learning platform, said,

> *"As we enter the next Industrial Revolution, with some jobs being automated and entire new job categories being created, CEOs expect their employees to build new skills in areas needed for the future workplace. These include both technical and human skills in areas such as cloud architecture and data science as well as innovation, design thinking, collaborative team building, and learning how to learn. We have found that while many of these skills were once developed in face to face classrooms, they can now be delivered at scale and with greater impact in a collaborative learning platform…"* (Meister, 2018).

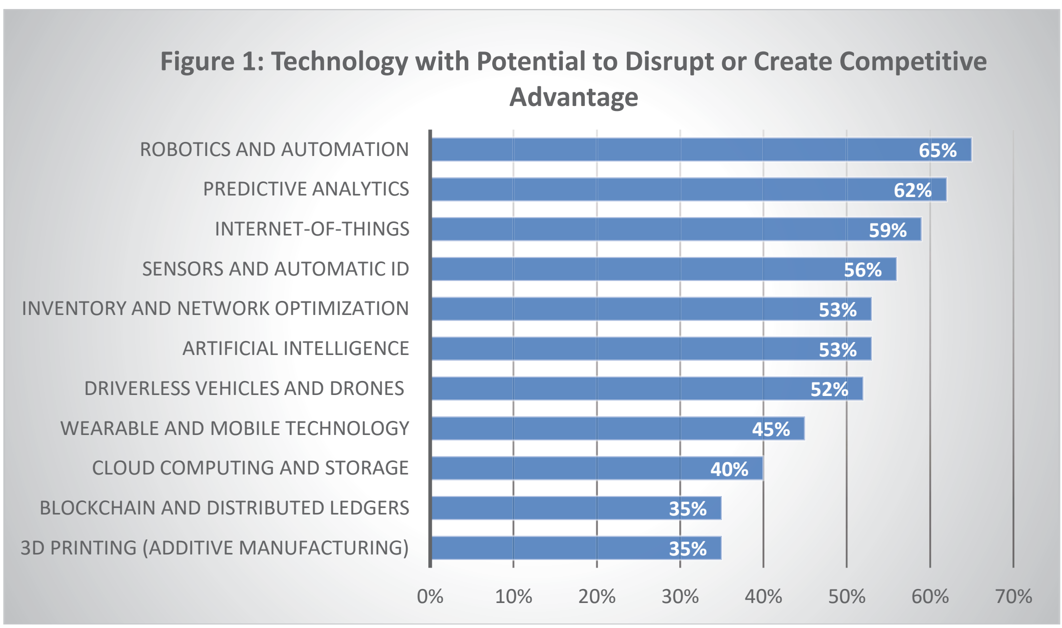
This paper explores digital technologies that are transforming supply chains, the need for skill upgrades and retraining, and sources of training that are available. In particular, answers are sought to the following questions:

1. What specific digital technologies are expected to have the greatest impact on supply chains?
2. What are currently available sources of the training needed to skill, reskill, and upskill supply chain employees to use these technologies?

The paper begins by describing the particular digital technologies that are transforming supply chains, followed by a discussion of the need for supply chain employee training, background on educational theories that are applicable in structuring workforce training, and results and insights about training options that are currently available for supply chain personnel.

DIGITAL TECHNOLOGIES THAT ARE TRANSFORMING SUPPLY CHAINS

New technologies are streamlining response times, cutting through complexity, reducing the assets needed to carry out operations—and transforming supply chains (Lyall, Mercier, & Gstettner, 2018). New sources of data and technological capabilities are enabling analytical decision-making and secure system interactions (Gezgin et al., 2017). Cognitive analytics, powered by AI and data captured through network automaton, can now do routine supply chain tasks, enabling employees to focus more on strategic and exceptional decisions. In a survey conducted for the MHI & Deloitte 2018 Annual Report (MHI and Deloitte, 2018), supply chain professionals identified the following eleven technologies as having potential to disrupt or create competitive advantage for supply chains (See Figure 1).



(Source: MHI & Deloitte, 2018, 5)

The following paragraphs describe the eleven technologies identified in Figure 1 and the role they play in digital supply chains.

Robotics and Automation

Robotics and automation are being employed for traditionally routine, manual tasks such as picking, packing, inspecting, classifying, and sorting orders; loading, unloading, and stacking; receiving and put-away; assembly operations; and processing such as welding, painting, and cutting (MHI & Deloitte, 2018; McKinsey & Company, 2018; Treblicock, 2018). This frees employees from dull, repetitive tasks in which mistakes can be made, and can operate round the clock. From automatic vehicles that could only travel along established pathways, robotics and automation now make it possible to use autonomous, self-driving vehicles that are equipped with sensors that provide information about the environment around them and can even work together to complete tasks (Alick, Rocher, & Seyfert, 2016; Treblicock, 2018; Deloitte Development, 2017; MHI &d Deloitte, 2018; Stank, Scott, & Hazen, 2018).

Predictive Analytics

Predictive analytics uses statistical models, data mining, and machine learning techniques to provide insights about data provided by digital supply chains and to identify the likelihood of future outcomes based on historical data. Predictive analytics uses big data, which are datasets of large size, high velocity (i.e., continuously growing via real or near-real time data acquisition), and variety (Ellis & Santagate, 2018). Big data are often unstructured and are derived from crowdsourcing, internet applications, direct from customers (i.e., point of sale, membership programs, etc.), and other sources. Models capture relationships among many factors to enable the assessment of risk or potential associated with a particular set of conditions. This is used to forecast consumer behaviors and risk, and also to gauge operations efficiency and maintenance needs (MHI & Deloitte, 2018) Businesses are using predictive analytics to maximize efficiency and predict anomalies across the IT infrastructure to prevent interruptions (Hanifan, Sharma, & Newberry, 2014).

The Internet of Things (IoT)

The Internet of Things refers to physical devices, vehicles, home appliances, and other items that are embedded with electronics, software, sensors, actuators, and network connectivity that enable them to connect and exchange data (Deloitte Development, 2017). Each object is uniquely identifiable through its embedded computing system and inter-operates within the internet infrastructure. IoT makes it possible to access or control remotely located objects across the network and creates opportunities for integration of the physical world into computer-based systems (Supply Chain Management Review, 2018). For supply chains, IoT is mostly used for real-time analytics, customer/market insights, customer and/or supplier collaboration, quality control, streamlined production, AI and machine learning, and cold chain temperature/humidity integrity (MHI & Deloitte, 2018; Lund et al, 2019; Supply Chain Management Review Staff, 2018; Stank, Scott, & Hazen, 2018).

Sensors and Automatic ID

Automatic sensory and identification technologies enable robots to sense, identify, and react to, other devices (Hanifan, Sharma, & Newberry, 2014; Lund et al, 2019). Radio Frequency Identification can identify a specific sensory-tagged item up to several meters away, without direct line-of-sight, and can also sense thousands of sensory-tagged items at the same time (Treblicock, 2018). Global Positioning Systems (GSPs) go even farther by identifying the exact location of tagged items. GPS receivers receive signals from GPS satellites that enable calculations of an object's position and time. Sensors on pallets track location, temperature, humidity, and tilt and shock (Hanifan, Sharma, & Newberry, 2014). Real-Time Locating Systems (RTLS), can identify and track the location of objects within a building or other enclosure, track products and supplies through an assembly line, and locate pallets in a warehouse. (Sainathan,

2018) Additionally, Bluetooth is now used as part of RTLS to track items, for indoor navigation, temperature track, and data generation. Bluetooth devices like smartphones can also monitor assets as they move around, and they send movement data to the supply chain cloud (Richardson, 2018).

Inventory and Network Optimization Tools

Inventory optimization tools can provide efficient and effective management of inventory throughout the supply chain, resulting in minimal cost for holding and storage (MHI and Deloitte, 2018; Excess stock level and shortage level are not static for every period, and inventory optimization's mathematical algorithms can determine the most probable excess stock level and shortage level. Inventory optimization tools can help a company achieve multi-echelon inventory optimization; cost-effective postponement strategies; stock keeping unit rationalization; optimization of all inventory components, including cycle stock, safety stock, raw material, work-in-process, and finished goods; strategic use of Vendor Managed Inventory (VMI); enhanced supplier intelligence for precise inventory planning and zero out-of-stock situations; demand forecasting and planning; and Just-in-Time (JIT) strategies (MHI & Deloitte, 2018; Stank, Scott, & Hazen, 2018).
Network optimization tools use mathematical modeling to reduce supply chain network complexities and improve responsiveness to customer needs by optimizing asset locations across the supply chain. Enterprise priorities and supply chain competencies in all areas of the supply chain network (sourcing, transportation, inventory, warehousing) are identified, prioritized, and mapped (Stank, Scott, & Hazen, 2018; EYGM, 2016). Network optimization makes supply chains more flexible, more efficient and more responsive to dynamic business scenarios and uncertainties, such as new product introductions, shifts in demand and consumption patterns, and changes in regulation. It enables companies to create accurate models of their end-to-end operations to identify major improvements in cost, service, sustainability and risk (MHI & Deloitte, 2018).

Artificial Intelligence (AI)

Artificial intelligence combines several types of other technologies in the simulation of human intelligence and the rapid solution of complex problems. AI can include machine and deep learning, reasoning, voice recognition, augmented reality, cognitive computing, natural language processing, and translation (Ellis & Santagate, 2018). These cognitive systems are adaptive, and they learn as information, goals, and requirements evolve, enabling them to resolve ambiguity and tolerate unpredictability; they interact easily with other processors, devices, and cloud services, as well as with people; and they are iterative, defining a problem by asking questions or finding additional source input if a problem statement is ambiguous or incomplete (Stank, Scott, & Hazen, 2018). They can also process multiple sources of information, including structured and unstructured digital information and sensory inputs (visual, gestural, auditory, or sensor-provided) to understand, identify, and extract meaning, syntax, time, location, appropriate domain, regulations, user's profile, process, tasks, and goals (MHI & Deloitte, 2017). AI technologies can enhance supply chain decision making, improve service elements, reduce cost, and shorten inventory turnarounds. In particular, AI technologies can improve demand prediction to better match supply with demand at lower cost, with less asset investment and with better response time; predict maintenance needs in manufacturing and transportation; check warehouse stocking levels to trigger re-orders; manage transportation mode and carrier selection by transaction; and manage and/or mitigate risk and disruption self-correction (MHI & Deloitte, 2017; Stank, Scott, & Hazen, 2018).

Driverless Vehicles and Drones

With enhanced vehicular sensor technology, driverless cars and trucks will be able to be more aware of their surroundings than is possible for human beings. They will be able to monitor a road continuously, judging the speed and distance of objects around them, and operating 24/7 (Wittemeier, 2017). This will necessitate the placement of logistics and service nodes along highways, so that trucks can notify an upcoming service station of their need for power/fuel, air for the tires, fluids or lubricants. Smart warehousing systems will direct the trucks to the correct inventory bay, where they will be unloaded by robot forklifts, while flying drones inspect and verify the load (Alicke, Rachor, & Seyfert, 2016; Wittemeier, 2017). Final Mile of delivery is already being performed by smaller vehicles or drones. Drones can fly up to 100 miles per hour and are faster than ground delivery, because they are not subject to traffic delays. They currently can only deliver limited-weight packages, but solutions to this are on the horizon. Additionally, it is possible that line-of-sight flying regulations may be lifted, making it possible for drones to fly and deliver packages in a wider span of locations (MHI & Deloitte, 2018; Treblicock, 2018).

Wearable and Mobile Technology

Factories are often very spacious venues. In the past, employees had to walk to and from stock to record/update data on stationery computers or to printout pallet labels, leaving a lot of room for error. Mobile devices now eliminate wasted “travel” time within a warehouse by enabling employees to input/update data and create and print labels right on the spot (Advantech, 2019). That real-time data is then available to everyone in the company, as well as to other outside stakeholders, such as supply and distribution partners. With mobile printers, workers can print out labels and reports on the spot, saving time and avoiding costly recording and reporting errors (Advantech, 2019). Wearable technologies are application-enabled computing devices, worn or attached to the body, that accept and process inputs from the Internet or from other devices. Workers equipped with wearable technology do not need to input information and can capture, hands-free, leads and sales updates via voice messages. Smart glasses graphically guide staff through the warehouse by virtual reality (Supply Chain 24/7, 2014; Michel, 2017; Van den Bossche, 2016). SmartWatch systems can enable managers to receive 24/7 emails, voice mails, text message, and notifications, giving them visibility into what is happening in their operations. Fitness bands can measure efficiency and ergonomics by tracking the steps required to complete particular operations. This information can be used to optimize storage locations to minimize the movements necessary to access and process inventory.They can also provide input about employee biometrics that identify activities that are overly stressful on employees, so that location adjustments can be made. Voice control headsets can also provide needed voice command updates and direct workers to issues or tasks (MHI & Deloitte, 2017).

Cloud Computing and Storage

Cloud computing and storage use a network of remote servers to access shared resources like data servers, storage, applications, and other services. The advantage offered by cloud computing and storage is that users can store and process data in a privately-owned cloud or a third-party server, making data readily accessible from anywhere. This has the effect of minimizing the cost of infrastructure and maintenance in information technology. Supply chain data stored on a cloud is available to anyone inside the company, as well as distributors and suppliers, so that all of the stakeholders can access the same accurate, real-time information (MHI & Deloitte, 2017; Alicke, Rachor, & Seyfert, 2016; MHI & Deloitte, 2017).

Blockchain and Distributed Ledger Technologies

Blockchain is a continuously growing list of digital records, like a spreadsheet of duplicated records that are linked, secured using cryptography, and continuously updated. There are thousands of duplicated records across networks, and they are public and easily verifiable. Blockchain can be used for transaction processing, records management, and other data-driven tasks. For supply chain clouds, blockchains can provide continuously updated and verified information from data inputs throughout the supply chain in shared ledgers that are available 24/7 to all enterprise stakeholders—internally and externally (MHI & Deloitte, 2018; Ellis & Santagate, 2018; Lund, et al., 2019; EYGM, 2016).

Additive Manufacturing

In additive manufacturing, structures are made by the addition of thousands of minuscule layers which combine to create a product. The process involves the use of a computer and special CAD software which can relay messages to the printer so it "prints" in the desired shape, one wafer-thin layer at a time. These layers are repeatedly printed on top of each other and are fused together during the process until the shape is complete. One of the greatest benefits is the greater range of shapes that can be produced, because. designs that can't be manufactured in one entire piece with traditional means can be created (Beyer, 2014). Additive manufacturing offers many advantages, including reduction in material inputs for leaner manufacturing, simplification and reduction in cost of production processes, lowered risk by providing a contingency plan, improvement in process flexibility and faster reaction to demand changes, and reduction in the cost of entry into new markets (Solel, 2018: Stank, Scott, & Hazen, 2018; MHI & Deloitte, 2018).

Workplace Transformation

The 2017 Gartner Workplace Survey predicts that digital technologies like those described above will transform the workplace of the future in a number of significant ways (Escherich & Jump, 2016; Hansen & Malone, 2019; World Economic Forum, 2018). Instead of having established roles within a company, groups of independent teams will be resized and reformed dynamically to facilitate the achievement of specific outcomes. Interestingly, as well as a good sign, a survey of high school students revealed that 4 out of 10 students prefer working for companies that encourage and support teamwork (Poitevin, 2016; Thurman, 2016). Algorithms will take over many managerial functions, functioning as "Robobosses" (Lee et al., 2015, 4; Cappelli, 2018), enabling fewer managers to oversee many workers in an optimized manner at a large scale (Lee et al., 2015; Poitevin et al., 2017). Upskilling and employee digital dexterity will be valued more than tenure and experience. "The Illiterate of the 21st century will not be those who cannot read and write, but those who cannot learn, unlearn and relearn" (Toffler, 1971, 414). The demand for employees with digital skills has already grown by 60% over several years, and this trend is expected to continue or even increase (Waller et al., 2017). Nonroutine work is expected to increase significantly by 2028, due to the growing automation of many routine jobs. (Autor & Price. 2013). Nonroutine work in the digital era, in which each day can present unexpected, dynamic issues and challenges, requires complex problem solving, effective teamwork, and digital dexterity. A conscientious habit of continuous, lifetime learning, as well as corporate support for it, will be necessary for employees to succeed in a challenging and evolving work environment like this (Manyuka et al., 2017; Griffin & Coleman, 2018).
It is also predicted that each employee will have at his/her disposal multiple smart machines, such as software, applications, avatars, artificial intelligence, and personal virtual assistants, which will be customized to suit each individual user's work needs (Buytebdijk, 2018). By 2018,

“robot resources” departments may become as common as Human Resource departments are today (Roth, 2018). Current high school students demonstrate a passion for volunteering in support of causes like education, health, social justice, and the environment (Thurman, 2016). They will bring the same commitments to the workplace and will view their jobs as more than just the opportunity to earn money. They will seek purpose in their professional lives and will support companies that have agendas for the causes that are important for them (Hurst, 2014; Hurst, 2017).

THE CRITICAL NEED FOR SUPPLY CHAIN EMPLOYEE TRAINING

At the same time that digital technologies like those described above are transforming supply chains and the workplace, employee expertise in mastering and using new technologies is more crucial than ever (Carnevakem, Smith & Strohl, 2014; Lund et al., 2018). It has been projected that by 2030, the work of approximately 375 million people, approximately 14% of workers worldwide, will be so disrupted by digital technologies that they will have to seek other types of work (McKinsey Global Institute, 2018; Berry & Mok, 2018). The following statement describes the need for workplace learning in general, and it applies to learning opportunities for supply chain employees, as well.

> “Leadership at all levels must embrace and require a continuous learning climate. Knowledge acquisition, sharing and dissemination across the organization must become a part of the day-to-day operations of the enterprise. The organization must provide an array of learning resources, tools, access and time devoted to gathering knowledge and using that knowledge to improve individuals as well as areas where it is needed in the organization” (Griffin & Coleman, 2018, 6-7).

The results of the *Industry 4.0 Paradox*, a survey conducted by Hanley & Holdowsky (2018), pointed out that, although strategic investment in digital supply chain efforts is critical, the supply chain is still not always recognized as a strong driver of innovation and transformation. As a result, the chief supply chain officer (CSCO) is often not included in digital investment decisions. There are signs, however, that this trend is changing--In 2004, only 8% of Fortune 500 companies had in place an executive in charge of the entire supply chain. By 2016, 68% of these companies had CSCOs (Mussomelli, Gish, & Laaper, 2016; O’Marah, 2016), indicating their recognition of the integral and vital role of supply chains in the achievement of digitalization.

For supply chain employers, in particular, the results of both the 2018 and 2019 MHI Annual Industry Reports, each of which surveyed more than one thousand manufacturing and supply chain leaders around the globe, identified the urgent need for a number of specific digital workforce skills (MHI & Deloitte, 2018; MHI & Deloitte, 2019).

Interestingly, the MHI Reports (2018; 2019) identified both technological skills as well as business, communication, and interpersonal skills, as important. The 2018 MHI report also noted that not all of these areas of expertise need to be possessed by one employee, but that they should be part of the collective expertise of a supply chain team (MHI and Deloitte, 2018). Although this current research recognizes the importance of business acumen, communication, and interpersonal skills, the current focus is technology skills needed by supply chain employees.

At the same time, supply chain managers have identified workforce challenges faced the most by supply chain managers (MHI & Deloittte, 2018). At the top of the list were finding (83%), hiring (76%), retaining talent (63%), and offering talented staff a compelling career progression (63%). Again, the need for training, uptraining, and retraining supply chain employees was underscored (Gexgin, et al., 2017; Lund et al., 2018; Lund et al, 2019; Stank, Scott, & Hazen, 2018; Alicke, Rachor, & Seyfert, 2016; MHI & Deloitte, 2017; Lyall, Mercier, & Gstettner, 2018). Similar results are reported in the 2019 Annual Industry Report (MHI and Deloitte, 2019), which also noted that companies in the early stages of digitalization are in a chicken-or-the-egg dilemma, in which they are aware that they seriously need digital supply chain talent, but cannot attract it because they have not yet adopted digitalization (Kane et al., 2016). The MHI 2019 report emphasized the importance of providing ongoing opportunities in the workplace for employees to develop digital skills; tying career growth to employee participation in training; using younger digitally-savvy employees to mentor older employees and assist in facilitating digital transformation; and establishing partnerships with STEM programs in universities that encourage the development of future employees with the skills companies need.

Competency-Based Learning and Social Learning

In the past, many companies provided employee training internally. However, the complexity of new technologies has often made it necessary to seek expertise outside the firm, from sources like non-profit supply chain professional organizations, consulting companies, MOOC providers, and online courses developed with universities. Workplace training programs increasingly use two pedagogical approaches—competency-based learning and social learning. With the mastery of specific skills in mind, competency-based learning is appropriate, because it can be used to define specific competencies or skills, and gives learners the flexibility to develop mastery of each competency or skill at their own pace and progress as they demonstrate mastery of academic content, regardless of time, place, or pace of learning (Exner, 2019). Competency-based learning emphasizes the customizability of content, according to the needs of the learner or a group of learners. Learners can develop a specific skill, for which they often receive a badge or other form of validated recognition. Such recognitions are often “stackable”, meaning that they can be combined to enable the learner to earn a full qualification, such as a certificate or diploma. Competency-based learning is increasingly delivered fully online, because many students taking such programs are already working or seeking work. Student engagement and outcomes improve, because the content is relevant to each student and tailored to their unique needs (Flesher & Carson, 2018). Currently, 41.7% of the most profitable companies in the world, in the Fortune 500, including Shell, Toyota, Paypal, and Booking.com, are using online tools for training (Wins, 29-019). Such solutions are helpful for training new employees and also help to make ongoing employee education both affordable and effective.
At the same time, social learning theory is very applicable for workplace learning, because it emphasizes the use of learning from others, mentorships, and online learning in place of formal learning methods like traditional curriculum-based education (Brown, 2017). With social learning, skill-building opportunities are relevant to specific employee needs, efficient, open, and accessible to all employees, while also offering them greater flexibility and control over their learning. Social learning also emphasizes how employees can learn from each other, either through participation in group learning activities or by observing others. Companies can create and maintain an atmosphere for ongoing learning, by rewarding employees who contribute to a culture of learning, creating corporate mentorship programs, and encouraging employees to connect, interact, and learn from each other. With platforms like Skype, Slack, Basecamp, and social media channels, employees can learn from each other by sharing informative content, links, ideas, and other information (BigThinkEdge, 2018).

Employee Training Preferences

Many firms are seeking a better understanding of the crucial need for employee skill development and of employee perceptions/preferences about workplace training (Coursera for Business survey, 2018). In winter, 2017, Coursera surveyed 750 managers and more than 1,000 employees about on-the-job training, yielding many valuable insights that can guide workplace education efforts. First, learning and development budgets are being increased, and

63% of those surveyed say that training available is now varied in content and variety. The greatest emphasis is on building a culture of continual learning (51%), followed by mentoring (45%), big data to analyze learning outcomes (35%), the use of virtual/augmented reality to improve training (33%), redesign of learning experiences (33%), new learning credentials (27%), gamification as a learning motivator (26%), artificial intelligence to guide employee development plans (24%), and the use of crowdsourcing content in learning (24%). Employers and employees agree that they both share responsibility for training—employers for providing it and employees for participating in it.

The survey continued by reporting that in the year to come (2018), 62% of employees plan to learn a new skill. Their reasons for wanting to learn are to improve performance in their current job (42%), build on existing skills in their current job (42%), learn skills for future jobs (36%), increase credibility and expertise (36%), stay up-to-date in industry (31%), feel more confident professionally (28%), learn new skills to complete a task (10%), and/or get a new job (9%). These employee motivators for seeking training were echoed in research by Egloffstein & Ifenthaler, 2016. Sixty-three percent of employees said that receiving high-quality training makes them more likely to continue to work for their current employer. Millennials, in particular, see training as an important perk in choosing a place of work. Hard skills receive more training funding (41%) over soft skills (23%), although employees rate soft skills higher. Training quality is valued the most (51%), over cost (29%), ease of implementation (22%), ability to assess employee learning (20%), and user friendliness (19%).

Only 48% of employees are satisfied with current learning experiences, and only 53% with the quality of learning content. Employees prefer content that is relevant and applicable (49%), learning that fits their schedule (32%), content that is valued by colleagues (28%), the ability to earn a valuable credential (23%), and lastly, content provided by the employer (20%). Sixty-five of employees say that lack of time is the number one obstacle to taking training, and 69% of employers agree. Employees prefer training that is 45 minutes or less in length, followed by 45-minute to 2-hour trainings, and then training that is half-day or longer. Employees also prefer more mobile training options, valued credentials, and online courses (as opposed to in-class training, studying training materials, attending conferences and webinars, and consulting co-workers and mentors). Employees (66%) show interest in certificates that can be earned quickly, and 76% of employers believe certificates are valuable.

It should be noted that the main tenets of competency-based training and social learning-based training—flexibility, online format, customized content, performance-focus, and recognitions—correspond closely to the employee workplace training preferences identified above in the Coursera survey. The following section evaluates sources of digital supply chain training and the extent to which they follow these training tenets.

SOURCES OF DIGITAL SUPPLY CHAIN SKILL TRAINING

An Internet search yielded a number of types of supply chain training options. These options fall into several general categories—professional supply chain organizations focused on certifications, supply chain consultants, MOOC providers, and university Micromasters programs.

In order to address the tenets of competency-based and social learning-based workplace training, and the employee preferences pointed out in the Coursera survey, the following criteria were used to evaluate supply chain training. The author began by choosing only those training programs that are available to complete online. Training providers who met this first criterion were included, and were subsequently evaluated according to the following: 1) supply chain content and/or digital technology content, 2) flexibility in terms of time frame and self-paced format, 3) customizable to the needs of particular employees or employee teams, and 4) credentials. It should be noted that training offered by corporations that focuses on the use of their specific products, such as Oracle, SAP, and IBM, were not included; nor were sites like Class Central, Udemy, Mooc-list.com, which are search engines for courses offered by other organizations and may include courses that are not validated. The supply chain training providers included in this study are described below.

Supply Chain Professional Organizations

Association for Supply Chain Management

The Association for Supply Chain Management (ASCM), formerly known as the American Production and Inventory Control Society (APICS), is the largest global nonprofit association for supply chain management, providing industry-leading APICS certifications and training (https://www.ascm.org/). Certifications include Certified in Production and Inventory Management (CPIM), the standard of professional competency in production and inventory management; Certified Supply Chain Professional (CSCP), which focuses on knowledge and organizational skills needed to develop streamlined operations; Supply Chain Operations Reference Professional (SCOR-P) Endorsement, which includes managing and measuring global supply chain performance using the SCOR model with the SCOR Professional program; and Certified in Logistics, Transportation and Distribution (CLTD), which focuses on -in-depth knowledge of a broad range of supply chain logistics topics. On-demand online courses are offered on Demand Management, Material Requirements Planning, Distribution and Logistics, Supply Chain Risk Management, and Inventory Accuracy. Individual employees or teams can study at their own pace, where and when it is convenient, thus avoiding the expense of off-site training and time away from work.

The Council of Supply Chain Management Professionals (CSCMP)

The CSCMP is a not-for-profit organization that works with academics and supply chain leaders to develop and offer degrees, certifications, and continuing education programs (https://cscmp.org/). In addition to SCPro™ Certification programs, CSCMP offers a variety of virtual and on-site educational options for supply chain professionals and organizations. An online Supply Chain Management Essentials (SCME) course covers supply chain management fundamentals, including supply chain planning, processes, and global operations. Self-paced Quick Courses are also taught via instructional web-based videos, each of which is 45-75 minutes in length.

The Institute of Supply Chain Management (IoSCM)

The IoSCM is a UK-based international organization and professional body that represents the interests of the supply chain industry (https://www.ioscm.com/).The organization encourages professional development, produces publications on supply chain management interests and offers accredited supply chain training courses and qualifications. The Institute of Supply Chain Management offers distance learning qualifications from entry level through to Senior strategic level to meet business and/or learner development requirements. Flexible distance learning packages enable students to adapt the course to study at their own pace and time. An easy to use online learning platform provides unlimited access to customized resources and course materials. Self-assessments, assignment preparation and tailored tutor feedback are available, as well as guidance and feedback from IoSCM's industry tutor team and individually assigned Student Support Liaisons. Students can connect with students and professionals across the globe, interact on forums, offer or receive peer support, and expand their network with IoSCM's online platforms. Accredited courses from levels 2 to 7 include Supply Chain Management, Manufacturing, Production and Planning, Logistics and Transport, Management and Leadership, Import and Export, Warehousing and Inventory, Ports and Shipping, Purchasing and Procurement, and Quality Management. Students can earn IOSCM awards, certificates, and diplomas.

The Institute for Supply Management® (ISM)

Institute for Supply Management® (ISM®) is the largest not-for-profit professional supply management organization worldwide (https://www.instituteforsupplymanagement.org/). ISM has over 50,000 members located in 100 countries. The ISM offers education, certification, leadership development and research, as well as ISM's Certified Professional in Supply Management (CPSM), and Certified Professional in Supplier Diversity (CPSD) designations. ISM features both self-paced and instructor-led online courses as well as short micro-learning videos that help supply management professionals master their craft. Each course focuses on specific competencies.

The ISM also maintains the ISM Mastery Model™, which includes 16 competencies and 69 sub-competencies that serve as an outline of the skills included in supply chain management. The sixteen competencies include business acumen, category management, corporate social responsibility, cost and price management, financial analysis, level, logistics management, negotiation, project management, quality management, risk, sale and operations, sourcing, supplier relationship management, supply chain planning, and systems capabilities and technology. For each competency, the skills needed at four levels (Essentials, Experienced, Leadership, and Executive) are detailed. The model was developed to guide supply chain professionals as they advance in their particular area of expertise. The competencies in the model are updated on a continuous basis to reflect trends and new developments in the supply chain field.

The ISM also maintains a list of institutions offering supply management-related degree programs, certificate programs, CPSM® review courses, and distance learning opportunities. Distance learning opportunities include courses offered via the Internet, video, satellite or other means. ISM’s Corporate Program addresses critical skills needed, delivered in flexible channels that can be adapted to meet the specific needs of an organization--category management, strategic sourcing, negotiating, supplier relationship management, contracting and legal aspects of procurement to risk management, strategy development and leadership.

Consulting Companies

Accenture

Accenture is a provider of supply chain management consulting and outsourcing services (https://www.accenture.com/us-en). Consulting courses include manufacturing and production management, purchasing and procurement, supply chain management, leadership and management, manufacturing and production management, purchasing and procurement, and supply chain management.

The Accenture Academy supports industry certifications provided by leading professional societies and provides an online study program to support the Certified in Production and Inventory Management (CPIM) review process and the Chartered Institute of Logistics and Transport (CILT) qualifications. Accenture Academy also offers an extensive, proven supply chain management curriculum, integrated with specialty and business management skills (in areas such as analytics, process excellence, project management, risk management, leadership and sustainability) that supply chain professionals must have to better partner with the business to achieve desired business outcomes. Courses are designed to help organizations achieve measurable business outcomes. Learning professionals work with organizations to keep learning plans aligned with changing strategies and business goals. Accenture Academy provides a supply chain management curriculum that is based on up-to-date functional competency models and job frameworks and is tailored to the goals of an organization and its employees. The academy assists in assessing an organization's current skills, analyzing skill gaps, and matching learning plans to those needs. The Accenture Academy's integrated supply chain management curriculum (https://www.accenture.com/us-en/service-supply-chain-operations) includes the following subject areas: Product Innovation and Lifecycle Management, Supply Chain Planning, Sourcing and Procurement, Manufacturing, Logistics, and Customer and Service Management.

Cognitive Class for Business

Cognitive Class, which is dedicated to addressing skills shortage in emerging technologies, is a source of courses on artificial intelligence (AI), machine learning, data science, blockchain, cloud computing, big data, analytics, and databases (https://cognitiveclass.ai/business/) The site offers a virtual lab in which students can practice what they learn. Customized learning paths can be tailored for specific training needs. Learners can earn digital badges, which can be shared as a recognizable form of achievement. Courses include Blockchain for Developers, Lightbend Reactive Architecture, Containers, microservices, Kubernetes, and Istio on the Cloud, Big Data with IBM, Applied Data Science with Python, Applied Data Science with R, Lightbend Reactive Architecture, Deep Learning, Text Analytics, Data Science Foundations, Big Data Fundamentals, Scala Programming for Data Science, Hadoop Fundamentals, Spark Fundamentals, Data Science for Business, Big Data Analytics, Hadoop Programming, Hadoop Administration, Hadoop Data Access, Data Management with IBM, and Cognitive Analytics with IBM.

Supply Chain Academy

The Supply Chain Academy is a Belgium-based consulting company that offers elearning courses on a variety of topics, including inventory control, demand planning, supply planning, order management, transportation, warehousing, manufacturing, procurement, legal issues, supply chain foundation, and project management (https://www.supplychain-academy.net/). The Supply Chain Academy combines best practice and current research to focus on competency development for corporations, providing supply chain course formats to meet an organization's specific objectives and challenges. Courses are scenario-based, using real life situations, and learners can work at their own pace. The academy also offers Virtual Application Labs, focused on implementing course content into practice, with focus on real-life implementation issues, knowledge development, and the analysis of theoretical concepts. Currently, 230 E-learning courses are available, covering nine supply chain competencies—supply chain basics, inventory control, supply planning, demand planning, transportation, order management, warehousing, manufacturing, procurement, legal issues, and digitalization and analytics in supply chains. Supply chain courses can be taken individually or in bundles, as Master Classes.

MOOC Courses

A growing trend is to facilitate employees in taking online MOOC (Massive, Open Online Courses) courses, some offered by universities and others through MOOC platform providers such as Cognitive Class, Coursera, edX, FutureLearn, iversity, NovoEd, and Udacity, MOOC courses are usually shorter than the usual university course and can be tailored to focus on a particular skill or technology which fits the needs of the company.

MOOCs (massive open online courses) were first developed by Canadian educators George Siemens (2005) and Stephen Downes (2008) as a way of implementing connectivist pedagogy, which views learning as totally learner-driven and consisting of the building of connections, with other people, information, and systems. In connectivism, learning is self-directed and not dependent on direction from a knowledgeable expert. This type of MOOC is mostly unstructured, with learners themselves creating a learning network as they share and build knowledge and connections. Connectivist MOOCs are often not associated with a particular university and are free and open to registration by anyone who cares to participate. A second major category of MOOCs is a type of mass enrollment course offered by major universities that features pre-taped lectures, a pre-defined body of topics to be covered, online quizzes, and other online assignments. Instructors at Stanford University held an xMOOC in 2011 and then formed Udacity, a for-profit company that provides a platform for xMOOCs. Coursera is another for-profit xMOOC platform that originated at Stanford. MIT and Harvard collaborated to form edX, an open source not-for-profit MOOC platform. Futurelearn works with a consortium of universities in the United Kingdom.
Recently, the MOOC concept has evolved into an alternative, viable pathway to education and training. MOOCs are no longer necessarily massive or open, and they now offer a number of types of credit/credentials for completion of courses. Credentialing can include verified certificates, completion certificates for all courses, college credit, learning pathways, specializations, and accredited degrees. These incentives have had a positive impact on course completion, an issue that has been proven to be a weakness of MOOCs in the past. With specific goals in mind, such as advancement at work, or upgrading undergraduate skills, students are more motivated to finish a MOOC course to earn the “carrot” of credit or credentials.

Coursera

Coursera is an online learning platform supported by Stanford professors that provides an online learning library in multiple subjects including sciences, marketing, engineering, and business (https://www.coursera.org/). The site currently offers over 2,000 courses and has more than 25 million registered users. Coursera offers 77 supply chain courses. Through Coursera, a student can take courses from instructors and universities around the world. Course certificates are given at the completion of a course. Specializations can be earned for mastery of a specific career skill. Professional certificates prepare students for passing an industry certification exam, Mastertrack™ certificates divides master’s degrees into online modules that can be used toward a full university master’s degree. Coursera for Business helps companies design a learning program for their employees, in topics like business, technology, leadership, social sciences, and health. Coursera offers a Specialization in Supply Chain Management that includes the following courses: Supply Chain Logistics, Supply Chain Operations, Supply Chain Planning, Supply Chain Sourcing, and Supply Chain Management Strategy.

edX

EdX, founded by Harvard University and MIT in 2012, is an online learning destination and MOOC provider that offers high-quality courses from 130 universities and institutions (https://www.edx.org/). Specializations include the MicroMasters program (standalone course or earn credit toward a Master’s Degree, Professional Certificates, and XSeries Programs (cutting-edge or in-demand fields), and XSeries Certificate programs, which offer recognition for the completion of a series of related MOOC courses, on the topics of Supply Chain Management, Education Technology and Aerodynamics.The MITx MicroMasters program in SCM program offers courses that include Supply Chain Analytics, Supply Chain Fundamentals, Supply Chain Design, Supply Chain Dynamics, and Supply Chain Technology and Systems.

FutureLearn

FutureLearn is a private company owned by UK's The Open University that offers courses from leading universities and cultural institutions from around the world that are accessible on mobile, tablet, and desktop (https://www.futurelearn.com/).FutureLearn for Business offers customized courses built around social learning pedagogy, creating collaborative online social learning where employees can learn from each other. Learning analytics can be used to track employee progress. Supply chain courses offered include Open Innovation, Business Futures: Understanding Omni-channel Retailing and Supply Chains, Farm to Fork: Sustainable Food Production in a Changing Environment, and Trust in Our Food: Understanding Food Supply Systems. FutureLearn courses are created by experts from leading universities and organizations. Learning can happen anytime, anywhere. Courses are customizable to fit specific organizational training needs. Online programs allow learners to deepen understanding of a subject and develop career relevant skills, with the chance to earn an academic or professional credential. FutureLearn Awards can be earned, which can include a professional or academic credential.

iversity

Iversity is a German-based online education platform that provides online courses and lectures in higher education, delivered through MOOCs (https://iversity.org/). iversity develops high-quality online courses in collaboration with corporate and academic experts, delivers them on a proprietary platform and distributes them to individual and corporate clients Students can choose between different study paths to earn certificates. iversity offers help to organizations in preparing customized courses for employees, with emphasis on the digital transformation of business. Ready-to-use online courses covering topics such as Agile Management, Predictive Analytics and Digital Marketing, can be used by companies. European Credit Transfer and Accumulation System (ECTS) credits can be earned by participants. iversity courses can be accessed anytime, anywhere, in an interative, online course community. iversity recently joined the brand portfolio of STEM publisher Springer Nature, to further enhance iversity's existing collaborations. Iversity's PRO courses help organizations prepare for the digital transformation of business. Companies can use a set of online courses on topics like Decent Work in Global Supply Chains, Critical Thinking, Predictive Analytics and Digital Marketing, or they can collaborate with iversity to create a customized, online course. Courses include Critical Thinking for Business, Presentation Skills for Business, Visual Thinking for Business, Digital Marketing – Strategies & Channels, Digital Marketing – Critical Success Factors, Predictive Analytics in Commerce, and Agile Management.

NovoEd

NovoEd, founded at Stanford University, specializes in social and collaborative learning for enterprises (https://www.novoed.com/). NovoEd's cloud-based learning platform creates and delivers global learning experiences to teach innovation and design thinking skills, and enhances learning through team-based projects, online team workspaces, social sharing and feedback, peer-to-peer feedback, and the design of customized platform content. NovoEd's philosophy is to advance the online learning experience by making courses more experiential, interactive, and collaborative. Students have access to lectures by leaders and professors from top universities and can also form teams with people around the world to work on class projects.

NovoEd also emphasizes the benefits of micro-learning, a type of learning with bite-sized and specific content, in answering the need for ad hoc learning from short and appealing content.

OpenLearn

OpenLearn is a free learning platform, delivered by The Open University, through which one thousand free courses are offered, featuring topical and interactive content, videos and online games (https://www.open.edu/openlearn/). Some OpenLearn courses carry a free digital badge, which is awarded in addition to a Statement of Participation. Courses are 24 hours in length and require learners to read every page of a course and pass compulsory online quizzes. OpenLearn offers numerous courses in supply chain, as well as the new digital technologies that are impacting supply chains--robotics, automation, predictive analytics, Internet of Things, sensors, automatic ID, inventory optimization, network optimization, artificial intelligence, driverless vehicles, wearable technology, mobile technology, cloud, blockchain, and 3-D printing.

Udacity

Udacity focuses on vocational courses for professionals, with emphasis on technology (https://www.udacity.com/). Most courses are free, but students can earn Nanodegrees, which are designed to build skills in a particular career area. Udacity partners with companies to develop a customized, end-to-end, managed solution to transform their workforce and build agility into the organization so they can operate at scale. Udacity offers nanodegree programs in critical areas where the need is high, and talent is hard to find. Udacity helps a company identify current levels of knowledge and generate custom learning paths for employees, which they can develop fluency and mastery on a timeline of the company's choosing. Employees learn and apply new techniques, analyze results, produce actionable insights, and build a dynamic portfolio of work. The Udacity for Enterprise program comes with an interactive dashboard (Enterprise Management Console), that allows administrators to manage employees, track course progress, perform bulk enrollments and more.

College and University MicroMasters Programs

A number of universities offer certificates in supply chain areas, some online and others on-site. The Institute of Supply Management maintains a database of universities that offer supply chain degrees, undergraduate and graduate, and certificates. in Supply Chain Management, Materials Management, Logistics, Operations, Purchasing, Contract Management, and Operations.These programs are not discussed here in detail, because most do not offer the ad hoc types of training that fit the needs of workplace learning.
Important exceptions to this are the MicroMasters programs offered on edX.org, which are very appropriate for workplace learning. MicroMasters programs have several major benefits for workplace learning—they are shorter in length than traditional Master's programs, they enable learners to engage in advanced study in an affordable and flexible manner, are career outcome-focused, recognized by top companies, affordable when compared to a standard master's degree program, and offer the flexibility of a self-paced program which workplace learners prefer (Gordon, 2018). The number of MicroMasters programs continues to grow, as it is recognized as a strong option for workplace skill development. Learners who successfully earn the MicroMasters Credential in Supply Chain Management are eligible to apply to a number of institutions across the globe to pursue a full Master's degree. MicroMasters can also be earned at Columbia University, University of Pennsylvania, Georgia Tech, Boston University, University of Michigan, UC San Diego, University System of Maryland, and Rochester Institute of

Technology (RIT) (https://www.edx.org/micromasters). In addition, the programs are offered at schools in other countries, including the University of British Columbia, Universitè Catholique de Louvain, and the University of Adelaide. MicroMasters programs are flexible and free to try, and they offer learners valuable knowledge to enhance their careers. Because these certificates are offered from prestigious universities, the programs are recognized by some of the top companies in the world, including Walmart, GE, IBM, Volvo, Bloomberg, Adobe, Fidelity Investments, Booz Allen Hamilton, Ford Motor Company, PricewaterhouseCoopers, and Equifax. MIT's MicroMasters in Supply Chain features five courses: Supply Chain Analytics, Supply Chain Fundamentals, Supply Chain Design, Supply Chain Dynamics, and Supply Chain Technology and Systems (https://scm.mit.edu/micromasters).

MicroMasters programs currently offered by several other schools have a strong focus on new technology skills areas—data science, artificial intelligence, Internet of Things, robotics—that are also important for supply chain professionals: MIT(Supply Chain Management; Data, Economics, and Development Policy), University of Maryland (Cloud Computing, Instructional Design and Technology, Bioinformatics, Software Testing, and Verification), University of Michigan (User Experience, Research and Design, Social Work, Leading Educational Innovation and Improvement), Columbia University (Business Analytics, Artificial Intelligence; UC San Diego, Data Science), Georgia Tech (Analytics: Essential Tools and Methods), University of Pennsylvania (Robotics), and Boston University (Digital Product Management) (https://www.edx.org/micromasters.)

AT&T's experience with skilling, reskilling, and retraining its employees provides a good example of a successful collaboration between a corporation, a supply chain training provider, and academia (Donovan & Benko, 2016). When AT&T moved to cloud services, it needed to upskill nearly 300,000 employees. Instead of searching for talent elsewhere, AT&T decided to retrain its employees. Human resources launched an online self-service platform, with tools and processes for performance management, career development, and talent planning. Udacity helped AT&T develop "nanodegree" programs to deliver training and certification in technical specialties like software engineering, coding, and web development. Nanodegrees can be completed in 6-12 months, at a cost of $200 a month for unlimited courses, and AT&T refunds tuition for all courses completed. Georgia Tech, Udacity, and AT&T collaborated on the development of an accredited online master's degree in computer science, which costs $6,600, compared to the $45,000 price of a campus-based program. The company offers up to $8,000 in annual tuition aid per employee for degrees and nanodegrees. Thousands of employees have earned nanodegrees and master's degrees. AT& T proved that a skills gap can be overcome by providing learning opportunities to employees that are flexible, relevant, and feature credentials, by using performance metrics to measure employees' achievements and value in the workplace, and by increasing financial compensation for employees with skills in high demand (Simon B, 2018).

DISCUSSION AND CONCLUSIONS

This paper has examined the current demand for rapid change in supply chains, due to new digital technologies being adopted that can transform a supply chain into a transparent, always-on, end-to-end intelligent network. Companies around the world are realizing the importance of supply chain in the digitalization of their enterprise and the benefits which this transformation can bring to them—end-to-end transparency, precision in planning and forecasting, tighter collaborations with suppliers and distributors, enhanced customer relationships, efficiency and cost savings, They also realize that none of this is possible without preparing employees for the new roles they will play in implementing a digital supply chain. Veteran employees have supply chain expertise built over years, understanding of the company and their particular function, and good business acumen. Newer employees grew up as digital natives who are more comfortable in learning and mastering new technologies, but lack knowledge and experience in the particular environment of an enterprise. Both veterans and novice workers need training to prepare them to use digital technologies to enhance the supply chain.

Fortunately, as this paper has shown, there are numerous sources of training that is customizable to each individual or team’s need. Employees can engage in training that begins where their knowledge and skills are and builds on this to bring them up to speed. All of the providers identified offer courses online, for both individuals and groups, with flexible start/finish parameters, credentials, and customizable formats. These course features are consistent with the employee preferences and the competency-based learning and social learning educational philosophies discussed above.

Table 1 shows the number of digital technology courses offered by each of the supply chain training providers included in this study.

Table 1: # of Digital Technology Courses Offered by Supply Chain Training Providers

Supply Chain Training Providers	Robotics/ Auto ID	Predictive Analytics	Internet of Things	Sensors/ Auto ID	Inventory Optimization/ Network	AI	Driver-less Vehicles	Wearable/ Mobile Tech	Cloud	Blockchain	3-D Printing

OpenLearn		6		yes	yes	
Udacity		28	yes	yes	yes	yes
Micro Masters	5	15	yes	yes	yes	yes

Four sources of supply chain training were identified in this paper. First, supply chain training is available from non-profit professional supply chain organizations, such as the Association for Supply Chain Management (ASCM), the Council of Supply Chain Management Professionals (CSCMP), the Institute of Supply Chain Management (IoSCM), and the Institute for Supply Management (ISM). These organizations provide supply chain training, much of which is geared toward certifications, but tend to concentrate on more traditional aspects of supply chain management. They do offer flexible, customizable, credentialed course opportunities, but their courses do not feature the digital technologies that are so vital in organizational digitization. These providers are best recommended for employees who want to achieve a particular type of certification.

The second category of supply chain training providers is the consulting company, such as Accenture, the Supply Chain Academy, and Cognitive Class. The offerings of these providers are mixed. Accenture offers the most courses on traditional supply chain content (232) and also 240 courses that cover digital supply chain technologies. The Supply Chain Academy offers 153 courses in supply chain content and nine courses in digital technologies. Cognitive Class offers only two supply chain content courses but 60 digital technology content courses.

The third category is MOOC courses, available from Coursera, edX, FutureLearn, iversity, NovoEd, OpenLearn, and Udacity, with a wide variation of training content. Coursera offers 61 courses with supply chain content and 937 courses with digital technology content. edX offers 38 courses with supply chain content and 488 with digital technology content. FutureLearn offers 12 supply chain courses and 56 digital technology courses. Iversity offers 2 supply chain courses and 4 digital technology courses. NovoEd offers 3 digital technology courses. OpenLearn offers 6 digital technology courses, and Udacity offers 28 digital technology courses.

The fourth category of supply chain training providers includes colleges and universities that offer certificates and other advanced degrees in supply chain areas. These programs were not discussed in detail in this paper, because they are mostly long-term programs and not directly suitable for workplace learning applications. An exception to this is the MicroMasters programs that were developed with edX.org, the nonprofit online learning destination founded by Harvard and MIT. MIT offers a five-course MicroMasters degree in Supply Chain Management, and other universities offer MicroMasters programs in a number of technology areas that are important for employees to master for digitalizing supply chains. The number of MicroMasters programs continues to grow, as it is recognized as a strong option for workplace skill development.

This study is unique in addressing the specific needs of an organizational function—supply chains—as it moves to being digital, and in presenting an overview of the workforce development options available for employee skilling, reskilling, and upskilling. The results of this study reveal that, although many sources of supply chain training exist, they do not all cover the digital skills that supply chain employees need going forward. However, since digitalization of supply chains is, for the most part, still in the beginning stages in many companies, it is highly likely that formal certification standards like those offered by professional supply chain organizations like the Supply Chain Management, the Council of Supply Chain Management Professionals, the Institute of Supply Chain Management, and the Institute for Supply Management will update their certification requirements to reflect mastery of the new technologies discussed in the paper. The same is true for supply chain consultants, MOOC providers, and MicroMasters programs, who, as corporations begin to demand more upgrades to address the digital skill needs of their employees, will offer more advanced technology courses and/or will integrate them into their supply chain course offerings.

The results of this study are, of course, limited by the fact that the number of supply chain training providers identified is not exhaustive and because the study examined training opportunities available at a particular point in time. Course offerings discussed will change over time, certification requirements will be updated, and new providers will appear. Future research will most certainly reveal even more training opportunities for supply chain professionals. However, this study has provided a sense of the severity of the employee skill gap facing corporations as they move to digitize their operations, including their supply chains. By identifying sources of supply chain training that are currently available to help bridge this serious skill shortage, the results can serve as a guide to enterprises moving toward supply chain digitalization.

Internet of Things and Artificial Intelligence for Smart Airports

Dothang Truong
Embry-Riddle Aeronautical University
Email: truongd@erau.edu

ABSTRACT

The Fourth Industrial Revolution, or Industry 4.0, promotes innovation and automation. In this new era, Internet of Things and Artificial Intelligence can drive the implementation of smart airports that will improve the airports' outcomes and productivity based on real-time and situation-specific conditions. The objective of this research is to propose a framework for implementing an Internet of Things based Artificial Intelligence (ITAI) system for smart airports and a research process for identifying and mitigating potential risks associated with ITAI implementation along with critical success factors.

KEYWORDS: Internet of Things, Artificial Intelligence, smart airport, innovation, machine learning, deep learning

INTRODUCTION

The Fourth Industrial Revolution, or Industry 4.0, promotes innovation and automation, in which machines are getting more advanced in predicting, learning, and managing themselves. In this new era, Internet of Things and Artificial Intelligence have driven the world to a new level of networked connection of people, systems, and smart products. They become the main drivers for innovation and automation to improve outcomes and productivity. Among public sectors, airports have a substantial contribution to economic growth. According to the FAA (2017), airports contributed $76 billion in total output to the U.S. economy in 2014. Airports maintain communications and interactions within their own internal operations, and among themselves, the airlines, and the passengers and guests who arrive and depart. Airports have numerous facilities and components that can be connected, but the number of components and parties involved often creates difficulties in ensuring safe and effective operations and providing satisfactory customer services. Industry 4.0 provides technological capabilities to create smart airports. There is no consensus definition of a smart airport in the current literature. Zmud et al. (2018) describe a connected airport as a system using a "variety of technologies through the Internet of Things, with the goal of improving the passenger experience and bringing monetary benefits to the host airport." Smart airports are more than just connected airports. Essentially, a smart airport is a system that uses an Artificial Intelligence platform to collect and analyze real-time data in a connected airport ecosystem and automatically solves airport business problems through generating optimal solutions in a real-time manner to enhance the safety and security, operational optimization, environmental sustainability, and financing solutions of the airport. In a smart airport, manual processing and human interventions are minimized to avoid human errors and delays and ensure the automation or airport safety and efficiency.

Internet of Things and Artificial Intelligence are critical components of a smart airport. Internet of Things is the third wave of information-technology-driven competition and promises more innovation, productivity gain, and economic growth (Porter & Heppelmann, 2014). The *Internet of Things* (IoT) is defined as “an infrastructure of interconnected objects, people, systems, and information resources together with intelligent services to allow them to process information of the physical and the virtual world and react.” (ISO, 2015). The IoT is characterized by monitoring capability (monitoring a product’s condition, operation, and external environment through sensors and external data sources), control capability (controlling through remote commands of algorithms built into the device or in the cloud), optimization capability (optimizing the performance through data analytics to improve output, utilization, and efficiency), and autonomy capability (incorporating autonomous product operation and enhancement, self-coordination, and self-diagnosis and service) (Porter & Heppelmann, 2014). An IoT system can create automatic and smart communications among objects, people, and systems, and IoT devices collect data in real-time and store them in the cloud.

The rapid growth of Artificial Intelligence (AI) creates a perfect combination with the IoT to enhance the automation. A combination of AI and IoT is a prerequisite for success in IoT-based digital ecosystems (Hwang, 2019). AI can be defined as a system that simulates human intelligence for either solving a problem or making a decision (Chouwdhury & Sadek, 2012). AI can learn, predict, improve, and solve. Through training, an AI application is able to generate optimal solutions and apply them to novel situations not encountered before. Thus, AI can process a large amount of data provided by IoT devices to make a prediction and automatically produce an optimal solution and even take actions. An *Internet of Things based Artificial Intelligence (ITAI)* system can be defined as a system that senses, monitors, connects, controls multiple components, and processes the data to automatically produce an optimal solution and take actions to solve business problems.

An ITAI system can enhance innovation and automation in airport ecosystems to create smart airports by connecting airport components, passengers, and stakeholders in a synchronized system. In this system, machine learning algorithms can be used to analyze data to detect unknown patterns, based on which ITAI can automatically produce solutions to solve business problems and take actions. Such a smart system allows airports to maintain safe operations at the highest level of effectiveness and, at the same time, provide passengers with satisfactory services. In order to implement this system successfully, an operational framework is needed. The current literature on applications of IoT and AI in airport research seems to focus on the use of a specific IoT device for a specific task rather than a comprehensive framework that shows the linkage between IoT devices, data storage, machine learning, and AI applications. Such a framework is needed to enable airport authorities to develop, deploy, and implement ITAI to enhance airport safety and operations.

Despite its advantages, ITAI is not without challenges. Airports need to meet strict technical, process, and managerial requirements to be able to successfully implement the ITAI. The biggest challenges are to connect all components and store a very large amount of data, deal with the complexity of interconnecting multiple components and data sources, and process big data with the aging infrastructure. Additionally, the ITAI is often considered a black box, which may pose some serious threats, such as technical (system and application failures), security, and privacy risks (Lykou et al., 2018). The risks may cause serious issues for airports, such as system failure, unavailable customer services, cyber-attacks, security vulnerabilities, and identity thefts. Airport executives need to gain sufficient understanding of the ITAI’s applications and components, implementation processes, and requirements. They must also learn about potential risks associated with ITAI implementation and know how to manage and mitigate these risks, so they can successfully implement the ITAI while ensuring the security and privacy of the airport and passengers.

The objective of this research is twofold: 1) to propose a framework for implementing ITAI for airports, including steps and requirements; 2) to propose a research process for identifying and mitigating potential risks associated with ITAI implementation at airports along with critical success factors.

LITERATURE REVIEW

IoT Studies for Airports

Despite the rapid growth of IoT in industries, IoT research studies in the airport environment are very limited. Cao et al. (2013) proposed a design for airport perimeter security system based on the IoT. The authors described the features and applicability of the airport perimeter security system using IoT. The authors conclude that IoT sensors provide a novel, low-cost, low maintenance choice to improve the capability to detect, locate, and classify intruders at airports. Wang et al. (2013) conducted a field survey that adopted IoT-based emergency monitoring and warning models to estimate the disaster losses and to prevent a secondary disaster from occurring. The authors used relative displacement sensing technology and Global System for Mobile Communications (GSM) technology to remotely monitor ground cracks in the landslide. Troiano and Pasero (2014) developed sensors to detect the presence of ice or water on the airport surface. They did experiments both in a laboratory and in the field to evaluate the repeatability, stability, and reliability of the sensor. Three sensors were embedded in the runway to check the state of the surface. Each sensor was connected to a GPRS modem to allow the data to be collected and stored. The state of the runway surface based on the collected data from the sensors is virtually represented the IoT features. Finally, Liu and Lu (2015) developed a perimeter intrusion detection system (PIDS) using sensors that detect illegal intrusion to an airport. The PIDS can accurately detect an intrusion, identify the type of intrusion, locate the intrusion target, and reduce false alarms due to unexpected interference. The PIDS has been successfully deployed and implemented by Shanghai Pudong International Airport. While these studies provide some interesting designs and applications of IoT systems for airports, they mainly focus on developing single systems using IoT sensors at airports. They lack the holistic view of airport systems and how AI can be used to support airport safety and effectiveness.

In order to determine the changes that airports need to make in a new era, Robinson (2017) explores the opportunities and challenges faced by airport authorities. The author indicates that the new digital age presents “the opportunity to not only reinvent the travel experience but also to develop solutions that result in cost-effective capital expenditure and optimize existing infrastructure.” The main challenge to the adoption on a global scale is the non-uniformity of the solutions. While digital solutions can be developed at an airport-by-airport level, the global air travel system will require strong collaborative initiatives across airports and stakeholders in different countries. In a more recent study, Zmud et al. (2018) developed a primer for airport operators and stakeholders in the Internet of things (IoT) within the airport environment. The authors described airport systems as a whole consisting of multiple connected components inside and outside of its boundaries. Additionally, the study described IoT enabling technologies that can be used for airports and obstacles to the implementation of connected devices and data sharing. The study also examined the passenger experience with IoT solutions at Atlanta International Airport (ATL), San Francisco International Airport (FSO) and Dallas Fort Worth International Airport (DFW).

Overall, the literature in IoT for airports seems to focus mainly on using a specific IoT device to accomplish a specific task, and the focus on a connected airport ecosystem is missing. As stated by Robinson (2017) and Zmud (2018), airport is a complex system consisting of multiple components that are connected to passengers and stakeholders. However, these studies are conducted at the conceptual levels and have not explored the role of AI in IoT systems for smart airports. A more comprehensive and robust system should be used at airports to take advantage of IoT and AI capabilities in the Industry 4.0 era. ITAI is a system that can automatically collect data, predict, learn, and generate solutions to help airport authorities solve business problems with minimal human intervention. Given the important role of this system for developing and deploying smart airports, further exploration and investigation are required.

IoT Components and Process

The objectives of IoT are to connect objects through smart technologies to be able to monitor and control these objects through a robust process. Table 1 presents the IoT components described in the literature. In an IoT system, physical objects are interconnected through a reliable network (Zmud et al., 2018). To connect physical objects and collect data in real-time, sensors, and communication devices are required (Madakam et al., 2015, Zmud et al., 2018, Deloitte Insights, 2018). Additionally, in order to ensure the consistency, validity, and usability of the data, uniform standards are needed for these devices (Deloitte Insights, 2018). Once the data are collected, they will be stored in cloud data storage, which should be large and powerful enough to manage the data and allows accessing data securely and effectively. Last, but not least, IoT requires analytics tools that can analyze the data to support the decision-making process (Madakam et al., 2015, Zmud et al., 2018, Deloitte Insights, 2018).

Zmud et al. (2018) and Meyers et al. (2015) also describe the IoT process, which typically starts with collecting data by smart sensors. Then data will be aggregated and analyzed to provide business insights, which in turn will lead to recommendations for decisions or acts. This process is to ensure the connected smart things can connect and operate smoothly in a connected system to support the decision-making process. Madakam et al. (2015) suggest some prerequisites for an IoT solution, including dynamic and real-time demand, access to data, end-user applications, security, and privacy.

Table 1: IoT components and process

Madakam et al. (2015)	***Zmud et al. (2018)***	***Meyers et al. (2015)***
IoT Components • Hardware (sensors, IP cameras, communication devices) • Middleware (demand storage and data analytic tools) • Presentation (visualization and interpretation tools)	IoT components • Physical objects (person, luggage, or boarding pass) • Instrumentation (smart components such as sensors or data collection system) • Connectivity (network-based device facilitating the interconnection between an object, its	IoT components • Sensors • Network • Standards • Augmented intelligence • Augmented behavior

	environment, and data management system) • Analytics (information gained from data analysis)	
<u>IoT Prerequisites</u> • Dynamic resource demand • Real-time need, exponential growth of demand • Availability of applications • Data protection and user • Privacy • Efficient power consumptions of applications • Execution of the applications near to end-users • Access to an open and interoperable cloud system	<u>IoT Basic framework</u> Data captured by sensors → Sensor data communicated and aggregated □ Sensor data analyzed to modify future acts	<u>IoT process</u> Business activities □ Sensors produce data □ Data is analyzed in the cloud □ Analysis leads to insights □ Decisions and actions

Roles of Machine Learning, Deep Learning, and Optimization Modeling in Artificial Intelligence Applications

Artificial Intelligence (AI) can be defined as a system that simulates human intelligence for either solving a problem or making a decision (Chouwdhury & Sadek, 2012). AI can process data to learn, predict, improve, and solve problems. Through training, an AI application is able to generate optimal solutions and apply them to novel situations not encountered before. In the airport context, faced with the challenges of growing air traffic, resource demands, increasing uncertainties, and operational complexity, AI can automatically predict issues in an airport ecosystem and provide real-time optimal solutions and decisions under uncertainties, hence solving the problem. However, AI is not without limitations and challenges. Since AI is often regarded as a black box, there are concerns about AI's capabilities to generalize to new situations or how AI determines the best decisions, hence some skepticism on AI's capabilities. It is also a challenge to integrate AI to current airport systems. Furthermore, AI could also be a potential liability, given its autonomous nature (Chouwdhury & Sadek, 2012). Some key components of AI include machine learning, deep learning, and optimization modeling (Sadek, 2007; Tien, 2017).

<u>Machine Learning</u>

Machine learning is a key component of an AI system. SAS defines machine learning as "a method of data analysis that automates analytical model building. It is a branch of artificial intelligence based on the idea that systems can learn from data, identify patterns, and make decisions with minimal human intervention." (https://www.sas.com/en_us/insights/analytics/machine-learning.html). Machine learning is an important component of an AI system since it allows the AI to learn and uncover unknown patterns from large and noisy data and predict the desirable outcome (Sadek, 2007). The model can be adjusted and improved with real-time data feeding to the algorithms. Machine learning is usually used in a data mining process, which uses various machine learning algorithms to analyze large and noisy data to uncover new patterns that would provide information for business decision making (Nisbet et al., 2009). Popular machine learning algorithms include, but not limited to, regression, decision tree, subject vector machine, memory base reasoning, Bayesian network, neural network, random forest, and gradient boosting tree. Machine learning can be categorized into supervised learning and unsupervised learning. Supervised learning requires identifying a variable as a target variable and determines the relationships between the predictors and the target variable, hence, predicting this variable (Sarma, 2013). For example, prediction models can be used to predict the probability of an aviation incident. Truong et al. (2018) used decision tree and Bayesian networks learning algorithms to predict the probability of a flight delay between two cities. Additionally, Truong (2018) uses various machine learning algorithms to predict the risk of small unmanned aircraft systems (sUAS) violations in the National Airspace System. Unsupervised learning discovers probabilistic relationships among a large number of variables, without having to specify predictor and target variables (Sarma, 2013). For example, unsupervised learning can be used to detect anomalies in pilot behaviors during an unstable approach or passengers' perception of airport service performance.

Deep Learning

Deep learning is a growing field in the past few years and plays an important role in AI systems (Arel et al., 2010). Essentially, deep learning is an advanced class of machine learning algorithms that use Artificial Neural Network (ANN) to train the model. Unlike machine learning, which requires structured data through a data cleaning, coding, and variable identifying process to train the model, deep learning can automatically handle unstructured data without preprocessing. Deep learning learns the same way as the biological neural network of the human brain by using multiple hidden layers in ANN. Deep learning can automatically extract information from large and noisy data and detect patterns at a high level of accuracy (Smidhuber, 2015). Convolutional neural network (CNN), a commonly used algorithm in deep learning, is a multi-layer neural network designed for use on two-dimensional data, such as images, audios, and videos. Image recognition and classification are good examples of how CNN can be used to detect physical and human subjects in images or videos (Arel et al., 2010). Image or audio recognition can be used to improve passenger services at airports or to ensure airport security. Similarly, audio or text recognition can be used to detect anomalies in runway safety. While machine learning requires structured data, identified variables, and interferences of the data analyst, deep learning automates the entire process. In essence, deep learning makes AI work. Nonetheless, this does not necessary means machine learning is not useful in an AI system. In a system where a specific target variable is identified, a supervised learning model works best to predict the target variable and predictors contributing to this prediction. Such a prediction model would allow the system to predict the risk of a certain aviation incident, which can lead to a solution to mitigate the risk (Truong et al., 2018). Accordingly, when to use machine learning and when to use deep learning depends on the business problem and the organizational objectives.

Optimization Modeling

While machine learning and deep learning are great methods to discover unknown patterns which help detect a problem, an AI system needs to automatically generate a solution and even take actions. In order to do so, optimization modeling is needed to find the optimal solutions for the problem (Van Zuylen, 2012; Zhang and Xie, 2012). Optimization modeling is a decision science method that determines the optimal values of decision variables to achieve the objective function, given the constraints of resources. Methods such as linear programming, integer linear programming, goal programming, non-linear programming, and dynamic programming have been used extensively in many areas. In an AI system, such an optimization model can be developed based on the outputs of machine learning or deep learning, business resources, and business objectives. The optimal solution of this model along with sensitivity analysis provide the AI system necessary information about what actions should be taken to solve the problem.

PROPOSED INTERNET OF THING BASED ARTIFICIAL INTELLIGENCE (ITAI) FRAMEWORK FOR AIRPORTS

The capabilities of IoT can be combined with AI to create a smart system that can connect, sense, monitor, and control objects, collect data in real-time, learn, predict, produce optimal solutions, and take actions to improve the safety and operational efficiency of an airport. Figure 1 presents the proposed framework for Internet of Things based Artificial Intelligence (ITAI) implementation for smart airports.

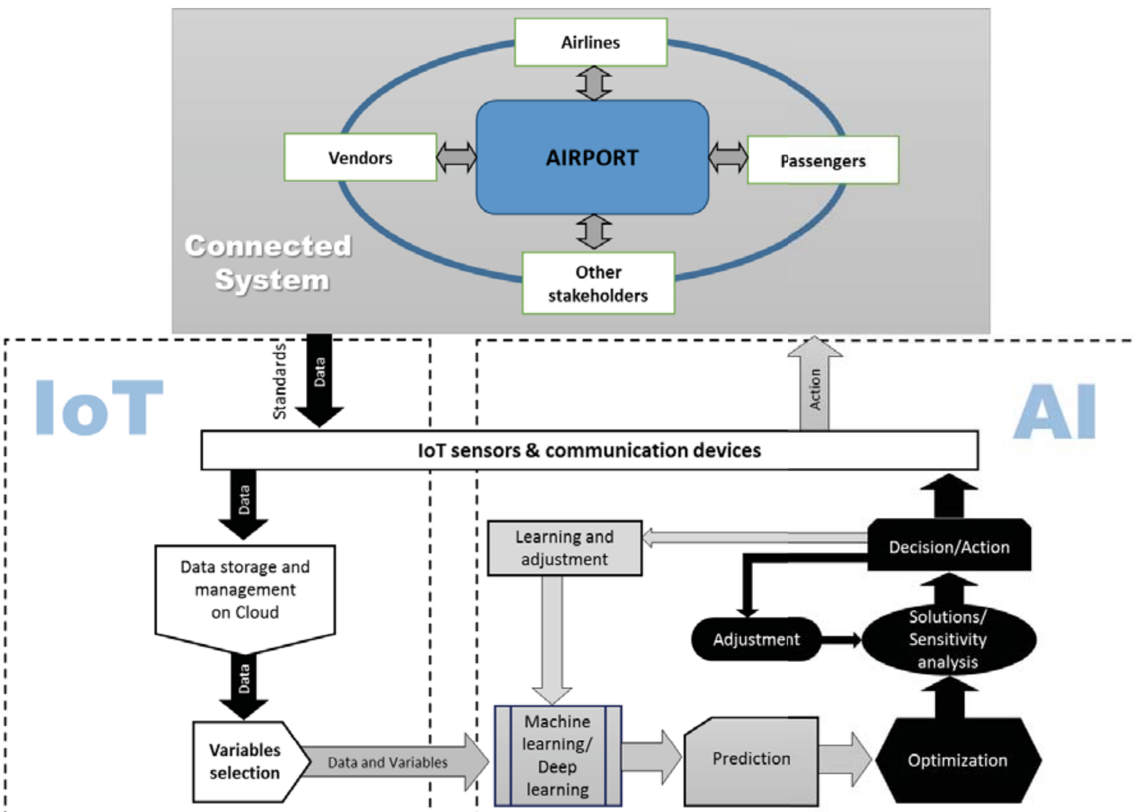

Figure 1: Internet of Thing based Artificial Intelligence (ITAI) framework for smart airports

The framework consists of the following components.

- **Connected airport system**: Airport is a complex transportation hub serving aircraft, passengers, cargo, and surface vehicles. An airport typically consists of airside facilities, landside facilities, and the terminal building (Office of Technology Assessment, 1984). In a connected airport ecosystem, the airport is connected with airlines, passengers, vendors, and other stakeholders, to ensure the visibility and effectiveness of airport operations.

- **IoT system**: A wide variety of IoT sensors and communication devices are installed and deployed at the airport. These devices are able to sense, monitor, and control objects. They communicate with each other to share and collect data throughout all airport-related operations. Uniform standards are needed to make sure sensors and devices are seamlessly communicated, and data are consistently collected in real-time. The data are collected in real-time and stored in the cloud through an effective big data management system. This system plays a critical role in ITAI, given the tremendous amount of data is collected continuously (Tien, 2017). The data need to be stored effectively and securely, and at the same time, must be accessible. Cloud computing provides a scalable solution for big data management and allows accessibility (Truong, 2010). Nonetheless, given the sensitivity of the data, the system must guarantee the security and privacy for the stored data. Furthermore, the system must be reliable to ensure uninterrupted operations. Finally, various data analytic methods can be used to explore the data and identify relevant variables.

- **Artificial Intelligence:** ITAI framework takes the data analytics to the next level by automating the entire process so airport operations can be done with minimal human interference. The first component of the AI in the ITAI framework is machine learning, in which machine learning or deep learning algorithms are used to detect unknown patterns. The process requires to develop, train, and validate prediction models. Then, these models are evaluated and compared based on pre-determined selection criteria, and the best prediction model with the highest prediction accuracy is selected. Machine learning algorithms can handle large and noisy data to build a prediction model with high predictive power (Sarma, 2013). This prediction algorithm is used to make a prediction with real-time data feeding to the algorithm. The prediction model can be automatically adjusted to improve its performance with new data coming in. Supervised machine learning can be used to predict a specific target variable, such as runway safety incident, maintenance issue, flight delay, or security issue. If unstructured data, such as images, audios, videos, and texts are provided, deep learning can be used to detect anomalies or patterns (Arel et al., 2010). Image and audio recognition can be used to enhance airport security, provide passengers with directions, or help them find lost items or needed services. Similarly, audio and text recognition can be used to detect anomalies related to runway safety or maintenance errors. Finally, an optimization module in the AI system uses the results of machine learning or deep learning to find an optimal solution to the airport business problem, such as to either maximize the performance or minimize the cost of operations. The optimal solution usually includes the values of decision variables. Additionally, sensitivity analysis can be conducted to evaluate various what-if scenarios to determine the best course of actions needed to solve the problem. Then, the AI makes the decision and take actions by sending commands to IoT devices, which control the connected objects to take corrections. The information about the decision and results is sent back to the AI system to allow this system to learn and make an adjustment. The machine learning will be continuously improved.

In order to implement this ITAI framework, specific steps should be followed. Figure 2 presents a process consisting of specific steps. These steps are to allow airport authorities to correctly deploy and implement the system to meet the business objectives.

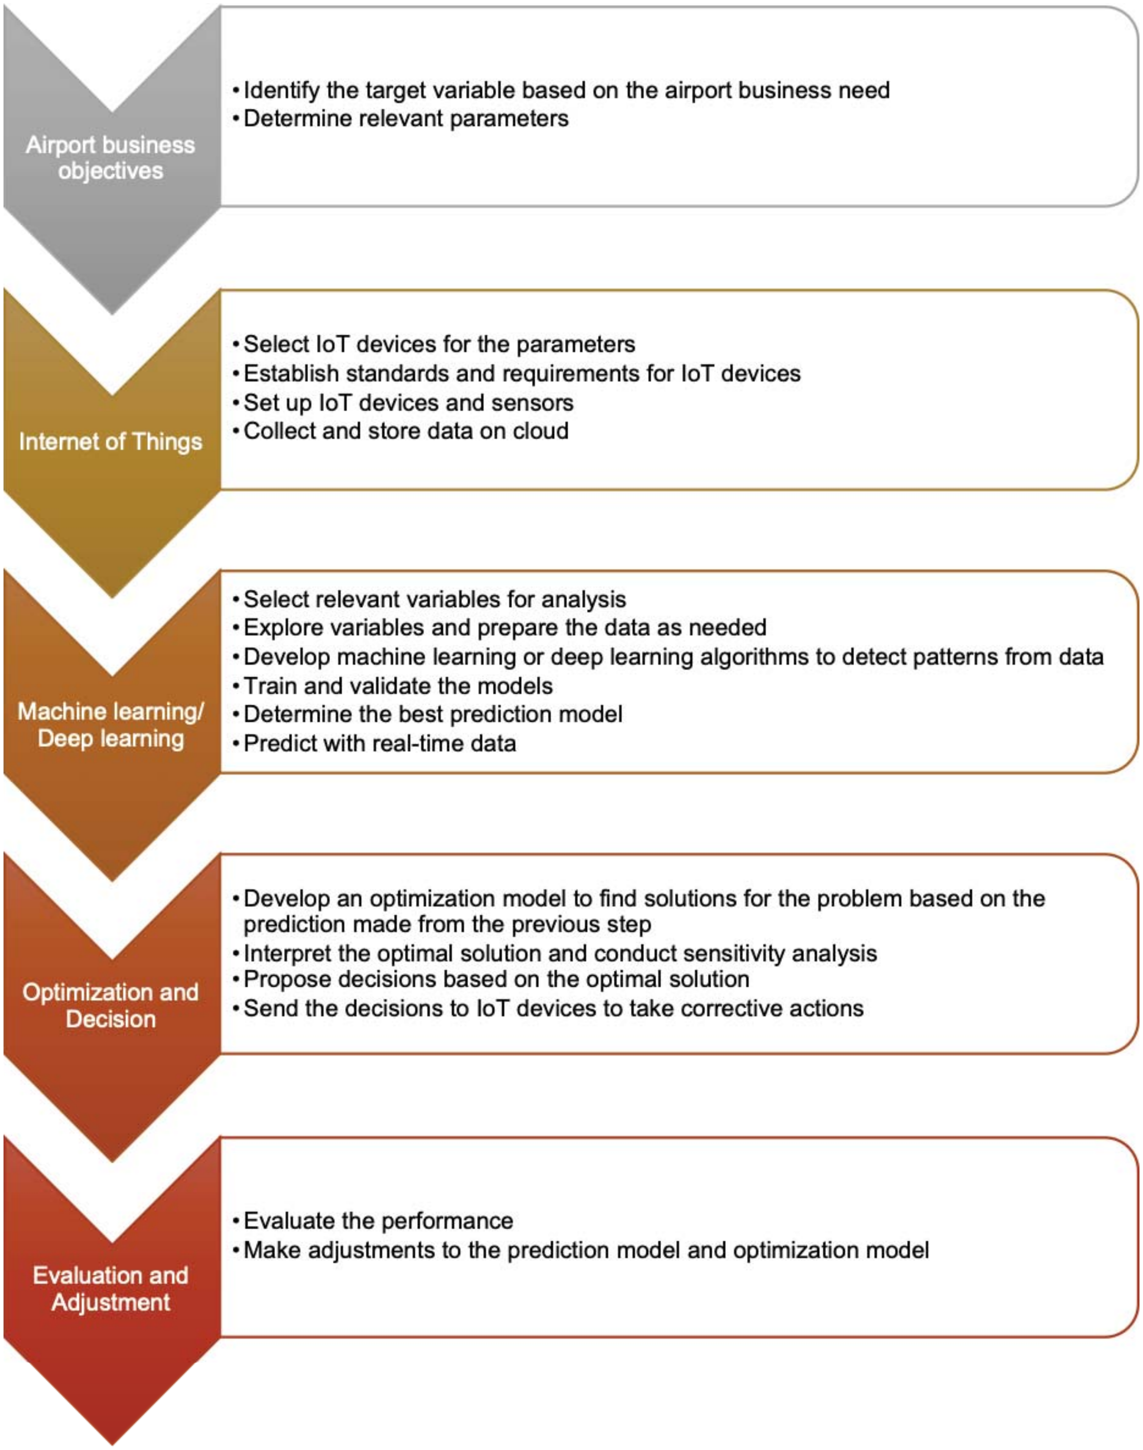

Figure 2: Steps for implementing the ITAI framework

PROPOSED RESEARCH PROCESS FOR IDENTIFYING AND MITIGATING RISKS

Since ITAI is considered a black box, there are risks associated with deploying and operating this system. In order to identify the risks and develop mitigation strategies, a combination of research synthesis and case study methods is proposed. In phase one, the research synthesis method will be used to collect information about the IoT, AI, and airport operations. The goal is to present the state of knowledge concerning innovation at airports through the implementation of ITAI and associated risks. This research will use seven steps proposed by Cooper (2010).

1. *Formulating the problem*. In this step, the specific objectives of the research will be identified. Important research questions include: What are the benefits and challenges of the ITAI? What are major applications of the ITAI at airports? What are technical and managerial requirements for ITAI deployment? How can airports successfully implement the ITAI to improve productivity and outcomes? What are the risks associated with using the ITAI, and how can they be managed and mitigated?
2. *Searching the literature*. Studies relevant to the objectives will be searched and collected from various resources: Embry-Riddle Aeronautical University's Hunt Online Library (which contains thousands of academic and professional databases), American Association of Airport Executives, Airport Services Association (ASA), The Internet Society, Internet of Things journals, Internet of Things Community IEEE, Artificial Intelligence journals, and Artificial Intelligence IEEE. Literature, including research articles, professional reports, technical reports, and cases will be collected and reviewed.
3. *Gathering information from studies.* The relevant information being gathered includes not only characteristics of the study, but also how the study was conducted and the results. The collected information will be stored and categorized for easy lookup and analysis. Bibliography and glossaries will be developed as well.
4. *Evaluating the quality of studies*. Quality of studies will be evaluated by examining the methodology to determine whether the data will be reliable and valid for addressing the research questions. Bad data will be discarded or given minimum credibility.
5. *Analyzing and integrating the outcomes of studies*. Collected data will be analyzed, summarized, and integrated into a unified picture.
6. *Interpreting the evidence*. The researchers will interpret the cumulative evidence and determine which conclusions are warranted by the data.
7. *Presenting the results*. Results will be presented to describe the investigation that answers the research questions.

In phase two, case studies will be conducted to provide best practices and lessons learned in implementing the IoT at airports. The results of phase one, along with case studies in phase two, will allow other airports to apply successfully the ITAI. Case studies will be conducted following Yin's (2009) process.

1. *Defining and designing case studies*. This research will use the two-case, embedded design to provide analysis of ITAI applications in airports (Yin, 2009). Since ITAI is new to airports, case studies will focus on collecting inputs from airport operators regarding smart airports and potential implementation of ITAI. US airports will be reviewed in order to identify two airports that have applied IoT sensors, big data analytics, and AI applications in their operations.
2. *Preparing case study evidence*. The case study protocol will be developed to ensure the quality of the data collection process. Interview questions and the survey questionnaire will

be designed to achieve the research objectives. The questions will be shared with subject matter experts for feedback to ensure the face and content validity.

3. *Collecting case study evidence*. Case study information will be collected through multiple sources, including interviews, survey, and archived records. To collect needed information and evidence, researchers will contact each airport manager, director of information technology, and director of operations. Data should include details of the ITAI applications, associated risks, risk management strategies, and critical success factors.
4. *Analyzing case study evidence*. Both quantitative and qualitative data analyses will be performed. Techniques such as pattern matching, explanation building, logic modeling, and cross-case synthesizing will be used in this research.
5. *Reporting case studies*. Results and findings of case studies will be reported to provide the audience with best practices in ITAI implementation and risk management. These results will be integrated and aligned with phase one results.

CONCLUSIONS

The rapid growth of IoT and AI in Industry 4.0 will drive airports to embrace automation and innovation to be able to improve and succeed. The results of this research will shed light on the applications of ITAI systems for smart airports. The requirements for ITAI implementation and deployment provide airport authorities and stakeholders with useful information about the investment needed to transform airports to smart airports to become more innovative and effective in the new era. The critical success factors, risk management strategies, and lessons learned are critical to airports' success in implementing and deploying the system. The findings of this research will also be useful for companies in other industries adopting an ITAI system.

ABSTRACT

The purpose of this paper is to analyze the performance impact of collaborative working capital management (WCM) approaches. The results indicate that a relationship between collaborative WCM approaches and supply chain performance exists, but the direction and power of this relationship varies between the used proxies and the estimated performance metrics. The paper at hand contributes to SCF-related research by validating several proxy variables. Several practical implications are derived, demonstrating how companies can increase the efficiency and effectiveness of the financial supply chain network in which they operate.

KEYWORDS: Collaborative working capital management, Supply chain finance, Corporate performance, Financial supply chain management

INTRODUCTION

The relationship of working capital management (WCM) and corporate performance has received attention from researchers through a multitude of publications. Evidence has been brought forward that supports various shapes and directions of this relationship between WCM and firm performance: Jose, Lancaster and Stevens (1996) support the notion of a negative relationship between the amount of NWC and performance, Padachi (2006) found evidence for the opposite, whilst Singhania and Mehta (2017) found evidence that this relationship is of non-linear nature. However, those researchers have looked at WCM from a single firm perspective, and thus their findings only concern single firm performance. Hofmann and Kotzab (2010) were amongst the first authors to take a different approach to WCM by considering the effect of working capital decisions made by a firm on its suppliers and customers. From a conceptual standpoint they argue that in contrast to the classical paradigm, decision making in WCM should not be undertaken by a firm alone but should be aligned with the partner firms of the respective supply chain. In the long run, such supply-chain oriented collaborative WCM practices would be more performance enhancing than a myopic approach to WCM which focuses on keeping maximum liquidity within the own firm. A few authors subsequently took up this notion and identified leverages how collaborative WCM can contribute to supply chain and firm performance (e.g., Viskari & Kärri, 2012; Randall & Theodore Farris, 2009). In this paper, the claim that collaborative WCM is beneficial for performance is put to test. To do so, after a review of extant literature, proxies for collaborative WCM are developed and then applied in regression models to assess whether supply chains that exhibit a higher degree of collaboration in their working capital practices also demonstrate superior performance. Moreover, attention is given to the performance of the member firms within the supply chains, by testing whether the degree of WCM collaboration of a supply chain has an influence on performance of its member firms. The method used to identify and measure supply chains has first been introduced by Lanier, Wempe and Zacharia (2010) and is adapted to the use within the context of this paper.

THEORETICAL BACKGROUND

Single Company Perspective on Working Capital and Performance

The cash conversion cycle (CCC) is a WCM's key indicator for assessing the performance of individual companies or industries. According to Shin and Soenen (1998), CCC is calculated as CCC = (accounts receivable/sales)∗365+(inventories/sales)∗365−(accounts payable/sales)∗365. When looking at the existing literature on the relationship between working capital levels and profitability of a firm, extant evidence allows for multiple explanations of the nature of this relationship. Shin and Soenen (1998) propose a linear negative relationship using a sample of 58,985 firms and investigating a time span from 1975-1994. They demonstrated a significant negative relationship between CCC length and firm profitability which is supported by numerous studies such as Deloof (2003), Wang (2002) or Lazaridis and Tryfonidis (2006), which confirmed the findings of Shin and Soenen (1998). There are several theoretical explanations for these results. Exemplary, lower working capital implies lower financing and interest costs and thus improved shareholder value (Kieschnick, Laplante, & Moussawi, 2013; Brandenburg, 2016; Kim & Chung, 1990). In addition, firms may be forced to draw capital away from alternative value-enhancing projects if they have too much capital tied up in working capital positions (Deloof, 2003; Baños Caballero et al., 2014)
Alternatively researches propose a positive linear relationship. Higher investments in working capital is thought to increase firm’s profitability (Tauringana & Afrifa, 2013; Afrifa & Padachi, 2016). Reasons cited for the alternative view are rooted in considerations on the impact of higher working capital levels on business operations. For example, by extending payment periods (i.e., accepting higher DSO), firms may differentiate themselves from competitors in offering a unique selling proposition when there is low differentiation in the market, which in turn translates into better profitability measures (Shipley & Davies, 1991; Deloof & Jegers, 1996; George & Kirk, 2003). Such extensions of payment periods may be perceived as a price cut (Petersen & Rajan, 1997; Emery,1984), and reduce the risk for the buyer in using payment period to inspect the quality of the purchase (Biais & Gollier, 1997). Furthermore, according to Blinder and Maccini (1991) and Schiff and Lieber (1974) larger inventories reduce the risk of price fluctuations, distortions in the production process and of out-of-stock situations, which are costly because they limit a firm’s sales opportunities.
Ultimately, research papers tried to conciliate the two aforementioned theories of a negative and a positive relationship between working capital and performance. According to these recent studies, the relationship between levels of working capital and firm performance is a non-linear inverted u-shape, which implies that an optimal level of working capital exists. Previously proposed by Rafuse (1996), working capital is an investment to keep a business running, so that each firm has to manage a trade-off between too much capital tied up and too little working capital available for its operational daily business. This theory is supported by different research papers (Afrifa & Padachi, 2016; Baños-Caballero et al., 2014; Mun & Jang, 2015; Altaf & Shah, 2017; Pais & Gama, 2015). According to Baños-Caballero et al. (2014), the optimal level of working capital can differ between different firms, arguing that financially constrained firms have lower optimal working capital levels. It becomes apparent from the review of extant studies, that there is yet no consensus on the relationship between working capital and firm profitability.

Supply Chain-Oriented View on Working Capital and Performance

Studies which apply a multi-firm perspective have only been published more recently and emerged at the interface between the field of logistics and finance (Pfohl & Gomm, 2009). The SCF-orientation takes into account that management of working capital directly influences affiliated supply chains through accounts payable, inventories and accounts receivable along the supply chain partner firms. In particular, self-centered working capital improvements are made at the expense of affiliated supply chain partners. Hofmann and Kotzab (2010) used model calculations, to show that the optimization of working capital by a single firm in a supply chain does not add value to supply chain members. An illustrative example is that a DPO reduction by one supply chain member results in an increase of another members' DSO (zero-sum game). Grosse-Ruyken, Wagner and Jönke (2011) studied CCC's of different industry sectors and detected a strong negative correlation between average industry CCC and average industry ROCE. They thus argue that industries which collaborate in their WCM activities signified by a lower average industry CCC, are rewarded with a higher average industry ROCE.

Implications and Proposition Building

The aforementioned research outputs conclude that the application of a supply chain-oriented perspective to WCM will be beneficial for the performance of the supply chain. In their scenario, Viskari and Kärri (2012) found that the shift of inventory to upstream partners in a supply chain can reduce overall costs for the supply chain due to the increasing value of a product as it passes through the value chain (Porter, 1985). In addition, after a supply chain transaction is undertaken shifting the associated financial burden towards the supply chain partner with the lowest WACC poses an opportunity to lower incurred total supply chain costs and helps generate higher profits (Randall & Theodore Farris, 2009; Aberdeen Group, 2006).

Proposition 1: *Supply chains which shift working capital components between its members with the goal to minimize the cost associated with these components exhibit superior performance.*

Grosse-Ruyken et al. (2011) illustrate how the CCC is linked to profitability and provide evidence that industries with a shorter average CCC exhibit on average higher profitability. However, intense collaboration of all supply chain members, involving upstream and downstream partners, is necessary to achieve a sustainable reduction of the CCC. Hofmann and Kotzab (2010) showed that an isolated reduction of a CCC by a firm within a supply chain does not affect the collaborative CCC length at all. Such practices might even be detrimental to a supply chain in the long run. Weaker members will incur higher financing costs if their CCC is stretched by stronger supply chain members (Protopappa-Sieke & Seifert, 2017). This can lead to downstream delays, quality issues and ultimately higher costs of goods sold for the affected supply chain members, diminishing the competitive advantage of this supply chain (Hofmann & Kotzab, 2010).

Proposition 2: *Supply chains that manage their chain CCC collaboratively will exhibit superior performance.*

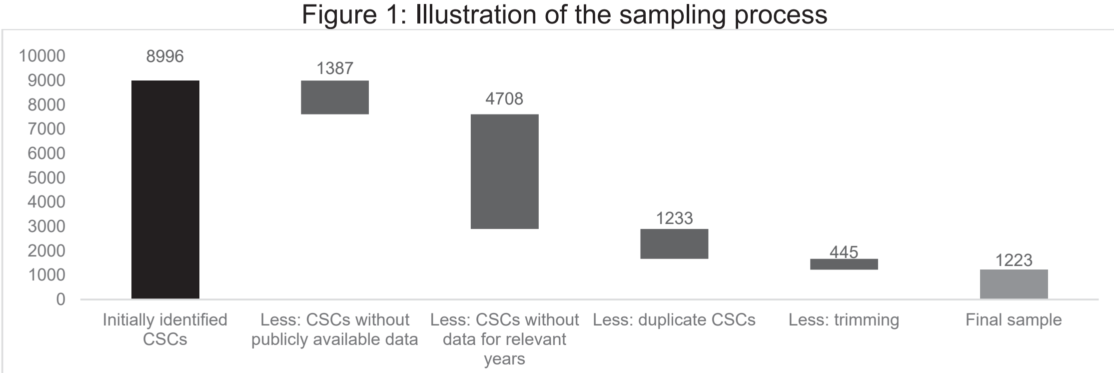
According to Rafuse (1996), working capital is an investment and comes with associated costs and benefits, and thus a reduction of working capital will enable the use of capital in a more productive way. Consequently, Hofmann and Kotzab (2010) identify the optimal collaborative CCC to be "the one that minimizes the cost of tied up capital […] across all collaboration members". Furthermore, simulations showed that a shared working capital pool in a supply chain overall is less costly than if members each keep their separate working capital stock, which is partly caused by the reduced overall requirement of working capital in case of a joint pool (Protopappa-Sieke & Seifert, 2017).

Proposition 3: *Supply chains which harmonize their members' activities to reduce the overall amount of net working capital in a supply chain exhibit superior performance.*

RESEARCH METHODOLOGY

The approach introduced by Lanier et al. (2010) is used to investigate financial performance of 3-firm supply chains adapted for the investigation on WCM. The Statements of Financial Accounting Standard No. 14 (1976) and No. 131 (1997), which require firms to disclose major customers, i.e. customer that account for 10% or more of a firm's sales in one year, is used for the construction of supply chains. If in the same year, a firm reports a major customer and appears as a major customer in the disclosures, then that firm is a focal company of a concentrated supply chain (CSC) (Lanier et al., 2010). The 3-firm CSCs were chosen as the subject of this study because the building of 3-firm CSCs allows for the creation of a larger sample as compared to larger CSCs, which will ceteris paribus lead to more meaningful results in a study (Littler, 2015). This will result in an increased robustness and validity of the results.

Figure 1: Illustration of the sampling process



The COMPUSTAT database delivered 137,063 major customer disclosures, which covered a time span from 1978 to 2018. This database is reduced to an initial dataset of 8,996 possible CSCs for the study (Figure 1) by identifying FCs that reported a major customer and were named as a major customer likewise. In the next step, identifiers are applied to screen the information that is needed for the calculation of the proxies resulting in a sample size of 7,609 CSCs. Subsequently, as not all data necessary for the calculation was available the number of CSCs was reduced to 2,901. Then, duplicate CSCs were removed in a screening within the reduced dataset resulting in 1,668 CSCs. Finally, to diminish the effects of statistical outliers and to improve robustness of the results, the dataset was trimmed using the 1.5x interquartile step fence, applied for all used proxy variables (Wilcox, 2001). This step delivered the final dataset, consisting of 1,223 CSCs, aggregated of 704 suppliers, 188 focal companies and 162 customers. Seeing that the database consists of an international sample of companies, which do not necessarily all calculate their income statement after the cost-of-sales method (some use the full-cost method), the inventory and payables turns are based on a company's sales.
The CSC performance metrics (dependent variables) EBITDA margin, EVA, profit margin, asset turnover and ROA are used to measure CSC performance. To diminish the risk of a regression

outcome that is biased by other influencing factors, the regression models are controlled using the following variables adapted from the study of Baños-Caballero et al. (2014). Size (natural logarithm of sales), leverage (ratio of total debt to total assets) and growth opportunities (ratio of book value of intangibles assets to total assets) represent the control variables. The calculation of metrics and variables on chain level follows the procedure outlined by Lanier et al. (2010). The five performance metrics (ROA, EBITDA margin, profit margin, EVA and asset turnover) are calculated on a chain level, interpreting the CSC as a quasi-entity. For the measurement of chain level oriented propositions one to three, proxy variables (formula (1)-(5)) are calculated for the supply chain in form of a supply chain as a quasi-entity (Lanier et al., 2010; Blois, 1972). This procedure allows the formulation of regression models, which then are used to assess the propositions for significance and power.

In order to evaluate proposition 1, proxy variable Inv_{shift} is used to measure the degree to which inventory is stored upstream within the supply chain as the associated costs for inventory are lower in the earlier stage of a good's production cycle (Viskari & Kärri, 2012):

$$Inv_{shift} = \frac{\left(Inv_{Supplier} + Inv_{Focal\ Company}\right)}{\left(Inv_{Supplier} + Inv_{Focal\ Company} + Inv_{\text{Customer}}\right) * \left(\mathrm{S}_{\text{supplier}} + S_{Focal\ Company}\right)} \quad (1)$$

where Inv_x means inventory held by the position within the supply chain (Supplier, Focal Company, Customer) defined in the index. $\mathrm{S_x}$ represents the relative sales of chain sales by the position within the supply chain (Supplier, Focal Company, Customer) defined in the index.
The second proxy variable NWC_{Costs} to assess proposition 1, builds on the contributions of Randall and Theodore Farris (2009) as well as Hofmann and Kotzab (2010) who recognize that firms within a supply chain may be exposed to different costs of capital. They argue that supply chains as a whole may benefit from such differences. NWC_{Costs} is used to calculate to which degree supply chain members with a lower WACC undertake financing activities for chain members with a higher WACC:

$$NWC_{costs} = \frac{\sum_{i=1}^{3}(NWC_i * WACC_i)}{\sum_{i=1}^{3}(NWC_i) * WACC_{chain}} \quad (2)$$

where $WACC_{chain}$ is calculated as the sum of $WACC_x$ of the members weighted by their relative sales (S_x) of the chain members. The first proxy variable CCC_{chain} to assess proposition 2 builds on the contribution of Hofmann and Kotzab (2010) who showed that harmonized WCM within the supply chain lead to shorter CCC. It is further supported by Grosse-Ruyken et al. (2011), who provided evidence on the negative relationship between CCC_{chain} and ROCE on industry level. Thus, CCC_{chain} is calculated as:

$$CCC_{chain} = CCC_{supplier} + CCC_{focal\ company} + CCC_{customer} \quad (3)$$

The second proxy variable $CCC_{balance}$ to assess proposition 2, builds on the contribution of Grosse-Ruyken (2011) who states that CSCs can increase their performance if they aim for a collaborative CCC which is balanced across member firms. According to Farrar and Glauber (1967), a log transformation in the calculation of $CCC_{balance}$ is necessary to prevent issues of multicollinearity with CCC_{chain}. An increasing $CCC_{balance}$ is perceived as a decreasing balance within the CCC. Thus, the proxy variable $CCC_{balance}$ attempts to measure the degree to which a CSC achieves an equal distribution of the collaborative CCC. $CCC_{balance}$ is calculated as follows:

$$CCC_{balance} = ln\left(\left(\frac{CCC_{chain}}{3}\right) - CCC_{supplier}\right)^2 + \left(\left(\frac{CCC_{chain}}{3}\right) - CCC_{Focal\ company}\right)^2 + \left(\left(\frac{CCC_{chain}}{3}\right) - CCC_{customer}\right)^2 \quad (4)$$

The proxy variable $NWC_{difference}$ to assess proposition 3 builds on the contribution of Protopappa-Sieke and Seifert (2017) who showed that a joint point of working capital in supply chains may reduce the overall need for working capital in supply chains. Thus, adapted from Vazquez, Sartal and Lozano-Lozano (2016) the proxy variable $NWC_{difference}$ attempts to measure the degree to which invested capital could have deployed in a more productive way (Rafuse, 1996).

$$NWC_{difference} = \frac{NWC}{Sales} - \frac{\overline{NWC}}{\overline{Sales}} \quad (5)$$

where $\overline{NWC}$ and $\overline{Sales}$ express the particular means. The following models are used to estimate effects of the before described proxy variables on the CSC performance metrics. Support for proposition 1 is expressed if regression (6) results deliver positive value for β_1 of Inv_{shift}. Support for proposition 1 is expressed if regression (7) results deliver negative value for β_1 of NWC_{costs}.

$$CSC_{metric} = \beta_1 Inv_{shift} + \beta_2 size + \beta_3 leverage + \beta_4 growth \quad (6)$$

$$CSC_{metric} = \beta_1 NWC_{costs} + \beta_2 size + \beta_3 leverage + \beta_4 growth \quad (7)$$

Support for proposition 2 is expressed if regression (8) results deliver negative value for β_1 of CCC_{chain}. Support for proposition 2 is expressed if regression (9) results deliver negative value for β_1 of $CCC_{balance}$.

$$CSC_{metric} = \beta_1 CCC_{chain} + \beta_2 size + \beta_3 leverage + \beta_4 growth \quad (8)$$

$$CSC_{metric} = \beta_1 CCC_{balance} + \beta_2 size + \beta_3 leverage + \beta_4 growth \quad (9)$$

Support for proposition 3 is expressed if regression (10) results deliver negative value for β_1 of $NWC_{difference}$.

$$CCSC_{metric} = \beta_1 NWC_{dfference} + \beta_2 size + \beta_3 leverage + \beta_4 growth \quad (10)$$

Each of the introduced models is used to estimate performance metrics, ROA, EBITDA margin, Profit margin, EVA and Asset turnover. Having five models and five performance metrics to be estimated results in a total of 25 regressions.

RESULTS

Table 1 shows the descriptive statistics for the independent and dependent variables giving insights into the distribution of variables. Exemplary, two variables are proven with corresponding literature. The mean CCC_{chain} is slightly higher than results of corresponding studies on firm level (Jose, Lancaster, & Stevens, 1996; Afrifa & Padachi, 2016), which is due to the created CSC with an increasing CCC along the upstream partners. The mean ROA of 0.050, is corresponding to the values found in similar studies (Baños-Caballero et al., 2014). Table 2 shows the estimation results of the derived models and assesses to what extent the proxies for collaborative WCM may explain CSC performance metrics.

Table 1: Descriptive statistics; N=1,223 for all coefficients

	Mean	Std. Dev.	Perc. 25	Perc. 50	Perc. 75

Inv_{shift}: The results indicate a significant influence of Inv_{shift} on ROA as well as asset turnover on the 1% significance level for profit margin as well as EVA on the 5% significance level. No significant influence of Inv_{shift} was found on EBITDA margin. The performance metrics where a significant influence was found, the direction is for all metrics positive, i.e. a higher value of Inv_{shift} would predict a higher value of ROA, Asset turnover, Profit margin and EVA. Regarding the power of the influence of Inv_{shift} in the statistically significant relationships, the highest standardized coefficient is found for the predictor of ROA, whilst the smallest power is found for the predictor of Profit margin.

NWC_{costs}: The results indicate a significant influence of NWC_{costs} on all performance metrics of CSCs on the 1% significance level. However, the directions of the relationships differ among the metrics. Whilst the performance metrics ROA, EBITDA margin, EVA and profit margin are positively influenced by NWC_{costs}, asset turnover is negatively influenced by NWC_{costs}. Regarding the power of the obtained regression results, the strongest statistically significant influence observed was the one of NWC_{costs} on EBITDA margin, whilst the least power was found for the influence of NWC_{costs} on ROA

CCC_{chain}: The results indicate a significant influence of CCC_{chain} on EBITDA margin, asset turnover, and profit margin on the 1% significance level and for EVA on the 10% significance level. However, the directions of the relationships differ among the metrics. Whilst the performance

metrics EBITDA margin, EVA and profit margin are positively influenced by CCC_{chain}, asset turnover is negatively influenced by CCC_{chain}. Thus, one out of five models support proposition 2.
$CCC_{balance}$: The results indicate a significant influence of $CCC_{balance}$ on ROA, as well as profit margin on the 1% significance level and for EBITDA margin and EVA on the 5% significance level. However, the directions of the relationships differ among the metrics. Whilst the performance metrics ROA, EBITDA margin and profit margin are positively influenced by $CCC_{balance}$, EVA is negatively influenced by $CCC_{balance}$. Regarding power of results, the strongest significant influence of $CCC_{balance}$. was found on Asset turnover, whilst the least powerful influence was found for ROA.
$NWC_{difference}$: The analysis of $NWC_{difference}$ yielded mixed results. The level of working capital present within a supply chain seems to have a significant influence on chain level performance, as all but the model that attempted to estimate ROA with $NWC_{difference}$ found a significant relationship between $NWC_{difference}$ and chain performance, for Asset turnover, EBITDA margin as well as EVA on the 1% significance level and for performance metric Profit margin on the 5 % significance level. There is no common direction of the influence of $NWC_{difference}$ on the performance metrics where statistical significance was detected. Whilst $NWC_{difference}$ is positively correlated with EBITDA margin, Profit margin, and EVA the regression that estimated Asset turnover using $NWC_{difference}$ found a negative correlation Regarding the power of the obtained results, the standardized coefficient in models with statistical significance was largest for Asset turnover, and smallest for Profit margin.

DISCUSSION

Regarding proposition 1, the results strongly indicate a relationship of shifting working capital components between its members and chain performance, as the regression models that test the influence of Inv_{shift} and NWC_{costs} on the performance metrics exhibit significant results. The effect of shifts of inventory towards upstream supply chain partners was investigated with models that employ proxy Inv_{shift}. These models showed that supply chains which exhibit a high level of Inv_{shift} are rewarded with a higher ROA, Asset turnover, EVA and Profit margin. When looking back at the interpretation of these financial ratios, it thus can be concluded that such supply chains are deploying their assets more efficiently to generate sales (positive relationship between Inv_{shift} and Asset turnover), returns on their assets (positive relationship between Inv_{shift} and ROA), economic value (positive relationship between Inv_{shift} and EVA) and turning sales into net profit (positive relationship between Inv_{shift} and Profit margin). The strongest effect, measured using the standardized regression coefficients, is found in the relationship of Inv_{shift} on chain ROA. This strongly supports proposition 1. The analysis therefore complements previous research on WCM in the interorganizational context (Viskari & Kärri, 2012). It is also in line with previous work that has shown that inventory stored upstream, when product value and associated inventory costs are lower, a supply chain may reduce its overall inventory costs (Randall & Theodore Farris, 2009). According to Hofmann and Kotzab (2010) the synchronization of the goods/material and financial flows within the supply chain is a key to improve CSC performance. The effect of shifting net working capital within CSCs on the performance metrics was investigated with models that employ proxy NWC_{costs}. Most performance metrics seem to be affected in the opposite direction as postulated by proxy NWC_{costs}. A lower level of NWC_{costs} is related with a lower ROA, EBITDA margin, profit margin as well as EVA and is related with a higher asset turnover. Thus, the models that predict influence of NWC_{costs} on chain performance metrics do not support proposition 1 since only one out of five assessed performance metrics support proposition 1.

Regarding proposition 2, the results do not indicate a strong relationship between a collaborative CCC and chain performance, as the regression models that test the influence of CCC_{chain} and $CCC_{balance}$ on the performance metrics exhibit mixed results. Supply chains which strive to balance their collaborative CCC cannot expect to achieve superior performance, in fact they face a worsening of chain level performance: A negative effect of such efforts can be observed on a supply chain's ability to generate return on assets (positive correlation of $CCC_{balance}$ and ROA*)*, its ability to minimize operating expenses needed to produce sales (positive correlation of $CCC_{balance}$ and EBITDA margin) and its ability to turn its sales into net profit (positive correlation of $CCC_{balance}$ and Profit margin). However, the results indicate that CSCs may increase chain EVA, if they strive for a more balanced collaborative CCC. Thus, regarding proposition 2, the models using $CCC_{balance}$ reject proposition 2 for four of the assessed performance metrics and offer support for one performance metric. The effect of the length of the collaborative CCC on the performance metrics was investigated with models that employ proxy CCC_{chain}. Most performance metrics seem to be affected in the opposite direction as postulated by proxy CCC_{chain}. A higher level of CCC_{chain} is related with a higher EBITDA margin, EVA and profit margin and is related to a lower asset turnover. Thus, the models that employed CCC_{chain} to predict chain performance metrics do not support proposition 2. The effect of supply chains that strive to balance their collaborative CCC on the performance metrics was investigated with models that employ proxy $CCC_{balance}$. Thus, the models that employed $CCC_{balance}$ to predict chain performance metrics reject proposition 2 for four of the assessed performance metrics and offer support for one performance metric.

Regarding proposition 3, the results do not indicate a clear relationship between a collaborative CCC and chain performance, as the regression models that test the influence of $NWC_{difference}$ on the performance metrics exhibit results for both supporting and rejecting proposition 3. The effect of collaboration in WCM on the overall working capital level was investigated with models that employ proxy $NWC_{difference}$. The applied regression models found correlation between $NWC_{difference}$ and four out of five assessed chain performance metrics. However, the direction of this relationship varies between the assessed performance metrics. Having larger amounts of net working capital seem to enable supply chains to improve their capability to turn generate economic value (positive relationship between $NWC_{difference}$ and EVA), minimize operating expenses needed to produce sales (positive relationship between CCC_{chain} and EBITDA margin) and to achieve a higher Profit margin. On the other hand, having lower levels of net working capital correlates within efficient use of chain assets to produce sales (negative relationship between $NWC_{difference}$ and Asset turnover). Thus, evidence to support proposition 3 is offered solely by the model that estimated Asset turnover with $NWC_{difference}$. Thus, the models that predict influence of $NWC_{difference}$ on chain performance metrics seem to reject proposition 3. Although four out of five assessed performance metrics measured a significant influence, evidence to support proposition 3 is only offered for one out of five performance metrics.
Asset turnover compares sales to total assets, thereby revealing to the analyst how efficiently a business has used its assets to generate sales revenue (Warren & Reeve, 2006). Since asset turnover is a coefficient to measure the efficiency of a business entity one might assume that a business that uses working capital more collaboratively uses its assets more efficiently to generate sales revenue. However, there is no clear evidence of the effect on ROA. It is calculated as the fraction of profit margin by asset turnover. Thus, the root cause might be in the profit margin, since there is no clear evidence for profit margin likewise as shown in Table 1. Profit margin is an indicator of the overall profitability of an entity as it shows the net income relative to sales, which shows the percentage of sales that remained in the company as net profit (Metha, 2016).

CONCLUSION AND OUTLOOK

This study makes several theoretical contributions to SCF-related literature. First, a relationship between collaborative WCM practices and the performance of supply chains and their member firms has been proven to exist. Second, there is strong evidence that collaborative WCM influences the efficiency of the asset usage in a positive direction. Third, the measured contradicting direction of the relationships between WCM and chain performance mirrors the current state of knowledge on the relationship between collaborative WCM practices and chain performance. Future studies should apply more sophisticated modeling approaches to isolate the performance impact of collaborative WCM approaches. This would potentially lead to more consistent results because special effects arising during a certain business period would no longer have a major impact on the considered performance metrics.

The exploratory character of the paper leads to certain limitations. Using COMPUSTAT as a secondary source to retrieve the necessary data, there is no certainty that the data used is fully accurate and that the companies worked collaboratively on purpose to increase chain performance. The proxies used to measure the degree of collaboration have been, with the exception of $NWC_{difference}$, untested constructs derived based on extant literature. Hence, the proxies could contain errors as the analysis gives partially indistinct results.

In future studies researchers who take on the challenge of improving the database could gather primary data. According to Lanier et al. (2010), the receipt of survey-based measures could add greater validity to any deductions made. Additionally, future SCF research should aim to validate or improve the used proxies for collaborative WCM.

ABSTRACT

This study investigates the effect of U.S. institutional investor's funding liquidity on various nations' securities returns using data from 25 countries in the exchange-traded funds market (ETFs) and 22 countries in the financial future markets. Our results show that when U.S. investors face insufficient liquidity issues, leading to decrease on stock returns in other countries. We also find evidence that US government monetary policies have significant impact to money market and funding market. In sum, our study provides a better overall understanding of the effect of the liquidity–supplier funding constraint on returns.

KEYWORDS: Funding liquidity, Daily returns, 25 EFTs index, 22 Future index, Monetary policies

INTRODUCTION

The issue of funding has received considerable attention from numerous recently scholars. As a fundamental concept in finance, liquidity can be defined as the ability to buy or sell large quantities of an asset quickly and at low cost. Liquidity is risky and has commonalty: it changes over time not only individual stocks, but also whole market (Chordia et al., 2000; Hasbrouck & Seppi, 2001; Huberman & Halka, 2001). Liquidity plays an important role in financial markets, especially during a financial crisis. The continuous arrival of bad or uncertainty news within the market can cause in redemption pressure from retail investors on liquidity suppliers (e.g., intermediaries, speculators, and arbitrageurs). They therefore may be faced with funding constraints the risk of higher margins. Albert S Kyle and Xiong (2001), Gromb and Vayanos (2002), Brunnermeier and Pedersen (2008) all argued that market declines and adverse shocks can result in funding constraints, leading fragile equity liquidity and a liquidity spiral effect. Liquidity control is one of the cores of banking industry. The Basel Accords therefore requires banks or large institutional investors maintain a certain level of funding liquidity per day to meet the capital adequacy ratio (CAR). Under typical circumstances, investors may apply for loans from the interbank market to adjust their funding liquidity. However, when a negative shock occurs, market uncertainty increases, banks will reduce their level of lending willingness, leading to the lending channels are more tightened, causing loan interest rates by interbank markets is significantly increased (Comerton-Forde et al., 2010). At this time, borrowing from banks becomes more difficult, large institutional investors who need funding must sell their liquid assets to maintain required necessary CAR ratio, this action is called pull back liquidity.

A significant example of the liquidity pull-back phenomenon is the 2008 financial crisis, the impact of subprime crisis on margins has led to the instability in the financial system, impacted many countries around the world. Brunnermeier (2009) argued that liquidity has commonality across securities because shocks to funding liquidity impact all securities in which speculators are marginal investors. Moreover, the US dollar has high liquidity in the international market, transactions by US dollars are the most often and highest frequency in the banking system. Therefore, the withdrawal of liquidity occurs not only in the US, but also in other countries. As large institution investors implement that behavior, stock returns decrease, a connection between interbank market and stock market is created (Nyborg & Östberg, 2014).
This paper therefore explores whether US institutional investors' funding liquidity affects the securities returns of other countries. Based on above literature, we hypothesize that a higher funding liquidity leads an increase in returns.
Our study adds several findings to the extant literature on the ways in which funding liquidity affects returns. First, past studies have explored how liquidity impacts financial market prices (Amihud & Mendelson, 1986; Jacoby et al., 2000), the interaction of liquidity and returns in stock markets(Hasbrouck, 1991), time-varying liquidity in Treasury bond markets (Krishnamurthy, 2002), liquidity predicts expected returns in the time series (Pástor & Stambaugh, 2003). To our knowledge, there is little empirical evidence emphasize the role of funding liquidity. Gromb and Vayanos (2010) who undertake explore the effect of funding liquidity and market liquidity, Hameed et al. (2010)find an indirectly effect of funding liquidity on equity liquidity during a period of market decline, Chiu et al. (2012) used index and financial exchange-traded funds (ETFs) to explored the relation between funding liquidity and equity liquidity during the subprime crisis period. We argue that liquidity shocks, market uncertainty, the announced of bad news forced the speculators to reduce their leverage and provide less liquidity to the markets, reduces asset liquidity (Brunnermeier, 2009). An important implication of their study is liquidity has commonality across securities because funding liquidity shock impact all securities in which speculators are marginal investors. However, the interaction between funding liquidity and in stock markets has not been directly deeply examined.
Second, prior studies have analyzed the effects of monetary policy and fund flows on financial markets. Monetary shocks are associated with large changes in bond and stock prices (J. Fleming & Remolona, 1997), fund flows affect price formation in equity markets (Goetzmann & Massa, 2002). The impact of monetary policy to liquidity emphasize in recent literature. Albert S. Kyle (1985), Admati and Pfleiderer (2015) argue from the speculation paradigm that strong find that market-wide changes in liquidity could closely related informational events such as Federal announcements about the state of the economy, Garcia (1989) examine the ways in which Fed's monetary stance impact liquidity by adjusting the margin lending terms and reducing dealers' borrowing restrictions; J. Fleming and Remolona (1997) and Fair (2002) argue that monetary shocks are associated with large changes in bond and stock prices. However, the impact of funding liquidity on returns in stock markets in the periods of monetary policies implementation has not been studied much. Past studies mainly focused on the tightening monetary policies; we focus on the quantitative easing methods. We argue that government applied the bailouts or funding injections have a direct impact on banking system and mutual funds (Lin et al., 2014), increases the bank's interest margin and decreases the default risk (Chen & Chang, 2015).
Third, Goldsmith-Pinkham and Yorulmazer (2010) describe the spillover effect under the bank run and the bailout announcement. The subprime crisis occurred, investors' willingness to enter the market decrease. The notice of bankruptcy or bailout of an individual bank will effect on the rest of the banking system. Nyborg and Östberg (2014) describe the phenomenon about "liquidity pull-back" which involves selling financial assets by banks directly or by levered investors in the interbank market. The typical example of "liquidity pull-back phenomenon" is the 2008 subprime crisis has led to the instability in the financial system. The 2008 funding crisis

emphasize the role of the liquidity spirals affect all interbank market, causing central banks around the world have to intervene in the monetary market at a level never seen. Many countries around the world are affected during the crisis. Laeven and Tong (2012) explore how US monetary policy affects to overseas stock market outside U.S. They discover that monetary policy has a negative relationship with the other countries' stock price. They also discover directly the impact of U.S monetary tighten or loosen to other stocks. We extend our studies how funding liquidity effects on returns in the international market. This paper also examines whether funding liquidity affects returns at varying degrees when the US market is tightening or loosening.

We use ETFs and future market data for the following reasons. First, both markets are usually more liquid and therefore more suited to our research question. Second, we also focus on the ETFs and future market because the financial industry is the sector most directly affected by the subprime crisis. Third, ETFs data is as known represent for the equity market, while future data of the capital market, we explore whether the impact of funding on these two markets is in different levels.

Our empirical findings are summarized as follows. First, our results show that higher funding liquidity leads to an increase in returns, which indicates that an increase in funding liquidity can improve returns. However, these affects to various countries are in different levels. Second, we find that with a decline in funding liquidity, investors tend to prioritize withdraws money at the higher liquidity countries first.

Third, our results generally reveal that funding liquidity is higher significant impact to returns when the market is loosening. Finally, we find that when US government implemented the monetary policies will have the effects to monetary and capital markets.

The remainder of this paper is organized as follows. Section 2 provides a description of the data and the research methodology. Section 3 presents and analyzes our empirical results. Finally, Section 4 offers the conclusions drawn from this study.

DATA SOURCE AND RESEARCH METHODS

Data source and sample selection

We use financial ETFs market from 25 countries and Global Future market from 22 countries in the period from January 1, 2004 to December 31, 2015 to explore the relationship funding liquidity and daily returns [List countries in financial ETFs market and global Future market is shown in Appendix A]. We collect the daily transaction data for individual stocks, daily trading volume, and daily trading volatility from DataStream database. Because GDP are macro-economic data with quarterly frequency, that is complicated to calculate. We consider that the information quantity in quarterly frequency will reduce the credibility and affect the explanatory ability. Therefore, we follow Allen et al. (2012) to adjust the frequency to monthly data information to avoid the insufficient number of sample situation.

Funding liquidity measures

We follow Brunnermeier (2009) to construct our funding liquidity measure. We use the spread between the 3-month US Treasury bills and Eurodollar Libor rate (i.e., Ted ratio). US Treasury bills are considered risk-free interest rates, while Libor rate reflects the British bank lending rates, implied risk premium. The Ted spread measure the degree of attention for the credit risk and dollar liquidity. We argue that with an increase in the Ted spread, leading to expanded market risk premiums, capital markets and interbank borrowing costs are tightened, leading to increase company's borrowing costs, therefore U.S. investors face the liquidity insufficiency situation, reducing invest to the securities markets, impact on stock market returns.

Measure daily returns

We use daily returns in the individual countries, which calculated as *ln* (P_d /P_{d-1})*;* where P_d is the stock price at the day d, P_{d-1} is the stock price at the prior day. To control for the factor that may be important in determining daily returns, we adopt daily trading volume (Duffee, 1992; Gallant et al., 1992; Karpoff, 1987), daily trading volatility (French et al., 1987; Schwert, 1989), returns in last period (Chan et al., 1996; Fama, 1990; Lee & Swaminathan, 2000), GDP (Binswanger, 2000; Schwert, 1989) to investigate the following regression model:

$$Ret_{i,d} = \alpha + \beta_{i,d} Ted_d + \gamma X_{i,d} + \varepsilon_{i,d}$$

Where $Ret_{i,d}$ is the daily return for ETFs and Future market for country i on day d. Ted_d is the Ted spread in day d. $X_{i,d}$ is control variable, consists of daily trading volume ($Vol_{i,d}$), daily trading volatility ($Volatility_{i,d}$), lagged daily returns (Ret_{d-1}) and growth rate ($GDP_{i,m}$). Ted_d is the spread between the 3-month US Treasury bills and Eurodollar Libor rate, $Vol_{i,d}$ which is collect from DataStream database, $Volatility_{i,d}$ is calculated form past 30th $Ret_{i,d}$, Ret_{d-1} is measure by lagged $Ret_{i,d}$, , $GDP_{i,m}$ measured by *ln*($GDP_{i,m}/GDP_{i,m-1}$).

Basic Statistic

Table 1 reports the descriptive statistic for daily returns, funding liquidity and the other control variables. The number observations are 98,793 and 56,339 in financial ETFs and Future market, respectively. The min of *Ret* are -0.340 and -0.162 with a standard deviation of 0.019 and 0.015, respectively. The min of *Ted* is -0.309 with a standard deviation of 1.194 and 1.309 in both markets, respectively. ETFs market has the min value of *Vol*, *Volatility*, Ret_{d-1} are 100, 0.001, -0.340, respectively; while the min value of *Vol*, *Volatility*, Ret_{d-1} are 0.001, 0.001, -1.378, respectively in the future market.

Table 1. Descriptive statistic

Variables	Obs.	Min	Max	Average	S.D.

GDP	56339	1.762	4.488	2.891	0.796

Notes: This table provides the descriptive statistics for the dependent and control variables, with the data covering the period of 1 January 2004 to December 31, 2015.

EMPIRICAL RESULTS

Main results

This section explores how the funding liquidity affects daily returns using the following regression model:

$$Ret_{i,d} = \alpha + \beta_{i,d}Ted_d + \gamma X_{i,d} + \varepsilon_{i,d}$$

Where the dependent variable $Ret_{i,d}$ is the daily returns for country i in day d. The independent variables include the TED spread (Ted_d) and control variables ($X_{i,d}$). The control variable ($X_{i,d}$) includes daily trading volume ($Vol_{i,d}$), daily trading volatility ($Volatility_{i,d}$), lagged daily returns *(Ret_{d-1})* and growth rate ($GDP_{i,m}$).

We separated the results using data from 25 different countries in financial ETFs market in Panel A and 22 different countries in global future market in Panel B of Table 2. Our findings show that the coefficients of *Ted* are significantly negative at -0.001, with significant at the 1% level for both equity market and future market sample. These results suggest that when the large U.S. institutional investor lack of funding liquidity leading to a decrease on stock returns in other countries.

Vol has a significant negative impact on *Ret,* ranging from -0.001 to -0.003, significant at the 1% level in ETFs market and future market, respectively. These results posit that a higher on daily trading volume can lead to decline on daily returns (Campbell et al., 1993; Hutson et al., 2008). Table 2 shows that the coefficient of *Volatility* is significantly negative at -0.071, with significant at the 1% level in the Future market (Campbell & Hentschel, 1992; Duffee, 1995). While, *Volatility* has a significant positive impact on *Ret* at 0.763, with significant at the 1% level in financial ETFs market (as shown in Panel A), this results are line with (Duffee, 1995; GRULLON et al., 2012; Veronesi, 1999), it has important theoretical implications because it is inversely related with "leverage effect" hypothesis (Christie, 1982; Fischer, 1976). These empirical results imply that higher daily trading volatility can lead to an increase (decrease) in securities returns. Our results also shows that Ret_{d-1} has a negative significant impact on *Ret*, with the coefficients of Ret_{d-1} range from -0.075 to -0.117, significant at the 1% levels in both ETFs and Future markets. In addition, the coefficients *GDP* have insignificant positive impact on *Ret* in both markets.

We also analyze the effects of funding liquidity on index returns in each individual country. The coefficients of *Ted* in 14 countries in Panel A and 17 countries in Panel B are significant negative, with significant at least the 10% level. The most impact of funding liquidity to daily returns clearly in South Korea, Thailand and Turkey on ETFs market (as shown in Panel A), and Germany, Hong Kong, India, Italy, Malaysia, Netherlands, Singapore, Switzerland, Taiwan on future market (as shown in Panel B) at the 1% significant level. While, the coefficients of Ted are negative significant at -0.001, with significant at the 10% levels in China, Switzerland (as shown in Panel A); and Brazil, South Korea, Spain and the United Kingdom (as shown in Panel B). Those results imply that when large institutional investors have insufficient liquidity, index returns will be affected, lead to a decrease returns will occur. In addition, our results posit that the effects of funding liquidity on index returns in different countries are in different levels. The majority of control variables also show significant coefficients that are mostly consistent with our conjectures and prior literatures. These results show that the control variables used in this study are appropriate and play an important role in our model.

Notes: This table provides details of the funding liquidity effect on the daily returns. The regression model is as follows:
$Ret_{i,d} = \alpha + \beta_{i,d} Ted_d + \gamma X_{i,d} + \varepsilon_{i,d}$
Where the dependent variable is the daily returns for country i in day d. The independent variables include the TED spread (Ted_d) and control variables ($X_{i,d}$). The control variable ($X_{i,d}$) includes daily trading volume ($Vol_{i,d}$), daily trading volatility ($Volatility_{i,d}$), lagged daily returns (Ret_{d-1}) and growth rate ($GDP_{i,m}$). In Panel A, we use the panel regression for 25 different countries on Financial Exchange Traded Fund (ETFs) market. In Panel B, we perform the panel regression for 22 different countries by using Global Future data. The t-values examine whether the regression coefficient is significantly different from zero. ***, ** and * indicate significance at the 1%, 5% and 10% levels, respectively.

Classification Discussion

This section explored whether funding liquidity effect on daily returns in different groups of countries is in different level. To reduce the characteristics of individual countries, we used five different classified methods to divide countries into groups; we then use panel regression to analysis which group is deeply impacted when large-scale U.S. institutional investors face the liquidity insufficiency situation.

<u>Classify by Volume</u>

Information flow is the main cause of price or return volatility, however the reality indicates that information flow cannot be observed. Previous literatures showed that trading volume responds to information flowing (Karpoff, 1987), can be considered as a transmission information in the financial market (Lamoureux & Lastrapes, 1990a, 1990b). We consider that when U.S. investors face insufficient liquidity issue, they will inevitably consider the market liquidity to facilitate for withdrawing their funds. We next classified countries into three groups: large, medium and small trading volume countries [More detail classified countries by trading volume as shown in Panel A of Appendix B]. Table 3 presents separate results using data from financial ETFs market in Panel A, and Global Future market in Panel B.
Our results show that the coefficients of *Ted* are significantly negative at -0.001, with significant at the 1% level for all groups both in Panel A and Panel of Table 3. These results suggested that when the liquidity of U.S. investors is insufficient can lead to decrease daily returns in our all group countries. In addition, *Ted* has a deeply significantly negative impact on *Ret* in the medium and trading volume countries in both equity and future market. These results are consistent with our conjectures; it implies that when the U.S. investors face insufficient liquidity issues, they likely to withdraw their funds from better liquidity markets.

Notes: This table provides details of the funding liquidity effect on the daily returns in small, medium, and high daily trading volume countries in the period from 1 January 2004 to December 31, 2015.Where the dependent variable is the daily returns for country i in day d. The independent variables include the TED spread (Ted_d) and control variables ($X_{i,d}$). The control variable ($X_{i,d}$) includes daily trading volume ($Vol_{i,d}$), daily trading volatility ($Volatility_{i,d}$), lagged daily returns (Ret_{d-1}) and growth rate ($GDP_{i,m}$). In Panel A, we use the panel regression for 25 different countries on Financial Exchange Traded Fund (ETFs) market. In Panel B, we perform the panel regression for 22 different countries by using Global Future data. The t-values examine whether the regression coefficient is significantly different from zero. ***, ** and * indicate significance at the 1%, 5% and 10% levels, respectively.

Classify by Economic Freedom

Economic freedom reflects the nation's long-term economic growth and prosperity. To measure economic freedom, Wall Street Journal and the American Heritage Foundation established indexes to measure the economic freedom level, covers 179 countries and regions around the world based on 50 indicators. The score ranges from 0 to 100. The higher the score of an indicator, the lower the government intervention in the economic and the degree of economic freedom is higher. We then classify countries into different group based on level of economic freedom and use the panel the regression to exam the relationship between funding liquidity and daily returns in individual group [More detail classified countries by Economic Freedom as shown in Panel B of Appendix B]. Table 4 presents separate results using data from equity market in Panel A, and future market in Panel B.

Table 4 shows that the coefficient of *Ted* is significantly negative at -0.001, with significant at the 5% level in the group of countries has almost no economic freedom (as results shown in Panel B of Table 4). In addition, the coefficients of *Ted* are significant negative at -0.001, with significant at the 1% level for other three groups of countries in both ETFs and Future market. These results suggest that when the liquidity of U.S. investors is insufficient, investors will withdraw funds from the countries with higher economic freedom level, lead to negative effect on their countries returns.

Notes: This table provides details of the funding liquidity effect on the daily returns in mostly unfree, moderately free, mostly free and free countries in the period from 1 January 2004 to December 31, 2015. Where the dependent variable is the daily returns for country i in day d. The independent variables include the TED spread (Ted_d) and control variables ($X_{i,d}$). The control variable ($X_{i,d}$) includes daily trading volume ($Vol_{i,d}$), daily trading volatility ($Volatility_{i,d}$), lagged daily returns (Ret_{d-1}) and growth rate ($GDP_{i,m}$). In Panel A, we use the panel regression for 25 different countries on Financial Exchange Traded Fund (ETFs) market. In Panel B, we perform the panel regression for 22 different countries by using Global Future data. The t-values examine whether the regression coefficient is significantly different from zero. ***, ** and * indicate significance at the 1%, 5% and 10% levels, respectively.

Classify by Volatility

Changes in the level of trading volatility can have important effects on capital investment, consumption, business cycle and returns (Schwert, 1989). In this section, we explore the impact of funding liquidity on returns on different volatility groups. We classified countries into different

groups consist of: group of countries which small volatility, medium volatility and large volatility [More detail classified countries by trading volatility as shown in Panel C of Appendix B].
Table 5 presents separate results using data from financial ETFs market on Panel A and Global Future market on Panel B. Our findings show that the coefficients of Ted are significantly negative, at -0.001, with significant at the 1% level for all groups of countries in both ETFs and Future market. In addition, our results show that Ted have more significant impact on large volatility group in Panel A; and small volatility and medium groups in Panel B of Table 5. These results imply that when the liquidity of U.S. investors is insufficient, all groups of countries which small, medium, large volatility are impacted by withdraw of U.S. investors, lead to a decrease on their daily securities returns.

Table 5. The panel regression results which classified by volatility

Variables	Small groups	Medium groups	Large groups

Notes: This table provides details of the funding liquidity effect on the daily returns in small, medium, and daily trading volatility countries in the period from 1 January 2004 to December 31, 2015.Where the dependent variable is the daily returns for country i in day d. The independent variables include the TED spread (Ted_d) and control variables ($X_{i,d}$). The control variable ($X_{i,d}$) includes daily trading volume ($Vol_{i,d}$), daily trading volatility ($Volatility_{i,d}$), lagged daily returns (Ret_{d-1}) and growth rate ($GDP_{i,m}$). In Panel A, we use thepanel regression for 25 different countries on Financial Exchange Traded Fund (ETFs) market. In Panel B, we perform the panel regression for 22 different countries by using Global Future data. The t-values examine whether the regression coefficient is significantly different from zero. ***, ** and * indicate significance at the 1%, 5% and 10% levels, respectively.

Classify by the change of Ted spread

Next, we classified our sample to three different groups based on the change of Ted spread to examine whether funding liquidity affects to daily returns in different groups is in different levels. We collect the change of Ted spread in a given day compared with prior day (ΔTed_d), we considered if ΔTed_d is positive means that the monetary market is tighter, $\Delta Ted_d$is negative means the monetary market is looser, and ΔTed_d equals zero means the monetary market is unchanged. Table 6 presents the asymmetric relationship between Ted and daily returns using data from equity market (in Panel A) and future market (in Panel B).
Our empirical results show that the coefficients of *Ted* are significantly negative at -0.001, with significant at the 1% level when the U.S. monetary market is looser for both Panel A and Panel B of Table 6. These results suggest that when U.S. investors have abundant funds, they will invest spill into the global market, driving the increase market returns. While, the coefficients of *Ted* have a negative insignificant impact on daily returns when the U.S. monetary market is tightening for both markets. These results posit that when U.S. funding market is tighter, U.S. investors face insufficient liquidity problem, they will prioritize recover the required funds from the domestic capital market first. To the international market, this process takes a long time to wait and sell, leading to solve the capital shortage problem and avoid the risk of liquidity gaps are ineffective, therefore its impact to returns cannot be reflected immediately. Panel A of Table 6 also shows the coefficients of *Ted* is at -0.001, with significant at the 1% when U.S. monetary market is unchanged. These empirical results are line with our expectation. They indicating that higher *Ted* spread can lead to a decrease in market returns.

Table 6. The panel regression results which classified by the change of Ted spread

Notes: This table provides details of the funding liquidity effect on daily index returns by the change of TED spread in d day and d-1 day (ΔTed_d). We classify ΔTed_dinto three groups are bigger, smaller and equal to zero. Where the dependent variable is the daily returns for country i in day d. The independent variables include the TED spread (Ted_d) and control variables ($X_{i,d}$). The control variable ($X_{i,d}$) includes daily trading volume ($Vol_{i,d}$), daily trading volatility ($Volatility_{i,d}$), lagged daily returns *(Ret_{d-1})*, and growth rate ($GDP_{i,m}$). In Panel A, we use thepanel regression for 25 different countries on Financial Exchange Traded Fund (ETFs) market. In Panel B, we perform the panel regression for 22 different countries by using Global Future data. The t-values examine whether the regression coefficient is significantly different from zero. ***, ** and * indicate significance at the 1%, 5% and 10% levels, respectively.

As the results show in Panel A of Table 6, *Ted* also have strongly negative significant to market returns when U.S. monetary market is unchanged. We next deeply explore the relationship between *Ted* and *Ret* in this group. We continue collect the change of Ted spread in day d-1 and day d-2 (ΔTed_{d-1}). We classified three difference subgroups based on the unchanged of ΔTed and the change of ΔTed_{d-1}. Our three subgroups consist of unchanged ΔTed_d and positive ΔTed_{d-1}; unchanged $\Delta Ted_d$and negativeΔTed_{d-1}; unchanged ΔTed_d and unchanged ΔTed_{d-1} [The number observation in the subgroup: unchanged ΔTed_d and unchanged ΔTed_{d-1} is only three observations, so we ignored this subgroup]. Table 7 shows that the coefficient of Ted is significant negative at -0.002, with significant at the 1% in group unchanged $\Delta Ted_d$and negative ΔTed_{d-1}. It implies that when the U.S. funding market looser than previous period, it not only has positive impact to market returns in this period, but also leading to an increase returns in the next period. Our results also pointed out the coefficient of *Ted* does not have a significantly negative impact on *Ret* in subgroup unchanged$\Delta Ted_d$and positive ΔTed_{d-1}, this result is similar to our expectations and consistent with prior findings on Table 6. These results strongly imply the asymmetric relationship between U.S. tighter (looser) monetary market and market returns.

Table 7. The panel regression results which classified by the unchanged of ΔTed_d and the change of ΔTed_{d-1} for ETF

Variables	$\Delta Ted_d = 0$ and $\Delta Ted_{d-1} > 0$	$\Delta Ted_d = 0$ and $\Delta Ted_{d-1} < 0$	$\Delta Ted_d = 0$ and $\Delta Ted_{d-1} = 0$

Notes: This table provides details of the funding liquidity effect on the daily returns by the unchanged of TED spread in d day and d-1 day (ΔTed_d), and the change of TED spread in d-1 day and d-2 day (ΔTed_{d-1}). We also classify ΔTed_{d-1}into three groups are bigger, smaller and equal to zero. The dependent variable is the daily returns. Where the dependent variable is the daily returns for country i in day d. The independent variables include the TED spread (Ted_d) and control variables ($X_{i,d}$). The control variable ($X_{i,d}$) includes daily trading volume ($Vol_{i,d}$), daily trading volatility ($Volatility_{i,d}$), lagged daily return *(Ret_{d-1})*, and growth rate

($GDP_{i,m}$). The t-values examine whether the regression coefficient is significantly different from zero. ***, ** and * indicate significance at the 1%, 5% and 10% levels, respectively.

Classified by Quantitative Easing

The financial crisis 2008 was considered as the most serious financial crisis since the Great Depression of the 1930s, caused by the U.S. subprime mortgage market and developed into the banking crisis, impacted to the world financial system. Financial market faced the insufficient liquidity issues. Therefore, U.S. government performed the quantitative easing methods, injecting a large amount of money into the market to rescue the confidence of investors. In this section, we deeply explore how the funding liquidity effect on daily returns when U.S. government performed the quantitative easing methods. We classified our sample into four difference groups based on three times of quantitative easing by the US government, consisting of QE1 (first quantitative easing), QE2 (second quantitative easing), QE3 (third quantitative easing), NonQE (other non-quantitative easing period).
[QE1 (first quantitative easing): QE1 is implemented from March 2009 to March 2010, and the scale is around 1.725 trillion US dollars, an average of more than 100 billion US dollars per month. The funding used to buy 1.25 trillion US dollars of mortgage-backed securities (MBS), $300 billion in US Treasury bonds, and $175 billion in institutional securities (Agency MBS).
QE2 (Second quantitative easing): The implementation time is from the end of November 2010 to June 2011, and the scale is about 600 billion US dollars. It is mainly used to purchase long-term bonds issued by the Ministry of Finance. The average monthly purchase amount is 750. Billion.
QE3 (Third Quantitative easing): Implementation time is from September 2012, with Agency MBS as the target, September purchase of $23 billion, and monthly purchase of $400 trillion from October. Different from the previous two rounds, the QE3 has no clear implementation deadline and will continue to be implemented until the US job market recovers. In January 2013, QE3 was further intensity, in addition to continuing to implement monthly purchases of $400 trillion in MBS, and increasing monthly acquisitions of $450 trillion in long-term public debt, that will increase the monthly bond purchases to $850 trillion. Although QE3 still has no clear deadline, it has joined the exit trigger, which is begin to adopt a gradual reduction in the scale of debt purchase when the expected inflation rate in the United States is higher than 2.5% and the unemployment rate is lower than 6.5%.].
Table 8 presents separately results using data from ETFs market in Panel A and Global Future market in Panel B. Our empirical result shows that the coefficients of *Ted* are significant negative at -0.001, with significant at the 1% level in both equity market and future market when US government do not perform the quantitative easing policies. Those results suggest that when the US government does not implement monetary and fiscal policies, U.S. investors face the shortage liquidity problem; they will withdraw their fund from the capital market, resulting in a decrease returns on securities market. In addition, the coefficients of *Ted* do not have a significantly negative effect on *Ret* for all three times of quantitative easing by the U.S. government (as shown in both panel A and panel B of Table 8). These results are line with our expectation. It indicates that during implementing three times easing methods, US government monetary policies not only directly impact the liquidity of funding market but also indirectly impact the capital market.

Notes: This table provides details of the funding liquidity effect on the daily returns on three quantitative easing periods of the U.S. government. QE1 is implemented from March 2009 to March 2010, QE2 implementation time is from the end of November 2010 to June 2011, QE3 implementation time is from September 2012, and NonQE presents other non-quantitative easing periods. Where the dependent variable is the daily returns for country i in day d. The independent variables include the TED spread (Ted_d) and control variables ($X_{i,d}$).The controlvariable ($X_{i,d}$) includes daily trading volume ($Vol_{i,d}$), daily trading volatility ($Volatility_{i,d}$), lagged daily returns (Ret_{d-1}) and growth rate ($GDP_{i,m}$). In Panel A, we use the panel regression for 25 different countries on Financial Exchange Traded Fund (ETFs) market. In Panel B, we perform the panel regression for 22 different countries by using Global Future data. The t-values examine whether the regression coefficient is significantly different from zero. ***, ** and * indicate significance at the 1%, 5% and 10% levels, respectively.

Effect of quantitative easing methods and the change of Ted spread

In this section, we classified our sample into groups based on the change of Ted spread and three times of quantitative easing by the US government. We explore whether exist the asymmetrical relationship between funding liquidity and returns in quantitative easing period. Table 9 presents separately results using data from ETFs market in Panel A and Global Future market in Panel B.

Table 9 shows that *Ted* have a significant negative effect on *Ret* at the 5% level in the ETFs market and the 1% level in the future market when U.S. government do not implement quantitative easing and market is loosening. The coefficient of *Ted* is -0.001, with significant at the 1% level when market unchanged (as shown in Panel A). These results are line with our expectation. It indicates that funding liquidity effects on returns when US government do not implement monetary policies.

In the first quantitative easing period, the coefficient of *Ted* is negative significant, ranging from -0.003 to -0.055, with significant at the 5% levels when monetary market is unchanged and loosen, respectively (as shown in Panel A). In Panel B of Table 9, the coefficients of *Ted* are significantly positive at 0.007, with significant at the 5% level, when the monetary market is loosening. This result clearly demonstrates that quantitative easing affects the relationship between the money market and the capital market.

In the second quantitative easing period, *Ted* has a significant negative significant effect on *Ret* at the 1% level when the monetary market is tightened (as results shown in Panel A). It implies that although the funding market is tightened, U.S. investors believe their government willing to inject capital into the market, thereby encouraging U.S. investors to invest to capital markets, leading to an increase price and returns.

Finally, in the third quantitative easing period, the coefficient of *Ted* does not have significant negative effect on *Ret* in both ETFs and future market. The main reason probably is the market has been injected a large amount of money, leading the excess liquidity in the capital market, therefore the impact of funding liquidity to returns not so significant. These results show strongly evidence that quantitative easing clearly affect the relationship between the money market and the capital market.

Notes: This table provides details of the funding liquidity effect on the daily returns on three quantitative easing periods (QE) of the U.S. government and the change of Ted spread in d day and d-1 day (ΔTed_d).We classify ΔTed_dinto three groups are bigger, smaller and equal to zero. QE1 is implemented from March 2009 to March 2010, QE2 implementation time is from the end of November 2010 to June 2011, QE3 implementation time is from September 2012, and NonQE presents other non-quantitative easing periods. Where the dependent variable is the daily returns for country i in day d. The independent variables include the TED spread (Ted_d) and control variables ($X_{i,d}$). The control variable ($X_{i,d}$) includes daily trading volume ($Vol_{i,d}$), daily trading volatility ($Volatility_{i,d}$), lagged daily returns (Ret_{d-1}) and growth rate ($GDP_{i,m}$). In Panel A, we use thepanel regression for 25 different countries on Financial Exchange Traded Fund (ETFs) market. In Panel B, we perform the panel regression for 22 different countries by using Global Future data. The t-values examine whether the regression coefficient is significantly different from zero. ***, ** and * indicate significance at the 1%, 5% and 10% levels, respectively.

CONCLUSION

We explore the relation between the funding liquidity of US institutional investors and returns, using data from 25 financial ETFs and 22 financial future markets. We investigate the ways in which funding liquidity may have affected returns during the period from 1 January 2004 to 31 December 2015.

We observe that when the large US institutional investors face insufficient of liquidity, index returns of other countries will be negative effect. These results provide evidence to support for our hypothesis, a liquidity shock can trigger enormous redemption pressure for investors, causing the problems for the financial intermediaries funding. Our results show that the effects of funding liquidity on returns in the different countries are in different levels. Moreover, the impacts are in different level when the monetary market is tighter or looser. We also find evidence that US government monetary policies have significant impact to money market and funding market. In sum, our study provides a better overall understanding of the effect of the liquidity–supplier funding constraint on returns.

ABSTRACT

Hospitals rely heavily on their workforce to develop and deliver innovative care. We examine key mediators that link service innovation and financial performance; namely, a committed workplace, experiential quality, and patient satisfaction. Data from three sources reveal important positive and negative relationships that are contingent on teaching status.

KEYWORDS: Healthcare Management

INTRODUCTION

Patients' perceptions of quality and satisfaction are important operational metrics for hospital leaders (Chandrasekaran et al. 2012; Nair et al. 2013). Reimbursement structures are shifting away from volume-based systems to programs that link hospital reimbursement payments to hospital outcomes, including experiential quality and patient satisfaction (Powell et al. 2012; Ding 2014). Concomitantly, as insurance plans increase patient out-of-pocket costs (Salzarulo et al. 2011), patients are becoming more engaged in selecting hospitals based on their level of satisfaction (Salzarulo et al. 2015). Patient Satisfaction is defined as the extent to which patients judge the overall hospital stay as favorable (Marley et al. 2004; Ancarani et al. 2011). Experiential Quality, on the other hand, has more to do with the service encounter and is defined as the extent to which patients judge the physical service setting and the multiple moments of contact with hospital employees as meeting their expectations (Pine and Gilmore 1999; LaSalle and Britton 2003; Gentile et al. 2007; Senot et al., 2016c). As such, experiential quality embodies the physical and social dimensions of a service encounter, sometimes referred to as servicescape in the service operations literature (Bitner 1992; Bitran et al. 2008; Rosenbaum and Massiah 2011). Patient satisfaction can be challenging and costly to achieve because it requires careful management of both the physical environment as well as the service encounter, which necessitates coordination among highly specialized service professionals to collectively deliver fairly customized care (Bitran et al. 2008; Lahiri and Seidmann 2012). Recent research has found that higher patient satisfaction scores are actually linked to increased healthcare costs (Fenton et al. 2012). As such, hospitals are increasingly interested in understanding how to improve patient satisfaction and translate those efforts into financial performance (Press Ganey 2013; Senot et al. 2016c).

Service innovations are frequently pursued for financial motivations, such as increasing net profits (Griffin and Page 1993). In addition, service firms develop innovations not only for financial reasons, but also to achieve other performance objectives like customer satisfaction (Ottenbacher 2007). In healthcare, researchers, government and industry leaders alike have suggested that a service innovation orientation is necessary to improve hospital performance across a multitude of dimensions (Dobrzykowski et al. 2015). This is due, at least in part, to the belief that operational performance measures, like experiential quality, patient satisfaction, and financial performance, are predicated on the service delivery system designed by healthcare operations managers (Cook et al. 2002; Zepeda and Sinha 2016; Zheng et al. 2017). Designing and managing the healthcare delivery system is challenging, given that hospitals operate as professional service organizations (PSOs) (Day et al. 2012; Heineke 1995). Specifically, as PSOs, a hospital's patient satisfaction scores rely on fostering a committed workplace that delivers new and innovative services that create positive patient experiences. This is because PSO's depend heavily on employees (e.g., individual healthcare providers) to possess and skillfully apply abstract expert knowledge during complex, high-customer contact interactions (Goodale et al. 2008). Furthermore, PSOs face a unique challenge of managing a flat management hierarchy with loose subordinate–supervisor relationships (Nembhard et al. 2009). These operational conditions can diminish organizational commitment, shifting loyalties toward self-interests, peers, professional societies and other constituents (Schneller and Smeltzer 2006; Nembhard et al. 2009; Boyer and Pronovost 2010). As such, the operational context is important to consider as hospitals attempt to deliver on service innovation because of the key role played by service providers in designing and delivering services that patients desire (Umashankar et al. 2011).

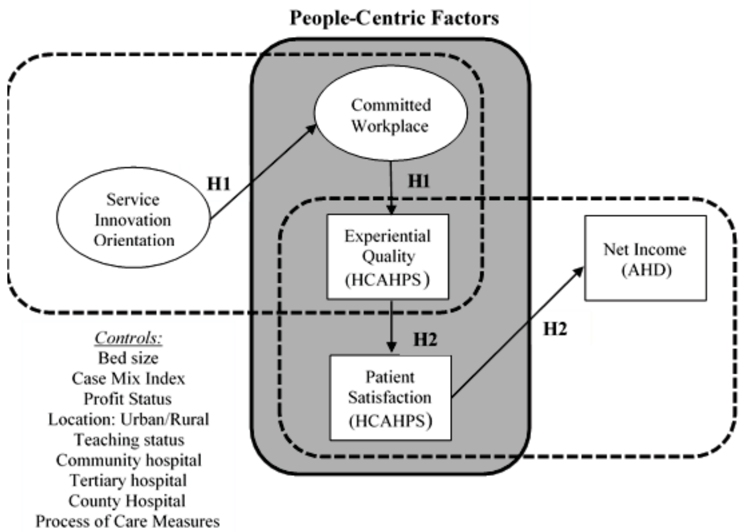
Our study investigates the roles of people-centric factors, namely a committed workplace, experiential quality, and patient satisfaction in linking a hospital's desire for innovation to improved financial performance. We address our research objective by conceptualizing a model based on the services operations (informed by the healthcare, PSO, and servicescape streams) and organizational commitment literature. The model is tested using a unique dataset collected from three sources: 1) primary data collected via survey measuring the extent to which hospitals report a service innovation orientation and committed workplace, 2) secondary archival data from the Centers for Medicare and Medicaid Services (CMS) measuring experiential quality and patient satisfaction, and 3) objective archival data from the American Hospital Directory (AHD) measuring net income.

RESEARCH MODEL

A Service Innovation Orientation is defined as the extent to which a hospital promotes new, pioneering services and is on the leading edge of technology (Dobrzykowski et al. 2015). It is created by hospital leaders and is one of many possible orientations (McFadden et al., 2009; Boyer et al., 2012; Dobrzykowski et al. 2015; Dobrzykowski et al., 2016). This study focuses on a service innovation orientation, given the recent mandates from the United States federal government requiring healthcare delivery innovations. For instance, the Centers for Medicare and Medicaid Services (CMS) is requiring hospitals to deliver experiential quality and patient satisfaction at a lower cost or suffer penalties as high as 2% of their CMS reimbursements (CMS, 2017). In order to achieve positive results from a service innovation orientation, the service organization must be able to understand the voice of the customer and translate their wants and needs into service design specifications that can be used in the delivery of quality service. In a service organization, the front-line employees (physicians, nurses, and other healthcare providers) are in the best position to learn from customer feedback (Dobrzykowski et al., 2015). Therefore, it is important to foster a motivated and committed organizational environment as a means of enhancing quality.

As a theoretical basis for this research, we draw from the service operations (informed by the healthcare, PSO, and servicescape streams) and organizational commitment literature streams to frame relationships among service innovation, committed workplace, experiential quality, patient satisfaction and net income. See Figure 1.

Figure 1: Hypothesized research model



The professional service operations literature motivates our study, and provides contextual support for our research model. A professional service organization (PSO) has been defined as "any organization which provides a service which is based on a professional diagnosis, i.e. on a thorough analysis by a qualified professional in a given field of facts or problems in order to gain understanding and guide future actions" (Harvey 1990, p. 6). The professional services literature highlights the distinct characteristics, environment and managerial challenges required for managing PSO processes (Goodale et al. 2008; Lewis and Brown 2012; Brandon-Jones et al. 2016; Zhang et al. 2016; Lawrence et al. 2016). PSOs' distinct characteristics make the organizational environment a key consideration as managers orchestrate operations with an eye toward organizational performance.

The PSO literature, with its inherently high focus on customer contact/customization, flexible processes with high labor intensity, and the need for "nudging" service personnel rather than implementing standard operating procedures, supports the idea that a committed workplace would enhance experiential quality. A Committed Workplace is defined as the extent to which the work environment enhances employees' attitudes towards work, encourages hard work and high-level job performance (Bargagliotti 2012; Jambulingam et al. 2005; Vera et al. 2016). Gowen et al. (2006) explains that the employee commitment approach has been conceptualized at both an individual and an organizational-level behavioral theory. This study follows the approaches of Bou and Beltan (2005) and Gowen et al. (2006) in conceptualizing workplace commitment at the organizational level.

Hypothesis 1. A Committed Workplace partially mediates the relationship between Service Innovation Orientation and Experiential Quality.

Patient experience is an important aim for hospital leaders as it is considered a cornerstone in the evaluation of health care quality (Danielsen et al. 2010). However, experiential quality may not improve a hospital's financial performance. Some firms have found that their investments to improve service offerings, with an aim toward 'delighting' customers, have proven unprofitable primarily because they fail to benefit from the economies of scale and learning curves realized in manufacturing settings (Rust et al. 1995; Sasser et al. 1997). In hospitals, economies of scale are difficult to achieve due to the substantial fixed costs associated with investments in cutting-edge infrastructure and amenities thought to improve patient experience (Senot and Chandrasekaran 2015). It may also be difficult to achieve consensus regarding infrastructure decisions among professional service providers given their autonomy and influence in the workplace (Harvey 1990; Schneller and Smeltzer 2006; Boyer and Pronovost 2010). Learning curves are hampered by the volume and variety of sources considered by patients in evaluating the quality of their experience (i.e., nurses, physicians, other staff members, and even "hotel-like" amenities such as the cleanliness of their hospital room) (LaSalle and Britton 2003). What is clear is that the customer plays an important role in the profitability of service firms (Bolton 1998). "Competition for healthcare dollars often rests on how satisfied patients are with their provider," (Russell, Johnson and White 2015: p. 1159).

Hypothesis 2. Patient Satisfaction partially mediates the relationship between Experiential Quality and Hospital Net Income.

METHODS

Survey data were collected from 166 hospitals in 46 states in the USA, and paired with data from two other sources – 1) archival data from the Centers for Medicare and Medicaid Services (CMS) collected using individual patient surveys to measure experiential quality and patient satisfaction, and 2) objective data on net income from the American Hospital Directory (AHD).

Instrument Development

We collected survey data to measure service innovation orientation and committed workplace as multi-dimensional psychometric measures. These are hospital phenomena which are behavioral in nature and thus it is appropriate to capture these variables using psychometric approaches (Gowen et al. 2006; Dobrzykowski et al. 2015). We developed measurement instruments using a three step process (Churchill, 1979; Bardhan, et al. 2007).

Measures

Service innovation orientation and committed workplace were collected from primary data with the scales developed using the procedures described above. Experiential quality and patient satisfaction were collected from the Center for Medicare and Medicaid Services (CMS) Hospital Consumer Assessment of Healthcare Providers and Systems (HCAHPS) survey. HCAHPS measures patients' perspectives on their care following inpatient stays at acute care facilities in the USA (see also Chandrasekaran et al. 2012; Ding, 2014; Senot et al. 2016b). The HCAHPS survey is administered to a random sample of patients on an ongoing basis and reported publically via the Hospital Compare website. This process produces a dyadic sample – paired sets featuring hospitals reporting on operational practices and patients reporting on their experience and satisfaction. The mean of the seven items was calculated to produce an aggregate measure of experiential quality. This methodological approach is common in the OM literature (See Boyer et al. 2012; Goldstein and Iossifova 2012; Queenan et al. 2011). Patient satisfaction was also collected from the HCAHPS survey and deals with the overall hospital experience (Ancarani et al. 2011; Marley et al. 2004).

Our dependent variable is net income, which is reported as a percentage by the American Hospital Directory (AHD). AHD is a publically available data source providing financial performance data for more than 6,000 hospitals in the USA. AHD data is derived from both public and private sources, including the Federal Centers for Medicare and Medicaid Services. Smith et al. (2013) is a related study that has analyzed AHD net income data.

Data Collection

The dataset was populated by a cross-sectional self-administered internet-based survey. The sample frame was created from a random list of acute care facilities that are members of the American Hospital Association. A telephone solicitation method was employed to populate the sample frame with email addresses of prospective respondents (see McFadden et al. 2009). Our response rate is 46.8% (302 responses / 644 prospective acute care facilities). Two statistical tests were conducted to examine non-response bias (Armstrong and Overton 1977): the chi-square test and t-tests (Bardhan et al. 2007). Chi-square tests performed on dichotomous binary variables for hospital type (tertiary, community, or critical access) as well as for membership in a hospital system. A t-test examined mean differences for bed size, similar to Meyer and Collier (2001). A total of 124 hospitals declined participation in the survey and were designated as non-respondents. We collected non-respondent data for hospital type using the internet, and data for bed size and system affiliation membership was provided from the AHA. These tests produced no statistically significant differences between the respondents and non-respondents, providing evidence of an absence of non-response bias (Armstrong and Overton 1977).

Analysis and Results

The analysis and results will be discussed at the conference.

Discussion and Conclusion

Our study makes several important contributions to the literature that ought to influence the way hospital operations leaders design healthcare services with an aim toward satisfying patients and improving hospital net income. First, we show that service innovation plays a dual role in positively influencing workplace commitment, but negatively affecting experiential quality and patient satisfaction. Second, we found that service innovation has a positive indirect effect on experiential quality, partially mediated by a committed workplace. Third, experiential quality and patient satisfaction do not generally drive net income. Fourth, our results show that the pathway from service innovation orientation to hospital financial performance is contingent upon teaching status, or a hospital’s strategic positioning toward differentiation. We find that teaching status mutes the negative effect of service innovation on patient satisfaction, and amplifies the effects of experiential quality and patient satisfaction on net income. Thus, it is important to understand how their hospital’s strategic position influences the patient outcomes they achieve from an innovation orientation, and when (under what conditions) to expect positive financial results.

York, PA 17403
jzk99@psu.edu
1-717-718-6775

ABSTRACT

The paper presents the results of a systematic review of the literature pertaining to the use of blockchain technology in the engineering and manufacturing activities. The uses of blockchain have been growing quickly in the literature, and this fast pace can make it difficult for researchers to keep abreast of the state of the art. Using a systematic approach to search the primary electronic indices, the compiled list of papers is then analyzed and a number of themes are identified. The paper concludes with a set of conclusions about the current state of the literature and suggestions for improvement.

INTRODUCTION

Interest in blockchain technology, the data management method underlying cryptocurrencies, has gotten the attention of researchers and developers in a widening number of industries. After finding a following in the financial industry (Nakamoto, 2008), it has become a focus of interest in the supply chain (Treblmaier, 2018), insurance (Sehgal, 2017), and agriculture (Lin et al, 2017) industries. In many of these industries, the interest has only begun to take shape within the past few years as an understanding of blockchain has become more widespread. In some fields, such as engineering and manufacturing, the evaluation of blockchain as an appropriate tool did not begin until a few years ago, but has continued with an increasing rate and scope. Because of this phenomenon, it becomes difficult for researchers and practitioners to keep abreast of the current approaches to the use of the tool. This situation is exacerbated by the wide variety of current research streams that include blockchain as well as the sheer number of possible outlets for this research. While journals are relatively easy to identify with the use of one or more widely available electronic databases, conference proceedings can be much more challenging to identify and obtain. To assist researchers and practitioners in gaining an understanding of the current state of the research, a systematic review of the literature that surrounds the application of blockchain to engineering and manufacturing systems is undertaken in this paper.

Engineering and manufacturing systems are targeted in this review because of their importance to the creation of value and wealth in any society as well as the very nature of these activities. Both engineering and manufacturing involve the creation and use of high-precision information that must often be shared between users and departments within a firm, or between organizations within a supply chain or joint venture. The distributed nature of these operations, both geographically and organizationally, creates vulnerabilities as these information items circulate within the system. Each change of possession or transformation event must be tracked within a record that cannot be changed or deleted as they are of vital importance to both the success of the enterprise and its ability to analyze its internal processes toward the goal of continuous improvement. Blockchain's ability to provide data immutability in a widely distributed environment is one of its most important features and makes it a likely candidate for use in these fields.

The paper is organized as follows: The next section provides an overview of blockchain technology and extends the discussion as to its application to the engineering and manufacturing processes, the following section describes the methodology followed in the review, the findings of the review are detailed next, and that is followed by a discussion and conclusion including the limitations of the study and directions for additional research.

BLOCKCHAIN OVERVIEW

Blockchain is a distributed ledger data storage mechanism that allows data to be stored in a manner that is available to all entities having the proper level of permission but does not allow for the changing of those data without the notice of all other entities in the ecosystem (Nakamota, 2008). In order to accomplish these two objectives, blockchain utilizes a cryptographic hashing mechanism to determine how data are stored on the chain and to prevent it from being changed. Data to be stored on the chain is combined into blocks of a predetermined size. These blocks are presented to the entities entrusted with the control of the block additions, which might be one entity on a private blockchain architecture or many on a public chain. In order for the block to be added to the chain, a hash puzzle must first be solved. The hash puzzle requires that a random number (called the “nonce”) be found that, when hashed together with data from the new block and the last block added to the chain, results in a hash reference value that meets some predetermined criterion (e.g. three leading zeros). The properties of a cryptographic hash function are such that knowledge of the hash reference requirement does not assist in the identification of the nonce, which means that the entities wishing to solve the puzzle must guess at a nonce and then execute the hashing algorithm repeatedly until the nonce is found. Only when the nonce is finally identified and verified can thee new block be added. After that occurs, work begins on the next block to be added.

The data immutability inherent in blockchain derives directly from this hashing process. Once data are successfully added to the chain, another property of cryptographic hashing requires that any change to the underlying data in a given block necessarily changes its hash value, rendering the solution to the hash puzzle using those data invalid, which in turn renders all subsequent hash solutions invalid (Drescher, 2017). The longer the data are on the chain, the further “buried” it becomes in subsequently added data, and the more difficult it is to change without all other hashes being affected. Therefore, data added to the blockchain remains unchanged and can act as an “official” or immutable version of the data, which is very useful for data that is being used in important and/or expensive operations across multiple organizational or national boundaries, such as exists in a typical engineering or manufacturing environment.

Blockchains have additional characteristics or options that make them a compelling choice for the applications being considered in this paper. The option exists to store data not on the blockchain, but rather in an off-chain storage facility with only the hash value of the data stored on the chain. This has the advantage of increasing the speed of adding blocks to the chain as well as removing the ability of entities with access to the chain to view the data of other entities in the chain environment. This allows all entities to validate the data by comparing hash values with those held in off-chain storage without divulging the actual data. The speed by which blocks are added can also be increased by reducing the complexity of the hash puzzle. An easier puzzle will enable the puzzle to be solved more quickly and still provide data immutability, but might only be applicable to a private chain with only trusted parties involved. Lastly, access to the blockchain can be left open to all (permissionless) or to only those with the need to access it (permissioned). These permissions can be customized to permit only those entities that own the chain to write to it but others that depend on it for verification to have read only access.

With these and other beneficial characteristics available to blockchain designers and users, there would seem to be several aspects of engineering and manufacturing that would benefit from a blockchain-based architecture. The methodological approach to reviewing this literature is detailed in the following section.

METHODOLOGY

In order to perform a systematic literature review, a repeatable and verifiable process must be in place (Briner & Denyer, 2012). For the present research, the process used consists of the following steps:

- Identify the research question(s).
- Locate and select relevant studies
- Critically appraise the studies
- Analyze and synthesize the findings
- Disseminate the findings

The research question for this review is:

- For what aspects of the engineering and manufacturing processes have researchers or developers proposed or applied blockchain?

Within this research question, two research objectives are also investigated:

- Within the engineering/manufacturing blockchain literature, what types of methodologies are being used?
- Within the engineering/manufacturing blockchain literature, how long has blockchain been investigated as a possible solution technology?

To locate relevant studies, a set of “ground rules” are developed to frame the literature to be evaluated. For the current study, the focus will remain on peer-reviewed articles in journals, conference proceedings, or book chapters in edited volumes. Future expansion of the study will involve other sources such as trade journals, unpublished studies, and other so-called “gray” literature in order to both identify any applications not covered in the present study and to understand any differences in emphasis between the traditional academic literature and other sources of information.

Searches are performed in major electronic databases including ABI Inform Global, Emerald, IEEE Explore, JStor, ScienceDirect, Scopus, and Springer, using the following keywords in all possible combinations: blockchain (including digital ledger, distributed ledger, and shared ledger), engineer(ing), design, Manufacture(ing), and Industry 4.0. Searches were accomplished in the article title, abstract, and keywords. All articles having one or more of these search terms were selected for initial inclusion in the study. This initial search resulted in sixty-nine studies.

The selected studies were examined to ensure that they actually were focused on the topics at hand. In most cases, the abstract was sufficient to determine the article’s suitability for the study, however some abstracts were not sufficiently descriptive and the full text of the article was consulted. After this step, six studies were removed as they were not specifically focused on either engineering or manufacturing but were rather more general descriptions of blockchain that only mentioned its possible application to these processes. The results of the analysis of the included studies are presented in the following section.

FINDINGS

The results of the literature analysis are divided into two sections. The first section presents the descriptive statistics of the literature and describes the characteristics of the body of work derived based on the previously described inclusion criteria. The second section describes the themes identified in the literature that describe the research surrounding the application of blockchain to engineering and manufacturing.

Descriptive Statistics

The sixty-two articles included in the study have the following characteristics:

- 50 manufacturing applications, 12 engineering applications
- Only nine articles include any empirical analysis, the rest are descriptive or propositional
  - 6 studies utilized some form of experiment to validate the proposed system
  - 3 studies used a formal case study to demonstrate the proposed system
- Sixteen studies are focused on a particular industry, the rest are more general in nature.
  - construction (9)
  - automotive (2)
  - pharmaceuticals (2)
  - chemical (1)
  - appliances (1)
  - mining (1)
- The articles are published in one of the following three forms:
  - conference proceedings (31)
  - journal articles (26)
  - book chapters (5)

The search process described in the article identification protocol does not use any date specification. Nevertheless, there were no articles retrieved prior to 2016. Figure 1 shows the rapid rise in the number of studies applying blockchain to engineering and manufacturing. The data reflect articles retrieved on May 1, 2019, which suggests that the number of applicable studies published during 2019 will likely be even higher if the pace of publication continues.

Research Themes

After examining each of the articles included in the study, six research themes or emphases emerged, and these will be detailed in this section. There is necessarily a certain amount of overlap between these categories, largely because of the level of integration of the applications being described or proposed. However, the papers are categorized based on the most significant contribution put forth by the authors.

Blockchain and Data Validity

The first, and most popular (21 papers), research emphasis centers on blockchain's ability to provide assurance regarding the validity of a value, information entity, or even an individual. This ability is applied in order to prove the identity of a person or part, determine the level of access of a user, and more broadly, to create trust between two parties that might not have much of a basis to trust each other. This is in keeping with blockchain's reputation as a trust-

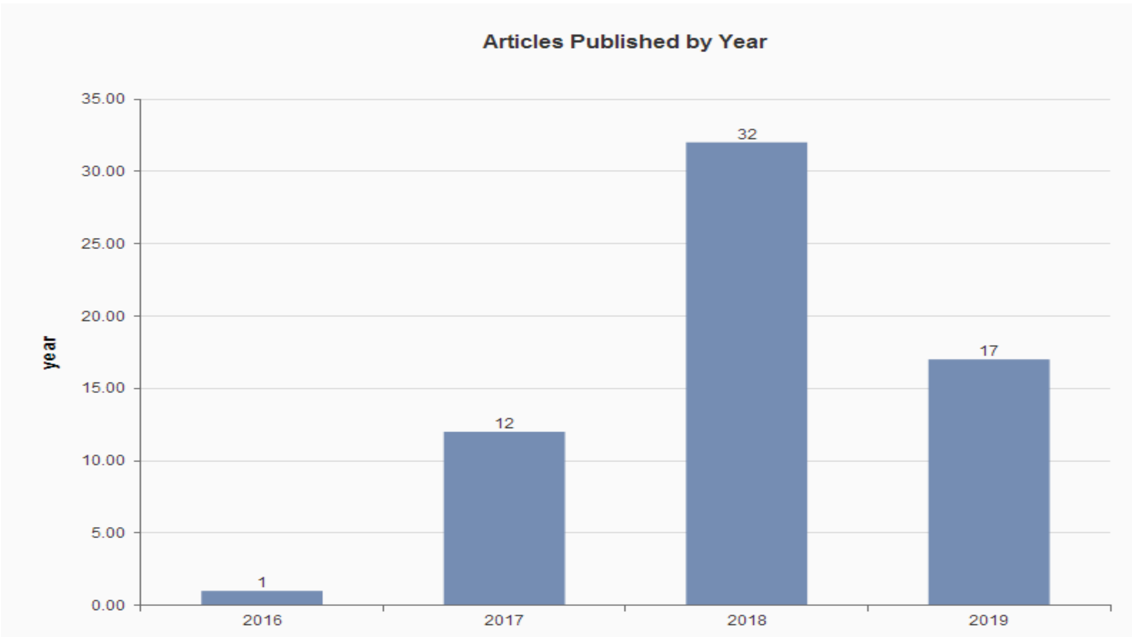

Figure 1: Number of Articles Published Applying Blockchain to Engineering or Manufacturing as of May1, 2019

building tool (Kundu, 2019). Most of the papers in this category discuss blockchain's potential contribution to trust-building from a theoretical perspective, but some of them offer system designs that propose in more detail how blockchain can contribute to inter-organizational or interpersonal trust. For example, Mohamed and Al-Jaroodi (2019) describe a middleware approach to provide more trustable and reliable communications between autonomous manufacturing machines in a distributed manufacturing environment. In the same vein, Oak, Jhala, & Khare (2018) proposes a solution that ensures that none of the multiple parties in a design process dominates the process and makes changes to the design without notification of the other contributors. This is written for a software design environment but is equally applicable to other design and manufacturing processes. Lastly, Kasten (2019) describes a blockchain-based system to ensure that no changes can be made to a CAD-based product design without all parties in the process, including both internal and external partners, knowing about it. This allows the parties to have trust in the data they are using, if not in the parties they are working with. Table 1 lists the papers in this research theme, its research paradigm (description of possible use or concrete system proposal) and their key findings.

Each of the papers in this section leverage the data immutability properties of blockchain to provide the services described. With data embedded on the chain, or at least their hash references, there is very little chance that the data can be changed without the notice and approval of the other entities in the ecosystem. This characteristic takes the place of trust in providing confidence that the data is as it was supposed to be at the time of its creation, regardless of the intention of some to tamper with it. Thus, data maintains its validity and processes that depend on it can continue safely without the overhead of a third party to maintain its safety.

Table 1: Papers focusing on use of blockchain to increase trust and validity

Blockchain and Communication

Blockchain is identified by these authors as a tool to enhance the ability to communicate and to foster interaction among the entities in a system, be they machines, organizations, or humans. The twelve papers in this section include a number of proposals for tools that use blockchain to enhance the communication abilities of various types of systems to achieve various goals that support the overarching goals of the organization. Some examples include an Internet-of-Things (IoT) approach for gathering data from the structure supporting the walls and ceilings of underground mines to provide more meaningful warnings to miners (Singh, Kumar & Hötzel, 2018), a system that will assist in the management of the product design process (Papakostas, Newell & Hargaden, 2019), and helping to track the specific parts applicable to a specific version of an automobile (Heber & Groll, 2018). Interestingly, there are a higher percentage of proposal-based papers in this grouping, possibly due to the relative ease of conceiving of the role of blockchain in the communications process. Table 2 provides an overview of the papers discussing the role of blockchain in enhancing communications and integration.

Author(s)	Descriptive/Proposal	Key Findings
Ablyazov & Petrov (2019)	descriptive	Use BC to improve communication among construction participants
Afansez et al (2018)	descriptive	BC to create network of industrial components
Chung et al (2019)	proposal	Use BC to help interpret sensor data from equipment and human body
Downey, Bauchot & Röling (2018)	descriptive	BC for contract and workflow
Goldstein & Imbault (2018)	descriptive	Use of BC in fractal manufacturing
Heber & Groll (2018)	proposal	Use BC to trace products throughout product lifecycle management
Papakostas, Newell & Hargaden (2019)	proposal	BC for managing product design process
Sikorski, Haughton & Kraft (2017)	proposal	BC use to facilitate machine-to-machine interactions
Singh, Kumar & Hötzel (2018)	proposal	BC and IoT to enhance mine safety
Yan et al (2017)	proposal	BC to facilitate the cooperative dev of power electronic devices
Zhang, Liu & Shen (2017)	proposal	BC to coordinate collaborative manufacturing
Li et al (2018)	proposal	BC to promote knowledge sharing within a manufacturing ecosystem

Table 2: Papers focused on using blockchain to enhance communications

The distributed nature of the blockchain technology can take the place of more complicated communication processes, thus simplifying the inter- or intra-organizational communications that need to take place. With the peer-to-peer communications process inherent in a distributed ledger architecture, the requirements of communications, local access, data immutability and validity can all occur simultaneously without the need for external monitors to moderate the process. Depending on the particular architecture, certain rules might be needed to control the order in which data are added to the chain or permissions might be adjusted to ensure that only certain entities can add data, but once in place these rules will maintain order on the chain without user or organizational intervention.

Blockchain and Cloud Manufacturing

Cloud manufacturing can be defined as an outgrowth of cloud computing in that manufacturing resources are located outside of the manufacturing firm (Zissis & Lekkas, 2012). These resources can be strictly manufacturing process (machining, assembling, etc.) or can be broadened to include ancillary processes such as engineering and design, testing, supply chain, and other activities necessary for the creation of physical products. Like cloud computing, these resources are interacted with via the Internet, usually including the provision of engineering and manufacturing data, contracts, and other information necessary for the creation of products. The relationships can be short or long term, and involve entities spread around a town or around the world. With that as background, the third research theme is the use of blockchain in the cloud manufacturing environment (11 papers).

The papers that are placed in this category utilize blockchain to address certain issues found specifically, but not exclusively, in cloud manufacturing, such as trustworthiness and distributed manufacturing networks. Bahga and Madisetti (2016) combine blockchain with the Internet of Things (IoT) concept to improve the level of interaction between peers without the need for an intermediary. A cloud manufacturing system with thirty-two manufacturing services is evaluated as to its ability to provide increased scalability and security using blockchain over more traditional, centrally controlled data storage approaches (Li, Barenji & Huang, 2018). Lou et al (2018) simulate the use of a blockchain-based approach in the coordination of distributed manufacturing resources using a punishment mechanism to promote cooperation. The papers comprising the cloud manufacturing theme are presented in Table 3.

As mentioned above, the papers in this section utilize the characteristics of blockchain to enhance the ease, accuracy, and efficiency of the cloud manufacturing process. By creating an agreed-upon version of the data required for this distributed system to operate and leverage the inherent advantages of the cloud platform, blockchain acts as a lubricant of sorts to ease the flow of data (and therefore trust) between machines (Barenji, Li, & Wang, 2018), organizations (Li et al, 2018), and credit-granting organizations (Liu, Jiang, & Leng, 2017).

Author(s)	Descriptive/Proposal	Key Findings
Angrish et al (2018)	proposal	Verification of BC data on distributed network
Bahga & Madisetti (2016)	proposal	Enable peers to interact without trusted intermediary
Barenji et al (2018)	descriptive	BC for decentralized peer to peer network
Barenji, Li & Wang (2018)	proposal	Use BC to promote machine-to-machine comm.

Li, Barenji & Huang (2018)	proposal	Use BC to improve security and scalability of dist. mfg
Li et al (2018)	proposal	Use BC for knowledge sharing for injection mold redesign
Liu, Jiang & Leng (2017)	proposal	Use NC to coordinate credit assurance within social manufacturing context
Lou et al (2018)	proposal	Use NC to encourage cooperation among nodes in cloud manufacturing
Yu et al (2019)	proposal	Use BC to enhance information transparency and decentralization

Table 3: Papers focused on using blockchain to support cloud manufacturing

<u>Blockchain and Efficiency</u>

The fourth theme of research is the use of blockchain to improve the efficiency of a manufacturing process or system and to increase the value it brings to the product and, thus, to the firm (10 papers). If the literature is a guide, there are a number of areas in manufacturing and engineering that can be made less costly and bring more value using blockchain in some manner. Sorting of materials and goods can be an expensive, manual process, but Petrali, Isaja, and Soldatos (2018) provide guidance in the use of blockchain and smart contracts to model and optimize the sorting process. Carreno et al (2018) use blockchain to control data entry into an installation design expert system. The costs of data storage and manipulation using blockchain and traditional database technologies are compared by Rimba et al (2018). The papers that utilize blockchain to bring about efficiency and increase value are listed in Table 4.

Author(s)	Descriptive/Proposal	Key Findings
Backman et al (2017)	proposal	Use BC to enhance autonomous equipment leasing
Berger, Penzanstadler & Drögehorn (2018)	descriptive	Identify use of BC in safety-critical systems to reduce liability
Carreno et al (2019)	proposal	BC as a means of controlling data intro to designer ES
Isaja & Soldatos (2018)	proposal	Industrial autonomous systems using BC and edge computing
Miller (2018)	proposal	BC enabled sharing of IoT data to all participants in business network
Kapitonov et al (2018)	descriptive	BC supported autonomous agent network

Mohamed, Al-Jaroodi & Lazarova-Molnar (2019)	descriptive	Describes the role of Industry 4.0 technology, inc BC, to reduce greenhouse emissions and costs
Petrali, Isaja & Soldatos (2018)	proposal	Use of BC to support optimal sorting mechanism
Rimba et al (2018)	descriptive	compares cost of BC and traditional RDBMS

Table 4: Papers focused on using blockchain to increase efficiency and value

Blockchain and Building Information Model

A building information model (BIM) is used in the construction industry to plan, design, construct, and maintain buildings (Belle, 2017). They are essentially 3D Computer Aided Design models that display the foundation, structure, electro-mechanical lines, HVAC, and other aspects of a building’s construction. It is used as a design and engineering tool, a construction guide, and a repository of data that can be used to efficiently run the building as well as plan for improvements. This understanding of BIM should relate easily to the use of blockchain. As a single source of information, a technology that provides for data immutability while facilitating access would seem to fit well. Zheng et al (2019) find that blockchain is useful in providing for security of the BIM as well as guarantees that the current data has not been tampered with. Zheng et al (2019) provide for a blockchain-based BIM that provides for context-aware access of data, thereby creating a much more responsive construction tool. Table 5 presents the five articles in this theme.

Author(s)	Descriptive/Proposal	Key Findings
Li, Greenwood & Kassem (2019)	descriptive	Suggest BC not yet mature enough for BIM use
Mathews, Robles & Bowe (2017)	descriptive	Explores role of BC in the evolving construction industry
Zheng et al (2019)	proposal	BC used to facilitate BIM data security and audit
Zheng et al (2019)	proposal	BC to provide context-aware BIM access
Ye et al (2018)	descriptive	BC to increase security and transparency of BIM

Table 5: Papers focused on using blockchain for BIM

Blockchain and Additive Manufacturing

Additive manufacturing, sometimes known as 3D printing or direct digital manufacturing, is the process of creating a part from a CAD model by applying layers of material (plastic, metal, etc.) until the final part shape is reached. This technology can be used to build prototypes and production parts. Because it is always created from a CAD model, the validity of the model is of paramount importance. The three papers in this last group focus on anti-counterfeiting (Kennedy et al, 2017) and intellectual property protection (Engelmann et al, 2018; Holland et al, 2017). These papers are listed in Table 6.

Author(s)	Descriptive/Proposal	Key Findings
Engelmann et al (2018)	descriptive	BC as a tool to protect intellectual property
Holland et al (2017)	descriptive	BC as a tool to protect intellectual property
Kennedy et al (2017)	proposal	Use BC to trace lanthanide nanomaterial to prevent counterfitting

Table 6: Papers focused on using blockchain in additive manufacturing

DISCUSSION

There are a number of themes that emerge from these results beyond those of the research areas already identified. The first is the lop-sided nature of the results in terms of the ratio of engineering to manufacturing research emphases. This review was planned to include both engineering and manufacturing because of the close relationship of the two disciplines. In essence, they are highly interconnected segments of the same value chain (Porter, 1985). Therefore, a simultaneous search of both literatures was a logical approach to the project. In reviewing the papers included in this review, the reason for the emphasis on manufacturing is that most of them concentrate on the use of blockchain to improve the logistical aspect of manufacturing (production line management, part authentication, contract and workflow management) or the management of manufacturing information (intellectual property of additive manufacturing, machine-to-machine communication, credit assurance validation), both of which have already been shown to be useful applications of blockchain in other contexts (Wang, Han, & Beynon-Davies, 2019). The use of blockchain in engineering seems to be limited, at the present, to verification and validity, which is another application of blockchain that has been shown to be very useful (Kasten, 2019).

The second theme that is apparent from this collection of papers is that there has been a significant amount of prescriptive activity in this area of inquiry, but very little in the way of empirical analysis of the applicability of blockchain to the engineering or manufacturing processes. Some of the papers discuss the evaluation of blockchain in a well-controlled experimental or simulation environment, and others apply a limited case study approach, but there has yet to be a substantial empirical investigation performed that would provide evidence of the applicability, or lack thereof, of blockchain to these activities. This is similar to the application of blockchain to other activities such as supply chain (Treiblmaier, 2018) and healthcare (Casino, Dasaklis, & Patsakis, 2019). The cause of this imbalance has a few roots, not the least of which is the relative newness of this technology beyond its initial introduction to the financial sector. The level of activity displayed over the previous two years suggests that there will be an increasing focus on empirical research in the near future as long as these proposed systems become reality. However, there are significant barriers to the implementation of blockchain-based systems, as there are with any new technology.

Despite the level of interest in both the academic and popular literature, there are pervasive questions surrounding the performance and complexity of blockchain-based solutions, as well as questions of whether this is a ground-breaking technology or a solution looking for a problem. These misgivings are being dealt with in a theoretical basis in the literature, as shown by this review, but they will act as significant barriers to implementation until they are investigated by empirical research. Blockchain, and the literature surrounding it, need to mature so that the normal resistance to change often brought about by technology change can be addressed. This expansion of the literature will also serve to reduce the uncertainty felt by decision-makers about how it works, what benefits it brings, and the expenses involved in its implementation.

There was very little mention of the changes to existing organizational processes, if any exist, required to introduce blockchain-based systems. Users' perception of a system's usability as well as their perception of how it will help them do their job and bring value to the organization has a great deal to do with how well a newly implemented system is accepted by the user community (Davis, 1989). Many of the systems described will operate in the background and as such will have little impact on user processes or the user interface, but in some instances a new way to look at manufacturing data and its management will require a change in how processes, and even the data itself, are conceived of on the part of both the user and management. So, like any other technological innovation, organizational change processes must accompany these implementations. Moving up the decision-making hierarchy, management must first determine if the evolution of their technological architecture requires the use of blockchain in order to support their strategic arc. As always, the alignment of technology and strategic direction is essential to the success of the organization's attempt to use technology to gain a competitive advantage.

The last theme is also one that becomes apparent with its absence. Blockchain has difficulty accepting changes to data already existing on the chain. This difficulty is due to the requirement of solving the hash puzzle to add the next block to the chain. Changing data is difficult, or possibly impossible, because it would disrupt the hash reference of the block being changed as well as the hash references of all subsequent blocks, requiring all subsequent hash puzzles to be solved again. In cases of chains with millions of blocks and fairly difficult hash puzzle requirements this could be an infeasible process. However, engineering and manufacturing processes require the ability to revise data easily and quickly, while retaining the validity of its original form. In some blockchain systems, revisions are handled by adding a block with the revised data to the end of the chain and revising any connected pointers accordingly. However, this might require significant programming effort and might not be feasible in all environments. Further research is needed to fully understand this shortcoming (some will consider it a feature that provides data immutability) in the various applications outlined in the papers that make up this review.

CONCLUSION

This paper provides a systematic review of the extant academic literature that describes the use of blockchain technology in the engineering and manufacturing activities. The literature surrounding these two activities were reviewed together because of the close relationship between these two pursuits and, therefore, the presumed close relationship between their literatures. The review of the literature finds that while there is a quickly growing body of work that provides descriptive and proposed uses of blockchain in these fields, there is scant empirical analysis that accurately describes how well this technology serves these activities. Thus, this article serves as a call for not only an effort to examine existing blockchain installations in these and other fields, but also for a broadening of the exploration of blockchain applicability to these and other undertakings.

There are a few limitations of this study. First, while this is a systematic review of the literature, it cannot claim to be exhaustive. Most of the major indices have been examined, but not all, though the level of duplication of publications experienced leads to the conclusion that the research is very near the point of exhaustion. The second limitation is that the study does not include non-academic literature such as trade journals, unpublished studies, and the like. Third, it does not include literature found by searching terms such as Internet of Things, autonomously guided vehicles (AGV), or other terms which have applicability in many industries beyond engineering and manufacturing. The reason for their omission is to decrease the complexity of this stage of the study. They will be included in subsequent stages.

Future directions of enquiry include the inclusion of other forms of literature and search terms, as noted above, to provide a fuller picture of the state of the knowledge base surrounding this topic. It is hoped that a review article such as this, which is by definition only a snapshot of the field under examination, provides a starting point for future researchers and practitioners to address a particular research direction, and that it can form a foundation for research that will add to the work already accomplished.

ABSTRACT

Startups are increasingly becoming suppliers to established firms. However, prior research has only studied how buying firms select established firms as suppliers. It remains unclear which processes, tools or organizational approaches firms use when selecting startup firms as suppliers. This inductive, qualitative case study research collects data from 20 established buying firms and investigates how they select startups as suppliers. The results suggest that firms that are willing and able to adapt their selection approach to startups are expected to show a higher selection performance, meaning that they are more likely to select suitable startups as suppliers.

KEYWORDS: New venture supplier, startup, supplier selection, supplier evaluation, open innovation, case study

INTRODUCTION

Under the umbrella of the open innovation paradigm, established firms are tapping into external sources of innovation to increase their innovation output (Chesbrough, 2006). Suppliers and startups are considered particularly attractive innovation partners for established organizations (Azadegan & Dooley, 2010; Weiblen & Chesbrough, 2015). Traditionally, both sources have been studied from different perspectives. While the selection of suitable startups has been studied primarily from the perspective of strategic alliances, venture capital, or corporate incubators and accelerators (e.g., Baum & Silverman, 2004; Aerts, Matthyssens & Vandenbempt, 2007; Moschner et al., 2019), selecting innovative suppliers has been an important stream within the supply chain management literature (e.g., Koufteros, Cheng & Lai, 2007; Oke, Prajogo & Jayaram, 2013). However, scholars and business practice have only recently recognized the potential of merging the two perspectives.

Following several calls for research (Kickul et al., 2011; Shepherd & Patzelt, 2013), scholars have started integrating the supply chain with the entrepreneurship literature by investigating buyer-supplier relationships between established buying firms and new venture suppliers [Following Zaremba et al. (2016), we use the term new venture supplier for startups that became suppliers to established firms.] (Zaremba, Bode & Wagner, 2016; Rottenburger & Kaufmann, 2019). At the same time, leading corporations such as the premium automaker BMW announced that it would be increasing its supplier relationships with startups (Gimmy et al., 2017). We define *new venture suppliers* as young and innovative startups that can bring radical benefits to buying firms through sourcing or co-developing new technologies, products or services.

The first step in building such asymmetric buyer-supplier relationships is the selection of suitable new venture suppliers. Along with buying firms' increasing outsourcing activities in the last decades (Spina et al., 2013), scholars have studied various aspects of the supplier selection process such as its link to overall firm performance (Kannan & Tan, 2002), product quality (Gonzalez, Quesada & Mora Monge, 2004) or the use of evaluation criteria for determining suitable suppliers (Ho, Xu & Dey, 2010). However, these studies do not distinguish established from startup firms as suppliers, even if startups are struggling with legitimacy and are thus less likely to be selected (Stinchcombe, 1965; Brachtendorf, 2016). Furthermore, because of startups' lack of resources, established processes, and their high failure rate, buying firms face substantial challenges evaluating the true capabilities of NVS (Stuart, Hoang & Hybels, 1999; Reuber & Fischer, 2005). In addition, buying firms prefer suppliers with well-recognized certifications and strong track records of high quality and timely delivery (Choi & Hartely, 1996; Kannan & Tan, 2002).

Recent empirical findings indicate that buying firms need to organize the selection process of new venture suppliers differently. For instance, Zaremba et al. (2016) investigated how established buying firms can work with new venture suppliers to achieve desired relationship outcomes. They show that buying firms that demonstrate an innovation orientation during supplier selection tend to buy more from startups and to be more innovative with them. By the same token, a cost orientation during supplier selection reduces the number of successful innovations with startups. In a later study, Zaremba et al. developed the concept of *new venture partnering capability* (*NVPC*), which captures a buying firm's effectiveness in leveraging the potential of new venture suppliers (Zaremba, Bode & Wagner, 2017). They show how buying firms evaluate, develop, and communicate, as well as how they govern the buyer-supplier relationship with startups. Their findings with regard to the selection of suitable new venture suppliers suggest that startups' evaluation requires more time and effort. At the same time, the evaluation criteria must be applied more flexibly to give these young firms a chance against their more mature competitors.

These two studies are a valuable first attempt at exploring this new phenomenon. However, we still know remarkably little about how buying firms actually identify and evaluate this new supplier type, what makes a startup a suitable new venture supplier and which organizational functions are involved in the selection process. A better understanding of how established firms can identify, evaluate, and select suitable new venture suppliers would help to improve the success rates of subsequent collaborations with positive effects on established firms' innovation output and startups' survival rates. This study therefore answers the following research questions: What are the dominant profiles (or archetypes) of the buying firms as they select new venture suppliers? How are these profiles linked to the chance of selecting suitable new venture suppliers?

To answer these questions, we adopt a multiple case study design, which is particularly suitable for generating theory (Eisenhardt, 1989). The findings of this study extend the sparse research in the emerging field of new venture suppliers and contribute to the supplier selection literature. Our analysis led to the development of a typology of three distinct buying firm archetypes which differ (1) in their strategic focus, (2) in the type of startups they are engaging with, (3) the organizational responsibility of the selection process, (4) in their identification strategy, and (5) in their evaluation approach. Based on these findings, we derive a set of propositions that describes how the likelihood of selecting a suitable new venture supplier is connected with specific adaptations that the case firms made regarding their selection approaches. Moreover, we provide an initial description of a suitable new venture supplier. The archetypes offer insights into how and why buying firms select startups as suppliers and help firms classify and benchmark their selection processes.

LITERATURE REVIEW

New Venture Suppliers as a Source of Competitive Advantage

From a resource-based perspective, firms can achieve competitive advantage by combining their valuable, rare, imperfectly imitable, and non-substitutable resources with the complementary assets of other organizations (Barney, 1991; Dyer & Singh, 1998). Some scholars even consider resource complementarity as the most important driver for interorganizational collaboration (Dyer, Singh & Hesterly, 2018). New venture suppliers offer vast opportunities for established firms to complement their existing resources bases. Perhaps, most importantly, startups are a source of radical innovation and a driver of technological change (Ireland, Hitt & Sirmon, 2003; Song & Di Benedetto, 2008). In contrast, a buying firm's incumbent supply base might be a source of incremental and routinized innovation since buying firms initiate numerous innovations on their own, which rarely results in truly radical improvements (Wagner & Bode, 2014).

Startups also differ from established firms in terms of worse access to financial resources and a lack of management and manufacturing capabilities (Hitt et al., 2001; Terjesen, Patel & Covin, 2011). However, they are often recognized as excellent problem solvers and product developers for several reasons. First, their organizational prerequisites such as their ability to make quick decisions without lengthy approval procedures create an advantage regarding speed and flexibility compared to mature organizations (Hogenhuis, van den Hende & Hultink, 2016). Second, their way to communicate is more direct, informal, and more frequent than that of established firms facilitating collaborative activities (Das & He, 2006). Finally, young firms must develop their innovations quickly to reach market maturity as they risk exhausting their funding. This risk puts their focus on fast market introduction in order to generate first cash flows (Poutziouris, 2003). In sum, these characteristics make them ideal partners for large firms, particularly for accelerating product development projects.

For startups, strong and partnership-like supply chain relationships can yield substantial advantages. As Arend and Wisner (2005, p. 405) point out: "To the entrepreneur, SCM has many potential benefits […] (e.g.) the ability to leverage its scalable competences in a cooperative network through fast and feasible access to complementary partner assets." For example, established firms can contribute tangible and intangible resources that startups can access through participating in their customers' supplier development programs (Zaremba et al., 2016). Moreover, relationships with buying firms that offer specifications, feedback, and finally purchase orders help startups generate cash flows and gain market legitimacy (Bhalla & Terjesen, 2013; Gimmy et al., 2017). In fact, some studies support these theoretical arguments. For instance, Dutta and Hora (2017) find that startups' downstream alliances (to industry incumbents) increase their invention and commercialization success and Terjesen et al. (2011) show that the value of a startup's operational capabilities depends on its operating environment and the type of alliances it forms. Alliances with a diverse set of customers and suppliers, which are geographically dispersed, seem to have a positive effect on the value of startups' operational capabilities.

New Venture Supplier Identification

The traditional supplier selection literature often describes supplier selection as an optimization problem, in which buying firms select the most suitable supplier out of a given set of available firms without the necessity of identifying them (e.g., Kim & Wagner, 2012). The identification process typically relates to the ability to distinguish innovative from less-innovative suppliers. For example, Pulles, Veldman and Schiele (2014) emphasize that buying firms should search for suppliers with a collaborative attitude, high levels of professionalism (i.e., skills and expertise), and deep technical knowledge. Buying firms use a variety of strategies to engage with potentially innovative suppliers, such as supplier days, supplier workshops, or supplier competitions (Langner & Seidel, 2009; Schiele, 2010). Nonetheless, also for these approaches, buying firms need to be aware of a set of potential suppliers they can invite. Startups, however, are probably not part in this pool of firms, as many established firms lack experience in collaborating with them (Schaettgen & Mur, 2016) and thus miss ties to startup ecosystems. Moreover, startups often do not belong to a specific industry since neither the potential applications for their technology, nor their potential customers are well-defined (Chesbrough, 2006). Thus, buying firms must search for attractive startups in different supply markets.

The open innovation literature describes the ways in which firms can search for external innovations. Companies might hire technology scouts, use intermediaries (e.g., consultants), or search the internet for attractive startups (Ili, Albers & Miller, 2010). Using the internet to find potential innovation partners has decreased search costs, as companies now can find attractive startups in communities, blogs, or via crowdsourcing platforms (West & Bogers, 2014). While screening has become more affordable, many companies face the challenge of having to process large numbers of identified startups. Siemens, for instance, identifies about 1,200 startups every year (Weiblen & Chesbrough, 2015). As processing and evaluating such large numbers is time-consuming, West and Bogers (2014) conclude that firms must find an optimal level of search.

In contrast, there are initiatives where buying firms passively identify startups through web-based innovation platforms where suppliers can submit their ideas or products (Kurpjuweit, Reinerth & Wagner, 2018). For startups, these web-based platforms are usually the interface to outside-in programs with the objective to make the "existing startups' technology accessible and useful for the sponsoring corporation" (Weiblen & Chesbrough, 2015, p. 72). According to

Weiblen and Chesbrough (2015), these new engagement models differ from traditional models such as corporate venture capital by the absence of the corporation's equity involvement. For building buyer-supplier relationships with startups, these traditional models have had problems with the innovation transfer in the past and might be unsuitable as their equity involvement may create difficulties for startups to engage with customers that are competing in the same industry as their equity provider (Gimmy et al., 2017). Therefore, the identification of potential new venture suppliers might rely on non-equity based models such as scouting and screening or web-based innovation platforms. However, both mechanisms require the buying firm to view the identification process as an integral part of the supplier selection problem which distinguishes the selection of new venture suppliers from the selection of mature suppliers.

New Venture Supplier Evaluation

Evaluating suppliers against predefined criteria is one of the major tasks in supplier selection contests. Based on a supplier's recent history, buying firms apply evaluation criteria such as price, quality, flexibility or consistent delivery to determine the supplier's qualifications (Choi & Hartely, 1996; Ho et al., 2010). However, startups lack a proven track record of high performance which pose challenges for buying firms to apply these criteria properly. This lack of history is often referred to as *legitimacy*, defined as "a generalized perception or assumption that the actions of an entity are desirable, proper, or appropriate within some socially constructed system of norms, values, beliefs, and definitions" (Suchman, 1995, p. 574). Missing legitimacy constitutes a major disadvantage for startups in supplier selection (Brachtendorf, 2016). In addition, startups' organizational limitations and their lack of supplier resources and capabilities (Das & He, 2006) might pose substantial challenges in later collaboration stages that require project management and manufacturing capabilities (Hogenhuis et al., 2016).

From the buying firm's perspective, this liability of newness creates considerable uncertainty about a startup's true supplier performance potential, decreasing its chance of being selected as a supplier, especially when competing against an established firm (Zimmerman & Zeitz, 2002). Zaremba et al. (2016, p. 162) even point out that "new ventures should be regarded as a distinct subset of suppliers in the marketplace." Therefore, buying firms must adjust their supplier selection process in response to the specific requirements of startups. According to Zaremba et al. (2017), buying firms that have integrated the capabilities of new venture suppliers, examined these startups more closely by performing additional evaluations and by allocating more time and human resources to the selection process. However, once a startup has shown that it possesses specific base capabilities, the standard evaluation criteria were relaxed and applied more flexibly. For example, buying firms required the startups to present fewer references or certifications.

In general, the literature indicates that buying firms must adapt their supplier selection process when considering new venture suppliers. This study, therefore, aims to shed light on how different archetypes of buying firms tailor their selection process to startups, and how these adaptations affect the likelihood that a suitable new venture supplier will be chosen.

METHODOLOGY

The unexplored phenomenon of buying firms selecting startups as suppliers demands an inductive case study approach (Barratt, Choi & Li, 2011). This research design fits best with the nascent stage of the research in the field of new venture suppliers (Edmondson & McManus, 2007) and is well suited for generating new theory (Glaser & Strauss, 1967; Ketokivi & Choi, 2014) – especially for developing typologies and archetypal classifications (e.g., Bode, Hübner & Wagner, 2014; Pauwels et al., 2016).

Research Setting and Case Selection

The empirical setting of this research is established buying firms which have recently selected at least one startup as their supplier. We refined our new venture supplier definition from the introduction by setting an age limit of six years. This is consistent with the entrepreneurship literature (Song et al., 2008) and has been used in other investigations of new venture suppliers (Zaremba et al., 2017). We restricted the sampling process to buying firms which have selected startups that offered a tangible product that was either integrated into the buying firms' products or intended to improve the value creation process of a buying firm's core business (e.g., new production machines). The technology had have been developed by the startup and required at least some form of customization (not solely distribution). We focused on the selection of manufacturing ventures as we expected from this setting to be able to observe selection decisions that are particularly relevant for the buying organizations. Furthermore, we analyzed supplier selection decisions that cannot be easily reversed. Relationships with component suppliers are often difficult to terminate, as they can involve relationship-specific investments and highly specific product interfaces which require domain knowledge so that buying firms hope to build long-term relationships with those suppliers to safeguard their investments (Wagner & Bode, 2014).

Both in academic research and in business practice, sourcing from manufacturing ventures is relatively new. In order to identify buying firms that have already selected new venture suppliers, we screened German-speaking startup blogs and magazines. We then contacted established firms that formed asymmetric collaborations that fit our criteria. In the contact email, we described the purpose of the study and requested the name of the person within the organization who was in the best position to talk to us about an example of the firm's selection process. Then, we had a brief conversation over phone or email over whether or not the example fit our study setting. Informants who provided useful examples were then asked for an expert interview. At the end of each interview, we asked each interviewee whether he or she knew of another case from his or her professional network that would be appropriate for our research (i.e., snowball sampling).

The firms that we considered for our sample generate annual sales exceeding USD 100 million and have been in business for several decades. In fact, most firms were founded more than 80 years ago; only one firm is substantially younger (*3D Printing*). However, this firm develops, manufactures and distributes selective laser sintering (SLS) machines, which is still a fledgling but increasingly important business (Durach, Kurpjuweit & Wagner, 2017). In addition, with more than 1000 employees and sales exceeding USD 300 million, *3D Printing* is one of the leading organizations in additive manufacturing today.

By setting the USD 100 million threshold for sales, firm size within the sample naturally varies. Since firm size seems to affect a firm's ability to partner effectively with startups (Zaremba et al., 2017), by including established firms with different sizes, we expected to bring more variation to the phenomenon, which usually generates deeper insights (Flick, 2014). Table 1 summarizes the sample demographics. Notably, the informants' organizational functions vary considerably among the case firms, indicating that procurement is not the dominant function of the selection process.

Table 1: Overview of Case Firms

#	Company Code	Industry Sector	Employees	Revenues (in EUR)	Firm age (in years)	Country	Informant(s)	Archival data (pages)
1	Adhesive	Consumer & Industrial Goods	10k-50k	>20bn	>100	GER	Dir. new business development	54

Data Collection

For each case firm, we conducted at least one semi-structured interview with the manager, who was responsible for the selection process. We used a semi-structured interview guide with open-ended questions that let the interviewees reflect on a specific example (see Appendix). We began by asking the informant to refer to the example they had mentioned in the phone call or email prior to the interview. In some cases, we changed the example if the informant came up with a more suitable one at the beginning of the interview. During the interviews, we tried to determine how the case firms identified, evaluated and chose this specific startup, and whether the selection process differed in relation to established or other new venture suppliers. We also asked how the case firms managed the relationship after the selection, and how successful the collaboration has been so far, to understand the impact of the selection process on the buyer-supplier relationship.

In the second part of the interview, we asked more general questions about the case firms' motivation to engage with new venture suppliers, how risky the selection process was, and how they would characterize a suitable new venture supplier. While the core topics of the interview guide remained consistent, we adapted individual questions during the course of data collection and added firm-specific questions for each interview (Patton, 2015). After each interview, we took notes to capture first impressions and thoughts (Miles & Huberman, 1994).

The interviews took place between February and November 2016; each lasted an average of 60 minutes. All informants agreed to be audio recorded as long as we treated the collected data confidentially and guaranteed their anonymity. We transcribed the recorded interviews, resulting in 280 pages of text stored in a database to which all researchers had access (NVivo 10). One of the authors translated the quotes presented in this manuscript from German to English while a research assistant checked the translated quotes for semantic correctness. A professional copy editor then checked for grammatical correctness and for comprehensibility. We concluded the data collection when new interviews generated only few additional insights (Glaser & Strauss, 1967; Flick 2014). In total, we conducted 26 interviews with 20 case firms. We carried them out in person whenever the proximity and availability of the informants permitted (18 out of 26).

Since especially in large firms, many people participate in the selection process, we triangulated the information provided by our informants by conducting additional interviews within the buying firms' organizations. Two large case firms (*Robotics* and *Transportation*) granted us such access. The remaining informants of the other large companies in our sample were confident that they had provided sufficient details about the selection process and were therefore unwilling to provide access to their colleagues.

To complement and triangulate our interview data, we collected additional information about the case companies' collaborative activities with startups. Specifically, we collected press releases from the firms' websites and newspaper articles using the WISO database, one of the largest databases for magazine and newspaper articles published in German. We limited our search to the last five years and collected only press releases and newspaper articles in which the word "start-up" appeared. This procedure resulted in 189 pages of press releases and 616 pages of articles for analysis. In this article, quotes from these archival sources are marked "AD."

Data Analysis

We analyzed and coded the interviews simultaneously with the data collection (Glaser & Strauss, 1967). We began the data analysis by writing individual case descriptions of each firm's typical selection approach and how it differs from selecting established firms. We also prepared a short version of the case description including the key learnings of each case which we sent to our interviewees. We discussed their feedback and included it in our analysis.

After analyzing the cases individually, we moved on to a cross-case analysis in order to investigate the variations among cases. To this end, we used various case displays, but we also compared cases pairwise to identify similarities and differences (Eisenhardt, 1989). In a first step, we inductively generated first-order concepts (codes) without any predefined coding structure. Thereby, we tried to stay as close as possible to the terminology of our informants, in order to generate truly informant-centric codes (Gioia, Corley & Hamilton, 2013). For example, we generated codes such as "close future technological gaps" something that had been explicitly stated by the interviewees. Two researchers participated in this coding process. One of the authors and a research assistant coded the transcripts independently to avoid biased coding and ensure a free interpretation of the data. A code could be only one sentence or a whole paragraph, and the same sentence could belong to different codes. This process resulted in dozens of codes generated by each researcher. During data collection and analysis, we constantly compared the codes generated by each researcher. We discussed differences, and merged codes when necessary. For example, several codes had the same meaning but slightly different names (e.g., startup stage vs. startup maturity) or were based on different levels of analysis (e.g., passive identification vs. internet-based application form). We drastically reduced the total number of codes to ensure alignment with our research questions, which resulted in a final list of 13 codes.

After coding all interviews with this joint coding structure, we calculated the inter-rater reliability. With a Cohen's κ of .67, the two researchers arrived a substantial agreement (Landis & Koch, 1977). Then, both researchers discussed all nodes which were zero or below and adjusted them accordingly. This procedure increased of the inter-rater reliability to .81, reflecting an "almost perfect" agreement (Landis & Koch, 1977).

In a second step, we were able to aggregate the generated 13 codes to five design themes (second-order themes): *strategic focus*, *startup type*, *organization*, *identification*, and *evaluation*. In contrast to our first-order codes, they are more abstract and theory-centric (Gioia et al., 2013). In a final step, we aggregated the five design themes under three overarching theoretical dimensions (i.e., archetypes). We provide a detailed explanation of this procedure in our analysis and results section. Table 3 provides an overview of the resulting data structure.

ANALYSIS AND RESULTS

This section presents the findings of our cross-case analysis. We first provide evidence of how a suitable new venture supplier can be characterized. Then, we inductively develop five design themes by comparing the selection approaches of the case firms. Finally, we use these themes to build a typology of buying firms selecting new venture suppliers.

What is a Suitable New Venture Supplier?

Before we can answer the question of how the case firms select new venture suppliers, we must clarify the objective of the selection process. In general, buying firms want to select suitable suppliers based on pre-defined evaluation criteria, such as cost, delivery, or quality performance (e.g., Choi & Hartely, 1996; Ho et al., 2010). In contrast to the selection of established suppliers, it is, however, less clear which characteristics a suitable new venture supplier should and should not exhibit. Since no single case firm could give us an explicit definition of a suitable new venture supplier, we analyzed the features our informants were looking at when making their selection decisions. By asking them why they were selecting a specific new venture supplier, we could identify four categories that distinguish suitable from unsuitable new venture suppliers. We provide representative quotes for each category in Table 2 and describe each category.

Table 2: Representative Quotes Supporting the Definition of Suitable New Venture Suppliers

	Related Questions	Suitable New Venture Supplier	Inadequate New Venture Supplier
Quality Fit	• Does a startup possess above-average resources and capabilities? • Do startups' resources and capabilities fit to a buying firm's requirements for a specific use case?	"[A high-quality startup] has already passed a well-known accelerator or is already funded by venture capital. Before that, we do not take the startups because we do not want to do this due diligence. We do not want to worry about whether the team is good enough, whether they have their investing agreements […] the whole legal basis of the company. I do not want to do that. Others do this better." (Automotive)	"If a startup has not yet raised any money with its idea, then there will be a reason for that […]. Does the team have strategically relevant competencies? For example, an IT startup without software engineers [...]. This is not a K.O. criterion, but it would become very difficult." (Logistics) "In the end, it was a very negative experience for us, because the startup did not survive [because it ran out of funding]." (Robotics)
Strategic Fit	• Does the technology fall into a buying firm's strategic innovation roadmap?	"Is the startup's technology applicable for measuring the tire pressure or is it interesting for autonomous driving? Autonomous driving would be better in this case." (Automotive) "I strongly believe that there needs to be a strategic link. […] The strategic link is extremely important […] and it could be that a startup has a technology that complements our own technology	"If a startup supplies us with a critical component, then the question is whether we would collaborate at all, because we should produce such components by ourselves." (Automation) "[The startup] only delivers a single part, because we aim to keep the core know-how with us." (Automation)

		portfolio, which was the case with [startup name].” (Adhesive)	
Technological Fit	• Is the technology better than everything comparable in the market?	“There was a technical due diligence, where different benchmark parts were produced to compare the technologies, and it was quickly clear that [startup name] was already leading in terms of quality.” (3D Printing) “Startups are always relevant when it comes to specific, new know-how. New know-how where there are no resources on the market and no established players yet.” (Piping)	“There were cases where startups questioned the existence of the second law of thermodynamics. If such statements come, you can sort them out. For me, that would be such a technical KO criterion. In the meantime, they have also gone bankrupt.” (Robotics)
Market Fit	• Is there someone willing to pay for a startup’s technology inside the buying firm?	“The product must bring benefits, which means you have to recognize, where you gain something. [The product] needs to address someone’s current or long-term pain point.” (Automation) “It is the best for us when a startup already has concrete visions for the application of their technologies. We have just received an application for freight transport that is very detailed regarding the problem of train composition. Of course, this is great for us because we can immediately see the USP very clearly.” (Logistics)	If the technology is not interesting for anyone within our organization, then we do not have to talk about the other things.” (Robotics)

Quality fit. This attribute stands for the quality of startups’ resources and capabilities compared to other startups in the market. According to our interviewees, a startup’s quality can be assessed independently from its product since some startups are better managed, have better processes, possess more know-how, or have acquired more funding than others. Consequently, these startups are expected to have higher survival rates and are easier to manage as suppliers. Besides seeking startups with above-average qualities, suitable new venture suppliers should possess resources and capabilities that fit the potential use case, on which they will be collaborating, as the quote of *Logistics* in Table 2 illustrates.

Strategic fit. The second attribute refers to the fit between a startup’s technology and the buying firm’s innovation strategy. As the quote of *Automotive* in Table 2 shows, autonomous driving is a key technological area for this case firm. *Automotive*, thus, aims to engage with startups that help to strengthen its competitive position in this area which seems to be particularly important for the entire automotive industry today. Our data further suggest that although some technologies lie within the scope of buying firms’ innovation roadmaps, firms such as *Automation* refuse to collaborate in what they consider as their core technological areas. Both firms would always prefer an acquisition to a buyer-supplier relationship as they both prefer engaging with new venture suppliers in more distant technological fields. Nevertheless, both examples show that established firms align their selection decision with their innovation strategy in order to achieve a strategic fit.

Technological fit. The third category suggests that a startup’s product must fit the technological requirements of the buying firm. Often this implies that the offered technology must be substantially better than comparable products in the market, or that a startup offers something so new that buying firms cannot compare it with technologies provided by established suppliers. According to our interviewees, startups’ selection chances become very low, if comparable products from established suppliers are available.

Market fit. According to our data, high-quality startups which offer technologically sophisticated and strategically important products to buying firms do not always find a paying customer within the buying firm's business units for their technologies. Since neither startup relationship managers nor the innovation management department have the budget and the decision making power to purchase startups' technologies, startups need to convince business unit leaders, purchasing, or product managers of the advantages of their technology. Hence, a suitable new venture supplier is one whose technology finds a paying internal customer. Clarifying whether a real demand for a technology in a business unit exists is, therefore, an integral part of the selection process.

New venture suppliers exhibiting all four of these attributes are expected to have better chances of survival, as their resource bases and their value propositions are highly attractive for potential customers. Accordingly, we define a suitable new venture supplier as a high-quality startup that offers technologies, products or services that fit the buying firm's strategic, technological and market needs.

Comparing the Selection Approaches of Buying Firms

In this section, we compare the selection approaches of our 20 case firms. We inductively develop five design themes that describe how buying firms selecting new venture suppliers. Specifically, the selection processes of the case firms differ with regard to a buying firm's (1) strategic focus, (2) type of the selected startups, (3) organizational approach, (4) identification efforts, and (5) its evaluation approach. These five elements emerged from our qualitative data during the coding process (Table 3). To estimate how they differ across the case firms, we assign intensities (+, ++, +++) for each element and each case firm. In the following, we explain the five themes and the way in which we assigned the intensities.

Table 3: Representative Quotes Supporting the Data Structure

Second-Order Themes	First-Order Concepts	Representative Quotes
Strategic Focus	Solve a current technical problem	"In our industry, you only cooperate with a startup, if there is a customer request that is not easy to solve." (Excavator)
	Close future technological gaps (Innovation focus)	"There are many startups with which we have only loose collaborations in order to evaluate the technology. These collaborations are not based on a specific product or a decision that we need this technology now, but rather we try to find out how the technological landscape looks like." (Robotics)
	Profit from startups' innovations and capabilities	"Depending on where [the startups] come from, they have different intellectual approaches and opportunities which we do not have. For example, at some universities, there are highly specialized labs and they can try things out and accept risks which we cannot." (Adhesive)
Startup Type	Startups' stage	**Early stage** "We had the idea to do something with early-stage startups. We have collaborated with many later stage startups but what about all these startups with maybe five employees? These early-stage startups are even more interesting for a company like ours in the sense of innovation impact." (Automotive) **Later stage** A startup that contacts us and says it has an entirely new product has only a 0.01 percent chance to become selected." (Food)
	Distance to buying firm's knowledge base	**Distant to own knowledge base** "I am open to all good ideas. We do not restrict ourselves, because if we do, we miss the opportunity to find something exciting." (Logistics) **Close to own knowledge base** „We are only interested in material science startups." (Adhesive)

Organization	No clear responsibility	"Either strategic procurement or the research group that is interested in the technology." (Excavator)
	Responsibility assigned to existing department	"We have alerted our sales departments to keep us informed of new startups in the market. The intention is that all roads lead to our department." (Biopharma)
	Dedicated startup department	"In 2016 we established an independent unit designed to partner with […] start-ups with innovative ideas for shaping the future of electrification, automation and digitalization, and thereby turn those ideas into viable businesses" (Electronics; AD).
Identification	Active Identification	No active identification "No, we do not screen the market." (Smarthome) Active identification "There is this search and evaluation team […] This means the colleagues go to all the fairs out there and look out who has something to offer." (Pharma)
	Passive Identification	**No passive identification process** "Depending on whom they [the startups] are contacting, they can be lucky or unlucky. Sometimes they contact developers who know only their area, but if they contact people who have an overview, these people would then contact our corporate research department, and then it would reach me. This is based on an internal network without a formal process behind it. However, it works best if you contact the right people directly." (Robotics) **Passive identification process available** "The application form is a way to efficiently scan through startup applications." (Automotive)
Evaluation	Process	**No established evaluation process** "This startup contacted our HR manager, so we invited the founders to present their ideas. They were very convincing, so we decided just to try it out." (Piping) **Established evaluation process available** "We have developed a catalog of 20 to 30 criteria. This is like a blind tasting. Each of us evaluates the startups independently, then I merge the results, and we make an analysis. […] If a startup gets a poor evaluation, against our initial expectations, we ask why and we discuss it." (Logistics)
	Criteria	**No startup specific criteria** "We assess which quality management system they have, if the product documentation is available if the registrations are all correct […] We evaluate the typical things." (Medtech) **Startup specific criteria** "We evaluate a startup's team, its technology, innovation, the strategic relevance for us, the financial conditions of the startup […]" (Logistics)
	Functions involved	**No expert involvement from other functions** They [the startup and the potential user] typically meet somewhere and figure out whether the product would be attractive. Then this manager checks out whether it makes sense for him, so that he could profit from it and then it goes its way." (Piping) **Experts from other functions involved** "Of course we are working closely with people from R&D and the business unit for the technical and commercial evaluation. We will never collaborate with a startup if there is not one business unit which says: good idea! We are going to support you." (Adhesive)

Strategic focus. The motivation for firms' selection of startups as suppliers differs across the case firms. Some firms started buyer-supplier relationships with startups because they had a specific (technical) problem for which they could neither find any established supplier nor had the expertise in-house. We assigned buying firms with this narrow strategic focus with

"+." Other firms adopt a more forward-looking approach and develop technology roadmaps from which they derive the areas in which they aim to engage with startups. Such companies clearly seek to profit from startups' innovations and consider them as a potential source of external innovation (++). The third type of firm emphasizes the particular strengths of startups. Besides innovativeness, they aim to tap into startups' special capabilities such as their speed, and flexibility, their ability to take the risks that established firms will not, or they hope to be able to bring some of the younger firm's entrepreneurial spirit to their own corporate cultures (+++).

New venture type. The second design element refers to the profile of the selected startups. Our analysis reveals two distinctive features of the selected startups: maturity and distance to the buying firm's knowledge base. Both factors determine a new venture supplier's risk-return profile. Early-stage ventures from a distant knowledge base can be expected to have a stronger innovation impact than later-stage ventures from a buying firm's own knowledge base. The reason is that when engaging with the latter type, it is more likely that competitors have already adopted the technology and that such innovations tend to be more incremental than innovations from completely different areas. We assign buying firms that put more emphasis on searching for early-stage startups from distant knowledge fields with "+++." The other extreme comprises buying companies that prefer later-stage ventures from the own knowledge base (+). Finally, firms in an intermediate position are assigned "++."

Organization. This category relates to the organizational structures with which buying firms approach the selection of new venture suppliers. These approaches range from organizations without any defined responsibilities for startups (+), to organizations with defined responsibilities, embedded in existing departments (++), to firms that have established dedicated startup departments sitting between the corporates and the startups, thus facilitating the engagement process (+++).

Identification. The most renowned firms constantly receive so many applications from startups that processing them poses a challenge. We describe this way of identifying startups as *passive identification* because the buying firm becomes identified by startups. However, a sole passive approach is unsatisfactory for most buying firms. Therefore, many firms also search for new venture suppliers, which we term *active identification*. In contrast to selecting established firms as suppliers, there is no pool of former suppliers to which buying firms can send a request for proposal, which makes this search process difficult. Overall, the intensity and procedure of the identification activities vary across the case firms. While some firms do not identify any startups at all (+), other firms follow either an active or a passive identification strategy (++). The third group of firms identifies startups both actively and passively (+++).

Evaluation. This category contains all evaluation efforts a buying firm makes to assess a startup before the relationship begins. The findings indicate that firms differ primarily in the procedures they follow and the evaluation criteria they apply. The two extremes range from having no processes or any predefined criteria to structured multi-stage evaluation approaches involving different departments and experts. Consequently, companies that do not evaluate any startups at all or that follow a completely unstructured evaluation process are assigned "+." We assign companies "+++," if they have implemented a structured evaluation process, assess startups according to predefined startup-specific evaluation criteria and regularly involve experts in the evaluation process. If at least one of the three evaluation constructs is available (established evaluation process, startup-specific criteria, or involvement of different functions), we assign these firms "++."

Selection Archetypes of Buying Firms

Based on these observed differences and similarities in the five design themes, we were able to assign all case firms to one of three overarching theoretical dimensions (i.e., archetypes): (1)

Skeptical Buyers, (2) *Realistic Adapters*, and (3) *Systematic Selectors*. The assigned archetype is based upon the average score of the five elements and a discussion among the authors (Table 4). In the following, we will outline the key characteristics of the archetypes, which are summarized in Table 5.

Table 4: Assigned Intensities per Case Firm

Company Code	Strategic Focus	Startup Type	Organization	Identification	Evaluation	Resulting Archetype[a]
Adhesive	+++	++	+++	++	++	RA
Automation	+++	++	++	++	++	RA
Automotive	+++	+++	+++	+++	+++	SS
Biopharma	++	+	++	++	++	RA
Car	++	++	++	++	++	RA
Electronics	++	++	+++	+++	++	RA
Excavator	+	++	+	+	++	SB
Filtration	++	++	+	+	+	SB
Food	+	+	+	+	+	SB
Lineartech	+	++	+	++	+	SB
Logistics	+++	+++	+++	+++	+++	SS
Piping	+	++	+	++	+	SB
Medtech	++	++	++	++	++	RA
Pharma	+++	++	+++	+++	++	SS
Robotics	++	+++	++	++	++	RA
Rollercoaster	+	+	+	+	+	SB
Security	+	++	+	++	+	SB
Smarthome	+	++	+	+	+	SB
Transportation	+++	++	+++	+++	+++	SS
3D Printing	+++	+++	+++	++	++	SS

Note: [a] “SB” = Skeptical Buyer, “RA”= Realistic Adapter, “SS” = Systematic Selector.

Table 5: Overview of Different Archetypes of Buying Firms Selecting New Venture Suppliers

	Skeptical Buyers	Realistic Adapters	Systematic Selectors
Theme	*Do not adjust their supplier selection process to startups.*	*Do partially adjust their supplier selection process to startups.*	*Do fully adjust their supplier selection process to startups.*
Strategic Focus	• Select startups to solve specific business problems • Startups are often the only option for a specific problem	• Aim to close future technological gaps in their roadmaps • Startups are one potential source of external innovation	• Aim to get access to innovations, which could not have come from own R&D or other external sources • Aim to get access to startups’ unique capabilities
New Venture Type	• Later stage startups close to own knowledge base • Rather incremental innovations	• Medium position between Skeptical Buyers and Systematic Selectors	• Early stage startups from more distant knowledge bases • Rather radical innovations
Organization	• No clear responsibilities • Responsibility highly depends on the first contact person	• Responsibility is assigned to an existing department or manager	• Dedicated startup department that manages the selection process
Identification	• No identification efforts	• Focus on active identification, processes for passive identification are missing	• Focus on active and passive identification
Evaluation	• Completely unstructured evaluation process • Startups are evaluated based on the intuition of managers who established the contact	• Somewhat structured evaluation process • Dedicated team/manager evaluates startups according to relaxed standard criteria • Involve experts from other departments in startup evaluation	• Structured evaluation process with several stages and predefined startup-specific evaluation criteria

Skeptical Buyers. Firms of the first archetype use a highly unstructured approach when selecting new venture suppliers. *Skeptical Buyers* do not pursue the strategic objective to engage with startups in the first place, they engage with them by accident or because no other established supplier was available. Hence, *Skeptical Buyers* neither actively nor passively identify startups. For *Skeptical Buyers*, the risks of asymmetric collaborations often outweigh the potential benefits. They are particularly risk-averse and prefer sourcing only noncritical technologies from new venture suppliers. One reason for this is that these firms do not trust these startups to be reliable suppliers. As one informant states:

> We had serious internal discussions about this topic [supply risk]. Especially that [the startup] has no experience in managing production processes. (Excavator)

The lack of trust can also result from the lack of experience in selecting new venture suppliers; firms of this archetype do not assign clear responsibilities for startups. However, *Skeptical Buyers* do not use their traditional supplier selection process either. Only *Excavator* once invited a startup to make an offer for a new steering unit for its construction machines. This startup had to compete against several established suppliers, all of which offered less innovative products but met the remaining evaluation criteria (e.g., financial stability, certifications). In the end, the buying firm selected the startup because a senior R&D manager convinced his CEO of the advantages of the startup's unique technology. Other case firms do not use their traditional supplier selection processes as they know that they are not suitable for selecting new venture suppliers:

> […] as a startup, being able to participate in tenders is almost impossible. That is why we are trying to keep them away from this topic as long as possible. (Transportation)

Since *Skeptical Buyers* neither use their traditional selection processes, nor establish any new processes, they typically assess startups without utilizing any predefined criteria. Instead, senior managers decide whether a startup is a suitable supplier or not. These managers frequently rely on their intuition, so they often start collaborations simple because they like an idea or the founders of the venture. Hence, it is more an ad-hoc decision than a well-considered choice.

Realistic Adapters. The innovation strategy of the firms we assigned to the second archetype emphasizes open innovation, in which collaborating with startups is considered a potential source of external innovation. From their innovation strategy, these companies derive technological areas that may become important in the future. Hence, these firms base their engagement with new venture suppliers primarily on the motivation to close technological gaps and to access startups' innovativeness. As one of our informants explained:

> Although we offer a lot of different surface coatings, we are not able to produce this specific one. However, this coating lies within a relevant technological area for us which is why the collaboration is a useful completion for our portfolio. (Adhesive)

From an organizational perspective, *Realistic Adapters* define clear responsibilities for startups within their organizational structures. For example, *Medtech* has appointed a business developer to be responsible for startups, while *Robotics* assigned the startup competence to its strategic R&D department. These dedicated managers or teams carry out this new responsibility in addition to their daily business. They are keen to be recognized as the principal startup contact within their organizations so that all relevant information is gathered in one place. The designated managers orchestrate all identification efforts, whereby firms of this archetype emphasize identification activities such as going to fairs or conferences, searching the internet and most importantly, using their industry network to find attractive new venture suppliers. These companies also realized that they can screen their industry by leveraging internal departments with external contacts such as sales, procurement or local R&D:

> We have alerted our sales departments to keep us informed of new startups in the market. The intention is that all roads lead to our department. (Biopharma)

For *Realistic Adapters*, evaluating new venture suppliers is a matter of teamwork. The dedicated team evaluates all proposals. Nonetheless, this evaluation team is not always capable of evaluating all relevant aspects. Then, they enlist experts from other departments as needed. For instance, R&D engineers often conduct the technical assessment of the startup's product. Furthermore, *Realistic Adapters* know that they cannot apply their standard evaluation criteria to new venture suppliers. Most firms of this archetype, therefore, relax these criteria or conduct only a light version of the supplier assessment. As the informant of *Electronics* told us:

> I cannot expect a startup to have all the certifications upfront. Instead, we use a special approach that is simpler and less complicated in order to be able to begin a collaboration with a startup. […] We do not carry out full audits but we assess the most important things. For example, who owns the IP rights? (Electronics)

> We need to make compromises with such small suppliers. The reason we want to cooperate is because we want access to the innovation. But one cannot expect this firm to think and act like a large supplier that has been on the market for a long time. We are definitely aware of that. (Electronics)

Systematic Selectors. The third archetype has the most advanced supplier selection approach. For these companies, engaging with startups is a strategic objective since they believe that such collaborations offer radical benefits that other external partners do not. In addition, they not only consider startups as attractive partners due to their innovativeness but they also emphasize their special capabilities. *Systematic Selectors* generally do not restrict themselves to startups from their own knowledge base. As the following quote shows:

> I am open to all good ideas. We do not restrict ourselves, because if we do, we miss the opportunity to find something exciting. (Logistics)

Systematic Selectors have modified their organization by creating dedicated startup departments in which relationship managers work full-time positions on issues related to startups. These departments are more visible within the organization than, for example, an R&D department that has been tasked with this responsibility. Even though *Systematic Selectors* actively search for startups, they are also comfortable with the passive way of identification, because they know how costly and labor-intensive it is to screen the market themselves. By encouraging startups to apply via the firm's website, they can focus on evaluating the incoming proposals instead of screening the whole market. These firms can even convince their actively identified startups to submit an application in order to evaluate all proposals by the same process. In addition, this procedure provides an overview of all startup contacts, facilitating comparisons and enabling the management to analyze their startup activities statistically. The firms of this archetype provide information about technologies they are interested in on their web pages so that applicants can know immediately whether or not their products meet the needs of the buying firm. These "pain points" are coordinated with top management and the related business units.

The evaluation process consists of several stages with a clear objective to sort out applicants who do not fit the buying firm's requirements. Hence, contingent on the stage, experts from different departments are involved alongside the relationship managers who are present throughout the process. *Systematic Selectors* are the only firms whose evaluation criteria are akin to those that venture capital firms typically apply before investing. One informant describes their standard process for applying these criteria as follows:

> We have developed a catalog of 20 to 30 criteria. This is like a blind tasting. Each of us evaluates the startups independently, then I merge the results, and we make an analysis. […] If a startup gets a poor evaluation, against our initial expectations, we ask why and we discuss it. (Logistics)

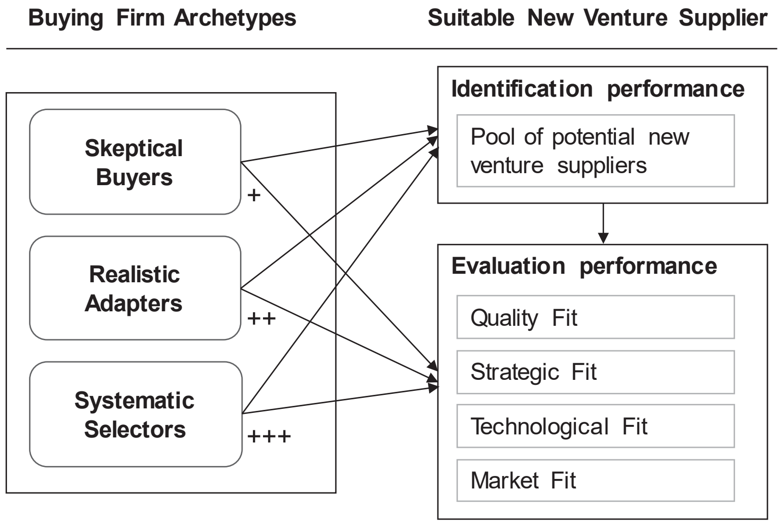
As these criteria differ from traditional supplier evaluation criteria, our case firms highlight that the evaluation team possesses the skills to apply these criteria properly. Therefore, many of the employees from the startup department have previously worked in the entrepreneurial sector. A final peculiarity of the evaluation process of *Systematic Selectors* is that the potential adopter of the technology is involved in the last evaluation stage:

> Before startups are ever accepted, the internal clients are identified within [Automotive]. They need to have a strong interest in using a startup's technology in the future. These internal clients then collaborate with the startup in a real innovation project, like they would work with any other technology partner, like Bosch or Conti. (Automotive, AD)

A MODEL OF SELECTING NEW VENTURE SUPPLIERS

In this section, we compare the characteristics of each archetype with the dimensions of suitable new venture suppliers (quality, strategic, technological, and market fit), and develop propositions regarding the performance implications of major adaptations of firms' selection approaches. We summarize our findings in a theoretical model in Figure 1.

Figure 1: Theoretical Model that Connects Buying Firm Archetypes with their Likelihood to Select Suitable New Venture Suppliers



Note: “+” = limited chances to select suitable new venture suppliers, “++” = medium chances to select suitable new venture suppliers, “+++” = high chances to select suitable new venture suppliers.

The analysis of the selection process of firms of the first archetype reveals that most *Skeptical Buyers* have only selected a small number of new venture suppliers. They would engage with more; however, they do not actively search for potential new venture suppliers in the market but wait for accidental encounters with them. For instance, *Piping’s* informant explained that the startup they selected was located next to one of their facilities and that other contacts to startups were always established through personal networks; sometimes startups simply contacted senior managers directly:

> This startup contacted our HR manager, so we invited the founders to present their ideas. They were very convincing, so we decided just to try it out. (Piping)

This statement reveals another problem of the selection process. Although *Skeptical Buyers* are skeptical of startups’ capabilities, they do not carefully evaluate them. They invite startups for pitches or they discuss their products in personal meetings but there is no formal evaluation, which raises doubts whether these firms properly assess the quality of new venture suppliers. In particular, the lack of predefined evaluation criteria and the missing startup specific experience of the selecting managers increase the risk of selecting low-quality startups. We know from *Realistic Adapters* and from *Systematic Selectors* that they adjusted their selection processes because they found them unsuitable for selecting new venture suppliers. For instance, the head of *Automotive’s* startup department explained how the selection process had worked before they professionalized it:

> [Before we adjusted the evaluation process] an engineer went to a conference at the MIT and got approached by 20 startups who all told him that they have invented the Holy Grail. Of course, he is thrilled. Because he compared them with his team which is still using Windows Explorer 6. […] of course he is enthusiastic, but he cannot tell the difference between a good startup and a bad one. He has never heard of the Y Combinator and does not know what the difference between seed stage and later stage

> is, and he probably thinks, if a startup has not yet raised venture capital, then that is even better. (Automotive)

This quote shows that selecting new venture suppliers requires special processes and skills that *Skeptical Buyers* do not yet possess. Therefore, it is unlikely that they will make the best choice of new venture supplier. Accordingly, we propose:

> **Proposition 1**: Buying firms that do not adjust their supplier selection process for startups are unlikely to select suitable new venture suppliers.

Identification performance. The analysis of the selection process of *Realistic Adapters* and *Systematic Selectors* in terms of their identification efforts reveals several important findings. Unlike *Skeptical Buyers*, *Realistic Adapters* use a variety of channels to establish contacts with startups. They are open to external innovation and strongly emphasize active identification strategies which are consistent with previously defined strategic search areas. These search areas are coordinated within the organization. *Realistic Adapters* keep the whole organization apprised of the technologies that interest them, so that employees can evaluate whether or not a startup could be a worthwhile supplier. Especially managers from departments that maintain close contacts with universities (R&D), customers (sales), or suppliers (procurement) are instructed to notify the dedicated team whenever a potentially attractive startup appears. This seems to be an efficient way to screen close markets without having to employ large screening units. For instance, *Medtech's* dedicated startup manager receives dozens of proposals of potential partners from other departments every year; this has already resulted in a small number of collaborations.

Although the centralization of the identification process facilitates engagement, and *Realistic Adapters* get in contact with substantially more startups than *Skeptical Buyers*, the identification process of *Realistic Adapters* has also some weaknesses:

> Depending on whom they [the startups] are contacting, they can be lucky or unlucky. Sometimes they contact developers who know only their area, but if they contact people who have an overview, these people would then contact our corporate research department, and then it would reach me. This is based on an internal network without a formal process behind it. However, it works best if you contact the right people directly. (Robotics)

In contrast to *Medtech*, *Robotics* is a multinational company with facilities all over the world. The informal forwarding of startup proposals is considerably more difficult than for a smaller company like *Medtech*. It is also hard to keep the whole organization informed about strategic search areas. The *Robotics* informant admitted that only a very small fraction of business units forward proposals to him, which shows that the responsible managers of *Realistic Adapters* often lack internal visibility. However, this missing external visibility might be even a more serious challenge as *Realistic Adapters* tend not to advertise their startup activities on special web pages, making it difficult for startups to find the right contact.

Systematic Selectors have found a solution for this problem. Their dedicated startup departments are much more visible internally and externally as they announce that they want to engage with startups. At the same time, through the online application forms, applications always receive the right contacts while keeping identification costs low:

> We communicate through startup media that we are interested in startup collaborations. The startups then come to us. Screening the whole market by yourself is enormously expensive. (Transportation)

In conclusion, the firms of the third archetype present the most sophisticated means of identifying startups. Although they use the same kinds of active identification and they leverage other departments to identify more startups, they can be distinguished from *Realistic Adapters* because their central focus is on passive identification strategies supported by a highly visible startup department. The following propositions summarize our findings regarding the identification process:

> **Proposition 2a**: Buying firms that effectively orchestrate departments with external contacts for active identification purposes identify more potential new venture suppliers and are thus more likely to select suitable new venture suppliers.

> **Proposition 2b**: Buying firms that establish a passive identification strategy receive more incoming startup proposals and identify startups more efficiently than firms that only pursue an active identification strategy. Thus, they are more likely to select suitable new venture suppliers.

> **Proposition 2c**: Buying firms that establish a dedicated startup function enhance their visibility which increases the number of incoming startup proposals. Thus, they are more likely to select suitable new venture suppliers.

Evaluation performance. The supplier selection process of *Realistic Adapters* seems to be better suited for achieving the objective of engaging with suitable new venture suppliers than is the process of the *Skeptical Buyers*. They have adjusted their selection process in two important ways. First, there is a clear organizational responsibility for selecting new venture suppliers. The team that evaluates these new suppliers gains experience and accumulates startup-specific knowledge, which might lead to a more accurate assessment of the startup's quality. Second, this team does not work completely unassisted. Instead, it involves potential adopters of the startups' innovations or technological experts from the R&D function to evaluate whether the technology fulfills technological and market requirements. As one informant explains:

> Of course we are working closely with people from R&D and the business unit for the technical and commercial evaluation. We will never collaborate with a startup if there is not one business unit which says: good idea! We are going to support you. (Adhesive)

Although these two measures make the evaluation process less permeable for unsuitable startups, firms of the second archetype have not adopted a fully standardized evaluation approach. Every startup is evaluated individually without any predefined startup-specific criteria. They only use the standard criteria that have been developed for their established suppliers. This is a major difference from *Systematic Selectors* who send all applicants through the same funnel-shaped evaluation process. Each stage of this evaluation process has predefined criteria and experts who evaluate them. The following two quotes show the differences between the evaluation criteria used by *Realistic Adapters* (Medtech) and *Systematic Selection* (Logistics):

> We assess which quality management system they have, if the product documentation is available if the registrations are all correct […] We evaluate the typical things. (Medtech)

> We evaluate a startup's team, its technology, innovation, the strategic relevance for us, the financial conditions of the startup […] (Logistics)

Finally, after ensuring that only high-quality startups with technologically attractive products that meet the strategic objectives of the buying firm have gone through the process so far, the startup department seeks a business unit or a department to act as an "internal client" interested in sourcing the product. This last stage ensures a market fit, because only if a business unit wants to purchase the innovation and provides the budget for a joint innovation project can the startup be selected. Hence, *Systematic Selectors* offer startups a clear path after selection. Among them, *Automotive* put a great deal of effort into achieving market fit through this "pull process." As its informant explains:

> This is a pull from the business unit and not a push. We do not say work together with the startup, instead, we ask them, whether they want to work with the startup. Then, they must prove that they would benefit from the collaboration and they have to offer a real project. […] Thus, there is no "Not-Invented-Here syndrome" because each department is convinced that they get access to a technology that they cannot find somewhere else. (Automotive)

In sum, *Systematic Selectors* appear to be more likely to select suitable new venture suppliers than *Realistic Adapters* or *Skeptical Buyers* as all startups go through the same evaluation process and put more effort and qualification into the assessment of the startups' quality. Based on our analysis, we formulate the following propositions about the evaluation process:

> **Proposition 3a**: Buying firms with clear organizational responsibility for startups' selection accumulate startup specific knowledge which improves their ability to evaluate startups' quality and are thus more likely to select suitable new venture suppliers.

> **Proposition 3b**: Buying firms that apply startup specific evaluation criteria can better evaluate a startup's quality and are thus more likely to select suitable new venture suppliers.

> **Proposition 3c**: Buying firms that involve experts from different functions in the evaluation process can better evaluate the strategic, technological, and market fit and are thus more likely to select suitable new venture suppliers.

> **Proposition 3d**: Buying firms involving potential internal clients (i.e., potential users of the technology) in the evaluation process can better evaluate the market fit and are thus more likely to select suitable new venture suppliers.

DISCUSSION

The main purpose of this study was to examine how buying firms select startups as their suppliers. From our observations, we developed a typology of three archetypes based on five elements of differentiation. By analyzing the commonalities and differences among them, we derived propositions explaining performance differences of the analyzed selection approaches. The findings of this study have the following implications.

Theoretical Implications

Despite requests for research on the supply chain management/entrepreneurship interface (Kickul et al., 2011; Shepherd & Patzelt, 2013) and increasing evidence from business practices that established firms regularly select startups as suppliers (Gimmy et al., 2017), the selection of these non-traditional suppliers has scarcely been studied. The development of three selection archetypes in this study is thus one of the first attempts to generate insights into this new phenomenon. Many other scholars have also developed archetypes, especially to explore a new topic (e.g., Bode et al., 2014; Pauwels et al., 2016). Our typology underlines the importance of distinguishing established from new venture suppliers in supplier selection (Zaremba et al., 2016). The results indicate that buying firms that hesitate to tailor their supplier selection process to the peculiarities of startups are less likely to select suitable new venture suppliers. In other words, business practices and the supplier selection literature should consider startups as a distinct supplier type for which different sets of tools, evaluation criteria, and processes are necessary.

We also found that determining the suitability of a new venture supplier is quite challenging as standard evaluation criteria are not applicable. Through this exploratory multiple case study research, we discovered that in addition to a new startup's *quality*, its product needs to fit the *technological*, *strategic* and *market* requirements of the buying firm. These findings extend previous studies suggesting that startups must fulfill a certain base capability to become selected (Zaremba et al., 2017). This base capability is akin to our concept of new venture quality fit, which *Systematic Selectors* in particular emphasize during the selection process. Zaremba et al. (2017) found that buying firms that have developed a *new venture partnering capability* (*NVPC*) adapt their supplier management and evaluation process to the peculiarities of new venture suppliers and evaluate their new venture suppliers more thoroughly than their established suppliers. *Systematic Selectors* therefore seem to be the only group of firms from our sample that exhibit a strong NVPC. Consequently, one can expect *Systematic Selectors* not only to select more suitable new venture suppliers but that also to collaborate more effectively with them after the selection.

The exploration of *Systematic Selectors'* evaluation processes reveals that buying firms not only need to apply standard evaluation criteria more flexibly, as found by Zaremba et al. (2017) but that they also need to develop new evaluation criteria designed to distinguish *high-quality* from *low-quality* startups. The venture capital literature has explored the evaluation criteria for a long time (e.g., Baum & Silverman, 2004). This research stream could thus provide useful insights for the selection of new venture suppliers. Buying firms and venture capital companies share the objective to select startups with above-average survival rates. Hence, criteria that determine whether to invest in a startup might overlap with criteria that determine whether a startup has the potential to become a reliable supplier. Nevertheless, despite adding more concrete evaluation criteria, the selection process remains less formalized, less deterministic and perhaps also less rational than the selection process of established suppliers which many studies describe as an optimization problem where the best-performing companies according to several evaluation criteria will be selected (e.g., Wetzstein et al., 2016). When new venture suppliers are being selected, there will probably never be an objectively best solution.

The proposed archetypes illustrate differences in the selection processes of the case companies. In response to their strategic objective to establish asymmetric buyer-supplier relationships, *Systematic Selectors* have made the most modifications to the supplier selection process for startups. They are the only ones with a systematic approach to selecting startups, whereby they put substantial emphasis on creating and filling a funnel of potential new venture suppliers from which they actively select the most suitable. By doing so, they remove as much randomness as possible from the process, which makes them the archetype most likely to select suitable new venture suppliers.

Realistic Adapters recognized that they need to actively identify potential new venture suppliers as they cannot select suppliers from a given set of available firms (Kim & Wagner, 2012). They have somewhat adapted their selection process for these suppliers, but they still hesitate to fully adapt and allocate resources for this purpose. For *Realistic Adapters*, startups are means to an end. They have long-term innovation roadmaps and want to source the technologies externally. They consider startups as one of many potential innovation sources. Consequently, many of these companies adopted a “wait-and-see” attitude, trying to gain experience while avoiding significant investments.

Finally, *Skeptical Buyers* do not create special processes, criteria or organizational structures. They are particularly skeptical whether the potential advantages of such asymmetric partnerships outweigh the risks. Therefore, these companies do not actively screen for startups, which gives these relationships a random character. They are also less interested in close collaborations after the selection has taken place. Instead, they focus more on directly purchasing the product. Moreover, their selection process greatly depends on principal decision makers. In most cases, top managers follow their intuition in choosing startups and then promoting the collaboration, often against internal obstacles. These findings support prior studies’ findings regarding the key role of principal decision makers in asymmetric collaborations (Minshall et al., 2010; Zaremba et al., 2017). Generally, firms of this archetype are expected to have only limited chances to select suitable new venture suppliers.

Managerial Implications

The proposed typology provides managers with a framework to classify their new venture supplier selection process, enabling them to identify potential areas of improvement. In particular, *Skeptical Buyers* should reconsider their current supplier selection practice and adjust their structures and processes accordingly. In this way, they can orient themselves on the five elements of differentiation (i.e., design themes). For identifying startups, buying firms should leverage their departments with external contacts. This approach would broaden the reach of the search without incurring additional costs. Moreover, buying firms should consider collaborating with external screening firms to extend the search to other industries which would help to overcome any lack of identification capabilities (Zaremba et al., 2016). On top of this, buying firms need to communicate their needs to startups. To do this effectively, they also need to offer a standardized way of gaining access to the buying firm (e.g., via an application process). Then, buying firms should concentrate their supplier evaluation efforts on determining the inherent quality of a startup. Therefore, buying firms need to adapt their evaluation criteria to the startup environment. To acquire the necessary know-how, the selecting managers need to be constantly involved in the selection process. Buying firms should internally assign the responsibility for new venture suppliers. Often, the responsibility is not assigned to procurement but R&D or a newly created startup department. Then, it is important to clarify the role of procurement to avoid conflicts over competences. Finally, becoming a *Systematic Selector* might not be advisable for all buying firms, as the establishment of a startup department could add more bureaucracy and tie up resources. Thus, many firms might be better off assigning the startup topic to an already existing department.

Limitations and Future Research Opportunities

We are aware of the following limitations which should be considered when interpreting the results. We used an exploratory qualitative research design that can lead to idiosyncratic conclusions (Eisenhardt, 1989). We tried to compensate for this potential shortcoming by selecting our case firms carefully and by interviewing informants from a variety of manufacturing firms and industries. In addition, we focused only on manufacturing ventures offering tangible high-tech products. Nonetheless, we are confident that our findings are also relevant for selecting startups with intangible products (e.g., service or software ventures) since most of our case firms have also selected service ventures with the same approach.

Naturally, distilling firms into archetypes is a simplification of reality, but we are convinced that this archival classification is a good starting point for future research. Specifically, future quantitative research could test the presented propositions with a larger sample. Furthermore, many established firms lack a general understanding of startups and are not familiar with how to identify them. Therefore, scholars could investigate how established firms can effectively outsource their identification activities to external intermediaries. Also, there is still a great deal of uncertainty about how established firms can manage new venture suppliers systematically after they became selected. Finally, from the startup perspective, it would be worthwhile to explore how startups perceive the supplier selection process and how they can successfully maneuver through it.

APPENDIX

Interview guide

A) Profile
- What is the main business of your company? What products does it cover?
- Please describe your role/competencies in the organization.
- What strategy does your company generally follow when selecting suppliers?
- What experience has your company already gained with startups?
- Which startups has your firm selected as suppliers within the last 12 months?

B) Specific selection example
Let us talk about the selection of [name of specific startup discussed prior to the interview]
- How did you find this startup? (Or did it find you?)
  - Is this the usual way you identify startup suppliers?
  - How is the identification process organized in your firm?
- How did you evaluate this startup?
  - Which evaluation criteria did you apply?
  - Had this startup fulfill certain base/minimum criteria to become selected?
  - Who did evaluate this startup?
  - Did the evaluation process differ from other startups you or your firm selected?
- If you compare the selection process of this startup with the selection process of a normal supplier, what is different?
- How did you proceed after the selection?
  - What is the current state of the collaboration?
  - How do you manage this collaboration? (Is this the usual approach?)
  - Who manages the collaboration?
  - How would you assess the collaboration so far? Has it been successful? If so, why?

C) General questions
- If you think about the other startups your firm has selected in the last 12 months, why did you selected them? What makes these startups attractive to you as suppliers?
- Which products/technologies are these startups delivering to you?
- What is a suitable startup supplier for your firm in your opinion?
  - Is [name of the startup from the exemplary case] a suitable startup supplier? Why? What are inadequate startup suppliers?
- Do startups also approach you?
  - What are you doing then? Are there some processes in place? How do you decide whether the product/technology is of interest to you?
- Do startups also apply for traditional tenders?
  - How do you proceed then?
- Do you see particular risks when selecting a startup as your supplier?

D) Conclusion and outlook
- Please draw a brief conclusion. How would you assess the current state of your firm's startup supplier selection process?
- What are the main insights and learnings you have gained in selecting startup suppliers?
- How can your firm become better in selecting startups as suppliers?
- Would you like to add something to the answers?

ABSTRACT

Innovation has become a value co-creation process where people make new creation together with emerging technologies (e.g., 3D printing and laser cutting) in innovation communities, which often provide their members with diverse resources. This study draws upon motivation-opportunity-ability (MOA) theory to understand members' value co-creation experiences in innovation communities. Makerspaces are selected as the research context due to their practical significance. After interviewing 16 participants from different Makerspaces, the results indicate the types of value co-creation and MOA-relevant antecedents in innovation communities. Finally, implications for innovation research and practice are discussed.

KEYWORDS: Value Co-creation, Emerging Technology, Innovation Community, Makerspace, Motivation-Opportunity-Ability Theory

INTRODUCTION

With the advancement of emerging technologies, people often make innovation and creation in different innovation communities, such as crowdfunding platforms and Makerspaces. For example, the Maker movement has rapidly become a global phenomenon (MacMillan, 2012). Makers, the creators and innovators in Makerspaces, can now fabricate new items with open source software, hardware and the emerging technology like 3D printing and laser cutting (Wang, 2013). Free, accessible and editable open source resources have also empowered individuals, and various communities to participate value co-creation across socioeconomic classes, geographies, and cultures.

According to a report from the *Times*, the output value of the Maker industry and 3D printer reached 2.2 billion USD in 2012, and an expected value of 8.41 billion USD by 2020 (Bajarin, 2014). *USA Today* also reported that the annual funding given to Maker-related industries is about 29 billion USD (Stewart, 2013).

Makers tend to join innovation communities like Makerspace, which give them the opportunity to find new co-workers with mutual interests and to build a team or found a company. Makerspaces also convene talented people in various types of activities such as a speech or a startup competition. Compared to a traditional office unit, the cross-disciplinary environment found in Makerspaces draws more attention to the creative workers (Cavalcanti, 2013). This is why Makerspaces have become more and more important in new innovation and product development.

Makers and creators have transform the creating experience into the value co-creation process with others in communities of innovation. Value co-creation relies on Makers' and co-creators' enthusiasm in exploring, experimenting, and fabricating, while also requiring knowledge, expertise, and a degree of community's support. However, little extant research has investigated makers' value co-creation or innovation experiences in Makerspaces.

As a result, this study attempts to explore members' value co-creation experiences in innovative communities (e.g., Makerspaces) and analyze how value co-creation occurs from the perspective of MOA theory (MacInnis & Jaworski, 1989; MacInnis et al., 1991). Drawing on empirical data from in-depth interviews, the analysis reveals an interactive relationship between Makers and their communities on value co-creation. Our findings are signification contributive to innovation research and technology management.

RESEARCH CONTEXT

This study takes Makerspace as an example of innovation communities. The term “Maker” originates from the “DIYer (Do it yourself)” culture, which focused on empowering individuals to learn simple handcraft techniques on their own in one’s garage in the 70s and 80s in America. One quintessential example is Steve Jobs, the founder of Apple, who successfully built the prototype of the Apple I with his friends in his garage (Gray, 2014). This kind of environment has now known as the community of innovation, which indicate the place like Makerspace and Hackerspace that allows creators can discuss their work and collaborate with the community. The idea of the Makerspace has its root in MIT (Massachusettes Institute of Technology)’s Fab Labs (fabrication laboratory), which has had a significant influence on Makerspaces. Fab Labs are defined as the design to fabricate things, and “consist of digital equipment for designing products and the digitally driven tools to create them” (Burke, 2014).

Typical equipments in Makerspaces include 3D printers, and laser cutters, which may provide coaching and consulting services to help to hone and implement startup collaborations. Several developed countries such as the United States, the United Kingdom, and Singapore have established industrial parks for talented people to exchange their ideas, which give Makers the opportunities to pursue and share further development of their products and ideas to the worldwide audience. It also aims to support members by creating an open platform and a space for cross-disciplinary idea exchange, conducting brainstorming and creative workshops. These spaces also encourage Makers, self-learners and micro-startup teams to identify and learn about the resources and technologies they will need for their work. There are more and more design schools in Taiwan starting to operate their own Makerspaces to help students to strengthen collaborative skills. To facilitate group cohesion and creativity, they encourage forming teams that interdisciplinary members to facilitate spontaneous learning and integrative discussions (Sawyer, 2007).

Innovation communities like Makerspaces build friendly, well-resourced environments for value co-creation among members; they give creators multiple channels to learn new knowledge and skills; and they organize regular events for sustained idea exchange in the innovation community. These help to motivate creators to actively participate in these spaces. With resources and opportunities from these communities, Makers can convert their imagination and ideas into real, tangible works. They can also find ways to give back to the community after learning new skills. Makers strive to transcend time and resource limitations of traditional products by exploring new methods and technologies together.

LITERATURE REVIEW

Innovation as Value Co-Creation

In this study, innovation is treated as a process of value co-creation. From a perspective of marketing, value co-creation is defined as consumers assume an active role and create value together with the firm (Koleret al. 2011; Prahalad and Ramaswamy 2004a). And process-based value co-creation framework consist three main typess: (1) customer value-creating process—in a business-to-customer relationship, (2) supplier value-creating process (3) encounter process. These types have share the different indications in innovation communities. First, the *customer value-creating process* is similar to the creators who tend to explore themselves and build their own product. This type of the maker start their creation with their problems in daily life, which inspire them to create a better solution to help themselves and others. Second, the *encounter process* is more about team-based co-creation. New ideas and products that are co-created by multiple groups in school labs or startup competition, share a mutual collaborative essence and match the culture of value co-creation in the Maker community. There are less samples about the *supplier value-creating process* for now, which is the part that community could work on in the future.

For Makerspaces, the more makers engage in community events like meetups and workshops, the more they have the chance to learn from each other. These participatory experiences help them to build things in teams and to bring products to market. This cyclical system helps build an accumulation of creative energy in the community, which gives creators a better chance to achieve breakthroughs in their work. The recent trend of micro-enterprise (Cheng, 2014) has led increasing numbers of people to start their own businesses. The process of value co-creation with different teams makes it possible for a product's creator to get an actual response from the market. The innovation community can be built to support the pattern and the environment of the creative industry (Anderson, 2012). There are industrial parks that support local Makers in other countries, such as Tech-city in England (*The Economist*, 2013), D camp in Korea (Wu, 2014) and BLOCK71 in Singapore (Lee, 2014). These industrial parks create an ecosystem for Makers by providing resources for startup groups, including consulting services, incubators, and accelerators.

Motivation-Opportunity-Ability (MOA) Theory

MOA theory is derived from the Motivation-Opportunity-Ability model. This theory was first applied in the field of industrial psychology (Lawshe, 1945). MacInnis and Jaworski (1989) extended this initial work by examining the influence of the three elements of MOA theory on marketing communication from the viewpoint of social psychology. Recently, MOA theory has been used to investigate value creation in consumer communities (e.g., Gruen et al., 2007). MacInnis, Moorman, and Jaworski (1991) argued that all three factors are essential and irreplaceable in accounting for human work processes. If one of the elements is missing, it is likely to lead to a major negative effect on productivity and value creation. In the MOA framework, Motivation represents the factors affecting how an individual pursues purposive action; Opportunity accounts for the environment and mechanisms constraining individual behavior; and Ability refers to personal assets, skills, and knowledge (Rothschild, 1999).

Hallaban (2000) views Motivation as the primary factor in the MOA model. This driving force represents an abstract process, which is an important component in initiating action. Macinnis, Moorman, and Jaworski (1991) conceive of Motivation as a combination of will, pleasure, interest, and desire to engage in meaningful conversation. Schiffman and Kanuk (2000) defined Motivation as a private inner force, which leads people to take action. In their model, the existence of this force is triggered by unsatisfied needs. The rise of crowdfunding platforms has helped many Makers turn their creations into businesses, shifting their activities from simply making fun and useful works to producing full, commercial product lines. Typical communities exchange ideas through workshops or one-off classes using simple tools. Makerspaces have provided the community with an alternative that incorporates digital tools such as 3D printers, CNC and laser cutters. Maker activities not only attract experienced Makers, but they also extend the variation of activities and facilitate new challenges in the production process. Fab cafe, a combination of a Makerspace and a coffee shop, is a new type of Makerspace. It offers a comfortable place for people to make new connections and create new works together.

The second factor of MOA theory is Opportunity, which reflects a situation that is conducive to achieving a desired outcome. An opportunity can be evaluated based on its achievement or failure (MacInnis et al., 1991). Rothschild (1999) explained that opportunity is the external environment plus a relational mechanism, which can bring about practical action in an individual. For Makers, opportunities include high-speed delivery in information, networks of human resources, and consulting services. Creators can use online public information such as open source tutorials to help their creation work (Wang, 2013). Different from Makers, the community at large is often managed by the operator of the Makerspace. These operators tend to add value by offering traditional handcraft classes. Creating good experiences in the space can encourage people to organize other events in the community, which makes interdisciplinary idea exchange possible. These opportunities are appealing not only to Makers and investors with common interests but also to other creative members of the community who wish to connect with each other.

Ability is the third factor of the MOA model. Rothschild (1999) indicated that ability comprises many aspects, including the relevant skills that a person is equipped with as well as the individual's ability to implement practical solutions using theoretical knowledge. Hoyer and MacInnis (1997) described ability as any resources an individual possesses that can contribute to creative achievements, including funds, social capital, skills, and knowledge. Gruen et al. (2006) defined ability as the crucial resources that can make things happen, such as intelligence and knowledge. Makers today often have backgrounds in design, electronics, and architecture, which give them the advantage in learning and using digital tools. Cross-disciplinary collaboration expands the range of possibilities and tends to maximize the interests of all individuals involved. Online platforms make the communication widely accessible, and help Makers promote and share their ideas more broadly. A Maker community can promote its vision by convening people from different industries and giving them a chance to learn collaboratively. Shared knowledge and tools in the space can allow new types of works to be imagined, prototyped, and completed. The community can also invite international speakers to share their experience, thereby building international bridges in both academic and industrial fields.

METHOD

Participants

This study conducted in-depth interviews with 16 Makers and Makerspaces operators in Taipei. Over 90% interviewees were males, which shows that female creators remain minority in the community. The average age of the interviewees were 32 year-old, whom are from design, creative, education and medical sectors. Sample innovation communities included Makerbar, Open Lab, Taipei Hackerspace, and Fablab Taipei, where the interviewees have their membership joined at least five to seven years, and one of the most experienced operator have been in the community for over 11 years.

Interviewees shared their experiences openly, and exhibited their works in the Maker Faire exhibition and participated in value co-creation in communities of innovation with digital tools like 3D printer and laser cutter. Interviews took place in Makerspaces or community gathering spaces, which allowed the researcher to observe interactions between Makers and their communities. The factors considered in gathering these data were chosen to test application of MOA theory, which emphasizes the influence of space, environment, and resources on human behavior.

Data Collection

This study used qualitative research methodology and gathered data through semi-structured, in-depth individual interviews. Semi-structured interviews are also known as semi-standardized interviews or guided interviews. For this approach, the researcher designs an outline before the interview based on the questions and the aims of the research. However, the interviewer does not always follow the order of the outline in the process. Normally, the interviewer can adjust the order and scope of questions based on the context and flow of the interview. Semi-structured interviews have the following advantages: (1) They allow the interviewer to collect data with a relatively open-mind on specific issues. The researcher may receive an unexpected result by taking a semi-standardized interviews approach. (2) The interviewee tends to reflect their experience more openly with fewer limitations in the interview. (3) Semi-standardized interviews tend to be an adequate approach for researchers who wish to learn about personal experiences of the interviewee or to compare the results with other data. (Guan, 2010)

The participants in this study were divided into two groups for in-depth interviews: (1) Makers who build their works in Makerspace, which includes MakerBar Taipei, FutureWard and Fablab Taipei; and (2) Operators who run Makerspaces, including Open Lab and Taipei Hackerspace. The follow-up interview questions are listed below: (1) How do you know about the Makerspace? (2) What is the reason you started operating this new type of space/ community? (3) What do you wish to change by running this space/community? (4) Have your experiences and the collaborations in Makerspace/Community influenced your work? If so, how?

After conducting in-depth interviews with Makers and Operators, the researcher analyzed the data using the motivation, opportunity, and ability framework. By reviewing the goals and achievements of both groups, the research aims to interactively identify weaknesses and gaps in these Maker programs in order to advance the development of this new industry.

Data Analysis

After conducting in-depth interviews, they were transcribed and analyzed. Two authors extracted and categorized the elements of value co-creation and its MOA antecedents. After the initial result was completed, it was validated by academics who specialize in this area of theory and checked by our interviewees.

FINDINGS

After qualitative analysis, this study illustrates the value co-creation experience and relevant factors within the MOA framework that foster member creation in innovation communities. These factors are related to the time when each individual began participating in communities of innovation (i.e., Makerspaces) and their reason for choosing to join this particular environment, which also helps to understand value co-creation experiences in innovation communities.

Types of Value Co-Creation in Innovation Communities

The results showed that two genres of value co-creation and innovation process in innovation communities (i.e., Makerspaces). The first type of value co-creation is innovation by yourself but inspired by others. In this type, innovation is created by an individual maker whose idea is inspired by his or her interaction with other members in communities of innovation. Interviewee G described that "*Maker is about inventing and modifying what you need. You will need to search information online and ask helps in the community to accomplish your project. Instead of offering you all the resource, you gather interdisciplinary people here at the same time, and inspire their imagination*."

The second is team-based innovation. In this type, innovation is an outcome of group dynamics among several members who work together for creation. Makers collaborate with cross-disciplinary talents to expend their project into a bigger scale. As Interviewee H described that "*For me, I care about work division. If it's a hard core project, I tend to collaborate with someone who already have knowhow. Like people in the community or people who know the program, and I will work on the design part to help finishing the project*."

Motivations for Value Co-Creation in Innovation Communities

Motivation is the first factor in MOA theory, which represent the driving force that leads an individual to take action. Our analysis revealed three categories that are related to motivation in this context, which included the following: (1) a delight in the making process, (2) a sense of achievement resulting from creation, (3) an interest in innovative experimentation. These three categories of motivation sparked Makers' interest in the Maker movement and captured the reasons for their continued involvement. These are discussed in detail below.

1. A Delight in the making process

Most interviewees first discovered the Maker movement through their interest in fabricating items. Different experiences in educational backgrounds also led to various results. Once a Maker had an initial experience of experimental creation, they typically discovered many more possibilities for continuing in the creative process. Different operation methods may also trigger Makers motivation and interest in creating new items. There were also some people whose motivations were closely linked with their own personal interests. Interviewee F stated: "*That was also the first time for us to do a workshop with another organization. One just felt that the process was so fun and interesting, even if it didn't balance your cost. You wouldn't think about the cost when making it. It's more about having this amazing opportunity for everyone. We used a 3D printer to make that piece at that time.*"

2. Sense of achievement resulting from creation

After experiencing the fun of fabrication, Makers often try to extend the development and value of their creations. It is easier for people to feel a sense of achievement when making items that match the Maker's original idea. Being motivated by a sense of achievement also leads to a pattern in the creative production process. In the community events and the co-creation process, most Makers are proud of the works they build from scratch. Aside from seeking a sense of achievement, community operators are dedicated to creating platforms that allow members to participate in more activities. Interviewee B explained: "*For me, it's about gathering people in my life, and we solve problems together. It is not about showing off how good I am in fixing things but about how we live. I have a sense of satisfaction when making my creation and helping other people. The more that people help others, the more they will get the sense of achievement. The reason I didn't emphasize [the importance of helping others] in the first place is that people will just show up if they are interested*."

3. An interest in innovative experimentation

There are also people who think their interests and development are limited by current environments and systems of production. They wish to break out of the status quo by changing fields and make improvements to other industries using digital fabrication. Interviewee O said: "*My system supports medical design with design. I hope to use digital tools to update the complicated medical systems in a modern way. My approach is to make products that are easier for people to operate*."

Opportunities for Value Co-Creation in Innovation Communities

The presence of an Opportunity indicates that a situation is conducive to achieving a desired outcome, and its presence can help to predict achievement or failure. Opportunity represents the external environment that brings about practical action from an individual. People not only join a Maker community to start creating; they also gain various opportunities in the process, which allow them to complete their project. There are three categories of opportunities, which include the following: (1) new opportunities from the community to extend an individual's work; (2) diverse modes of learning; and (3) interdisciplinary knowledge exchange.

1. New opportunities from the community to extend an individual's work

Normally, Makers will not buy their own 3D printer, so they go to a nearby makerspace to use specialized tools. It is important for makers to meet and collaborate with the community in the space. With technical assistance, creators can speed up production and execution on their project. Interviewee C described a Makerspace as: "A place with machines where one can also make things and conduct research with other people."

2. Diverse learning

Based on the type of Makerspace, a community may organize various events such as workshops and speeches. Workshops are chances for makers to develop new learning patterns, which let them engage people from different background and interests. Adjustments and improvements in their work may also lead to creative collaborations and finding new business partners. Aside from participating in workshops, members in the Maker community also have the opportunity to offer courses on their own, which can be a memorable experience. Interviewee I commented: "*I got the opportunity to start my own workshop. This resulted from a discussion with OO who helped to make it really happen. I think this was an important experience, which affected me a lot. It was not just the project but also the space that provides you with this kind of environment and people, which allows you to have chances to learn. It also helped to build a starting point for the future. I think this was the best part, and I also learned a lot*."

3. Interdisciplinary knowledge exchange

Unlike creators who are used to working on their own, Makers in this generation tend to share their creations online, which has led to an interdisciplinary knowledge exchange between online and offline members in the Maker community. Even foreign creators who have never heard of the Maker movement or have no experience in creating can connect with other members in the Taiwanese community. Interviewee N remarked: "*It's all about sharing knowledge and getting knowledge from each other about different subjects*." Those who cannot participate in an actual community may still be aware of information about Makerspaces online. Interviewee A described: "*What Fablab is doing is actually extending the spirit of things. You have to do things, learn things, and share them. You can make your creations and their influence extends through the Internet*."

Other than online information exchange, events like seminars are equally important. Seminars and forums often allow interdisciplinary talents to reach large audiences. Discussion is also a way to increase knowledge exchange.

Abilities for Value Co-Creation in Innovation Communities

Ability is the third factor of the MOA model, which comprises resources that an individual possesses that contribute to creative achievements, including funding, social capital, skills, and knowledge. The types of creations that people can complete are determined their ability. There are three categories of ability, which include the following: (1) integration of new and old cultural practices and repurposing outdated technologies, (2) empowerment resulting from creative modes of education, and (3) fabrication of novel, customized products in startup businesses.

1. Integration of new and old cultural practices and repurposing outdated technologies

Makers today not only have the ability to learn about digital tools, but they also apply what they know in their life, such as repairing objects. This incorporation of lived experience helps to renovating the production process using cultural practices. It shows that makers can solve actual problems that benefit people while extending the spirit of their traditional culture. With the access to new tools and spaces increases public

familiarity with fabrication techniques. Introducing easy, accessible techniques can engage more people to join the movement. Interviewee A commented: "*Fablab was originally built for facilitating all kinds of knowledge collaboration with digital fabrication. What digital fabrication does is lower the requirements [of using this technology] by equipping normal people with machines they would normally use only in the lab*."

2. Empowerment resulting from creative modes of education

Innovation communities represent social structures that link creators together. These concepts help contribute to the goal of empowering individuals. Many Taiwanese feel that their actions and imaginations are limited by aspects of their formal education. However, new tools adopted recently in new educational programs have shaped new perspectives. Interviewee L, a teacher, said: "*I'm actually organizing [Maker activities] in our school club, which gives me the opportunity to create, as well as the time, the space, and the ability to give back to the kids, mainly to provide resources to them. I think it's important for teachers to provide resources and direction to students, which is more akin to guiding than directing*." Makerspaces are equipped with all kinds of tools to support creators and encourage people to develop new abilities. More participation from a community also inspires more creation.

3. Customization and creative, entrepreneurial ability

To adapt to a quickly-changing entrepreneurial environment, makers not only must find a way to develop customized products, but they also must find suitable Makerspaces for themselves. This can help them connect to new product lines and online platforms, ultimately enabling them to build strong business models. Products made by the new generation of designers thus focus more on personalization and customization. It is natural for producers and creators to incorporate digital fabrication into the customization process. In addition, digital fabrication also lowers requirements for digital fabrication and encourages more people to create at home. This has already been applied to several fields. Interviewee G described his experience: "*I was making customized products. With digital tools and design, this often leads to customization for the majority [of customers]. It means everyone can make their own product*."

Discussion

Recently, communities of innovation have become more and more popular. Makerspaces is one of such communities where emerging technologies are provided for value co-creation among members or makers. This study applied the Motivation-Opportunity-Ability (MOA) theory to explain the interactive relationship between Makers and their communities, considering each actor's creative assets in order to extend the applicability of the MOA framework and provide pragmatic recommendations to the Maker movement in Taiwan.

This study relies on evidence from 16 interviews with key figures in Taiwan's Maker movement, finding three principal motivations for joining this movement: (1) a delight in the making process, (2) a sense of achievement resulting from creation, (3) an interest in innovative experimentation. Through pursuing these motives, the Makers typically discovered new opportunities in their communities to extend their work, such as marketable applications, diverse learning, and interdisciplinary knowledge exchange. Finally, through these opportunities, Makers sustained further creative collaborations, whose scope included (1) integration of new and old cultural practices and repurposing outdated technologies, (2) empowerment resulting from creative modes of education, and (3) fabrication of novel, customized products. According to our findings, this study is helpful for practitioners in innovation communities, such as crowdfunding platforms, Makerspaces, and R&D departments. Our findings can be applied to (1) innovation education, (2) new product development, (3) innovation management through group dynamics, (4) crowdfunding, and (5) micro-entrepreneurship.

Even if there are successful promotions in some communities government, Current promotions in communities have yet to reach the mainstream. There is also a lack of public discussion between communities. Taiwanese design education could also better support students in incorporating handicrafts into their work. Most students come to Makerspaces for school assignments, which may inhibit their space for making new creations. Lastly, many people do not pursue innovative business models due to the popularity of the original equipment manufacturer (OEMs) model in Taiwan. This discourages the independent development of new technologies. With limited ideas about how firms can operate in Taiwan, co-working spaces and service-oriented businesses do not flourish, which reduces the resources available to local Makers. Aside from rare corporate sponsorship opportunities, most makers must fund their own initial investments in learning and research. It is important to provide actual resources, expand funding channels, and improve communication with the community at-large. This study is a rare academic study on Makers and the Maker community in Taiwan. The issue of how to effectively foster Maker communities has become increasingly important to modern society. This analysis provides an academic perspective on Makers and suggests a need for further investigation of creative collaboration processes. It aims to fill a gap in the current MOA theory framework. Gathering feedback from Makers and community operators allows for triangulation of diverse perspectives, which can inform the process of designing public policy, educational curriculum, and community ecosystems. This study can also be used to promote the Maker movement, which imbues daily life and education with new possibilities involving technology, design, medicine, entertainment, and cultural preservation. Overall, incorporating maker culture into local communities can encourage new Makers to collaboratively build creative works and foster deeper connections.

Kevin Linderman
University of Minnesota
Email: linde037@umn.edu

ABSTRACT

From a resource-based view, this research examined the role of corporate strategic resources in innovation optimization. Based on data analysis from 257 U.S. companies, key findings are that (i) firms that heavily rely on knowledge-based resources tend to focus their efforts on process innovation; (ii) process innovation serves as an order winner in a dynamic market condition, while product innovation functions as the order winner in the stable market. This study contributes to the Operations Management literature by providing an alternative new resource-based innovation paradigm, rather than the existing market-based PLC innovation perspective, to optimize product and process innovation decisions.

ABSTRACT

This research concerns the use of building information modeling (BIM) in building project management. Design science research was adopted to design and develop a model to solve a project management problem. The integration model was built by the development of a plug-in for Revit software, capable of providing information in a database powered by a planning software. An empirical study on a large building site was carried out to evaluate the model applicability and utility. Integration between BIM and project management through verification of constraints, visual management, and union of the parties involved with the project make both more efficient.

KEYWORDS: Project management, Information systems and technology, Manufacturing and production planning, Construction management, Building information modeling

INTRODUCTION

The Last Planner System (LPS) is a planning model, which aims to improve workflow reliability, reduce variability and losses in construction processes, and promote the reduction of costs and construction time (Ballard, 2000; Sacks et al., 2010). LPS consists of collecting sets of tasks to be performed and selecting those that can be efficiently assigned to executing teams. The plan´s approval occurs after the removal of constraints related to labor, materials, project specifications, and equipment.

Machado & Heineck (2006) suggest performing the planning of anticipations, which consists of raising requirements to ensure efficient work, involving actions to ensure elimination of restrictions and maintaining those elements that positively interfere in the uninterrupted workflow. The complexity of this proposal refers to the structuring of an information system capable of supporting the anticipation actions management in production planning.

The proposed changes in construction planning processes affect the quality and the amount of information required for decision-making. Building Information Modeling (BIM) emerges as an essential element in this scenario by providing the advantage of aggregating information into a single database. Furthermore, BIM supports the decision-making process in construction management systems. BIM allows configuring a reliable basis for decisions to support and improve processes of the project lifecycle, from digital representations of physical and functional characteristics of buildings (National Building Information Modeling Standard, 2007).

According to Sacks et al. (2010), lean thinking applied to construction has contributed to the development of production planning and control systems. According to these authors, the proposal presented by Koskela (2000), which conceptualizes production concerning transformation, flow, and value, clearly shows the repercussion of information maturity on benefits generated by the workflow. In this context, the use of LPS appears to reduce variability in construction processes and improve coordination workflow. According to Sacks (2010), a new conception of technology capable of providing required information to the planning system is necessary. Leite et al. (2016) state projects deal with a significant amount of data generated in a great variety of different formats. BIM emerges as a technological option that comprises all necessary functions for the project´s lifecycle. When adopted correctly, BIM contributes to a more integrated design and construction process, which generates higher quality projects with lower costs and durations (Eastman et al., 2011). Other benefits of BIM adoption can be mentioned, such as improving communication, facilitating logistics management, analyzing implementation plans, and controlling physical construction progress.

Information requirements that arise in the application of LPS are essential to establish the link with benefits provided by the BIM model. Sacks and Harel (2006) showed LPS reduces the information gap between project managers and subcontractors with the improvement of resources assignments decisions. According to Sacks, Treckmann, and Rozenfeld (2009), computer-aided visualization of construction product and processes facilitate reporting of project status and provide a support decision making to achieve stable production flow. Sacks et al. (2010) analyzed the existence of convergences between theoretical principles of lean construction and BIM and identified 56 possible interactions. Mendes Junior et al. (2014) presented a synthetic framework determining seven interactions associated with production planning and control after analyzing the results obtained by Sacks et al. (2010). Biotto (2012) presented a method for building site planning and control using BIM 4D generating information used in the decision-making process at all hierarchical levels plans. Bhatla and Leite (2012) verified the synergy of lean construction and adoption of BIM in a case study on medium and short-term planning processes in electrical, hydraulic, and mechanical work packages. Amongst the positive findings, they highlighted the functionality for removal of constraints, verifying of conflicts among projects, reducing cycle time, and support in communication between project participants in understanding the construction process. Mendes Junior et al. (2014) presented a theoretical framework of integration of BIM to LPS, based on the proposal developed by Bhatla and Leite (2012). Moreover, they found it is possible to obtain more information for production using integrated documents into a single database. Because of the research, they observed the reduction of variability, improvement of communication among those people involved with a project, reduction in cycle time, and decreasing of rework. Sacks et al. (2013) developed and applied an integrated BIM model to LPS, called KanBim. The authors elaborated a proposal in which production teams can check online the information about the current stage of work concerning the removal of its restrictions until the tasks that constituted them are ready to begin.

In analyzing the studies presented previously, there is a need to improve integration between BIM and LPS through visual management and automatic verification of constraints. The general objective of this research is to operationalize the integration of BIM to the LPS, focusing on medium and short-term plans managed visually in the 3D model. Given this primary goal, three secondary objectives emerged: to check constraints automatically, to generate medium and short terms plans (through the development of a plug-in), and to apply the model in an empirical study to assess their usefulness and applicability.

LITERATURE REVIEW

Last Planner system

Ballard and Howell (1998) proposed the LPS in the mid-1990s and constituted the primary application of the philosophy of lean manufacturing in the construction industry. LPS endeavors to apply lean manufacturing planning principles to construction projects. LPS emphasizes the need to manage production flows and commitment of work teams and provides a more reliable production, by promoting the reduction of the variability of the workflow (Ballard, 2000).
According to Laufer and Tucker (1987), LPS involves elaboration of long-term planning, the look-ahead planning (for the medium-term), and weekly or commitment planning (for the short-term). Long-term planning, also called master plan, should establish overall objectives that guide the enterprise and define the project's macro stages sequence, duration, and rhythm (Ballard, 2000). The master plan serves several purposes, such as expenditure projection and disbursement (Ballard, 1997). As stated by Fernández, Cárdenas, and Armiñana (2011), the master plan incorporates planning of all project activities, establishing deadlines and spatial relationships between different scheduled activities. On the other hand, look-ahead planning has the primary function of controlling workflow, through systematic identification and removal of constraints (Ballard, 1997). At this level of planning, the master plan is detailed and adjusted according to the available information (Ballard and Howell, 1998). The primary function of the look-ahead is the link between long and short-term planning. Look-ahead planning serves as a production protection mechanism in the short-term horizon, making it more efficient since it releases to execution only activities whose constraints have been removed (Ballard, 2000). The third level of LPS comprises commitment planning (or weekly work scheduling). In this plan, conciliation occurs between what should and what can be done. In this regard, the decision refers to what will be accomplished, considering work packages and those responsible for running them, based on available resources and prerequisites fulfilment (Ballard and Howell, 1998). According to Ballard (2000), weekly work scheduling occurs at the short-term planning level, by guiding assignments of teams responsible for each work package, after removing constraints in look-ahead planning. Priven and Sacks (2015) showed that weekly work plans (WWP) meetings promote a social network among the subcontractors involved with the project, with improved communication, which enhances coordination and improve workflow.
The essence of LPS is on information management regarding constraints to generate a reliable and uninterrupted workflow. Modeling information by BIM's proposal appears as a significant potential opportunity for applying LPS in the scenario discussed earlier.

Building information modeling (BIM)

According to Eastman et al. (2011), BIM is a modeling proposal associated with the processes of producing, communicating and analyzing the design of a building. Succar (2009) states BIM as a set of policies, procedures, and technologies that generate a methodology to manage building projects, from digital format data, throughout the life cycle of the building.
The main difference between BIM and 3D modeling software is the ability to generate parametric objects. According to Leite et al. (2016), information modeling concerns different sources of information to be shared throughout the project life cycle, interchangeability enabled by designed data formats and interoperability, and gathering data on work packages performed, among others. Parametricity allows generating editable objects, which can be changed automatically and support the BIM platform. Without this capability, a BIM software is just a three-dimensional modeler. Eastman et al. (2011) classify the uses and benefits of BIM considering the phases of the project life cycle, as follows:

(a) project design, involving a preliminary study and its viability;
(b) design, encompassing visualization, correction of elements in the model, generation of 2D drawings, multidisciplinary work, automatic extraction of quantitative, improvements in the process of energy analysis and sustainability;
(c) execution, including synchronization of the planning of work with objects of the model, the discovery of interferences between elements of the building, implementation of lean construction, synchronization of phases of acquisition, design, and construction;
(d) and operation, promoting improvement in managing operation of building systems.
Multiple dimensions discriminate BIM. According to Rodas (2015), the most explored model is BIM 3D. The dimension known as BIM 4D refers to time, which can offer temporal planning, enabling manage the building throughout its life cycle. In this aspect, one can visualize and evaluate the progress of activities to be carried out during the construction of the building. BIM 5D is associated with cost estimates, assigning the model ability to attribute values to the project elements. In this dimension, BIM becomes an aid to budgeting, automatically reflecting any change in the plan in costs. BIM 6D and 7D involve aspects related to sustainability, management and preventive maintenance of the enterprise.

RESEARCH METHODOLOGY

In this research, the authors adopted the methodology of design science. This approach establishes a systematic process, whose purpose is to design and develop innovative artefacts with problem-solving conditions relevant to the practice field (Van Aken, 2004; March and Storey, 2008; Dresch, Lacerda, and Antunes Jr, 2015). The adherence to the primary objective presented before determined the selection of design science research, as it required the creation of a practical model to improve interaction between project and building site medium and short-term planning. The research was carried out in four phases, as presented in Table 1.

Table 1: Research Design		
PHASE	DESCRIPTION	PERFORMED ACTIVITIES
1	Literature review	Identification and delimitation of the research problem
2	Exploratory studies	Search of knowledge about Revit, database, and software intended to accomplish the LPS Choice of organization adopted as study object Understanding the production planning and control process and implementation stage of BIM modeling in the organization adopted for study
3	BIM model development	Choice of building site Preliminary design project Model Application Model Evaluation
4	Consolidation of the BIM model	Communication on the results achieved Evaluation of the theoretical / practical contribution of the model

The literature review sought to ensure adoption of a problem with relevance to production planning and control within architecture, engineering and construction industry. In phase 2 of the exploratory study, the authors performed the analysis and evaluation of alternatives for BIM. According to Bilal et al. (2016), while there are many BIM design software on the market five products are the most considered for the users: Autodesk REVIT, Bentley MicroStation, Graphisoft ArchiCAD, Vectorworks, and Digital Project. REVIT is the most popular BIM design software among architects, engineers, designers, and contractors. The information generated by REVIT is stored in a centralized database allowing information sharing and collaboration among stakeholders of the project. REVIT supports many building simulations (for this research, the authors focused on construction planning and control). The authors adopted the REVIT software platform for research and training of researchers. After, it was selected a company involved in the implementation of BIM and accessible to interventions sought by the analysis. An organization that was carrying out an initial BIM implementation process was adopted for the study. The phase 3, regarding modeling, involved empirical research in the building site of the chosen company.

The empirical study was carried out in three stages, aiming to understand the problem studied, to develop and test the proposed model and to identify the practical and theoretical contribution of the solution obtained, as shown in Table 2.

Table 2: Stages of the Empirical Study

STAGE 1	STAGE 2	STAGE 3
Preliminary meeting with company managers	Plug-in adaptation	Model application
Participation in planning meetings	Planning software development	Model evaluation and improvement
Development of a data flow diagram	Performing model tests	Presentation of the proposed model to the project managers
Proposal of a preliminary model	Model refinement	Model application

The selected object of study was a building site from a construction company located in a large city, in the Midwest region of Brazil. The building site studied was chosen due to the process of implementation of management and planning, using BIM. The building site involved a project of a shopping center with a constructed area of 52,134.09 m² and an estimated value of US$ 32.845.823,00. The project was started in November 2014 and completed in April 2017.

In the phase 4 the generated model was evaluated considering the constructs presented in Table 3.

For each sub-construct, a question was generated and applied in the interview. The evaluation process took place through the configuration of a focal group, consisting of the planning engineer, the project-coordinating architect and the engineer responsible for the production, as well as trainees who use the model.

Initially, interviewees were informed about results achieved by the project and the peculiarities of the model generated. After this introductory phase, participants in the focused group were asked to evaluate the effects of the project. The authors used focused group interviews to verify the validity and applicability of the proposed model. According to Bilal et al. (2016) focused group interviews allows to understand multiple viewpoints and to collect the real-life experience of construction industry practitioners. At the end of the interviews, the research team analyzed the theoretical and practical contribution produced by research.

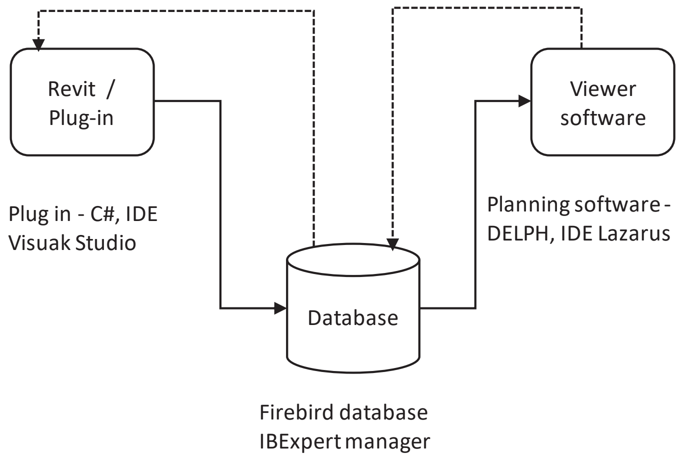
Table 3: Questions for Evaluation of Constructs		
CONSTRUCT 1	SUBCONSTRUCT	RESEARCH QUESTION
Utility	Information reliability	Is the information generated by the proposed model faithful to reality? Can information be viewed in time to allow its use?
	Increase of communication	Does the information generated by the model increase communication among stakeholders?
	Use of generated information	Is the information provided by the model used in production planning and control to make it more efficient?
	Integration of the information	The information that was previously in different databases have been aggregated into a single database?
Functionality	Easiness to use	Is the model's operation easy to learn?
	Easiness to understand information	Is the information generated by the model understandable?
	Effective feedback	Is it easy to feed the model with information from the construction site?
	Interest in continuing using the proposed model	Is the company interested in continuing using the proposed model?

INTEGRATION MODEL DEVELOPMENT

Introduction

Figure 1 shows the communication flow between the 3D model and LPS. The data connection between elements of the integration model was accomplished through classification of identification codes of geometric structures of the 3D model in Revit.

Figure 1: Data Communication



As can be seen in Figure 1, a database served as an intermediary element to establish communication between Revit modeling software and L7 planning software. Revit software in version 2017 was adopted in the model. The plug-in software was developed in C # programming language, and Visual Studio IDE environment was used in its construction. The database was structured in Firebird 3.0 environment, and IBExpert was used for its management. The planning software was built on Lazarus IDE platform and encoded in DELPHI programming language. The work of Rodrigues (2017) presents more details about configuration of the structure shown in Figure 1.

Development of a plug-in for the planning process

In order to structure medium and short-term plans, a plug-in was developed, as presented in Table 4.

Table 4: Functionalities, Parameters, and Goals of the Integrated Model

FUNCTIONALITY	PARAMETER	GOAL
Building site link to 3D model	Service Group of services	Assign geometric element to the structure of the building site
Look-ahead	PW – Productivity weight LI – Linked input LIC –Linked input consumption CD – Constraint Description	Assign labor consumption Assign necessary input to service Assign input consumption Assign project constraint
Weekly work plan	WWP	Assign commitment date Assign service completion
Service progress	Percentage executed	Assign service completion

The plug-in also received functionalities that enabled visualization of what was executed in the building site, to allow the monitoring of the project progress. According to Bilal et al. (2016), in the context of construction industry visualization provides a better understood of the building site allowing taking better decisions to resolve critical issues before fieldwork.

Among the features developed in the plug-in, the most relevant for this research was related to look-ahead planning. This functionality was created to select the part of the project that was intended to be carried out within four to six weeks and to check its restrictions regarding labor inputs, materials, and project specifications.

For deployment of the look-ahead functionality, it was necessary to create some parameters in the REVIT model. A numerical design parameter to verify labor constraint (PW - productivity weight) was created, which made it possible to assign different weights about the sections that involved different levels of labor consumption for the same service.

To verify constraints related to the materials needed to execute the programmed service, two design parameters were created: one of numeric type (LIC - linked input consumption), and another one of type text (LI - linked input). The parameter LI was created to associate the geometric element belonging to service to part name required to perform it. The parameter LIC was created to associate to the geometric element the consumption of material related to service to which it is linked.

In order to verify constraints related to project specifications, it was created the parameter CD – constraint description, whose function was to register pendency associated with a specific part of the project, if it was selected for inclusion in look-ahead planning. This parameter was intended to record some change in the design of a constructive element.

With the creation of parameters relating to project information and required inputs to work packages, it was possible to select a part of the 3D model, assign a period of running, check inputs available in building site and to analyze the existence of restrictions.

When checking through the plug-in, a procedure was activated that made the selected part to be included in the look-ahead receives green color, if needs of workforce, materials, and design were met. When the chosen section did not have its needs met concerning some restriction, it was presented in red color.

Another feature included in the plug-in was related to short-term plan - WWP, which showed visually what work packages were able to be carried out in the coming week, after removal of constraints and commitment from the team. It was enough to select the part of the project and assign it a date for its execution, which received the green color in a tone darker than the color assigned to look-ahead. Plug-in also allowed selecting in the 3D model a part of the building site that had already been executed and to assign it the date of execution. In the 3D model, the completed part of the building site changed from orange to blue.

Development of the planning software

For monitoring of the building site and insertion of data regarding available materials and workforce that fed the database, a desktop software was developed.

The first functionality inserted in the software allowed to create the managed building site and to segment it into groups of services, which were decomposed into work packages, to enable the formation of a more detailed look-ahead than the master plan. This procedure allows for insertion of information about unit compositions of work packages created in the software. In this way, each geometric element can be associated with the various inputs required for its execution.

In order to control the progress of building site, a functionality in the software was developed to generate comparative charts between scheduled and performed work packages. Another feature designed to monitor building site was to associate team’s settings (expressed in the number of employees) with labor consumption obtained.

Another functionality created in the software was related to management of existing materials in the building site. After the creation of this functionality, all material that entered the building site inventory was registered in the model, which allowed verifying availability of this input in the analysis of constraints in look-ahead.

Integrated model between BIM and LPS

BIM was supported by coupling of a plug-in to the REVIT software, to provide connection of geometric elements to logical structure of the project (transforming data generated by Revit with .rvt extension in data that fed a database created in Firebird 3.0 system with .fbd extension, and vice versa). Another association necessary to integrate with planning was the insertion of data referring to inputs (materials, workforce, and design specifications) necessary to carry out the scheduled work packages, making possible visual production planning and control within a 4D model.

The artefact developed by this research, involving integration of LPS with 3D modeling, started to function according to the model presented in Figure 2.

As indicated in figure 2, the detailed analytical structure of the project that allows the formation of medium and short-term plans is inserted in the software developed in the research and defines the master plan to serve as a reference of the contractual term. At that moment, unitary compositions of each work package provided in the project are determined, concerning material and labor inputs required for its execution. This structure is recorded by numerical codes generated in the Firebird 3.0 database, in which information created for communication between the 3D model and the planning software will be stored.

Next step is the preparation of 3D model for planning. To execute each of the geometric elements of the 3D model is necessary to connect them to the logical structure of the project and consumption of inputs required. This procedure requires creating project parameters described previously. Thus, the database is linked to the 3D model by plug-in added to Revit software.

Through plug-in, it is possible to transform .rvt data from Revit software into data with .fbd extension of Firebird database, and vice versa, making planning possible.

From this stage, the model is ready for application of LPS logic, which will be performed visually in Revit software. The process starts with look-ahead, where, through the functionality added by the plug-in, it is possible to select parts of the project to run.

Work packages selected for inclusion in planning undergo a procedure for checking material requirements, workforce and design specifications, informed by planning software to identify existing constraints.

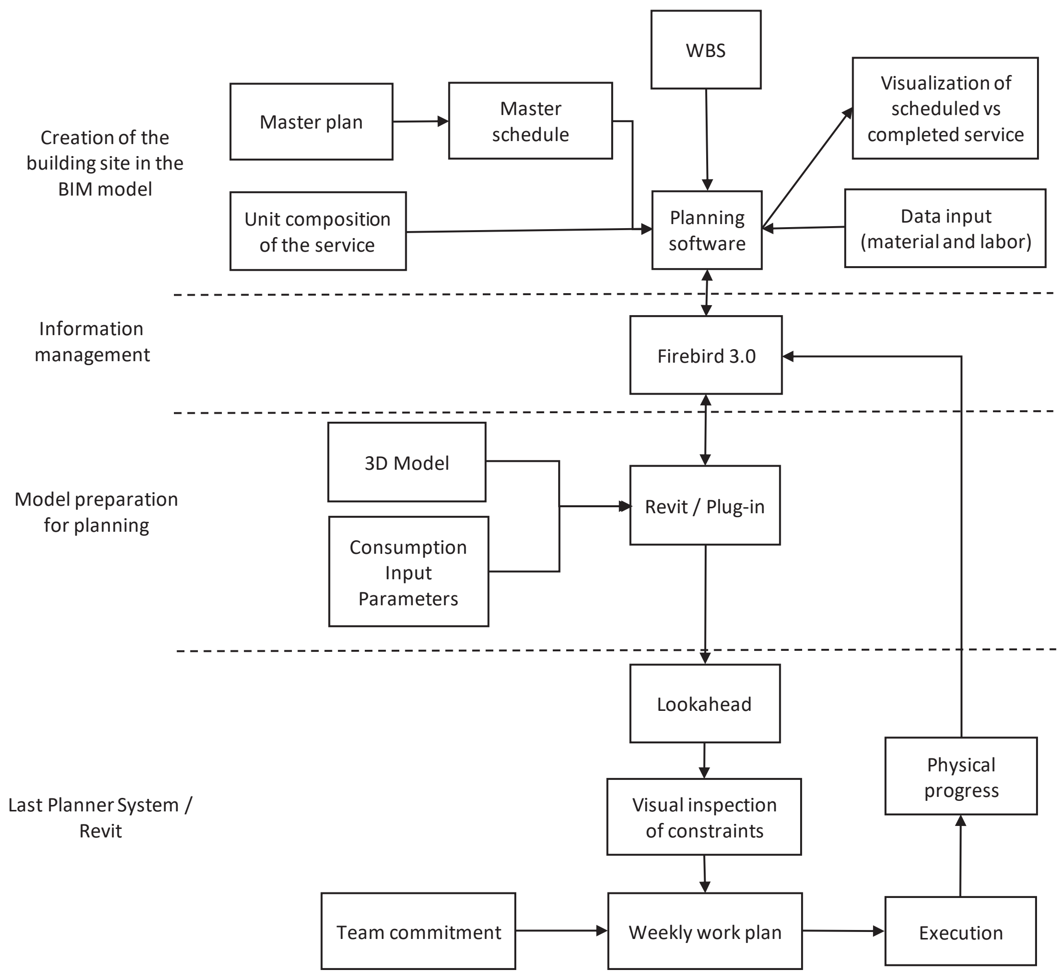
Management is done visually, since, with constraints, part of the building site in the 3D model will be displayed in red color, issuing a warning about what constraints should be removed.

When there is no constraint, the part selected is presented in light green color, indicating tasks available to be included in the WWP. After commitment approval session with teams responsible for work packages, the plan is selected to take place in the next week. Work packages approved at this stage will receive visual accompaniment to green in a darker tone that indicates approval for the look-ahead.

Following execution of the service, a physical advance is assigned indicating the date of implementation of the section selected in the 3D model. Subsequently, the executed part will receive a blue color for visual management within the Revit software. Automatically, through the plug-in, this information goes to Firebird 3.0 database and can be viewed in the planning software. Constructive steps controlled in separate files can be visualized together in graphs and spreadsheets, with dates and schedules, as well as the comparison between expected and achieved progress.

In the planning software information referring to the workforce and existing materials in the building site is entered. This control can be done weekly, daily or when necessary, allowing updating of information regarding current inputs in the building site. In this way, planning cycles are performed until services are fully completed.

Figure 2: BIM 4D Model developed in the Research



IMPLEMENTATION OF THE PROPOSED MODEL

Implementation of the proposed model occurred in four weeks, in January 2017. This temporal delimitation coincided with the completion period of monitored work packages. Throughout this period, data were collected to monitor building site progress concerning work packages performed, labor consumption and materials, to compare them with data generated by the model, to verify their potentialities and vulnerabilities. Work packages of fire installations and coating granite were studied.

In the preparation of the 3D model, weights were assigned to Revit software design parameters created to compare productivity, to control material consumption and to associate specific materials for each part of executed work.
After inserting work breakdown structure and unit compositions of each service in the planning software and defining parameters of projects used in definitions of quantities of labor and materials required in parts of work to be executed, the model BIM 3D was considered prepared to be used in the integration model proposed in this research.
There was a need to update visible progress to follow work packages applying the proposed model. Also, it was necessary to enter information on the workforce used in the planning software. For that, the working document titled "Information Diary" was analyzed, in which work of employees who performed services was systematically recorded. Information regarding materials has been entered by approved purchase orders.
The model was considered ready to run after fed with information regarding labor, materials purchased, the physical progress of parts of building site already executed, and projects details.
The first look-ahead plan performed referred to January 2017. Then, WWP and the monitoring of executed service were performed. With the application of the model in the coating granite work package, it was possible to identify it brought relevant information about the workforce, previously recorded in another worksheet, with no connection to planning. In this sense, managers were able to learn where contractor's workforce was being applied and to understand the reason for the delay in service, as well as to identify the best place to work for the team.
Constraints related to design specifications needed to be identified before the start of planning. In this sense, the model promoted the interaction of stakeholders, increasing communication between sectors of the company.
Changing in the plan of last week was only possible by identifying the causes occurred in previous weeks, providing better management and, consequently, improving the efficiency of short-term planning and making it formal, with use of the model.
With the group of services of the fire-fighting facility, it was clear the model could anticipate a lack of material and avoid delay in execution of services.
If the execution did not follow the project, the model would be useless since the report generated would not be compatible with reality. Therefore, verification of constraints in the look-ahead functionality would not be accurate either, concerning materials.
Another point verified was the number of sections of the 3D model pointed out as concluded that needed to be finished. The model had an option of registering partial advance of work packages in percentage values. This procedure could have been used to signal the formation of teams for these finalizations was necessary, and to adjust the schedule to include new work packages, or not to initiate parts of building site without completion of previous ones.

EVALUATION OF THE PROPOSED MODEL BY ITS USERS

After application of the model in the experimental study, a meeting was held with collaborators of the building site where the research took place, to evaluate its usefulness and functionality.

Usefulness evaluation

In the evaluation of the reliability of information, the authors noticed the divergence between the material requested from the supply department and the one required by the model. This problem was caused by actions that were executed deliberately different from what was predicted in the project.
Information regarding workforce proved reliable, as confirmed by building site production sector, which ratified data on productivity and quantity of employees at each work package front.

Another element that presented reliability was monitoring of parts of the building site executed, which could be identified in the model with visual management, through different colors adopted.
Increased communication was the most useful result generated by the model, according to interviewees. Improvement occurred when the project department inserted visual design changes directly on the model.
It was found those involved in planning envisaged possibility of using information integrated into a single database for management and execution of building site. Anor aspect emphasized by the planning team was the use of visual management with different colors for services executed, planned with constraints, and without constraints. Insertion of look-ahead in the planning process was also considered as positive, since it anticipated constraints, to eliminate them before the beginning of services.
Automatic search of the workforce and material needs in the model, provided by plug-in and database functionalities, was also pointed out as a facilitator of scheduling. Planning of construction site was improved since such verification was not performed systematically before.

Functionality evaluation

Visual management simplified understanding of information generated by the model since it facilitated analysis of the progress of scheduled work packages compared to executed one. Planning sector, which operated Revit software, had a very satisfactory interaction with the proposed model, presenting no difficulty in running it. However, the production sector showed no interest in using the model.
Most significant difficulties encountered in operation of the model were related to insertion of material data since different suppliers often adopted different identifications for the same input, which, in turn, were different from what was registered in geometric element modeled in Revit software. Also, it was also observed a restriction regarding the collection of labor data for each work package, since construction site management team registered only the number of employees per aggregate service, while in the model there was a need to record the number of employees per service.

FINAL REMARKS

Through proposed model, a single database gathered information necessary for LPS logic, promoting interaction between departments and stakeholders and adding information that was previously in dispersed documents and sometimes not used in the production planning and control.
The developed plug-in added functionality to Revit software, capable of promoting visual management of look-ahead planning, automatically checking constraints on the workforce, materials, and project specifications. By issuing visual alerts with different colors for parts of the building site with unrestricted tasks and other with constraints, it became possible to generate a task bank to be included in WWP short-term planning.
During the implementation of the proposal, it was possible to observe approximation and improvement of communication between departments of planning, production, projects, and supplies. The model concentrated information necessary for the formation of medium and short-term plans, which were isolated in various departments.
Automatic verification performed by installed plug-in's look-ahead function achieved constraints identification and visual management. Visual management through colors proved very attractive to users, improving interpretation of verified information.

Finally, synergy resulting from the integration of BIM 4D with LPS, through automatic verification of constraints in the design of look-ahead, visual management, and integration of involved parties with planning, generated a more efficient medium and short-term production planning and control system.

An existing limitation in integration model occurs when there is a need to change some geometric element in the 3D model at the moment of its execution. Integration model still cannot automatically promote inclusion or elimination of geometric element in its update database, requiring a manual procedure. Another limitation of the integration model is the lack of verification of constraints regarding predecessor work packages.

This research emerged questions that offer the following suggestions for future work: a) improve integration model so it can receive automatic changes in the 3D model; and b) developing applications for mobile devices (like tablets or smartphones), to assist in the collection of field data directly in the model.

ABSTRACT

The objective of this research is to understand the adoption driver, challenge and outcome of business analytics for less technically-oriented users. We identify three challenges that may have a complicated impact over adoption: cognizant engagement, bounded rationality, and meaningful use pressure. We also hypothesize IT mindfulness and knowledge acquisition efforts can mitigate challenges and lead to substantial use. The performance implications of different usage patterns are also hypothesized. We develop and validate an instrument to test our theory of business analytics adoption. The results of Q-sort revealed a hit ratio of 82% with an inter-rater reliability of 75%. The future work and the potential contributions are discussed.

KEYWORDS: Business analytics, system adoption, Beyond dominant paradigm, micro-level decision-making process, mindfulness, knowledge acquisition

INTRODUCTION

Portrayed as “the next frontier for innovation” (Shollo & Galliers, 2016), Big Data and Analytics (BDA) continues to drive imaginations among practitioners and academics. One key promise that this stream of innovation holds is its ability to create actionable insights that can inform future strategy and day-to-day operations (Grover et al., 2018). In a worldwide survey of more than 3,000 business executives and analysts revealed that the top-performing organizations are twice as likely to apply analytics to various corporate activities (LaValle et al., 2011). Influenced by success stories of early adopters and the competitive pressures, increasingly, many private and public organizations are showing their interest in implementing similar systems (Wixom & Watson, 2010). According to one statistic, the global business investment in big data infrastructure and analytics software will continue to grow and will surpass $200 billion a year by 2020 (Carande et al., 2017).

In this work, we focus on a subset of BDA – business analytics. While BDA refers to a system of infrastructure, tools (software), skillsets, and capabilities, the business analytics is concerned with “the extensive use of data, statistical and quantitative analysis, explanatory and predictive models, and fact-based management to drive decisions and actions" (Davenport & Harris, 2007). When compared with BDA, business analytics has more end-user implications.

The diffusion of business analytics happens both in scale and depth. Thus far, the analytics related tasks are mostly performed by professionals with an extensive computer, statistics, and quantitative modeling background. But many moves indicate that the use of business analytics will be expected from employees with no or little technical training in analytics. Gartner in a 2018 report indicated that the analytics output of business users with self-service capabilities will surpass that of professional data scientists (Violino, 2018). GM is gradually moving toward a platform where employees in many levels (e.g., executives, engineers, business analysts, etc.) can query through a Google-like search interface for information about specific business needs (Boulton, 2018). Colleges are also actively embracing the trend by revising or/and reconfiguring existing curriculums to maximize the number of students who can gain hands-on experiences in business analytics (Wilder & Ozgur, 2015). This trend of "analytical empowerment" (Alpar & Schulz, 2016) is to fully realize the value creation potential of business analytics by allowing "casual users" to engage with business analytics without adding extra burdens to already busy IT professionals (Lennerholt et al., 2018).

This changing landscape in the user base calls for more scholarly attention to the end-user adoption processes of business analytics. Thus far, majority of research in business analytics studied the organizational level phenomena, such as, firm performance implications (Müller et al., 2018; Torres et al., 2018; Song et al., 2018; Wamba et al., 2017), business value creation (Krishnamoorthi & Mathew, 2018; Xie et al., 2016; Chen et al., 2015; Grover et al., 2018), business analytics and intelligence capabilities building (IşıK et al., 2013; Gupta & George, 2016; Wang et al., 2018). Only a handful of research studied the end-user adoption-related issues (Li et al., 2013; Grublješič & Jaklič, 2015). However, the unique combination of socio-technical characteristics and occupational context that are embedded in and accompanied by the business analytics can potentially help IS researchers to expand and to enrich existing understanding about the innovation adoption processes.

In addition to well-known system adoption driver constructs such as effort and performance expectancy, a theoretical model should consider following three challenges that average users will encounter during the adoption process: 1) cognizant engagement challenge, 2) bounded rationality challenge, and 3) meaningful use challenge. The cognizant engagement challenge requires users to be able to cognitively differentiate the use cases between business analytics and other similar enterprise business intelligent systems (e.g., DBMS, SAP report, etc.). The bounded rationality challenge expects users to keep up with a substantial body of knowledge that is necessary for accurately identifying the input and output parameters (e.g., specification of distributions, coefficient significance, etc.). And lastly, as placed within the work environment, the use of the system is expected to produce meaningful outcomes (e.g., whether use the system is less important than the quality of work). Therefore, business analytics adoption research should embrace these challenges in their research design.

In this work, we attempt to develop a theoretical model and measurement instruments by extending the reasoned-behavior theory framework (Fishbein & Ajzen, 1977; Ajzen, 1991) with mindfulness, knowledge complementarity, and IS system usage literature. Through the model, we seek to capture users' underlying micro-level decision-making processes that lead to meaningful use of business analytics in the work environment. We believe our work has the following contributions: 1) our work attempts to approach the business analytics adoption processes more holistically than existing theoretical frameworks by considering task, user, and system characteristics; 2) it highlights the role of a nascent attention/state construct, namely, IT mindfulness, during the process of innovation adoption, and 3) it seeks to explore and explain the adoption beyond the dominant paradigm (Fichman, 2004).

This paper is organized in the following order: In the next section, we scan background and extant literature landscape related to business analytics adoption. Then, we present the theory development and the research model. In the subsequent section, we discuss the measurement items and the refinement process. We conclude this article after discussing future research plan and result-contingent managerial implications.

BACKGROUND AND LITERATURE REVIEW

Business Analytics and Competitive Advantage

Increasingly, firms are exposed to a competitive environment where data-driven decision-making cultures and practices are greatly rewarded (McAfee & Brynjolfsson., 2012; LaValle et al., 2011). Strategic management literature suggests that valuable, rare, inimitable, and non-substitutable (VRIN) resources and capabilities are the basis of competitive advantage and economic rent (Barney, 2001). Under this view, when a harmonious integration of firms' data infrastructure, organizational culture, and human capital is achieved, big data and analytics can become the source of competitive advantage (Erevelles et al., 2016)

Recent empirical evidence supports the view. Based on the results of an econometric analysis of 814 firms, Müller et al. (2018) report that a firm's productivity growth is positively associated with the firm's big data and analytics assets. The magnitude of increase in productivity was on average 3~7 percent each year. Based on a study of 179 sample firms from large publicly traded firms, Brynjolfsson et al. (2011) find that firms that adopt data-driven decision-making practices have output and productivity that is 5~6 percent higher than that would be expected given their other investments and information technology usage.

There are several distinct but highly related concepts in this context. The Institute for Operations Research and the Management Sciences (INFORMS) defines *analytics* as *the scientific process of transforming data into insights for the purpose of making better decisions* (Rose, 2016). *Business analytics* is concerned with "the extensive use of data, statistical and quantitative analysis, explanatory and predictive models, and fact-based management to drive decisions and actions" (Davenport & Harris, 2007). The term *business analytics* is often associated with the term *business intelligence* (Chen et al., 2012) as both concepts are concerned with making a more informed decision based on data. According to Adair (2018), while the former is primarily more concerned with the prediction of trend/pattern and offering a prescription to a problem, the latter is primarily concerned with creating a summary of historical data. While *business analytics* is a relatively new concept, *business intelligence* is around since the 1950s. The recent advancement in data capturing and storage technology, coupled with much improved computation power, both techniques together contribute greatly in extracting insights from a large amount of structured and unstructured data.

Bughin et al. (2016) present a data and analytics transformation model with five different phases: 1) defining clear business needs, 2) gathering data from data ecosystem, 3) modeling insights, 4) redesigning of workflow, and 5) managing change for adoption. They assert the importance of the adoption by arguing that the value of analytics depends on its ultimate use.

Business Analytics Task Characteristics

Adapted from Rose (2016), we categorize users into four groups based on their strategic orientation and the primary purpose of use. This research focuses on decision-centric users whose main decision goals are related to their day-to-day operations.

Table 2.1 Areas of interests in Big data and analytics

	Data-centric camp	Decision-centric camp
Strategic decision	Chief data officer/architect	C-level executives
Operational decision	Data scientists	Data-driven users

(Source: Adapted from Rose, 2016)

Power et al. (2018) provide interesting examples of business analytics that simulate what data-driven users may expect from using business analytics.

> "Banks and other businesses use business analytics to *classify* and *segment* customers based on credit risk, usage, and other characteristics, and use algorithms to *match* customer characteristics with appropriate product offerings. An airlines manager who is considering investing in a new route uses analytics to *predict* future travel demand for the destination. Managers prepare revenue *forecasts*. Operations analytics might *examine* product cost, quality control, and the throughput of resources in production lines. Machine *monitoring* and machine failure *tracking* are common. *Optimizing* production and work schedules has been ongoing for many years. … Marketing groups use *predictive analytics* for sales lead scoring. Patient costs and care metrics are *monitored* in many hospitals." (Power et al., 2018, pp.47)

These examples illustrate the predictive and prescriptive nature of business analytics. Solution providers and firms' IT departments are gradually introducing more "*user-friendly*" business analytics suites over the years. *Einstein Analytics* by salesforce.com *Cognos Analytics (formerly Watson Analytics)* by IBM, *Business Intelligence* by Oracle are those examples. These solution suites serve as *intelligent*, *self-service analytics platform* by providing an intuitive dashboard and *what-if* analysis features through which users can capture the status of their business and identify upcoming patterns. This move will allow more users to engage with business analytics without relying too much on data scientists or IT professionals. Some solutions like *Oracle Analytics* also offer user adoption status monitoring function to help organizations to maximize the value of analytics implementation. According to one survey involved 2,679 firms, *self-service business analytics* is considered the third most important trend among the respondents (Durcevic, 2018).

Business Analytics and Adoption Challenges

Although the *self-service analytics* efforts lower the level of technical knowledge to utilize business analytics, the acceptance and usage process will not be totally frustration-free. Below, we synthesize three challenges that average workers will encounter during the use of business analytics. Burton-Jones and Grange (2012) emphasize three key areas that are concerning the effective use of a system: users' competence and challenges, task structure, and system characteristics. Our following synthesis seeks to understand these three areas.

The *cognizant engagement* challenge arises when users attempt to determine whether the use of business analytics platform is a necessary condition for the given task. For the average users, the use of business analytics is not a necessary condition to complete the traditional lines of task, but the information is. Business analytics is a means for ends. There will be established ways of gathering information such as making phone calls to the floor level managers, digging through a spreadsheet to identify a pattern, and attending the staff meeting to discuss an issue. When a user does not know how to take full advantage of business analytics, he/she may under-use, over-use, or even abuse business analytics systems. Users can cope with this challenge only when they are clearly aware of the strength of business analytics and its difference with other similar enterprise systems.

Bounded rationality is another important challenge that users will need to cope with. Even when a user has a firm belief that business analytics is appropriate for the given task, he/she may still find it challenging to navigate through the mountain load of information being displayed throughout the use process. Especially, jargon, terminologies and underlying concepts will continue to challenge the user's limited knowledge base. An analytical process typically relies on data, model, and algorithm to deliver a solution. Considering the sheer number of options and variations tied to each artifact, the number of factors the user needs to consider is combinatorially limitless. Another area of the challenge will arise when the user has to confront the results delivered by an algorithm that he/she is not sufficiently familiar. For professionals, additional robustness checking process can add confidence to the results, but for decision-driven average users, they will need to carefully make sense of the results within his/her understanding.

The *meaningful use* challenge is relevant because the use of the system is not the ultimate measure for his/her job performance. An employee is judged by job performance. In other words, the use of business analytics is not a sufficient condition to receive favorable evaluations from the superior, but an informed decision is. After all, a user will have to find a meaningful way to use the system to ensure the quality of the decision.

In sum, users will feel *cognizant engagement* challenge when determining *whether* to use or not. They will also experience *bounded rationality* challenge when seeking how to use it properly. And lastly, they will feel *meaningful use* challenge when they realize *what* to deliver is the ultimate concern, not the use of business analytics.

Adoption Decision as Micro-level Decision-Making Process

Although many scholars have studied business intelligence systems acceptance (Li et al., 2013; Grubliešič & Jaklič; Yoon et al., 2017), business analytics research remains as a vacuum.

Grubliešič and Jaklič (2015) conducted a business intelligence acceptance study using case study methods. Their conceptual framework highlights the importance of organizational factors, such as result demonstrability, social influence, and facilitating conditions with sufficient resources that help create an adequate information culture. The artifact in their study is ERP system. Yoon et al., (2017) investigate the end-user acceptance of business intelligence applications by using survey data collected among ERP system users in large to medium-sized organizations. Their study found that individual motivation to learn determines the usage intention. Also, they identified the relative advantage, situational constraints, and organizational learning climate serve as the driver of individual motivation to learn. Li et al. (2013) identify perceived usefulness, intrinsic motivation toward accomplishment, intrinsic motivation to know, and intrinsic motivation to experience stimulation are the antecedents of system use. Their work highlights the importance of personal innovativeness with IT as the moderator that amplifies paths to innovative use.

Business intelligence system shares many similarities with business analytics, but we see the needs of complementing acceptance studies from both areas as business intelligence is primarily descriptive in nature, and business analytics seeks to conduct predictive and prescriptive analytics. We also felt the needs of enriching existing constellation (Yoon et al., 2017 provide a good summary of the list) of antecedents of acceptance by adding constructs that help address users' micro-level decision-making process (Fiol and O'Conneor, 2003).

Recently, the academic discourse of being mindful (Dane, 2011) has expanded its reach to information systems research (Sun et al., 2016; Thatcher et al., 2018). Essentially, mindfulness is a psychological state of consciousness. Dane (2011) defines it as a state of consciousness in which attention is focused on present moment phenomena occurring both externally and internally. Therefore, mindfulness in its original form is a *state* or an *attention* construct (not intention or traits). When mindfulness states are activated, people will attempt to identify novel distinctions of the current artifact within the current context. Therefore, it leads to a number of consequences: 1) a greater sensitivity to one's environment, 2) more openness to new information, 3) the creation of new categories for structuring perception, and 4) enhanced awareness of multiple perspectives in problem-solving (Langer & Moldoveanu, 2000; Dane, 2011). The mindfulness concept has been studied under many contexts and it generally improves subjects' health, creativity, productivity, learning outcome, and decision-making quality (Langer & Moldoveanu, 2000).

In IS research, Sun et al. (2016) seem to be the first group of researchers who adapted the concept in the adoption research. They specified the mindfulness concept as a second-order construct with four sub-dimensions and named it as MTA (mindfulness technology adoption. Together with TTF (task-technology fit), they formulated an MTA-TTF framework through which users' adoption and continued use decisions are observed. Thatcher et al. (2018) followed similar formative-measure of mindfulness and used it to predict users' active and automatic system use. Both their studies use a fairly simple technology artifact: wiki and office suites.

THEORETICAL DEVELOPMENT/MODEL

User's Reaction and Usage Intention

In this research, we see users as rational beings who adjust behavioral intentions based on the various responses within the social context. There are three specific layers of social contexts we would like to specify in our model: macro-, meso-, and micro-level contexts. Prior to the actual use, the macro-level social context influence users' perceptions on the ease of use (or effort expectancy) and the usefulness (or performance expectancy) through media, press, word of mouth, or sometimes through knowledge-entrepreneurs (Fichman, 2004). The significance of these two constructs are well-established through seminal works of Davis (Davis, 1989) and Venkatesh (Venkatesh & Davis, 2000; Venkatesh et al., 2003; Venkatesh et al., 2012).

In the meso-level context, a user's usage intention will be influenced by the firm's strategic approach with regard to the use of business analytics. If a firm has developed a significant business analytics capability through implementing effective data governance policy, business analytics policy, and decision-making culture that is favorable to the use of business analytics (Gupta & George, 2016), the user will demonstrate a higher level of usage intention. In the micro-level, a user will adjust his/her usage intention based on the amount of pre-requisite knowledge he/she possesses, whether the use of BA is consistent with the career goal and whether the use of BA enhances his/her image within the peers (Moore and Benbasat, 1991).

Vroom's expectancy theory (1964) suggests that the level of motivation is the product of valence (i.e., attractiveness of the outcome), expectancy (i.e., a person's belief that he/she will be able to reach the desired outcome) and instrumentality (i.e., a belief that a strong performance will be rewarded) (Vroom, 1964). Therefore, our explanation on the formation of a user's intention in meso-level and micro-level context seem plausible.

Thus, we hypothesize,

- *H1. (a) Effort expectancy and (b) performance expectancy are positively associated with the intention to use.*
- *H2. The level of organizational BA maturity is positively associated with the intention to use.*
- *H3. The level of individual motivation is positively related to the intention to use.*

For the measurement, we specify BA maturity as a formative measure of data governance, BA policy, and BA culture, and specify individual motivation as a reflective measure of the level of pre-requisite knowledge, career path congruence, and image.

Usage Patterns and Performance

To understand the impact of usage on the job performance, following Delone and McLean (1992), we conceptualize the usage as an antecedent of job performance. This connection between the *drivers of use* and the *impact of use* will help picture the complete adoption process.

Burton-Jones and Straub (2006) assert researchers measured the usage in various ways including binary scale (use/not use), continuous scale (frequency, extent), or nominal scale (nature of use), and the measurement of usage should be specific to the context of research. In this research, we envision two different types of usage: *substantial use* and *symbolic use*. In the former, a user's engagement with a system is more substantial and is considered more meaningful from performance achieving perspective. In the latter, the usage pattern is more routinized, superficial, and passive. Saeed and Abdinnour (2011) modeled a similar idea using a linear path of usage stage: routinization (Users use the various features that IS has to offer) to infusion (users integrate the IS in their work) to extension (user explore the potential of the IS in novel contexts). But, following Li et al., (2013), we differentiate *symbolic use* and *substantial use* to highlight the qualitative, not quantitative, differences between two type of usage.

Thus, we hypothesize,

- *H4. There will be two distinct usage patterns: substantial and symbolic use*
- *H5. The substantial use will have a greater contribution to the task outcome than symbolic use.*

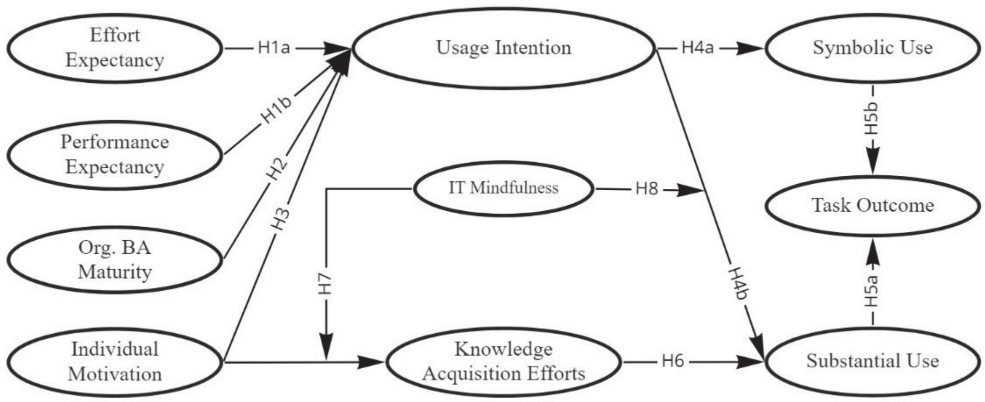
Knowledge Complementarity (Knowledge Acquisition Efforts)

Due to the complicated nature of analytics tasks, a user will find his/her current level of knowledge is inadequate. Cohen & Olsen (2015) asserts that both codified knowledge management capability and employee's knowledge management capability serve as the antecedents of service outcome. Their view is consistent with what innovation management literature sees about the knowledge complementarity, that is internal and external knowledge together form a “whole” knowledge that contributes to the innovation outcome (Fang, 2011; Cassiman & Veugelers, 2006). Thus, we believe when a critical piece of knowledge flowed through users' efforts, it will contribute toward more meaningful use.

Thus, we hypothesize,

- *H6. Knowledge acquisition efforts will mediate the relationship between the level of individual motivation to substantial use.*

Figure 3.1 Research Model



IT Mindfulness

To capture the users' micro-level psychological engagement during the adoption process, we incorporate the notion of mindfulness in this research. Followed by Thatcher et al. (2018) and Sun et al. (2016), we name it as IT mindfulness and specify the construct as a formative measure with four sub-dimensions. Based our existing understanding about the role of mindfulness (Dane, 2011; Langer & Moldoveanu, 2000), we believe a user with a higher level of IT mindfulness will have better ability to amplify its usage intention. Thus, the path under the influence of IT mindfulness will be more likely leading to a substantial use while the path without the IT mindfulness will lead to a symbolic use. We also believe it amplifies the users' motivation to engage with business analytics, so that the users will increase their knowledge acquisition efforts.

Thus, we hypothesize,

- *H7. The level of a user's IT mindfulness will positively moderate the relationship between individual motivation and knowledge acquisition efforts.*
- *H8. The level of a user's IT mindfulness will positively moderate the relationship between the usage intention to substantial use.*

Since mindfulness is a state and/or attention construct, it does pose some challenges in terms of measuring with a satisfactory level of validity in empirical research. However, since there are people who tend to exercise mindfulness more often (Dane, 2011), and also the state is malleable through training (Thatcher et al., 2018), it is also appropriate to measure it as a trait construct.

Table 3.1 List of Key Constructs

Construct	Definition	References
Effort Expectancy	The degree to which a person believes that using a system would be free of effort.	Davis, 1989

Performance Expectancy	The degree to which a person believes that using a particular system would enhance his or her job performance.	Davis, 1989
Organizational BA Maturity*	An organization's overall readiness in leveraging from business analytics through the key artifact (data), surrounding processes, and supportive organizational culture.	
Individual Motivation	The extent to which an individual is motivated to use BA.	
Usage Intention	Level of intention to use the system.	
Knowledge Acquisition Efforts	The level of efforts to obtain relevant information to use BA from outside of the work context.	
IT Mindfulness*	The degree to which a person compares the technology with existing technologies so that the individual is more aware of its uniqueness.	Sun et al., 2016
Symbolic Use	A usage pattern that is passive and is reluctant to explore beyond initial instruction.	
Substantial Use	A usage pattern that is active and seeks to maximize the returns from using BA.	
Task Outcome	Immediate task outcome from using the BA.	

(Notes: * indicates a higher-order construct)

Figure 3.1 exhibits our research model and table 3.1 lists all the key constructs of the model. Next, we discuss the measurement development and the result of validity test.

INSTRUMENT DEVELOPMENT

Since many constructs used in this research do not have readily available measurements, one of the major objectives of this research is to develop valid and reliable measurement instruments for the constructs used in the proposed research model. To ensure the validity of constructs and identify ambiguity in items, three steps of the instrument development process were conducted: 1) item generation, 2) pre-test of content validity and 3) Q-sort study. Specifically, items generation is a process that produces measurement items for newly developed constructs through a comprehensive literature review. The pre-test of content validity has been done through a structured interview with scholars from the information systems field. The Q-sort study is used to ensure the convergent and discriminant validity of these measurement instruments (Churchill, 1979; Moore & Benbasat, 1991).

Item Generation

In this research, there are a total 10 of the main constructs, two constructs are the higher-order constructs which formed by second-order constructs, and 65 measurement items generated through a comprehensive literature review. Measurement items were developed through A combination method of self-developing and adapting of existing research. Initial items were tested through pre-test of content validity and Q-sort study.

Pre-test

In order to ensure content validity, a group of academic experts was invited to pre-test the initial measurement instruments. They were asked to evaluate the appropriateness, clarity, and accuracy of the instruments. We analyze their thoughts and suggestions by the discrepancies between their interpretations and our expectations. Based on their feedback, the initial measurement items were modified.

Q-Sort

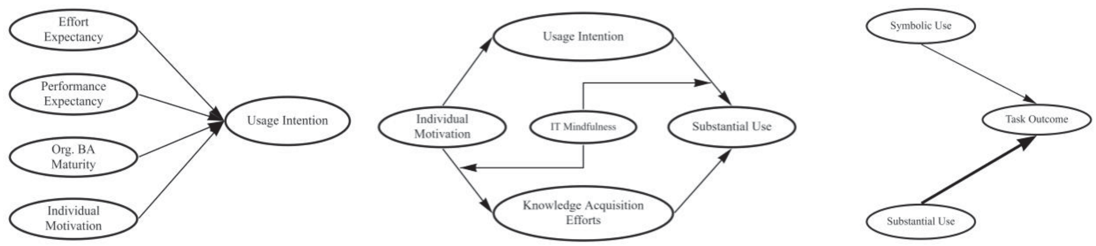
In this research, the Q-sort method was employed to develop the measurement instrument, which is widely used in psychology and other social sciences disciplines to investigate the individual's subjectivity. A structured interview was conducted among two information technology scholars. In the beginning, the general research idea, the conceptual model and definitions of each construct were presented to the interviewees. Then, the interviewees were given a set of randomized index cards that contain the candidate items. Interviewees were asked to categorize these cards based on the construct definitions. A *non-applicable* category is provided so that the interviewees can store the items that they think do not belong to any of the provided constructs. The first-round inter-rater reliability is 53%. A further discussion of the discrepancy between our expectations and interviewee's interpretation was conducted. Based on the discussion and communication, measurement items were modified, deleted, or combined. The second iteration of Q-sort was done after a week of the first iteration. The inter-rater reliability was increased to 75%. Cohen's Kappa method is the most robust statistical method that has been widely used to test the measurement of inter-rater agreement (Cohen, 1960; Cohen 1968). As suggested by Landies and Koch (1997), the coefficient greater than 0.6 is considered as substantially acceptable (Table A.1). Cohen's Kappa coefficient based on the analyze of second-round Q-sort results is 0.728 for this study.

FUTURE WORK AND DISCUSSION

We are planning to conduct a pilot test among a small group of people. In the full test, it is preferable to have two separate sources of respondents to avoid common method bias: 1) managers or supervisors can answer the organization-related questions such as level of BA maturity and task outcome about a user; 2) their subordinates who are the decision-driven users of business analytics can answer the rest of the survey. This paired sample approach can greatly increase the rigor of the research.

If the hypothesized model receives empirical support, then this research will be able to provide rich insights regarding the end-user adoption of business analytics systems. Those insights can be categorized into three areas: 1) the factors (figure 5.1) that determine the general level of usage intentions, 2) the mechanisms (figure 5.2) through which substantial use is facilitated, and 3) the usage pattern that is more desirable (figure 5.3). Managerial implications pertaining to the first and the third area are clear and intuitive.

Figure 5.1	Figure 5.2	Figure 5.3
Key antecedents to intention	Mechanisms to substantial use	Desirable usage pattern



Along with users’ perception (i.e., effort and performance expectancy) of the technical aspect of a business analytics system, organizational readiness and individual’s motivations also contribute to the formation of users’ usage intention.

Business-analytics-friendly *data practices*, well-defined *organizational processes*, and supportive *decision-making culture* will create an environment conducive to the use of business analytics by lowering users’ interaction cost. This line of thought encourages the management to review the current states of readiness in data management and analytics related practices. This necessitates the existence of a well-developed business analytics maturity model (BAMM) or a similar normative framework that can help management identify the firm’s current standing and/or future directions. In the literature, there is much discourse, both from practitioners and academics, regarding such frameworks. For details, please see Halper & Stodder (2014), Comuzzi & Patel (2016), Rajterič (2010), and Cosic et al. (2012). Meanwhile, a user may be motivated to use a business analytics system independent of a system’s technical characteristics and surrounding organizational environment. This research attempts to establish three antecedents that could be used to predict the formation of individuals’ motivation. These three antecedents together demonstrate the path-dependent nature of such motivation: 1) skillsets a user accumulated from the past, 2) incentives that could stimulate the user’s behavior today, and 3) the career planning that focuses on long-term future will all together determine the level of motivation to engage with business analytics systems. Business analytics workforce management should become aware of this fact.

Overall, the first area of insights emphasizes the fact that the formation of a user’s usage intention is influenced by multiple forces; thus, it suggests that management should use more holistic perspectives in terms of planning for the end-user adoption.

The third area of insights is based on the anticipation that the path coefficient from *substantial use* to *job performance* will be much greater than that from *symbolic use*. Supply chain research often suggests that “last mile delivery” is the constraint or the bottleneck of the entire system performance (Boyer et al., 2009; Hübner et al., 2016). Likewise, in this research, we conceptualize that the end-user adoption is “the last mile delivery” in terms of business analytics value creation process. The key take-away for managers, those who work through other people and coordinate (Robbins et al., 2008), is that the insight clarifies the area that needs constant attention from management – *it is to help users facilitate and achieve substantial use of business analytics system*.

The second area of insights in this research seeks more attention from management as it is related to a nascent field – *mindfulness*. More attention is needed because the *attitudinal/state nature* makes it somewhat abstract and ambiguous, yet it carries much performance implications. The concept of mindfulness has several overlapping dimensions across many fields, including management, education, clinical therapy, Buddhism philosophy, and religious studies (Dane, 2011; Sun et al., 2016). Historically, mindfulness is seen as cultivated through meditative practice. Therefore, confusion between mindfulness and meditation arises as people often use both terms interchangeably (Conze, 2003; Dane, 2011).

However, as demonstrated in this research design, we follow Sun et al. (2016) and Thatcher et al. (2018) by implementing it as a conscientious attitude/psychological states construct. These efforts somewhat demystify "Zen-like" appearance of the mindfulness concept. Essentially, in this research design, the practical utility of mindfulness emanates from being a moderation factor: 1) It augments users' intention to engage with the system, and 2) it amplifies users' motivation to spend greater efforts in seeking the necessary knowledge to use the system. Then the relevant question will be: *How to induce such attitude/states* in *the current context*?

In business research in general, and the IS field in particular, the systematic activation mechanisms of mindfulness are an area that is open for on-going exploration. Thus, based on the assumptions, definitions and dimensions used throughout this research, we propose management to review the following three ways that firms can help users to be more mindful in using business analytics system. Although we anticipate that mindfulness will lead to substantial use, we also believe that not all users will demonstrate mindfulness. Thus, our following discussion presumes the fact.

1) *Activate through general mindfulness*: Firms in a fast-moving environment have implemented mindfulness therapy and meditation sessions to help employees overcome stress and become more productive (Levin, 2017; Dane 2011). Since mindfulness is malleable (i.e., can be changed through training) and is also enduring (Thatcher et al., 2018), general mindfulness training may have a positive impact over domain-specific mindfulness (e.g., IT mindfulness in this research).
2) *Activate through substitute mechanisms*: The key role IT mindfulness plays during the adoption process is through invoking constant awareness of the distinctive characteristics of business analytics given the current context. Inspired by social cognitive theory (Bandura, 2001), we propose that firms implement business analytics usage experience sharing programs through online or offline media to help users become aware of how other people are using the system. This effort not only helps users learn from others but also makes them aware of their own usage patterns. We expect this substitute mechanism may help active mindfulness.
3) *Activate through system design and technical features*: Firms can request the developers of business analytics systems to implement technical features that can help users to be more mindful.

CONCLUSION

In this work, we attempt to model the drivers, challenges, coping mechanisms and outcomes of business analytics adoption. We identify three levels of drivers. Our research design seeks to understand users' micro-level psychological engagement process when they encountered challenges while using the business analytics platform. We hypothesize IT mindfulness and knowledge acquisition efforts can help users cope with the challenges effectively. Such mechanisms help users to form a meaningful use pattern that precedes a superb task outcome.

To re-iterate our contributions in innovation adoption research: 1) our work attempts to approach the business analytics adoption processes more holistically than existing theoretical frameworks by considering task, user, and system characteristics; 2) it highlights the role of a nascent attention/state construct, namely, IT mindfulness, during the process of innovation adoption, and 3) it seeks to explore and explain the adoption beyond the *dominant paradigm*, and lastly 4) we develop and validate instruments that can be used to test hypothesized relationships.

APPEDIX

Table A.1 Cohen's Kappa value and the Interpretation

Cohen's Kappa	Meaning
<0	No agreement
0-0.19	Poor agreement
0.20-0.39	Fair agreement
0.40-0.59	Moderate agreement
0.60-0.79	Substantial agreement
0.80-1.00	Almost perfect agreement

(Adapted from Landis and Koch, 1977)

Table A.2 Measurement Items

Effort Expectancy and Performance Expectancy

Constructs	Code	Measurement Items
Effort Expectancy	EE1	Learning to operate the system would be easy for me.
	EE2	I would find it easy to get the system to do what I want it to do.
	EE3	My interaction with the system would be clear and understandable
	EE4	I would find the system to be flexible to interact with.
	EE5	It would be easy for me to become skillful at using the system.
	EE6	I would find the system easy to use.
Performance Expectancy	PE1	Using the system in my job would enable me to accomplish tasks more quickly.
	PE2	Using the system would improve my job performance.
	PE3	Using the system in my job would increase my productivity.
	PE4	Using the system would enhance my effectiveness on the job.
	PE5	Using the system would make it easier to do my job.
	PE6	I would find the system useful in my job

Organizational BA Maturity (A Second-order Construct)

Construct	First-Order	Code	Measurement Items
Organizational BA maturity	Data Governance	DG1	Our organization has a well define data gathering policy.
		DG2	Our organization pays great attention to data gathering process.
		DG3	Our organization knows the importance of good quality data.
		DG4	Our organization has a well-defined administrative policy with regard to the collection and the use of data.
	BA Policy	BAP1	In our organization, the policy is clear on how to initiate a BA related project.
		BAP2	In our organization, the policy is clear on how to secure a budget for a BA related project.

		BAP3	In our organization, the policy is clear on how to be coordinated for a BA related project.
		BAP4	In our organization, the policy is clear on the reporting structure on a BA related project
	BA Culture	BAC1	In our organization, people generally believe BA is important for our business.
		BAC2	In our organization, executives generally believe BA is important for our business.
		BAC3	In our organization, functional managers generally believe BA is important for our business.
		BAC4	In our organization, colleagues generally aware of the importance of BA.

Individual Motivation

Construct	Code	Measurement Items
Individual Motivation	IM1	I am motivated in using BA on my job.
	IM2	I want to learn more about BA.
	IM3	I wish I can be more fluent in using BA.
	IM4	I am looking for opportunities to improve my BA skills whenever possible.

IT Mindfulness

Construct	First-Order	Code	Measurement Items
IT Mindfulness	Technological Novelty Seeking	ITM1	I paid attention to differences of this new technology from any other technology I previously used.
		ITM2	I tended to figure out how this tool was unique in relation to the tools that I am currently using.
		ITM3	I was mindful about how this tool differs from similar tools I had used.
	Engagement with the Technology	EWT1	I was engaged in investigating this tool when making the adoption decision.
		EWT2	I gathered factual information about this tool before making the adoption decision.
		EWT3	I got involved in exploring this tool before I adopted it.
	Awareness Of Local Contexts	ALC1	When making the decision to adopt this tool, I thought about how this tool might help my work.
		ALC2	When making the decision to adopt this tool, I thought about how this tool might change the way my work was done.
		ALC3	When making the decision to adopt this tool, I thought about how this tool may be compatible with my work requirements
	Cognizance Of Alternative Technologies	CAT1	I attended to alternative views regarding the tool before making the adoption decision.
		CAT2	I was aware of other tools than this tool before deciding to adopt it.

		CAT3	I paid attention to equivalent tools to fulfill my needs before deciding to adopt this tool.
		CAT4	I thought about alternative tools to address my demands when deciding to adopt this tool.

Usage Intention

Construct	Code	Measurement Items
Usage Intention	UI1	I intend to use BA to accomplish my work
	UI2	To the extent possible, I would use BA to do different things.
	UI3	I intent to use BA as much as I can in my work

Knowledge Acquisition Efforts

Construct	Code	Measurement Items
Knowledge Acquisition Efforts	KAE1	I reach out to vendors when I find the generic guideline is not clear.
	KAE2	I search internet when I find the vendor solution is unconvincing.
	KAE3	I find the vendor's training uses example that is too simple.
	KAE4	I find the real-world situation is much more sophisticated than the vendor's training materials.
	KAE5	I will use external sources of knowledge (other than the vendor) to solve a problem that I encountered while using BA.

Symbolic Use and Substantial Use

Construct	Code	Measurement Items
Symbolic Use	SU1	When I use BA, in general, I often navigate randomly to see if there is anything that matches with the given task.
	SU2	When I use BA, in general, I feel I have a groundless hope that it can do some magic for me.
	SU3	When I use BA, I often find myself wondering without knowing what to do.
	SU4	When I use BA, I use vendor provided standard procedure of the BA.
	SU5	When I use BA, I use it in the way the vendor trained me.
	SU6	When I use BA, I use the BA features and functions that are familiar to me.
Substantial Use	SBU1	When I use BA, I first make clear what is the nature of my inquiry through BA.
	SBU2	When I use BA, I purposefully navigate the interface to look for something I need for that task.
	SBU3	When I use BA, I put a greater emphasis on understanding the problem than worry about software.
	SBU4	When I use BA, in general, I use it to complement my educated guess.
	SBU5	When I use BA, I only use it when I believe it is more meaningful than other tools available.
	SBU6	When I use BA, I use it in novel ways to support my work.

Task Outcome

Construct	Code	Measurement Items
Task Outcome	TO1	My supervisors perceive my work outcome through BA reliable.
	TO2	My supervisors use my work outcome through BA in their decision-making process.
	TO3	My supervisors often find surprising insights from the work I generated through BA.
	TO4	My BA related tasks now have better quality because of BA.

ABSTRACT

Several published studies have ranked journals based on perceived quality according to operations management (OM) researchers. This study presents a citation analysis of OM research articles published in *International Journal of Operations and Production Management, Journal of Operations Management*, *Manufacturing and Service Management*, and *Production and Operations Management* between 2013 and 2017. The results of this analysis compared to previous research show some striking differences suggesting the evolution of OM research away from operations research and engineering. The results also illustrate the diversity of OM research ranging from analytical modeling to empirical studies influenced by other business disciplines, economics, and the behavioral sciences.

KEYWORDS: Operations Management, Journal Ranking, Citation Analysis

INTRODUCTION

The field of operations management (OM) has been evolving for many years and may broadly be construed as incorporating supply chain management, quality management, product and process design, project management, and other topical areas. OM is defined as the design, operation, and improvement of the systems that create and deliver the firm’s primary products and services (Jacobs & Chase, 2018). Given the breadth of the discipline and the overlap with other fields of inquiry, it is often difficult to distinguish between OM research and research related to the fields of general management, industrial engineering, and management information systems. This is particularly true of the overlapping, but distinct field of operations research/management science (OR/MS), which is defined as the application of quantitative methods to decision making in all fields (Jacobs & Chase, 2018). Operations management is moving in the direction of placing greater emphasis on the management aspects of problems and less emphasis on the techniques of OR/MS (Fuller & Martinec, 2005). As a logical consequence, there are many viewpoints about what constitutes high-quality OM research. To help identify quality OM research, several studies have examined journal rankings according to OM researchers.

There are many reasons for evaluating the quality of journals (Coe & Weinstock, 1984; Barman, Hanna, & LaForge, 2001; Meredith, Steward, & Lewis, 2011) beyond promotion and tenure (P&T) decisions and faculty merit evaluation including:

- Nominations for professorships, endowed chairs and fellowships
- Editors seeking feedback on their article selection process
- Research grants and awards
- Library administrators making journal acquisition decisions
- Business school/program rankings.

The next section examines recent journal ranking studies focused on the OM field. This review focuses on identifying the survey respondent or citation analysis base journals (i.e., basis for study), the measure of journal ranking used by each study (e.g., quality, influence, or relevance), and the degree to which authors distinguish the OM and OR/MS fields. The authors examine OM journals using a citation analysis based on articles published in four highly regarded OM journals. Results of the analysis are then discussed.

LITERATURE REVIEW

Opinion surveys, author affiliation indices (AAI), and citation analyses are well established methodologies for evaluating journals within the various business and related fields such as accounting (Chan, Tong, & Zhang, 2012), finance (Oltheten, Theoharakis, & Travlos, 2005; Chen & Huang, 2007), information systems (Peffers & Ya, 2003; Katerattanakul, Han, & Hong, 2003; Barnes, 2005; Ferratt, Gorman, Kanet, & Salisbury, 2007), management (Podsakoff, MacKenzie, Bachrach, & Podsakoff, 2005), and marketing (Baumgartner & Pieters, 2003; Guidry, Hollier, Johnson, Tanner, & Veltsos, 2004; Pan & Chen, 2011). This section examines similar studies focused on the OM field.

Literature Review of Surveys, AAI, and Other Methods

The first published studies of OM journal ranking are Saladin (1985) and Barman, Tersine, and Buckley (1991). Saladin surveyed members of the Operations Management Association to rate various journals based on perceived quality. Barman et al. (1991) surveyed Decision Sciences Institute members who listed OM as their primary interest by asking them to rate journals according to their perceived quality and relevance to OM research. The base list of journals considered within these studies has influenced subsequent studies within the OM field. Three survey studies have since been published where each study focuses on a different respondent population.

Soteriou, Hadjinicola, and Patsia (1999) sampled European members of INFORMS and EurOMA and had respondents rate journals based on “perceived quality and relevance to OM research.” These authors suggested the uniqueness of the operations management by omitting from their survey several industrial engineering and OR/MS journals considered in previous studies.

Barman et al. (2001) provided a “10-year update on the rankings of perceived relevance and quality of selected POM journals” by surveying U.S. members of the Production and Operations Management Society whose primary interest is OM. Results showed the perception of journals had changed since Barman et al. (1991) study They also found several journals were perceived as high quality but were not perceived as being relevant to OM research. For example, *Management Science* and *Operations Research* were the top ranked journals according to perceived quality, but they were ranked much lower regarding relevance to OM. This was an interesting outcome, yet the authors did not separate OM and OR/MS as being different domains. The authors also identified *Manufacturing and Service Operations Management* with its first issue in 1999 as being relevant to OM based on survey write-ins.

Theoharakis, Voss, Hadjinicola, and Soteriou (2007) examined how the diversity or background of self-identified OM researchers affects their “perceived quality and relevance of a journal.” The authors clarified relevant research as that which stems from real industry problems, rather than being relevant to the OM field. Their definition of quality remained consistent with prior studies as being the perceived quality of OM related articles that the journal publishes. The authors found the journal ratings differed significantly based on the region of the world and by whether the researchers identified themselves as an empiricist or as a modeler. This research also made great strides towards distinguishing the OM and OR/MS fields by reporting results for only the 11 academic journals perceived as being most relevant (i.e., based on real industry problems). This decision resulted in the exclusion of journals focused primarily on OR/MS, but they stopped short of explicitly distinguishing the two fields. The authors provided a complement paper that looked at the demographic, geographic, and type of research in more detail (Voss, Soteriou, Hadjinicola, & Theoharakis, 2014).

Harless and Reilly (1998) conceived author affiliation index (AAI) as a way to develop an objective indicator of journal quality and one that is highly correlated with who publishes in these journals which is where researchers from leading U.S. universities publish their scholarly efforts. Gorman and Kanet (2005) were the first to use author affiliation index (AAI) to 27 OM journals and compare their results to survey and citation analysis. Gorman and Kanet (2007) updated their research by applying AAI to 23 journals ranked by their previous research and Olson’s (2005) survey rankings to show that top researchers from top universities publish in top journals.

Other methods have been used to measure journal quality or to examine OM or OM-related research. Xu, Cheang, Lim, and Wen (2014) evaluated 31 OR/MS journals using Google’s PageRank and found that their results matched survey and AAI rankings. Watson and Montabon (2014) developed a ranking of supply chain management journals based on departmental journal ranking lists and discussed some differences in perceived quality based on geographical location. Holsapple and Lee-Post (2010) addressed some of the limitations of surveys, AAI and citation analysis, and developed a behavior-based approach for assessing OM journal importance based on publishing behaviors of 90 tenured OM professors at 31 leading U.S. universities. This led to a set of 27 journals for which they developed three scores to rate these journals in terms of their importance: 1) publishing breadth. 2) publishing intensity, and 3) publishing mode.

Literature Review of Citation Analysis

Vokurka (1996) conducted the first citation analysis study of OM journals and used *Decision Sciences, Journal of Operations Management*, and *Management Science* as the base journals from 1992 to 1994. After culling non-OM articles, Vokurka identified 146 OM articles with a total of 4049 citations. Of the 332 unique journals cited, his analysis identified 25 journals that accounted for nearly 80% of the total journal citations.

Goh, Holsapple, Johnson, and Tanner (1996) described two basic methodologies for conducting citation analysis. The first method inspects data published in the Social Science Citation Index (SSCI), but the authors note this is problematic since some OM-related journals are not indexed in the SSCI. A second approach involves selecting a set of base journals and then manually collecting citation data for all OM-related articles within those base journals. Goh, Holsapple, Johnson, and Tanner (1997) use *International Journal of Production Research, Journal of Operations Management,* and *International Journal of Operations and Production Management* as the base journals for their analysis of citations from 1989 to 1993. The results are normalized to avoid undue weighting towards one of the three base journals. This was accomplished by dividing the number of times a journal is cited in a base journal by the total journal citations in that base journal. The results of this study illustrate the breadth of the OM field by identifying citations of a sizable number of engineering, OR/MS and management journals.

Pilkington and Meredith (2009) used citation analysis combined with a network analysis of co-citation data from *International Journal of Operations and Production Management*, *Journal of Operations Management,* and *Production and Operations Management* to show statistically significant changes in the intellectual structure of the OM field between 1980 and 2006.

Petersen, Aase, & Heiser (2011) used meta-analysis of five journal ranking studies and performed a citation analysis using *International Journal of Operations and Production Management*, *Journal of Operations Management, and Production and Operations Management* from 1999 to 2005. Their results show that OM research has evolved away from operations research and engineering, and that the diversity of OM research ranges from analytical modeling to empirical studies which are influenced by behavioral nature of management and marketing research.

All these studies are subject to inherent limitations associated with the respective methodology used citation analysis. MacRoberts and MacRoberts (1989 & 1996) and Vastag and Montabon (2002) identify and discuss several problems with citation analysis including: uncited primary research, biased citing, self-citing, and other problems associated with the type of publication, nationality, specialty areas, and coverage of literature.

Survey studies also have several potential problems when a list of journals is provided. Beed and Beed (1996) found a typical economist knows no more than eight journals in their relevant field and asking them to rank a long list of journals often reveal personal biases to certain journals. They also identified a study where economists claimed knowledge of journals that did not exist. An example of this is found in a study of electronic commerce journals where a journal was ranked in the top ten even though its first issue was not printed for more than two years after the survey study was completed (Bharati & Tarasewich, 2002). Another issues with survey research is the low response rate. Author affiliation index (AAI) also has drawbacks related to composition of the universities and the numerical nature of the AAI scores (Agrawal, Agrawal, & Rungtusanatham, 2011)

Several citation studies and survey-based journal-ranking studies have been published for the OM field. Although these methodologies have some limitations, they are well established methods for evaluating journals. We also believe the subtle evolution of the OM field based on the discussions in these journal ranking studies is quite interesting. Beginning with the first study of Saladin (1985), authors gradually distinguished OM from the OR/MS and other related fields. However, none of the prior studies explicitly distinguish OM and OR/MS as distinct fields of inquiry.

CITATION ANALYSIS METHODOLOGY

The authors selected four OM journals as the base journals for this citation analysis study: *International Journal of Operations and Production Management (IJOPM), Journal of Operations Management (JOM)*, *Manufacturing and Service Operations Management (MSOM)*, and *Production and Operations Management (POM)*.

These OM journals were selected for several reasons. Articles published in these journals tend to focus solely on the OM field. Craighead and Meredith (2008) stated that these journals are moving toward the OM paradigm, while *Decision Sciences* and *Management Science* do not fully focus on the OM paradigm. Including these two highly regarded journals in the base journal list would require us to determine which articles are OM-related. We prefer to avoid any bias associated with this type of subjective decision.

The four journals selected also represent the broad cross section of research methodologies employed by OM researchers, which will likely instill some heterogeneity into the study. Results of this study support this premise. Over time and with encouragement of many leading academics, the OM field has grown to include both empirical and modeling research. OM journals such as *IJOPM* and *JOM* currently cater more to empirical research, while *MSOM* and *POM* tends to publish more modeling-based OM research that some OM researchers may feel falls into the OR/MS domain. Consequently, these base journals accurately represent a breadth of the best work published in the OM field.

Citations from articles published in the four base journals between 2013 and 2017 were entered into a common database. According to *Academic Journal Guide* (2018), these base journals are all categorized as OM journals, thus we assume the 1,415 articles published in these journals are all OM-related and consequently are included in our analysis. Table 1 summarizes the journal and citation statistics for the four base journals. These articles contained a total of 78,337 citations of which 60,316, or 81.3%, were research journal articles. Results show that citations from all four base journals are comprised of similar percentages between journal citations, books and other categories. These values are consistent with previous studies (Vokurka, 1996; Goh et al, 1997; Petersen et al, 2011).

Table 1: Journal and Citation Statistics for *Journal of Operations Management (JOM)*, *International Journal of Operations and Production Management (IJOPM), Manufacturing and Service Operations Management (MSOM)*, and *Production and Operations Management (POM)* for the years 2013 through 2017

	IJOPM	JOM	MSOM	POM	Total
Number of issues	60	30	20	54	164
Number of articles	343	200	213	659	1,415
Articles per issue	5.7	6.7	10.7	12.2	8.6
Total citations	27,060	15,932	8,391	26,954	78,337
Citations per article	78.9	79.7	39.4	40.9	55.4
Journal citations	21,894	12,422	5,669	20,331	60,316
as a percentage	80.9%	78.0%	67.6%	75.4%	77.0%
Book (etc.) citations	5,089	3,401	2,359	5,873	16,722
as a percentage	18.8%	21.3%	28.1%	21.8%	21.3%
Misc. citations	77	109	363	750	1,299
as a percentage	0.3%	0.7%	4.3%	2.8%	1.7%
Number of unique journals cited	942	601	356	883	1,805

Note: Misc. citations include Working papers, dissertations/theses, and Non-traditional sources.

Based on the procedure used by Goh et al. (1997), we normalized the data for each base journal by dividing the number of citations for each cited journal by the total number of citations for that base journal. These normalized indices essentially represent the percentage of citations for a journal in each base journal. For example, *JOM* was referenced a total of 1,952 times within the issues published by *JOM* between the years of 2013 to 2017. This value is normalized by the total journal citations of 12,422 yielding a normalized index of 15.7%. The four normalized indices for a journal are then averaged across the four base journals. For *JOM* as an example, these indices are 9.6% for *IJOPM*, 15.7% for *JOM*, 0.6% for *MSOM*, and 3.5% for *POM* to yield an average normalized index of 7.3%.

Citations within a journal are often biased toward a few select journals. This phenomenon is common, and perhaps expected, particularly in diverse fields such as OM. Moreover, journals commonly contain a larger percentage of self-citations. As pointed out by Goh et al. (1997), normalizing the data helps compensate for biases associated with differences in the number of journal issues published during a year and the number of articles published annually. It also mitigates the bias associated with the self-citation phenomenon for the base journals.

CITATION ANALYSIS RESULTS

A total of 1,805 cited journals are ranked based on the average normalized index across the based journals, with the top 40 most cited journals listed in Table 2. The articles cited from these journals account for 48.96% of all the journal citations across the four base journals, while they account for 46.42%, 52.68%, 46.60%, and 50.04% of the journal citations within *IJOPM*, *JOM*, *MSOM*, and *POM*, respectively. These un-normalized rankings are based on the total citations a journal received from the base journals. Results of a Sign Test show that there is no significant difference between the normalized and un-normalized ranking at the 10% level. The normalized and un-normalized rankings share the same top 14 most cited journals. *Management Science* is ranked the first in both normalized and un-normalized ranking, followed by *JOM* as the second place in both rankings. One may observe the significant differences in the total citations between two closely ranked journals based on the normalized index. For example, *JOM* is ranked the second and *Operations Research (OR)* the third in the normalized ranking, but *OR* received a much smaller total (2,002 citations) from the base journals which is only 41.73% of total citations of *JOM* (4,798 citations).

Interestingly, the *Wall Street Journal* (*WSJ*) is ranked 36th in the normalized ranking. Although *WSJ* is not an academic journal, its appearance in the top 40 list evidently demonstrates the importance of real-world applications amongst the OM research. Hence, we decide to keep it in the list.

Consistent with Petersen et al. (2011), *JOM* is ranked in the top ten cited journals for most base journals except *MSOM*. Similarly, *POM* is amongst the top ten for all base journals except *IJOPM*. Furthermore, *MSOM* is highly cited in *MSOM* and *POM*, but relatively low in *IJOPM* and *JOM*; whereas *IJOPM* is ranked in the top ten for in *IJOPM* and *JOM* citations, but not in *MSOM* and *POM*. These observations echo the phenomenon that *MSOM/POM* and *IJOPM/JOM* emphasize on different streams of research, respectively.

Tables 1 and 2 together facilitate the detection of existence/extent of self-citation issues. The results show that the percentage of self-citing is 11.2% for *IJOPM*, 15.7% for *JOM*, 9.7% for *MSOM*, and 8.4% for *POM*. Although *JOM* has the highest self-citing rate of 15.7%, the self-citing rates are considered relatively low across all base journals, therefore do not raise a concern in our study.

The list in Table 2 indicates that all four base journals cite research works from a wide variety of domains in addition to OM domain. Following *Academic Journal Guide* (2018), Table 3 categorizes the journals in Table 2 into seven domains: Operations Management, Operations Research/Management Science (OR/MS), Management (MGMT), Marketing (MKT), Economics

(ECON), Information Management (IM), and Sector/Miscellaneous. Ten out of 40 journals fall in the OM domain, the largest group, followed by the OR/MS domain with eight journals. This is attributed to the close relationship and ambiguous boundary between OM and OR/MS field. Compared with Petersen et al. (2011), the number of management journals decreased from ten to eight, whereas the number of marketing journals stayed the same although the list is slightly different. Note that such change of the journals in each domain may be partially due to the changes in the categorization. For example, *IISE* (former *IIE Transaction*) was categorized as an Industrial Engineering/Other Engineering journal by *Academic Journal Quality Guide* (2009) but has been recently re-categorized as an OR/MS journal by *Academic Journal Guide* (2018). Interestingly, the economic and information management journals have emerged with six journals that fall into these two domains and are all considered top journals in their respective fields. This observation is aligned with the trend of the application of economic theories in OM studies and the rising interdisciplinary research between the OM and IM fields.

Sign Tests are performed to compare the normalized rankings of the cited journals between every two base journals (Siegel & Castellan, 1988). The results, presented in Table 4, reveals that the OR/MS journals are consistently more important for the modeling-oriented journals (i.e., *MSOM* and *POM*) than for the empirical-oriented journals (i.e., *IJOPM* and *JOM*), whereas the management journals are more important for *IJOPM* and *JOM* than for *MSOM* and *POM*. Within the empirical-oriented stream, the number of higher-ranked journals cited in *JOM* is significantly more than that in *IJOPM* at the 5% level; the differences are not significant on the domain level. Within the modeling-based stream, journals in OM and management domains are both reported to be more important for *POM* than *MSOM*. One explanation may be that *MSOM* tends to be more OR/MS oriented compared with *POM* since *MSOM* appears to cite relatively more OR/MS journals, although the difference is not significant.

DISCUSSION AND CONCLUSIONS

This study is the first citation analysis study of OM journals in eight years. Interestingly, the results of this study share the same top OM journals (i.e., *Management Science* and *Journal of Operations Management*) with the most recent study by Petersen et al. (2011). In fact, seven of the top ten journals and 28 of the top 40 journals are the same as the prior study. Our results show that there are five OM journals, three OR/MS journals, and two MGMT journals in the top ten.

The results of this study show that OM researchers cross boundaries into other business domains, OR/MS, engineering, and the behavioral sciences, but unlike the results shown by Petersen et al. (2011), OM research has been recently drawing upon the research in Information Management and Economics. This study affirms the increase in the breadth of research conducted in the OM field, particularly in empirical research. Fisher (2007) suggested that increasing the empirical elements of operations research would be highly beneficial to OM research. Meredith (2009) advocates for expanding our OM research paradigm from not only empirical and modelling research to one consisting of interpretivism by working with business professionals to help them solve relevant business problems. Operations management is a diverse field that continues to embrace both empirical and modeling research (Krajewski, 2002; Theoharakis et al, 2007). The results of this citation analysis show that this idea is quite valid.

A limitation of this study is the selection of our base journals for the citation analysis: *International Journal of Operations and Production Management*, *Journal of Operations Management*, *Manufacturing and Service Management,* and *Production and Operations Management*. The authors chose these journals because they are highly regarded OM journals that publish a breadth of both empirical and modeling research. Even though self-citation is sometimes an issue with citation analysis, these four base journals had self-citation rates between 8.4% and 15.7% which are low enough to not raise concern over self-citations skewing the results of this study (Nisonger, 2000).

Table 2: Citation Analysis Ranking of Journals for OM Research

Normalized Objective Rank	Un-normalized Objective Rank	Cited Journal	IJOPM Citations	JOM Citations	MSOM Citations	POM Citations	Total Citations	Normalized Average
1	1	Management Science (MS)	393	727	1,238	3,229	5,587	11.3%

ABSTRACT

This study analyzes the factors affecting college rankings. The question is whether rankings signal quality. Findings reveal that ranking systems use different parameters; but how do those parameter relate to student learning, faculty research and service to the community. The results should explain why institutions emphasize on some performance measures.

KEYWORDS: University ranking, school rating, Teaching, Student performance, Faculty performance, university service, school quality, Information Technology.

INTRODUCTION

Every day, we are called to make decisions that affect our lives. For instance, we have to choose restaurants when opting to eat out, cars and cars dealers when selecting a mode of transportation, house style and location when buying or renting a home, schools when deciding on education and so forth. However, some choices are more important than others in the sense that they have greater impacts on our lives. The choice of the type of education one get can shape the future health and wealth of an individual. Therefore, during the decision-making process, one usually takes into account inputs from a variety of sources. One critical decision that will affect many people life is their choice of institution of higher education (Mårtensson & Richtnér, 2015). The Economist (2010) reported that higher education seems like a market for an expensive product, where students, in order to spend money on out-of-state tuition or private school, want to make sure the school is ranked better than the public schools in their state. School ranking has become an important tool used by students, faculty, and other stakeholders to compare institutions. Rankings start as early as nursery schools and continue all the way beyond to post-graduate programs.

Studies on rankings of educational institutions have been conducted at different levels and in many disciplines including but not limited to management, economics, law, organizational sociology, strategy, and corporate reputation. Professional programs particularly, business and Law schools are very driven by ranking. It is believed that rankings may (1) help set the standard for what is considered a good school in terms of both 'identity' (Albert & Whetten, 985; Devinney, et al., 2008; Rindova & Fombrun, 1999) and competitive ‘landscape’ (Devinney, et al., 2008; Wedlin, 2006); (2) confer authenticity, legitimacy , and positional status on the schools that are ranked (Devinney et al., 2008; Gioia & Corley, 2002); (3) help expedite changes when key stakeholders show concerns about the school image the school (Elsbach & Kramer, 1996; Martins, 2005; Zemsky, 2008); (4) adjust programs to fit local needs while opening doors to distant opportunities and challenges. There is a need to understand the methodology used to rank schools. Especially because there has been little evidence or attempt to assess rankings in a more systematic manner; given the attention attributed to these rankings in addition to the fact that people have divergent views about what they represent and how they work (Dichev, 2008). The current research examines as Devinney et al. (2008) suggests the sub-component scores of rankings and the performance criteria used by ranking organizations.

LITERATURE REVIEW

A multitude of rankings emerged over the years for different purposes. To understand the dependence/reliance on rankings, it is important to understand the origin, retrace the history of college rankings, then examine what college rankings are used for, finally, analyze the use of the rankings.

The Origin and Evolution of Ranking

In 1906, a distinguished American psychologist, James McKeen Cattell (Cattell, American Men of Science: A Biographical Directory, Second Edition 1910), laid the foundation of today's college and university rankings by first compiling and publishing a list of more than 4,000 men he deemed accomplished scientists based on the degrees earned, achievements, and socio-economic status. That publication was "*American Men of Science: A Biographical Directory*." The list was updated and resulted to another publication "*American Men of Science: A Biographical Directory, Second Edition*" at the end of 1910, which included the biographies of about 5500 prominent scientists, the institutions they attended and where they taught at post-graduation (Cattell, American Men of Science: A Biographical Directory, Second Edition 1910). The institutions were also ranked based on how many scientists were associated with them. This was the first published academic quality ranking of American universities. The five leading institutions were Harvard, Chicago, Columbia, Hopkins, and Yale. The third edition of the "*American Men of Science*" was published in 1921 and contained about 9600 scientists and the analysis further includes occupation/discipline and position (Cattell and Brimhall, American men of science; a biographical directory 1921). Today, the "American Men of Science" is published as "American Men and Women of Science". These early 1900's ranking were Outcome-based rankings as opposed to the reputation based ranking which began much later.

Outcome-based rankings

In 1910, The American Association of Universities (AAU), believing that an impartial ranking would be widely accepted, requested that the United States federal government through the Bureau of Education Study (EBS) rank colleges based on quality. The goal of the AAU was to help institutions select the best undergraduate students for their graduate programs. However, the release of the results of the study was prohibited by an executive order from the then United State President William H. Taft (Ranking Everything College 2018). Stephen S. Visher (1931) produced another example of Outcome-Based rankings by analyzing the institutions and regions most associated with the "Who's Who in America" leaders (Visher 1931). He claimed that New England produced about twice as many "Who's Who in America" as did the middle Atlantic states and about ten times as many as the south central states.
Between 1930 and 1951, Beverly Waugh Kunkel, a biologist at Lafayette College, and Donald B. Prentice, then president of the Rose-Hulman Institute of Technology, used a methodology

like that of Cattell and Visher to assess academic quality. They believed that “undoubtedly the most reliable measure” of a higher education institution was “the quality of product.” Therefore, they ranked universities based on the number of alumni listed in "Who’s Who in America" (Kunkel and Prentice 1951) (Myers and Robe 2009). These outcome-based rankings were not the only ranking methodologies with roots in the early 1920; other methods included hinge on peer-review opinion as well as the ever-popular reputational-based rankings.

Reputational-based Rankings

In 1924, Raymond Hughes compiled the first list ranking a department’s quality based solely on reputation rather than the popular outcome-based methodologies; faculty, from 36 institutions and 20 fields, rated instructors in their respective disciplines (Ranking Everything College 2018). Hayward Keniston (1959) compiled list of fifteen strongest departments in their discipline at twenty-five top universities, then gathered the results into institution-wide rankings (Keniston 1959); which contributed to the rise of reputational rankings.

Reputational rankings have grown in popularity and become the predominant method for generating academic quality rankings; as the reputation of institution has a greater impact on ranking than the eminence of students produced (Ranking Everything College 2018). Reputational-based methodologies considered faculty quality as a criterion in the assessment of program quality and fixed the research gap on the evaluation of graduate programs. The main emphasis has been on institutions with high national visibility (Conrad and Pratt 1985) (Hughes, A Study of the Graduate Schools in America 1925) (Hughes, Report of the Committee on Graduate Instruction. 1934).
