A Blockchain-Based Deep Learning Neural Network

Liqiang Chen
University of Wisconsin – Eau Claire
Email: chenliqi@uwec.edu

ABSTRACT

This research proposes a blockchain-based deep learning neural network. The proposed deep learning neural network uses blocks in the blockchain as neurons to learn and memorize knowledge. The blockchain-based deep learning neural network is shared and distributed on the Internet and it is also a constantly adapted learner with more blocks being added on the blockchain. There are many advantages of applying blockchain in the deep learning architecture, for example, it is more secure, constantly learning from doing, shared and distributed memories, and specialized in a specific knowledge domain.

KEYWORDS: Blockchain, Deep Learning, Biological Neural Network, Artificial Neural Network, Artificial Intelligence

INTRODUCTION

The rises of blockchain technologies and the bloom of cryptocurrencies (Tapscott & Tapscott, 2016) have been attracting more and more interests and investment in the business community. Blockchain has not only the potential to disrupt the existing business processes in finance, but also in many other areas (Nofer *et al.* 2017). “Blockchain is emerging as a game changing technology in many industries.” (Salviotti *et al.* 2018)

Similarly, widely adopted artificial intelligence (AI) (e.g., machine learning) and robotic technologies have been greatly changing the business landscape and our daily life. In addition, advancement in AI and automation is replacing many jobs in many industry sectors. McKinsey Global Institute’s report (2017) predicts that by 2030, AI and automation may displace 400 million to 800 million people who need to switch job categories and learn new skills.

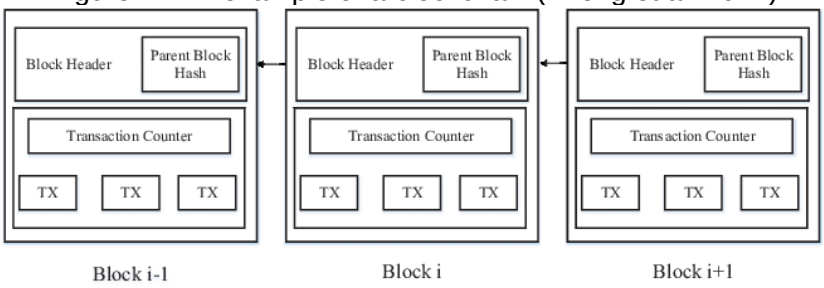
By investigating blockchain and AI together, this research proposes a new deep learning architecture aiming to explore new algorithm and application of AI in the business community. Deep learning is a type of machine learning, which is also one of the most important disciplines in AI. This paper is organized as follows. We introduce blockchain, deep learning and neural network first, and then propose a blockchain-based deep learning neural network followed by discussing its academic and practical implications.

BLOCKCHAIN

Blockchain is a binary tree data structure in which two sibling tree nodes are linked to its parent node. This binary tree structure is called “Merkle tree” (Merkle 1988) and a tree node is a data object called “block” in the blockchain. A “block” consists of a block header and a block data set. The block data consists a large number of messages (e.g., bank account transactions) and the summarized information of the entire Merkle tree up to the current tree node. This summarized Merkle tree node information is hashed/encrypted. The block header consists of the current

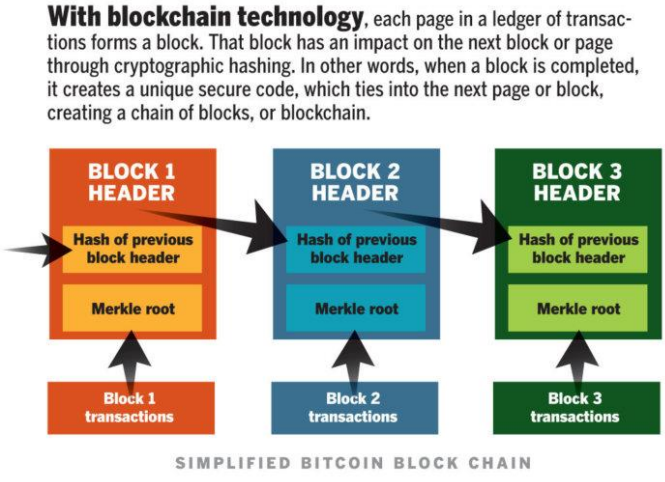
Merkle tree node's summary information and the hash value of the preceding (parent's) block header (Fill and Härer 2018). Accordingly, all the blocks in the Markle tree are linked and forms so-call blockchain as shown below.

Figure 1: An example of a blockchain (Zheng et al. 2017)



The blockchain or the Merkle tree is a peer-to-peer distributed and shared data management system on the Internet in that a block can be stored anywhere - at any IP address or on a computer on the Internet. Each block (e.g., on a computer) in the blockchain can keep a copy of the entire blockchain. The following diagram illustrates a business application of blockchain, a distributed shared transaction ledge system. When a new transaction gets into the blockchain in which a block represents a company, the block "executes algorithms to evaluate and verify the history of the individual blockchain block that is proposed." (Hassell 2016). If this transaction is verified to be valid in terms of the transaction history and signature, the transaction is added to the block. The new transaction is then broadcasted to the entire network in which all copies of this blockchain are updated. The blockchain has many advantages, for example, the information is transparent and any changes can be seen by all owners of the blockchain, it is more secure due to high degree encryption, the information is distributed and shared without concerns of data lost, etc.

Figure 2: An example of blockchain application (Hassell 2016)

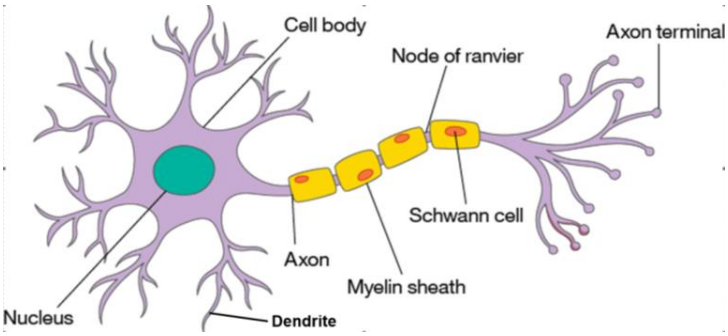


DEEP LEARNING AND ARTIFCIAL NEURAL NETWORKS

Before we discuss the deep learning algorithm, we introduce human neural networks and artificial neural networks.

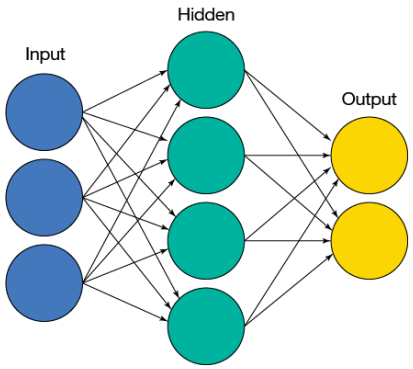
Biological neural networks like human brains store and process information through a huge number of neurons shown in Figure 3. A neuron is a nerve cell that receives and processes information through electrical and chemical signals. In a neuron cell, the dendrites receive signals, the cell body processes them, and the axon sends outputs (processed input signals) to other neurons. All neurons are connected in a nonlinear manner forming a network.

Figure 3: Neuron – a major components of biological neural network (Kienzler 2017)



An artificial neural network is a mathematical model that simulates the biological neural network. The artificial neural network consists of several layers: input layer, output layer and hidden layers. There can be many hidden layers. Each layer has many nodes which mimic biological neurons. A node consists a mathematical function which takes the input signals from the nodes in the previous layer. When the input signal strength is above a threshold value, the function is activated and generates an output signal sent to the nodes in the next layer. Accordingly, the function in a node is called activation function. See a simplified artificial neural network model in Figure 4.

Figure 4: Artificial Neural Network (Kienzler 2017)



Although the artificial neural network models the biological neural network, there are some major differences between them. In addition, we are still in the very early stage in understanding biological neural networks or human intelligence. Compared to biological neutral network, artificial neural network is much simpler, for example, the biological neural network has much more neurons (e.g., 10^{11} neurons) than artificial neural network has (up to 10^{8} nodes) and the connections among neurons are nonlinear rather than layers, which means biological neural networks are much more complicated and more effective (e.g., more intelligence). The

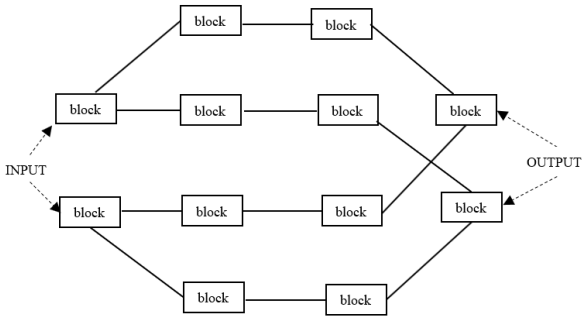
biological neural network memorizes information in the connection parts between neurons which are called synapses. Memory recall requires many neurons and synapses to work together and they can be much more complicated than we currently know. Instead, the artificial neural network memory information (e.g., knowledge) in the weight of the link between two nodes, which is much simpler than the biological neural network. Thank to the model computer operation capability, today's artificial neural network has much faster operations (i.e., logic and arithmetic operations) and much more storage capability than biological neural network. As a result, the artificial neural network can use big data to train itself and achieve so-called deep learning.

Deep learning is one type of artificial intelligence (AI) models that use large data set to train a model to make it smarter. Most deep learnings are built upon artificial neural networks that have deep architecture or many hidden layers. Deep learning is becoming one of the most promised AI methods and has been widely used in all industry sectors. For example, automated driving is one of the most disruptive technology in IT and auto industries. The core technology in automated driving is the application of deep learning that automatically detect objects such as stop signs, traffic lights, moving vehicles, pedestrians, etc. The deep learning uses a large amount of data to train the automated driving software before the vehicle gets on the road. By using more and more real time driving data or road experience, the deep learning software is constantly learning and improving its self-driving skills.

BLOCKCHAIN-BASED DEEP LEARNING NUERAL NETWORK

By applying the blockchain technology in the deep learning method, we propose a blockchain-based deep learning neural network as shown below.

Figure 5: Blockchain-based Deep Learning Neural Network



Compared with the layer-based neural network, the blockchain-based neural network has many advantages.

- The blockchain is a nonlinear tree structure and thus the knowledge is stored in many different blocks over the Internet. This memory mechanism is closer to the biological neural network than the traditional layer-based neural network. We expect the blockchain-based deep learning architecture to be more intelligent and efficient.
- It is more adapted in the real-time learning environment. Learning process occurs at any time when new blocks and/or new transaction data is added to the blockchain. As a result, this AI technique is a purely learning from doing.
- It integrates real-time business processes in the decision making so that it provides fast decision support.

- It is specialized in a specific knowledge domain and can be a good "decision maker".
- It is shared and distributed - knowledge can be accessed anywhere at any time globally.
- It is more secure.

ACADEMIC AND PRACTICAL IMPLICATIONS

The proposed blockchain-based deep learning neural network has great academic and practical implications. In academia, the proposed deep learning architecture explores a new algorithm/technique for machine learning. It has many advantages than the traditional layer-based neural network as discussed above. In practice, this new deep learning architecture integrates business processes and decision-making processes from self-learning – learning from doing and thus it would greatly improve decision-making performance by using real-time data. In sum, the blockchain-based deep learning architecture is a fast and smart AI that constantly learns from doing using real-time business data.

A Causative Analytic Approaches for Improving Graduation and Retention Rates

Xuan Wang

Email: xuan.wang@utrgv.edu

Helmut Schneider
Louisiana State University
Email: hschnei@lsu.edu

ABSTRACT

Six-year graduation rates have attracted the attention of educational researches and policy makers for decades. However, the graduation rate has not improved much during that time. Retention rates are a good predictor of graduation rates. This study explores the use of causative analytics for identifying the true magnitude of factors affecting retention. The study assesses the actual effect size that on campus living and math preparation have on dropping out of a business college. A detailed discussion of issues that need to be addressed when exploring the magnitude of factors at different stages in a student's program is provided.

KEYWORDS: Graduation Rates, Retention Rates, Causative Analytics, Inverse Probability Weighting

INTRODUCTION

Student success, retention and graduation has been a focal point of public debate (Elton, 1988; Keams, 1998; Dill, 1999; Alexander, 2000; Kitagawa, 2003; Huisman, 2004; Bailey, 2006). According to the most recent statistics, only between 30% to 40% of students graduate within four years from a four–year program, and about 60% students graduate within six years in the United States (ACT, 2014). The stakeholders, educational researchers and policymakers have made countless efforts to identify the factors that can affect retention and graduation rates. While "earlier attempts by states to measure institutional effectiveness have generally been met with passive resistance and benign neglect by academics" (Alexander, 2000), the above-inflation rise of tuition and the growth of student loan debts have created an urgency for change (Jackson, 1975; Shin, 2006; Hemelt, 2011; Shenand, 2009). Additionally, with the drastic budget reductions for public universities, faculty members have been asked to serve increasing numbers of students. Increasing retention and graduation rates could be beneficial for both the students and the universities. The students would pay tuition for a shorter time and thus could earn money earlier to pay off their debts, and the universities could save considerable money when fewer students take up resources. Because of the significant role graduation rates play in the evaluation of universities, they merit an in-depth analysis. While there is no silver bullet that guarantees an increase in graduation rates, analytics is suitable for providing necessary insights into how university administrators can increase retention and graduation rates. The objective of this article is to explore the use of causative analytics in an academic institution with the aim of identifying the true effects size of factors affecting retention rates.

The remainder of the paper is organized as follows. Section 2 reviews the literature about retention rates and graduation rates to provide the domain knowledge for our analytics case that

is necessary in the application of analytics in order to avoid the misinterpretation of results. Section 3 introduces and clarifies the differences and importance of causative analytics. Section 4 contains two subsections; the first subsection applies logistic regression to conduct an initial approach in order to gain insights into the data of identifying key factors on campus living status and math preparation that affect graduation rates and retention rates at different stages. Additionally, we compare results between naïve estimate and logistic regression. The second subsection applies inverse probability weighting for identifying the true effect size of on campus living and math preparation on retention. Section 5 closes with recommendations regarding the application of causative analytics in academics to increase retention and graduation rates.

LITERATURE REVIEW

Despite the massive literature examining the factors effecting student retention and graduation rates (rankings, e.g., U.S. News & World Report), very few assessments of campus retention initiatives exist and evidence is thus scarce as to whether these initiatives are effective (Hossler, 2008). This is partly due to the slow adoption of advanced data management systems by universities. However, as new low-cost analytics solutions have become available in recent years, there has been a growing interest in using analytics to gain better and timely insight into what affects student retention and to allow for the tracking of the effects of new initiatives (Pirani, 2005). The use of descriptive analytics has focused on analyzing the admission process and pre-college factors and their impact on graduation rates. Predictive analytics can be used to identify students at risk of dropping out of university and can therefore allow for advising students in time to increase student retention and subsequent graduation rates (Campbell, 2007). Prescriptive analytics compromises the understanding from descriptive and predictive analytics for allowing corrective actions to be taken for making the decisions. As new technologies are adopted and available data grows larger, more complex models can be used to monitor and assess student success. Despite the numerous empirical studies testing models, explaining retention and graduation rates, and studying methods to improve them, graduation rates at public colleges are still very low. There has been little work done on using data collected by colleges to provide a more effective management of retention and graduation rates. While universities collect and store information about students' performance and demographics and students' background, administrators struggle with how to use the data to improve graduation rates. Therefore, understanding the capabilities of analytical methods and knowing how to apply them to student data is a crucial step toward developing an effective program to increase graduation rates. When using analytics for improving retention and graduation rates, it is important to distinguish between pre-college factors and in-college factors that affect graduation rates throughout college. While pre-college factors are used for selective admission, in-college factors are time dependent, measuring the student's progress towards graduation.

Pre-college factors include academic factors such as High School GPA and ACT assessment scores as well as non-academic factors such as socioeconomic status, self-confidence, achievement motivation, and academic goal orientation which attempt to measure personal traits. Academic factors have been shown to be important for college success and have been widely adopted for selective admission (Schnell, 2003; DesJardins, 2003). In this study, the pre-college factors include student demographic information, academic factors and some non-academic factors. In-college factors are significant keys for effecting the performance after the students enrolled in college, and the factors might vary with the students' performance over time. First-year retention rates have received special attention because it is critical for college success (Hossler, 2008). Moreover, there are some researches that focus on examining specific strategies to

increase first-year retention (Schnell, 2003). In this study, in-college factors contain the grades in core courses and semester-based cumulative GPA.

ANALYTICS

While the objective of descriptive analytics is to gain insight into possible relationships between factors that affect a variable of interest such as graduation, predictive analytics is used to make predictions regarding individual observations. Predictive modeling is therefore different from explanatory modeling (Shmueli, 2010). In explanatory modeling the objective is to determine whether certain factors such as pre-college preparation measured by the high school GPA or SAT/ACT explain college success. In contrast to statistical hypothesis testing where "significance" and thus associated "p" values are important criteria for concluding that a relationship between dependent and independent variables exists, predictive modeling does not concern itself with these issues. The objective of causal analytics is to obtain estimates from observational data that are unbiased. While inferential statistics is only concerned with whether a factor is statistically significant, causative analytics is trying to identify the true effect size of key factors that affect an outcome such as graduation rates.

This article focuses on applying causative analytics using data from the E. J. Ourso College of Business at LSU to assess the actual effect size of on campus living and mathematics preparation on retention and graduation rates. As mentioned above, predictive analytics and prescriptive analytics do not make any causal claims nor do they suggest which factors affect the target. All that is important is that the model is able to predict the outcome. In many cases this is sufficient for the practical application at hand. However, there are many situations where one is interested in what factors cause the target to change and how much they will change the target. For instance, when predicting what student is likely to drop out it may be of interest to know what factors have a large effect. If living on campus makes a big different, in graduation rates then university administrators could plan for more on-campus housing. But, one needs to know that living on campus causes an increase in graduation rates before investing in significant resources. Thus, having good predictions for individual students is not enough. Much of statistics has focused on statistical significance instead of practical significance.

MODELS AND RESULTS

College success requires different models for different points in time. This study covers outcomes from two perspectives, it measures 4-year graduation rate and retention rate at different stages. It focuses on applying causative analytics using data to explore the true effect size of on campus living for improving retention and graduation rates. A model evaluating 4-year graduation was developed using data with 5,582 students who entered college between 2006 and 2011 and would have graduated between 2010 and 2015 if they had graduated within four years. In order to have a more timely model for decision making, two models were developed for assessing dropout rate at different semesters using a data set with 9,913 students who entered college between 2006 and 2015. The data consisted of precollege information collected on all freshmen and in-college information about programs, courses taken and grades. The data include the demographics, high school GPA and ACT test results, whether students will live on campus or not, information about the type of high school, distance between home and campus, whether they are Pell grant recipients, the number of college credits they have taken and the intended major they want to enroll in. Three models were built based on different points in time. For the first and second semester models, all pre-college factors and the additional in-college factors are included for the respective semester models. Since there are too many courses a student can take as electives,

we only included individual grades from required courses in the first and second semester that exhibited some confounding that affect the power of dropout with specific factors. The student information and the course table were put into a data warehouse, a quality check was performed, and missing information was identified. In this study, two treatments are evaluated; the first treatment is on/off campus living, and the second is mathematical preparation. The status of on campus living is determined when the students enroll the university. We have examined the effect size of on-campus living status on the dropout after the first and second semester. The effect of mathematical course preparation is also measured by the dropout after the first and second semester.

Naïve Estimate & Logistic Regression

As a baseline model, logistic regression was used on 75% of the data (training set) to identify factors that are highly statistically significant. Logistic regression has the advantage of providing an interpretation, namely the odds ratios. As Table 1 shows, the precollege factors Gender, HSGPA, ACT, CAMPUS and Distance are statistically significant at the 0.05 level.

Table 1 shows that academic qualifications such as ACT and high school GPAs, while important predictors for 4-year graduation, are less important factors for affecting return to the college after the second semester. For the third model, grades in college are the most important factors affecting the dropout after the first semester, specifically, failures of passing courses such as Algebra (MATH1021), Calculus (MATH1431), Information Systems (ISDS1102), Economics (ECON2000) and first-semester GPA. Both cumulative GPA at the end of the first semester and at the end of the second semester are statistically significant for dropout after the first and second semester, respectively. Generally, the statistical significance of pre-college factors decline as more in-college information becomes available. However, Math preparation is the foundation of other courses, passing courses Algebra(MATH1021) and Calculus (MATH1431) are very crucial for student further success.

Table 1. Logistic Regression Results of Factors for Predicting 4-Year Graduation and Retention

Because the study focuses on examine the true effect size of on campus living and math preparations, the logistic regression provides an important step by identifying key performance indicators. Additionally, the logistic regression model also has the added benefit of providing odds ratios which are depicted in Table 2. For instance, living on campus in the first semester increases the odds of a student graduating in 4 years by 66% compared to the odds of a student who does not live on campus in the first semester. This indicate that students who live on campus in the first semester are more likely to graduate in 4 years than students who did not live on campus in the first semester. Moreover, with the comparison of effect size between naïve estimate and logistic regression, the average treatment effect for on campus status holds the same trend in table 2. However, the average treatment effect for math preparation does not hold the same trend in table 3. To the extent of native estimate, logistic regression only adjusts for covariates, but it does not completely provide the causal estimates, and this is the reason why we need to do further study for exploring the true effect size.

Table 2. Average Treatment Effect for On Campus Status (Naïve vs. Logistic Regression)

	Naïve Estimate		Logistic Regression	
	Estimate (Percentage Points)	Stand Error	Estimate (Percentage Points)	Stand Error
Four-Year Graduation	14.7	0.015	1.66	0.035
First Semester	1.2	0.005	1.28	0.067
Second Semester	4.1	0.009	1.49	0.051

Table 3. Average Treatment Effect for Math Preparation (Naïve vs. Logistic Regression)

		Math 1021		Math 1431	
		Naïve Estimate (Percentage Point for Estimate)	Odds Ratio	Naïve Estimate (Percentage Point for Estimate)	Odds Ratio
First Semester Dropout	Estimate	8.3	1.68	4.4	2.38
	Stand Error	0.009	0.09	0.005	0.098
	Estimate	45.4	1.9	25.4	1.97

Second Semester Dropout	Stand Error	0.024	0.11	0.001	0.071

Causative Analytics - Inverse Probability Weighting

Inverse probability weighting is a common method used by researchers to identify causal estimates. Inverse probability weighting is helpful for bias reduction under various situation (Mansournia & Altman, 2016). Additionally, it is often used to overcome the selection bias in multiple disciplines (Hernan & Robin, 2010). In this study, we will employ inverse probability weighting for comparing the actual effect size for on/off campus living and math preparation at different semesters. Inverse Probability weighting applies the conditional probability of treatment given the covariates, in order to create the pseudo population by weighting each individual in the population by the inverse of the conditional probability of receiving the treatment level that one indeed received. In another word, the entire process for inverse probability weighting is trying to double the population, in order to achieve the conditional exchangeability between treatment group and control group in each of strata. The hypothetical population that is twice as large as the original population is known as the pseudo-population (Hernan & Robin, 2010).

As mentioned in the previous section, there are many confounders. Although the effect size of on campus living on retention rate is estimated at different times, the in-college factors cannot be treated as confounders because the on-campus status is decided when the students enter the university. Therefore, only the pre-college factors are treated as confounders in different models for measuring the effect size of on campus living on the retention rate.

Table 4. Average Treatment Effect for on/off campus (Naïve Estimate vs. Inverse Probability Weighting)

	Naïve Estimate		Inverse Probability Weighting	
	Estimate	Stand Error	Estimate	Stand Error
Four-Year Graduation	0.147	0.015	0.118	0.014
First Semester	0.012	0.005	0.009	0.005
Second Semester	0.041	0.009	0.032	0.009

Table 4 shows lower results from Inverse Probability Weighting. If a student decides to live on campus, there is a 1.0 percentage point increase in staying in college after the first semester, and there is around 3.2 percentage point increase of staying in college after the second semester. These estimates are causal provided there are no other unknown confounders. Additionally, the campus living status takes heavier effect on graduation rate. If a student decides to live on campus there is about an 11.8 percentage point increase in graduation within 4 years.

The causal effect of math preparation is also examined. In this study, the effect of grades in Algebra and Calculus is evaluated by semesters. The grades of two courses have eight different levels (P(Pass), A, B, C, D, W, F, NT (not taken)). A student who has a grade of P, A, B, C are passing the course while (D, W, F, NT) indicate no passing. When assessing effect size of math preparation, the in-college factors are potential confounders as well and are added in the model for reducing bias. The additional confounders are the grades in required courses. Classes' grades in different classes may be correlated because better students tend to have better grades.

Table 5. Average Treatment Effect for math preparation (Naïve Estimate vs. Inverse Probability Weighting)

		Math 1021		Math 1431	
		Naïve Estimate	Inverse Probability Weighting	Naïve Estimate	Inverse Probability Weighting
First Semester Dropout	Estimate	0.083	0.125	0.044	0.095
	Stand Error	0.009	0.034	0.005	0.022
Second Semester Dropout	Estimate	0.455	0.200	0.254	0.080
	Stand Error	0.024	0.062	0.001	0.029

Table 5 also shows that the causal estimate is larger than the naïve estimate. For instance, there is 12.5 percentage point increase in retention after the first semester and a 20-percentage point increase in retention after the second semester. However, for the second semester the causal estimates are smaller than the naïve estimates. This is due to the second semester having only students that remain in college and the true effect of math performance is smaller than for the first semester.

DISCUSSION AND IMPLICATIONS

This study contributes to an understanding of the important of specific factors that improve retention rates and graduation rates. While logistic regression allows for a more straightforward interpretation because of the estimated odds ratios, the results can be misleading when researchers rely only on p-values, which provide statistical significance and odds ratio for explaining and are not a metrics for identifying true effect size of specific factors. This study applies causal inference method – Inverse probability weighting to identify two factors that have a large effect on 4-year graduate rate and first and second semester retention. There are several findings. First, living on campus does improve the retention rate after the first and second semester and 4-year graduation. And there is a higher affect on 4-year graduation compared to the first and second semester retention. Second, mathematics preparation is a crucial factor affecting retention after the first and second semester. Specifically, the results indicate that students who have not passed algebra in by the second semester have a 20 percentage point higher dropout rate than students who pass algebra. This result should lead to policy changes regarding suggested courses taken in high school. High school councilors should advise their students that they must be well prepared in mathematics in high school if they intend to study business in college.

This paper contains several limitations that influence the potential generalization of its findings. First, the average effect is only a causal effect if there are no other unknown confounders. Although we have made attempts to control for some known confounders when considering the effect of on-campus living, there may be other unknown confounders such as family background and family income. However, applying the causal analytics could help researchers to approach the true effect size of specific key performance indicators.

ABSTRACT

This paper considers the problem of scheduling jobs in a no-wait flow shop with the objective of minimizing total earliness and tardiness. Several dispatching heuristics that have been used previously for other environments were modified for use in no-wait flow shops. These heuristics were tested under a variety of conditions. It was found that two of the heuristics consistently perform best.

KEYWORDS: Scheduling; Heuristics; No-Wait Flow Shop; Earliness and Tardiness

INTRODUCTION

Scheduling problems with the objective of minimizing total earliness and tardiness have gained increased attention during the past four decades. A key reason for this is the adaption of supply chain management in which customers and suppliers have tried to have better coordination in their operations. This causes the early and tardy delivery of products to be viewed as poor quality service. Early deliveries result in unnecessary inventory that requires space, cash and resources needed to maintain and manage the inventory. Lost sales and the loss of customer good will are penalties that are the result of tardy delivery of products. This paper addresses this trend by considering an objective that sums the penalties for earliness and tardiness for a set of jobs to be processed in a no-wait flow shop.

A flow shop is a production shop which consists of two or more machines. In a flow shop each of the jobs to be processed uses the machines in the same order. In a no-wait flow shop once a job starts processing it must continue through the flow shop without any intermediate waiting. In some cases the nature of the product is such that the no-wait restriction is a requirement. In many cases organizations are adopting a lean production philosophy and want to minimize waste by not having any waiting between the machines. When jobs do not have to wait between the machines there is no in-process inventory and space is not wasted.

The objective in this problem is non-regular, therefore the insertion of idle time into a schedule could help to reduce the earliness of some jobs and thus improve the objective. In a no-wait flow shop there could be idle time on any of the machines but if additional idle time (unforced idle time) was to be used in the no-wait flow shop environment it would have to occur on the first machine because the storage of jobs is not allowed in between the intermediate stages. There are production environments, however, where the insertion of unforced idle time may not be productive. (Korman, 1994; Landis, 1993) provide specific examples of the undesirability of unforced idle time. For instance, idle time should be avoided when the capacity of the shop is limited when compared with the demand. Also, idle time should not be inserted when the machine has a high operating cost, and / or when starting a new production run involves high

setup costs or times. In this research only schedules without unforced inserted idle time are considered.

LITERATURE REVIEW

Research that is relevant to our problem is scheduling with earliness and tardiness penalties, scheduling flow shops with earliness and tardiness penalties and scheduling in a no-wait flow shop with these penalties.

Literature Review of Earliness and Tardiness

Many papers have been published that consider earliness and tardiness penalties. The first comprehensive survey that covered the early papers dealing with early/tardy scheduling was provided by (Baker and Scudder, 1990). (Hoogeveen, 2005) provides a survey of multicriteria scheduling which includes more recent research on problems with earliness and tardiness penalties. The single machine environment has the greatest amount of research early/tardy objective. (Valente, 2009) summarized more recent research for single machine environments with no idle time and an early/tardy objective. (Kanet and Sridharan, 2000) reviewed scheduling models when inserted idle time is allowed. Several of the papers consider how idle time can be inserted optimally in a given sequence for the single-machine problem. (Fry et al., 1987) were the first to address this problem. They formulated the problem as a linear program. Special characteristics of the problem were used by (Davis and Kanet, 1993) and (Yano and Kim, 1991) to develop more efficient timetabling procedures. Branch-and-bound procedures were developed by (Davis and Kanet, 1993; Kim and Yano, 1994; and Schaller, 2007) for the single-machine problem for finding an optimal sequence and schedule. Dominance conditions were developed for the single-machine problem with inserted idle time by (Kim and Yano, 1994; Szwarc, 1993; and Schaller, 2007) in order to eliminate partial sequences within a branch-and-bound algorithm.

Literature Review of Flow Shop Earliness and Tardiness

We know of nine papers that investigate flow shop environments with objectives that consider earliness and tardiness costs. In none of these cases was the flow shop a no-wait flow shop.

(Zegordi et al., 1995; and Rajendran, 1999) were the earliest papers. (Zegordi et al., 1995) considered a permutation flow shop with the objective of minimizing the sum of weighted earliness and tardiness and presented a simulated annealing algorithm for the problem. (Rajendran, 1999) considered scheduling a kanban flow shop with the objective of minimizing the sum of weighted flowtime, weighted tardiness and weighted earliness of the kanban containers and presented heuristics for the problem.

An optimal procedure was presented by (Moslehi et al., 2009) for minimizing the sum of maximum earliness and tardiness in a two-machine flow shop. The problem of scheduling a permutation flow shop with earliness and tardiness penalties when all the jobs have a common due date was investigated by (Chandra et al., 2009). Branch-and-bound algorithms were presented by (Madhushini et al., 2009) for a variety of objectives including minimizing earliness and tardiness.

A genetic algorithm was proposed by (Schaller and Valente, 2013b) and was compared with five other neighborhood search and metaheuristics for a permutation flow shop to minimize total earliness and tardiness. A variable neighborhood search heuristic was developed by (M'Hallah ,2014; and Fernandez-Viagas et al., 2016) developed a constructive heuristic and local

searches for the problem (Schaller and Valente, 2013b) investigated. (Schaller and Valente, 2013a) incorporated family setups into the permutation flow shop problem to minimize total earliness and tardiness. Several metaheuristics were compared for this problem and it was found a genetic algorithm worked best.

Literature Review of No-Wait Flow Shops

To the best of our knowledge there have been no papers that have addressed the problem of minimizing total earliness and tardiness in a no-wait flow shop. However, there has been a great deal of research on scheduling problems in the no-wait flow shop environment. A review of early work was provided by (Hall and Sriskandarajah, 1996). Much of the research dealt with objectives that were measures of efficiency such as minimizing makespan or flowtime. Recent research with an objective of minimizing makespan includes (Pan et al., 2008; and Laha and Chakraborty, 2009). For the flowtime objective, (Framinan et al., 2010 and Gao et al., 2011) are recent examples. There has been increased research in recent years on objectives that measure the shop's ability to meet due dates and include tardiness in the objective. Minimizing total tardiness is similar to our objective but does not penalize the early completion of jobs. (Aldowaisan and Allahverdi, 2012; Liu et al., 2013; and Ding et al., 2015) are recent examples of research for minimizing total tardiness in no-wait flow shops.

THEORETICAL DEVELOPMENT/MODEL

Formally, suppose there is a set of n jobs to be processed in a no-wait flow shop with M machines. Let d_j be the due date of job j $(j = 1, \ldots, n)$. Let p_{jm} and C_{jm} represent the processing time and completion time of job j $(j = 1, \ldots, n)$ on machine m $(m = 1, \ldots, M)$. The earliness of job j, E_j, is defined as: $E_j = max\{d_j - C_{jM}, 0\}$, for $j = 1,\ldots, n$ and the tardiness of job j, T_j, is defined as: $T_j = max\{C_{jM} - d_j, 0\}$, for $j = 1,\ldots, n$. The objective function, Z, can be expressed as:

$$Z = \sum_{j=1}^{n} E_j + T_j. \quad (1)$$

In this paper we only consider no-wait flow shops. A permutation flow shop is a flow shop in which the order the jobs are processed remains the same on each machine. Therefore no-wait flow shops are also permutation flow shops so a solution is defined by determining the sequence of processing the jobs that need be processed in the flow shop. Also, for each pair of jobs it can be determined how much idle time is needed on the first machine between the finish time, on the first machine, of the job sequenced first and the start time, on the first machine, of the job sequenced second. This time is the same regardless of where the pair of jobs appears in the sequence so it can be calculated before sequencing jobs. Once a start time for a job is determined, its completion time on the final machine is easy to determine as we only need to add the sum of the job's processing times to its start time. We refer to this time as the delay or offset time and use OS_{jk} to denote the offset time needed on the first machine if job j is sequenced immediately after job k for job j not to wait at any of the machines. A dummy job 0 is used to take into consideration that a job may be first in a sequence and $OS_{j0} = 0$ for j = 1, …, n. For a given sequence of jobs in which the job to be sequenced in position j is denoted as $[j]$, the completion time of job $[j]$ on machine M will determine the earliness or tardiness of the job in position j of the sequence. The completion time:

$$C_{[j]M} = C_{[j-1]1} + OS_{[j][j-1]} + \sum_{m=1}^{M} p_{[j]m} \text{ , where } C_{[0]1} = 0 \quad (2)$$

To calculate the offset time between a pair of jobs j and k when job j is to immediately follow job k (OS_{jk}) we can use the following.

$$OS_{jk} = \max_{m=1,\ldots,M-1} \{\sum_{l=1}^{m} p_{kl+1} - \sum_{l=1}^{m} p_{jl}\} \quad (3)$$

DISPATCHING HEURISTICS TESTED

Several heuristics were tested for the problem. All of the heuristics tested are either variants of heuristics used in other environments or were motivated by heuristics used in other environments but were modified for the no-wait flow shop environment.

In the heuristics that follow let S be the current partial schedule and $C_{jM}(S)$ be the completion time of job $j \notin S$ if j is scheduled at the end of S. Let $s_j(S)$ be the slack of job $j \notin S$ if j is scheduled at the end of S, where $s_j(S) = d_j - C_{jM}(S)$. Additionally, let $t_1(S)$ be the current availability time of machine 1 under schedule S. This is the time the last job in schedule S completes its processing on the first machine. For convenience, the current time on the first machine will also be denoted by t, so $t = t_1(S)$. Finally, let $P_j(S) = C_{jM}(S) - t$ be the total time (total processing time plus any idle time on the first machine between the completion of the preceding job and start of job j on the first machine) between the completion of the last job in the schedule S on the first machine and finish of job $j \notin S$ on the final machine if j is scheduled at the end of S.

Simple Dispatching Heuristics

Four simple dispatching heuristics are considered: earliest due date (EDD), modified due date (MDD), minimum slack rule (SLK), and minimum slack per work (SLK/P).

The earliest due date (EDD) rule was first proposed by Jackson (1955). This rule schedules the jobs in non-decreasing order of their due dates d_j.

In the modified due date (MDD) heuristic (Baker and Bertrand, 1982; Vepsalainen and Morton, 1987), at each iteration we select the job with the minimum value of the modified due date.

$$MDD_j(S) = \max\{d_j, C_{jM}(S)\} \quad (4)$$

The minimum slack (SLK) rule (Panwalkar & Iskander, 1977; Vepsalainen & Morton, 1987) chooses, at each iteration, the job with the minimum slack:

$$s_j(S) = d_j - C_{jM}(S) \quad (5)$$

The minimum slack per required time (SLK/P) (Panwalkar & Iskander, 1977; Vepsalainen & Morton, 1987) selects, at each iteration, the job with the minimum value of the ratio:

$$SLK/P_j(S) = s_j(S)/P_j(S) \quad (6)$$

Dispatch Rules with More Advanced Indexes

In this section we present dispatching rules that utilize priority indexes that consider a variety conditions that may be present. The indexes in these rules have multiple branches to allow for flexibility to respond to conditions.

LIN-ET Rules (LIN1 and LIN2)

The first two rules are based on the LIN–ET procedure proposed in (Ow & Morton, 1989) for the weighted single machine problem. These rules, which will be denoted by LIN1 and LIN2, choose, the job to be selected for the iteration, the job with the largest value of the following priority indexes:

$$LIN1_j(S) = \begin{cases} \frac{1}{P_j(S)} & if \quad s_j(S) \leq 0 \\ \frac{1}{P_j(S)} - \frac{s_j(S)}{slk\_thr} \times \frac{2}{P_j(S)} & if \quad 0 < s_j(S) < slk\_thr \\ -\frac{1}{P_j(S)} & if \quad s_j(S) \geq slk\_thr \end{cases} \tag{7}$$

and

$$LIN2_j(S) = \begin{cases} \frac{1}{P_j(S)} & if \quad s_j(S) \leq 0 \\ \frac{1}{P_j(S)} - s_j(S) \times \left(\frac{1}{slk\_thr \times P_j(S)} + \frac{1}{P_j(S)} \right) & if \quad 0 < s_j(S) < slk\_thr, \\ -\frac{s_j(S)}{P_j(S)} & if \quad s_j(S) \geq slk\_thr \end{cases} \tag{8}$$

where slk_thr, which stands for “slack threshold”, is a parameter meant to represent a value such that slacks which are greater or equal to that value are considered large.

In the first branch of the priority index, identical in both heuristics, a job is late or on time if scheduled next. When one or more such jobs exist, LIN1 and LIN2 select the job using a shortest time rule, in line with various heuristics for earliness and tardiness problems (Kenneth R. Baker, 1974; Ow & Morton, 1989; Smith, 1956). Here the shortest time refers to a job’s cumulative processing time plus the idle time on the first machine to ensure the job does not have to wait between machines.

In the third branch, the job has a large slack, and is quite early. If all jobs are quite early, LIN1 chooses the job using a longest time rule, again in line with several heuristics for early/tardy problems (Ow & Morton, 1989; Valente, 2007; Valente & Alves, 2005). LIN2, on the other hand, selects the job with the minimum slack per required time. Finally, the middle branch performs a linear interpolation between the priority values corresponding to $s_j(S) = 0$ and $s_j(S) = slk\_thr$. Such an interpolation was first performed in the LIN–ET procedure (Ow & Morton, 1989).

The slk_thr parameter is calculated as follows. At each iteration, representing a partial schedule S with k jobs, the slack threshold is set equal to

$$slk\_thr = w * (C_{\max}^{LB} (S) - t), \quad (9)$$

where $C_{\max}^{LB} (S)$ is a lower bound on the completion time of the last job on the final machine (makespan), given the current schedule S, and $0 \leq w \leq 1$ is a user-defined parameter. To calculate this lower bound we first obtain a lower bound on the completion of processing on the first machine of the unscheduled jobs and then add to this time the minimum cumulative processing time on machines two through M. To find the lower bound for completion on the first machine we sum the processing times on the first machine of the unscheduled jobs and add this to t ($t + \sum_{j \notin S} p_{[j]1}$). This lower bound is weak because the offset times of the unscheduled jobs is not included. To strengthen this lower bound we find the lowest offset time for each unscheduled job if it is not scheduled next ($\min\{OS_{j \notin S, l \notin S}\}$ and sum the n – k – 1 of these times and add to this the minimum offset time among the unscheduled jobs if scheduled next. The lower bound on the offset times is then added to the lower bound above to obtain a lower bound on the completion time on the first machine. We then add the minimum among the unscheduled jobs of the cumulative processing time for machines two through M to obtain a lower bound on the makespan.

The procedures formed using these indexes are referred to as LIN1 and LIN2 in this paper.

A heuristic based on Fernandez-Viagas et al. (2016)'s Constructive Heuristic

A constructive heuristic for permutation flow shops when waiting is allowed between machines was developed by Fernandez-Viagas et al. (2016). In this heuristic a sequence is built from the beginning to the end by adding one job at a time to a partial sequence. An index is used to select the next job to be added to the partial sequence. During an iteration of the procedure the problem is classified according to the due dates of the jobs that remain to be sequenced into one of three cases: 1) tight due dates, 2) loose due dates, 3) due dates that are not tight or loose. Based on this classification the index used to select the next job changes.

To help define the classifications, if k jobs have been scheduled (kth iteration) let NT_k be the number of jobs from the unscheduled set (n – k) that would be tardy if scheduled next. Let NE_k be the number of jobs from the unscheduled set that would have an earliness that is greater than (n – k) * c if scheduled next, where c is a user defined parameter. The classifications are as follows. 1) Tight due dates – if the fraction of tardy jobs is greater than a, where a is a user defined parameter:

$$NT_k/(n - k) \geq a \quad (10)$$

2) Loose due dates – this case is divided into two subcases:
Subcase A) if there are at least four jobs still to be scheduled (n – k > 3), all the unscheduled jobs will be early if scheduled next, and $NE_k = n - k$.
Subcase B) there are at least four jobs still to be scheduled (n – k > 3), all the unscheduled jobs will be early if scheduled next, and:

$$b * (n - k) \leq NE_k < n - k \quad (11)$$

where b is a user defined parameter.
3) If the above criteria are not met than the due dates are not tight or loose.

Let EI_{jk} be the index for job j if scheduled next. Each time a job is to be selected, the job with the lowest index among the unscheduled jobs is selected. Let E_{jk} equal the earliness of job j if scheduled next. In the original Fernandez-Viagas et al. 2016 heuristic a variable is used to calculate the weighted idle time of the candidate jobs. We modify this heuristic by using the idle time on the first machine for each unscheduled job if scheduled next. Let IT_{jk} be the idle time on the first machine of the candidate jobs if scheduled next (in the $k+1^{st}$ position):

$$IT_{jk} = OS_{j[k]} \tag{12}$$

The indexes are:
1) Tight due dates.

$$EI_{jk} = (n - k - 2)/4 * IT_{jk} + C_{jM} \tag{13}$$

2) Loose due dates
Subcase A) Extremely loose due dates.

$$EI_{jk} = -(n - k - 2)/4 * IT_{jk} - C_{jM} \tag{14}$$

Subcase B) Moderately loose due dates.

$$EI_{jk} = -(n - k - 2)/4 * IT_{jk} - C_{jM} + E_{jk} \tag{15}$$

3) Due dates are not tight or loose. $EI_{jk} = E_{jk}$.

The procedure formed using this index is referred to as FV in this paper

COMPUTATIONAL TEST

The proposed algorithms are tested on randomly generated problems of various sizes in terms of the number of jobs and number of machines and under various conditions of due date range and tightness.

Data and Performance Measures

The dispatching heuristic procedures described in section three were tested on problems of various sizes in terms of the number of jobs and number of machines for nine sets of distributions of due date range and tightness. Each problem set consists of 10 problems. The problems within a problem set have the same number of jobs and machines, and the due dates for the jobs are generated using the same distribution. Eight levels of number of jobs (*n*) to be scheduled were tested: *n = 15, 20, 25, 30, 40, 50, 75* and *100*. Three levels of number of machines (*M*) were tested: *M = 5, 10* and *20*. The processing times of the jobs for each machine were generated using a uniform distribution over the integers 1 and 100. The due dates for the jobs were also randomly generated using a uniform distribution over the integers *MS (1 – r –*

R/2) and *MS (1 – r + R/2)*, where *MS* is an estimated makespan found for the problem using the makespan lower bound proposed in Taillard (1993), and *R* and *r* are two parameters called due date range and tardiness factors. Three levels of due date range (*R*) were tested: *R = 0.2, 0.6* and *1.0* and three levels of due date tightness (*r*) were tested: *r = 0.0, 0.2* and *0.4*. These levels of *R* and *r* result in nine sets of due date parameters for each *n* and *M* combination.

A second set of 10 problems for each of the sets of parameters described above were created to use in preliminary tests to determine the parameter w for the LIN1 and LIN2 procedures. This parameter is multiplied by the estimated makespan to create the slack threshold (*slk_thr*). Based on these experiments a value of w = 0.6 was selected for LIN1 and w = 0.5 was selected for LIN2. The values selected for the FV procedure were a = 0.90, b = 0.75, and c = 300.

The procedures were coded in Turbo Pascal and were tested on a Dell Inspiron 1525 GHz Lap Top computer. The measure of performance used to evaluate the dispatching procedures for the problems is percentage deviation (*% Dev*) of the total earliness and tardiness of the solution generated by each procedure from the total earliness and tardiness generated by the EDD procedure.

$$\% \ Dev = [(Z_h - Z_{EDD})/ Z_{EDD}] * 100 \quad (16)$$

where Z_{EDD} = the total earliness and tardiness of the solutions generated by the EDD procedure, and Z_h = the total earliness and tardiness of the solutions generated by the dispatching heuristic procedures (MDD, LIN1, LIN2, SLK, SLKP, FV). The EDD procedure would always have a % Dev equal to 0.00 so it is omitted. The results of this test are described in the next section.

Results of the Test

Tables 1, 2 and 3 show the *% Dev* for each procedure for each level of number of jobs to be sequenced (*n*) as well as the averages across all the levels of jobs. Table 1 shows the results for *M =5*, table 2, for *M = 10* and table 3, for *M = 20*.

	Procedure					
n	MDD	LIN1	LIN2	SLK	SLKP	FV
15	-26.17	-23.48	-20.33	17.17	7.91	-15.90
20	-26.18	-22.83	-20.82	15.88	4.55	-16.29
25	-28.44	-26.47	-23.12	16.05	2.49	-21.29
30	-28.79	-26.22	-23.81	19.31	2.22	-20.77
40	-29.20	-27.37	-25.65	18.70	-2.38	-23.02
50	-30.81	-28.80	-27.26	19.48	-5.59	-27.26
75	-32.51	-31.19	-28.78	19.33	-10.31	-26.53
100	-33.47	-32.69	-30.28	19.79	-12.83	-28.57
Ave.	-29.45	-27.38	-25.01	18.21	-1.74	-22.45

The results show that the LIN1 procedure had the lowest average *% Dev* for M = 5 and the MDD procedure had the lowest average *% Dev* for M = 10 and 20. The LIN1 and MDD procedures were either first or second best for all combinations of n and M. These procedures were the only procedures to have an average deviation that was more 10% below the EDD solution for of the combinations of n and M. The LIN2 procedure had the third best average *% Dev* for all the combinations of n and M and had an average deviation that was more than 10% below the EDD solution for all the problem sizes with the exception of n = 15 and M = 5. The FV procedure also generated better solutions than the EDD procedure for all of the combinations of n and M. The SLK and SLKP procedures performed the poorest. For all of the combinations of n and M the SLK procedure had a positive % DEV and SLKP procedure had a positive % DEV for n < 30.

In order to show the effect of the due date range (*R*) and tardiness factor (*r*) on the results tables 4 and 5 are presented. Table 4 shows the *% Dev* by due date tardiness factor (*r*) for *n = 50* and *M = 10*.

Table 4. % deviation from the EDD solution by *r* for *n = 50* and *M = 10*.						
	Procedure					
r	MDD	LIN1	LIN2	SLK	SLKP	FV
0.0	-22.32	-21.11	-17.02	20.25	-0.22	-13.84
0.2	-28.85	-27.10	-23.42	21.11	-4.82	-16.86
0.4	-31.86	-31.76	-27.85	17.24	-9.85	-21.89

The results by due date tardiness factor (r) show that the MDD and LIN1 procedures performed the best for each level of r for this setting of n and m. The two procedures had fairly close performance. It appears that the performance of both procedures improves as r increases.

Table 5 shows the *% Dev* by due date range factor (*R*) for *n = 50* and *M = 10*.

Table 5. % deviation from the EDD solution by *R* for *n = 50* and *M = 10*.						
	Procedure					
R	MDD	LIN1	LIN2	SLK	SLKP	FV
0.2	-23.71	-21.70	-19.65	23.83	-9.01	-14.01
0.6	-28.21	-27.21	-22.69	15.45	-4.14	-19.06
1.0	-31.10	-31.07	-25.95	19.32	-1.74	-19.52

The results show that the MDD and LIN1 MDD procedures were the best procedures for each level of R. The performance of the both procedures was fairly close for all the levels of R. It appears that the performance of both procedures improves as R increases.

CONCLUSION

In this paper seven dispatching heuristics were proposed for minimizing total earliness and tardiness in no-wait flow shops. These procedures were tested on problems of various sizes in terms of the number of jobs and machines, and nine sets of distributions that determine the tightness and range of due dates. All of the procedures are very efficient and were able to generate solutions quickly for all the problem sizes tested.

The results showed that the two procedures, MDD and LIN1 were the consistently top performing procedures and are recommended.

A future area of additional research would be developing additional dispatching procedures that generate better solutions for the problem. An improvement could also be developed that can be applied to the dispatching heuristics and could also form the basis for the development of metaheuristics for the problem.

ABSTRACT

This research-in-progress develops and empirically tests a model of country level e-government adoption. In doing so, it bridges important gaps in the literature. Factors such as accountability, quality of governmental policies, effectiveness of law, and corruption are included in our model to examine their influence on country level e-government adoption. Secondary data collected from 163 countries are used to empirically examine the hypotheses presented in the study. The hypotheses are confirmed using PLS analytical procedures and the findings are reported. We discuss the results and their implications for researchers and practitioners.

KEYWORDS: Electronic Government, Adoption, Corruption, and Cross-country

INTRODUCTION

E-government is defined as, “the use of information and communication technologies (ICTs) to improve the activities of public sector organizations” (Merhi, 2016). These tools are used to increase transparency and accountability between government agencies and public administrations and the people (Merhi and Koong, 2015). E-government systems facilitate easier access to information, services, and the governing practices of those in position of power (Al-Hujran et al., 2015). E-government is more prominent in developed countries while developing countries begin adapting to the change. Some benefits of e-government adoption may include, increased levels of convenience, decrease costs which can lead to growth in revenue, and decrease time and effort associated with e-services (Lu and Nguyen, 2016). E-government also has a positive effect on the infrastructure of a country. Increasing efforts in e-government development and effectiveness leads to technological innovations, and employment opportunities, thus increasing economic prosperity within the country (Hassan, 2017). Previous studies have shown that e-government can positively influence control of corruption, economic growth, and efficiency (Hasan, 2017). However, these potential benefits can only be achieved if the system of e-governance is implemented properly. For successful implementation a certain level of transparency and trust must be mutually assured from both the governing body and the citizens.

Even with all the benefits that come along with e-government adoption, many countries face barriers to its implementation, even at the lowest level (Al-Hujran et al., 2015). This research-in-

progress investigates the impact of macro-level factors on e-government adoption. These factors are: accountability, quality of governmental policies, effectiveness of law, and corruption. To our best knowledge, the impact of these factors have not been examined in the current literature. Thus, this research fills a gap in the literature and adds to the body of knowledge.

E-government is an international phenomenon that continues to be more and more appealing to countries worldwide. The United Nations E-Government Survey for 2016 shows that 148 countries are providing at least some form of transactional service online (UN E-Government Survey). This topic has become increasingly more relevant since the number of Internet users has increased over seven-fold in the last 15 years, reaching over 3.2 billion (Davidson, 2016).

This study examines secondary data gathered from 163 different countries. Our objective is to investigate the factors that affect a country's e-government adoption.

LITERATURE REVIEW

In literature, the primary variable used to analyze e-government within a country is the e-government development index, which is used to measure ability, and how willing a country's administration is to adopt ICTs with the intent deliver information and services to the public (Kosenkov, 2015). Another measure used is the e-participation, which is used to encourage the public to engage in the use of ICTs (Merhi and Koong, 2013). Government effectiveness measures the effectiveness of the government's actions based on the, level of quality of publics services and civil services, quality of policy formulation and implementation as well as government's overall commitment to these policies (Kaufmann et al., 2006). We use e-government development index as our dependent variable to measure adoption of e-government systems.

While the adoption of e-government by countries is increasing, the rates vary. Researchers (Pavlou 2003; Rose and Straub 2001, Mahmood et al. 2004) found that the adoption of e-governments by consumers is hindered by:

- Lack of efficiency and effectiveness of policies and rules,
- Need of infrastructure that supports these systems,
- Low e-maturity levels,
- Low level of education, and
- Government policies.

Studies that investigated the effects of country-specific factors on the adoption of e-services point to significant differences in e-government adoption between countries and that country-level factors may influence adoption rates. For instance, researchers (Ferguson and Yen 2006; Javalgi and Ramsey 2001; Zhu and Thatcher 2010) have shown that government policies, supportive legal environment, compatible socio-cultural infrastructure, ICT infrastructure, culture differences have impact on e-commerce adoption. We argue that these factors may also influence e-government adoption.

RESEARCH MODEL

The adoption and the use of e-government vary across countries because the institutional and resource environments in a country can influence the e-government adoption rates. In particular, it is proposed that a country's environment factors, namely accountability, quality of governmental policies, effectiveness of law, and corruption impact e-government adoption.

E-government implementation and acceptance within a country depends on the political stability of the government within a country. When citizens have the right to elect government officials, and the power to hold them accountable for their actions, the country has a democratic environment (Gallego-Alvarez et al., 2010). The more politically stable a government is, the more accepting its citizens will be to adopt new ICTs and other benefits of e-government. We hypothesize that an increase in voice and accountability will have a positive effect on e-government.

H1: Accountability positively impacts on e-government adoption.

Regulatory quality is measured by the ability of a country's government to implement policies and regulations that help promote the development of the country (Krishnan and Teo, 2012). Due to e-government typically allowing easier access to government resources, we hypothesize that regulatory quality will have a positive effect on e-government.

H2: Policies with high quality positively impact e-government adoption.

The rule of law stems from a country's use of laws to govern. World Bank describes Rule of Law as a measure that "...captures perceptions of the extent to which agents have confidence in and abide by the rules of society, and in particular the quality of contract enforcement, property rights, the police, and the courts, as well as the likelihood of crime and violence" (World Bank, 2017). We hypothesize that rule of law will have a positive effect on e-government.

H3: Effectiveness of law and rules positively impacts e-Government adoption.

Corruption is one of the biggest barriers to e-government adoption; furthermore, if control of corruption increases, it should be easier for e-government efforts to increase (Anderson, 2008). We hypothesize that reducing the impact that corruption has on e-government will increase the likelihood of e-government adoption within the country, and that control of corruption has a positive effect on e-government.

H4: Corruption negatively impacts e-Government adoption.

These research hypotheses are depicted in Figure 1.

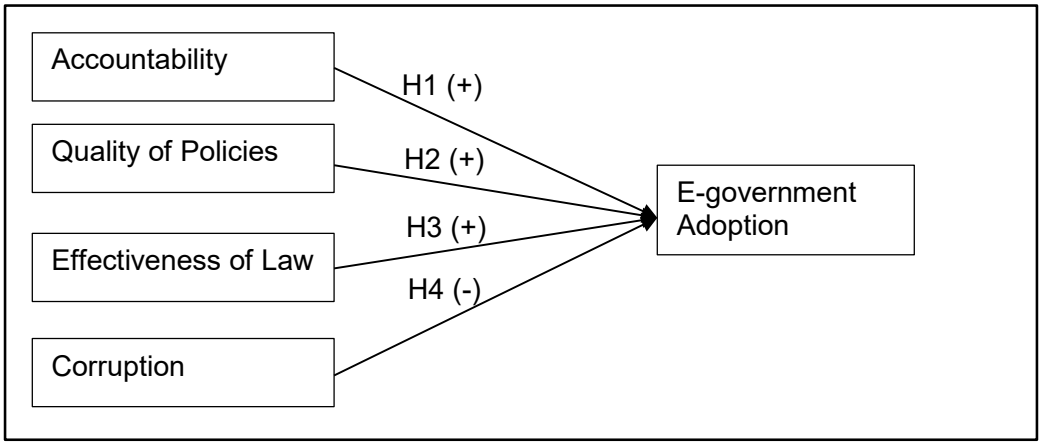

Figure 1: Research Model: E-government adoption and its antecedents

METHODOLOGY

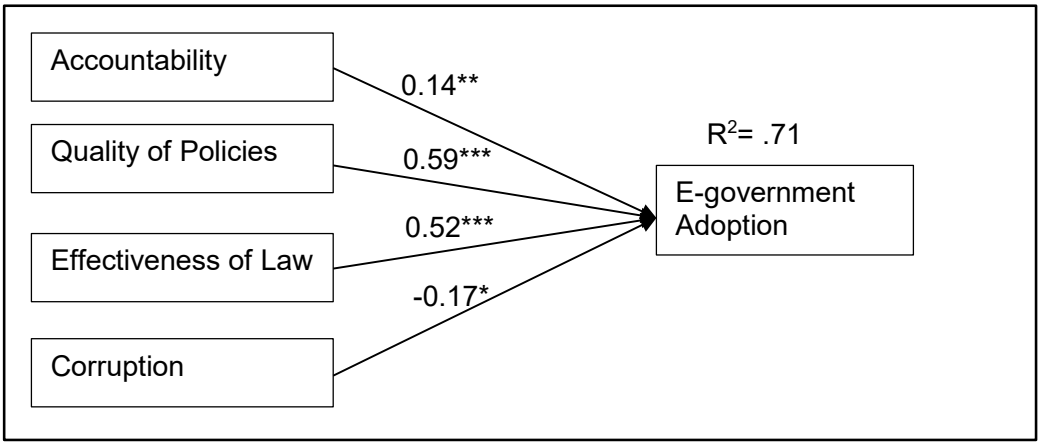
Data

Our original data consist of 193 countries from the UN E-government Knowledge Database. The datasets used come from the Transparency International 'Corruption Index 2016', The 'UN E-government Survey 2016', and the 'Worldwide Governance Indicators 2016'. After collecting the data on all the countries, we narrowed our selection to countries who had significant data on all variables, which brought our final count to 163 countries. The dependent variable is e-government, the independent variables are accountability, quality of governmental policies, effectiveness of law, and corruption, and the control variables are population and GDP.

Analysis and Results

The data were analyzed using descriptive statistical analytic procedures followed by testing the path model using SmartPLS software. The descriptive statistics are not included in this paper but will be presented at the conference. We are expecting to have more progress on this project by then and will present our findings at the meeting. Results of the paths are presented in Figure 2.

The collected were examined for potential outliers and normalization. We found no outliers and that our data were normal across all variables.



***: significant at 0.001 level; **: significant at 0.01 level; *: significant at 0.05 level

Figure 2: Results

The results of PLS analysis show that all hypotheses are supported. We posited that higher accountability level of citizens, higher qualities of governmental policies, and effective rules increase the level of adoption of e-government. We also hypothesized that lower level of corruption increases the adoption the level of e-government adoption.

IMPLICATIONS & CONCLUSION

The ever-increasing adoption of E-Government amongst varying governmental agencies has led to many studies that measure the effects E-Government has on countries and their citizens. This research-in-progress is an attempt to construct a model that depicts the relationships between country-level factors and e-government adoption and empirically test it. This study contributes to the literature in two important ways. Although researchers have studied the effects of country-factor on e-government, no study has yet investigated the impact of the selected factors used in this study. Thus, this research adds to the literature by introducing new factors, namely accountability, quality of governmental policies, effectiveness of law, and corruption. Second, empirically investigating the relationships, postulated between the macro-level factors and e-government adoption, using data from a relatively large number of countries.

This research offers some implications for policy makers. By identifying the factors that are related to the general environment, specifically the factors listed above, in a country, decision makers in governments can help improve the national development of their countries and get the best benefit out of e-government. E-government may provide governments, citizens, and commercial organizations with numerous benefits such as cost savings and convenient way to access and submit data to governments, transparency, interoperability which improve the societies. These benefits may in turn affect the national economy since organizations and citizens compose a big part of the economy.

The outcomes reported in this research-in-progress are confined to the secondary data. Second, this study examines the relationships of four macro-level factors and e-government adoption. Many other determinants have been found to also influence e-government adoption and diffusion. However, the variables used in this study have been found to be both stable and useful in describing the phenomenon. We are hoping to get feedback from the reviewer and the attendees at the conference to improve and continue this research.

ABSTRACT

This study proposes a decision-tree based e-visit classification approach (DTEVCA) to identify clinic visits as e-visits using the clinics' medical records and patients' demographic data. The efficiency and validity of the DTEVCA are verified using a large data set and the results indicate that this approach can accurately classify clinic in-office visits that could switch to e-visit services. This study can help the countries that have not yet implemented e-visits to improve the policy formulation process. The concept of this study is feasible not only for e-visit services but also for other new products or new policies.

KEYWORDS: E-Visit, Healthcare Analytics, Data Classification, Decision Tree, Healthcare Insurance Data Mining

INTRODUCTION

An e-visit represents a novel health care service, providing an online consultation platform for patients and physicians to communicate in a synchronous manner, which means that patients can consult physicians via real-time video conferencing technology (Kaufman, et al., 2009; Mehrotra, et al., 2013; Polinski, et al., 2016). Through e-visits, physicians make diagnoses, implementations, and prescriptions if necessary by asking patients' symptoms, inspecting patients' physical conditions, and checking patients' medical records.

Although some countries, i.e., the United States and Canada, have implemented e-visits for years (Gilman and Stensland, 2013; O'Gorman, et al., 2016), the implementation of e-visits is not in conformity with the medical laws and regulations in most of the Asia countries. In Taiwan, subjected to the related physician's act (Taiwan Legislative Bill, 2016), physicians must make the diagnosis, decide the intervention, and write out the prescription in person except for some rural areas and special cases permitted by the government.

To confront these aforementioned problems, adopting e-visits into the current medical system is a potential solution. E-visits allow patients to get health care online for nonemergency medical needs. Through information and communication devices such as computers or smart phones,

patients can have an online consultation with physicians instead of in-office visits (Hickson, et al., 2015). It can increase the rate of patient accessing to health care because patients can contact physicians with no limitation of fixed consulting hours and avoiding long travelling distances between home and the clinic (Nijland, et al., 2009). On the other hand, e-visit introduces more flexibility on scheduling of the medical workforce and decreases the burden of the clinic offering the in-office visits (Hickson, et al., 2015; Nijland, et al., 2009). In addition, e-visits are more efficient and effective compared to the in-office visits. Health care providers can serve the same quality of care at a lower cost by adopting e-visits that do not need bricks and mortar (Nijland, et al., 2009). E-visits can also lower the price for seeking health care since the cost of e-visits is only a small fraction of the cost of in-office visits (Rohrer, et al., 2010). Therefore, e-visits may be a promising solution to solve insufficient health care resource issues in many Asian countries, such as Japan and Taiwan.

However, e-visits are not the perfect solution because there presents some challenges before implementing e-visits. For instance, both health care providers and patients are worried about the reimbursement coverage of e-visits. A health care provider requires an adequate pay and a patient demands a reasonable price of an e-visit. One corresponding solution was that the medical insurance covers only under some situations, such as patients living in rural areas, to balance the cost. For another challenge, the scope of e-visits excludes certain medical conditions, such as emergency health problems and physical examinations; under these conditions, e-visits cannot substitute for in-office visits. Some inherent problems of in-office visits retain after implementing e-visits.

To solve the patient classification problem for reimbursing e-visits, the best approach is to use e-visit records to construct a classification model. However, there is no e-visit data in most of Asian countries since these countries have not implemented e-visits, yet. Therefore, the major issue of the e-visit classification problem is the lack of the target class attribute (whether the visits are e-visits or not) to train the classification model. To obtain the crucial target class label attribute for each clinic visit, this study proposes to assign the target class label based on the conclusion of three previous e-visit studies (Albert, et al., 2011; Mehrotra, et al., 2013; Polinski, et al., 2016).

Polinski et al. (2016) surveyed 1,734 patients using e-visits at a MinuteClinic in January-September, 2014. Mehrotra et al. (2013) compared e-visits and in-office visits at four practices in the Pittsburgh between January 2010 and May 2011. They examined two common conditions for e-visits: sinusitis and urinary tract infection (UTI). Albert et al. (2011) surveyed first users who were contacted within 6 months of the e-visits of UPMC's HealthTrak e-Visit system. The telephone interviews were completed in 2009 with 121 patients. The criteria found in these e-visit studies are: (1) the characteristics of patients who use e-visits in other countries; (2) the scope of e-visits from the opinions of the researchers in the related studies; and (3) the consideration of the local situation.

It is impossible to use the criteria to assign target class attribute directly due to the different formats of attributes between the criteria and the collected dataset; moreover, some studies in different countries may have contradicted results. Before generating the class label attribute, we have to perform three processes. First, we need to summarize the results and collect the classification rules from previous studies. Second, we need to make some justification of the classification rules from previous studies to fit the medical circumstance we are facing. Third, we need to preprocess the dataset to match the attributes of the classification rules from previous studies. After these three processes, we can apply the classification rules from previous studies to the dataset with the class label attribute to train the model to get the classification rules that fit

the medical circumstance we are facing. In conclusion, this study aims to build a decision-tree based classification model for the e-visits based on the demographic data and electronic medical record of patients for the countries where e-visits have not yet implemented.

PROBLEM DESCRIPTION

The aim of this study is to classify clinic visits into two classes: use and nonuse of e-visits, based on patients' demographic data and electronic medical records. This study assumes that a reliable medical record database exists, so how to collect data is not a concern in this study. The collected data is consist of *r* relation schemas. Each relation schema represents one topic of information, such as a patient, a medical institution, or a doctor visit record. The next step is processing the relation schemas to a dataset for classification. There are *n* tuples and each tuple represents the record of a visit in the dataset. A tuple has an *m*-dimensional attribute vector, representing the characteristics of a patient or a doctor visit. Each value of the vector measures one of the corresponding m database attributes, respectively. For example, the attributes may be gender, age, or education level in this study. For a more general case, each tuple should contain a class label attribute, which represents the inclination of using e-visits or not. Classification is a two-step supervised learning process. The first step builds a classifier by a training dataset, and the second step evaluates the classifier by a test dataset.

Based on the above description, there are three challenges in this study. The first challenge is to process data so that it is possible to derive a doctor visit dataset for classification from the collected data to build a classifier. The second is how to deal with the lack of the class label attributes. The last is to apply or modify a classification model with acceptable performance to obtain a set of clear, logical, and explainable classification rules, or in other words, to build a classifier.

For the first challenge, this study must handle some issues of a dataset because it is critical for the quality of classification results to depend on the quality of input data. The first issue is to deal with missing-value data. The second issue is the lacks of the expected data attributes in the whole dataset. For example, the travelling distance between the home and the clinic of each visit may be a significant attribute to determine if a patient uses e-visit or not, as shown in Mehrotra et al. (2013). In most cases, the distance data is not including in the dataset due to difficulty of data collecting. The third issue is to avoid random data errors, such as typos and conceals.

The fourth issue is the outliers in the dataset that significantly affect the classification results. The fifth issue is the inconsistency of data among relations. For example, the gender data is usually represented categorically by Male and Female, or sometimes by binary data, 0 and 1, in different relations. The sixth issue is the inadequate forms of the data, making them hard to be adopted in the classification model. For example, there may be birthday data of patients in some datasets but only birth year in others. The seventh issue is to consider two aspects of redundancy in attributes: removing the redundant attributes and dealing with the huge amounts of attributes that are impossible to be included all in the classification model. Lastly, a drawback of decision-tree algorithm is that the discretization of continuous variables in the separating processes may cause errors. Therefore, this study should carefully consider and exercise the process of data discretization before classification model building.

The second challenge is dealing with the class label attribute, also called, *Y*, in this study. For the countries where the e-visits have implemented, collecting the value of *Y* for each doctor visit is not a problem. The classification model can use the value of *Y* collected from the medical

institutions providing e-visits service directly. In contrast, for the countries where the e-visits have not implemented, how to assign a value of *Y* to each tuple for classification becomes a tough difficulty to tackle. This study faces the condition that there is no value of *Y* in some of the Asia countries because in these countries, health insurance does not reimburse patients for e-visits. Therefore, how to assign a value of *Y* is a critical problem before building a classifier for e-visits. To reduce the complexity of classification, this study assume that the value of *Y* is binary, representing use or nonuse of e-visits, or in other words, the class label attribute $Y \in \{N, Y\}$, where "*N*" is for nonuse and "*Y*" is for use.

The last challenge is to fit a classification model for e-visits with acceptable performance. In addition, the output of model has to accord with the expected result. Therefore, this study needs to consider some important issues. The first issue is choosing the most suitable decision-tree algorithm based on the overall picture of data. The second issue is to split the dataset into a training dataset and a test dataset. The third issue is specifying the node splitting criteria when building a decision tree. The fourth issue is to select the attribute for splitting when building a decision tree. The fifth issue is setting the stopping condition for splitting nodes. The sixth issue addresses the underfitting or overfitting problem. The seventh issue is estimating the accuracy of model. The last issue is to compare the performance among different models.

In summary, this study aims to solve the classification problem of identifying the e-visits. Three challenges are addressed: (1) to process data so that a dataset is sufficient to build a classifier; (2) to generate the class label attributes; and (3) to build a classifier that provide a set of clear, logical, and explainable classification rules.

THE DTEVCA

This study aims to classify clinic visits into two classes: use and nonuse of e-visits. In order to derive a set of clear, logical, and explainable rules, we propose a data classification approach called the Decision-Tree Based E-Visit Classification Approach (DTEVCA). The four major steps of the DTEVCA are: (1) data collection; (2) data preparation; (3) assigning the class label attribute, *Y*; and (4) model building. Firstly, we have to collect the demographic data and electronic medical records of patients. Then we preprocess the data to derive a visit dataset for classification. For the countries that have not yet implemented e-visits, the class label attribute, *Y*, is assigned to identify a visit as an e-visit or not. Lastly, the DTEVCA trains the decision-tree based classification model and summarize the classification rules.

To understand the characteristics of patients and the pattern of the medical behavior, we need to gather the demographic data and medical records. For the countries that have constructed the electronic medical database, we can obtain the data directly; otherwise, we can collect the data from the hospitals or clinics. In addition, the collected data should exclude patients under 18 years old, since they usually do not have the self-determination rights in medical care in most countries.

To derive a feasible dataset for classification, the steps for data preparation are cleaning, reduction, transformation, and integration. If the data is from different sources, we need to deal with the inconsistency problem of the dataset. Since the collected data may be from different sources or from one source maintained by different divisions, different attributes refer to the same meaning. We convert the different attributes in different datasets with the same meaning to the same single attribute. The visit dataset may contain many redundant attributes unrelated to the target class label attribute. To solve the redundancy problem and reduce the volume of the dataset, we need to remove the irrelevant attributes directly and use correlation analysis to detect

redundancy among the remaining attributes. Next, to solve the missing data problem, the way to fill the missing value of this attribute depends on the numerical attribute's distribution. If the attribute is approximately normally distributed, the missing value is assigned as the mean whereas if the attribute is extremely skewed, the missing value is assigned as the median. If the data type of an attribute is categorical, we assign the value of the mode class to the missing value.

Since the DTEVCA is a decision-tree based approach, the attribute tends to be split at a particular value of a numerical attribute without any explainable reason when training the model. Hence, we use the discretization to convert numerical data into categorical data. For taking account of rationality, the discretization method will follow some well-known standards or statistical criteria. For example, the age data can be divided into age groups based on the standard of UN or WHO. Other numerical data can use mean and standard deviation to determine the intervals.

In this study, we collect three experts' opinions. From the literature review, we choose the three researches related to e-visits as our experts' opinions. The first expert is the research of Polinski et al. (2016), called Expert 1 in the following discussion. The second expert is the research of Mehrotra et al. (2013), called Expert 2 in the following discussion. The third expert is the research of Albert et al. (2011), called Expert 3 in the following discussion.

In addition, we need to adjust the experts' opinions to make them more suitable to the countries that have not yet implemented e-visits since different countries have different situations and different patient distributions. For example, Mehrotra et al. (2013) studied e-visits in Pittsburgh of Pennsylvania in U.S. and found that the season is a significant factor of using e-visits. In other words, the usage of e-visits is higher in the winter than in the other seasons of the year. It can infer that the bad weather in the winter may increase the inconvenience of office visits. However, in the places such as Taiwan or other subtropical countries, the weather in the winter is completely different from Pittsburgh of Pennsylvania in U.S. and thus is not a significant factor to affect patients using e-visits. Therefore, we should adjust this expert's opinion if we want to apply it to the case in other subtropical countries.

According to the opinions of Expert 1, 2, and 3 (Albert, et al., 2011; Mehrotra, et al., 2013; Polinski, et al., 2016), DTEVCA generates three new attributes, Y_1, Y_2, and Y_3 to represent the classification results of the three experts, respectively. We assign the value of Y_1, Y_2, and Y_3 for the training dataset. In order to ensure the values of Y_1, Y_2, and Y_3 corresponding to the experts' opinions, we use the Chi-square test with significance level of 5% to compare the distributions of patients' characteristics. We then integrate the outcomes of each record by the majority rule to combine experts' opinions, which means that the visit is e-visit if half of experts' opinions are positive. In other words, for a tuple, if two or more Y_1, Y_2, and Y_3 are positive, the value of Y of this tuple will be positive. Lastly, the training dataset with Y_1, Y_2, Y_3 and Y is ready for training the expert classification models.

To build the e-visit classification model, we will follow three steps: (1) train several tree-based models by altering the parameters for better performances with the training dataset; (2) use the test datasets to assess the tree-based models generated in (1) by performance measurements; and (3) perform statistical techniques on performance measurements to select the best model. To build a decision-tree based model, it is important to choose proper attributes and criteria for node splitting. The parameters that we can choose include the attribute selection rules, node splitting criteria and stopping condition. The criteria for node splitting include information entropy, Gini index, misclassification error, etc. In addition, the way to split the nodes can be multi-way or binary way. We can set the stopping condition as the minimum data number of leaf nodes or the

maximum depth of tree levels. In the model building algorithm, we can also choose pre-pruning or post-pruning the tree to optimize the model. In this study, as the expert classification model, DTEVCA uses the well-known algorithms CART, C5.0, and Ctree.

We use four measurements to evaluate the performance of each model by the test data. First, we construct the confusion matrix to compare Y and Y' (the classified Y) to summarize the counts of true positive (TP), true negative (TN), false positive (FP), and false negative (FN). The four measurements, accuracy, recall (true positive rate), specificity (true negative rate), and precision are computed by the following formula.

The probability of being correct or Accuracy is computed as (TP + TN) / (FP + TN + TP + FN). Recall or true positive rate which can be computed as TP/(TP + FN), such that the denominator represents actual positive cases. Recall indicates an ability to identify the positive case of a model correctly, so higher Recall implies fewer Type-II errors have occurred when applying the model. Specificity, computed as TN/(FP + TN) or 1 – FP/(FP + TN), is the true negative rate and tells us how accurately our model will identify true negatives. Precision, computed as TP/(TP + FP) or 1 – FP/(TP + FP), is the exactness or percentage of tuples that the classifier labeled as positive that are actually positive. Precision tells us how accurately our model will identify true positives.

For each model, we will compute one set of measurement with accuracy, recall, specificity, and precision for each trial run of test dataset. If the DTEVCA builds decision tree models on a large collected dataset, it is suggested that the DTEVCA take 30 random samples as test data and thus there will be 30 sets of measurements with accuracy, recall, specificity, and precision for evaluation.

To distinguish which model has better performance, we use statistical tools such as *t* test or ANOVA test to compare the models. In addition, before applying the statistical tests, we should check all requirements of the tests. Taking a large collected data for example, there are 30 test datasets with 30 sets of measurements with accuracy, recall, precision, and specificity for each model. To compare the performance of accuracy, we gather all accuracy measurements of each model, and check the requirement condition of ANOVA test. We can then do the two-way ANOVA test for comparing three models by the accuracy measurements.

For the final model selection, we rank the priority of these four measurements. In this study, the distribution of Y is not expected to be extremely imbalance, so to accurately identify each object as positive and negative is very important. However, it is estimated that the number of negative counts is more than the number of positive counts and hence the count of true positive will be more influential than the count of true negative when analyzing the performance of classifiers. Moreover, the underestimate of the positive value is more serious than overestimate the positive value since the stability of the e-visit system is important. The underestimate may lead to system crashes. Hence, the priority of four measurements used to select the final best model is: (1) accuracy, (2) recall, (3) precision, and (4) specificity. Using the statistical tools and priority of measurements, we can determine the best tree-based model for the problem in this study and sum up a set of clear, logical, and explainable classification rules of identifying patients who should be reimbursed by insurance policy when adopting e-visits.

COMPUTATIONAL ANALYSIS

In this section, we implement the DTEVCA with the National Health Insurance Research Database (NHIRD) in Taiwan to demonstrate its feasibility. Moreover, we try to estimate the

possible usage of e-visits; though e-visits are not yet available in Taiwan. In addition, to show the relative merits of the DTEVCA, we design an experiment for comparison with two other binary classification algorithms: logistic regression (Cox, 1958) and random forests (Breiman, 1958) (a black-box algorithm). We implement the logistic regression and random forests algorithms by the packages stats (R Core Team, 2016) and random forest (Liaw and Wiener, 2002) in R (R Core Team, 2016).

The demographic data and medical records of patients are collected from the National Health Insurance Research Database (NHIRD) in Taiwan, provided by the National Health Research Institutes (2015). The NHIRD is a complete patient medical database because nearly 100% population in Taiwan was enrolled in the National Health Insurance Policy. The NHIRD not only spans decades but also contains the details of each doctor visit for each patient. In this study, to reduce the complexity, we only focus on one-year-period data in 2012. For some factors, we may use the data in the previous year (2011) as well. This study only covers the population above 18 years old and the doctor visits of western medicine. We exclude the population under 18, the visits of Chinese medicine, and dentistry at first. Since the data is from the same NHIRD database, there is no inconsistency problem. DTEVCA merges the related attributes into one visit dataset.

To assign values to the class label attribute, Y, we adopt the majority rule to combine three experts' opinions. First, we create attributes, Y_1, Y_2 and Y_3, according to the opinions of Expert 1 (Polinski, et al., 2016), Expert 2 (Mehrotra, et al., 2013) and Expert 3 (Albert, et al., 2011), respectively. However, the opinions obtained from these three experts may be inconsistent for some records and thus the DTEVCA determine the value of Y for each record by the majority rule to combine experts' opinions. Before applying the opinions of the experts to generate the values of attributes, Y_1, Y_2 and Y_3, we adjust some of experts' opinions according to the conditions in Taiwan, such as the medical insurance coverage factor and the bitter cold winter weather factor.

We then assign the values to the three attributes, Y_1, Y_2 and Y_3, according to the three experts' opinions and applicability. If the applicability of a visit is "N", the value of Y_1, Y_2 and Y_3 is "N." If the applicability of a visit is "Y", the values of Y_1, Y_2 and Y_3 follow the experts' opinions respectively. To confirm that the distributions of Y_1, Y_2 and Y_3 are corresponding to the experts' opinions, we apply Chi-square test to check the proportion of each rule and the positive value in Y_1, Y_2 and Y_3. Because the p-values are all larger than significance level 5%, we can confirm that the distributions all follow the rules of the experts' opinions. Finally, we use the majority rule to determine Y.

We build three decision tree models for the three experts respectively, by CART, C5.0, and Ctree, and assess the model by 10-fold cross-validation. To obtain the highest accuracy and the minimum number of nodes used in the rule to avoid overfitting problem, we should choose C5.0 as the algorithm to build these three experts' classification models. Then, we can apply these experts' classification models to classify the 30 test datasets to derive Y_1, Y_2 and Y_3. Lastly, we apply the majority rule to determine the value of Y.

To select the best final classification model from $\text{Tree}_{\text{CART}}$, Tree_{C50}, and $\text{Tree}_{\text{Ctree}}$, we use the 30 test datasets to evaluate these models and calculate the four performance measurements (accuracy, recall, precision, and specificity) for each model. Consequently, we will compare these performance measurements by statistical tools at the significance level 5%. First, we compare the accuracy measurements of these three models by two-way ANOVA and conclude that the accuracy performances of $\text{Tree}_{\text{CART}}$, Tree_{C50}, and $\text{Tree}_{\text{Ctree}}$ are different. We then compare the accuracy measurements for each pair of models by Tukey's multiple comparison test and

conclude that $Tree_{C50}$ = $Tree_{Ctree}$ > $Tree_{CART}$, which implies that though $Tree_{C50}$ is better than $Tree_{Ctree}$, the evidence is not strong enough to show the difference.

Second, we compare the recall measurements of these three models by two-way ANOVA and conclude that the recall performances of $Tree_{CART}$, $Tree_{C50}$, and $Tree_{Ctree}$ are different. We compare the recall measurements for each pair of models by Tukey's multiple comparison test and conclude that $Tree_{C50}$ = $Tree_{Ctree}$ > $Tree_{CART}$. Hence, though $Tree_{Ctree}$ is better than $Tree_{C50}$, the evidence is not strong enough to show the difference.

Third, we compare the precision measurements of these three models by two-way ANOVA and conclude that the precision performances of $Tree_{CART}$, $Tree_{C50}$, and $Tree_{Ctree}$ are different. By applying Tukey's multiple comparison test on the precision measurements for each pair of models, we conclude that $Tree_{C50}$ > $Tree_{Ctree}$ > $Tree_{CART}$. In other words, there is a strong evidence to show that $Tree_{C50}$ performs better than $Tree_{Ctree}$ based on the precision measurement. Finally, we can select $Tree_{C50}$ as the decision tree algorithm to generate our final e-visit classification model.

In the experiments, we compare the results of $Tree_{C50}$ to the results of logistic regression model (Cox, 1958) constructed by stats (R Core Team, 2016) and the random forests model (Breiman, 1958) built by randomForest (Liaw and Wiener, 2002) in R (R Core Team, 2016). For the logistic regression model, we first identify the multicollinearity problem among the attributes of the training dataset by computing the generalized variance inflation factor (GVIF). We remove the attribute edu_level because the GVIF of edu_level is 5.29, which is higher than 5. We then remove the unrelated attributes by coefficient test or p-value > 5% until remaining attributes are significant. Finally, we obtain the final logistic regression model (LM).

For random forest, we control two parameters to fit the random forests model: the number of trees to grow (ntree) and the number of attributes randomly sampled at each split (mtry). We tune the random forest model on parameters of ntree and mtry by 10-fold cross-validation and select the best random forest (RF) model of ntree = 300 and mtry = 4 with the highest accuracy performance. We then classify each visit by this RF model. Because random forest is a black-box algorithm, the classifying result of each visit is obtained without clear rules to explain the RF classification result.

Finally, we compare average performance measurements of accuracy, recall, precision, and specificity by the selected three different binary classification models, $Tree_{C50}$, LM, and RF, as listed in Table 1. We compare the accuracy performances of three models, $Tree_{C50}$, LM, and RF, by two-way ANOVA. Because the p-value of the two-way ANOVA is $4.86 \times 10\text{-}72$, we reject the null hypothesis and conclude that the accuracy performances of $Tree_{C50}$, LM, and RF are different. By applying Tukey's multiple comparison test on the accuracy measurements for each pair of models, we conclude that $Tree_{C50}$ = RF > LM, which implies that though $Tree_{C50}$ is better than RF, the evidence is not strong enough to show the difference.

We then compare the recall performances of three models, $Tree_{C50}$, LM, and RF, by two-way ANOVA. Because the *p*-value of the two-way ANOVA is $3.6 \times 10\text{-}72$, we reject the null hypothesis and conclude that the recall performances of $Tree_{C50}$, LM, and RF are different. By applying Tukey's multiple comparison test on the recall measurements for each pair of models, the evidence is strong enough to conclude that $Tree_{C50}$ > RF > LM. For precision performance, since the p-value of the two-way ANOVA is $5.38 \times 10\text{-}65$, we reject the null hypothesis and conclude that the precision performances of $Tree_{C50}$, LM, and RF are different. The Tukey's multiple comparison tests on the precision measurements for each pair of models show that the evidence is strong

enough to conclude RF > $Tree_{C50}$ > LM. For specificity performance, because the p-value of the two-way ANOVA is 5.9×10-54, we reject the null hypothesis and conclude that the specificity performances of $Tree_{C50}$, LM, and RF are different. The Tukey's multiple comparison tests on the precision measurements for each pair of models show that the evidence is strong enough to conclude RF > $Tree_{C50}$ > LM.

Table 1: The average performance measurements of $Tree_{C5}$, LM, and RF

Average Performance	Model		
	C5.0	LM	RF
Accuracy	0.9400	0.9075	0.9397
Recall	0.8591	0.7306	0.8483
Precision	0.8244	0.7610	0.8303
Specificity	0.9584	0.9478	0.9605

To sum up, because LM has the worst performance on all four measurements, LM is not a good choice to solve the problem of e-visit classification. $Tree_{C50}$ has the best performance on recall measurement but RF has the best performance on both measurements of precision and specificity. Though $Tree_{C50}$ performs a little better than RF does on accuracy measurement, the evidence is not strong enough to show the difference. Moreover, the $Tree_{C50}$ model provides a set of clear, logical, and explainable rules but the RF model, a black-box model, provides no such rules. According to the research objectives in this study, the $Tree_{C50}$ model can provide a set of clear, logical, and explainable rules for e-visit classification. Moreover, these rules provide more information for the governments to plan the medical policies about e-visits. Therefore, we can conclude that $Tree_{C50}$ is a better choice for solving the e-visit classification problem.

CONCLUSIONS

This study proposes a decision-tree based e-visit classification approach (DTEVCA), a systematic approach to identify those clinic visits which are qualified as e-visits by using the clinics' medical records and patients' demographic data. For the counties that have not yet implemented e-visits, this study proposes a way to identify a visit as an e-visit so as to assign the value of class label attribute. The result of the DTEVCA provides a set of straightforward rules due to the tree-based algorithm and these rules can help insurance providers to classify and explain the clinic visits as an e-visit or not clearly. Moreover, the performances of DTEVCA are better compared with the other two binary classification algorithms: logistic regression and random forest.

Though e-visits are generally not available in every country, the DTEVCA is able to deal with both cases: e-visit available and e-visit unavailable. For the places where e-visits are not available, the governments could apply the DTEVCA to estimate the possible number of e-visits as well as to establish rules of reimbursing e-visits on behalf of the insurance providers. Furthermore, the governments can also make a complete plan of allocating resources before implementing the new e-visit policy. The concept of DTEVCA is not only feasible for e-visits but also other "new services" such as new products or new policies. For example, when a company plans to launch a new product in a new market, they can use the concept of DTEVCA to estimate the sales and find the target customers according to the results of the existing products in the developed markets.

DECISION SCIENCES INSTITUTE
A Global Supply Chain Production and Distribution Network Design Model

Kanchan Das
College of Engineering and Technology,
East Carolina University
Email: dask@ecu.edu

ABSTRACT

A global supply chain network design model that plans procurement of inputs, realization of products of multiple design categories for various customer classes and distribution of products to global markets is proposed. Products with higher level designs are realized in supply chain's own plant and the basic level outsourced. Location and allocation of production and distribution centers are planned to maintain proximity for facilitating quick replenishment to retail outlets. The overall objective of the research is to address customer requirements for products with multiple design categories at globally located retail outlets for optimizing cost and obtaining superior supply chain performance.

KEYWORDS: Multiple design category, Outsourcing, Customer class, Global supply chain model, Quick replenishment.

INTRODUCTION

Given the current competitive business situations, Supply chains(SCs) have been planning innovative ways to differentiate (Fitzsimons et al, 2014) their products and services in the eyes of customers. For consumer product like automobiles and apparels such differentiation is difficult because of the various design levels as expected by various classes of customers. But offering of such multiple design products, especially in the case of Fashion SC and Automobile SC where customers prefer new designs and changes in design, may be considered as one of the responsive SC strategies (Roh et al, 2014). Such variation is also expected by the customer with respect to raw materials used in the product, product outlook, and colors. Over and above, these customers do not want to wait for the product of their choice. We may note that today customers do need to wait for their delivery when businesses are offering innovative ways to ensure quickest possible delivery (Marino et al, 2018).They need fastest delivery of product or would like to pick their product with expected design and specification from brick and mortar store if they have time. For global companies the main challenge is the location of plant and distribution center(DCs) and allocation of product to them in such a way that time needed for transportation of product from plants to DCs, and DCs to markets (retailers) should be as low as possible. As such added with the complexities of managing production and distribution of products with multiple designs, strategic global Supply Chain(GSC) network design should consider and integrate location and allocation of resources in the GSC design process for the effectiveness and superior performances of a GSC (Song et al, 2018; Melnyk et al, 2013). Most of the global companies manage distribution time and cost by deciding optimum route within the available alternatives for the multimodal routes for DC-retailer combinations. Since distribution to market may sometimes be needed to be made within the quickest possible time based on the following up or special requests from sales outlets, SC operations may not have much control on distribution at the operations level. But SC design at the strategic level should plan location and allocation of distance of Plant-DC combinations to ensure minimum possible distance for plant -DC combinations to minimize cost and influence overall delivery time to customer for improving response time to market. One of the possible other alternative solution could be

keeping high level of inventory at the sales outlets such that customer service for picking up from store/show room or retail centers can be managed at the highest possible level. But such policy is not only expensive but also not feasible for apparels and automobiles. There is always a probability of product becoming obsolete if such inventory cannot be sold before next model/design comes out. In such situations location of production and distribution center is critical for optimizing cost and satisfying customers. The next challenge for the business is to display the latest designs and taking out the old designs and making sure that relatively older products are not occupying space, such that new product can be sufficiently displayed to attract visiting customers. Addressing design change and handling of issues of taking out old products are not within the scope of this research.

Given the business objective to address multiple design products for various customer class, realization of products of such designs including optimum location allocation of plants and DCs are addressed by the proposed research model. Fulfilling product realization that includes multiple design levels is a very difficult and complex planning process complying with market needs. SCs for premium apparel, automobile and similar products should take the responsibility for managing higher level designs in their own plants as a core part of business and go for outsourcing for general design category to obtain cost competitiveness. Outsourcing decision is a much-discussed issue in SC management. SC literature recommends outsourcing considering advantages to manufacturing plant of SC (see Li et al, 2015; Lin &Chen, 2015). Since in this research, the SC is going for outsourcing general category of product which is almost a commoditized item, the outsourcing decision of this research is following the approach of Brewer et al. (2013) to obtain cost advantage without affecting any other business factor.

For ensuring fulfillment of customer expectations as well as achieving competitive advantage the SC should manage realization of all or at least critical components of the products in their own controlled plants and depend on a high-quality supplier pool for non-critical component. Based on above discussion a global supply chain(GSC) network design that includes plant-DC location and allocation for quick replenishment, outsourcing of products for general designs, managing higher design levels in their own plants taking noncritical components from suppliers if possible, should be highly competitive in the market places. This research proposes a GSC network design model for addressing each of these features to obtain superior performance by a GSC. To the best of our knowledge GSC design literature does include such a model based approach that contributes by including innovative approach for addressing a complex business situation for handling product with multiple designs, and each design with multiple customer class levels, and a commitment for competitive cost by outsourcing a part of demand in addition to quickest delivery to market for the overall success of a GSC. An effective SC model-based design for addressing each of the complex requirements are very much necessary for becoming competitive and successful in Fashion marketing, apparel SC and in Automobile. This research will facilitate complex GSCs for apparels, premium automobiles and similar products for achieving such requirement effectively. It will also facilitate SC managers to derive critical managerial insights for achieving these objectives to become competitive in the market places.

The paper is organized in the following way: it studies relevant background literature in Section 2 and presents methodology in Section 3 which also includes the mathematical model for designing effective GSC network discussed above. Section 4 illustrates applicability of the model using a numerical example and Section 5 concludes and discusses.

LITERATURE REVIEW

GSC network design for location and allocation resources(plants, DCs, retail outlets) for quick replenishment of product at sales outlets and SC design for managing realization of products of various design categories are the two streams of research that created background of this research.

Location and Allocation of Resources in GSC Network Design Stream:

It is now established in SC literature that an effective SC management should be an integrated process for sourcing and management of inputs, transforming them into customer expected product, and distribution of product to customers (Melo et al, 2009; Caniato et al. 2013). For addressing such an integrated management process effectively, SC network design is recognized by the practitioners to be a strategic issue for a business. Such an effective network design is crucial for the success of a GSC considering that an optimal SC network structure facilitates achieving high level of performances in the global market (Melnyk et al, 2013). For designing SC network one of the critical issue is the location of facilities including distribution centers, plants, and sales outlets. Here strategic issues are deciding the locations for warehouses and assigning them to sales outlets (see the review study in Bougelben & Boulaksil, 2018) and similar is the assignment of plants for supplying to warehouses, and may be allocation of products to plants in a GSC. Since this research needs to decide location of plants and warehouses to supply product to multiple global markets, multi-level facility location is also relevant to this study (Astorquiza et al, 2018). The products addressed by the GSC(premium apparels and automobiles) of this research attract the customers based on availability of design categories as current as possible. As such prompt/speedy delivery of product from plant to DCs and from there to sales outlets/retailers is a crucial requirement. In addition, based on discussion before, distribution of product from DCs to sales outlets are often influenced by the following up of sales outlets with the DCs, importance for location of DCs considering optimum DC-sales outlet distance combinations may often get compromised. Location allocation model addresses optimal cost and times for transporting product from plants to DCs and for distribution of product from DCs to sales outlets. Despite the fact that SC planning and design should address both(as discussed), location allocation decision issues that may be mentioned as the specific characteristics of a Facility Location model should have to adequately address SCM planning needs (Melo et al, 2009) for its effectiveness. Similar specific characteristics of SCM planning needs seem to be applicable for designing Apparel SCs. In such SCs strategic decisions for location and allocation of DCs considering optimum distance for plant-DC combinations becomes crucial for ensuring prompt /speedy delivery of product with multiple designs from plant to DCs. Such is also the case because of close monitoring or following up by Sales outlets for availability of latest designs in their store as discussed before. A similar approach is the market-plant strategy as covered in Stevenson (2015) where plants take the role of DCs to ensure quick replenishment of product. Optimum distance for Plant-DC combinations followed in this GSC model serves almost similar purpose by keeping plants-DCs in the same country. In addition, in the era of Omni Channel when customers have been preferring e-tailing, distribution-retailer location is not as important as the distances for plant-DC combinations for supplying product to customer directly and quickly, when percentage of customers going for brick and mortar store is decreasing. Recent OMNI channel review study in (Melacini et al, 2018) mentions progressive growth of e-commerce sales and rising interest of research in OMNI-Channel retailing in academicians and practitioners even if there are some limiting issues in OMNI channel operations.

GSC Network Design for Managing Realization Product of Various Designs Stream:

Planning and managing of product for different design categories for a SC is always a complex problem (Gunasekharan et al, 2014, Jacobs & Swink, 2011). For large products such a problem starts from the selection of product architecture. Often times, influence of modular and integral product architectures is studied for large size products (Pashei & Olhager, 2017). In a GSC, selection of architectures influences cost and operations. But in both the cases (integral or

modular) number of capable plants for assembly equipped with required technologies in SC corporate operated plants and suppliers (or outsourcing vendor) selections are key influencing issues as observed in Pashei & Olhager's research. Such influences are obvious because in a GSC network the firm needs to concentrate on meeting customer's requirements through manufacturing products in its plants and by outsourced vendors, distributing products through DCs, getting components from suppliers (Olahager et al, 2015) based on designs selected from some architecture. Product Design has been mentioned in the literature as large determinant for cost of producing and delivering product (Hong & Roh,2009). In today's competitive market product designs decide the direction of competitive advantage for the years to come (Hong et al, 2011). This is such because it is established in the operations management literature that product design is the main determinant for process design (Marsillac & Roh,2014). Marsillac & Roh's research considered case study based exploration to identify support that may be obtained from suppliers. With the aid of suppliers one of the case could reduce the cycle time for the production. This research procured noncritical components and raw materials from the suppliers to manage components needed for products of various designs and obtain some degree of cost competitiveness. In that perspectives allocation of supply orders to suitable suppliers is also important in managing a GSC network with multiple designs. So, it is apparent that for managing product designs aligning with effective process design, expectation of retailers/customers in the markets and important suppliers need to be incorporated in an extended view in the manufacturing network (Cheng et al, 2011, Olhager et al,2015). Chen & Fung (2013) empirically studied relationship configurations of SC with supplier and customer and their effect on SC performance studies. Based on their several findings they mentioned that relationships continuously develop and change in a dynamic global SC situation. As such managers need to continuously evaluate current relations and its impact on other relationship and their value creation potential.

GSC network for Fashion items, especially for international fashion retail based SCs the problem of new product Development(NPD) is considered as the integration of new product development and design(NPD). Similar to offerings of multiple product to make it almost customized product, NPD is considered as a success factor (Caniato et al, 2014). It is apparent that NPD makes the GSC network dealing with fashion retail a complex one with multiple products by adding several NPDs.

This research considered findings in the above background literature and planned the methodology for developing GSC network design model aligned with the findings.

METHODOLOGY

Considering complexity of multiple products with multiple designs for each having multiple levels for each design, multiple distribution centers, and markets at global locations, a mathematical model based planning and design of the proposed global supply chain seems to be appropriate. The model proposed is a Mixed Integer programing model for Designing a GSC model that will address multiple design products for multiple markets quickest possible delivery of products to customers. This section includes Problem Statement, Notations to define the mathematical model equations and the GSC network design model.

Problem Statement

We consider the problem of a global supply chain(GSC) that needs operation and marketing plan to handle a complex business similar to Zara, the fashion marketing supply chain. Let $P(p \in P)$ be the set of products to follow set of design $D(d \in D)$ to address various customer class requirements based on quality and feature. Let ($d \in D^{hl}$) set of design category considered as high-quality level; ($d \in D^{ml}$) set of medium level product design; $d \in D^{bl}$) set of basic level product

design. Products of designs D^{hl}, D^{ml} are realized in GSC operated plants J and design D^{bl} are managed through outsourced Vendors J' and transported to a set of globally located distribution center K(k∈K) from which products are distributed to a set of retail outlets R($r \in R$) at various globally located markets M($m \in M$).The overall objective of this research is to design a GSC network planning model that will minimize cost and in turn improve overall performance of the business by addressing multiple products of different design category targeted for various customer segments at different countries by addressing production, outsourcing, procurement of inputs and distribution of product to retail outlets according to their expected delivery performance.
We could not locate any research in the SC literature that addressed integration of such complex but practical and innovative business planning issues of multiple designs with multiple levels for each design involving multiple products in the GSC network design model. In addition, it addressed location and allocation of resources, realization of product by manufacturing and outsourcing and planned fast replenishment of product at globally located sales outlets with competitive cost. As such this research contributes significantly by introducing this innovative model based GSC network design approach.

Notations: Indices

$C(c \in C)$ set of components
$D(d \in D)$ set of designs, Let $(d \in D^{hl})$ set of design considered as high quality level based on quality and feature; $(d \in D^{ml})$ set of medium level product design; $d \in D^{bl}$) set of basic level product design; D^{hl}, D^{ml}, and Dl^{b} are partitions of D
L: set of levels, L=(hl,ml,bl)
$I(i \in I)$: set of inputs/raw materials
$J(j \in J)$: set of plants operated by supply chain
$J'(j' \in J')$: set of vendors who have been enlisted by the supply chain for outsourcing production of product of design D^{bl} and sending them to distribution centers.
K ($k \in K$) : set of distribution center(DC) K at the country of production center
M ($m \in M$): set of markets
τ=*transportation mode: 1: truck, 2 air, 3 air and truck* (*multimodal*)
P ($p \in P$) set of products
Q(q∈Q) a set of Quality assurance vendor to conduct final inspection of product before distributing to retail outlets.
S(s∈S): set of enlisted suppliers who are in agreement with SC to supply ensured quality raw materials.
T($t \in T$) periods.
R($r \in R$): retail outlet.
Q($q \in Q$): set of accredited quality assurance contractor.

Parameters

a_{st} =1, if supplier s is assigned supply order at period t; 0 otherwise.
BNN : a big number.
CA_{pdlj}: cost of assembling product p of design *d level l(hl, ml)* by plant j.
CAW_{kpd} : capacity of DC k for accommodating product of design d.
$CS_{pdlj'}$: cost of producing product p of design *d level l(bl)* by outsource vendor *j'.*
CM_{cj} : cost of manufacturing component c in SC operated plant j
CQI_p: quality inspection cost per product *p.*
CR_{is} : cost of raw material i from supplier *s.*

CQA_p : average final inspection cost for each product at the DCs.
cz_{cj}^{t} : Component *c* to be manufactured in SC operated plant *j* in period *t*.
$DN_{pkr\tau}$: average distribution cost of product *p* from DC k to retail outlet *r* using transportation mode τ for unit distance.
ds_{pd} =1, if product *p* selected design *d*; 0 otherwise.
DM_{pdl}^{tm} : Average demand for product *p* of design *d* of level *l* from market *m* for time *t.*
$ds_{krm:}$ distance between DC *K* may be in any country/market identified by DC # and the retailer in market *m* (may be in any country, identified by market #).
$Dtrt_{jk}$: distance between plant *j* and DC *k;* they can be in any country.
FA_{pdj} : fixed cost of assigning assembly jobs of product *p* of design *d* to plant SC plant *j*
$FS_{pdlj'}$: fixed cost for assigning production of product *p* of design *d* and design level *l*(*BL*) to outsource vendor *j'*
FM_{cj} fixed cost for manufacturing component *c* in plant *j.*
FR_{is} fixed cost for assigning orders for raw material *i* to supplier *s.*
FQA_{qp} fixed cost for assigning QA job of product *p* to quality assurance firm *q.*
y_p^{kmrt} : product *p* of design *d* level *l* distributed to retail outlet r from DC *k* in market *m* at time period *t.*
x_{pdl}^{tjk} : product *p* of design *d* level *l=hl* and *ml* that are realized in SC plants j and sent to DC *k.*
$xo_{pdl}^{tj'k}$: product *p* of design *d* level *l=bl* from outsourced vendor *j'* at time period *t* sent to DC *k.*
w_{kmr} =1; if *DC k* is allocated to supply product to retail outlet *r* in market *m*; 0 otherwise.
wo_{kpd} =1, if DC k is opened and it has the capacity to accommodate product *p* of design *d.*
ρ_{pdc} : component *c* needed for producing product *p* of design *d.*
$os_{pj't}$ =1, if outsourcing of product order is assigned to vendor *j'* in period *t*; 0 otherwise.
$qa_{qp:}$ 1, if final inspection is conducted by the quality assurance vendor *q* on the product *p* received in DC ; 0 otherwise.
$TR_{ic:}$ estimating equivalent raw materials/inputs requirements by component *c*.
TD_{kmr} =a big number distance which is the set highest distance possible to travel by truck .
u_{cjt} =1, production of component *c* is assigned to plant *j*, 0 otherwise.
v_{jpd}=1, if assembling of product *p* of design *d* is assigned to GSC operated plants *j* 0 otherwise.
z_{ist}: input/raw materials *i* to be procured from supplier *s* in period *t*
$trt_{krm\tau=1:}$ time for transportation by truck
$trt_{kmr\tau=2:}$ time by air*;* $trtkmr_{\tau=3;}$ time by mixed mode
α =1, if $trt_{kmr\tau=2}$ (Air transportation mode) is selected; 0 otherwise; β=1 , if $trt_{kr\tau=3}$ (multimodal) is selected from $\alpha+\beta\leq 1$
Seemod: an auxiliary 0/1 variable to decide transportation mode
FW_{kp} fixed cost for opening DC *k* to warehouse product *p.*
FAR_{kr} fixed cost for allocation of DC *k* to supply retailer *r*.

GSC Network Design Model

Constraint (1) ensures selecting a design by a product for its production. Constraint (2) provides the option of selecting at least one category out of three categories (*bl, ml,* and *hl*) for the selected design. Constraint (3) balances product supplied by outsourced vendor and product realized in the GSC operated plant with the overall average demand for product of the GSC. Constraint (4) balances product distributed from DC to retail outlets with the product supplied to DCs. Constraint (5) allocates DCs to retail outlets at markets. Constraint (6) allocates each DC to more than one retail outlets and constraint (7) allocates more than one DC to a retail outlet in markets to improve product availability resiliency of the retailers. Constraint (8) limits

transportation of product from outsourced vendor and from SC operated plant to a DC based on capacity of DC. Constraint (9) ensures allocation of only an open DC to supply to a retail outlet. Constraint (10) decides distribution distance from DC to retailer if the DC is allocated to retailer based on constraint (5). Constraint (11) ensures transportation of product from a plant to a DC only when the DC is allocated to a retailer. Constraint (12) sets transportation distance limit between plant-DC combinations to minimize such distances for quick product availability by the customer. Constraint (13) allocates a plant to a DC for transporting product. Constraint (14) checks whether the final inspection has been conducted by a competent QA vendor. Constraint (15) determines components needed to be produced in SC operated plants for the production of planned products at the top two levels of design. Constraint (16) computes raw materials and other inputs to be procured from suppliers. Constraint (17) assigns production of product of higher design level product to a GSC operated plant. Constraint (18) assigned outsourcing product order to the vendor with whom SC has a contract. Constraint (19) assigns supply order to suitable suppliers. Constraint (20) allocated production of critical components to the SC operated plants. Constraints (21), (22), (23), (24) and (25) selects transportation mode based on distances. Distribution distance between a DC and retail outlet of a market verified by constraint (21). If it is higher than the set limit that cannot be travelled by transportation mode truck, constraint (22) decides travelling distance for the (DC-retailer) combination based on air transportation mode. Based on constraint (21) if the distance cannot be covered by truck, alpha becomes 1, but if it needs a domestic airline support, then beta becomes 1, alpha becomes zero and constraint (23,24 and 25) come into action. Constraint (26) imposes integrality

$$ds_{pd} = 1 \qquad \forall p, d \tag{1}$$

Objective Function

Objective function of the GSC Network Design Model defined in equation (27) minimizes *Total GSC cost*. Total GSC cost is defined in equation (28) in terms of its components: Product Realization cost (*PRC*), Raw materials cost (*RMC*) and Transportation and Distribution cost(*TDC*). *PRC* defined in equation (29) includes: costs for manufacturing of product of different designs at high and medium level in SC operated plants; procurement cost of product at basic level for different designs from the outsource vendor; fixed cost for allocating(setting up) medium and high design level products of different designs in the SC operated plants; fixed

cost for assigning procurement order to outsource vendor; cost of manufacturing components for high and medium design level products in the SC operated plants, and fixed cost for allocating (setting up) manufacturing of components to SC operated plants for computing product realization cost. RMC defined in equation (30) computes raw materials cost by considering supply cost of raw materials from the supplier and fixed cost for assigning orders to the suppliers. TDC defined in equation (31) computes transportation and distribution cost by incorporating quality assurance cost for the high and medium design level products transported from SC operated plants to DCs and the basic design level products supplied to DCs by the outsource vendor; cost for distributing products from DCs to retail outlets based on distances travelled and average cost of distributing a product; fixed cost for assigning quality assurance responsibility to an accredited quality assurance organization; fixed cost for opening a DC to accommodate product supplied from the SC corporate operated plant and outsource vendor; fixed cost for assigning a DC to retail outlets to distribute product, and transportation cost based distance for plant DC combination and average cost for transporting products form SCs own plant.

Objective Function: *minimize Total GSC Cost* (27)

Total GSC cost: Product realization cost (*PRC*) +Raw materials (*RMC*) +Transportation and Distribution cost (*TDC*) (28)

$$PRC = \sum_{p\in P}\sum_{d\in D}\sum_{j\in J} FA_{pdj}\sum_{t\in T} v^{t}_{pdj} + \sum_{p\in P}\sum_{d\in D}\sum_{j'\in J'} FS_{pdj'}\sum_{t\in T} os_{pj't} + \sum_{c\in C}\sum_{j\in J} CM_{cj}\sum_{t\in T} cz^{t}_{cj} + \sum_{l\in\{hl,ml\}}\sum_{j\in J} CA_{pdlj}\sum_{t\in T}\sum_{k\in K} x^{tjk}_{pdl} + \sum_{p\in P}\sum_{d\in D}\sum_{l=\{bl\}}\sum_{j'\in J} CS_{pdlj'}\sum_{t\in T}\sum_{k\in K} xo^{tj,k}_{pdl} + \sum_{c\in C}\sum_{j\in J} FM_{cj}u_{cj} \quad (29)$$

$$RMC = \sum_{i\in I}\sum_{s\in S} CR_{is}\sum_{t\in T} z^{t}_{is} + \sum_{c\in C}\sum_{j\in J} a_{is}FAR_{is} \quad (30)$$

$$TDC = \sum_{p\in P} CQI_{p}\sum_{t\in T}\sum_{d\in D}\sum_{k\in K}\left(\sum_{j'\in J'}\sum_{l=bl} xo^{tj'k}_{pdl} + \sum_{j\in J}\sum_{l=\{hl,ml\}} x^{tjk}_{pdl}\right) + \sum_{p\in P}\sum_{k\in K}\sum_{r\in R}\sum_{m\in M}\sum_{\tau\in TM} DN_{pkmr}ds_{krm}\sum_{m\in M}\sum_{t\in T}\sum_{d\in D}\sum_{l\in L} DM^{mt}_{pd} + \sum_{p\in P}\sum_{q\in Q} FQA_{pq}qa_{qp} + \sum_{k\in K}\sum_{p\in P} FW_{kp}\sum_{d\in D} wo_{kpd} + \sum_{k\in K}\sum_{r\in R} FAR_{kr}\sum_{m\in M} w_{krm} + \sum_{j\in J}\sum_{k\in K} DTC_{jk}DTR_{jk}\sum_{d\in D}\sum_{l\in\{hl,ml\}}\sum_{p\in P} x_{pdljk} \quad (31)$$

NUMERICAL EXAMPLE

An example GSC firm (mentioned as GSC henceforth) that markets 6 products with 3 designs having 3 design levels (high, medium and basic levels) for each design of each product is considered to illustrate applicability of the model by generating random assumed data. The GSC markets the products in 5 global markets (USA, UK, Singapore, India and Italy) through 10 retail

outlets in each market. The GSC manages realization of high and medium design level products in its 5 plants (located 3 in USA, 1 in UK and 1 in Singapore) and transports the products to 5 DCs, also located in globally (3 in USA, 1 in UK and 1 in Singapore), and from there products are distributed to retailers in 5 global markets. The GSC manages basic design level products for designs 1,2, and 3 through 4 outsource vendors from India. The GSC operates through contractual arrangement with the outsource vendors based on the quoted cost for receiving the product at DCs according to the schedule mentioned in the contract. In addition, the GSC procures raw martials and other inputs for manufacturing from a pool of 4 suppliers through contractual arrangement to supply the ordered items to manufacturing plants according to contractual stipulations. The GSC knows average demand of product for its 5 products based on its marketing and operations data from the past several years. This section presents model output based results mainly. It includes limited information on the model inputs. Input data are included when such inputs are necessary to understand and explain model outputs.
In this research countries are not identified as a model index to reduce complexity of solving the model. The model is designed as a linear one for facilitating solution such a complex business situation. The model is already complex with several indices. Markets, Plants, DCs and Retailers are identified by the numbers tagging the number with location. Meaning the numbers also provides information about its country of location. The model decides distribution of product, assignment of product to plants based on capacity and cost; allocation of plants to DCs based on transportation cost and distances, allocation of DCs to markets based on distribution distances and cost and demand from Retailers. Costs and distances are based on tagged location for the facilities.
Table 1 presents average overall demand of products in the markets. For an example, average demand for product 1 in market 1(USA) is 10,090 units as shown in Table 1.

Table 1: Average Demand of Product in Markets

	USA	UK	Singapore	India	Italy	
Product	Market 1	Market 2	Market 3	Market 4	Market 5	Total
1	10,090	10,403	10,929	10,210	10,985	52,617
2	11,682	11,508	10,381	10,511	10,417	54,499
3	10,917	10,175	11,458	11,207	10,164	53,921
4	10,800	10,179	11,003	10,021	10,561	52,564
5	11,448	11,442	10,837	11,361	11,095	56,183
6	10,962	12,138	10,631	10,668	10,297	54,696

Table 1a: Demand of a Typical Product (Product 1) at three Design levels for 3 Designs in Markets

		Design 1 levels			Design2 levels			Design 3 levels			
Product	Market	HL	ML	BL	HL	ML	BL	HL	ML	BL	Total
1	1	1,237	1,314	1,034	1,153	1,259	1,210	1,103	934	846	10,090
	2	1,082	1,271	990	925	891	1,126	1,558	942	1,618	10,403
	3	1,181	974	1,064	1,399	1,322	1,098	1,459	1,134	1,298	10,929
	4	1,364	1,015	1,282	1,096	930	1,017	1,058	1,521	927	10,210
	5	1,495	1,017	1,267	1,212	1,261	1,371	1,208	1,076	1,078	10,985
		6,359	5,591	5,637	5,785	5,663	5,822	6,386	5,607	5,767	
	HL: High level; ML: Medium Level; BL: Basic level										

Table 1.a presents details of product 1 demand for designs 1,2, and 3 and at three levels for each design. According to Table 1.a demand for product 1 at market 1 for design 1 at high, medium and basic levels are [1,237,1,314, and 1,304], for an example.
Table 2 presents model decision on production and transportation of product from GSC's own plant to DCs. As discussed before GSC's own plant only produces high and medium level product of three designs used by the GSC firm. According to Table 2, the model allocated products 1 to 6 to Plant1 and assigned plant 1 to supply product to DC1, for an example, as may be observed in Table 2. The model assigned products 2,3,4 and 6 to plant 2 and transported products from plant 2 to DC2. The model similarly assigned only product 3 to plant 3 and transported them to DC 3. The model decided similar transportation decision for the plants 4 and 5 also. Such transportation decision by the model is obvious because in each country where the GSC has a plant, it has a DC also. The model had the option to transport product from a plant in other country to a DC. But constraint (12) restricted the model to limit transportation distance to a set limit for obtaining fast delivery to retail outlets. We may also verify whether the model manufactured required HL and ML product amount in GSC's plant to fulfill market demand. For an example the model realized product 1: 23,398(in plant1) +6,386(in plant 4)+5,607(in plant5)=35,391 units of HL and ML level product 1 from this Table 2, which should be same: if we add: demand for HL and ML product [1,495+1,017+1,212+ 1,261+ 1,208+1076]=35,391for all three designs as presented in Table 1.a.

Table 2: Model Output for Production and Transportation of Product from Supply Chain's Own Plant

	Products of **designs** at HL and ML						Total	Transferred to DCs
Plants	1	2	3	4	5	6		
1	23,398	17,721	23,659	17,526	19,241	18,814	120,359	1
2		12,386	6,059	10,793		11,526	40,764	2
3			6,305				6,305	3
4	6,386	5,503		6,444	17,959	5,696	41,988	4
5	5,607						5,607	5

Table 3: Typical Supply of Basic Level Product by Outsource Vendor 1

Outsource Vendor	**Products** with 3 designs at Basic level						Supplied to DC
	1	**2**	**3**	**4**	**5**	**6**	
1	975	725					1
	1,720	4,847		9,48			2
	1,707	2,291		6,383			3
		2,586		1,927			4
	1,420	3,005		2,876			5

Table 3 presents supply of basic level products by a typical outsource Vendor (out of 4 vendors). For an example Vendor 1 supplied 975 units of product 1 to DC 1 and 1,720 units of to DC2.
Table 4 presents assignment of DCs to retailer based on which the model distributes product from the DCs to retailers in the 5 markets. For an example:M:1-5 shown at the intersection of row for DC1 and column for Retailer 1means DC 1is allocated to retailer 1 in all five markets (M1-5); M:0 at the intersection of row for DC 2 and column for Retailer 1: means DC2 is not allocated to retailer 1 in any market (M:0). Taking one more example for further discussion:

M:1,3,4 in the intersection of DC3 and Retailer 1 means DC 3 is allocated to Retailer 1 in markets 1,3, and 5.

Table 4: Model Output on Allocation of DCs to Retailers in Markets.										
	Retailers in markets									
DC	1	2	3	4	5	6	7	8	9	10
1	M:1-5	M:1-5	M:2-5	M: 1,4	M:1-5	M:1,2,4,5	M:1,3	M:0	M:1-5	M:1
2	M:0	M:1,2,4,5	M:1	M:1-5	M:0	M:1-5	M:3,4	M:1,2,3,5	M:0	M:3,5
3	M:1,3,4	M:0	M:1-5	M:1,2,4,5	M:0	M:3	M:0	M:1	M:1,4	M:1-5
4	M:2,5	M:2-5	M:1,3,4,5	M:1,3,4,5	M:0	M:0	M:2,5	M:1-5	M:1,2,3,4	M:2,4
5	M:0	M:0	M:5	M:0	M:1-5	M:0	M:1,2,4,5	M:1,4	M:0	M:0

Table 5: Model Output on Typical Distribution of Product from DCs to Retailers in Markets.											
	Distribution of **Product 1** from DCs to **Retailers in Market 1**										
DCs	1	2	3	4	5	6	7	8	9	10	Total
1				648	688	545	426		688	688	3,683
2				677		688		426			1,791
3				482				688		688	1,858
4				262				253	262		777
5					688		688	605			1,981
	Distribution of **Product** 1 from DCs to **Retailers in Market 2**										10,090

5			599		654		654				1,907
Sum of 10,985+10,210+10,929+10,403+10,090=52,617											10,985

Table 5 presents typical model output for distribution of product (only product 1 is shown out of 6 products) from the DCs to Retailers in each of the 5 markets for illustration and some

verification. It may be mentioned here that the products distributed from DCs are transported to DCs from GSC operated 5 plants (see the Table 2) and outsource vendor in Table 3. According to Table 5 information 648 units of product 1are distributed from DC1 to retailer 4 in Market 1(see the market 1 information in the top part of Table 5) and, similarly 422 units of product 1 are distributed from DC1 to retailer 1 in market 2 (see the Market 2 distribution part), for example. Please verify assignment of DC 1 is allocated to Retailer 4 in Market 1 and 4 and DC 1 is allocated to Retailer 1 in all market according Table4. We may verify some more information on allocation of DCs to retailers in Markets of Table 4 based on these select model output in Table 5. Let us first check exceptional retailers and related DCs. For an example, based on Table 4, DC 1 is not allocated to supply Retailer 8 in any market. Based on Table 5, no product is distributed from DC 1 to retailer 8 in any market (see tables 4, and 5). Similar verification may be done for M:0 in Table 4 for Retailer 1and DC2; or Retailer 1 for DC5 and others. We may partially verify for M:1-5, since such allocation is made for all products and all retailers. But we have only Product 1 in Table 5. For an example M:1-5 for retailer 1from DC1 in Table 4. Market 1 does not have distribution from DC 1 to retailer 1 for product 1 (see Table 5). But for all other markets 2,3, 4 and 5, Retailer 1 is supplied from DC1 for product 1(See Table 5). Overall product 1 distributed may also be verified whether it complies with demand as shown in Table 1. Based on last row and column for Table 5 overall 52,617 units of product 1 is distributed from 5 DCs to 10 retailers, which is equal to the demand shown in Table 1.

As discussed before since overall objective of model is minimizing cost the Model took the shortest transportation distance and located DCs, and allocated plants to DCs based on constraint (12) where set distance considered were 180 miles. In addition model only transported product from plant 1 to DC1 and Plant 2 to DC2 and similar for other plant- DC combinations. By such allocation the model ensured transportation from plant to DC within one country and managed with transportation mode truck only. This will facilitate GSC ensuring quickest product availability in the retail outlets.

In the case of distribution, the model took similar measures within the routes available for fastest delivery with minimum cost. Based on Market 1 segment of Table 5, the model distributed most of the products (3,683+1,791+1,858)/10,090=73% for retailers of market 1(USA) from DCs 1, 2, 3 which are located in USA and managed with minimum cost with limited air travel.

For market 2, which is in UK (see the Market 2 part of Table 5) , the model took highest possible units (see 3,898 units) from the DC4 which is in UK for the retailers of market 2. The model took the remaining products are from USA DCs, and only 576 units from Singapore DC to reduce distribution cost.

For markets 3, 4, and 5 the model favored USA based DCs because of multi-modal and Air cargo related cost advantages. For India and Italy market freight charges from USA is better than from Singapore or UK, so these were obvious. For Singapore the model took product mostly from USA also because of cost advantages in the as assumed for the example case.

GSC uses 18 components for producing their 6 products with 3 designs at high and medium design levels in their plants.

Table 6: Model Output on Components Manufactured by GSC Operated Plants

	Components manufactured by the assigned plants for the products								
Plants	4	5	6	10	11	12	16	17	18
1	75,140	75,140	37,570	107,251	142,718	71,359			
2							41,634	47,000	41,634
3							6,305	12,610	6,305
4							54,075	71,280	54,075
5							5,607	11,214	5,607

Based on usage of components/per product (BOM) model equation (15) determined the components needed for the product considered for this example case and assigned to SC operated plants. Table 6 presents model output for the components that are realized by the assigned GSC plants. According to Table 6 GSC needs 9 components (components 4 to 6; 10 to 12;16 to18) out of 18 components. For an example, plant 1 manufactured 75,140 units of component 4. The model assigned plant 1 for manufacturing components 4 to 6; 10 to 12. The model assigned plants 2,3, 4 and 5 for realizing components 16 to 18, as may also be seen in Table 6.

Table 7: Model Decision on Procurement of Raw Materials from Assigned Suppliers

	Estimated raw materials in thousand yards assigned to suppliers								
Suppliers	1	2	3	4	5	6	7	8	9
1					1,497				
2			3,009			6,000	5,360	5,360	
3	902	869							5,360
4				2,464	6,000	3,217			

Table 7 presents model decision on procurement of raw materials from the assigned suppliers 1 to 4. The model estimated raw materials requirements and assignment of suppliers for their procurement through equation (16). For an example, 1,497 thousand yards of raw material 5 are procured assigning order to supplier 1, as shown in Table 7.
The overall GSC total cost (Total cost, objective 1) as computed by the model is $119.6 million that includes Production cost (PRC): $2.04 Million, Raw materials cost (RMC) : 117.05 million and Transportation and Distribution cost (TDC): $0.52Million for complying with market demand as presented in Table 1. The model is solved using commercial solver LINGO 14 in a Dell Latitude Series Desktop computer with processor Intel® core (TM)i7- 4800 CPU @2.70GHZ 2.70 GHZ, with RAM: 8 GB. The Model involved: 21, 473 total variables, 1761 integer variables, and 56,161constraints for the numerical example and it took at an average 7 minutes to arrive at the global optimum solution for the example case.

Table 8: Model Sensitivity for Variation of GSC Cost with the Change in Demand

Demand	In $ Million	Components of Total GSC cost in $ Million		
	Total GSC cost	Total Production Cost	Total Raw materials Cost	Total transportation and Distribution Cost
Base Case*0.7	81.21	1.44	79.3	0.47
Base Case*0.85	99.73	1.74	97.5	0.49
Base Case	119.6	2.04	117.05	0.52
Base Case*1.15	139.63	2.33	136.76	0.54
Base Case*1.30	160.24	2.64	157.05	0.55

Based on the above analysis it is apparent that the model effectively decided all GSC planning issues including procurement of raw materials; realization of high and medium level products for the three designs of products in SC operated plants and basic level products from outsourced vendor, transportation of the realized products to the allocated DCs, and distribution of the products to retail outlets from the DCs assigned to them within optimum time and successfully

complied demand of product with optimum cost. The model is sensitive to demand changes if we consider other SC requirements do not change.
We tested such sensitivity by making the plant, DCs and suppliers un-capacitated. Table 8 presents model sensitivity for the total GSC cost and components of total GSC costs with the increase and decrease in the product demand. For this sensitivity analysis we considered model result without increase and decreases as the base case and computed model outcomes for optimized cost figures by decreasing demand in two steps at the rate 15% in each step and similarly by increasing the demand in two steps at the same rate as presented in Table 8.
As expected, with the increase in demand the optimized cost figures increased compared to base case and the costs decreased with the decrease in demand as may observed in the Table 8. It is also apparent that the optimized figures due to the increment and decrements of demand are not proportional. For an example, based on model outcomes in Table 8 with 15% increase in demand Total GSC cost increased to: $139.63million , which is higher than 119.6(base case optimum cost)*1.15=$137. 54Million. Similar is the case for decrement in demand; with 15% decrement in demand optimized total cost decreased to $99.73 Million which is lower than 119.6(base case optimum cost) *0.85=$ 101.66 Million. The reason for such variations are not-changing of fixed costs for setting up an allocated plant for production; opening a DC, or assigning orders to suppliers do not change with change in demand. Only variable costs are affected by change in demand for handing higher or lower units of products, raw materials, and truckloads.

CONCLUSION AND DISCUSSIONS

The overall GSC network design model contributed in SC literature by introducing an effective approach for planning realization of multiple products having multiple designs including multiple levels for each design of product to address various customer classes in the globalized market. The GSC design model took the innovative approach for allocating plants to DCs within the shortest distance possible. It also effectively planned allocation of DCs to retailers to obtain optimum route for distribution to achieve optimum replenishment cost at the retail outlets of globally spread markets. The design approach utilized core competency of the GSC by realizing higher design level products at their own plants and addressed cost competitiveness by outsourcing basic level designs. This strategic GSC network design model can be very effectively applied for planning and managing Fashion SC like Zara, where multiple designs, variation of fabrics and frequent changing designs are addressed in its globally located retail outlets. It may also be also applied in premium Automobile industry to handle design variations and suppliers at multiple tiers in addition to Fashion SC.
The research has the scope to extend it for handling rolling over the old designs with new designs after a specified time frame for keeping the retail outlets attractive to various classes and to reduce inventory and obsolescence cost.
The research provides many managerial implications. The following may be considered for significant business benefits:1) when dealing with complex business situations of marketing product in GSC network with multiple designs, controllable levers are critical to obtain superior performance in terms of quick delivery of product to sales outlets. Allocation of production plant and DC in close proximity, if possible in the same country may be considered as a controllable and assuring beneficial lever. Next implication of this research is to exploit outsourcing to obtain cost competitiveness when the organization has one or more almost commoditized product or part of a product in their product portfolio. Finally, a planning and design model of proposed caliber should be used by the SC managers to simulate with different alternatives and making informed decisions.

ABSTRACTS

In this paper, we conduct a literature review to examine the impact of supply chain flexibility, agility, redundancy, and collaboration (as the most widely known resiliency practices) on mitigating supply chain disruption risks. We investigate the relationship between disruption and resiliency through assessment of the impact of each resiliency enhancer on mitigating each supply chain disruption (demand, supply, process, control, and environmental disruptions). Our results showed that while flexibility has been mentioned frequently in the literature as the most important strategy to cope with demand, supply, process, and environmental disruptions, collaboration has been regarded as the most important strategy to cope with control disruptions.

KEYWORDS**:** Supply chain resilience, Supply chain risk management, Flexibility, Agility, Collaboration, Redundancy

1. INTRODUCTION

Supply chain risk management (SCRM) is “the management of supply chain risks through coordination or collaboration among the supply chain partners so as to ensure profitability and continuity” (Tang, 2006a, p. 453). According to Aqlan and Lam (2015), SCRM is an asymmetric approach for identifying, assessing, mitigating, and monitoring the risks for potential disruption in a supply chain network, in order to mitigate the negative effects of the disruptions on supply chain operations. According to a report by IBM (2008), supply chain executives at IBM believe that SCRM is the second-most important issue for their company.

A general categorization of supply chain risk is to classify risks into operational risks and disruption risks (Kleindorfer and Saad, 2005; Tang, 2006; Chen et al., 2013). Disruption risks typically are defined as unplanned events that restrict a supply chain system; they may result from man-made or natural disasters such as economic downturns, technology changes, terrorist attacks, hurricanes, and strikes. Operational risks are more about supply-demand coordination events, which may result from inadequate or failed processes, control, people, or systems (Christopher and Peck, 2004; Wakolbinger and Cruz, 2011; Chen et al., 2013; Ghadge et al., 2012; Lockamy and McCormack, 2010; Gurning and Cahoon, 2011; Nooraie and Parast, 2015; Yang et al., 2017). Thus, operational risks are relatively more controllable than disruption risks. Moreover, catastrophic events such as 9/11 in 2001, the tsunami in 2004, hurricane Katrina in 2005, hurricane Harvey in Houston in 2017, and hurricane Maria in Puerto Rico in 2017 are motivation for supply chain researchers to consider supply chain risk and its effects on the design of supply chains (Chopra and Sodhi, 2004; Tang, 2006a; Thun et al., 2011; Wilding et al., 2012; Heckmann et al., 2015; Ho et al., 2015; Kamalahmadi and Parast, 2016a).

Supply chain resiliency (SCR) reduces the impact of disruption risks by identifying strategies that allow a supply chain to react while recovering to its original or even better functional state. SCR has received more attention in recent years as one of the main characteristics of a firm to improve responsiveness to unexpected dynamics in the business environment (Kamalahmadi and Parast, 2016; Borekci et al., 2015; Ponomarov and Holcomb, 2009; Ates and Bititci, 2011).

Melnyk et al. (2014) asserted that SCR is at the heart of current supply chain management thinking. A study by the World Economic Forum (2013) indicated that more than 80% of companies are concerned about their SCR (Tukamuhabwa et al., 2015). Hence, SCR is of a great interest for firms and organizations (Ivanov, 2017; Borekci et al., 2015; Scholten and Schilder, 2015; Jüttner and Maklan, 2011).
In this article, we aim to address these key questions in SCRM and SCR:
(1) What is the current state of research in SCR and in supply chain disruption risks?
(2) Regarding the various sources of disruption risks in supply chains (i.e., supply risk, demand risk, environment risk, process risk, and control risk), which SCR capability should a firm invest in as the best strategy to build a supply chain resilient against disruption risks?
(3) What are the gaps in current research that future research should address?
We address our research questions by reviewing the articles published in major academic and practitioners' journals from 2000 to 2017 using a systematic literature review process (Kamalahmadi and Parast, 2016b; Tukamuhabwa et al., 2015; Ho et al., 2015).
The remainder of this study is organized as follows: Section 2 is a review of the literature on SCR and the supply chain resiliency enhancers: flexibility, agility, collaboration, and redundancy. Section 3 is a discussion of the research methodology. Section 4 is a discussion about the major findings of this study. Section 5 has the conclusions and Future Research of this study.

2. LITERATURE REVIEW

In this section, We provide a review of the literature for flexibility, agility, collaboration, and redundancy as the most important enhancers of supply chain resiliency.

2.1. Supply Chain Resilience (SCR)

Resilience in a supply chain can be defined as a firm’s ability to withstand a disruption and recover from the disruption to its original state, or even move toward a more desirable state after being disturbed (Christopher and Peck, 2004). Pettit et al. (2013) defines resilience with the “four Rs”: robustness, resourcefulness, recovery, and review. To improve SCR, diverse strategies have been recommended in the literature (Urciuoli et al., 2014; Colicchia et al., 2011; Tang, 2006a). While resiliency enhancers can include a wide range of organizational practices, the literature recognizes the impact of flexibility, agility, collaboration, and redundancy strategies as the most important organizational capabilities to improve a firm's responsiveness to supply chain disruption (Tukamuhabwa et al., 2015; Yang et al., 2017; Tomlin, 2006; Simchi et al., 2013; Christopher and Peck, 2004; Sheffi and Rice, 2005; Das and Lashkari, 2015; Kamalahmadi and Parast, 2016a; Pettit et al., 2013; Ponis and Koronis, 2012; Jutnner and Maklan, 2011; Sodhi et al., 2012; Jain et al., 2017). Christopher and Peck (2004) recommended the inclusion of resource redundancy, agility, supplier flexibility, and a collaborative planning approach (as a part of risk management culture) for creating SCR. Tukamuhabwa et al. (2015) indicated there are twenty-four different strategies for achieving SCR. They showed that increasing flexibility, improving supply chain agility, forming collaborative supply chain relationships, and creating redundancy have the most effect on improving SCR.

2.2. Flexibility

Flexibility refers to the ability of a firm to flexibly respond to long-term or fundamental changes in the supply chain and market environment by adjusting the configuration of the supply chain. So this measure indicates the flexibility of a firm in responding to environmental changes, demand changes, supply changes, and technology changes (Overby et al., 2006; Li, et al., 2009; Dominik et al., 2015; Blome et al., 2014). Some research indicated the important role of flexibility in enhancing SCR (Das and Lashkari, 2015; Tukamuhabwa et al., 2015; Tang and Tomlin, 2008; Sheffi, 2005; Christopher and Peck, 2004). Das (2011) asserted that the inclusion of effective flexibility measures is an established fact that makes a business more responsive by resolving most supply chain uncertainty issues. Fang et al. (2012) asserted that through flexible

system organization, a resilient supply network can be realized both effectively and efficiently. Also, flexibility creates SCR by enhancing prompt adaptability during turbulence (Christopher and Holweg, 2011).

2.3. Agility

Agility is described as the ability to efficiently change operating states as a response to environmental uncertainty or volatile market conditions (Lim et al., 2017; Narasimhan et al., 2006; Faisal et al., 2006a). Agility is one of the most powerful ways to achieve a resilient supply chain capable of rapid responses to changing conditions (Christopher and Peck, 2004). Tukamuhabwa et al. (2015) indicated that agility is one of the most important capabilities to enhance SCR. Braunscheidel and Suresh (2009) asserted that agility is critical for disruption mitigation and response time efficiency. They defined agility as a risk management initiative that enables a firm to respond rapidly to market changes and potential or actual disruptions in the supply chain. Supply chain managers can decrease the risks that are related to inventory management by dealing with extremely responsive suppliers (Chopra and Sodhi, 2004).

2.4. Collaboration

Supply chain collaboration refers to the ability to work efficiently with other entities for mutual benefit in areas such as forecasting, postponement, and risk sharing (Pettit et al., 2013). In a collaborative culture, supply chain partners openly communicate and work together to share information, in order to improve supply chain visibility, reduce supply chain uncertainty, and enhance competitiveness (Chen et al., 2013). Collaboration plays an important role in enhancing the competitive advantage of a supply chain and can significantly reduce overall cost and uncertainty (Gold et al., 2010; Carter and Rogers, 2008). Moreover, a high level of collaboration across a supply chain can help mitigate disruption and reduce risk (Jain et al., 2017; Li et al., 2015, Chen et al., 2013). Beske and Seuring (2014) maintained that collaboration can be understood as one step further than cooperation. According to Świerczek (2014), supply chain integration is a strategic collaboration of both intra-organizational and inter-organizational processes. He believes that cooperation, collaboration, and coordination between supply chain members provide an intensive integration in the supply chain. Decision synchronization and incentive alignment are two major contributions of collaboration in a supply chain; they are essential for successfully responding to the disruption in the supply chain (Jain et al., 2017).

2.5. Redundancy

According to Christopher and Peck (2004), redundancy involves the strategic and selective use of spare capacity and inventory that can be invoked to cope with a crisis, such as demand surges or supply shortages. Sheffi and Rice (2005) recommended that building redundancy is an effective option to create resiliency and enhance recovery from disruptions. Kamalahmadi and Parast (2017) showed how implementation of three types of redundancy strategies (inventory, backup suppliers, and protected suppliers) can improve a firm's performance in a turbulent and complex business environment that requires mitigating the effects of supply chain disruption.

To provide a review of the effect of SCR drivers, we examine the impact of flexibility, agility, collaboration, and redundancy on mitigating supply chain disruptions in terms of demand, supply, process, control, and environmental disruption (Christopher and Peck, 2004). To the best of our knowledge, this is the first study to investigate the effect of supply chain resiliency enhancers on mitigating each type of supply chain disruption. Our research indicates which enablers of supply chain resiliency (flexibility, agility, collaboration, and redundancy) have been identified by research as the most important strategies to mitigate each type of supply chain disruption (demand, supply, process, control, and environmental). In addition, our review thoroughly covers both academic and practitioner journals, book reviews, conference proceedings, and other related reviews and reports. Our study covers all the publications from 2000 to 2017, using three phases in collecting publications: (1) searching databases and

journals by using keywords to find articles, (2) screening the articles in a first phase, and (3) analyzing the information of the articles.

3. RESEARCH METHODOLOGY

In this research, we adopt a literature review methodology that has been recently encouraged by Kamalahmadi and Parast (2016b) and Tukamuhabwa et al. (2015), in order to advance theory in supply chain risk management research. In accordance with Tukamuhabwa (2015), we use a three-phase approach in order to avoid bias, improve validity of the findings, and collect the relevant publications (Figure 1). First, we searched databases and journals using specific keywords (Phase 1: sourcing articles). Second, we screened publications obtained in the first phase (Phase 2: article screening process), with several objectives: (1) remove duplicates, (2) do two-stage inspection of articles, and (3) check cited articles. Third, we extracted and analyzed the information from the publications obtained from Phase 2. According to Kamalahmadi and Parast (2016b), since the concept of SCR was not discussed much before 2000, we considered publications starting with the year 2001.

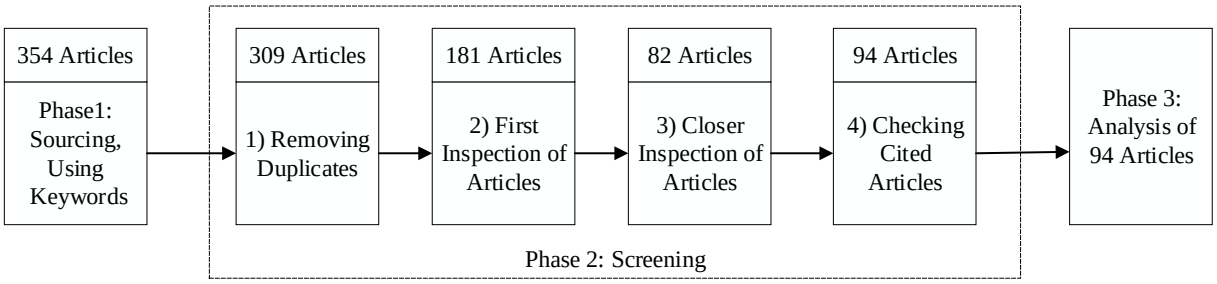

Figure 1. Overview of the review process

Phase 1: Sourcing articles

In this phase, in order to start with high-quality databases for our research and in line with Kamalahmadi and Parast (2016b), we used the widely accepted quality rating published by the Association of Business Schools (ABS), UK, as Academic Journal Guide 2015 (AJG 2015). Using AJG 2015, we consider three different domains of management for this research: Operations Management (OM), Operations Research and Management Science (OR/ MS), and General Management (GM). Table 1 identifies the journals where the reviewed articles were published. Each journal's AJG 2015 ranking is on a scale of 1 to 4, where 4 is highest.

Table 1. List of journals reviewed and their AJG 2015 rankings

List of Journals	AJG Ranking
Operations Management (OM)	
Production and Operations Management (POM)	4
Journal of Operations Management (JOM)	4
International Journal of Operations and Production Management (IJOPM)	4
International Journal of Production Research (IJPR)	3
Manufacturing and Service Operations Management (MSOM)	3
International Journal of Production Economics (IJPE)	3
IEEE Transactions on Engineering Management (IEEE-TEM)	3
Journal of Supply Chain Management (JSCM)	3
Supply Chain Management: An International Journal (SCM)	3
Journal of Business Logistics (JBL)	2
Operations Research and Management Science (OR/ MS)	

Management Science (MS)	4
Operations Research (OR)	4
European Journal of Operational Research (EJOR)	4
Decision Science Journal (DSJ)	3
General Management (GM)	
Harvard Business Review (HBR)	3
MIT Sloan Management Review (SMR)	3
California Management Review (CMR)	3

In order to identify and collect the publications for our research, we used major business and management databases, including Emerald, Elsevier Science Direct, ABI/ Inform Global ProQuest, Wiley, INFORMS, Google Scholars, Springer, Taylor and Francis Online, along with each journal of Table 1. A total of 19 keywords were identified by the authors for this research ("Flexibility/ Flexible", "Agility/ Agile", "Redundancy/ Redundant", "Collaboration/ Collaborate", "Cooperation/ Cooperate" "Supply Chain Flexibility/ Agility/ Collaboration/ Redundancy/ Cooperation" together with "Disruption", "Uncertainty", "Risk", or "Resilience"). This search was conducted using keywords contained in the article titles, abstracts, and keywords, as well as in the articles. Using these keywords, 354 publications were retrieved.

Phase 2: Article screening process

The retrieved articles were subjected to these four steps:

First, we cross-checked all the articles to eliminate duplicate results retrieved from different databases. This reduced the number of articles from 354 to 309. Second, we reviewed and screened the articles. This involved conducting an initial check with regard to the title, abstract, and keywords identified in the articles. This step retrieved the papers that are related to supply chain resiliency strategies (supply chain flexibility, agility, collaboration, and redundancy). This reduced the number of articles to from 309 to 181. Third, we reviewed the introduction, conclusion, and implication sections of the 181 papers to retrieve the papers that investigated the effect of each type of supply chain resiliency strategy on mitigating each type of supply chain disruption (demand, supply, control, process, and environmental disruption). This step can help to identify which strategy of supply chain resiliency enhancer (supply chain flexibility, agility, collaboration, or redundancy) has been discussed to mitigate which supply chain disruption (demand, supply, process, control, or environmental). This reduced the number of articles to from 181 to 82. Finally, by checking the references and citations in each of the 82 papers, we could increase the number of publications to 94. This procedure resulted in 94 quality research publications that are the basis of the literature review presented in this study.

Phase 3: Analysis of the articles

This phase involved extracting and documenting information from each of the 94 papers. The information extracted included the definition of each supply chain resiliency enhancer and its effect on each type of supply chain disruption risk driver, along with strategies for building a resilient supply chain.

4. FINDINGS

For this study, we discussed the most important strategies of SCR to cope with each sources of disruption risk. Our results showed that while flexibility has been mentioned frequently in the literature as the most important strategy to cope with demand, supply, process, and environmental risk, collaboration has been mentioned several times in the literature as the most

important strategy to cope with control risk (Figure 2). Moreover, our findings showed that for mitigating demand disruptions, manufacturing flexibility is the most important dimension of supply chain flexibility; for mitigating supply disruptions, supplier flexibility is the most important one; for mitigating process disruptions, process flexibility is the most important one; and for mitigating environmental disruptions, logistics flexibility and operational flexibility are the most important ones. Finally, to mitigate control disruptions, collaborative communication, information sharing, and trust are the most important dimensions of supply chain collaboration.

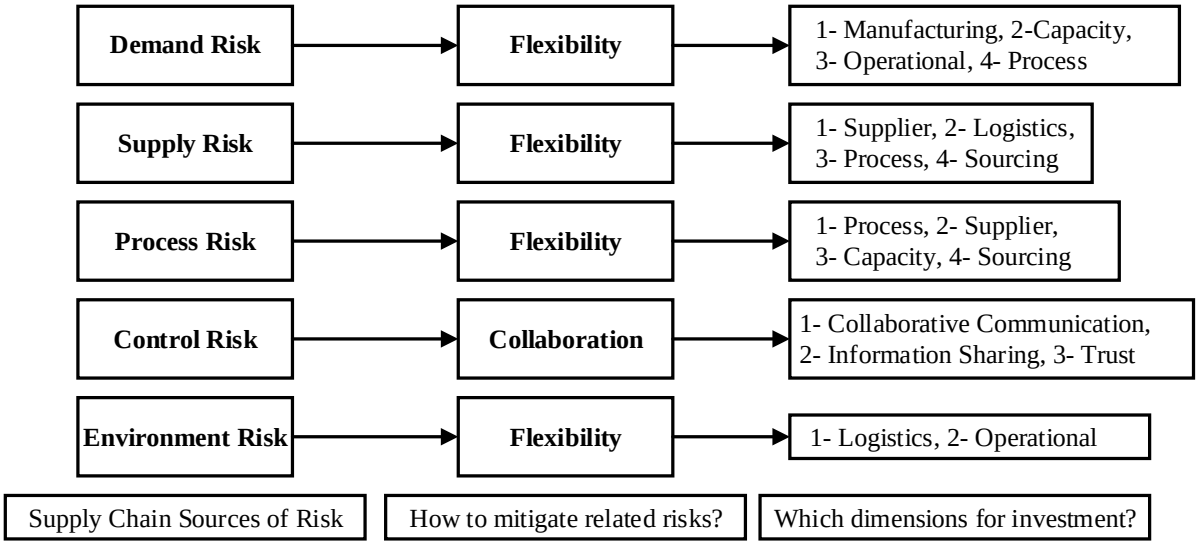

Figure 2. SCR strategies and their dimensions to mitigate each type of supply chain disruption risks

5. CONCLUSIONS AND FUTURE RESEARCH

In this research study, we addressed several research questions in SCRM and SCR. First, we investigated the current state of SCR in the literature. Then, we identified some important strategies of SCR enhancers that mitigate supply chain disruption risks. In addition, this study showed investing in which strategy of SCR enhancers (flexibility, agility, collaboration, and redundancy) is of great importance for firms when faced with different types of disruption risks (demand, supply, process, control, and environmental risk).

The literature review presented here is different from previous studies in terms of its aim, scope, approach, methodology, and contribution. The research for this paper was performed via a structured review of 94 peer-reviewed publications, including journal papers, conference proceedings, and book chapters within an 18-year time frame (2000 to 2017). After conducting a comprehensive review of the literature in the SCR, our findings showed that while flexibility has been mentioned frequently in the literature as the most important strategy to cope with demand, supply, process, and environmental risk, collaboration has been mentioned several times in the literature as the most important strategy to cope with control risks. We then proposed an SCR timeline and framework for identifying the most important strategy of SCR in coping with each type of supply chain disruption risk (Figure 2).

Despite of the findings and implications, this study also presents limitations. First, while we considered the impact of four important antecedents of SCR, considering the role of the other antecedents of SCR such as visibility, integration, structure and knowledge, and reengineering can be investigated in future research. (Kamalahmadi and Parast, 2016b; Ponomarov and

Holcomb, 2009; Christopher and peck, 2004). Second, other categorization of supply chain risks (e.g. Ho et al., 2015; Simangunsong et al., 2012; Sodhi et al., 2012; Tang, 2006a; Peck, 2004) can be considered for investigation in future research.

ACKNOWLEDGMENTS

This research is based upon work supported by the National Science Foundation (NSF) under Grant number 123887 (Research Initiation Award: Understanding Risks and Disruptions in Supply Chains and their Effect on Firm and Supply Chain Performance).

APPENDIX

Appendices (the summary of 94 reviewed papers) are available upon request.

DECISION SCIENCES INSTITUTE
A New r^2 for Time Series Forecasting

Rick Hesse
Lincoln Memorial University
Email: rick.hesse@LMUnet.edu

ABSTRACT

Forecasting time series data minimizing RMSE using Solver moving averages allows comparison with better naïve models (parameters do not need optimizing) than the standard average of the data (Y-bar). R^2 values for regression formulas can be misleading comparing model error measures with Y-bar.

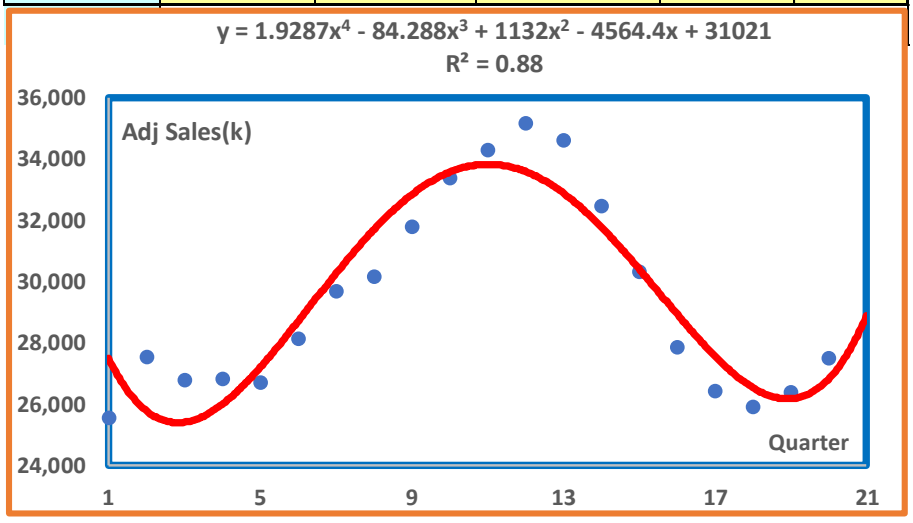
KEYWORDS: Forecasting, Time Series, Error Measures, Moving Averages, Regression

INTRODUCTION

The deseasonalized data (adjusted) sales in $(000) for Food Service Corporation (feeds firefighters in California during wildfires during the fire season) is shown in Figure 1, with an Excel Trend Line for a quartic (4th power) equation and the biased R^2 value of 88% shown above the graph. This R^2 value is very misleading value, if we use the Solver with moving averages instead of regression. This regression R^2 means that 88% of the error incurred if you used just a straight line average is explained by the quartic curve, which seems to indicate that this is a very good curve fit but is far from it, and certainly not the best forecasting model.

Figure 1: Deseasonalized Data for 20 quarters and forecast for QTR 21 with Excel Trend Line

Seasonally Adjusted Foodservice Co. Quarterly Sales $(000)					
Sales	Year 1	Year 2	Year 3	Year 4	Year 5
Quarter 1	25,542.7	26,703.5	31,778.8	34,614.2	26,428.0
Quarter 2	27,534.1	28,117.4	33,370.8	32,474.4	25,917.9
Quarter 3	26,757.2	29,676.7	34,298.8	30,320.6	26,383.5
Quarter 4	26,813.3	30,165.1	35,166.0	27,861.0	27,485.1



"HOW ARE YOU? COMPARED TO WHAT?" 5 NAÏVE MODELS

Figure 2 shows the results of a 2-period Solver Moving Average with the 5 **naïve models** (no Solver and just simple math) comparisons for 3 types of errors, with RMSE being chosen to minimize at this time. The two-period weights are in **D32:E33**. **Figure 3** is the Solver setup.

Figure 2. Summary of 2-period Solver Moving Average and Naïve Models and Weightings

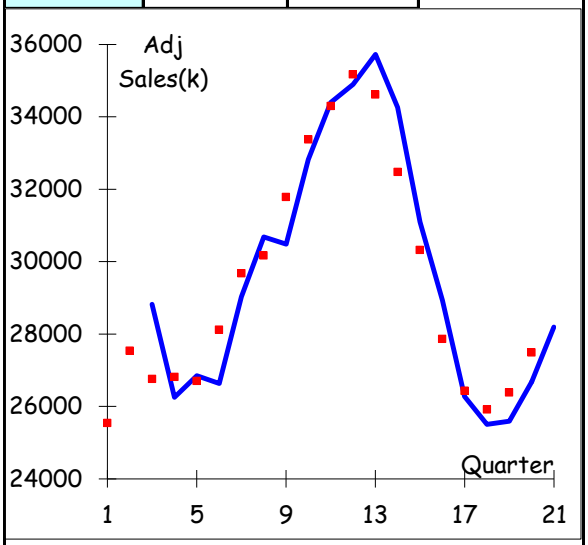

Figure 3. Solver Setup for 2-period Model

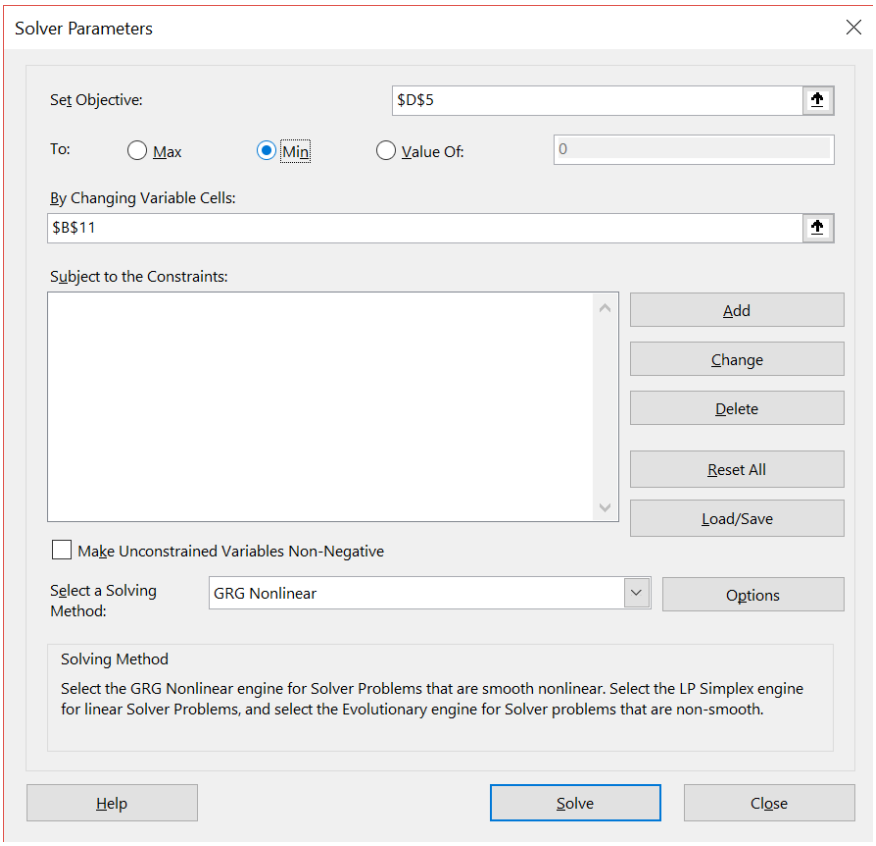

There are many naïve models besides Y-bar (overall or total average) which we can compare with our 2-period Solver model to determine how "well" this fit explains error. *A "naïve" model requires no optimization* and for causal data (X,Y) used in forecasting, the only regression naïve model is the average of all the data to be used (Y-bar). However, if time series data is used (Y values for consecutive time periods with no missing data in the sequence), then there are several naïve (or simple models), as listed below. Figure 2 shades the best naïve models for each error measure in light pink.

Total Average (Y-bar) - 1

This average is compared against all the known Y-values and RMSE, MAD or MAPE is calculated for each data point. A fallacy in using this is that one does not know the total average until the end!

Cumulative Average - 2

This would be the average of the first period to predict the second, the average of the first two periods to predict the 3rd period, up to all n periods to predict Y_{n+1}, which is the value Y-bar. The idea is that in period *i* you really only know *i-1* pieces of data but have a good estimate of Y-bar.

3-period smoothing - 3

This uses a simple moving average of the last 3 periods of information, weighted equally. Thus you can only start predictions for $\acute{Y}_4$, and predict $\acute{Y}_{n+1}$ as $(Y_{n-2} + Y_{n-1} + Y_n)/3$.

2-period smoothing - 4

This uses a simple moving average of the last 2 periods of information, weighted equally. Thus you can only start predictions for $\acute{Y}_3$, and predict $\acute{Y}_{n+1}$ as $(Y_{n-1} + Y_n)/2$.

1-period smoothing - 5

(Next=Last). "Next = Last" is the simplest of the naïve models in that the forecast for next period, $\acute{Y}_i$, is the previous actual value, Y_{i-1}, or technically a 1-period moving average. For most time series data with any movement, this usually gives the best error measures of all 5 naïve models.

The results for 2-period Solver Moving Average and the 5 naïve models minimizing RMSE (and showing results for MAD and MAPE, has been shown in Figure 2 and has blue shading in row 11 to indicate an $r^2 \geq 30\%$ and a good forecast model by my rule of thumb. If there are no Solver models with $r^2 \geq 30\%$ then use the best naïve model and forecast.

The problem with standard moving averages, is that usually the weights are equal and no optimal set of weights is determined, because it was too difficult mathematically to determine those weights 25 years ago. Also weights were restricted to being non-negative, which turns out to be a huge mistake. But in the last 25 years, with the introduction of PCs, spreadsheets and the built-in Solver with gradient search, determining the optimal weights (and now just P_1 and/or P_2, is no longer a barrier. In fact, 2-period and 3-period Solver models reduce to quite simple formulations (Hesse, 1977; Hesse, 1998-2018). Minimizing RMSE is very stable for even 4th order polynomials, while minimizing MAPE or MAD has convergent difficulties which are usually overcome by using the RMSE coefficients as starting points for the gradient search routine.

SOLVER MOVING AVERAGE MODELS:

2-Period Solver: Next = Last + $P_1 * \Delta_1$ P_1 unrestricted (1)

3-Period Solver: Next = Last + $P_1 * \Delta_1 + P_2 * \Delta_2$ P_1, P_2 unrestricted (2)

where P_i is unconstrained, and Δ_1 = difference between the last two data points and Δ_2 is the difference between the 2nd and 3rd last points.

Originally, I used weights (W_i) (but allowed them to be unsigned) and then realized that since the sum of them should be 100%, the formulas could be modified more simply. So instead of having 2-3 variables, one constraint, and non-negativity requirements, the problem is actually one less variable, no constraints and unrestricted variables. This led to my discovery that 2- and 3-period Solver models were just an adjustment of the last data value (or adjusting Next=Last)..

The problem with standard regression techniques for curve fitting linear, quadratic, cubic and higher order polynomials is that R^2 is compared to being dead – or "flat line"! The error of using

the average of the data (Y-bar) is taken as the comparison, and the general formula to compute R^2 is

R^2 = (1-(model error/naïve error)^2) (3)

and the error measure could be RMSE, MAD or MAPE or even MSE (but that's usually incredibly large).

For a 2-period Solver Model, the formula for the forecast is $\acute{Y}_{n+1} = Y_n + P_1*\Delta_1$ where Δ_1 is the difference between the last 2 data points, Y_n and Y_{n-1}. In this case, the optimal P value is -64.48% and equivalent to weights of 164.48% for Y_n and -64.48% for Y_{n-1}. Thus there is only one variable (P_1) for the Solver and it is unrestricted. Notice that by allowing the weights (and thus also the proportions P) to be negative, we can find much better error measures. This was not even dreamed of 25 years ago, and has revolutionized moving averages as a powerful predictor for time series data.

First notice the RMSE for each of the 5 naïve models. The Total Average RMSE for Y-bar is 3,194.14, and lowest of the 5 is Next=Last and is shaded and its RMSE is 1,363.46. The r^2 values are for the Solver models and those error measures are compared with Next=Last, so that r^2 for RMSE is 48.7% or 1-(976.80/1,363.46)^2. Notice also that there is not much difference in r^2 when using MAD or MAPE for this data set, although those values would be a bit higher if the Solver minimized each of those. What this tells us is that this data is very well behaved and since minimizing RMSE is the most stable of these 3 gradient search routines, we will stick with RMSE. If there was a lot larger value of r^2 for MAPE or MAD, we would then run the Solver minimizing the best of these. Also, my "rule of thumb" is that an r^2 of 30% or higher is acceptable and is thus shaded in light blue.

MOVING AVERAGE SOLVER MODELS SUMMARY

When we Move/Copy this worksheet, we can then use the Solver to find optimal values of both P_1 and P_2, which in turn determine the weights for the last 3 data points to forecast the fourth. P_2 is multiplied by the difference of 2 and 3 data points ago. In the summary shown in **Figure 4** we see that the 3-period Solver Moving Average produces an even better r^2 value of 62.03%. The red font indicates the optimal error measure in each column. Of course, what optimizes RMSE will also optimize its companion r^2. Also shown in Figure 4 are the weights derived from the P's.

Figure 4. Solver Moving Average Summary

Food Service Co for Firefighters in So Cal					
Moving Average Summary					
n = 20	Forecast	R.M.S.E.	R.M.S.E.	Δ_1	Δ_2
Best Naïve	Quarter=21	Error	r^2	1,101.57	465.64
Next = Last	27,485.084	1,363.457	0.00%	P_1	P_2
2-period Solver	28,195.383	976.800	48.68%	64.48%	N/A
3-period Solver	28,390.263	840.193	62.03%	88.11%	-14.05%
W_{-1}	W_{-2}	W_{-3}			
164.48%	-64.48%		2-period Solver Moving Avg		
188.11%	-102.17%	14.05%	3-period Solver Moving Avg		

IS YOUR FORECAST SMARTER THAN A 5TH GRADER?

Now let's turn to regression, and see what happens when we minimize RMSE in the summary portion of my Linear Regression template shown in Figure 5.

Figure 5. Regression Summary

Linear Regression Summary				Food Service Co for Firefighters in So Cal				
	R.M.S.E.	R.M.S.E.	Degrees of	Forecast Model				
n = 20	Error	Unbiased r^2	Freedom	a +	bX +	cX^2 +	dX^3 +	eX^4
Y-bar	3,194.14	0.00%	19	29,370.44				
Linear	3,259.11	-4.11%	18	28,788.97	53.838			
Quadratic	2,005.57	60.58%	17	22,637.92	1,731.398	-79.8838		
Cubic	1,998.32	60.86%	16	24,797.02	629.701	48.1260	-4.0638	
Quartic	1,245.47	84.80%	15	31,021.41	-4,564.402	1,131.9848	-84.2876	1.92868

For the Regression Summary in Figure 5, note that the polynomial coefficients in the Quartic row match the Excel quartic trend line seen in Figure 1, but r^2 is now the unbiased value of 84.80% instead of the biased R^2 of 88.00% because it takes into account degrees of freedom. This is the reason I used the symbol r^2 to avoid confusion with Excel's symbol R^2. Give this summary, we still see the Quartic model as the most viable of the regression models when errors are compared to Y-bar.

COMPARISON WITH BEST NAÏVE MODEL

But even this r^2 value of 84.80% is misleading, because it is measured against Y-bar and not the best naïve model. A complete summary of the Moving Average and Regression models is shown in **Figure 6**, where the base of r^2 is the RMSE of Next=Last (1,363.457) instead of 3,194.1 for Y-bar to recompute the real r^2 for the Linear Regression Summary in the 4th column.

Figure 6. Final Summary of true r^2

Moving Average Summary					
n = 20	Quarter=21	RMSE	RMSE	Δ_1	Δ_2
Model	Forecast	Error	r^2	1,101.6	465.6
Next = Last	27,485.1	1,363.457	0.0%	P_1	P_2
2-period Solver	28,195.4	976.800	48.7%	64.48%	N/A
3-period Solver	28,390.3	840.193	62.0%	88.11%	-14.05%

Linear Regression Summary								
n = 20	Quarter=21	RMSE	RMSE	Forecast Model				
Model	Forecast	Error	r^2	a +	bX +	cX^2 +	dX^3 +	eX^4
Y-bar	29,370.4	3,194.1	-448.81%	29,370.44				
Linear	29,919.6	3,259.1	-471.37%	28,788.97	53.838			
Quadratic	23,768.5	2,005.6	-116.37%	22,637.92	1,731.398	-79.884		
Cubic	21,609.4	1,998.3	-114.81%	24,797.02	629.701	48.126	-4.064	
Quartic	28,878.6	1,245.5	16.56%	31,021.41	-4,564.402	1,131.985	-84.288	1.92868

Now all only one of the regression curve fits has positive a r^2 value, and in this case (not always), the Quartic regression r^2 0f 16.56% is much worse than our best Solver Moving Average r^2 of 62.0%. So if we used the quartic curve fit, we would not even be as smart as a 5th grader! This because as a general rule, I don't use a model unless r^2 is $\geq$ 30%, and I recommend using the best naïve model, which now is Next=Last (and not Y-bar). Thus the forecast for Quarter 21 is 28,390.26k instead of 28,878.6k or about $490,000 less than the quartic forecast. This example should convince users that Regression statistics should be viewed with healthy suspicion if time series data is involved. The RMSE for the best Regression is actually about 50% higher than the best Solver Moving average (1245.5 vs. 840.2), and it only makes sense to go with the model with the much better error measures (lowest RMSE and highest r^2) unless the forecast seems beyond reason or reality.

ANOTHER WARNING AND INTERESTNG FACT

Another important lesson from this exercise is that even though the quartic fit "looks" graphically like it gets close to the actual data points, the error measure says differently. Many students will just say that the quartic fits the data the best because it has a smooth curve instead of the 3-period Solver model. The two graphs are shown below, side by side, in Figure 7. Many of my MBA students swear that just looking at the graph they can tell that the regression model has less error than the Solver moving average!

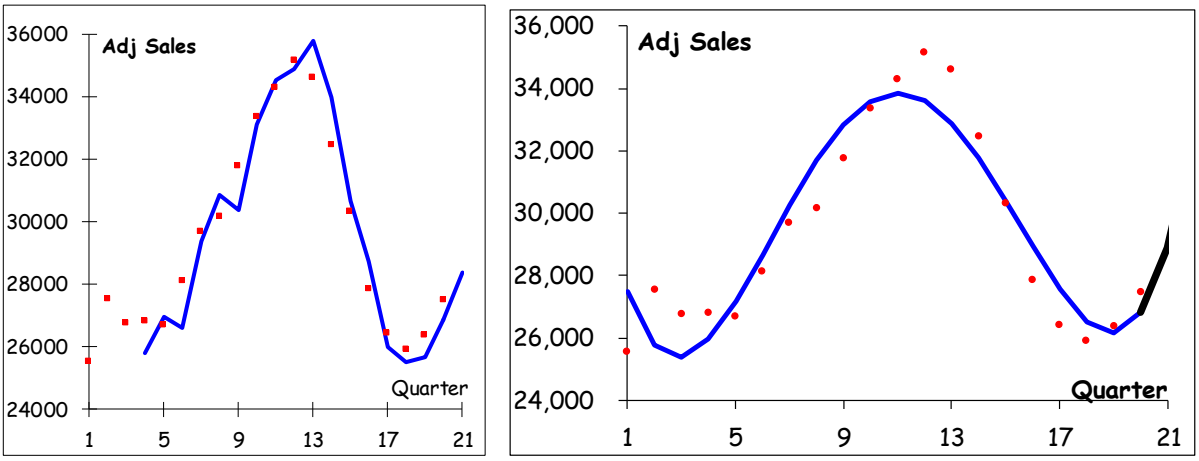

Figure 7. 3-period Solver Moving Average Quartic Regression

The only drawback about using Solver Moving Averages for forecasting is that you can only go forward one period. With regression formulas, you can go forward (or backwards or anywhere in between) as many periods as desired, but extending more than about 25% of the range of the data is fraught with possible pitfalls. The idea of using a regression formula (polynomial) is to capture the general trend of the curve and make sure that the r^2 is satisfactory as well as the error measure. But this r2 has to be measured using the error of the minimum naïve model.

Figure 8 illustrates an interesting fact with the summary of the 3-period Solver Moving Average. Note that the r^2 values for each of the 3 error measures in cells **D11:F11** are almost identical. This means that the data is fairly well behaved and without extreme ranges that would favor one error measure over another.

Figure 8. 3-Period Solver Moving Average Summary

	A	B	C	D	E	F	G	H
2	Food Service Co for Firefighters in So Cal							
3		Minimize		Error Measures				
4		R.M.S.E.	Forecast	R.M.S.E.	M.A.D.	M.A.P.E.	df	
5	3-Period Solver Model		28,390.26	840.19	708.97	2.39%	17	
6	Total Average		29,370.44	3,194.14	2,898.03	9.76%	19	N
7	Cumulative Average		29,370.44	3,355.51	2,801.76	9.18%	19	A

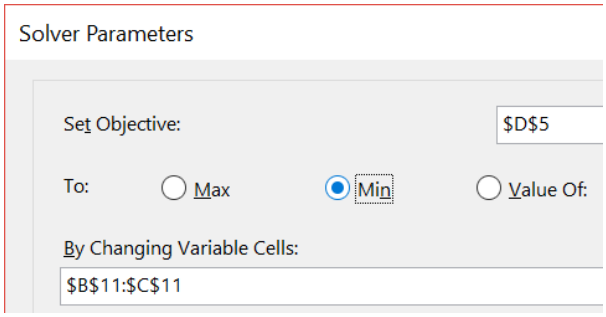
Figure 9 shows the Solver setup for this 3-period Solver Moving Average.

Figure 9. 3-period Solver Setup



CONCLUSION

When using Time Series data for forecasting, it is wise to use both Solver Moving Averages and Linear Regression and compute r^2 as compared to the best naïve model, and not just Y-bar (Total Average or Y-bar). This can make a huge difference in analysis, and by showing the actual error and an r^2 which makes sense, to help convince those who automatically think regression is always the best method and now should realize that there may be much better moving average Solver models to consider. ABSTRACT

As Safety Management System (SMS) deals with the management of safety risks, it is important to monitor its lifecycle in terms of its performance. Assessing the effectiveness of this lifecycle constitutes a systematic approach that leads to better management. In this paper, a two-part methodology is proposed, utilizing a set of problem reports as the basis, stemming from the dispatchers' SMS department of a major airline. Text analysis performed on these reports followed by the development of a regression model leads to a surprised/planned measure that contributes to the assessment of the effectiveness of the SMS lifecycle for the airline.

KEYWORDS: Safety management system, Lifecycle effectiveness assessment, Regression, Text analysis, Decision theory

INTRODUCTION

Safety Management System (SMS) is a system to assure the safe operations through effective management of safety risks. It uses policies, procedures, and bulletins among others to deal with safety issues. When one of these approaches is implemented, it is assumed that the targeted issue will be resolved. In reality, the implemented SMS method is only functional for a period of time. The issue may arise again at a later date or a similar type of issue may appear. Hence, the effectiveness of the SMS lifecycle needs to be assessed so as to improve the reaction time in managing emerging issues and to ensure all issues are properly dealt with.

One way of judging the success of an SMS lifecycle is through the problem reports written by the people actively applying new implementations. These problem reports are direct indicators of the performance of a new SMS execution; so, by extension, they are indicators of the

performance of the SMS lifecycle. Analyzing sets of problem reports can thus provide types of measures in how effective the SMS lifecycle is. In particular, the surprised or planned characteristic of a problem report can signal how well or not, the SMS lifecycle is functioning. The objective is then to determine the surprised or planned feature of a new problem report. To tackle this, the approach is broken up into two parts. In the first, text analytics is performed on a set of problem reports and its output is used as input in the second part to build two regression models, comparing manually given surprise scores and computer surprise scores.

The structure of the paper is as follows. The next section provides a brief overview of how SMS is implemented in various other sectors. We, then, explain the two-stage proposed solution methodology that consists of data analysis, metric creation and regression models. How this proposed framework can be performed to assess the effectiveness of the SMS is later discussed.

LITERATURE REVIEW

Numerous industry-specific instruments have been developed to measure the performance of SMS in sectors such as healthcare, manufacturing, construction, and aviation. Redinger and Levine (1998) developed a universal performance tool to measure the effectiveness of many Occupational Health and Safety Management Systems (OHSMS). Their model's inputs are auditable clauses, each of which describes one or more auditable issues within the selected management systems. Based on policy analysis and system theory, five key performance variables are generated, that also reflect the meaning and purpose of the inputs. They are given a score from zero to five, and the final output is an average of those scores.

Teo and Ling (2006) proposed a model to measure the effectiveness of the safety management systems of construction sites. Through surveys and workshops with experts, important factors affecting safety are gathered. The most crucial factors are then determined by using the analytic hierarchy process and factor analysis. The output of the model is a construction safety index, which is calculated based on the multi-attribute theory.

Kirezieva et al. (2013) developed an assessment tool of the Food Safety Management System (FSMS) implemented in the fresh produce sector. They established three sets of indicators for each step of the production chain (cultivation, processing, trade). Each indicator was validated by experts and has four levels (low, basic, average, advanced), describing the different ways the activities can be implemented. The system output is a comprehensive assessment of the FSMS, in which improvements are identified.

Hee et al. (1999) presents the Safety Management Assessment System (SMAS) that assesses human and organization factors in marine systems. An assessment is composed of three phases: an evaluation of information, system visits, and a final review. It is aided by a computer program, which takes in all numerical evaluations, creates a database, and displays the assessment results. SMAS also includes a training plan for the user and the criteria utilized are quantified with ranges, which considers uncertainty.

SOLUTION METHOD

R programming language is utilized for data analysis and for statistical computing. For statistical analyses, R programming has a broad set of facilities that has been specially constructed. R packages consist of inbuilt statistical algorithms with sheer amount of machine learning algorithms

and mathematical models. R also contains a broad range of graph drawing tools, which makes it to produce standard graphs of your data. The problem reports make up the basis of the data analysis and are from an SMS department of an aviation industry.

The data for this study is taken from United Airlines between the dates of September 1, 2015 and July 2, 2016. It constitutes problem reports emanating from the dispatcher's department of SMS. Specifically, the data contains information on the description of the issue, a list of its contributing causes, the date and time it occurred, the date and time the problem report was created, and a suggested resolution section. Here, the necessary information is taken from the data for building the regression model to improve the effectiveness of the SMS.

Part I

There are only so many synonyms pertaining to the emotion of surprise. Indeed, surprise can be elusive in a text if no actual synonym is present; it is often the context that provides the feeling of surprise. As a result, contextual metrics are defined, which, depending on their combinations, may indicate a measure of surprise or planned (whether the issue is already known). These metrics are split into two groups: one related to the causes or consequences of the issue at hand, the other concerning the emotions surrounding the issue. Specifically, the first group is comprised of the following categories: Oversight (M1), Communication (M2), Safety (M3), Recurring (M4), and Discrepancy (M5). And the second group consists of Ownership (S1), Blame (S2), Annoyance (S3), Confusion (S4), and Concerned (S5). Oversight is defined as a failure to notice something. Communication describes the exchange of information or the lack thereof. Safety encompasses anything related to safety and legality. Recurring designates actions or issues that occur repeatedly. Discrepancy refers to a non-compatibility between facts. Ownership characterizes someone acknowledging their mistake. Blame means a wrong or a mistake is assigned responsibility. Annoyance depicts irritation, anger, and being fed up. Confusion signifies uncertainty or a lack of understanding. Concerned includes the emotion of being worried or recommending.

To simplify the following steps, the set of problem reports are pre-processed; all letters are put in lowercase and common words such as very, also, then, are removed, as well as apostrophes. Then each of these categories is populated with text terms pertaining to the set of problem reports. Once the cluster of words or dictionaries are filled, they are optimized for textual analysis. To minimize the number of words, only the root of words with a variety of endings is kept. For example, the words misidentify, misidentifies, misidentification, and misidentified were all present in the initial oversight dictionary. Due to their common root, these words are replaced with misidentif in the final dictionary. This reduces the number of words in the dictionary and at the same time, increases the dictionary's reach.

Next, the metrics are run against the set of problem reports. For a problem report, it is given a value of 1 for a metric if one of the terms in that dictionary is present in the report; otherwise it is given a value of 0 for that metric. At the end of this step, the reports are categorized with respect to the aforementioned metrics, in binary scores. However, out of the 185 problem reports, only 5 are not captured by these metrics, either due to not containing enough text and/or being too technical.

Part II

Starting with the computer-scored regression, the independent variables are the metrics previously defined and the dependent variable is the time difference between when the implementation occurred and when the problem report was written. The idea behind the dependent variable is that the emotion of surprise is more intense when new issues stemming from the implementation arise and that feeling abates over time as more people are aware of those issues.

For the manual surprise-scored regression, the metrics are still the independent variables, but the dependent variable is a surprise score given by a human. In essence, each problem report is manually reviewed and scored for a human understanding of surprise. A group consensus is used to balance out the scores.

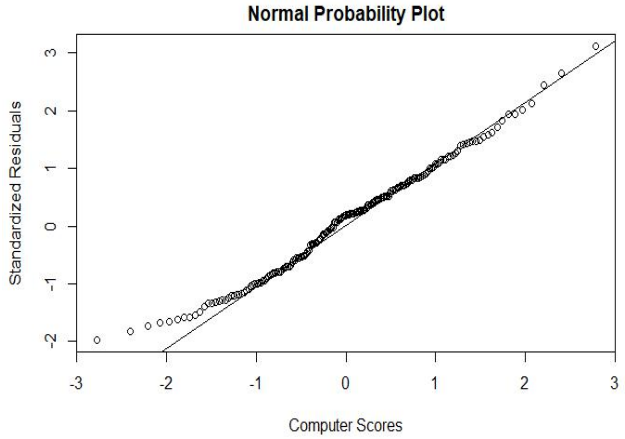
Both regression models are built progressively, starting with only the main metrics. Second order interactions are then added, followed by the removal of highly non-significant terms via a stepwise regression function. The most extreme outliers are then removed, which leads to the final regression model. Throughout each step, the normality of the residuals is inspected via a normal probability plot and multicollinearity is checked by calculating the terms' values of variance inflation factors (VIF) and flagging those with a VIF higher than 16.

RESULTS

Computer-scored Regression Results

The computer- scored regression model starts with only the main metrics of M1 through M5 and S1 through S5, and no constant term. This yields an adjusted R2 value of 68.10%. Given the relatively low value, all second order interaction terms are added to the regression. This generates a better adjusted R2 value of 74.24%; however, multicollinearity problems are present and many interaction terms are non-significant. Thus, a stepwise regression function is applied to better the model. The resulting regression model has all the main effects and fewer interaction effects, and an adjusted R2 value of 77.83%. Yet, the normal probability plot shows outliers at the upper end, so the most extreme outlier is removed from the regression. This produces a regression model with its residuals following a normal distribution as seen in Figure 1, no multicollinearity problems, and an adjusted R2 value of 79.05%. The extreme outlier that was taken out is one of the cases that has no metrics; because it is one of the later problem reports, it does not fit well with the model. This final model has linear main effects with some second order interaction effects. Table 1 and Table 2 presents a recap of the steps taken to build the computer-scored regression model.

Figure 1: Normal Probability Plot of Computer Scored Regression Model



Regression	Terms	Adjusted R^2
1st	Main metrics (M1 to S5)	68.10%
2nd	Main metrics and all second order interactions	74.24%
3rd	Main metrics and some second order interactions	77.83%
4th	Main metrics and some second order interactions	79.05%

Table 1: Computer Scored Regression model steps

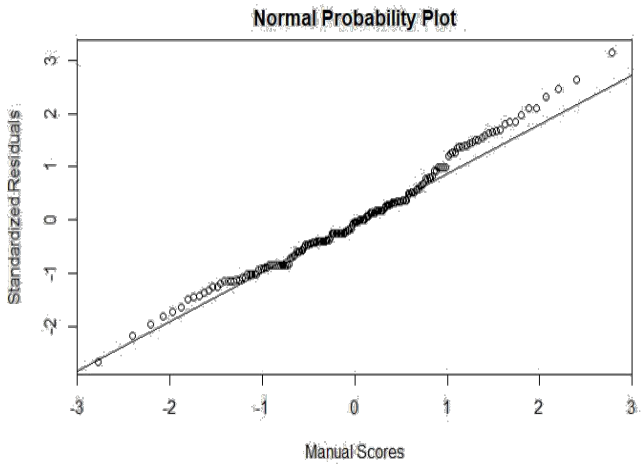
Regression	Multicollinearity	Normality Satisfied
1st	Absent	Yes
2nd	Present	Yes
3rd	Absent	Yes, but with outliers
4th	Absent	Yes

Table 2: Computer Scored Regression model steps

Human-scored Regression Results

Using a similar approach to the first regression, this final model has all main terms but M1, and some interaction effects. Figure 2 displays the satisfied normal probability plot and the adjusted R2 value is 87.67%. Table 3 and Table 4 shows the details of how the final manual-scored regression model was attained.

Figure 2: Normal Probability Plot of Human-Scored Regression Model



The manual surprise-scored regression model shows a strong relationship between the human reading of surprise and the metrics developed. This indicates that the dictionaries built are sufficient to have the computer scores used in the regression model, in place of the manual scores. The difference between the adjusted R2 values of both regressions can be explained by the fact that a human will always better grasp the emotion of surprise than a computer. Further details of the regression model in which all main metrics and all second order interactions have been incorporated and ran by Stepwise Regression can be found in Table 5.

Table 3: Manual Scored Regression model steps

Regression	Terms	Adjusted R^2
1st	Main metrics (M1 to S5)	80.33%
2nd	Main metrics and all second order interactions	83.94%
3rd	All main metrics but M1 and some second order interactions	86.29%
4th	All main metrics but M1 and some second order interactions	87.67%

Table 4: Manual Scored Regression model steps

Regression	Multicollinearity	Normality Satisfied
1st	Absent	Yes
2nd	Present	Yes
3rd	Absent	Yes, but with outliers
4th	Absent	Yes

Table 5: Regression Results-Main metrics and all second order interactions

	Coefficients				
	Estimate	Std. Error	t value	Pr(>|t|)

CONCLUSIONS

Using a dictionary-based metrics approach, two regression models are constructed that compare the human understanding of surprise with some computer's reading. This level of

surprise output gives a quantitative assessment of the effectiveness of the SMS lifecycle, and the model as a whole provides a framework for it. The approach presented in this paper may be applied to other industries that have a similar concept in how issues are reported. The metrics in and of themselves will need to be redefined specifically for that industry, as each sector has its own technical language and sets of issues.

In terms of future work, for part 1 of the overall approach, the dictionaries can be refined with additional or more root-based terms, and new dictionaries will need to be created to take into account the problem reports not represented by the current metrics. As only binary scores were used for the metrics, continuous variables may be considered as this might give more emphasis to certain dictionary terms. For part 2 of the approach, the output of the regression may be converted from a date to an actual surprise score that could assist in grouping the incoming reports. Each group of reports would then lead to a different corrective action plan. Finally, the reversing effect of when the model begins to show reduced rate of return could be integrated into the model to better mimic the SMS lifecycle.

ABSTRACT

UTAUT 2 provides a theory for understanding the adoption of consumer technology products such as smartphones. However, several key constructs in UTAUT 2, such as hedonic motivation, are centered on the user rather than the product. These constructs do not directly define how smartphone vendors can make the product more attractive. We approach the adoption of smartphones from the perspective of product attributes that engender adoption. These attributes, such as serviceability, supportability, extensibility and viability, are informed by the best-selling book Crossing the Chasm. This research is the first to approach consumer technology adoption from the standpoint of the product.

KEYWORDS: Technology acceptance models, TAM, UTAUT 2, consumer technology adoption, whole product concept

INTRODUCTION

The application of the technology acceptance model (TAM) to consumer technology adoption is a relatively recent development (Venkatesh, Thong, & Xu, 2012). Venkatesh et al. (2012) add new constructs such as hedonic motivation, price value, and habit to the UTAUT (Venkatesh et al., 2003). In the UTAUT 2 (Venkatesh et al., 2012), hedonic motivation is the enjoyment the consumer gets from the product or service (Holbrook & Hirschman, 1982), price value refers to whether the product represents good value for the money (Dodds, Monroe, & Grewal, 1991; Zeithaml, 1988), and habit is the automaticity of behavior (Limayem, Hirt, & Cheung, 2007). However, the adoption of consumer technology differs in a fundamental respect from the adoption of technology by users in businesses or other organizations where the TAM has historically been applied (Davis, 1989; Davis, Bagozzi, & Warshaw, 1989; Karahanna, Straub, & Chervany, 1999; Szajna, 1996; Venkatesh & Davis, 2000; Venkatesh et al., 2003). In the business context, the technology has already been purchased and the user has to decide on whether to use the technology based on its usefulness, ease-of-use, and other factors. In this article, “adoption” in the consumer context essentially means both purchase and use of the technology by the consumer.

As purchase is integral to the adoption decision by consumers, we turned to the literature of marketing practitioners to obtain insight into the drivers of the technology purchase decision. Geoffrey Moore (1991), a noted marketing practitioner, offers the notion of the “whole product”

in his best-seller *Crossing the Chasm*. Moore states that it is essential to consider not just the core of the product, or what the product does, but other attributes surrounding the product such as its extensibility and viability. In other words, one has to take a holistic or a "whole product" view in order to be successful in selling technology products. Moore (1991) identifies the key whole product attributes that facilitate the technology purchase decision as supportability, serviceability, extensibility, viability, and price. We build a model of technology adoption that includes these whole product attributes as drivers of adoption intention. Moore is viewed as a marketing guru by many and his book *Crossing the Chasm* was referred to as the "bible of marketing" in 2006, fifteen years after its publication, by Tom Byers, Faculty Director of Stanford University's Technology Ventures Program (Byers, 2006).

The TAM/UTAUT genre of research has a key weakness in that it does not address the question of what makes an information technology (IT) artifact useful (Benbasat & Barki, 2007). In our model of smartphone adoption, many other antecedents of adoption intention are incorporated, such as supportability, serviceability, extensibility, and viability, some of which make their influence on adoption intention felt not directly but indirectly via mediation by the perceived usefulness (PU) construct. If perceived usefulness is found to mediate the influence of these new constructs on intention, which means they are antecedents to PU, then we have in effect partially addressed the question of what drives usefulness.

We conducted a large-scale survey at a midsize university of about 20,000 students to understand the phenomenon of adoption of smart phones. An incentive was provided to return the survey, and we received 1400 surveys. We obtained a number of interesting results including finding intricate paths of influence in a complex nomological network such as *viability→supportability→perceived ease-of-use→perceived usefulness→adoption intention*. This brings out the importance of the new constructs such as viability and extensibility which are derived from the notion of the whole product mooted by Moore (1991).

LITERATURE REVIEW

Moore's notion of the whole product finds resonance in the shift from products to solutions that major management consultancies such as McKinsey and Booz Allen Hamilton have been advocating for some time. Emphasis on the complete solution is evident in the published works from both McKinsey (Foote et al., 2001; Krishnamurthy, Johansson, & Schlissberg, 2003; Roegener, Seifert, & Swinford, 2001) and also Booz Allen Hamilton (Bennett, Sharma, & Tipping, 2001). Sawhney (2006) notes that many firms from both manufacturing and service industries such as IBM, GE, and UPS have shifted their focus from a product-centric view to one that emphasizes complete solutions particularly as these products and services have become more complex (Davies & Brady, 2000; Gann & Salter, 2000; Hobday, 1998; Sawhney, Balasubramanian, & Krishnan; 2004, Slywotsky & Morrison, 1998; Wise & Baumgartner, 1999). Both management consultants and academics alike are focusing on areas such as value-based solution pricing (Anderson, Jain, & Chintagunta, 1993; Roegener et al., 2001) and solution customization (Krishnamurthy et al., 2003; MacMillan & McGrath, 1997) in a bid to drive value for the customer.

Moore's notion of the whole product and its validation in the solution-centric view of management consultants led us to develop a modified TAM based on the whole product notion. We extended TAM 2 (Venkatesh & Davis, 2000; Venkatesh & Morris, 2000), which itself extends the TAM by adding an antecedent for subjective norms or social influence, by adding

antecedents to adoption intention corresponding to Moore's (1991) whole product attributes such as supportability, serviceability, extensibility, viability, affordability, and monetary value. The incorporation of antecedents in our technology adoption model that are informed directly by the thinking of practitioners also serves to address the concern that some noted IS scholars have voiced that IS research sometimes lacks practitioner relevance (Benbasat & Zmud, 1999). This is not a new issue and is part of the "rigor versus relevance" debate that has been raging in the IS field for quite some time (Applegate & King, 1999; Benbasat & Zmud, 1999; Davenport & Markus, 1999; Lyytinen, 1999). As part of the solution to the problem, Benbasat and Zmud (1999) exhort academics to get more engaged in the discourse of practitioners as a way of learning what is important to them and then tailoring IS research accordingly. Benbasat and Zmud (1999) suggest "going to practitioner conferences, talking to practitioners, reading practitioner and general management journals, teaching executive education courses, and engaging in consulting activities." Davenport and Markus (1999) express similar sentiments and urge academics to produce research that is read and valued by practitioners. Clearly, in order to do so, academics would need to become more aware of what practitioners are discussing among themselves. We have in effect followed the advice and sentiments of Benbasat and Zmud (1999) and Davenport and Markus (1999) in primarily drawing upon practitioner literature (Moore 1991) in developing our model.

In addition to incorporating practitioner knowledge into our theoretical model of technology adoption as a way of addressing the relevance issue, we also tackle a key concern that has been raised by critics of the TAM genre of models. Critics of the TAM have argued that despite two decades of research, the TAM still does not address the central question of what makes an information technology valuable or useful (Benbasat & Barki, 2007). The TAM works with large aggregated constructs such as perceived usefulness in the original TAM (Davis, 1989; Davis, Bagozzi, & Warshaw, 1989) and TAM 2 (Venkatesh & Davis, 2000; Venkatesh & Morris, 2000) or its equivalent called performance expectancy in the UTAUT (Venkatesh et al., 2003) and UTAUT 2 (Venkatesh et al., 2012). Perceived usefulness or performance expectancy essentially captures the value of the information technology being adopted, but it begs the question of what drives usefulness. In other words, the TAM genre treats usefulness as a black box without providing insight into its drivers. Our model of smartphone adoption, on the other hand, shows that a number of the whole product constructs, such as extensibility, supportability, and viability, are actually mediated through the usefulness construct. Therefore, our model addresses the unanswered question in the TAM/UTAUT genre as to what drives usefulness.

THEORETICAL DEVELOPMENT

Model Constructs

Our smartphone adoption model uses as its foundation TAM 2 which identifies perceived usefulness (PU), perceived ease-of-use (PEOU), and social influence (SI) as key antecedents of adoption intention. To the TAM 2, we added additional constructs based on the whole product notion.

Supportability

Supportability (SUPP) refers to the level of support offered on the product and includes training, user documentation, facilities for problem resolution such as help desks, access to experts, and the availability of helpful online information. Supportability is akin to the facilitating conditions construct in the UTAUT (Venkatesh et al., 2003) and the UTAUT 2 (Venkatesh et al., 2012), but

with the difference that in the whole product vector concept, we recognize supportability and serviceability as two distinct constructs whereas the UTAUT and UTAUT 2 do not disaggregate the facilitating conditions construct.

Serviceability

While supportability is about getting help to use the product, serviceability (SERV) is about the ability to have the product repaired when it breaks. Hence, serviceability includes availability of service plans, easy access to service centers and retail outlets, and convenient mechanisms for sending the product back to the vendor for repairs.

Extensibility

Extensibility (EXTEN) refers to the capability of the product being extended and includes the potential of adding new features, availability of accessories, and the ability to integrate the product with other products possibly from third-parties. The notion of product extensibility has really not been addressed in the TAM genre (Davis 1989, Venkatesh & Davis, 2000; Venkatesh et al. 2003, Venkatesh, et al., 2012). Extensibility of the product can certainly be viewed as an element of a complete solution and is therefore supported by the general shift from the product-centric to a solution-centric view as indicted in both the academic and practitioner literature in marketing (Bennett et al., 2001; Foote et al., 2001; Sawhney, 2006; Slywotsky & Morrison, 1998; Wise & Baumgartner, 1999).

Viability

Viability (VIAB) refers to whether the product will continue to remain viable or whether factors such as failure of the vendor, obsolescence of the technology, or change of standards will make the product non-viable in the future. Like extensibility, viability is a new construct that has not been addressed in the TAM genre (Davis 1989, Venkatesh & Davis, 2000; Venkatesh et al. 2003, Venkatesh, et al., 2012). The salience of viability arises from the consumer's need to control risk. Smartphones are expensive and it is natural for the consumer to want to protect their investment. Ever since the introduction of the notion of perceived risk in product purchase decisions by Bauer (1960), many market research studies show that managing risk is indeed salient in consumer psychology (Cox & Rich, 1964; Reid, Teel & Van Den Berg, 1980; Ross, 1975; Simpcock, Sudbury & Wright, 2006; Woodside, 1972).

Monetary Value

Monetary Value (MV) captures whether the buyer is getting good value for their money and is similar to perceived monetary value in Hong and Tam's (2006) study of adoption of mobile data services, and also to the price value construct used in the UTAUT 2 (Venkatesh et al., 2012).

Affordability

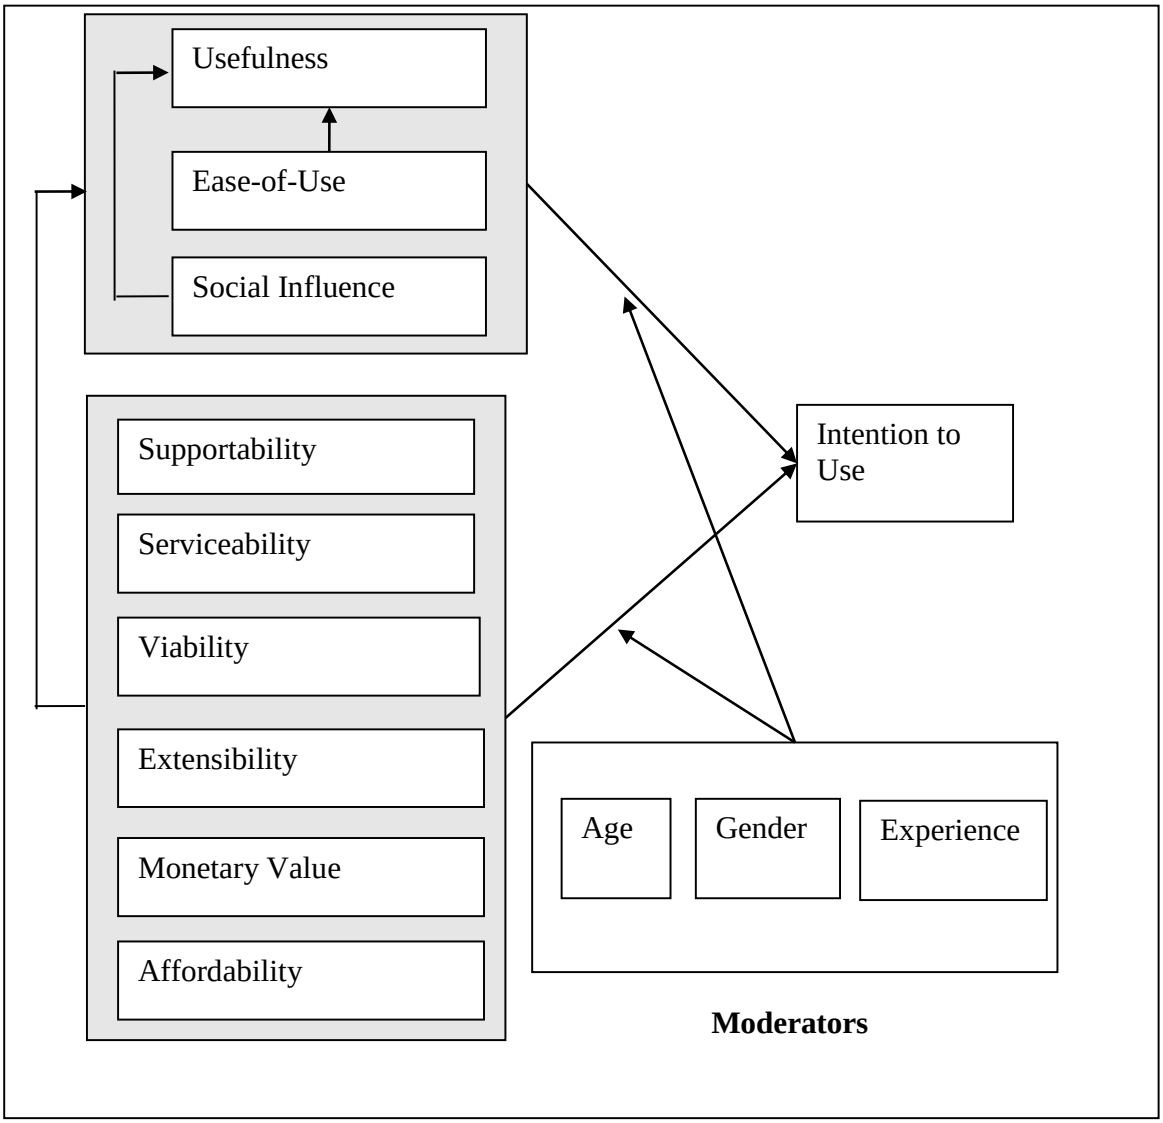
We make a distinction between whether a product represents good value for the money and whether the consumer can afford the product or not. Hong and Tam (2006) and Venkatesh et al. (2012) did not draw a clear distinction between monetary value and affordability (AFF) as they use a single construct for the user's price sensitivity. However, we argue that making such a distinction is necessary otherwise it is hard to tell if the popularity of the product from a monetary standpoint arises from its easy affordability, as appears to be the case with short

message services in China (Chan et al., 2008), or it is due to the highly quality of the product for the price charged.

Hypotheses

Our model of smartphone adoption is shown in Figure 1. For simplicity of presentation, our model is shown in Figure 1 at a block diagram level. The specific paths of causality, mediation, and moderation are described by the hypotheses formulated in this section.

Figure 1: Smartphone Adoption Model



Direct Effects

Since our smartphone adoption model uses TAM 2 as its base, the hypotheses of the TAM 2 are retained in our model. Hypotheses 1 through 3 are the TAM 2 hypotheses. To this we add

Hypotheses 4 through 9 corresponding to the whole product constructs. Conceptually, each construct would be considered to represent an increasingly positive trait of the product as the user perceives increasingly higher values of the construct; therefore, each construct should be positively related to the intention to adopt the product. The direct effects of the TAM 2 constructs and the whole product-based constructs on adoption intention are captured in the following set of hypotheses:

Hypothesis 1: *Perceived usefulness is positively related to adoption intention*.
Hypothesis 2: *Perceived ease of use is positively related to adoption intention.*
Hypothesis 3: *Perceived social influence is positively related to adoption intention*.
Hypothesis 4: *Perceived supportability is positively related to adoption intention*.
Hypothesis 5: *Perceived serviceability is positively related to adoption intention*.
Hypothesis 6: *Perceived extensibility is positively related to adoption intention*.
Hypothesis 7: *Perceived viability is positively related to adoption intention*.
Hypothesis 8: *Perceived monetary value is positively related to adoption intention*.
Hypothesis 9: *Perceived affordability is positively related to adoption intention*.

Mediated Effects

With regard to mediated effects, we know from previous TAM studies that PEOU and SI affect behavioral intention both directly as well as indirectly through PU (Davis et al., 1989; Venkatesh & Davis, 2000). Hence these indirect effects are incorporated in the following hypotheses:

Hypothesis 10: *Perceived ease of use is positively related to perceived usefulness*.
Hypothesis 11: *Perceived social influence is positively related to perceived usefulness*.

Extensibility, or the ability to add more features and capabilities that the user might find useful at a later stage, could be construed as adding to the usefulness of the device. Hence, we augment the mediating role of the PU construct by adding the hypothesis:

Hypothesis 12: *Perceived extensibility is positively related to perceived usefulness.*

In our model, which includes the constructs of supportability and serviceability, it is certainly arguable that the smartphone will be viewed as easy to use if the user can readily find the support needed to use the device as well as be able to repair it when it breaks or malfunctions. Hence, perceived ease of use can act as a mediator of the influence of serviceability and supportability on adoption intention. Consequently, we have:

Hypothesis 13: *Perceived supportability is positively related to perceived ease of use.*
Hypothesis 14: *Perceived serviceability is positively related to perceived ease of use.*

The influence of viability on adoption intention can be felt both directly, as captured by Hypothesis 7, as well as indirectly. Serviceability and supportability of the smartphone can be expected to depend on the long-term viability of the vendor, the technology, and the standards supporting the technology. Also, the extensibility of the smartphone can be expected to depend on the long-term viability of the vendor from whom it was purchased. This leads to the following hypotheses:

Hypothesis 15: *Perceived viability is positively related to perceived supportability.*
Hypothesis 16: *Perceived viability is positively related to perceived serviceability.*

Hypothesis 17: *Perceived viability is positively related to perceived extensibility.*

Moderator Effects

Historically, technology adoption studies have found that the key PU->I, PEOU->I, and PEOU->PU relationships are moderated by gender, where males give more weight to the usefulness of an IT (Venkatesh & Morris, 2000; Venkatesh et al., 2003). Traditionally, boys have been brought up to believe that they must be strong, provide for the family, fix things when they are broken, acquire useful work-related skills, and be more task-oriented. Task-oriented individualism with regard to technology use is less strong in females and they give due importance to how easy the technology is to use and whether there is a community that they are connected to and respect that is using this technology and influencing them to do the same (Venkatesh & Morris, 2000; Venkatesh et al., 2003; Venkatesh, Morris, & Ackerman, 2000). Hence, we capture the results of prior research in the following hypotheses:

Hypothesis 18: The relationship between perceived usefulness and adoption intention is moderated by gender such that it is stronger for males.
Hypothesis 19: The relationship between perceived ease of use and adoption intention is moderated by gender such that it is stronger for females.
Hypothesis 20: The relationship between perceived ease of use and perceived usefulness is moderated by gender such that it is stronger for females.
Hypothesis 21: The relationship between social influence and adoption intention is moderated by gender such that it is stronger in females.

While we have captured the results of prior research in Hypotheses 18 through 21, we also note that as the socialization processes are changed, gender roles can slowly change with time (Feldman & Aschenbrenner, 1983; Helson & Moane, 1987). In our study, given our population of predominantly young and college-educated males and females, we posited that these three key relationships would not be moderated by gender. The historical conditioning of boys and girls about their “appropriate” gender roles is arguably less relevant in today’s high-tech age than it once used to be. Since gender schema theory is really about socialization processes rather than biological gender, we felt that the PU->I, PEOU->I, PEOU->PU, and SI->I relationships would not be moderated by gender for our survey population, or that Hypotheses 18 through 21 would fail to be established in this study. With regard to how the influence of each of the new whole product-based antecedents on adoption intention is moderated by gender, since there is no prior theory on this, we elected to let the data drive the formulation of exploratory hypotheses in this area.

Age has been seen to play a role similar to that of gender in that older people, similar to women, place more emphasis on ease of use and social influence in their intentions to adopt technology (Morris & Venkatesh, 2000; Venkatesh et al., 2003; Plude & Hoyer, 1985). Younger workers as they respond more to extrinsic rewards (Hall & Mansfield, 1995) tend to pay greater attention to the usefulness of the technology (Venkatesh et al., 2003). They see the technology as a vehicle to obtain these rewards. Hence, past research has shown that the following hypotheses generally hold:

Hypothesis 22: The relationship between perceived usefulness and adoption intention is moderated by age such that it is stronger for younger people.
Hypothesis 23: The relationship between perceived ease of use and adoption intention is moderated by age such that it is stronger for older people.

Hypothesis 24: The relationship between perceived ease of use and perceived usefulness is moderated by age such that it is stronger for older people.
Hypothesis 25: The relationship between social influence and adoption intention is moderated by age such that it is stronger for older people.

Again, since our survey population is dominated mostly by young students, we suspected that Hypotheses 23 through 25 may likely not hold in our survey population. Furthermore, as we did in the case of the role of gender in moderating the influence of the whole product-based antecedents on adoption intention, we elected to let the data drive the formulation of exploratory hypotheses on the moderating influence of age since there is no prior theory on this.
The third moderating variable considered in our analysis is experience with the technology. The moderating role that experience with technology has generally played is that it blunts the salience of ease of use (Szajna, 1996; Venkatesh, 1999) and social influence (Venkatesh & Morris, 2000) on intentions to adopt technology. Although our population consists mainly of young college-going males and females with somewhat similar social conditioning, there could still be differences in terms of the breadth and depth of technology usage. A 22-year old female student majoring in computer science may well be more adept at using all the features of a smart phone than a 22-year old male or female student majoring in art history. Hence:

Hypothesis 26: *The effect of ease of use on adoption intention is moderated by experience so that it is stronger for people with less technology experience*.
Hypothesis 27: *The effect of social influence on adoption intention is moderated by experience so that is stronger for people with less technology experience.*

As we did in the case of gender and age, we elected to let the data drive the formulation of exploratory hypotheses on the moderating influence of experience on the relationships between the whole product-based constructs and adoption intention since there is no prior theory on this. Although we have not formulated hypotheses on the moderating influences of gender, age, and experience on the key relationships involving the whole product-based constructs given the absence of prior theory in this area, we saw a connection between viability of the smartphone and general experience with technology. People with long experience with using technology products know how important the viability of the product, the vendor, and the technology standards supporting the product are for the continuance of service and support on the product. All too often, as markets take different turns, start-up companies fail, and standards are superseded by others, service and support on the product stops and that leaves the customer holding the bag. This leads to the hypotheses:

Hypothesis 28: *The effect of viability on supportability is such that it is stronger for people with more experience with technology*.
Hypothesis 29: *The effect of viability on serviceability is such that it is stronger for people with more experience with technology.*

RESULTS

The survey data were analyzed using the methodology of structural equation modeling (SEM) with the help of the AMOS™ software tool. Confirmatory factor analysis (CFA) was first performed to assess the construct validity of all the latent variables in the model.

Confirmatory Factor Analysis

In confirmatory factor analysis (CFA), all items were constrained to load on their own constructs and the inter-construct correlations were allowed to vary freely. Using this approach, we examined the standardized factor loadings of the items to assess construct validity and the reliability of the instrument. Table 1 shows the standardized factor loadings for the initial instrument. In order to get a high Cronbach alpha reliability, we sequentially dropped low-loading items in an iterative process where the factor analysis was re-run at each step till all standardized factor loadings were above 0.7. The final instrument comprised the items PU1, PU2, PU3, PEOU1, PEOU2, PEOU3, I1, I2, I3, I4, I5, MV1, MV2, AFF2, AFF3, AFF4, SUPP5, SUPP6, SERV1, SERV2, SERV3, VIAB1, VIAB2, VIAB5, VIAB7, VIAB9, EXTEN1, EXTEN2, EXTEN3, EXTEN4, EXTEN5, EXTEN6, SI1, SI2, S3, and SI4. The Cronbach alpha reliabilities of the constructs for the refined instrument are given in Table 2. As seen from the table, the Cronbach alphas are all above 0.8 thereby indicating good reliability.

Model Fit

With regard to model fit, the indices in Table 3 generally indicate a well-fitting model. Most SEM researchers suggest that a root mean square error of approximation (RMSEA) of below 0.05 or below 0.06 is needed for a good fit (Hu & Bentler, 1995, 1999; Schreiber et al., 2006). We obtained an RMSEA of 0.057 thus approximately meeting this criterion. While there are several other fit indices that are used to assess the fit of a structural model, some authors (Hu & Bentler, 1999; MacCallum, Browne, & Sugawara, 1996) focus on the Comparative Fit Index (CFI) and the Non-Normed Fit Index, also referred to as the Tucker-Lewis Index (TLI), as being particularly important. Generally, it is recommended that CFI and TLI should be above 0.95 for a well-fitting model. As seen from Table 3, we obtained values of 0.936 for CFI and 0.93 for TLI, again indicating a reasonably good fit. We also report the values of other fit indices such as the Incremental Fit Index (IFI), Normed Fit Index (NFI), and Goodness of Fit Index (GFI) in Table 3. Looking at the various fit indices together, particularly the values of RMSEA, CFI, and TLI that some authors (Hu & Bentler, 1999; MacCallum et al., 1996) view as the key indices, the overall picture that emerges is that we have, perhaps not an exceptionally well-fitting, but certainly a well-fitting model.

Table 2: Cronbach Alpha Reliability Coefficients in Final Instrument

Latent Factor	**Cronbach Alpha**
PU	0.91
PEOU	0.86
SI	0.88
SUPP	0.91
SERV	0.93
EXTEN	0.91
MV	0.81
AFF	0.87
I	0.94
VIAB	0.9

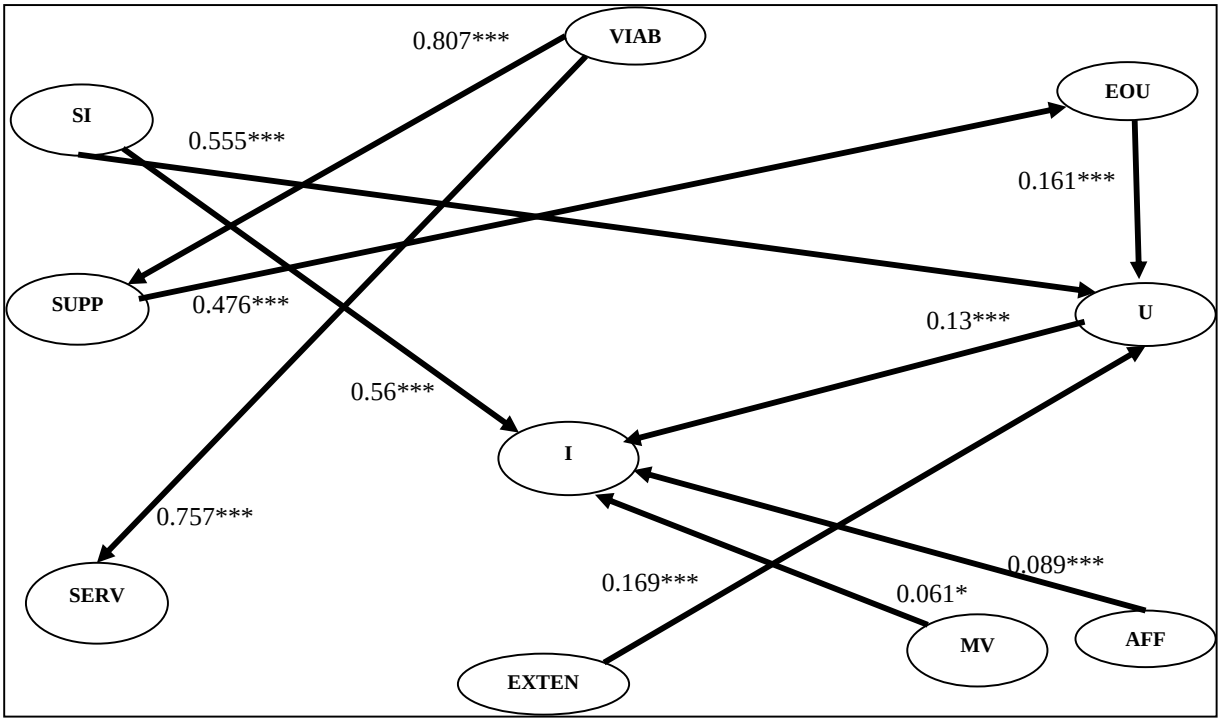
Path Model Hypothesis Tests

The refined instrument was then used to test the hypotheses in the path model as formulated previously. Figure 2 shows the values of the path model coefficients along with their level of significance. Of the direct effects, only Hypothesis 1 (PU->I), Hypothesis 3 (SI->I), Hypothesis 8 (MV->I), and Hypothesis 9 (AFF->I) were found to be significant. The fact that none of the constructs in our whole product vector of attributes other than affordability and monetary value drove adoption intention is, on the face of it, an interesting result. This however does not by any means imply that they are not relevant in the adoption decision. Several of them are indeed very

relevant except that their influence on adoption intention is mediated through other constructs rather than felt directly.

In terms of the mediating relationships, Hypothesis 10 (PEOU->PU) and Hypothesis 11 (SI->PU) tested significant, or that the effects of ease of use and social influence on intention are mediated through usefulness. This is quite consistent with what has been found previously in TAM studies (Venkatesh & Davis, 2000; Venkatesh et al., 2003). The new results on how the influence of the whole product constructs is mediated are that Hypothesis 12 (EXTEN->PU), Hypothesis 13 (SUPP->PEOU), and Hypothesis 15 (VIAB->SUPP) tested significant. Hence, the whole product constructs of extensibility, supportability, and viability do influence adoption intention, albeit they do so in indirect ways. In fact, while extensibility influences intention through one level of indirection via the path EXTEN->PU->I, supportability influences intention through two levels of indirection via the path SUPP->PEOU->PU->I, and viability influences intention through three levels of indirection via the path VIAB->SUPP->PEOU->PU->I. Although Hypothesis 16 (VIAB->SERV) also tested significant, serviceability did not either directly or indirectly influence adoption intention. Therefore, the effect of viability on intention is felt only through the VIAB->SUPP->PEOU->PU->I path involving multiple levels of indirection.

Figure 2: Structural Model of Smartphone Adoption



We also controlled for common methods variance in our study, which is a problem that has been noted about certain TAM studies (Sharma, Yetton & Crawford, 2009; Straub & Burton-Jones, 2007). The common methods variance issue arises from the fact that users tend to make their answers consistent across the independent and dependent variables in a questionnaire. So if a user had already indicated in the early part of the questionnaire that they think a certain IT artifact is useful, easy to use, and has good monetary value, they may be inclined to say that

they will adopt the artifact in the latter part of the questionnaire in order to make their responses appear rational and consistent. This is the consistency motif of common methods bias. But they may not truly have an intention to adopt the device. We addressed this common methods variance issue by giving the survey in two formats to the respondents. In one format, the questions on the antecedents, such as usefulness or supportability, preceded the questions on the dependent variable of intention. In the second format, the questions about the dependent variable of intention preceded the questions about the antecedents. Respondents were randomly chosen as to who received which format of the survey.

Effects of Moderators

We used the multi-group analysis capability in the AMOS™ tool to test the effects of the gender, age, and experience moderators on those relationships that had tested statistically significant. We used the critical ratio for differences between parameters test to evaluate whether a statistically significant difference existed between the corresponding path coefficients in the two groups being compared. The absolute value of the critical ratio for parameter differences was compared to 1.96 to determine whether a moderator effect existed on that relationship at a 0.05 level of significance.

For the gender moderator, we found two relationships that tested significant at the 0.05 level using the parameter differences test. One of them was PEOU->PU where the relationship was stronger for females, which is consistent with what previous studies have found (Venkatesh & Morris, 2000; Venkatesh et al., 2003) that women tend to give more weight to the ease of use of the technology, which is Hypothesis 20. The critical ratio for parameter differences had an absolute value of 2.11 for this relationship. Hypotheses 18, 19, and 21 were not supported. This finding of narrow and limited differences in the thinking of young college-educated males and females about the adoption of trendy consumer technology products is actually very consistent with our earlier surmise that unlike the traditional conditioning of males and females, present-day technically-savvy, college-educated, young males and females are likely to have more in common as far as their social conditioning about technology use is concerned.

For the age moderator, the parameter differences tests showed that the SI->I intention relationship had a statistically significant difference in the path coefficients between the younger and older groups. The absolute value of the critical ratio of differences was 2.83. However, although we had posited in Hypothesis 25 that the SI->I relationship would be moderated by age, our hypothesis was that the effect would be stronger for older people. We had structured Hypothesis 25 in that fashion because prior theory suggests that older people are more responsive to social influence (Rhodes 1983). In this case, the result was that, while the SI->I path coefficient was indeed different for the two groups, it was greater for the younger group. This result although not consistent with prior theory is not surprising when one considers the IT artifact that is the focus of the study. The smart phone is an inseparable fixture in the lives of young people given their heavy usage of cell phone voice calls, texting, and mobile apps for social networking. The smart phone is the quintessential way for youngsters to remain connected with their peer networks. Hence, the peer pressure factor clearly weighs heavily on the minds of young people as they contemplate acquiring gadgets such as smart phones. Also, we had correctly surmised that Hypotheses 22, 23, and 24 would fail to be supported given that our survey population is dominated by young college students.

For the experience moderator, the only hypothesis that tested positive was Hypothesis 28 which posits that people with more experience using technology products will give greater weight to

the importance of viability in terms of the continuance of support. People with longer experience using technology products know first-hand how service and support can be disrupted as companies go under, product lines are discontinued, markets take different turns, or technology standards change. We found that the VIAB->SUPP had a critical ratio for the parameter differences test of 3.1. The other hypotheses 26, 27, and 29 about the moderating influence of experience were not borne out in this study.

DISCUSSION

Theoretical Implications

Our model could potentially be generalized into a more universal model of consumer technology adoption. However, this study focused only on smartphone adoption. Hence, our model would need to be tested with several other types of consumer technology products, before it could be viewed as a general model such as the UTAUT 2. If our model is supported after it is tested with other consumer technology devices, then it would offer a different theoretical model of consumer technology adoption than the UTAUT 2 (Venkatesh et al., 2012). The UATUT 2 uses the UTAUT (Venkatesh et al., 2003) as the base model and adapts it to the consumer technology adoption context by adding antecedents such as hedonic motivation, habit, and price value. Constructs such as hedonic motivation and habit are centered on the user. We have approached the problem differently. The UTAUT 2 can be viewed as a user-centric model of consumer technology, whereas our model is more product-centric. In creating a more product-centric model, we were mindful of the rigor versus relevance debate that has been raging in the IS field for some time (Applegate & King, 1999; Benbasat & Zmud, 1999; Davenport & Markus, 1999; Lyytinen, 1999). That is why we first reached out to practitioner literature to understand their thinking on technology purchase and then incorporated this knowledge into our model of smartphone adoption. Moore's (1991) concept of the whole product, which emphasizes factors such as supportability, serviceability, extensibility, viability, and price in determining the purchase decision, was used to extend the TAM to the context of consumer technology adoption, in particular, the adoption of smartphones.

Another important difference between our model and the UTAUT 2 is that we have built a more granular model. A granular model with finer constructs leads to a more complex nomological network and allows us to find intricate paths of causality through this network. For example, as we found from this study, a construct such as viability makes its effect felt on intention through three levels of indirection via the VIAB->SUPP->PEOU->PU->I path. If all of the constructs in the VIAB->SUPP->PEOU->PU->I path were not explicitly incorporated in the model, one would simply miss the role that viability plays in technology adoption. Finding these paths of causality also helps address the call by Benabasat and Barki (2007) to open up the large black box constructs in the TAM such as PU and PEOU. By surfacing how the constructs of PU and PEOU act as mediators for many other antecedents such as supportability, extensibility, and viability, we are in effect opening these black boxes by showing what drives PU and PEOU.

Our use of more granular constructs also allows us to separate certain other issues more clearly. For example, we separate monetary value from affordability. In both Hong and Tam (2006) and Venkatesh et al. (2012), the monetary aspects are put in a single construct called perceived monetary value by Hong and Tam (2006) and price value by Venkatesh et al. (2012). We argue that the issue of whether one is getting good value for the price is quite different from whether one can afford to buy the product or not at the price being asked for. A buyer may

perceive a Mercedes Benz as providing great value for the price considering the quality of the product and yet not be able to afford it.

Managerial Implications

We have argued that our model of smartphone adoption, which could potentially be extended to a more general model of consumer technology adoption, is more practitioner relevant as it was partly informed by the rigor versus relevance debate (Benbasat & Zmud, 1999). Our technology adoption model directly incorporates practitioner knowledge. Organizational scientists lament the fact that much of the theory about organizational phenomena, such as a theory of what drives purchases of consumer IT artifacts, is not instrumental (Astley & Zammuto, 1992) in that it doesn't inform managerial decisions or practice. Beyer and Trice (1982) suggest there is too much distance between the domain of managers and that of organizational researchers for the theories spun by researchers to be instrumental. The approach we have taken in building our model tackles precisely this problem of non-instrumentality of organizational theory by first reducing the distance between researchers and practitioners through looking at the purchase phenomenon from the eyes of influential practitioners such as Moore (1991).

With the distance reduction accomplished, we develop a variable-rich theory of smartphone adoption, which is also potentially generalizable to a more universal theory of consumer technology adoption. Daft and Lewin (1990) indicate that researchers generally develop parsimonious theories based on a small number of variables that can explain phenomenon over a wide range of organizations. They also assert that organizations, however, represent complex, variable-rich phenomena thus implying a mismatch between the theoretical lens that we fashion and the objects we apply that lens to. Based on Daft and Lewin's (1990) views on the mismatch between parsimonious theories and variable-rich organizational phenomena, our model by being more granular and variable-rich can arguably inform managerial practice in the producers of consumer technology artifacts better than the UTAUT 2 (Venkatesh et al., 2012), which is a more parsimonious theory.

In testing our smartphone adoption model, we found that the whole product constructs of extensibility, supportability, viability, monetary value, and affordability indeed affect adoption intention, although they may do so in various circuitous ways, where their influence on intention is mediated through other constructs such as usefulness or ease of use. Whether their effect on adoption intention is direct or indirect, the empirical fact established here is that they do *matter*. Furthermore, they provide producer-manipulable variables. The producer can change the extensibility of the IT artifact they are offering. The producer can give more attention to creating an architecture for the product that allows for the integration of new functionality as well as the layering of value-added products possibly from other vendors. The producer can adhere to certain technology standards that offer a high level of plug-and-play thus making the integration of third-party products easier. Similarly, ensuring that service and support continue to be provided even on discontinued products can foster the customer's confidence in the viability of the product, which our model reveals is a variable that matters in the adoption decision.

Differentiating between monetary value and affordability also clarifies for the IT producer the main concern in the user's sensitivity to price. Does the user believe the product is priced too high in relation to the value returned, or is the user's problem that they cannot afford to buy the product even though it gives good value for the money? This clarity can enable the IT producer to fashion an appropriate response which could be to increase the quality of the product while keeping the price the same thus increasing the perceived monetary value. Alternatively, they

could develop a low-end product with fewer features at a lower price point to make it more generally affordable.

Other implications of interest to marketers have to do with user demographics and technology adoption. This study showed that there is really not a lot of difference in how young college-educated males and females think about adopting trendy consumer technology products such as smart phones. Traditional notions of gender roles which have historically led to differences in the adoption of technology really don't have as much salience as far as younger college-educated males and females are concerned. Rather than approach college-going males and females with different marketing campaigns, IT producers need to focus on how best to reach both groups through social media, and also to increase the utility of smart phones by providing more mobile apps for them. This would also be in keeping with the observed result of the greater salience of social influence on the intention to purchase such devices by young people. For all of the above ways in which our model can inform managerial decisions and practice, our model can indeed be viewed as an instrumental or utilizable theory (Astley & Zammuto, 1992).

Limitations and Future Research

To begin with, since our model was tested against smartphones only, it cannot yet be viewed as a general theory of consumer technology adoption. However, as it is tested against a variety of other consumer technology devices, our model could certainly grow into a more general model of consumer technology adoption. Another limitation of this study, even within the realm of smartphone adoption, is that it focused on a largely young and college-educated population. The external validity of the results of this study to the population at large therefore needs to be verified through further research. Another limitation is that there could also be other attributes of the whole product beyond the ones that Moore identified that could be incorporated into the model. Perhaps in today's age of social responsibility and environmental consciousness one could consider adding an antecedent on how "green" the product is as a driver to the adoption decision. Finally, a fruitful avenue of further research would be to integrate the UTAUT 2 and our model, once it has been generalized to a broader model of consumer technology adoption, to obtain a more powerful and unified model of consumer technology adoption.

CONCLUSION

In this study, we have proposed an extension to the TAM 2 that incorporates drivers of the technology purchase decision drawn from the notion of the whole product mooted by noted practitioner Geoffrey Moore. This notion implies that a technology product must be viewed holistically in that, in addition to its primary function, vendors must give due importance to the factors of pricing, supportability, serviceability, extensibility, and viability to ensure its success. We tested our model against smartphones and found that the whole product-based constructs of supportability, extensibility, and viability are indeed drivers of smartphone adoption decision, though they may influence this decision more indirectly.

APPENDIX

Instrument

Perceived Usefulness (PU)

- PU1: I do (or would) find this product useful for performing required tasks in my job or school environment.
- PU2: I do (or would) find this product useful for performing optional tasks in my job or school environment.
- PU3: I do (or would) find this product useful for performing personal, non-entertainment tasks (banking, shopping, information searching, etc.).
- PU4: I do (or would) find this product useful for performing personal, entertainment tasks (banking, shopping, information searching, etc.).

Perceived Ease of Use (PEOU)

- PEOU1: I understand how I would use this product.
- PEOU2: It is (or would be) easy for me to learn to use this product effectively.
- PEOU3: Using this product does not (or would not) take much effort on my part.
- PEOU4: I believe the user manuals and other documents are very clear on how to use this product.

Social Influence (SI)

- SI1: Friends and acquaintances would encourage my using this product.
- SI2: Other people who I respect would encourage my using this product.
- SI3: People with authority within organizations (school, business, clubs, etc.) I am involved with would encourage my using this product.
- SI4: My family would encourage my using this product.

Supportability (SUPP)

- SUPP1: I know many people who use the product that could help me if I needed it.
- SUPP2: It would be easy for me to find a lot of documentation for this product.
- SUPP3: I could get training for this product if I needed it.
- SUPP4: It would be easy for me to find user groups, discussion forums, or websites that I could use if I needed help with this product.
- SUPP5: There are vendors of this product that are known for providing a high level of support.
- SUPP6: There are vendors of this product that could quickly resolve any issues or problems I might have.

Serviceability (SERV)

- SERV1: I could easily get this product fixed if it ever failed to function properly.
- SERV2: It would be easy for me to find someone who could fix this product if it ever failed to function properly.
- SERV3: It would be easy for me to find a place to have this product fixed if it ever failed to function properly.
- SERV4: I believe there are vendors of this product that have a retail outlet within easy commuting distance.

- SERV5: I believe there are vendors that offer a variety of maintenance plans such as 1-year, 2-year, and 3-year plans.

Viability (VIAB)

- VIAB1: I believe the main manufacturers of this product will be in business for a long time.
- VIAB2: I believe this product would continue to be supported long after my purchase.
- VIAB3*: I would have a hard time finding a place to have this product fixed if it ever failed to function properly.
- VIAB4*: I believe newer versions of this same product will be made that will make this product quickly obsolete.
- VIAB5: This product has a reputation for being reliable.
- VIAB6*: I believe this product would need to be replaced with a newer version soon after I purchased it.
- VIAB7: I believe this product is available from well-known and established vendors.
- VIAB8*: I believe most vendors who supply this product are new and unproven.
- VIAB9: I believe the industry standards that this product needs to operate will be used for a long time.

Extensibility (EXTEN)

- EXTEN1: I believe there are a large number of accessories related to this product that I could use.
- EXTEN2: I believe this product integrates well with other products I have.
- EXTEN3: I could add accessories or services to this product to make it more useful to me.
- EXTEN4: I believe there are other separate products available that could make this product more useful.
- EXTEN5: I believe there are many vendors of this product that have a reputation for consistently adding features to their products.
- EXTEN6: I believe there are industry-wide standards for connecting this product to other products or accessories.

Affordability (AFF)

- AFF1: I could buy this product with funds I have available (or I did buy it with funds I have available).
- AFF2*: I would need credit to buy this product (or I did buy it on credit).
- AFF3*: If I purchased this device on credit, I would have higher debt than I am comfortable with.
- AFF4*: The product's purchase price likely exceeds my budget.
- AFF5*: The maintenance plans offered with this product would likely exceed my budget.

Monetary Value (MV)

- MV1: I believe this product would generally offer a good value for the money.
- MV2: I believe that at the current prices, this product would generally provide a good value.
- MV3: I believe the maintenance plans for this product generally offer a good value for the money.
- MV4*: The maintenance plans usually appear to be designed simply for the vendor to make money.
- MV5: I expect that this product is reasonably priced.

Intention (I)

- I1: I intend to use or continue to use this product during the next year.
- I2: I anticipate that I will use or continue to use this product during the next year.
- I3: I intend to apply or continue to apply this product in my work or school during the next year.
- I4: I anticipate that I will use this product more than I do right now during the next year.
- I5: I intend to apply or continue to apply this product for entertainment during the next year.

Notes: All items marked by * are reverse coded; all items were measured on a 7-point Likert scale.

Email: hrweistr@vcu.edu

ABSTRACT

Acceptance of healthcare information systems is largely determined by the functionality provided by the systems. Hence, it is important to identify the basic functional requirements that affect acceptance. In this study, articles related to information systems adoption theories and healthcare information systems are reviewed to determine these basic requirements.

KEYWORDS: Health Information Systems, Health Information Technology, Adoption, Acceptance, IS Success Model

INTRODUCTION

The hospital information system (HIS) is defined as the socio-technical subsystem of a hospital, comprising all information processing systems as well as the associated human or technical actors in their respective information-processing roles (Haux et al., 2003).

Information systems are used across different areas of healthcare such as in hospitals, telemedicine, etc. Electronic healthcare record (EHR) systems have largely replaced the paper-based record keeping of patients' history. They offer advantages ranging from integration of different tools (e.g. electronic prescription, decision support systems, emergency information...), to increasing efficiency, and securing access to healthcare information. Prior literature has elaborated on advantages of using these systems. While developing these systems, it is important to understand the factors that influence their acceptance and adoption. Two theories, namely technology acceptance model (TAM) and the unified theory of acceptance and use of technology (UTAUT) are widely used to determine factors influencing acceptance of technology.

Requirements in terms of system functionalities vary based upon end users. The research-based literature identifies factors such as costs, efficiency, efficacy, IS theories, model designed specific for a healthcare organization, and so on, that influence the acceptance and adoption of such systems by physicians, pharmacists, nurses, emergency rooms, etc. To our knowledge, no published study has investigated how IS theories such as TAM, UTAUT, and IS Success Model translate into system requirements for healthcare and its impact on their acceptance and adoption.

The objective of this study is to identify the basic requirements for health IS that impact the adoption and acceptance of these systems, based upon established adoption and success theories specifically the technology acceptance model (TAM), the unified theory of acceptance and utilization of technology (UTAUT), and DeLone and McLean's IS success model. This

review will be useful to researchers for advancing the application of other adoption theories and determining their usefulness in assessing adoption of healthcare systems.

The rest of this article is structured as: Firstly, we describe the published adoption and success theories used in our study, followed by a description of our research approach used for selecting and reviewing relevant published studies. The next section presents the reviews of the selected articles, followed by a discussion of the results and concluding remarks.

Overview of IS Theories

Technology Acceptance Model (TAM)

TAM has been applied in various samples of users and information technologies such as computers, business process applications, communication and collaboration systems, system software, worldwide web/internet, and healthcare applications (Aggelidis & Chatzoglou, 2009). It explains the motivation of users using these constructs – perceived usefulness and perceived ease of use.

Table 1: TAM Definition of Constructs (Davis, 1989)	
CONSTRUCT	DEFINITION
Perceived usefulness	The degree to which a person believes that using a particular system or technology would enhance his or her job performance.
Perceived ease of use	The degree to which a person believes that using a particular system or technology would be free of undue effort.

Social influence on adoption of information technology has not been considered as a construct in this model, which is applicable beyond the workplace (Taherdoost, 2018).

Unified Theory of Acceptance and Use of Technology (UTAUT)

UTAUT compares the similarities and dissimilarities among 8 models – technology acceptance model (TAM), theory of planned behavior (TPB), combined TAM and TPB, model of personal computer utilization, motivational model, diffusion of innovation, theory of reasoned action, and social cognitive theory (Khalifa & Alswailem, 2015). It has been derived by modifying the 14 constructs from these 8 models, of which the constructs effort expectancy, performance expectancy, social influence and facilitating conditions have been found to be significant. It includes 4 moderating variables – gender, age, experience, and voluntariness of use (Taherdoost, 2018; Venkatesh et al., 2003).

Table 2: UTAUT Definition of Constructs (Venkatesh et al., 2003)	
CONSTRUCT	DEFINITION
Effort Expectancy	The degree of ease associated with the use of the system.
Performance Expectancy	The degree to which an individual believes that using the system will help him or her to attain gains in job performance.
Social Influence	The extent to which the individuals believe that important others believe that he or she should use the new system.
Conditions	Technical infrastructure to support use of the system.

IS Success Model (ISM)

Based upon the literature review of empirical research articles published in 1981-1987, DeLone & McLean (1992) identified six constructs in their IS success model for determining the success of information systems.

Table 3: ISM Definition of Constructs (DeLone & McLean, 1992)

CONSTRUCT	DEFINITION
System quality	The desirable characteristics of an information system.
Information quality	The quality of information a system produces; characteristics that attribute to quality of information are timeliness, accuracy and meaningfulness.
Use	The interaction of information product with its recipients.
User satisfaction	The users are the decision makers.
Individual impact	The influence an information product has on management decisions.
Organizational impact	The effect of the information product on organizational performance.

Note: In the ten-year updated model, DeLone and McLean (2003) included service quality and net benefits as additional constructs.

METHODOLOGY

We review the literature on health and hospital information systems with respect to adoption and acceptance of the systems by users. We include experimental, non-experimental, and quantitative studies.

Search and Selection Strategy

In addition to the AIS "basket of eight" (*European Journal of Information Systems, Information Systems Journal, Information Systems Research, Journal of the Association for Information Systems, Journal of Information Technology, Journal of Management Information Systems, Journal of Strategic Information Systems,* and *MIS Quarterly*), we specifically searched the following journals: *Journal of the American Medical Informatics Association, International Journal of Medical Informatics, Procedia Computer Science, Informatics in Medicine Unlocked, Computers in Human Behavior, Journal of Biomedical Informatics, Computer Standards and Interfaces, The New England Journal of Medicine, and Health Affairs*. We also did a general search, using search terms: health information systems, health information technology, adoption, acceptance, and IS success model. The search was limited to studies published from 2003 to 2018. Commentaries and editorials were considered for background information or discussion, not for the review.

Our initial search resulted in 115 articles. The International Journal of Medical Informatics, and the Journal of the American Medical Informatics Association (JAMIA) had the most articles relevant to our search with 20 each.

Inclusion and Exclusion Criteria

Studies that defined health IT adoption and acceptance as their primary objective and provided detailed information about the methodology were included for the review. Full text articles were

then retrieved and examined so as to determine their appropriateness for the review. The scope of the review was restricted to hospital information systems used by physicians and nurses, as well as emergency operation center information systems, so as to better understand the factors influencing the adoption and acceptance of such systems.

Of the 115 articles found, 29 studies whose primary focus was not adoption and acceptance of Health Information Systems, and had little or no constructs identified in their model were excluded. Furthermore, studies focusing on pharmaceutical information systems, computerized physician order entry systems (CPOE), telehealth, telemedicine, were also excluded from the review. Thus, our review focuses on a final set of only 9 papers out of the initial 115. These are shown in Table 4 below.

Table 4: Articles Reviewed

Article #	YEAR	REFERENCES	JOURNAL
1	2003	Van der Meijden, Tange, Troost, & Hasman	Journal of the American Medical Informatics Association
2	2005	Odhiambo-Otieno	International Journal of Medical Informatics

9	2018	Aldosari, Al-Mansour, Aldosari, & Alanazi	Informatics in Medicine Unlocked

REVIEW OF THE SELECTED ARTICLES

Van der Meijden, Tange, Troost, & Hasman (2003)

This study reviewed the English and Dutch literature from 1991-2001 regarding the evaluations of patient care information systems that required data entry by health care professionals. The research objectives were to identify the attributes that were used to assess the success of such systems and to test the ability of the IS Success Model framework. The article distinguishes between objectivist and subjectivist studies so as to provide an overview of the study designs as described by Friedman and Wyatt. Of 1077 articles found initially, 202 were selected for further review. Ultimately, 33 articles were reviewed, describing general systems, including hospital information systems, nursing (bedside) documentation systems, and physician order entry forms (POE), and systems specific to a department, including intensive care unit (ICU) systems and anesthesia recording systems. 14 systems were systems used by only nurses, 5 systems used by only physicians, and 11 systems used by both nurses and physicians. The results found information quality to be evaluated the most, as compared to other constructs of the IS Success model. Furthermore, the findings found that evaluation of the systems finished within six months upon implementation, thus affecting the measurement of its impact on the organization's success. Although, this article focused more upon the evaluation criteria for information

systems, it identified the attributes affecting evaluations of failed initiatives, with system development being one of the attributes.

Odhiambo-Otieno (2005)

Odhiambo-Otieno identified the lack of evaluation criteria for the district health management information systems (DHMISs) in Kenya. The objective of the study was to design evaluation criteria so as to assess viability, sustainability and ultimate contribution of DHMIS in the management of the district health system (DHS) in Kenya. Feedback to the DHS personnel was one of the key reasons for designing such system. But the data collected on a routine basis was insufficient for planning and evaluation of the district level health services. This article focuses only on the evaluation criteria for the information systems, but it identifies the information needed by developers while designing the system and the users' requirements to use the system. No IS theories were used in this article.

Mantzana, Themistocleous, Irani, & Morabito (2007)

This study focused on the importance of actors involved with adoption of healthcare information systems. The objective of this research was to identify and define these actors using a structured approach, the IGOHcaps method. The authors classified the actors as accepters, providers, supporters and controllers. Healthcare actors, in the context of this paper were defined as any human and/or organization that accepts, provides, supports or controls healthcare services. Since single case-study was used for the purpose of evaluation of the instrument, the findings cannot be generalized. However, the study validated the importance of including healthcare actors for making decisions for IS adoption as reported in the literature. The actors were categorized as individual or group, but the issues regarding power, control and legitimacy were not considered, which were found to be highly influential towards both categories. As a result, the authors state that their method not only supports the researchers and managers, but is also useful in understanding the importance and effect of healthcare, identifying the healthcare actors as well as may help increase the adoption of IS in healthcare.

Desroches et al. (2008)

Desroches et al. assessed the adoption of outpatient electronic health records by physicians. The constructs measured were user satisfaction, perceived effect of systems on quality of care, and perceived barriers to adoption. The objective of this study was to develop and test measures of adoption, to deliver survey items that could be used to generate similar data over time on the diffusion of electronic records, and on physician's perceptions of the effect of such systems on their practices. Using a modified Delphi study, the determinants of a fully functional electronic health record system as identified by the investigators included: recording demographic and clinical data of patients viewing and managing lab results; managing order entries, including prescriptions; and supporting clinical decisions. The statistical analysis presented positive results from the responders using fully functional systems, as compared to those using the basic systems. 20% of the physicians with basic systems expressed concerns about ease of use and reliability of their systems.

Aggelidis & Chatzoglou (2009)

Aggelidis and Chatzoglou tested the applicability and effectiveness of technology acceptance models (TAM) within healthcare in Greece and determined the factors influencing the health

personnel's intent of using these systems. A modified TAM was used to determine the constructs in three different contexts – individual (anxiety, self-efficacy, and computer attitude), technological (perceived usefulness, ease of use) and implementation (subjective norms, facilitating conditions, and training). The paper analyzed twenty-three hypotheses using correlation, exploratory and confirmatory factor analysis. The reliability and validity of the measurement model were determined. Facilitating condition was the key influencer for behavioral intention. Sample included only those personnel who were using IS/IT systems to accomplish their tasks, the majority being administrative personnel and only 25% being medical and nursing personnel. The study found that health organizations must create favorable conditions by providing adequate training for motivating the users to use the system. The authors also recommend that management must encourage the staff to adopt and use the system so as to emphasize the importance and utility of technology in performing daily tasks.

Khalifa & Alswailem (2015)

Khalifa and Alswailem evaluated hospital information systems acceptance and satisfaction by exploring influential factors that may impact the acceptance and satisfaction levels among different healthcare professionals. Constructs were measured using the Technology Acceptance Model (TAM). Computer availability in the hospital was one of the most influential factors. The unavailability of laptops and computers on wheels were found to impact the direct and immediate entry of information and retrieval of records at the point of care. The study also found differences in users' perceptions of the systems – less experienced users found it to be less user friendly and difficult to use as compared to the experienced users. The study also determined the basic requirements for such systems, viz. improving software speed, responsiveness, increased availability of computers, laptops and computers on wheels, and screen designs focusing on sequence and logic of functions, tasks, buttons and font size.

Prasanna & Huggins (2016)

Prasanna and Huggins examined the end user acceptance of information system for emergency operations using a model with features integrated from TAM and UTAUT theories. Information quality was an additional independent variable considered in the research model.
Constructs from TAM – perceived usefulness, and perceived ease of use – were replaced with performance expectancy and effort expectancy from the UTAUT model so as to have a broader representation of user behavior. The research assumed that symbolic adoption was dependent on antecedents of performance expectancy, facilitating conditions, ease of use, information quality, and social influence. Prior research using UTAUT model did not consider mediating factors unlike perceived usefulness, which is a mediator in TAM. The study contradicts the assumption *"that facilitating conditions were insignificant amongst high levels of both performance expectancy and effort expectancy"* used in UTAUT model, since it focused on information systems implemented across various physical locations. The study also investigated the impact of age and gender on the relationships between endogenous and exogenous variables with performance expectancy as a mediator. Authors modified two mediating variables from UTAUT model – experience, and voluntariness of use – to experience of using the system and previous emergency operation center information systems (EOCIS).
The analysis put into perspective the importance of considering performance expectancy as a mediator while using UTAUT for EOCIS by identifying a significant mediation effect. Relationship between information quality and performance expectancy was examined. Significant moderation was found to be attributing to system use, gender and age. Thus, older age less than 50 years, and male users had stronger impact on the relationship, while system

experience had weaker impact. Similar results were observed when the same analysis was used for New Zealand, USA and Australia. Social influence was observed to have positive influence on technology acceptance and adoption. Authors also found that technology acceptance theories were fundamentally incomplete since prior research did not consider the mediation effect in both highly specific and generic context.

Handayani et al. (2017)

Handayani et al. developed a model of hospital information system that considered user acceptance based on human, technological and organizational characteristics to support government eHealth programs. The study used both qualitative and quantitative approaches with case studies for seven hospitals – three general hospitals and four private hospitals. The objective was to determine the obstacles faced by hospitals in Indonesia by identifying suitable user acceptance model based upon user groups in each hospital type. Authors modified TAM model by adding three constructs – human, technology, and organizational characteristics. Measures for these constructs were: human (user self-efficacy, compatibility, information security expectancy, and social influence), technology (information quality, system quality) and organization (management support, facilitating conditions, and user involvement on HIS implementation). The analysis indicated insignificant effect of self-efficacy, information quality and user involvement on perceived usefulness. Social influence was found to have no impact on perceived ease of use and perceived usefulness. Human, technological and organizational constructs were found to influence the acceptance of these systems. System quality and perceived usefulness did not have significant influence.

Aldosari, Al-Mansour, Aldosari, & Alanazi (2018)

In this study, the acceptance level of electronic medical records by the nursing staff was investigated, using TAM model. The study examined the factors impacting the nursing staff's attitude towards implementation and use of electronic medical records. Constructs used in the model were user demographics, top management, IT support, system quality, perceived ease of use, and perceived usefulness. User demographic characteristics, top management, IT support, and system quality were important factors to predict acceptance of EMR by nurses. Intention to use and user satisfaction had a positive impact on system acceptance. To increase the system acceptance, authors recommended full training courses for those nurses who had no formal training on using the system.

DISCUSSION

The aim of this study was to identify the key system requirements that impact the acceptance and adoption of health information systems, based on a review of the relevant literature. Table 5 below provides a summary of the findings from the articles reviewed.

.

Table 5: Summary of Findings				
#	CITATION	FINDINGS	IS MODEL USED	TYPE OF STUDY
1	Van der Meijden, Tange, Troost, & Hasman (2003)	Information quality evaluated the most as compared to system and service quality constructs. Article identified system development as one of the indicators that affected evaluations of failed initiatives.	IS Success Model	Literature Review
2	Odhiambo-Otieno (2005)	Identified information needed by system developers for designing the system and users' requirements to using the system. Study results indicated the lack of evaluation criteria in design stage. Focus group which consisted of IS designers and users identified the items that must be addressed during evaluation. Authors recommend including pre-, concurrent, and post-implementation criteria to be used before, during and at the end of implementation stage for assessing the system's viability and ultimate contribution towards DHS (District Health Systems).	None	Case study
3	Mantzana, Themistocleous, Irani, & Morabito (2007)	Proposed IGOHcaps method is useful in understanding the importance and effect of healthcare, identifying the healthcare actors as well as in possibly increasing the adoption of IS in healthcare.	None	Case study
4	Desroches et al. (2008)	Recording demographic and clinical data of patients, viewing and managing lab results, managing order entries including prescriptions, and supporting clinical decisions – determinants of fully functional health record system. Research analysis shows positive results for fully functional systems as compared to the basic systems.		Modified Delphi study
5	Aggelidis & Chatzoglou (2009)	Sample for analysis consisted of personnel using IS/IT systems for accomplishing tasks, mostly administrative and only 25% were medical and nursing personnel. Given the three constructs – individual, technological, and implementation studied, facilitating condition (implementation construct) was identified as the important factor. It was then determined from this study that health organizations must create favorable conditions for training system users so as to emphasize on the importance and utility of technology in performing daily tasks.	Modified TAM	Case study

6	Khalifa & Alswailem (2015)	This study about determining influential factors impacting the acceptance of hospital information systems amongst healthcare professionals identified improving software speed, increased availability of computers, laptops & computers on wheels, screen designs focusing on sequence and logic of functions, tasks, buttons, and font size as the 'basic requirements' for these systems.	TAM	Case study
7	Prasanna & Huggins (2016)	This study analyzed the user acceptance of IS for emergency operations using TAM and UTAUT theories. The integrated research model consisted of mediating variables which were not considered in prior research, suggesting that "to facilitate end-users' acceptance throughout an implementation process, an implementation team should consider the different needs of end-users alongside relevant behavioral implications."	TAM, UTAUT	Case study
8	Handyani et al. (2017)	Human, technological and organizational constructs were found to influence the acceptance of these systems. System quality and perceived usefulness did not have significant influence.	Modified TAM	Case study
9	Aldosari, Al-Mansour, Aldosari, & Alanazi (2018)	User demographic characteristics, top management, IT support, and system quality were important factors to predict acceptance of EMR by nurses. Intention to use and user satisfaction had a positive impact on system acceptance. To increase the system acceptance, authors recommended full training courses for those nurses who had no formal training about using the system.	TAM	Case study

This review resulted in determining the basic system requirements such as screen designs that focus on sequence and logic of functions, buttons, software speed, system responsiveness, high availability of computers, providing adequate training and IT support to end users in hospital and healthcare scenarios. Prasanna & Huggins (2016) determined the impact of gender and age on the end user's acceptance of emergency operation systems. Authors recommend considering these variables while designing similar studies. Handayani et al. (2017) determined factors impacting perceived ease of use and perceived usefulness on the acceptance of healthcare information systems. Aldosari et al. (2018) studied the factors impacting acceptance of electronic medical records for nursing staff. Upon surveying the nursing staff, it was determined that lack of adequate training to use these systems influenced the acceptance and adoption of these systems in addition to system quality, demographic characteristics and IT support.

LIMITATIONS AND FUTURE RESEARCH

The review considered only three IS theories – TAM, UTAUT, and IS success Model for studying the acceptance and adoption of health and hospital information systems as each of

these models keep into consideration different constructs that measure usefulness and quality of systems, service, and information. TAM does not consider other variables that impact perceived ease of use and perceived usefulness constructs. Some studies reviewed had modified TAM to study the impact of such variables.

Our study considered only physicians, nursing staff and emergency operators as the end-users. This was done so as to control the scope of our study. Also, the literature lacks a general definition for health information systems, rather definitions used are specific to research studies, and their findings cannot be generalized.

Future studies may consider multiple IS adoption and acceptance theories in the context of pharmacists, owners and managers of hospitals, and consulting doctors. DeLone and McLean's IS success model has system quality, information quality and service quality as key constructs that influence users to using the system and also determines the net benefits from using the system. Future studies may conceive a new model that includes constructs from the IS success model with respect to other mediating and moderating variables, to better understand the acceptance and adoption of the systems.

DECISION SCIENCES INSTITUTE
A Study of Informal Efficiency in the Acquisitions of Mobile Applications

Daniella Novak
Universidade Federal do Paraná
Email: novakdaniella@gmail.com

Jorge Eduardo Scarpin
Concordia College
Email: jscarpin@cord.edu

ABSTRACT

Facebook acquired WhatsApp in 2014 for $ 19 billion. Besides the substantial value of the purchase, another instigative fact was the growing performance of the Facebook's stock in relation to the S & P500 on that date. This could support a relationship between announcements of buying apps and market reaction. This paper aims to verify if the acquisition of mobile apps generates abnormal returns in the stock prices of IT companies. We developed an event study analyzing daily and cumulative abnormal returns. The results were sufficient to affirm that the announcement of acquisitions of mobile applications impacted the company value.

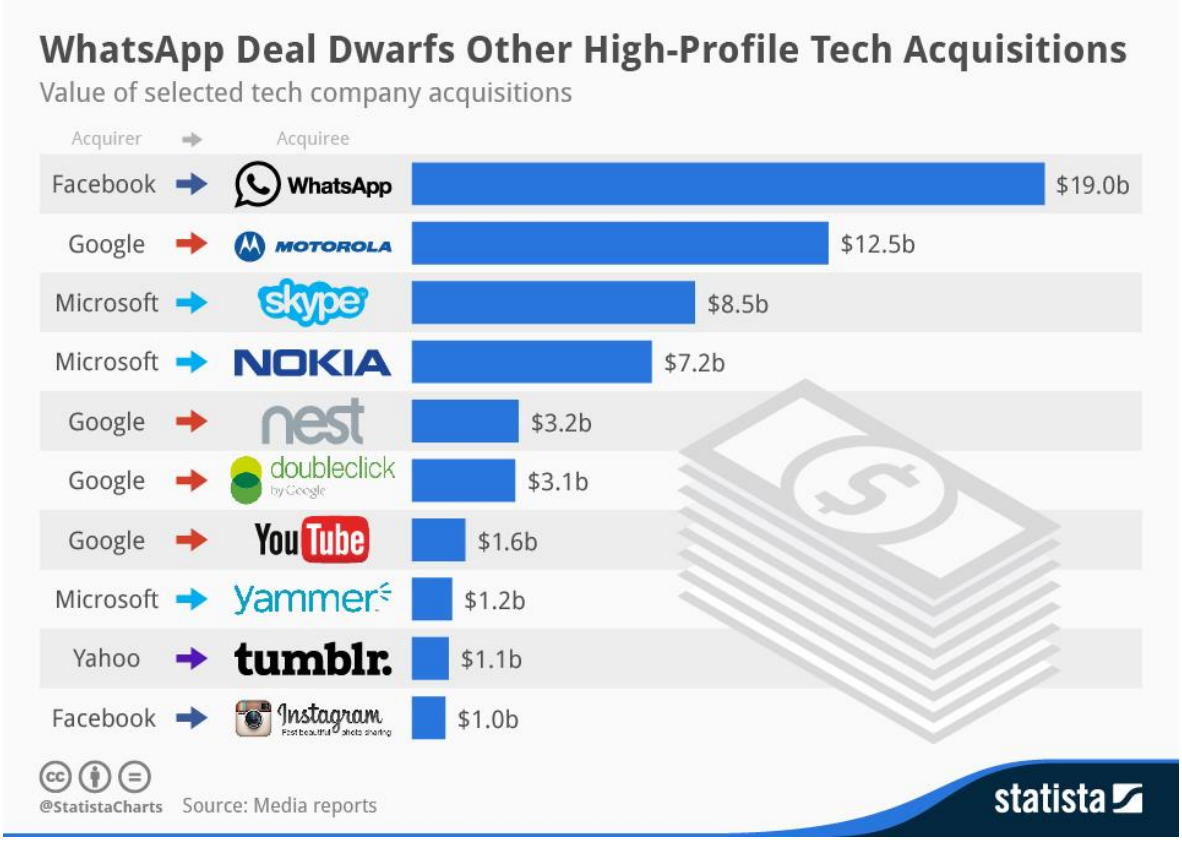
KEYWORDS: Event Study, Mergers & Acquisitions, IT firms, App Mobile.

INTRODUCTION

On February the 19th in 2014 the WhatsApp, the instant messaging service, was acquired by Facebook for $ 19 billion, approximately. This acquisition was reported by leading newspapers around the world. "JPMorgan analysts said the price tag seemed high, but added that mobile messaging was a "crucial part of the social network's core mission of 'connecting the world'" (KUCHLER; BRANDSHAW, 2014). In the following days many comments like this have been published. By 2014, the major indexes, Dow Jones and Nasdaq, as well as the Nasdaq Stock Market (NASDAQ) and the S & P500 had declined (NASDAQ, 2014). Despite the situation in the financial market and comments about the acquisition, Facebook shares registered growth.
The importance of the IT sector to the economy is growing every day, which raises the relevance of a more in-depth study of the sector. According to the PWC's report of Global Top 100 companies in 2016 "technology has overtaken Financials to become the largest sector in terms of market cap ($2,993bn)." (PWC, 2016)
To analyze the impact of this kind of acquisition, it must be remembered of the concept of efficient capital market, according to Ross, Westerfield and Jaffe (2002, p.298) tells us that "in this type of market, the information processed immediately is immediately incorporated into the stock price." The efficient markets hypothesis (EMH) assumes that the stock price reflects all available information (Fama, 1970). Therefore, according to signalization theory, investor can respond to announcements through buying shares, if they see potential or improvement (Asquith e Mullins, 1986). Thus, it is reasonable to think that the announcement of the

acquisition of an essential asset to the development of the company's main activity will change the market value of the company.
As pointed by Qin, Tang, Jang, & Lehto (2017) “the academia is starting to research on issues related to mobile channels.” Also, “studies that evaluate the impacts of mobile distribution are generally scarce”. In response of this, the present research aims to add new findings of this study area. There are some evidences that could support a relationship between announcements of buying an app and market reaction. As tells Kuchler and Brandshaw (2014) "Facebook’s shares fell as much as 3 per cent in after-hours trading after closing at $68.06 in regular hours trading in New York".
Another justify to the study of acquisition on technologies market is the volume that it has been negotiated. It can be seen up down in accord to Richter, 2014 study:

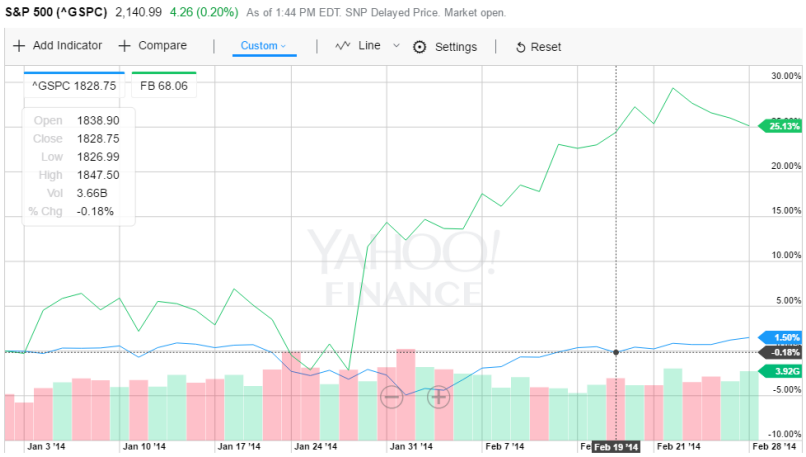
Figure 1: Value of selected tech company acquisitions



Richter (2014)

As mentioned earlier, Facebook acquired WhatsApp in 2014 for $ 19 billion. Besides the monetary representativeness of the purchase, another factor that draws attention is the performance of the action of Facebook in relation to the S & P500 on that date, as highlighted in Figure 2.

Figure 2: Facebook and S&P500’s Stock Quotes



Yahoo Finance (2016)

As can be seen in Figure 2, Facebook's share performance was higher than the US index (S & P500). This fact suggests that the company could create value higher than expected by market levels. According to the literature, intangible assets have played a key role in generating unexpected returns. In this sense, this research seeks to contribute to the discussion regarding the representativeness of intangible assets in the value of organizations.
Furthermore, technological intangible assets are the main asset of technology companies, thus, it is believed that the acquisition of a new app could impact on the byer company's share.
This paper aims to verify if the acquisition of mobile applications generates abnormal returns in the stock prices of technology companies listed on the Nasdaq Stock Market (NASDAQ) buyers. So, it is expected that the acquisition of these assets generates expectations of future value generation, thereby increasing their visibility and negotiability of the securities. Using traditional event-study methodology, this research aim to provide a financial market-based analysis of the impact of acquisition of mobile applications on the market value of buyer firms.

LITERATURE REVIEW

In this section, we discuss the idea of what is Mobile Apps, and how it could be recognized on mergers and acquisitions. Then, we review the theoretical development around efficient markets hypothesis (EMH).

Literature Review of Mobile Apps

Mobile Apps, or as they are popularly known, Apps are extensions that perform specific functions on mobile devices, such as smartphones, and are targeted at the end user (APPLE, 2015). As follows, they meet all criteria for being classified as intangible assets.

> intangibles have several particular characteristics that distinguish them from tangible assets and demand that intangibles be treated differently from tangibles. Three of these supposed distinguishing characteristics are said to be alternative uses, lack of separability, and great uncertainty of recoverability. (HENDRIKSEN and VAN BREDA, 1992, p.635)

There are many ways that Mobile App could improve shareholder value. The recent study by Qin, Tang, Jang, & Lehto (2017) enumerate five: “(1) accessing the booming Millennial market, (2) improving operating efficiency, (3) creating revenue opportunities, (4) reducing distribution cost, and (5) fostering customer loyalty and brand recognition”.

Literature Review of efficient markets hypothesis (EMH)

Hendriksen and Van Breda (1992, p.207) said about agency theory that “principals will always be interested in the outcomes generated by their agents, agency theory provides the underpinning for an important role for accounting in providing information after an event: a so called *postdecisorial* role.”

Fama (1970) states that the capital market is efficient in relation to information, in other words, all information is contained in the share price. This maxim expresses the following implications. First, business managers fail to create value by deceiving investors. Second, investors who use the information the market has should not expect abnormal returns on their investment.

There are three distinct types of efficiency, according to Fama (1991): weak form, the semi-strong form, and the strong form. Efficiency in the weak form assumes that only the set of information contained in the past prices is reflected in the stock price. This translates into some trends from investors who believe in price-value trends, such as head and shoulders. The semi-strong form of efficiency, most likely, indicates that in addition to past price information, the stock price immediately incorporates all available information. This theory is more reasonable since it requires time and knowledge for the analysis of an investment. Strong form of efficiency is considered by many to be utopian, since it assumes that all information, available or not, is immediately incorporated into the price.

Some evidence may suggest from the degree of efficiency of a market. The serial correlation, if there is, indicates a weak form, if it is zero, it can be said that it is a semi-strong form. (Ross, Westerfield, and Jaffe, 2002) Event analysis can prove that a market is semi-strong form when calculating the abnormal return on investments because it analyzes the impact of a disclosure on share price. If the performance of mutual funds is not divergent from common investors, it is also possible to evidence a semi-strong form.

In that way, this research aim to provide a financial market-based analysis of the impact of acquisition of mobile applications on the market value of buyer firms. It was considered a semi-strong form of efficiency.

Previous Studies of Market Reaction over acquisitions and new products

Several studies have already tried to relate market reactions to events that occurred in companies. Following are some studies that, using the methodology of study of events, aimed at demonstrating the creation or destruction of value due to acquisitions or the launching of new products.

Table 1: Previous Studies of Market Reaction			
Author	**Sample Size & Description**	**Sample Period**	**Returns to Acquiring Firm Shareholders**
(Pau Chaney, Devinney, & Winer, 1991)	1,101 announcements of new products and concepts Announced by 231 firms	1975-1984	0.75% over a 3-day period.
(P. Chaney & Dervinney, 1992)	1481 announcements of new products by 263 firms were usable for the empirical analysis	1975-1988	0.60 % over a three-day period centered on the product announcement date.
(Uhlenbruck , Klaus; Hitt, Michael A.; Semadeni, 2006)	1,029 acquisition of online firms by offline firms events	1995-2001	Positive abnormal return on the day of the announcement of 0.93 % for acquisitions of online firms by offline firms
(Sorescu, Shankar, & Kushwaha, 2007)	419 new product preannouncements	1984-2000	Approximately 13% during the one year after the preannouncement or up to introduction, whichever comes first
(Qin et al., 2017)	27 announcements of the mobile application of hotel and airline companies	2009-2011	On average, hotel companies and airlines that introduced mobile apps experienced a gain of 1.32% in abnormal returns on the event day
(Lee & Chen, 2009)	409 new product announcements	1990-1998	On average, the daily excess returns, 3.96% one day before and 1.02 % in the event day.
(Sood & Tellis, 2009)	5,481 announcements related to innovation projects	1977-2006	Average return for any event is 0.6%

These previously studies are evidence that market could react from acquisitions of mobile applications. Following, we present the empirical hypothesis, the methodology, the empirical results and, finally, the discussion and conclusions of this study.

HYPOTHESE

H1: The acquisition of mobile applications generates positive abnormal returns in the stock prices of technology companies listed on the Nasdaq Stock Market (NASDAQ) buyers.

METHODS

This study aims to verify if the acquisition of mobile applications generates abnormal returns in the stock prices of technology companies listed on the Nasdaq Stock Market (NASDAQ) buyers.

Data description

We analyze the Mergers and Aquisitions (M&A) listed on database from Bloomberg, we searched for all M&A from IT firms and Mobile Application. There is no sector defined as Mobile Application, so, to find our population we searched for M&A from IT firms listed on NASDAQ (buyers) and firms or assets categorized as Internet-Software. Also, we selected only M&A with the status of negotiation as completed. After this selection, our population had 823 events. We excluded the M&A which has as buyer multiple acquires (173), shareholders (12) and unnamed buyer (5), after this filter, our sample become with 633 announcements.

This research presents a positivist approach, since it seeks to test the presented hypotheses. The study's characterization in relation to the objective is descriptive-explanatory. Regarding the research problem, the approach is characterized as quantitative. In the present study it is proposed to carry out a research that will allow the ex post facto analysis.

The population of this study consists of technology companies listed on the Nasdaq Stock Market (NASDAQ). For the analysis of the data, the technique of descriptive statistics will be used initially, and then the technique of the event study will be used. In according to Elton and Guber (1995, p.426) who defend that event studies are used to “determine what information is reflected in price and, if its impact is unclear, to determine whether the announcement is good or bad news.”

The benchmark used to calculate abnormal returns is the S&P 500 Index, which includes all companies publicly traded in Nasdaq Stock Market (NASDAQ). These steps limited the number of studied announcements to a final sample of 52 announcements of 35 buyer firms. The complete list of announcements is displayed on appendix.

Table 2: Descriptive statistics of the sample

Panel A: Countries of the sample

Country	**Occurrences (%)**
USA	77%
CANADA	6%
ISRAEL	6%
CHINA	6%
JAPAN	6%

Panel B: Sample buyer firms statistics at the end of the fiscal year of the announcement

Market Value (in millions)	**Total assets (in millions)**	**Revenue (in millions)**	**Net Income (in millions)**	**Transaction Value (in millions)**
Mean	413,121.21	260,433.70	6,056.52	806.81
Median	974,05	486.05	12.60	73.89
Std Deviation	2,010,771.24	1,229,634.47	19,074.79	2,921.21

We found on Bloomberg the date of the announcement, and designated these dates as date zero. The window panel selected was 5 days before and after the announcement. For each of the announcements in the sample, we calculated the return for the buyer firm on each of the days being studied. In sequence, we computed the abnormal return for each of the days being studied for each company in the sample. So, we computed for each day in the event period the average abnormal return for all the firms in the sample.

This study considered the event window begins in March, 27th 2000 and ends in September 20th 2016. We calculate the daily asset return (R_i) and the daily market return (R_{mt}) as fallows:

$$R_i = LN(P_t/P_t\text{-}1) \quad (1)$$
$$R_{mt} = LN(C_t/C_{t-1}) \quad (2)$$

P_t = share price at time t; P_{t-1}= share price at time t-1; C_t= quotation of the Market Portfolio at time t (S&P 500); C_{t-1}= quotation of the Market Portfolio at time t-1 (S&P 500); and LN represents the logarithmic form used to determine the daily returns.

In the sequence, the estimation window analyzed was about 152 before the 5th day before the event. The estimation of expected return occurred besides the application of the method Ordinary Least Squares (OLS) in the form of a simple linear regression commonly called Market Model, which is demonstrate below:

$$R_i = \alpha_i + \beta_i R_{mt} + \varepsilon_i \quad (3)$$

α = parameter estimated from the OLS application, it represents the intercept that, operationally, is the mean difference between the dependent variable (R_i) and the independent variable (R_m), the latter being associated with the slope estimation of the linear model; β = parameter estimated from the OLS application, it is the ratio between the covariance between the observed daily returns (of the stock and the market) and the variance of the daily returns of the market.

The expected daily return would be generated by the estimated parameters (α and β) and by the market daily return on the estimation window. We calculate the expected daily returns ($E(R_i \mid R_m)$) as follows:

$$E(R_i \mid R_m) = \alpha_i + \beta_i R_{mt} \quad (4)$$

Then, we calculate the difference between observed daily returns (R_i) and the expected daily returns ($E(R_i \mid R_m)$). The result is the abnormal daily returns (AR_i):

$$AR_i = LN(P_t/P_{t-1}) - E(R_i \mid R_m) \quad (5)$$

or

$$AR_i = LN(P_t/P_{t-1}) - (\alpha_i + \beta_i R_{mt}) \quad (6)$$

The abnormal daily returns (AR_i) represents the exceed of return in relation to the expected daily return. It can be positive or negative. In this study, we calculate the abnormal daily returns (AR_i) for 11 days on our event window. The event window encompasses the 5 days before the event (5B;4B;3B;2B;1B), the event's day and the 5 days after the event (5A;4A;3A;2A;1A).

After that, we calculate the cumulative abnormal returns (CAR_i), which is the sum of the abnormal returns.

$$CAR_{i\,(t1,\,t2)} = \sum_{t=t_1}^{t_2} AR_i \quad (7)$$

t_1=first day of analysis; t_2=last day of analysis

This study aims to verify if the acquisition of mobile applications generates abnormal returns in the stock prices of technology companies listed on the Nasdaq Stock Market (NASDAQ) buyers, so for the hypothesis test we considerate the null hypothesis bellow:

Null Hypothesis (H0): $AR_i \geqslant 0$

Null Hypothesis (H0): $CAR_i \geqslant 0$

The ordinary t-statistic is calculated as follows:

$$t = AR_i / \sigma(AR_i) / \sqrt{n} \quad (8)$$

$\sigma(AR_i)$ =the cross-sectional abnormal return sample standard deviation.

Empirical Results

In this section, we analyze the short-term effects of an acquisition announcement on stock prices.

Table 3: Regression's standard error for each of sample which present significant abnormal return

Date	Ticket Buyer	Regression's standard error
27/03/2000	LBTE	0.088808166

a= significance level of 10%
b= significance level of 5%
c= significance level of 1%

As could be seen, the ticker PERI[48] had a significant (level of 1%) abnormal daily return on the 5th, 4th and 3th day before the event also on the 4th and 5th day after de event. The ticker INSG[25] had a significant (level of 1%) abnormal daily return on the day before the event. On the event day, tickers CALL[21], PERI[34], PERI[38] and LIOX[45] had a significant (level of 1%) abnormal daily return. Also, the tickers PERI[38] and KITQ[20] presented negative and significant abnormal return, on the date of the announcement, which means rejects the null hypothesis. Four tickers had a significant (level of 1%) abnormal daily return on the first date after the event.

Briefly, on the event day, only 8 companies presented significant abnormal return, being 6 positive and 2 negative. Over the 5 days after through 27 analyzed events, in 26 days was there an significant abnormal return, in other words, in 19,25% of the days had significant abnormal returns. About the 5 days before the announcement, only 13 days had significant abnormal returns.

Next, we calculate de accumulated abnormal returns (CARi) until the event day, as presented in table 5:

Table 5: Cumulative abnormal returns (CARi)

Additionally,, the ticker PERI[48] had a significant (level of 1%) cumulative abnormal return on the 5 and 4 accumulated days before the event. , 4th and 3th day before the event also on the 4th and 5th day after de event. The tickers ENGH[13], INSG[25], CALL[21], PERI[34], PERI[38] and LIOX[45] had a significant cumulative abnormal return in every accumulated days before the event. Unlike the daily analysis, FB[47] presented a significant cumulative abnormal return 5, 4, 3 and 2 days before the announcement.

DISCUSSION AND CONCLUSIONS

This study aimed to verify if the acquisition of mobile applications generates abnormal returns in the stock prices of technology companies listed on the Nasdaq Stock Market (NASDAQ) buyers. To test the abnormal returns we used the methodology of study of events, aimed at demonstrating the creation or destruction of value due to acquisitions of mobile applications

We expected that, based on a semi-strong form of market efficiency, will have abnormal returns as a demonstration of market reaction. Through daily analysis, we found 47 abnormal daily returns in 270 daily returns. Mostly of these, was during the announcement day or after that. That result is evidence that market see the relevance of the announcement.

Additionally, we analyzed the cumulative abnormal returns and we found 48 significant cumulative abnormal returns, from 135 observations. The combination of daily (ARi) and cumulative (CARi) results is sufficient to affirm that the announcement of acquisitions of mobile applications create or destroyed value of buyer company.

As Pau Chaney, Devinney, & Winer (1991) brought up there are many event study's limitations. They pointed some:

> First, stock prices are naturally noisy, implying that an event must trigger a reaction that is significant enough to be seen above the normal background noise. Second, most events have no true event date. That is, although a public announcement may exist, it is next to impossible to find out precisely when information has been incorporated into the stock price; hence there is a tendency to see abnormal returns prior to public announcements. Third, many events have a tendency to cluster. For example, firms use stockholders' meetings to announce earnings and major changes. Also, managers have the incentive to attempt to counter bad information, such as low quarterly earnings, with potentially good information, for example, the signing of a government contract or other corporate developments. Fourth, many events do not have a clear impact on the firm. The market reaction is an aggregate expectation. Events without clear consistent expectational effect may appear to be nonsignificant when only stock prices are examined.

As a suggestion for future studies we propose analyze as event date not the official announcement but the public announcement of intention of investment. The market may have a delayed reaction, or even the date considered as disclosure in Bloomberg may not be the date investors were aware of. In the case of a strong market, the information would be absorbed when the purchase intention arose.

DECISION SCIENCES INSTITUTE
A Survey of Techniques and Tools for Big Data Mining: the High Performance Analytics

Xiaoguang Tian
University of North Texas
Email: xiaoguang.tian@unt.edu

ABSTRACT

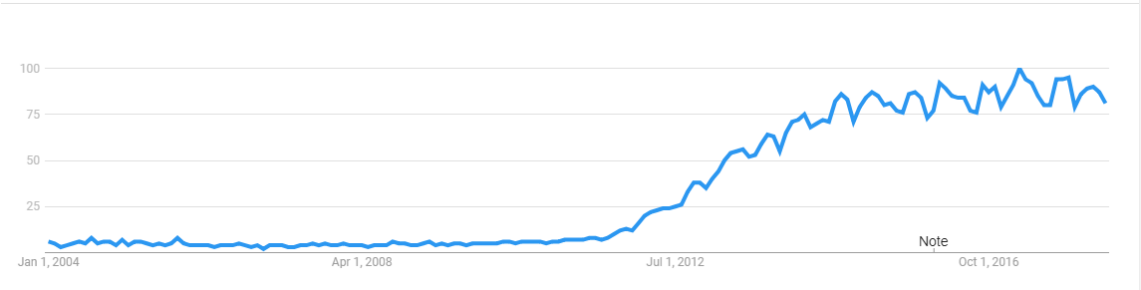
Big Data Mining extracts meaningful insight, hidden pattern, and useful information to support various decision making through analyzing structured and unstructured data. Handling big data is always a challenging task, especially in a distributed environment. To realize high performance computing and analysis, it is necessary to match suitable methods for particular Big Data Mining tasks. In this paper, we investigated data mining techniques, tools, and procedures to shed lights for future research; identified six distributed data mining environment; proposed a conceptual framework of Big Data Mining.

KEYWORDS: Business analytics, Big data, Data mining, Decision support

INTRODUCTION

The term ‘Big Data’ first discussed by John Mashey in 1998 and the first paper including ‘Big Data’ in title occurred around 2000 by Diehold (Fan & Bifet, 2013). Using Google searching term “Big Data” in May 2018, we can locate 136 million results, including 11 million news, 21 million videos, and 680 thousand books. The volume, velocity, variety, and value of data have grown unprecedentedly in recent years. Google Trend shows big data topic sustain a high popularity since 2013 (Figure 1). In today’s world, trillion terabytes of data are produced and 90 percent of the data today were generated in the last two years (IBM, 2018). Industries are facing unprecedented challenges to process and analyze tremendous amount of data to gain information and knowledge. Decision making process driven by data requires more analysis instead of intuition.

Figure 1: Google Trend for term “Big Data” (from 01/04/2004-05/22/2018)



Data is complex but important to business success. The structured and unstructured data are becoming valuable information as the Data Analytics methodologies and techniques make it possible for people to extract value from data. Data Mining is a computational process of extracting valuable information from given data to conduct predictions and supporting decision-making. Its major tasks include patterns and rule finding, clustering, classification, regression, dimensionality reduction, outlier detection and so on. The common data mining process includes three steps: harvesting and cleaning data (or data ETL), modeling, and deployment

(Hashmi & Ahmad, 2016). The final goal of the process is to identify valuable information and insight for better decision making in high speed.

In order to support data mining and business analytics, effective high-performance computing environment and infrastructure are required, which apply systematic designs to unleash the full power of the Big Data (Wu, Zhu, Wu, & Ding, 2014). Meanwhile, effective data analysis and prediction techniques are developed accordingly. There are many data mining applications in business world, such as customer profile, churn forecast, fraud detection, risk factor extraction, and health monitor and diagnosis (Fan & Bifet, 2013). Business giants, such as Google, Facebook, and Walmart have developed multiple initiatives to ensure effective and efficient services and responses to their customers (Wu, Zhu, Wu, & Ding, 2014). Many researches are available now to provide proposals and solutions to industries for handling big data challenges.

In this study, we investigate emerging tools, computing techniques, algorithms and procedures to shed some light to future researches. The paper proceeds as follows. In section 2, 3, 4, 5, we discuss important aspects, programming frameworks, system environment, algorithms, and procedures of Big Data mining and their recent development. Base on the surveyed components, we propose a conceptual framework for Big Data Mining with 4 primary layers and 2 support layers. Section 7 provides a conclusion of the study and potential future research fields.

BIG DATA PROGRAMMING FRAMEWORK

In most occasions, a single computer, which equipped with hard drive, memory and CPU, is adequate for small data analysis and miming project. But in Big Data scenario, data scale is more beyond the capacity that a PC can process. The most recent Big Data processing frameworks utilize cluster computers with a high-performance computing capability, supporting by parallel programming and data mining features.

Traditionally, companies have been making business decisions based on transactional data stored in relational databases. Big Data, such as system logs, tweets, e-documents, sensors data, images, is forcing companies to rethink their mining approaches for extracting more useful information, new insights, and hidden relationships from these unstructured data (Wu, Zhu, Wu, & Ding, 2014). There are many big data tools to support the mining works. Some of them are Apache Mahout, MOA, and Vowpal Wabbit (Fan & Bifet, 2013).The most popular Big Data programming model on parallel programming is MapReduce (Wu, Zhu, Wu, & Ding, 2014).

MapReduce's capability in the real-time and large-scale data processing has attracted extensive attention. As a batch-oriented parallel computing model, MapReduce provides a constructive solution for big data challenges. Data mining tasks usually have to walk through the training data to get statistics and ensure model parameters. Accessing to large-scale data is recurrent and numerous (Wu, Zhu, Wu, & Ding, 2014). In the data processing procedure, the Map executes filtering and sorting and the Reduce transact a summary, which makes it fit many descriptive and predictive algorithms. The down side of the MapReduce is the higher communication or I/O cost. Data process speed is slow due to constraints of replication and disk storage.

Recently, Apache Spark is emerging and joins the mainstream of processing and mining big data. It applies a programming language to a distributed collection data structure "Resilient distributed datasets" (RDDs). Through the collections of objects (RDDs), users can execute partitioning, storage allocation (memory, disk etc.), and parallel transformations (map, filter etc.) across a cluster. During the process, master node assigns jobs to worker nodes, which read data stored in HDFS or in local machine (Bharill, Tiwari, & Malviya, 2016).

As the most popular open source and large scale data processing engine, Apache Spark is broadly adopted in Big Data mining and advanced analytics projects. The advantages of the Spark makes it fit to various environments (e. g. Hadoop, Mesos, standalone, or in the cloud). By using the Spark, people can read data from various data sources (e.g. HDFS, Cassandra, HBase, and S3), interact with varied applications, and work with major programing languages, including Scala, Java, Python, and R (The Apache Software Foundation,2017).

Simply speaking, Spark can run traditional and streaming ETL, interactive or Spark-type SQL, advanced analytics (Machine Learning), graph processing (Graph X/Graph Frames), and Streaming (Structured Streaming) within the same engine. Compared to MapReduce, Spark is 100 times faster than MapReduce through data caching (Hashmi & Ahmad, 2016). It is suitable for fast data processing/in-memory processing, iterative processing, near real-time processing, graph processing, machine learning, and joining datasets (Bekker, 2017).

Although MapReduce has dominated big data processing for a long time and utilized by several companies and organizations, it would be replaced by Spark or other programming models or tools in the near future because of latter's multiple advantages. Besides MapReduce and Spark, there are some other high level programming tool and language are being developed such as Pig, Hive, and Scope (Chen, Mao & Liu, 2014).

BIG DATA MINING SETTINGS

With the businesses spread across the world, current dataset may not be stored in one centralized server. The data sources are often scattered in multiple places. Distributed data mining is designed to handle the distributed data and involving the application of particular algorithms in multiple environments and technique constraints. It is in high demand because of fast growing data volume and speed, storage locations, bandwidth limitation and privacy concerns (Zeng, Li, Duan, Lu, Shi, Wang, & Luo, 2012). It is hard to provide a unified framework for algorithms and there is no "One-Size-Fits-All" algorithm or solution. To deploy a data mining algorithm, a user should firstly consider to identify particular type of computing environments in which certain algorithms can fit.

Communicating among multiple process nodes, distributed data mining commonly utilizes the suitable algorithms to tackle local data and then combine the local pattern and information into a global solution. Srimathi et al. (2014) classified distributed data mining into three groups: DDM based parallel data mining agent, DDM based on mete learning, DDM based on Grid. Based on the summarizations of Zeng et al. (2012), Srimathi et al. (2014), and other most recent studies, we identified six types of distributed data mining setting:

Multi-core Supercomputers

Under this setting, all the computing units share the same memory and the communication cost among computing units is tiny. The disadvantage of such type devices are very obvious: expensive. People only consider this setting when the cost of data mining computation is very expensive and the algorithm can only be rewritten as an efficient fine grained parallel algorithm. Graphics Processing Unit (GPU) is a new type of setting under this category. Equipped with GPU with massive number of cores, supercomputers can now handle and accelerate data mining workload. When the data mining relates to simple and repeat operations, e.g. matrix operation, counting occurrence of item from a bitmap, or search K-nearest neighbors, the GPU can speed up the process significantly.

One of the success GPU-based data mining framework is Three Components Framework: a CPU-based storage and buffer manager is used to manage the whole program flow and data transferring between CPU and GPU; a GPU-CPU co-processing mining module; and a GPU-

based visualization module. Successful implementations include k-means clustering and the Apriori frequent item set mining.

Peer-to-Peer Based

Peer-to-Peer (P2P) environment does not depend on a central server, and each site gets the data and performs its own task. The nature of the peer-to-peer system is decentralization and each site has limited view to the entire system. This limit actually provides better security since sites do not need to observe irrelevant surroundings. P2P networks overcome constrains of communication bottlenecks or messages failure and provide an efficient platform for the distributed big data mining. One of example of P2P system is An extendible multi-agent data miner system (EMADS), comprising a set of peer agents in a set of containers, such as data agents, user agents, task agents, mining agents, and housekeeping agents. A big data mining task is accomplished under the cooperation of multiple agents.

Typical examples of P2P distributed data mining include distributed association rule mining, distributed decision tree. A few researchers proposed other solutions:

(1) Collective data mining. The approach vertically divides data and joins up-to-date results from local sources.

(2) Model to calculate the mean value and data mining application over distributed data and P2P networks.

(3) Ensembles of models, such as Bayesian model averaging for regression models, and partition learning.

Internet and Grid Computing Based

Internet generates huge amount of distributed data and various distributed computing resources. Internet computing maneuvers idle terminals and PCs to build robust distributed computing systems with a global reach. With the assistance of internet computing, we are able to begin many sound projects, which previously required participation of supercomputer, in an economy way. Most recent internet distributed data mining projects include:

(1) Models@Home for distributed computing in bioinformatics.

(2) SETI@Home for distributed computing to detect intelligent life in outer space.

Geographically distributed and users access through a single interface, a grid incorporates a group of similar machines to execute large-scale resource sharing, innovative applications, high-performance orientation, and data processing. Two examples of grid base data mining techniques compose of:

(1) Three layers Data Mining Grid. According to different functions, three layers accomplish grid software, data, and hardware resources management, middleware function, job scheduling, and security support, and results summarization.

(2) Grid-enable Weka. Weka is a broadly used software for machine learning and predictive modeling. In Grid-enable Weka, the machine learning tasks can be split across computers and accomplish producing, testing, and cross-validating a classifier on a remote machine.

Cloud Based

One of the major challenges to the big data mining is the parallelized use calculation power to save the time and reduce the communication cost. Cloud computing implies powerful interconnected servers with multi-core processors to process huge amount of data without physically running process in individual user's environment. Through the concentrated management and colossal storage resources, cloud technique can provide big data processing and storage with fine-grained computing capacity (Chen, Mao & Liu, 2014).

As the newest promising technology for IT industry. Cloud computing exploits the global memory and computing capabilities of computers and servers via a network, usually the Internet, providing us a flexible and considerable computing support and solution. This technique is becoming a business. Othmane and Hebri (2012) proposed an Agent-Based

Systems on the Cloud to handle distributed data mining. The system include following components: User Interface, Task Agent, Data Agent, Cloud Temporary Storage, Mining Agent, Process Agent, Visualization Agent. Through the approach, people can use the parallelism over the cloud platform and shorten the response time, as well decrease the communication costs.

Internet of Things

The Internet of Things (IoT) is the network embedded with software, electronics, sensors, and actuators. These devices generates large quantity of data that needs to be processed in a timely manner. Even though, it may be possible to send all data to a central serve for processing, that would introduce network delay and possibly overwhelm a centralized system because of large number of devices involved. Many businesses realized that data may need to be processed at the Edge, closer to the Things. Compared to a centralize setup, the Edge setup could be smaller and more nimble. By conducting data analytics on the Edge, the business can mine data in real time and make decisions in real time. The intelligence gained on the Edge can be pushed upstream to the centralized system for further processing and analysis. Highly optimized models built on intelligence from many Edge systems can be then deployed to Edge systems. The combination of edge computing and centralized data mining can offer powerful benefits to many IoT deployments.

The IoT is still at early development stage. The major issues of research focus more on efficiency of data processing and then on effectiveness of knowledge mining (Tsai et al., 2014). Chen et al. (2015) proposed an architecture for IoT and big data mining system, which includes five layers: devices, raw data, data gather, data processing, service, and security/privacy/standard. Through the architecture, the data from sensor, camera, RFID, and other IoT devices can be processed by multiple open source solutions, such as Hadoop, HDFS, Storm, and Oozie. The service layer provides data mining functions for extracting information, insights, and values.

BlockChain

Proposed by Nakamoto (2008), blockchain establishes a distributed system which secures and accelerates the online transactions without central authority and intermediaries (Tapscott & Tapscott, 2017). In the system, computers are chained each other in a sequence, no one can manipulate the data without agreement of majority users due to every block keeping a history of transactions. The timestamp and hashing function make the data change verifiable, trackable, and auditable across the block (Di Pierro, 2017). Through the mechanism of smart contracts, the blockchain platform can authenticate private, public and personal records (Treleaven, Brown, & Yang, 2017). Some researchers believe that the technology will transform the business to a low costs, better service, and effective value delivering model (Tapscott & Tapscott, 2017). While, most importantly, the blockchain provides a high-quality and adequate data to the data analysis, predictive modeling, and machine learning. The noise and error of data will be reduced significantly in the data mining process.

The data in blockchain is streaming and high-dimensional. To mining the data across blockchain, an effective mechanism is to connect the transaction flow of the blocks with the corresponding information across the member nodes. Meanwhile, one of significant challenges is extracting features of classification learning (Chen, 2018). Big data mining technique application in blockchain is scarce. Recently, Chen (2018) proposed a deep learning approach, akagi–Sugeno Fuzzy cognitive maps ANN, to fast make traceability decisions. His experiment shows that the method outperforms the consensus algorithm in speed and accuracy.

The quality of distributed data mining is partially hard to measure due to influence factors of data partitioning, assignment scheduling, and global integrating. As supplement of the distributed data mining, the parallel data mining could discover the same valuable information

through global, parallel, and sequential algorithm on full dataset. The precision may be somewhat promised, comparing to the distributed data mining (Zeng, Li, Duan, Lu, Shi, Wang, & Luo, 2012). In the near future, the parallel data mining algorithm will more and more be applied in different environment settings.

In practice, there is not a single best setting for each organization. The final solution depends on organization's decision according to its objective, resource, capability, status quo of systems, and management requirements.

BIG DATA MINING ALGORITHMS AND TECHNIQUES

The common task of analytics and data mining is prediction (Phillips-Wren & Hoskisson, 2015). Statistical models and machine learning algorithms are broadly applied in data mining projects (Hashmi & Ahmad, 2016). Commonly, data mining models can be divided into two categories: supervised and unsupervised mining.

(1) Supervised mining deals with training the model with existed data and making prediction or label new input observations. The typical models for supervised mining include: Regression, Naïve Bayes, Decision trees, Perceptron, and Support Vector Machines. For their importance to data mining tasks we describe each model as following Table 1.

Techniques	Description
Logistic Regression	Applied to predict the probability of a dependent variable (and thus classify the outcome based on that probability) through a logistic function.
Decision Tree	A flowchart-like structure where the final outcome relies on the rules across the internal path and nodes.
Neural Networks	In the system of Interconnected layers and nodes, outputs is calculated through the weighted sum of the values of the nodes activation function to that weighted sum.
Support Vector Machine	By given labeled training data, the discriminative algorithm produces an optimal hyperplane which can categorize new data.
Naïve Bayes	Based on applying Bayes' theorem with the assumption of independence between features.

Table 1: A Description of Typical Supervised Mining Models

(2) Unsupervised mining is concerned to extract patterns or clusters by giving data without a label. The algorithms for frequent pattern mining commonly include: Apriori algorithm, FP-Growth algorithm, Eclat, etc. Related techniques such as dimensionality reduction, ensemble learning, Outlier detection, and Machine Learned Ranking are also broadly discussed. For clustering, the popular algorithms accommodate: k-means, fuzzy cmeans (centroid models), BIRCH (hierarchical models), DBScan, OPTICS (density models). Other widely discussed techniques for clustering consist of Expectation-Maximization and Self-Organizing Maps (Hashmi & Ahmad, 2016).

With the fast increasing streaming data from multiple sources, streaming data mining models now are in high demand. To handle the streaming data, a good model should be capable of synchronizing and combine them efficiently and effectively. To harvest useful information from the streaming data, traditional existing models need to be transformed to handle the new

situation. Current available models, which can be deployed to process and analyze streaming data, incorporate following (Hashmi & Ahmad, 2016):
(1) For clustering of a streaming data , there are BIRCH, Scalable k-means, Single-pass k-means , Stream, Stream LSearch, CluStream, ODAC, DenStream, D-Stream, SWClustering , ClusTree , DGClust , StreamKM++ , SOMKE.
(2) For classification of streaming data, available algorithms/models can be categorized into two groups: incremental learning and ensemble learning. The classical algorithms for incremental learning include Incremental Bayesian algorithm, Incremental SVM, VFDT (Hoeffding Tree), and CVFDT; Streaming Ensemble Algorithm (SEA), Accuracy-Weighted Ensemble (AWE), and Dynamic Weighted Majority (DWM) are well-known ensemble learning algorithms.
(3) For regression and pattern mining, the most notable models are Hoeffding-based Regression trees,estDec FP Stream , Moment , IncMine, and CloStream.
In unstructured text, web, multimedia, and network task, besides some of techniques discussed above, other typical techniques (Chen, Mao & Liu, 2014) include:
(1) Information extraction, topic models, text summarization, classification, clustering, question answering, and opinion mining.
(2) Information retrieval, Page Rank, and CLEVER.
(3) Multimedia summarization, multimedia annotation, multimedia index and retrieval, multimedia suggestion, and multimedia event detection, and topic-oriented multimedia summarization system (TOMS).
(4) Link-based structural analysis and content-based analysis.

BIG DATA MINING PROCEDURE

Data mining follows certain steps to obtain optimal solutions. One of the most high-profile data mining process models is CRISP-DM (Kumari, Nandal, & Kataria, 2017), which include six major phases: business understanding, data understanding, data preparation, modeling, evaluation, and deployment. The procedure can be applied in big data tasks as well. Carrying the mechanism in the head can organize our thinking about big data mining tasks and problems (Provost & Fawcett, 2013).

We describe each step and specific big data mining tasks and considerations as follow:

(1) Business understanding. This initial phase focuses on understanding the problem under a business landscape, and then transferring business requirements and information into a big data mining project. During the business understanding step, an initial plan needs to be formed to ensure the achievement of business goals and missions.

(2) Data understanding. Data sources can be varied in today's digital world. Big data status quo makes data understanding more challenge and complicated than ever before. The data distributed geographically force us to recognize and understand it carefully. The data understanding phase starts from data harvest from multiple sources and environment, and data glimpse to figure out data quality problems, to identify initial knowledge from the data, and to identify meaningful sample data to form a hypotheses testing or experiment design.

(3) Data preparation. It should never be ignored to preprocess the data to ensure a high quality input before miming. The data preparation step is expected to generate the final dataset from "dirty" data. Data preparation tasks cannot be accomplished in one shot in a predefined order. The process is iterative and requires multiple tries. In this step, tasks like table and record manipulation, feature selection, data transformation, data filter, and data cleaning primarily serve to the future modeling task.

(4) Modeling. In this step, we utilize appropriate model and tune their parameters to seek optimal solutions. Commonly, people can try multiple techniques for one problem. Particular

requirements and data quality will sometime limit the performance of a certain technique. Returning to the former step, especially the data preparation phase, is necessary and often needed. For static and dynamic data, we should consider different algorithms according to our previous discussions.

(5) Evaluation. It is crucial to assess the quality and performance of model and review the procedure ran to produce the candidate model. We need to guarantee that the model can appropriately support us to reach particular business mission. One of the key issues is to check if business issue is ignored in whole or missed partially. During this process, we need to make a decision whether or not to implement the data mining results in the future.

(6) Deployment. Following the model creation and evaluation, we need to applied data mining experiment and project results to gain and add more business value to organization and stakeholders. We need to make sure the knowledge we obtain from data modeling can benefit organization and customers in an organized, understandable and applicable way. Producing a report, carrying out a repeatable data scoring, or embedding an autonomous process into current information system could be one of the data mining deliverables. Commonly, outside customer and inside decision makers are end users of created data miming products or services which we developed from above multiple phases.

CONCEPTUAL FRAMEWORK OF BIG DATA MINING

Base on the all components surveyed and discussed previously, we develop a conceptual framework for Big Data Mining. In this framework as show in Figure 2, it includes 4 primary layers and 2 support layers:

Primary layers are:

(1) Data source. Various data sources generate structured and unstructured data.

(2) Computing Environment. Data mining function and algorithms run on certain computing environment according to the characteristics of big data and business status quo.

(3) Algorithm. Due to requirements of different data-driven analysis, certain mining algorithm can be utilized. Major categories include supervised, unsupervised, streaming, and unstructured data mining methods.

(4)Product and Service. The final objective of big data mining is to provide business a better solution. The product and service from the data mining process improve and optimize business decision making.

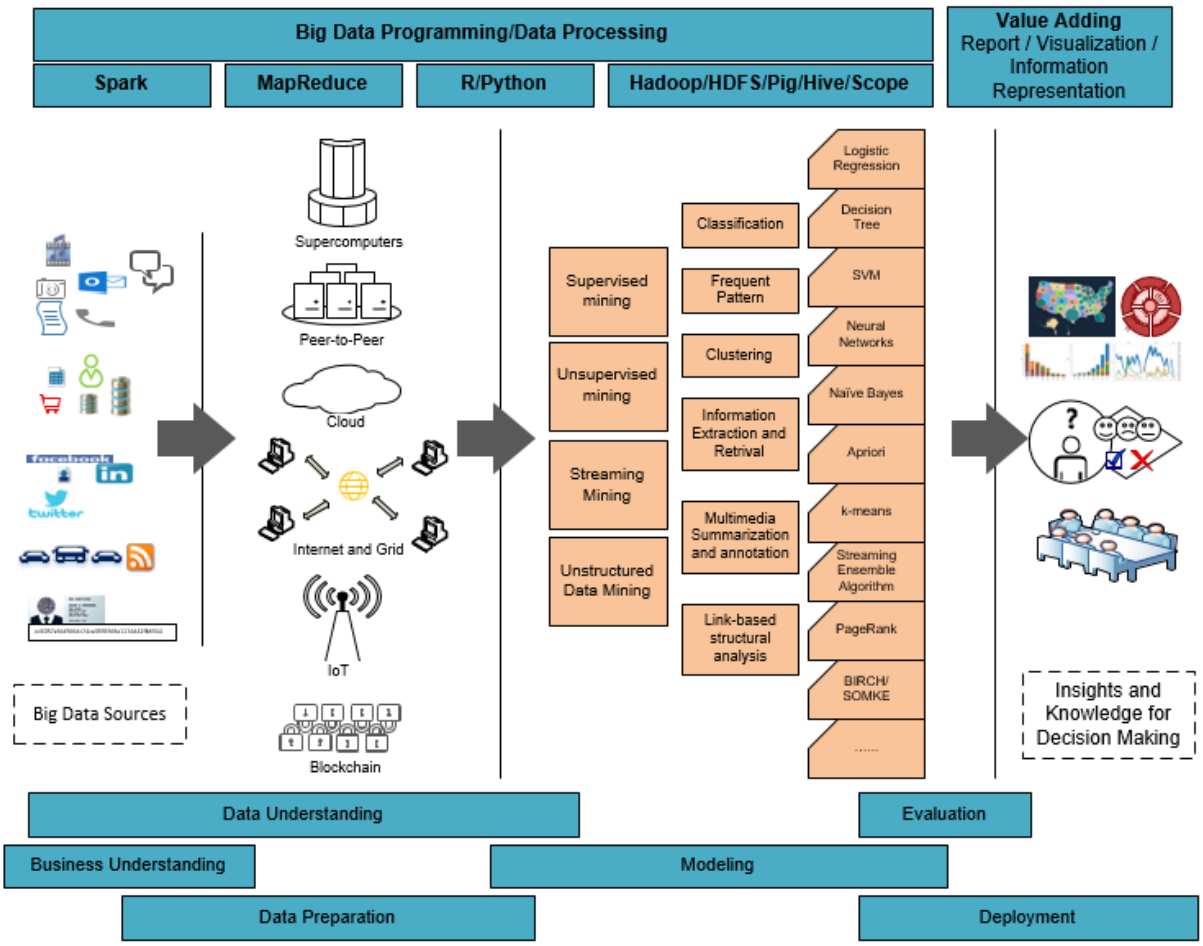
Support layers include:

(1) Big Data Processing and Value Adding. Based on data analysis supported by multiple tools, big data mining add value to business through methods of report, visualization, and information representation.

(2) Big Data Mining Procedure. Six continuous and overlapped steps guarantee a seamless pipeline for data-driven decision making.

There is not an exhaustive framework for big data mining because fast changing business environment. When new problem occurs and novel technology becomes mature, we need to reconsider their old works and then make updates and optimize the previous process and solutions.

Figure 2: Conceptual Framework of Big Data Mining



CONCLUSION AND FUTURE RESEARCH

Efficient data processing and analysis are major research areas in Big Data Mining. In this survey, we investigate previous researches and studies on tools, techniques and frameworks on Big Data Mining. In term of contribution, we state several challenges across big data mining process including analytics architecture, and distributed data mining settings and methods. We summarized centralized and decentralized data mining tools and algorithms which can handle big data problems. We also discuss major models and procedures to run a big data mining project. Our proposed framework consolidates and conceptualizes the big data mining life cycle and technique details. The framework could strength researchers and managers to better understand Big Data Mining and high performance analytics.

Big data technologies bring us beneficial and desired outcomes (Power, 2014). To choose decent programming tools, settings, technique, and model are very crucial for project and business success. Industry and academic researchers should study the upcoming and implemented evolving technologies like Hadoop, Spark, distributed computing, machine learning, deep learning and their use cases. Through the survey, we can find that there is not "One-Size-Fits-All" solution for processing big data and handle big data problems due to its

characteristics. An organization needs to select the best solution according to its tasks, ability and capability.

To expand our understanding of Big Data Mining, future research should consider following issues:

(1) Data quality and security. Big data is large scale, noisy, various, uncertain, incomplete, and sensitive. Effective processing mechanism of data cleaning, transforming, and dimensionality reduction should be studied and explored. Researchers need to consider the standard to protect data from breach.

(2) Efficient processing framework. Research effort is needed to improve the distributed and parallel programming framework. The potential problems include energy efficiency, dynamic resource allocation, processing big data in cloud computing, load balance, and real time processing (Hashem, Anuar, Gani, Yaqoob, Xia, & Khan, 2016). The use case of Spark and other big data mining platform should be identified and developed to stimulate broad application.

(3) Effective algorithms. As a new development of machine learning, deep learning is proving to be powerful in big data analytics, especially in identifying language, image and audio pattern (Najafabadi, Villanustre, Khoshgoftaar, Seliya, Wald, & Muharemagic, 2015). The approach applies to multiple big data projects across the industry and academia. However, deep learning with streaming, high-dimensional data, distributed computing, and IoT needs further investigation.

(4) Blockchain mining. Blockchain provides a quality data solution for big data mining. It will become a game changer for the business and regulation. The new research can address program framework and machine learning on specific block, segment, and whole chain. Machine learning execution with smart contract will be an interest topic.

(5) Data Visualization. In the data mining process, visualization strengthens the power of big data mining. Interdisciplinary studies like computer science, psychology, art, and statistics should be further explored to enhance the performance of descriptive and predictive data analysis, insights and knowledge presentation, and business storytelling.

Alliance Partner Selection and Firm Value: An Event Study

Yu Liu
Saginaw Valley State University
Email: yliu1238@svsu.edu

ABSTRACT

This study links an important phenomenon in alliance formation – partner selection – to alliance performance. Particularly we study how exploration in partner selection, as characterized by forming relationships with new partners from new industries, affects the value of an alliance. We find that generally exploration has a negative impact on the value of the alliance. However, after considering some contingency factors such as the industry environment we find that the relationship actually becomes positive in a dynamic environment. These findings suggest that the exploration choice in partner selection needs to fit certain contextual conditions to add value to the firm. The main effect of the choice and the contingent effect of the context provide important implications for alliance managers and corporate executives when they weigh the choice of selecting a value-adding partner.

KEYWORDS: Event study, Alliance partner selection, Exploration, Exploitation

INTRODUCTION

The abundant research on alliances has shed light on a typical alliance life cycle consisting of stages such as partner selection, alliance negotiation, contract formulation, and partnership termination (Kale, Dyer, & Singh, 2002). Although the importance of partner selection has long been recognized by strategy researchers (Harrigan, 1985), the question of partner selection has remained as an under-researched topic in the literature (Rothaermel & Boeker, 2008). The question of "who allies with whom" has been found to be related to issues such as dyadic complementarities or strategic interdependence (Rothaermel & Boeker, 2008; Gulati, 1995; Shah & Swaminathan, 2008), status similarities (Podolny, 1994) or technological similarities (Rothaermel & Boeker, 2008), trust and commitment (Shah & Swaminathan, 2008), the potential partner's status and reputation (Stern, Dukerich, & Zajac, 2014) and social structure such as repeated ties (Gulati, 1995). As the need for novel knowledge and new capabilities through alliances often drives the decision of partner selection, the issues above usually affect the incentive of learning, the efficiency of the learning process, and hence alliance performance.

Depending on the extent of learning, firms may engage in exploration and exploitation when forming alliances. Exploration involves experimentation with new knowledge domains. In the context of partner selection, this may require forming relationships with partners who can bring in new capabilities and resources. Exploitation, on the contrary, takes advantage of existing competence and knowledge. Hence exploitation in partner selection is more like forming relationships with partners whom the firm has been interacting with or been familiar with. In reality, firms often face the exploration-exploitation dilemma when choosing alliance partners. On the one side, choosing a partner who has existing relationships with the focal firm, which is often viewed as a form of exploitation, may ease the knowledge transfer process and enhance the efficiency of collaboration (Lavie & Rosenkopf, 2006). But the same relationship, sometimes characterized as a repeated or strong tie, may also restrict the firm's search for and access to non-redundant and novel information and knowledge, which sustain the growth and renewal of

the organization. On the other side, forming relationships with new partners, as a form of exploration, offers new growth opportunities for the focal firm. The knowledge obtained from such relationships, however, is likely to be very different from what the firm gained from past relationships, therefore represents a challenge in the knowledge assimilation process. Moreover, due to lack of familiarity and trust with the partner, the collaborative relationship may also be endangered by potential opportunistic behaviors and distrust between allying firms.

The dilemma is rooted in the well-established belief that exploration and exploitation lead to different performance outcomes – exploitation produces positive performance effects in the short run whereas exploration is more likely to pay off in the long run. The choice of partner selection, therefore, should determine the potential value of the relationship, which can be captured by the unusual movement of the firm's share price. Unfortunately research that links partner selection to alliance performance has been scarce. Recently there have been studies looking at the relationship between partner choice and performance at the firm level (Goerzen, 2007; Lin, Yang, & Demirkan, 2007), but very few studies have looked at the relationship at the alliance level. Previous research has shown that stock market investor-shareholders respond differently to R&D announcements with varied focus on exploration and exploitation, because investors perceive different value potentials in the two types of R&D projects (McNamara & Baden-Fuller, 2007). But will they also respond differently to choices of partners, which vary in the focus of exploration versus exploitation? The research needed to answer the question is hardly existent.

The main task of this study is then to investigate how the choice of partner selection, in terms of the focus on exploration versus exploitation, affects the market valuation of the firm's common shares. We agree with Lavie & Rosenkopf (2006) that there are domains where firms may tune this focus when forming an alliance, probably due to the different types of learning involved in the alliance. More importantly, theory explaining the difference in value creation will be incomplete without considering certain contingency factors. Because either choice of partners incurs some benefits and costs in alliance management, the value of the alliance is most likely to depend on factors that may change the balance. Combining March's (1991) exploration-exploitation framework with social network theory advanced by Granovetter (1973; 1983), we explore factors such as environmental dynamism and munificence with respect to their contingent effects on the value of the alliance. These factors influence the relative weights of the costs and benefits associated with exploration and exploitation in partner selection, and hence the economic value that can be expected from the alliance.

EXPLORATION VS. EXPPLOITATION IN PARTNER SELECTION

March's (1991) seminal work on exploration and exploitation has spawned a large number of studies applying the dual concepts to analyze a variety of phenomena such as organizational innovation, organizational adaptation, organizational learning, and competitive advantage. Exploration refers mainly to learning and innovation, i.e. the pursuit and acquisition of new knowledge (Gupta, Smith, & Shalley, 2006). By contrast, exploitation represents the refinement and extension of existing competencies, technologies, and paradigms (March, 1991). A key difference in the exploration-exploitation dichotomy is the level of learning involved in each type of activities (Gupta, Smith, & Shalley, 2006). As March theorized, both exploration and exploitation are of critical importance to organizations, but the two are fundamentally incompatible. The incompatibility comes from the competition for scarce organizational resources such that the interplay between exploration and exploitation occurs in the form of a zero-sum game (Gupta, Smith, & Shalley, 2006). Moreover, "failure trap" and "success trap" may yield self-reinforcing effects for both types of activities (March, 1991).

Alliances are often viewed as an interorganizational vehicle for learning new and external knowledge (Lavie, 2006). Given the involvement of learning in both exploration and exploitation, it is not surprising that the exploration-exploitation framework has been widely applied in the alliance research. Koza & Lewin (1998, p. 257) defined an exploitation alliance as "the joint maximization of complementary assets" and often takes the form of equity-based joint venture. On the contrary, an exploration alliance is likely driven by "a desire to discover new opportunities" (Koza & Lewin, 1998, p. 257). Other alliance researchers have linked the type of alliances to the different stages in the product development process (Rothaermel, 2001; Rothaermel & Deeds, 2004; Lavie & Rosenkopf, 2006; Stettner & Lavie, 2014). Some of these authors refer to exploration alliances as those that focus on upstream activities of the value chain such as drug discovery, development, and manufacturing, whereas exploitation alliances have a focus on downstream activities such as marketing and sales.

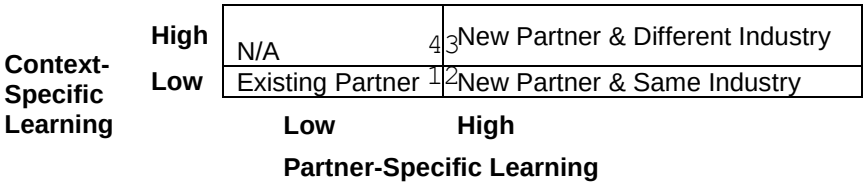
Lavie & Rosenkopf (2006) generalized three domains of exploration and exploitation in alliance formation: the function domain, the structure domain, and the attribute domain. Alliances can serve different value chain functions which exemplify the distinction of exploration and exploitation. The function-based differentiation is consistent with the conceptualization of Koza & Lewin (1998) and the operationalization of Rothaermel (2001) and Rothaermel & Deeds (2004). The structure domain considers the network positions of the firm's partners and differentiates between recurrent alliances and new alliances. The last domain taps into the difference in the organizational attributes of a firm's partners over time. The conceptualization by Lavie & Rosenkopf (2006) is interesting and allows the test of the ambidexterity hypothesis across different domains. Recent studies on exploration and exploitation in alliance formation have been focused on the structure-based distinction (Lin, Yang, & Demirkan, 2007; Goerzen, 2007), looking at the impact of repeated ties versus new ties.

In this study we build upon the previous conceptualization of the exploration-exploitation dichotomy in alliance formation with a focus on the choice of partner selection. Particularly we define exploration and exploitation based on the firm's choice of partner in the present alliance as opposed to in the previous alliances. We focus on whether an alliance represents a new tie to the firm, which would mean that the firm has no prior relationship with the partner. Forging relationships with existing partners is viewed as a form of exploitation in partner selection. The difference in the level of learning is evident across the two choices, i.e. a new tie or a recurrent tie. A new tie, which means exploration in partner selection, often leads to significantly more learning involved in the relationship. This type of learning taps into the knowledge about the partner, regarding various aspects such as its location, size, technology, structure, culture, and the like. Each time the firm forms a new tie, it needs to undertake such partner-specific learning in the entire alliance life cycle. When forming a relationship with an existing partner, on the other hand, chances are the firm has already possessed the relevant knowledge about the partner, which would largely reduce the effort of learning in the alliance. Moreover the mutual trust built through previous relationships may also reduce the likelihood of partners' opportunistic behavior (Lioukas & Reuer, 2015).

Besides partner-specific learning, firms may also engage in context-specific learning as a result of their partner choice. The term context refers to the technological environment in which a firm operates (Rosenkopf & Almeida, 2003). On the one hand, the firm may choose a partner with the same technological background as its previous partners, which may incur less learning regarding the context. As a firm's technology is often determined by its industry, the choice of a partner from the same industry as the previous partners represents a form of exploitation in partner selection. On the other hand, the choice of a partner from a different industry may

demand a significant level of learning about the partner's technological background, therefore can be viewed as a form of exploration in partner selection. Partner-specific learning thus intertwines with context-specific learning in the choice of partner selection. By combining these two types of learning, we can create a full spectrum of partner choice ranging from exploration to exploitation. Figure 1 uses a two by two matrix to illustrate the different learning activities involved in partner selection. The level of learning increases monotonically from Cell 1 to Cell 3 via Cell 2, indicating a distinction between exploitation and exploration.

Figure 1: Partner Selection and Learning Activities



PARTNER SELECTION AND ALLIANCE PERFORMANCE

Exploration activities and exploitation activities entail different performance implications due to the difference in the amount/level of learning involved in each type of activities. March (1991) argues that exploration activities such as basic research produce less certain results and last over longer time periods as they often involve a large amount of learning. Because of uncertainty in the scope of possible outcomes, exploration often leads to failure or at least its performance effect is hard to be captured by short-horizon measures. In contrast, exploitation has a quick self-correction mechanism as it uses knowledge that is most proximate and hence represents a closer feedback system. As a result, exploitation activities are more likely to yield positive returns in the near term (Levinthal & March, 1993). It is apparent then that exploration and exploitation will have different effects on a particular performance metric.

In the alliance literature, no research has been done on the relationship between exploration-exploitation in partner selection and alliance performance. At the firm level, there has been some empirical evidence that exploitation in alliance formation may have adverse effects on firm performance. Goerzen (2007), for example, reported that firms with a greater propensity to enter into repeated partnerships experienced inferior economic performance. There is also conjecture that both exploration and exploitation are important for the firm. For example, Lin et al. (2007) tested the ambidexterity hypothesis, which argues that firms pursuing exploration and exploitation simultaneously in alliance formation will outperform those who do not. Their empirical findings, however, failed to support the ambidexterity hypothesis but identified a set of boundary conditions of the hypothesis. Despite the scarcity of research on the relationship between partner selection and alliance performance, many studies have suggested that partner characteristics impact alliance performance (Afuah, 2000; Stuart, 2000; Zaheer & Bell, 2005; Lavie, 2007). These findings highlight the importance and need of studying a firm's choice of alliance partners and its performance implications.

So far there seems to be neither complete nor consistent empirical research regarding the economic impact of exploration versus exploitation in partner selection. Furthermore, none of the extant studies has been done at the alliance level. To link partner selection to alliance performance, we employ a market-based measure for the economic value of alliances, abnormal stock market returns during the announcement period of an alliance. Compared with conventional performance such as ROA, excess returns reflect the investor-shareholders'

evaluation of the potential value attributed to a particular event, which separate from the focal event other factors that might affect alliance performance. It is therefore a “cleaner” measure of alliance performance. In addition, there has been evidence that the stock market not merely reacts to the event itself, but also gathers all relevant information available in the market and uses it to adjust the assessment of value creation. For instance, investor-shareholders are found to respond differently to project announcements at various stages in the R&D process that are used to construct the exploration-exploitation dichotomy (McNamara & Baden-Fuller, 2007). Given these properties of abnormal stock market returns, we believe that they are appropriate measures for capturing the economic value that can be attributed to exploration and exploitation in partner selection.

The stock market will generally favor exploitation in partner selection as this choice reduces the need to learn about the partner and improves the alliance management process. Exploitation takes advantage of the past relationships between the firm and the partner. Choosing an existing partner may reflect the managerial intention to leverage the firm’s knowledge about the partner, maintain a long-term collaborative relationship, and most importantly streamline the transactions involved in the new partnership. Such information is often highlighted in the announcement of the alliance, producing some strong signals to the stock market that the firm probably will do well in managing the new partnership. As a result, investors and analysts will generally react favorably to exploitation in partner selection. On the contrary, exploration in partner selection produces some risks and uncertainty to shareholders. Lack of knowledge about the partner and lack of expertise in the technology to be tapped in the alliance create some serious challenge for managing the relationship and assimilating the partner’s knowledge. Such information can be easily picked out by investors and analysts and used against the valuation. Furthermore, the informational advantage of exploration is subject to information asymmetry between the managers and the shareholders, which might not be communicated well enough to the stock market upon the announcement of the alliance. Hence long-term benefits through allying with a new partner can be overshadowed, at least temporarily, by the difficulty in managing the relationship. Consequently, exploration in partner will generally incur less favorable market responses.

H1: Exploration in partner selection is negatively associated with abnormal stock market returns during the announcement of an alliance.

Value Contingency

Note that H1 does not imply that exploration in partner selection will cause negative abnormal stock market returns. Since on average alliances create value for the firm (Chan, Kensinger, Keown, & Martin, 1997), H1 suggests that on average exploration creates less value than exploitation in partner selection, all other things being equal. While there has been evidence that investors emphasize long-term growth potentials such as those stemming from R&D (Hansen & Hill, 1991), given the difficulty in assessing the outcome of these activities, it is likely that the valuation effect will be contingent. For instance, it was found that exploration in R&D was favored by investors in small firms (McNamara & Baden-Fuller, 2007), suggesting some contingent effect in value creation. Therefore it should be reasonable to argue that when evaluating a strategic move by the firm such as forming an alliance, investors and analysts will factor the contextual elements into their consideration. Given that the relative importance of the argued benefits and costs probably varies under different circumstances, we postulate that the value of the alliance will also depend on certain contextual factors. To be more specific we submit that it is the fit between the choice of the partner and the attribute of the context that determines how much value can accrue to shareholders. In other words, the alliance will have a

higher value if the partner choice in terms of exploration and exploitation is compatible with the circumstance. We label these contextual factors as value contingency.

Environmental Dynamism and Munificence

We are especially interested in contextual factors that may change the relative importance of the benefits and costs associated with exploration and exploitation in partner selection. It has been argued previously that in fast-changing environments the incidence of both exploration and exploitation alliances will be greater than in stable environments (Koza & Lewin, 1998). Thus environmental dynamism represents an important contingency factor that determines value creation in alliances. In fact many studies on exploration-exploitation in alliance formation incorporate environmental uncertainty in their analysis (Goerzen, 2007; Lin, Yang, & Demirkan, 2007). Environmental dynamism, also known as environmental turbulence or uncertainty (Dess & Beard, 1984), is characterized by the rate of change and innovation in the industry as well as uncertainty or unpredictability of the actions of competitors and customers (Miller & Friesen, 1983).

We argue that a dynamic industry environment will enhance the benefits of exploration in partner selection. Previous studies have shown that entrepreneurial strategic postures characterized by risk-taking, innovative, and proactive organizational behaviors are compatible with a dynamic environment (Miller, 1987; Miller & Friesen, 1983; Miles, Govin, & Heeley, 2000). Rowley, Behrens, & Krackhardt (2000) reported that dynamic environments favor a high level of investment in exploration alliances. It is also argued that to cope with uncertainty firms should connect themselves to non-redundant partners in an attempt to gain new information and knowledge (Goerzen, 2007). Fast technological change, therefore, drives the need for distant search (exploration) to maintain competitive advantage (Rosenkopf & Almeida, 2003). In such an environment, uncertainty in the outcome of exploration becomes less important compared to greater uncertainty imposed by the environment, whereas the informational advantage of exploration is likely to be even greater as the ability to quickly respond to changing market needs is crucial for superior firm performance. Moreover incremental performance enhancement through exploitation becomes short-lived in dynamic environments, whereas the informational disadvantage of exploitation exacerbates the challenge faced by the firm and might even endanger the firm's survival. All the above arguments suggest that in a dynamic environment, the value of exploration in partner selection may exceed the value of exploitation. Hence we hypothesize that,

H2: Exploration in partner selection is positively associated with abnormal stock market returns in industries of which competitive environments are changing fast.

A second contextual factor we are interested in is environmental munificence, defined as the extent to which a business environment supports sustained growth (Dess & Beard, 1984). Environments that are mature or shrinking are normally characterized as having low levels of munificence, whereas rapidly growing markets are typically associated with a high degree of munificence. Like environmental dynamism, environmental munificence influences organizational behaviors and outcomes. Specifically, it is argued that a munificent environment provides the needed resources to develop capabilities for managing an exploration strategy (Bierly & Daly, 2007). In hostile or less munificent environments, the scarcity of resources requires firms to avoid excessive risk-taking and pay greater attention to the conservation of resources (Goll & Rasheed, 1997). As such organizations respond to hostile environments through strategy-making characterized by greater analytical efforts and reduced innovation (Miller & Friesen, 1983). High uncertainty in the outcome of exploration becomes even more

costly to the firm in the presence of resource scarcity, causing the value of the alliance to decrease. In such an environment, incremental improvement through exploitation may represent a more viable strategy for the firm.

On the other hand, munificent environments invite extensive risk-taking, forceful proactiveness, and an emphasis on novelty in strategies since fast-growing markets often lack established standards, require new technologies, and allow innovation failures. This makes exploration in partner selection a promising strategy. Moreover, the profitable industry environment allows the firm to use slack resources toward exploration efforts, creating necessary in-house competencies to manage relationships with new partners. As the outcome uncertainty in exploration is reduced by better management and execution, the value of exploration will rise accordingly. Meanwhile, the effect of munificence on exploitation is at best minimal because the latter consumes limited organizational resources and often leads to predictable results. Hence it is reasonable to anticipate that as the level of environmental munificence increases, the value of exploration in partner selection will eventually surpass the value of exploitation, and building new ties become a more attractive strategy for the firm. As such we argue that,

H3: Exploration in partner selection is positively associated with abnormal stock market returns in industries of which competitive environments are munificent.

METHODOLOGY

Data

We collected the data on alliances from the Mergers, Acquisitions, and Alliances' database of the Securities Data Company (SDC). We chose a time period from 1997 to 2003, a period for which we believe SDC has the most comprehensive coverage. We collected alliance data for U.S. manufacturing industries (SIC 2000 – 3999). There are certain reasons for choosing the manufacturing division. First of all, a large number of manufacturing firms, such as those in the automobile, chemicals, computer equipment, electronic components, pharmaceuticals, and telecommunications equipment industries, have long-lasting tradition of using alliances for growth and success. Alliances are an important element in their corporate strategy. Second, restricting our sample to the manufacturing industries will reduce cross-industry differences in the purpose, management, and assessment of alliances, while at the same time will allow sufficient variance in some of our variables across these industries. For example, it has been reported that there was significant variance in the task environmental dimensions across the U.S. manufacturing industries (Dess & Beard, 1984).

As the term "alliance" often takes a vast array of organizational forms, ranging from licensing agreements to joint ventures (JVs), we restricted our sample to equity-based joint ventures, also in an attempt to controlling for differences in the management and assessment of alliances across different forms. We excluded joint ventures which involved more than two participants (including the focal firm). Since we needed to compare the firm's present partner with the past partners to get the measure for exploration in partner selection, it became difficult to measure the variable if more than one partner was involved in the joint venture. We also excluded announcing firms with only one alliance (not necessarily joint ventures) during the sample time period for the same reason. We compiled data from Compustat database as well, from which we obtained the measures for firm size, primary industry, and environmental characteristics. We also used the geography data published by the U.S. Census Bureau to calculate the variable of geographic distance. The final data set after excluding observations with missing data consisted of 1061 joint ventures made by 367 firms in the seven-year period (1997-2003).

Dependent Variable

Abnormal stock market returns

To measure the economic value that an alliance can add to the firm, we used the event study methodology to compute abnormal stock market returns following new alliance announcements. Finance and accounting researchers employ a standard asset pricing model to predict firms' stock returns and use the residuals obtained from the model as a proxy for firms' excess returns. Standard event study methodology uses daily data on the stock market returns of each publicly traded firm in the sample over a pre-event estimation period to estimate the following market model (Brown & Warner, 1985; Fama, 1976):

$$r_{it} = \alpha_i + \beta_i r_{mt} + \epsilon_{it}$$

In the above equation rit denotes the daily returns of firm i on day t, r_{mt} denotes the corresponding daily returns on the value-weighted market returns, αi and βi are firm specific parameters, and ϵ_{it} is distributed i.i.d. normal. The methodology then uses the estimated firm specific parameters $\hat{\alpha}_i$and $\hat{\beta}_i$ to predict the daily returns for each firm over a chosen event window surrounding the event day, using the following equation:

$$\hat{r}_{it} = \hat{\alpha}_i + \hat{\beta}_i r_{mt}$$

where $\hat{r}_{it}$ is the predicted daily return. The daily excess return for firm i can be calculated using the following equation:

$$\hat{\epsilon}_{it} = r_{it} - \hat{r}_{it}$$

However, a strong assumption of this approach is that there is no other event in the estimation period. When one or more events fall into the estimation period, they will confound the calculation of the expected normal returns$\hat{r}_{it}$. An alternative proxy for the expected normal returns, as suggested by previous research, is the value-weighted market returns or the equally-weighted market returns (Haleblian & Finkelstein, 1999; Brown & Warner, 1985). As our sample includes firms that had multiple alliances within the same year, we chose to use the value-weighted market returns as the expected normal returns. The equation to compute daily access returns then becomes

$$\hat{\epsilon}_{it} = r_{it} - r_{mt}$$

Brown and Warner (1985) have shown that the approach of standard OLS market model and the approach of using market adjusted returns have similar statistical power to detect abnormal market movements. The excess returns thus reflect the daily unanticipated movements in the stock price for each firm over the event period. To capture any information leakage or information lagging effects while simultaneously avoid the influence of other firm events that possibly occurred within the event window, we adopted a relatively small window to calculate the cumulative stock market abnormal returns (CARs). The window we used was a three-day period starting from one day before the event day and one day after the event day, i.e., day -1 through day 1. Regarding the use of abnormal returns to represent value gains from a strategic move such as forming an alliance, researchers have expressed concerns that the stock market reaction might not reflect the actual success of the implementation of the strategy. Past empirical research, however, has revealed that stock market-based measures such as abnormal returns and perceptual measures such as managerial assessment of alliance success are highly correlated (Kale, Dyer, & Singh, 2002; Koh & Venkatraman, 1991).

Independent Variables

Exploration in partner selection We measured exploration in partner selection in a two-step procedure. First, we compared the present partner with the firm's previous partners within one

year prior to the announcement date of the joint venture. For example, if the firm announced a joint venture on January 1, 1998, we then checked whether the firm had any previous alliance relationships with the same partner (not necessarily joint ventures) within the period from January 1, 1997 to December 31, 1997. If we found any such relationships, the new joint venture would be taken as a repeated tie and the variable of exploration in partner selection would have a value of zero, since this actually indicated exploitation in partner selection. If not, the new joint venture would be taken as a new tie to the firm. Then we compared the present partner's primary industry with the previous partner's primary industries, also dated back one year from the announcement day. If we could not find any previous partner with the same industry as the present partner (New Partner & Different Industry in Figure 1), the variable of exploration in partner would have a value of one. Otherwise the variable would have a value of 0.5, as it implied high partner-specific learning while low context-specific learning (New Partner & Same Industry in Figure 1). To summarize, if the present partner was an existing partner, the choice involved low partner-specific learning and low context-specific learning, and the variable was given the low end value zero. If the present partner and its industry were both new to the firm, which indicated high partner-specific learning and high context-specific learning, the variable was given the high end value one. If it was a new partner from an existing industry, the variable was given the middle value 0.5.

Environmental dynamism and munificence We focused on the announcing firm's primary industry and adopted the operationalizations by Dess and Beard (1984) for measuring the two environmental variables. According to the authors, the indicator for dynamism should reflect the volatility or unpredictability of the firm's dominant industry environment, whereas the indicator for munificence needs to reflect growth in the same environment. While Dess and Beard (1984) used the data obtained from the U.S. Census Bureau, we used the data from Compustat and followed a similar approach used by Keats and Hitt (1988). Specifically, we first aggregated annual net sales across all firms in each relevant manufacturing industry at the three-digit SIC code level by using the Compustat data. Then we constructed a time-series regression equation in which the dependent variable was the natural logarithm of the aggregated net sales and the independent variable was time as measured by year. For example, if the joint venture was announced in 1998, we used the industry sales data from 1994 to 1998 and the time variable to build the following equation:

$$Y_T = b_0 + b_1 T + \varepsilon$$

where Y is the natural logarithm of industry sales, T is year (1994~1998), and ε is residual. There were five data points in the regression above and the regression was run for each three-digit SIC industry in the sample. The measure for dynamism was the antilog of the standard error of slope b_1, reflecting the volatility in the growth rate for a particular industry. The measure for munificence was the antilog of b_1, indicating the average growth rate over the period.

Control variables

Alliance experience Like previous research on alliance experience, the announcing firm's alliance experience was measured by counting the number of each firm's alliances starting from January 1, 1997 to the event day when the firm announced the new joint venture (excluding the new joint venture). The data on alliances was obtained from the SDC database. When we collected the alliance data we read through the summary description of each alliance and removed any duplicate records. We also referred to other data sources such as the LexisNexis Academic database to verify the announcement dates reported by the SDC database. In case there was a discrepancy about the date we resolved the inconsistencies by referring to other news and wire sources. The accurate announcement dates would ensure the measurement reliability in both abnormal returns and alliance experience.

Firm size Like many previous studies that used abnormal returns to capture the value of an alliance, we controlled for firm size measured by the natural logarithm of total assets of the firm.

Partner relatedness Past alliance research has suggested that similarity or complementarity in partners' resources affects alliance outcomes (Lavie, 2006; Sampson, 2007). Hence we controlled for the relatedness in partners' industries by using a dummy variable, which was set to the value of 1 if the two partners had the same four-digit SIC code and 0 otherwise.

Foreign partnership Since our sample included joint ventures with foreign firms, we created a dummy variable named foreign partnership which was equal to one if the joint venture was a cross-border alliance.

Industry and year effects We also controlled for industry effects by using industry dummies at the two-digit SIC code level. Year dummies were included to control for potential time effects.

Alliance type The type of alliances was also controlled for by using dummy variables representing licensing services, R&D services, marketing services, manufacturing services, and supply services. Table 1 provides the descriptive statistics and the correlation matrix for all the key variables.

DATA ANALYSIS AND RESULTS

Our dataset consists of 1061 events over seven years and across 367 firms. We used ordinary least squares (OLS) regression for the pooled data. As we mentioned earlier, our sample included firms that made multiple announcements over the seven-year time period. Including firms with multiple events (records) may violate the homoskedasticity assumption of OLS, resulting in biased estimates of standard errors. To correct for this bias we ran the analysis with Huber-White standard errors clustering on firms, which will produce a robust estimation of standard errors given the presence of arbitrary correlations in error terms within the cluster. This method, also called Rogers standard errors (Rogers, 1993), is robust to different specifications of the dependence in error terms within a cluster.

Table 3 reports the results of regression analysis using the firm's cumulative abnormal returns (CARs) as the dependent variable. Model I includes only the main explanatory variable, exploration in partner selection, together with the control variables. The coefficient on exploration in partner selection is negative and significant at the 5% level, suggesting that forming a joint venture with a new partner from a new industry lowers the CAR by almost 1%, compared to forming a joint venture with an existing partner. This result is consistent with H1, which states that exploration in partner selection is negatively related to the value of an alliance. However, we realize that there could be self-selection bias by which the firm self-selected itself with respect to the partner choice based on other firm attributes. Without controlling for self-selection, the estimated coefficient of the choice variable is likely to be biased. To correct for self-selection bias, we employed Heckman selection model. Heckman model estimates two regression equations. The first is a probit model that estimates the impact of firm heterogeneities on the choice variable. The second is a regular regression model that estimates the impact on the dependent variable of the explanatory variables plus an additional parameter λ that measures self-selection bias. λ is obtained from the first equation.

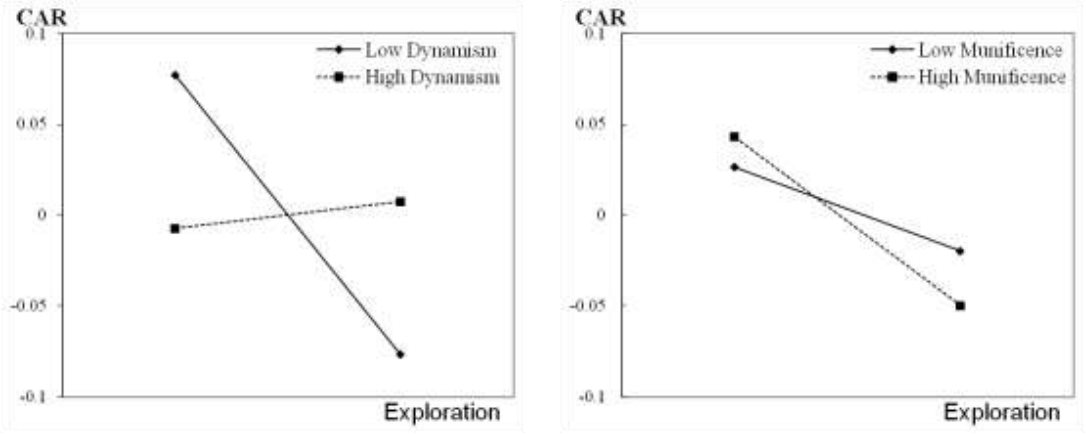
Model II includes λ as an additional variable and re-estimates the impact of exploration in partner selection on abnormal returns. We suspected that the choice variable might be affected by factors such as environmental conditions, the type of the alliance, and alliance experience.

As such we included these factors in the first equation of Heckman selection model. The results are not reported here but we found a positive effect of environmental dynamism on the choice variable and a negative effect of alliance experience on the choice variable. We report the results of the second equation in Table 3 under Model II. After controlling for self-selection bias, exploration still has a negative and significant effect on abnormal returns ($b = 0.943$, $p < 0.05$). The coefficient for self-selection bias is not significant.

Model III includes the major contingency variables into the regression model, namely, environmental dynamism and munificence and Model IV adds the two interaction terms between exploration and the two contingency variables, all centered before entering the regression. H2 states that exploration in partner will be positively related to abnormal returns in a dynamic industry environment. The exploration-dynamism interaction has a positive and significant coefficient ($b = 26.586$, $p < 0.05$), suggesting that at a high level of environmental dynamism, the negative relationship between exploration and abnormal returns can become positive. To illustrate this interaction effect, we plotted the relationship between exploration and CAR at low and high levels of environmental dynamism (Figure 2, left). At the low level of dynamism, the line has a negative slope, whereas at the high level of dynamism the slope turns positive, indicating a positive relationship between exploration and CAR. The result here supports H2. H3 proposes that at a high level of environmental munificence there will be a positive relationship between exploration in partner selection and abnormal returns. This prediction, however, is not supported by the result. The exploration-munificence interaction has a negative and significant coefficient ($b = -7.092$, $p < 0.05$), making the negative exploration-CAR relationship even stronger at a high level of environmental munificence. The interaction effect is depicted by drawing the line at different levels of munificence (Figure 2, right).

Figure 2: The Moderating Effects of Environmental Dynamism and Munificence



DISCUSSION

So far our empirical analysis has revealed some interesting findings, as well as some surprising results. We expected that exploration in partner selection would be positively related to abnormal returns, a proxy for the value of the alliance, in a munificent industry environment. Surprisingly, the empirical results revealed the opposite effect. The negative interaction effect of exploration-munificence can be interpreted in a different way, i.e. the positive relationship between exploitation in partner selection becomes stronger in a munificent environment. We suspect two possible reasons for this finding. First, firms may not choose exploration in a munificent environment. Exploration is usually driven by long-term objectives, often at the expense of short-term efficiency. In partner selection, exploration aims at accessing non-

redundant knowledge and seeking future growth opportunities through forming new ties. In a munificent environment, although firms can afford sacrificing short-term gains, they probably do not perceive the exploration option to be the optimal choice as competitive advantage can be well sustained. Exploitation, instead, is often initiated by short-term goals, such as capitalizing on excess production capacities or advantageous market conditions. Therefore, in a munificent environment, incremental improvement enabled by exploitation may be preferred by firms. The descriptive statistics provide some preliminary evidence that there is probably a negative relationship between exploration and munificence. Second, a munificent environment is often characterized by a high rate of growth. One implication of the high growth rate is that firms need to enhance their functional competencies, including those in procurement, manufacturing, marketing, sales, and logistics, to meet the market demand for their products. Under such circumstances, the strategic focus is the speed to market rather than the novelty or innovativeness provided by the product. To meet the need for speed, firms should formulate strategies that can produce certain and quick outcomes. Exploitation, as a result, may satisfy such needs and enhance the value of the alliance.

The alliance literature has called upon research on the important decision-making problem pertaining to partner selection. After reviewing the past research on partner selection, we found that antecedents to partner selection such as complementarity, similarity, or relational capital all can be linked to the learning activities involved in an alliance. This observation motivated us to adopt the perspective of organizational learning and use March's exploration-exploitation dichotomy to conceptualize the alliance partner selection decision. We defined exploration and exploitation based on the choice of the partner, with a significant difference existing in the level of learning in each of the choices. It should be noted that in our conceptualization, exploration and exploitation are mutually exclusive. We also found that the literature is short of studies on the relationship between partner selection and value creation in alliances. To address this research gap, we built a model linking exploration and exploitation in partner selection to the value of the alliance. We found that the choice of the partner has a direct impact on the value of the alliance, as measured by excess returns during the announcement period of the alliance. This finding should complete the existing alliance literature on partner selection. For example, using a similar argument, Yamakawa et al (2011) found that a higher ratio of exploration alliances in a firm's alliance portfolio were negatively associated with firm performance measured by return on assets (ROA). Our findings seem to suggest that the stock market reacts in a similar manner to such alliances.

While a choice of the alliance partner may be under managerial discretion, such a choice may also be affected by the environment, or at least the outcome of the choice would be affected by varied environmental conditions. We considered two environmental variables and found that the one that reflects the change and innovation has a positive moderating effect on the exploration in partner selection. In a dynamic industry environment, the negative relationship between exploration and value creation becomes positive, as the firm needs to continuously innovate to cope with uncertainty imposed by the environment. In other words, exploration in partner selection is more likely to add value to the firm in a dynamic environment than in a stable environment. In terms of the negative moderating effect of munificence, a recent study by (Jensen, Simsek, & Cao, 2012) suggested that resource munificence could mitigate resource constraints associated with ambidextrous activities, defined as pursuing both exploratory and exploitative activities simultaneously, and enhance the positive effect of such activities on unit performance. As a result, merely seeking exploration in partner selection under munificent environments may not yield the best anticipated value from such an alliance, thus deepening the negative effect of such a choice.

Managerial Implications

Our empirical findings should have important implications for managers, especially for those who make the decision as to "with whom we should ally". The negative relationship between exploration in partner selection and abnormal returns highlights the need to communicate critical information to outside shareholders and other investors. Exploration is often a decision made by managers, who as insiders may have some proprietary information about the importance of the partner choice, which might not be well conveyed to the stock market. The finding that exploration generally decreases shareholder value reflects not only the investors' concern as to forming a relationship with a partner unknown to them, but also to some extent the management's inability to release some critical transactional information into the market, such as the strategic benefits and importance of choosing a new partner. If the management can do a better job in reducing information asymmetry between shareholders and them, the market reaction to exploration selection might change in a way that is favorable to them.

The effects of the contingent factors are also important for decision makers in the firm. Managers need to be aware that dynamic environments require a proactive and forward-looking strategy, such as choosing a partner that can bring in new knowledge and capabilities. Exploration in partner selection therefore is a more viable strategy in a dynamic environment than in a stable environment. Also in a dynamic environment, exploration can create greater value than exploitation. Exploitation aims at short-term efficiencies and incremental improvement, which tend to be short-lived when the environmental conditions change rapidly. As such managers probably should avoid forming too many repeated ties with existing partners in such environments as they provide little value to the firm. Actually one study has shown that in the presence of technological instability, the effect of repeated ties is negative on economic performance at the corporate level (Goerzen, 2007). This suggestion demands managers' attention as they usually have positive attitude to partners with whom they have had relationships (Zollo, Reuer, & Singh, 2002). As managers choose to ally with new partners, they also need to work hard to take advantage of the ties to cope with environmental uncertainty. Extra coordination and collaboration efforts are probably required in such partnerships.

LIMITATIONS AND FUTURE RESEARCH

The first limitation pertains to the sample we used. We chose joint ventures that were formed by US manufacturing firms. This limitation may restrict the generalizability of our results to other industry sectors or other types of alliances. But as we mentioned earlier, restricting the sample to certain industries and a specific form of alliance should help minimize cross-industry and cross-type differences in the intention, governance, and evaluation of alliances, hence increasing internal validity of our model. Secondly, we used the partner's primary industry to approximate the technological background of the partner when constructing the measure for exploration in partner selection. This could overestimate the similarity between the partner and the previous partners. To address this issue, future researchers should consider some continuous measure such as a "technological distance" measure that captures the difference between the present partner and previous partners. The patent portfolio of the firm can be used to calculate this distance measure. Thirdly, there is a legitimate concern that our sample could be overrepresented by alliances with an exploration focus, as it has been found that recurrent alliance relationships are less likely to be equity-based (Gulati, 1995). Although it is not very clear how this limitation would affect our results, we conducted a preliminary t test of the exploration variable between a group of joint ventures and a group of non-JV type alliances. The results (not reported) showed that there was no significant difference in the mean across the two groups.

DECISION SCIENCES INSTITUTE
Allocation Decision: A Teaching Case for Accounting Classes

Sheldon R. Smith
Utah Valley University
Email: smithsh@uvu.edu

ABSTRACT

This paper presents a teaching case for use in several possible accounting classes. The case deals with the allocation of investment income among different segments of a nonprofit entity. Students are given the opportunity to determine if a proposed allocation is appropriate or to suggest a different allocation. In either case, students are expected to justify their response. This case allows students to do some allocation calculations and to think critically to evaluate the proposed or alternative allocations.

KEYWORDS: Allocation Decision, Revenue Allocation, Accounting Allocation, Allocation Base, Teaching Case

INTRODUCTION

In many accounting contexts, allocations are made (Zimmerman, 1995). Some of the common allocations include the following: (1) allocation of service department costs to the departments using those services (Anthony and Young, 1994; Garrison, et. al., 2015), (2) allocation of the cost of an asset over its useful life through depreciation, amortization, or depletion (Spiceland, et. al., 2018), (3) allocation of overhead costs to different activities or products in a production setting (Garrison, et. al., 2015), (4) allocation of joint costs to the multiple products produced from a common process (Garrison, et. al, 2015), (5) intraperiod tax allocation (Spiceland, et. al., 2018), and (6) allocation of revenues or expenses among different segments of an organization.

This teaching case focuses on the last of these items—the allocation of investment income among the various segments of a nonprofit association. It is loosely based on a real-life situation, but the names and numbers are disguised as they are presented in the case. It could be used in any of several classes, depending on the objective(s) to be met by the instructor. It could be used in an auditing class to discuss how an auditor should work with a client that has made allocations in the process of preparing the financial statements. It could be used in a governmental/nonprofit accounting class, as it relates to a nonprofit organization that will report net assets rather than stockholders' equity. It could be used in a managerial accounting class when different allocation methods are discussed. It could also be used in a financial accounting class as a discussion of how investment revenue should be allocated among the sub-entities of an organization.

Students will be given a suggested allocation of investment income from pooled investment funds across the segments of the organization. The students are then asked to either justify the allocation method used or to suggest a different allocation method. If a different allocation method is chosen, it should be justified with appropriate reasoning. This case allows students to not only work with specific allocation concepts and calculations, but it also allows the students to think critically about why an allocation method is appropriate or not.

CASE MATERIAL

The Humanities Professors Association (HPA) is a nonprofit academic organization of college and university humanities professors organized to provide a forum for the exchange of ideas related to teaching and research. It started many years ago as a small group of professors from a few institutions that were geographically close to each other. However, it has grown over time. It has become a national organization, consisting of humanities professors from around the United States. It even includes some members from other countries.

The HPA is led by a Board of Directors elected by the membership of the HPA. Board members are faculty members from various institutions who serve in rotating officer positions, finally serving as the HPA president for one year and then as the past president for one year before their board membership is concluded. These officer positions are non-paid positions, and the officers get financial support from their colleges or universities for the travel and meeting attendance costs involved in their service.

To provide continuity and administrative support for these volunteer officers, a home office has been established at Eastern State University (ESU). Four employees at the home office provide ongoing marketing, administrative, technology, and bookkeeping support for the organization. One of these employees is hired as the Executive Director who is a non-voting member of the Board of Directors. The employees are treated as employees of ESU, but the HPA reimburses ESU for the compensation and benefits paid to these individuals. Because the HPA objectives are consistent with the ESU mission, ESU provides facilities and equipment to support HPA operations. The HPA pays a set annual amount to ESU as a partial reimbursement for this support. As needed, the home office contracts with lawyers and CPAs for legal and accounting expertise.

From its inception, HPA has held an annual meeting where humanities professors can come and share their teaching ideas and their research. This meeting provides a networking opportunity for college and university professors to improve the humanities curriculum and teaching methods. It also provides an outlet for professors to share and get feedback on their research. In fact, over time, HPA began publishing an academic journal six times per year as an outlet for excellent research in this academic area.

The success of the annual meetings coupled with the inability of some faculty to get funding to attend when the meetings are far away and more expensive led to the creation of regional affiliates to the national organization. These regional affiliates are part of the national organization, but they hold regional conferences annually within the geographic area of the region. To date, three regions have been created and have actively sponsored annual regional meetings: Eastern Region (EHPA), Midwest Region (MHPA) and Western Region (WHPA). These regions each have a Board of Directors, faculty elected by members and who volunteer their time to help organize the regional annual meetings. Because these regional officers are not simultaneously members of the HPA Board of Directors, they do not make decisions for the national organization, but they do make decisions for the region in which they serve.

Each region has significant autonomy in choosing the venue for its regional meeting, determining an appropriate conference registration fee, and budgeting to ensure that the meeting revenues will cover the meeting costs. The regional officers contract with a hotel in the desired location to host the meeting and provide the food and beverage for functions that are included in the meeting registration fee. This usually requires the regions to commit to a certain number of room nights that meeting attendees will utilize during the meeting. It also requires

the region to commit to a certain minimum food and beverage cost that will generate additional revenue for the hotel property. By guaranteeing a specific number of room nights along with a food and beverage minimum, regions generally get a concession from the hotels that there will be no rental charges for the meeting rooms, as the hotel is already guaranteed to earn adequate revenue from the meeting through the occupied room nights and the food and beverage guarantee.

From time to time, a region may find that a specific meeting was not as successful as anticipated and meeting attendees do not fill the contracted hotel room block. This can result in a financial penalty to the region. In addition, once the contract has been signed with the hotel, if meeting attendance is lower than expected, resulting in less than the budgeted revenue, the food and beverage minimum must still be met. Therefore, regions can have losses in some years. To plan for the risk of losses, regions often set the meeting registration fee above the amount that would provide an expected breakeven for the meeting. Thus, the regions typically have a positive amount of net assets on their balance sheets, as they cannot expect the national organization to step in and subsidize them. Over time, each region, as well as the national organization, has increased its net asset balance, providing a safety net for the risk of an unsuccessful meeting and to provide funds for ongoing disbursements.

Over a period of years, HPA officers have improved in budgeting for meetings and contracting with hotels. As net assets grew, the home office began investing some of the cash in investment accounts with a major national investment company to earn a return on these assets. Other funds had been kept in non-interest bearing checking accounts. Regions have also pooled some of their net assets into these investment funds, with the understanding that a larger investment pool would result in a lower expense ratio and provide for better investment opportunities. With input from the regions, the HPA Board has decided to invest approximately 60% of the invested balance in equities and the remaining 40% in bonds. Since the investment funds have typically been growing, this was determined to be an appropriate diversification to provide an appropriate return without excessive risk. The national and regional boards each determine how much to invest in the pooled funds and how much they want to keep in non-interest bearing checking accounts. Purposes for amounts in the checking accounts would be to provide for ongoing transactions, to provide a safety net of easily accessible funds, and to avoid investment risk in the pooled investment funds. For at least the last two years, no withdrawals have been made from the investment funds, and no deposits have been made except the reinvested interest and dividends earned on the existing fund balance. Per Generally Accepted Accounting Principles (GAAP), the investment fund balance is listed at fair value at each reporting date, so unrealized gains are also reflected in the fund balance.

Meeting registration fees are collected by the home office, even for the regional meetings. All expense disbursements are made by the home office, with the regional expenses first being approved by regional officers. The annual financial statements are prepared by the home office. The statements are prepared with separate columns for the national organization and each of the regions. The home office contracts with a CPA firm for the annual audit of the financial statements.

The most recent financial statements have been prepared and were recently sent out to the regional officers. Exhibit 1 shows the Statements of Financial Position for 20X5 and 20X4. Exhibit 2 shows an abbreviated Statement of Activities for 20X5. Because the HPA is a service organization mainly providing an annual meeting for attendees, general teaching and research support for academics, and a journal, the types of assets and liabilities are very limited. Office supplies are immaterial, and space and office equipment are provided by ESU. Operating

revenues for the home office include mostly membership dues and meeting registration fees. Expenses are those related to meeting costs, journal publication, general support of members, and office employee costs. Since the regions have no employees, their operating revenues and expenses relate only to meeting registration fees and meeting costs.

Amy Jackson is the newly elected treasurer of the EHPA. She looked through the statements to make sure they reflected the appropriate revenues for the regional meeting and the approved expenses for the region. She wondered about the allocation of the investment income among the different segments of the organization. After inquiring further, she was able to obtain the spreadsheet which was used to allocate the investment income. This spreadsheet is provided in Exhibit 3; Exhibit 4 shows the formulas used in this spreadsheet. Since Amy is a humanities professor, she does not have much business or accounting background. However, she is very intelligent, and she is a clear thinker. She would like your input into the allocation method used to divide the investment income.

CASE REQUIREMENTS FOR STUDENTS

Look at the allocation of investment income among the different segments of the HPA. Analyze how the allocation was made and determine whether you feel the allocation is appropriate or not. If you feel it is appropriate, provide reasons to justify why you feel this way. If you feel there is a better way to allocate this income, provide calculations showing your preferred method and provide reasons to justify your preference. Present your justifications in a way that you think will make sense to Amy Jackson.

TEACHERS' NOTE

This case is not very long. The students could be given the case in advance and asked to read it. Either on their own or in groups, they could consider the appropriateness of the proposed allocation of investment income or present an alternative. The case discussion in class should easily fit within one class period. It is important to allow the students to think critically about the allocation process and make their arguments supporting either the proposed allocation method or their alternative. The allocation of expenses or revenues can have different objectives, so it will be informative to allow students to express their thoughts before leading them in a specific direction.

Hopefully, students will bring up the allocation base used in the proposed allocation—the average net assets of each segment—and determine that this might not be the best allocation for this situation. Since each segment can choose how much to put at risk compared to how much it holds in non-interest bearing checking accounts, it would seem to make more sense in this case to allocate the investment income over the average investment account balance for each segment. Since no additional investments or withdrawals were made during the year, an easy allocation could simply divide up the investment increase proportionately over the beginning investment account balances for each segment. Using this simple allocation, the investment income would be allocated as follows:

Home Office	($1,100,000/$1,415,000) x $123,000 = $95,618
Eastern Region	($215,000/$1,415,000) x $123,000 = $18,689
Midwest Region	($60,000/$1,415,000) x $123,000 = $5,216
Western Region	($40,000/$1,415,000) x $123,000 = $3,477

If a comparison is made between these two different allocation methods, it becomes obvious that the proposed allocation gives the Home Office and WHPA more and EHPA and MHPA less than the allocation based on investment account amounts.

	Proposed Allocation	Improved Allocation	Difference	Difference as Percent of Proposed Allocation
Home Office	$100,608	$ 95,618	$4,990	5.0%
Eastern Region	$ 13,899	$ 18,689	($4,790)	(34.5%)
Midwest Region	$ 4,926	$ 5,216	($ 290)	(5.9%)
Western Region	$ 3,567	$ 3,477	$ 90	2.5%
Total	$123,000	$123,000	$ 0	

This is because the Home Office and WHPA have a much higher percentage of their net assets in non-interest bearing checking accounts compared to EHPA and MHPA, which have a much higher percentage of their net assets in the pooled investment funds. If the percent difference is also examined, it becomes obvious why Amy Jackson may have initially been wondering about

the allocation proposed. While the differences may not seem material, percentage-wise, for the home office and the other regions, the percentage difference for EHPA is quite large.

An analogy to this situation could be raised. What if an employer has a defined contribution pension plan and contributes a specific amount each month for each employee. The employees can choose how the contributions for them will be invested among the different fund options—more in risky funds or more in less risky funds—depending on their risk tolerance. However, at the end of each period, the investment company takes the total returns and divides them equally across all funds regardless of individual fund risk or return. How would you feel if you were willing to bear more risk but got the same rate of return as those who were unwilling to bear risk? How would you feel if you chose less risky funds but ended up with an investment loss because the riskier funds you avoided lost value?

In fact, in the proposed allocation, think about what could happen if there are losses in the investment account. If the board members of one region anticipated the losses and withdrew that region's money from the investment funds and put it into their checking account to avoid the market risk, that region could still be allocated a loss if the loss is allocated across average net assets rather than on the average amount invested. Although that region wanted to avoid risk, it was unable to do so, because the allocation method was not consistent with the risk choices made by that region. In a risk-return tradeoff situation, the returns should be allocated where the risk lies, not in some other fashion.

The proposed allocation may also produce counterintuitive results or gamesmanship that may actually be detrimental to the organization. If segment leaders become aware of this allocation based on average net assets, they may intentionally keep more funds in the non-interest bearing checking accounts, thinking they will share in the investment gains anyway. However, as more and more funds are shifted to checking accounts, the investment account balance will become smaller, reducing possible investment income available to allocate.

In the case given, no investments or withdrawals were made to or from the investment funds. If investments or withdrawals occurred during the year, it would be better to use some average investment balance, either a simple average or a weighted average, depending on the amounts and timing of the deposits and withdrawals (and perhaps on the timing of the investment account increases, both realized and unrealized).

It may also be interesting to discuss why the auditors would have approved the allocation in the proposed method. Are there any reasons why or situations in which the proposed allocation might be appropriate?

FUTURE RESEARCH

This case is in its formative stages and has not yet been tested in a classroom situation. Future research will provide feedback from students after they worked with this specific case. Student perceptions of the case will be used to improve it over time.

CONCLUSION

Although it will likely be obvious to the students that the numbers in this case are disguised, they may find the case more interesting knowing that it is based on a real-life situation for a nonprofit entity. This case gives students an opportunity to evaluate a proposed method for allocating investment income among segments of a nonprofit entity. They can think about an

appropriate allocation base and use critical thinking skills to provide justification for either the proposed allocation method or an alternative method.

ABSTRACT

In this study, we use Latent Dirichlet Allocation to explore the reflections of students who faced a demanding classroom challenge, to which some responded by colluding. Our five-topic LDA solution describes the cheating event in terms of the nature of the course assignment itself, teams as a resource and support mechanism, the repercussions of cheating, and differences between majors or course tracks. The most relevant topics were the differences between the tracks and the repercussions of cheating. Teams and teammates also play a large role in the students' reflections. We conclude with the implications of these topics in future research.

KEYWORDS: Cheating, Collusion, Latent, Dirichlet, Allocation

INTRODUCTION

In late 2017, The *Washington Post* reported that over 80 marketing students were accused of cheating at a major Midwestern university (Bever, 2017). The accused students used a group-messaging application to share answers pertaining to classroom assignments. Unfortunately, cheating is not a rare occurrence. Business educators view cheating by college students as constituting a long-standing problem that is serious and widespread at both the graduate and undergraduate level (e.g., Cronan, Mullins & Douglas, 2018; McCabe & Trevino, 1996; Simha & Cullen, 2012; Simkin & McLeod, 2010; Wright, 2004; Klein, Levenburg, McKendall & Mothersell, 2007; McCabe, Butterfield & Trevino, 2006). Evidence suggests that the problem is worldwide (Ismail & Yussof, 2016). Cheating in business schools appears to occur no more or less than in other academic disciplines, however, business student attitudes toward what constitutes cheating has been found to be relatively more lax (Klein, Levenburg, McKendall, & Mothersell, 2007).

Cheating is most often defined as either purposefully obtaining access to another person's work without authorization, or as unpermitted collaboration on exams or collusion on assignments (Burrus, McGoldrick & Schuhmann, 2007; McCabe & Trevino, 1996; Sierra & Hyman, 2008) with intent to gain advantage over others (Cronan et al, 2018). Business school administrators and faculties have developed a heightened interest in cheating by students and in business in general (McCabe & Trevino, 2002; Lawson, 2004; Ballantine, Guo, & Larres, 2016). However, efforts to come to grips with classroom cheating have been inconclusive in part because of a lack of contextual studies and studies examining actual cheating behavior.

In an attempt to better understand the phenomenon of cheating, we examine a situation that captures students' guided reflections on an occurrence of classroom collusion in two

sections of an accounting course. Here, we define collusion as secretly sharing information without permission in order to obtain an advantage in the classroom. Ariely (2012) calls this collaborative cheating- where cheating takes place in context of a team. We use Latent Dirichlet Allocation to examine interviews of business students directly involved in a classroom situation where actual student collusion occurred on a relatively large scale. By studying this naturally occurring situation (i.e., where actual collusion has taken place) our results enrich a research stream based predominantly on self-reports of cheating behavior.

LITERATURE REVIEW

The context and morality of cheating and collusion

Most previous research studies have dealt with either the context for cheating or the morality of cheating. For example, McCabe and Trevino (1996: pg. 30) state, "the climate or culture of academic integrity found on campus may be the most important determinant of the level of student cheating on that campus." These authors found that both peer pressure and technology increased the variety of classroom cheating (McCabe & Trevino, 1996). Subsequent papers by McCabe, Trevino, and their colleagues support this conclusion. McCabe and Trevino (1997) also found that peer influence is among the strongest demographic and contextual factors affecting the level of cheating among students. Moreover, at the graduate level, McCabe, Butterfield, and Trevino, (2006) found that perceptions of unethical peer behavior were a justification students often gave for cheating.

Other researchers have also examined the context of student cheating. For example, Kaufmann, West, Ravenscroft, and Shrader (2005) found that students demonstrated immature ethical reasoning and rationalization when they believed peer behavior and the classroom environment encouraged cheating. In responding to open-ended questions about a cheating incident, students revealed both concern with following their perceived norms governing classroom expectations and an ability subsequently to rationalize their behavior. "When everybody cheats, it's okay to join the bandwagon." Another student said, "Coursework is based on the idea of working in teams efficiently and effectively. WE [sic] are so used to this that what others consider 'cheating' to us is 'teamwork'." At the same time, students were not amoral and tried to rationalize their behavior by distinguishing what they had done from what they considered to be more serious, actual cheating behavior. Both the line of reasoning articulated in the studies above and the quotes from Kaufmann et al (2005) suggest that when students perceive an ethical climate in the classroom that is dissonant from their pre-existing moral beliefs or other training, they may behave in ways that are not consonant with these pre-existing beliefs about what is ethically right and wrong.

Another line of research deals with individual understanding of morality and cheating. In the accounting ethics education literature linking moral judgments to actual behavior, Ponemon (1993) describes an extensive effort to teach accounting ethics over a year-long period. Ponemon found that the ethics intervention, as extensive as it was, had little effect on moral reasoning. More interestingly, however, he found free-riding (i.e. not paying the complete cost for study materials) was highest when the moral reasoning scores on the Defining Issues Test were the lowest. Woodbine and Aamirthalingam (2013) also found that Master's of accounting students exhibit very opportunistic behavior and relatively lax attitudes toward cheating when given the opportunity to cheat and advance test scores.

The influence of peer pressure and the moral intensity (Jones, 1991) of the situation may entice students into behaving in ways that others see as unethical (Peterson, 2002; Sierra & Hyman, 2008). As an example, Premeaux (2005) found differences between students at expensive schools with high entrance requirements (tier 1) compared to tier 2 schools. Students at tier 1 schools experience relatively more cheating on written assignments and

attached more significant social stigmas to cheating, while tier 2 students, attending local institutions, reported more cheating on exams were more accepting of the notion that even moral people cheat. Similarly, an organizational culture that tolerates widespread sharing of work may precipitate academically dishonest actions. Citing an example where cheating was observed firsthand, Flynn (2003) states that 'displaying concern for one's classmates and seeking to encourage them during an examination… was only natural for someone reared in a culture that emphasized the well-being of the group (pg. 438).' Consequently, organizational cultures may foster divergent attitudes toward cheating, and these different attitudes may create difficulties for course instructors. Such results highlight the importance of student perceptions of classroom context or climate. Therefore, both context and morality affect cheating. Morality effects are nuanced and related to instrumentality. Context effects appear to be somewhat more direct, that is, students respond to the situation at hand.

The point is that students do not always understand the line of demarcation between cheating and formally assigned group work (Ariely, 2012; Shrader et al, 2012). The widespread use of teams and group assignments may be adding to the level of general confusion about what kinds of sharing are permitted and what constitutes cheating (Kaufmann et al, 2005). For example, a student quoted in the Washington Post article mentioned above (Bever, 2017) said, "I think it [cheating] is not right, but collaboration is required for a lot of classes… so as long as you don't cross this boundary, I think it is good to use it." This statement is fascinating in that it recognizes both context and morality. Some might say it convolutes context and morality. In either case, it indicates that student perceptions of morality and context are important in understanding the phenomena of cheating and collusion (Briggs, Workman, & York, 2013).

Most previous research has examined cheating from an institutional level or has employed survey research to tap into student perceptions. Few have looked at actual situations where students were deeply involved with a particular cheating episode. The purpose of this paper is to present a unique form of analysis of a classroom event where collusion actually took place. In two sections of an advanced accounting course, students were given the assignment of preparing for two sides of a classroom debate. However, some students colluded in an attempt to reduce the amount of work and uncertainty associated with the assignment. We interview the actual students involved with the goal of trying to understand how they viewed the classroom where they either took part in or watched collusion take place. Our purpose here is to seek understanding of this decision to collude by examining what students had to say about the actual situation. Our goal, through the application of latent Dirichlet analysis (LDA), is to identify the underlying structure of words and topics students used to describe their experience. LDA offers the means to explore and provide unbiased insights into the way students actually talk about collusion.

THEORETICAL DEVELOPMENT/MODEL

Study Method

Academic collusion and cheating present researchers with a rather delicate set of research ethics challenges. It would not be ethical for researchers to entrap students into collusion. Moreover, researchers should be extremely cautious about even creating situations where students might be encouraged to collude. Yet few studies examine the background motivations and thought processes of students that collude. The infrequency of actual studies dealing with context belies the fact that collusion seems to occur regularly.

Researchers have relied on a variety of data ranging from student self-reports of cheating behavior (McCabe & Trevino, 1993) to hard evidence such as discarded cheat sheets (Pullen, Ortloff, Casey & Payne, 2000) in order to better understand student cheating. The focal point of these studies varies from the thought process of students who cheated in a particular

setting (e.g., Briggss et al, 2013; Kaufmann et al, 2005; West, Ravenscroft, & Shrader 2004; Shrader, Ravenscroft, Kaufmann, & West, 2012), to comparisons between spontaneous and intended cheating (Genereux & McLeod, 1995), to the role of new cheating technologies (D'Souza & Siegfelt, 2017; McCabe & Trevino, 1996).

Notwithstanding the focus or data source, previous studies have come to the general conclusion that cheating behavior is common (Lawson, 2004). More disturbing for those of us who teach in business schools, however, are the comparative studies that have found business students to be among the most prominent among the cheaters (McCabe & Trevino, 1993). For example, in a two-university study involving four hundred students across disciplines, Roig and Ballew (1994) found that students majoring in accounting and finance held the most lenient attitudes toward cheating among all students in their sample. Compounding this is the finding by Bloodgood, Turnley and Mudrack (2010) that merely taking a business ethics course does not seem to have a much influence on students' views regarding cheating.

Self-reported surveys of attitudes toward cheating, of intentions to cheat, of past cheating, and of reasons for cheating represent the dominant form of data on cheating (Spiller & Crown, 1995; Cizek, 1999, Cronan et al, 2018). While surveys are convenient and useful, and establish the seriousness of the collusion question, they do raise some doubts. There may be a wide gap between how students respond to a survey and how they may actually reflect and respond to questions about their own behavior (Scheers & Dayton, 1987; Karlins et al, 1988; Miceli et al, 1991; Nowell & Laufer, 1997). Consequently, actual behavior provides more validity than self-reports, but presents researchers with ethical challenges because of faculty members' obligation not to encourage collusion.

In this paper, we employ an objective and powerful form of analysis to explore a classroom event where collusion actually took place. We interview the actual students involved in order to tap into their firsthand observations of the classroom dynamics. The sample group is rather small but it represents a major portion of the universe of students involved in the situation. Our intent and method are exploratory. We are not trying to predict collusion. We already know it happened and are now using a powerful form of text analysis to delve into the verbal reasoning of the students about the context. Both colluders and non-colluders were interviewed.

Latent Dirichlet Allocation, Topic Modeling and Words

Current advances in machine learning have led to methods that can be used to uncover hidden or latent relationships present in large data sets. The main difference between these methods and traditional statistical methods is that they make no *a priori* assumptions about relationships present in the data. Latent Dirichlet Allocation (LDA), the topic modeling method used in this paper, is an unstructured machine-learning algorithm that uses probabilistic topic modeling to estimate the likelihood that words are grouped in similar topic areas (Zupic & Cater, 2015). LDA is an analytic technique where observations in a large set of data are explained by similarities in otherwise unclassified groups (Blei, Ng, & Jordan (2003). LDA extracts patterns from a large set of data without a priori assumptions so it is not designed to answer specific pre-formulated hypothese (Schwab & Zhang, 2018). Instead, it is an exploratory technique, one that provides fundamental word-level observations on basic language structure found in a large volume of text. In this way, LDA opens up large data sets to unrestrained discovery. It is a method of discovery that Moro, Cortez and Rita (2015) claim is useful for conducting progressive and relevant research in any disciplinary field. Implementations of LDA and its variants are available from data analytics firms, academic software repositories, or from open source software such as Github.

As an unstructured machine-learning algorithm, LDA makes no assumptions in terms of how information sorts into silos. A researcher inputs textual data to the algorithm, which

produces words and topics from the data. The richness of LDA is that it recognizes that there can be many probabilistic topics and that words are independently distributed among topics (Sugimoto et al, 2011). In our exploratory study, student interviews are the corpus (data set) from which we specify words based on probability distributions called topics.

The basic unit of modeling is the topic. Topics are combinations of words. A topic is a distribution of words over the entire set of words in a corpus (Sievert & Shirley, 2014). Most LDA applications focus on textual data because LDA is able to analyze the underlying structure of large amounts of text (Sugimoto et al, 2011). It is the most widely used topic modeling method because it allows researchers to extract a parsimonious set of an optimum number of latent dimensions or topics in collections of data (Sugimoto, Li, Russell, Finlay, & Ding, 2011; Tirunillai & Tellis, 2014). Dyer, Lang, and Stice-Lawrence (2017) use LDA to ascertain exactly "what is being said" in corporate reports. We use LDA in this study to look for the most referred words in a set of student interviews. In LDA, a 'word' is the basic unit of discrete data (Blei et al, 2003). A 'document' or interview is a sequence of words, and a 'corpus' is a collection of interviews. Specifically, we employed LDAvis (Sievert & Shirley, 2014), an LDA-based data visualization method, to analyze our data. LDAvis allows us to examine how different words contribute to the meaning of each topic, how different topics relate to each other, and the prevalence of each topic. Our corpus is the entire set of comments transcribed from the interviews with the students involved in the colluding and non-colluding class sections. The corpus includes the text from twenty-six student interviews.

In effect, LDA helps discover underlying themes in a set of data by generating key words. Words are allocated to topics in the analysis. As domain experts, the researchers in effect, interpret the topic results. In our study, the domain experts are both the authors and the LDA administrators. Therefore, a topic is a cluster of words specified by the domain experts. Unimportant words (e.g. a, and, are, is, the etc.) are often ignored or reduced in the analysis. Rather, the important key words, words that are idiosyncratic and exclusive to a topic, are identified and emphasized.

LDA does not create new words or concepts as with factor analysis or content analysis; rather topics in a set of data are represented by existing key words (Moro et al, 2015). In a well-formed topic model, certain topics will generate words from one conceptual area more than from another - for example, "repercussion-related" and "team-related" topics, where the former is more likely to generate words like "caught", "colluded", "decision", "fail' and "trust", and the latter words like "sharing" and "teammates." Therefore, if an interview contains primarily important words, the model will classify them by topic. For each interview, LDAvis determines the probability of the set of words in each interview belonging to a topic, and then it matches the words with topics. The LDAvis relevance metric sets the weight given to the probability of a word belonging to a topic (Sievert & Shirley, 2014). An interview may represent different topics. Topics are based on probabilities assigned by the LDA software.

In LDA, the administrator determines the number of topics. The appropriate number of topics is determined in many ways (Chen & Wang, 2018). Too many topics dilutes the meaning of each topic and too few is not discrete and does not separate ideas and words from each other. The appropriate number of topics for our dataset was determined by comparing the intra-topic similarity with inter-topic dissimilarity. We ran five, ten, and fifteen topic solutions. and chose a result that maximized the difference between topics (Chen & Wang, 2018). We determined the optimum number of topics to be five and the most illustrative relevance metric to be .6 (as recommended by Sievert & Shirley, 2014). Our LDA produced for each of the five topics a list of the most relevant words. Relevance of the word w to topic k given λ is defined as:

$$r(w,k/\lambda)=\lambda \log(\varphi_{kw}) + 1-\lambda \log(\varphi_{kw} / p_w) \quad (1)$$

where φ_{kw} is the probability that word w belongs to topic k and p_w is the marginal probability of word w being in the corpus. Lambda can be set to values between 0 to 1. A lambda of 0 would

equate relevance to exclusivity – where the top words would be the ones whose probability of being in the whole corpus and of being in the topic are the same or very close. A lambda of 1 equates relevance to the probability of being in that topic, which is the frequency of the words divided by all the total number of words in the topic. As recommended by Sievert and Shirley (2014) who developed the relevance measure, we use a lambda of 0.6 as noted above.

Based on each topic's most relevant words, we decided on topic names. We labelled topics by determining the mix between the probability and relevance of words belonging to topics (Sievert & Shirley, 2014). Our topic results and labels are based on output directly from the analysis, and represent the underlying themes students use to describe their personal experiences with collusion. Therefore, LDA emphasizes topics and words. Words structure the topics. We focus on words in particular because words represent the most subtle and yet critically important way to delve into the understanding and assumptions that made their way into student thought and action. Words provide a glimpse into the mind and will of the students as they describe the collusion incident.

Prior to performing this analysis, we had information that separated colluders from non-colluders. In the interviews, we expected that there would be clear differences in the question responses between colluders and non-colluders. However, our objective in using LDA was to engage in a more granular examination of the language or topic differences, if any, between the two groups. Therefore, we ran the analysis of the entire set of interviews as one corpus. We considered the colluders and non-colluders responses together in order to objectively examine the language. LDA is bias free in terms of caring what a colluder or non-colluder says. It simply accumulates words into clusters or topics and provides for a visualization of the differences. As part of this analysis, we attempt to examine the topic differences among individuals. We trace individuals to topics in an attempt to understand how colluders and non-colluders might be different.

Zupic and Cater (2015) state that LDA holds tremendous potential for "expanding the scope of mapping the management and organization domain (pg. 457)." In order to make wide application of LDA available in organization research, Zupic and Cater indicate that ethics scholars can either wait for new software to be developed or collaborate with information scientists. In our case, we interacted with technical experts from a data analytics firm- Kingland Systems. Kingland, headquartered in Clear Lake, Iowa, provides information technology and financial services to manage compliance and risk for firms. Company clients include some of the world's largest banks, financial services firms, and insurance companies. We worked directly with Kingland analysts, providing them the raw data, or corpus, and then collaborated with them to interpret LDA results.

Data for this study are derived from the complete set of interviews for all student participating in the interviews. We base our LDA on the analysis of the entire interview text, including the initial greeting, general conventions of opening a dialog, and the entire set of responses to the questions posed in Appendix A. This method is analogous to the corporate implementations of LDA used by our partner, Kingland Systems. For example, Kingland provides their clients full-text analysis of formal corporate reports and compliance documents. The authors of this paper interviewed the students and generated the transcripts. Kingland analyzed the transcripts and produced the LDAvis results. The Kingland experts directly helped the authors ascertain the number of LDA topics to best analyze the corpus and they offered advice on the relevance metric to best identify topic words. We use all the text of the interviews in our analysis, thus providing a complete unbiased corpus for analysis.

Sample- The Collusion Incident

A strength of this study is the sample. It is in effect, a naturally occurring filed experiment. We did not manipulate a cheating or collusion intervention. It would unethical to do so. The

collusion occurred naturally. Therefore, the strength or external validity of the experimental effect is greater than would normally be expected with a lab experiment or from a survey. We were able to obtain access to the students involved through the course instructor.

The incident we discuss and analyze occurred in a graduate-level course on accounting professionalism and leadership, taught at a large, public university in the Midwest. Most of the graduate students in the section were accounting/tax majors. A major, multi-part assignment of the course was a debate tournament. The faculty member involved professionals from the nearby metropolitan area to observe the debates and to offer their evaluation of the students' performance. While their presence added a connection to the "real world", the professionals added to the anxiety students felt about doing well on this assignment. The degree program the students were enrolled in is known to be intense and this course was considered very time-consuming.

The debate assignment was designed to develop multiple skills. Research and critical thinking and analysis were required to formulate a strong response to the ambiguous and technical accounting questions. Additionally, the professor wanted students to practice speaking publicly after having carefully prepared their main arguments, but also facing the challenge of speaking extemporaneously if the opposing side created new arguments or offered new evidence. Of course students could mitigate the likelihood of encountering new evidence or novel arguments by preparing very intensively themselves. To ensure students understood the issues thoroughly, the debate process required that teams flip a coin before each debate and the winning team could select the side of the issue they preferred. That uncertainty about which side they would be arguing caused students to spend even more time preparing.

Students did know which team they would be arguing against before the coin toss. However, they were told explicitly not to collude with their opponent to predetermine debate sides. The University has an honor code that mandates both that students refrain from cheating and that they disclose incidents of cheating which they observe. The instructor represented to the external judges that groups would not know which side they would debate until the coin toss.

Before the last round of the debate, the instructor became aware that some teams had colluded with the opposing team to predetermine which side each would argue. The professor overheard two teams deciding, despite the professor’s proscription, to work together and collude to pre-determine which side they would argue. After the debates concluded, a student (who had explicitly declined the possibility of collusion) reported to the professor that the collusion was more widespread than he had first thought.

The professor reacted strongly to the collusion for several reasons. Because of the collusion, he felt he had misrepresented the debate to the professionals who had volunteered their time and expertise. He believed (as did the students involved) that colluding provided a competitive advantage over teams that did not collude. More importantly, collusion was blatantly unfair and constituted a form of academic dishonesty and violation of the school’s honor code. On a personal level, he felt disrespected; furthermore his goals for the class had been stymied and the deep rapport he thought he had with the students was dissipated. However, he wanted to understand why some students had chosen this path, and he wanted the students to learn from the experience. Therefore, after confronting the class, he approached us about interviewing them about the incident.

Table 1 includes student comments made directly to the instructor regarding the collusion incident. In these comments can be seen some of the word topic themes that appear in our formal analysis. Student acknowledged that they felt team and peer pressure to collude. There also appear to be comments related to the idea that the students understood that they were being dishonest and that there would be repercussions for their actions. A majority seems to be remorseful for their behavior. However, the students also offer rationalizations that collusion helped lighten the perceived high-pressure workload. The corpus for analysis includes

the text from twenty-six student interviews. The twenty-six students volunteered to be interviewed - no one was compelled. Eighteen interviews were with non-colluders and eight were with colluders. Of the students interviewed, 12 were female. Of the eight colluders, three were female. Therefore, there was gender balance in the sample.

Interviews

The interviews produced 524 pages of text, and while not large by typical LDA standards, it does represent the entire set of comments about this incident. There were 167 pages of text collected from the colluders, 339 for non-colluders and 18 for the outside observer. This means that each colluder provided approximately 21 pages of text and each non-colluder provided approximately 20 pages.

Student subjects were interviewed via telephone by the study authors. Each interview was conducted with permission of the respondent and the home university's Institutional Review Board. The interviews were immediately transcribed by an independent service and the text of the interviews constitutes the corpus for this research. We asked each respondent a similar set of questions about the collusion incident. The questions are presented in appendix A.

We examined the complete text of all interviews that included 11,125 paragraphs and 218,993 words. There were 65,439 total words for the colluders and 153,554 words for the non-colluders. This results in approximately 8180 words per colluder and 8531 per non-colluder. Given that the responses were freely offered and not constrained, non-colluders were slightly more verbose. Non-colluders talked more about the experience.

Results

The results indicate the words most associated with the five interview topics. Topics in this case represent the substance of the interviews. The two visual features in figure 1 provide overall perspective on these five topics. Circles identify the topics plotted in terms of multidimensional scaling using LDAvis. The size or area of each circle indicates the proportional prevalence of topics in the corpus (Sievert & Shirley, 2014). Three topics (2, 4, and 5) are overlapped and comprise 76.1% of the entire corpus. Overlap simply means the topics are related. Topic 4 is the most prevalent in the corpus (40.7%). Topics 3 (19.1%) and 5 (23.9%) are also prevalent. Topic 3 is interesting. It is not overlapped but is near the other overlapped topics. It is rather important, however, in that it represents 19.1% of the corpus.

The other visual feature in figure 1 lists the top most probable or most salient terms or words from each topic cluster. The topic clusters all contain non-specific and common words, such as 'yeah', 'like', and 'okay.' This is an expected outcome of LDA. Each topic, however, also contains words that are more idiosyncratic or unique to the topic made manifest through the relevance metric. These words cluster to a given topic exclusively compared with the more common terms. We used the word clusters to describe each topic in Table 2 following convention practiced elsewhere in the LDA literature (e.g. Sugimoto et al, 2011; Lash & Zhao, 2017). A complete set of LDAvis diagrams is presented in appendix B.

Table 2 includes the topic description, percent of the corpus represented by each topic, and the most relevant and unique words. The authors determined the topic descriptions based upon relevant words and our understanding of the situation. These relevant words provide the bulk of our analysis. As noted above, relevant words are prevalent in the topic within and throughout the corpus. Unique words are those prevalent in one topic at the exclusion of others. Uniqueness was determined simply as the percent of a word in a topic, that is, the prevalence of a word in a topic divided by the prevalence of the word in the entire corpus. For example, in

Table 1	Sample post-collusion student comments made directly to instructor regarding the collusion
Student #1	“I wanted to inform you about my side of the collusion mishap. For the third debate only, about an hour before class, I was approached and asked if my team would take the Con side because one of my opponents was not prepared. I said yes because I felt bad and I didn't want my friends to be embarrassed. I realize that it was a bad decision and I wasn't happy about it at the time. I made a bad decision due to pressure and stress. Although it is not an excuse, my team was fully prepared on both sides of the debate. I am taking this situation as a learning experience about how easy it is to fall into unethical situations.”
Student #2	“I would like to tell you that my group only talked with the other groups about what side they preferred and then we flipped a coin to find out who would debate on what side. After that we parted our separate ways and didn't speak any more about the debate, the contentions or the evidence. Nonetheless, we still researched both sides of the issue, and prepared good contentions as well as provided strong evidence to support them. If you would like I can send you our contentions as well as our evidence to support them for both sides. It was never our or my intent to be disrespectful to you, the guest judges, or other members of the class. I feel that I learned a lot from this experience and will be more thoughtful about my actions when working on projects.”
Student #3	“First off, I know without a doubt that I was one of the people you overheard conversing with my opponent the day of the debate. As I look back, you probably watched me do it. On the final debate, there was an arrangement with our opponent that we would take the con side if we won the toss, and our opponent would take the pro side. What I am most ashamed of is that I knew it was wrong, but I did nothing to stop it. It is also wrong to rationalize it. I'm not going to blame my partner or say, "Well the other teams are doing it". Yes, it was a difficult week and I had a lot on my plate, but there is no excuse for what I did.”
Student #4	“The bottom line is that I panicked about 1 hour before the debates. I was personally extremely well prepared for both sides (seriously, I'll show you an epic amount of research organized in two folders pro and con), but my partner was not. I knew most teams strongly favored the con side, so I pushed him to focus on the pro. Additionally, in previous rounds I had been approached by other teams to pick a side days before, and I declined.”
Student #5	“I was a participant in the collusion! To be honest, I am pretty embarrassed about the situation. I took the approach to work smarter, not longer or harder during that week. Not very proud of it, but I cannot go back and change it.”
Student #6	“I am sorry to say that my team had our side predetermined in the final debate. Although we did not end up debating, I definitely regretted my decision after realizing the magnitude of what we did. I apologize for destroying the whole point of the debate, and I have no excuse that would validate it.”
Student #7	“I am responding to your message because member of my team was involved in the collusion. I had mentioned some of this in my final memo so part may seem repetitive if you have already read it. He made an arrangement with one member of the team we were supposed to face. He then sent a text stating

	what he had done. It was done without my knowledge or approval. I believe he did it to spite you or the debate. I think it was like you said in the email, he was overwhelmed by the work load and was doing what he could to make the work load manageable."
Student #8	**"** With heavy heart, I am admitting that group one participated in the collusion. We flipped the coin the day before debate. As ashamed as I and my teammates are, I don't feel it is appropriate at this point to try and justify our actions besides agreeing with what you put in your email. I am truly sorry for the disrespect, and for letting you down."

Figure 1- Topic map of student interviews
file:///C:/Users/cshrader/AppData/Local/Temp/Temp1_averaged.zip/averaged/5_topics_updated.html

topic 1, the word 'interview' has a uniqueness score of 99. This means that even though the word can appear elsewhere in the corpus, there is a 99% probability it will be associated with topic 1 in the LDA.

Evidence from the other high-loading relevant words reveal substantive topics dealing with the nature of the course assignment (topic 2), class teams (topic 3), repercussions of being caught (topic 4), and differences between the auditing and tax tracks in the accounting major (topic 5). Topics 2, 3, and 5 constitute over half of the corpus (55.4%). These topics include words related to taking sides in the debate, teams, and the differences between the auditing and tax majors. Therefore, in effect, students talk most about the immediate classroom situation when describing collusion. Topics 2, 4, and 5 cluster together and deal with class competition, taking sides, repercussions, and differences between majors. Topics 2, 3, and 5 deal with

Table 2 – Extended latent Dirichlet allocation results for student interviews

Topics and Words

	Topic 1	**Topic 2**	**Topic 3**	**Topic 4**	**Topic 5**	
Percent of Corpus	4.8%	11.5%	19.1%	40.7%	23.9%	Total = 100%
Topic Label	General context- honor code, starting the interview, naming important actors	Nature of class assignment itself	Teams - a resource and support mechanism	Repercussions of being caught	Tax and Audit class section ethical differences	
Important Words	Relevant words (LDAvis) thank interview code phone yeah hi hello	Relevant words (LDAvis) like going just really said article prepared	Relevant words (LDAvis) team did debate remember know teams groups	Relevant words (LDAvis) think class people know students caught colluded	Relevant words (LDAvis) think ethics just people know tax audit	

	Unique words (% of word unique to topic)	Unique words (% of word unique to topic)	Unique words (% of word unique to topic)	Unique words (% of word unique to topic)	Unique words (% of word unique to topic)	
	interview (99) code (99) honor (99) hello (96) codes (94) interviewer (93) honor (93)	confident (99) article (98) argument (97) argue (97) articles (96) pros (96) cons (90)	sources (99) shared (98) competing (98) agreement (95) teams (94) teammate (80) team (67)	dishonest (99) fail (98) recommend (98) hiring (98) failed (97) determining (97) probability (96) failing (95) stupid (93) caught (92)	ethics (99) tax (99) emphasis (99) engaging (98) preconceived (98) culture (96) curriculum (96)	

things more internal to the particular collusion incident while topic 4 deals with the external view of the reputation of the school. This appears to be evidence that internal course context has a lot to do with collusion. Table 3 provides samples of student interview comments that reflect the topic categories.

Topic 1 – General context, honor code and greeting

As evident in table 2, the relevant (common) words for topic 1 are thank, interview, code, phone, yeah, hi and hello. Words unique to the topic include interview, code, codes, interviewer, honor, thank and hello. Therefore, topic 1 captures language regarding the basic greeting and simple pleasantries associated with opening the dialog between interviewer and interviewee. It is also quite separate from the other topics on the inter-topic distance map and is much less prevalent than the others (4.8%). Along with this, it also appears to deal with the school code of ethics or honor code. This school did indeed, have an honor code and the interviewees seem to mention it as part of the general context of the situation. McCabe and Trevino (2002) argue that academic integrity is enhanced through a visible honor code. Here we find the code to be visible and part of a general context. The word ‘code’ does not figure heavily in the more prevalent topics.

Topic 2 - Nature of course assignment

Topic 2 is the second least prevalent topic in the corpus. The most relevant words are: like, going, just, really, said, article and prepared. When combined with unique topic words such as: confident, article, argument, argue, articles, pros, and cons, it is clear that this topic deals with the course assignment of developing an argument for the debate.

Topic		**Table 3 - Sample student interview comments**
Repercussion	Non-colluder	“Before the debates started, the professor was very adamant to our class that it was not an option and if we were caught-- I don't know if he said the consequences would be bad, but it was one of those things where it would not be tolerated and personally to him, he would be very disappointed in us.”
	Colluder	“I'm aware that we're cheating and being dishonest, so trusting people to keep their mouth shut is a little difficult. If they're dishonest on one thing, who's to say they're not going to be dishonest on another thing?”
Team	non-colluder	“I just think our class had a lot of students that were very talented, and I think we had people that wanted to succeed and were competitive. I think when you combine how you have a lot of talented and competitive people then it brings everyone up to that level of wanting to compete. There was definitely some rivalries between students as well; there was one team that me and some people that I knew in the class were really wanting-- hoping they would lose.”
	Colluder	“Teams would give other teams the references and show them where to find the things. I was thinking that we have to trust each other and we have to be quiet about it.”
Nature of assignment	Non-colluder	“Yeah I think there is a little difference. It's based on the seriousness of the debate compared to just one homework assignment.”
	Colluder	“We were in front of our classmates, we didn't want to look stupid. When the third one came around, we were just so exhausted from everything, we thought it was actually our right to cheat or make it a little easier for us to fix the third debate. We felt we had so much on our table that it was justified to just pick one side, because we have to do the debate anyway.”
Audit and Tax section differences	Non-colluder	“As weird as this is going to sound, the class that I was in consisted most of auditors, and we have skeptical minds to begin with, so we are a little more distrusting with each other. One of my concerns with even colluding would have been, "Hey, are they going to come back and throw me under the bus? If I say I'm going to be pro and they're going to be con, are they going to pick pro and I'm not going to have anything to argue with?" For our class we have a more competitive mindset than the other class. We're very close and talked about a lot of [?] and just-- they worked together on a lot of things. We were a way more competitive group than they were.”
	Colluder	“Tax is the outcast of the accounting program. Usually people go into audit where it's more regulatory stuff. The tax people are sort of-- I don't know, it's different. Everything in the audit program is very structured and you have to say the right words, or it doesn't

		make sense. They do more writing things and analysis. The tax people are more transactional. We have to be more outgoing with clients. We actually have to talk to our clients, and the work that we do is start to finish. We start a tax return, we finish it. An audit, you're auditing cash. You're only one segment of the big picture. It seems like tax people are more lawyers, we deal more with like cases and interpretation. Whereas an audit, it's more concrete and it's not just the same. Honestly, personality decides who's going to be an auditor and who's going to be a tax person."

Topic 3 – Teams

Topic 3, which deals with the team aspect of the course, appears to be somewhat independent of, but related to, the other main collusion topics in terms of the distance map. This may mean that the team aspect itself has a lot to do with the decision to collude, or at least teams create relevant context for the decision. The finding that 'teams' is a topic unto its own illustrates the importance of teams and teamwork in understanding cheating and collusion. Important relevant and unique words include- shared, agreement, sources, teams, competing, teammate, team, remember, and groups. These words clearly highlight the salience of the team concept in this situation.

Topic 4 – Repercussions of Collusion

The most prevalent single topic in the corpus (39.3%) is topic 4. The words fail, failed, failing and caught all led us to describe this topic as having to do with the repercussions of collusion. Both the immediate repercussions (fail and caught) and future consequences (future, recommend, and hiring) appear to be important considerations to the students. What is interesting is that even though repercussions of being caught are prevalent, many students were still willing to take the risk. This result follows that of West et al. (2005) who found students to become very instrumentally focused when faced with opportunities to cheat. In other words, when the payoff is large enough, even severe consequences many not deter the colluder.

Topic 5- Difference between audit and tax classes

The words 'tax' and 'audit' are both prevalent and unique in topic five. These words describe the nature of accounting majors in different sections of the course- one populated by tax majors and the other audit majors. Other important words are ethics, curriculum, engaging, emphasis, and culture. The collusion incident happened in a section populated by tax majors. It is clear that these students perceive the audit and tax people to be different. In this instance, the audit class did not have a problem with collusion. One explanation for why auditing students may be less susceptible to collusion is found in the work of Ballentine, Guo, and Larres (2018) who demonstrated that less cheating was found in instances where students were involved in deep and strategic approaches to the material. Tax laws and rules may concomitantly reflect what Ballentine et al, term surface learning approaches- requiring memorization without deep understanding. Whatever the reason, it is clear that in this situation involving collusion that the audit and tax sections were seen as different, and though surface versus strategic learning are not part of our research, the conditions appear to be consistent with our findings.

Colluders, non-colluders, and topics

We also extend the LDA results to individual students. Table 4 presents information linking individual students to LDA topics. The general pattern reflects the topic relevance in the

corpus as expected. Concern regarding repercussions, topic 4, was the most relevant topic for a vast majority of those interviewed. Topic 4 was not the most relevant topic for only two of the student respondents. There were only subtle differences between colluders and non-colluders in terms of relevant topics overall. However, according to the Kingland LDA experts, 'even subtle differences are important and interesting.' The difference between the audit and tax majors and the nature of the class assignment were slightly more relevant to colluders than non-colluders, while teams were marginally more relevant to non-colluders. Also, any names appearing in the list of terms are disguised and, therefore, do not violate anonymity.

Table 4- Extended LDA results
Most Relevant Topics by Individual Colluder/Non-Colluder

Colluder/Non-colluder	Most Relevant Topic	Second Most Relevant Topic	Third Most Relevant Topic	Fourth Most Relevant Topic	Fifth Most Relevant Topic
Colluder 1	4	5	3	1	2
Colluder 2	4	5*	3*	2	1
Colluder 3	3	4	5	2	1
Colluder 4	4	5	3	2	1
Colluder 5	4	5	3	2	1
Colluder 6	4	5	3	2	1
Colluder 7	4	3	5	2	1
Colluder 8	4	5	2	3	1
Non-Colluder 1	4	3	5	2	1

Conclusion and Discussion

To our knowledge, this is the first time LDA has been applied to a dataset to examine cheating or collusion. Evidence from our LDA suggests that a significant portion of the language used to describe collusion is manifested by four major topics. Students see repercussions of being caught, teams and class teamwork, course assignment structure and content, and class section differences to be important factors in the context of collusion. Indeed, the most salient topic in this research deals with repercussions. Our LDA results align closely with those of Briggs et al, (2013) indicating that collusion is a rational assessment on the part of students guided by the expectation that other teams will collude and fear of exclusion on an assignment, even when harsh repercussion may be applied. The discussion also centers on differences between auditor and tax functions in accounting. Taking the repercussion and auditing difference topics together coincides with previous research that finds auditor moral reasoning to be influenced by the potential for penalties (Jeffrey, Dilla, & Weatherholt, 2004). Repercussions as an assessment of the instrumental nature of decisions to cheat are common elsewhere in the literature (West et al, 2004).

Another of the topics resulting from our analysis centers on teams and teamwork. Our results suggest that collusion may be associated with team assignments. These results also confirm the survey results of Shrader et al. (2012) that teams and peers may put unintentional pressure on students to collude on class assignments. Teams were part of the class structure in this incident as they are in many business classrooms today. In business schools, we often use teams to teach consensus building and appreciation of diversity. Instructors place students in teams hoping to maximize individual performance and enhance inclusion. However, teams also can create blurred lines. Teams often result in shared work- both when desired and when not permitted. Team assignments may lead to free riders both within the team and including the whole team. Team based learning is a popular teaching technique, but using teams in the classroom requires careful structuring of activity and the team itself in order to be effective (Koppenhaver & Shrader 2003). It appears that whenever teams are formed there is an enhanced opportunity for students to use the team in an instrumental way to lighten the workload. As Ariely notes: “Some…forces might make it easy for group-based processes to turn collaborations into cheating opportunities in which individuals cheat to a higher degree because they realize that their actions can benefit people they like and care about (2012, pg. 222).” Ariely claims that under conditions where teammates perceive they can all benefit from the opportunity, the level of collaborative cheating tends to increase. The implication for future research is that team context must be considered because of its powerful effect on class assignments. The widespread use of classroom teams for presentations and debates may be creating confusion (or opportunity) in terms of what is allowed collaboration and what is illegal collusion. Forming classroom teams without providing team training and time for team development may be doing as much harm as good. Certainly team-based learning is more effective if teams operate as planned. One of the central issues of team-based learning is the degree to which the instructor may have influence on the teams. However, collusion and the subsequent conflict that commonly occurs is likely to have a negative impact on learning, and can minimize the effectiveness of classroom team assignments.

Our results also show that those who chose to collude and those who did not described the incident in similar terms. When asked a battery of detailed questions, there was no glaring difference in terms of how students described the incident. Often students may not see the line

of demarcation between cheating and formally assigned group work (Shrader et al, 2012). The widespread use of teams and group assignments may be adding to the level of general confusion about those specific instances when sharing is permitted (Kaufmann et al, 2005). For example, the student quoted in the Washington Post article mentioned above (Bever, 2017) sees no problem with taking advantage of opportunities to collude when not expressly prohibited.

One fundamental aspect of this paper is that we demonstrate the value of large data processing techniques such as LDA and LDAvis. LDA provides an objective and consistent means of examining large amounts of text. It allows the identification of underlying content and discloses words and topics to make the content interpretable. Our colleagues at Kingland use it to analyze volumes of corporate annual reports and technical documents. It is well suited to this task. However, to our knowledge, this is the first LDA study to examine the language of students who are actually involved in a classroom collusion incident. Moreover, even though not large, our sample represent the universe of data available on this particular collusion incident. Therefore, there is clearly an opportunity for future LDA researchers to systematically gather interviews from larger groups of students over time in order to ascertain even better understanding of cheating and collusion.

Consequently, our study is subject to the basic caveat of using LDA, namely, topics require interpretation by the researchers. The number of topics is subject to interpretation- it is not a necessary given from the analysis. However, we followed the conventions of prior LDA studies in terms of identifying topics, and used LDAvis to convey results. We also worked closely with the Kingland LDA administrators in deciding on the topic solutions and interpreting results. Therefore, we feel confident our interpretations are reasonable and accurate with regard to our data. So, what have we learned from LDA? We learn that students view classroom cheating from the classroom level. Rather than talk in terms of greater ethical principles or codes, they talk about instrumentalities and temporal immediacy. The nature of the assignment, the team dynamic, and the perceived immediate consequences weigh more heavily in their language than do big picture long term things. Students view the decision to collude as a function of course assignments and perceived workload. Their moral reasoning seems to be based on the here and what near-term consequences might be. The immediate context is more relevant to them than the bigger picture. Given this, our research fits with previous research indicating that both context (e.g. codes, McCabe & Trevino, 2002) and morality (West et al. 2005) matter. Our study found only small differences between how colluders and non-colluders describe a shared experience. Therefore, while not expressly tested, our results appear to be consistent with this general finding.

This is also the first time of which we are aware that unique words have been used to identify and discuss topics. By identifying unique words, we were, in turn, able to more clearly identify topics. LDA is free from a priori assumptions about the nature of concepts or factors. The identification of unique words aids in the exploration of the corpus and naming of topics, in our view. Uniqueness is used in this paper to refine, not define, the topics. It offers a more granular statement about the meaning of the topic and helps clarify the results of our exploration.

A weakness of this study is that the corpus is not large. The number of interviews and amount of text is not particularly great in terms of what most LDA studies examine. However, we do have all the possible or available interviews. Our sample is actually a universe and is, therefore, representative. We have all the possible data from this naturally occurring filed experiment. We believe it very reasonable to assume that our students were telling the truth in the interviews and that the interviews captured the essence of the collusion issue. We also view the accounting course in question as typical of other graduate accounting courses and that it created classroom dynamics similar to those of other business courses taught elsewhere.

However, even with these limitations, this research has practical teaching implications. Our results clearly indicate that the course context is salient in terms of collusion. Future research should delve more deeply into group and team issues, that nature and clarity of the course assignment, and the extent to which students will compare themselves with other in terms of the cheating opportunity.

APPENDIX A – Phone Interview Questions

1. How did the idea of colluding in general first come up? What made you think that this was an option?

2. Do you know who the first group to collude was?
    a. How did you find out about this group?

3. Did knowing that other groups were colluding influence your decision to collude? If so, how?

4. Who first brought up the idea of predetermining sides in your debates?

5. Do you believe that there would be any ramifications to saying no to a classmate who wanted to collude on the debates? If so, please elaborate.

    a. What about if a classmate wants to look over your homework before it is due?

6. Do you believe that students in previous sections of this course predetermined sides in the debates?
    a. - If so, why do you believe this?

    b. If previous sections engaged in the same behavior, do you have any feelings about the fact that you were discovered and they were not? If so, what are those feelings?

7. Has anyone taking the course this semester talked with you about the debate process?

8. Do you believe that your school's emphasis on ethics had an impact on the debate situation?
    a. If so, what? If not, why not?

9. Do you believe that there are repercussions for engaging in unethical behavior such as cheating?

10. What did you think would happen if you were caught predetermining sides in the debate?

11. Is there some difference between the classes that would make one more likely to predetermine debate sides than the other? If so, what?

12. Why do you think that the students in the other section did not collude?

13. Did the fact that the majority of the class was on the tax track and taking all of their classes together have any influence on the decision to collude? If so, can you describe that influence?

14. How do you think that members of the other class would feel or react if they knew that you had colluded on the debates?
    a. Do you know if anyone in the other section knows that you predetermined sides?

15. How stressed were people during the debate process?
    a. How did they deal with the stress?

16. What role do you think the debate stress played in people's decision to collude?
    a. (if significant) What was the difference between the students who were stressed and colluded and those that felt stress and did not collude?

17. How clear was Professor Smith in letting you know that predetermining sides in the debate would be considered cheating?
    a. Did Dr. Smith say anything before the debate about agreements between competing teams?

    b. Did Dr. Smith say anything before the debate about working with people outside your team on the debate?

18. How important was trusting the members of the other team on your decision whether to collude?

19. How prepared would you and your team have been if you had been double-crossed and your competition chose to argue the side that you had prepared?
    a. How confident were you that this was not going to happen? Why?

20. Is there anything about Dr. Smith or this class that would make students more willing to engage in collusion or similar activities when compared with other classes or other professors?
    a. Debate process itself?

21. How is this class viewed by the students?
    a. How does this class fit into the Accounting program?

22. What do you think about how Dr. Smith handled this situation after discovering the collusion? How do you feel about it?
    a. How would you have handled it if you were him? Why?

23. How well known is this response within the program?

24. Do you believe that there will be any repercussions associated with this response?
    a. e.g., on future cheating?

25. Do you believe any of teams shared evidence or sources with other teams during debate preparation?

26. Is there a difference between discussing arguments or sources with another team in the competition and discussing these things with the team you are competing against? If so, what is the difference?

27. Is there a difference between helping your friends / classmates on a homework assignment that is to be graded and colluding in the debates? If so, what is the difference?

28. Do you believe that your professors are okay with sharing homework assignments that are to be handed in for a grade?

    a. if yes, would you tell them you did it or keep it to yourself? Why?
    b. If no, how does sharing homework differ from predetermining sides in the debate?

29. Why do you think that you colluded on the debates?

30. What (if anything) do you believe you have learned or will remember about this debate experience?

31. Is there anything else we should know or you would like to say about the debate situation last fall?

DECISION SCIENCES INSTITUTE
An Analysis of Parenting from Online Confessions

ABSTRACT

Anonymous networks offer unique environments for emotion-expression. In this work, we study the expression of emotion in the Scary Mommy Confessional, an anonymous message board, where parents (mostly mothers) post anonymous comments about motherhood, and family life in general. This paper explores how the intensity of sentiment in a confession evokes specific reactions from the readers. Results show that three effects are at work: (1) Ancient Mariner effect: tendency to disclose more intimate information to strangers, (2) Dark Side: tendency to disclose information that has more negative sentiment and (3) Emotional contagion: tendency to be influenced by the emotions.

KEYWORDS: Anonymous social networks, Ancient mariner effect, Emotional contagion, and Online Parenting.

INTRODUCTION

Anonymous networks have been prized for the freedom of expression. In anonymous networks, people can express their thoughts without having to consider the norms of social exchange. For example, before posting content on a profile-centric network such as Facebook, users might think about the possible reactions that the post will elicit. These reactions span the gamut of social exchange. On the positive side, the comment might be well-liked as indicated by the Like and Love buttons or it might warrant significant discussion through threads of comments that affirm or encourage the user who posted the content. On the negative side, the user risks not receiving any feedback, receiving hostile comments, or having the comment reported as inappropriate, and in general degrades the online network reputation of the user. In addition to impacting the online network reputation, posted content and the reactions that it elicits also impact the offline reputation of the individual. While the theory of social exchange in (Meeker, 1978) was developed for traditional offline social networks, work done in (Moore & McElroy, 2012; Murimi, 2016; Wasko & Faraj, 2005) shows that people's behavior on social networking websites is an extension of their behavior in offline social networks. One reason attributed for this extension of personality and behavior is that social networking sites (SNSs) may contain identifying information about the user. Content posted on SNSs such as Facebook and Twitter can be linked to an account and its associated profile due to the profile-centric design of the user experience. However, there exist other SNSs where various parts of a user's profile information are optional, thus creating a range of SNSs that lie on the spectrum of anonymity. Multiple other levels of anonymity have resulted in pseudo-anonymous SNSs where users can choose the level of self-disclosure, and hence their adherence to social norms, by using different SNSs for specific applications. In (Leavitt, 2010), the author found that lower perceived anonymity on Reddit was a strong motivation for using "throwaway accounts". In other work on anonymity and self-disclosure, the authors in (Ellison et al, 2016) showed that selective anonymity allowed on Ask.fm was conducive toward critical development goals in adolescents. Research in (Suler, 2004) has coined this effect as the online disinhibition effect, where the anonymous nature of online communications has been shown to allow people to "feel less vulnerable about self-disclosure and acting out".

In this paper, we study the effect of anonymity on the nature of comments posted on the Scary Mommy Confessional, an anonymous message board, where readers post their comments called "confessions" about motherhood and family life in general. Using a dataset of roughly half a million confessions, we studied patterns in the sentiment of comments, distributions of various reactions, and emotional contagion. These patterns point to the tendency to utilize anonymity to "speak one's mind", and our results show that in the Scary Mommy Confessional, confessions are primarily negative in sentiment, more intimate and cause emotional contagion. Our findings about anonymous confessions provide a rich platform for investigation into the online lives of mothers, unfettered by the norms of face-to-face parenting and social exchange, thus creating a cultural snapshot of the life of an online mother in the age of anonymous SNSs.

RELATED WORK

While no work has yet analyzed the Scary Mommy Confessional, substantial research has been conducted into the use of SNSs by pregnant women, new mothers and motherhood in general (Balaam et al, 2013). Some specific expectations of these subgroups of users include gathering information about pregnancy (Hui, Ly & Neustadter, 2012), childbirth (Choudhury, Counts & Horvitz, 2013) and concerns of new mothers (Gibson & Hanson, 2013), keeping in touch with friends and family after the birth of a baby through updates of pictures and baby milestones (Jomhari, Gonzalez, Kurniawan, 2009), parenting advice, tracking milestones in a baby's growth and blogging about parenthood (McDaniel, Coyne & Holmes, 2012; Morris, 2014; Schoenebeck, 2013). The use of SNSs by fathers and their parenting methods – blogging, posting pictures and sharing information about children - was analyzed in (Kumar & Schoenebeck, 2015). In (Correa at al 2015), the authors analyzed the content posted on Whisper, an anonymous network, where users anonymously post content called "whispers". Whispers were compared to the content on Twitter, a non-anonymous site. The authors found that Whispers were more personal, social and informal than tweets, exhibited more negative sentiment and expressed more wants, needs and wishes than tweets. Another study on Whisper was conducted in (Wang et al, 2014) where the authors study interaction and the absence of persistent social links in anonymous networks. Similar to the work in (Correa at al 2015), the authors found that Whisper users posted highly personal content. This theme was further explored in (Andalibi, Ozturk & Forte, 2017), where the authors conducted an online experiment to study the relationship between content intimacy and willingness to self-disclose in social media. They found a negative relationship between these two factors and showed intimacy of content increased with the level of anonymity. They also found that people were more willing to share intimate content with weak ties such as online friends, than with people nearby. This finding points to the increased support that people find on online networks when dealing with intimate content. The authors in (Ma, Hancock & Naaman, 2016) studied image-based sharing to investigate the role of self-disclosure in the expression of depression-related thoughts. Another finding is that positive sentiment is more common than negative sentiment on profile-centric networks, whereas anonymity allows for more comments with negative valence. In (Ma & Kizilcec, 2014), the authors found that when offered a choice of a sharing platform for content sharing, users preferred anonymity for controversial content.

People's willingness to disclose more intimate content with strangers has long been documented and analyzed from the perspective of social sciences. In psychology literature, the tendency to increase self-disclosure with increase in anonymity is also known as the passing stranger effect, or the ancient mariner effect, after the poem The Rime of the Ancient Mariner written by English poet Samuel Taylor Coleridge (Coleridge & Pato, 1863). In this poem, the ancient mariner willingly recounts to a wedding guest repeatedly his horrific tale of a journey gone awry. Implications of the passing stranger effect have been studied in terms of self-disclosure through writing messages in (Rubin, 1975), where the subjects wrote longer messages to strangers. The passing stranger effect was also observed in (Rubin, 1974), where development of intimacy in relationships with passing

strangers was analyzed. Stranger support was also studied in (Cauce, Felner & Primavera, 1982) through the framework of social support to improve personal well-being by seeking intervention from strangers (for example, doctors and therapists). Our work differs from previous explorations of anonymous parenting behavior in that it analyzes anonymous user reactions to the confessions, thus providing an additional layer of interaction in complete anonymity.

METHOD

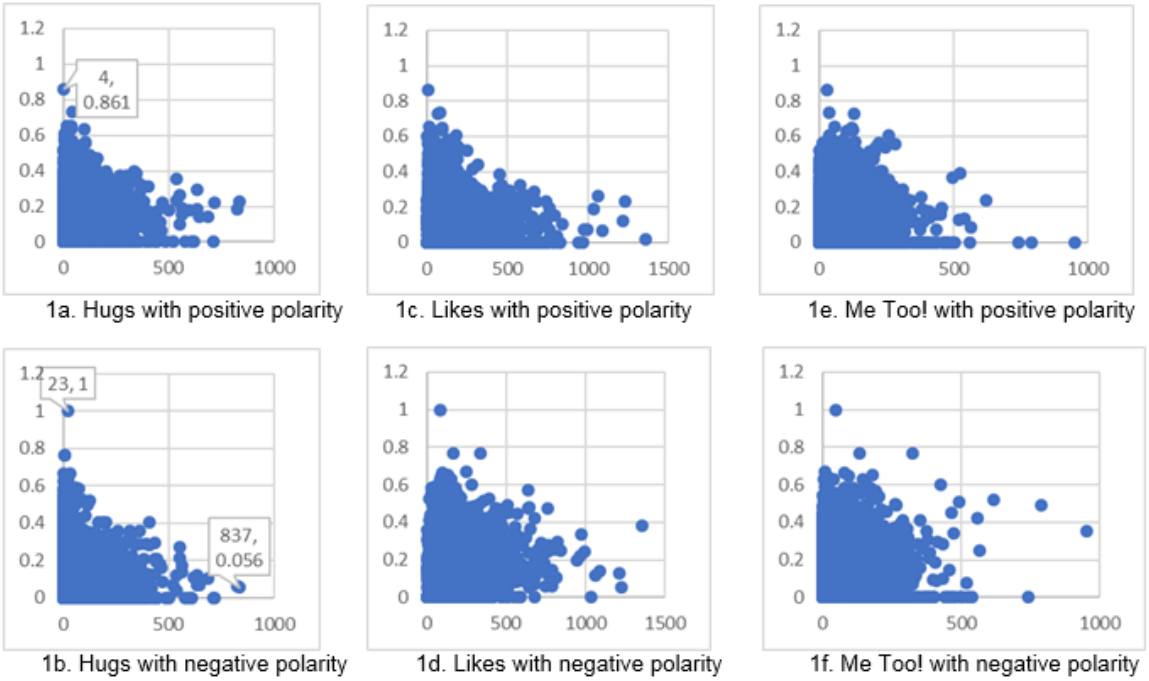
Our work in this paper deals with the Scary Mommy Confessional (Scary Mommy Confessional at http://www.scarymommy.com/confessions/) which is an anonymous message board where visitors to the site may anonymously post a comment called a confession, limited to 255 characters in length. Visitors to the Confessional can view all the confessions and have three ways to interact with the confessions. Similar to a Facebook Like and the broad spectrum of Facebook Reactions, the Scary Mommy Confessional allows a user to click once on one or more of the following options beneath every comment: Hugs, Likes, Me Too!. These one-click tools for interaction, called paralinguistic digital affordances, in (Hayes, Carr and Wohn, 2016) refer to the quick, easy modes of communication on SNSs. On the Scary Mommy Confessional, each click on a Hug, Like or Me Too! increments the current number of Hug, Like or Me Too! and is displayed inside parentheses.

Dataset

All of the confessions posted on the Scary Mommy website were crawled over a six-month period using Python from November 2016 to April 2017. The Scary Mommy Confessional has pages, each containing 10 confessions, and their corresponding numbers of Hugs, Likes and Me Too! reactions. of March 2017, there are little over 49,000 pages of confessions on the Confessional. However, the Scary Mommy Confessional does not have an API, and while it keeps all confessions on the site, it does not keep the number of Hugs, Likes and Me Too! reactions for the older confessions. Thus, older confessions have all zeros for the Hugs, Likes and Me Too! reactions. We found that the site deletes the number of reactions around page 600, and so we only chose the newer confessions on the Confessional. Thus, while our historical data set contains roughly half a million comments, our usable data set consists of confessions from pages from 1 (most recent) to around page 600, after which the site no longer retains the numbers of Hugs, Likes or Me Too! reactions on any confession. The dataset reveals interesting findings about relationships. Mentions of the dear husband (DH) are collectively more (63%) than all other categories, i.e. dear son (DS), dear daughter (DD) and dear child (DC) categories combined. We also found the frequency distribution of ages across gender in the confessions. The most common age of sons is 10 years, and that of daughters is 17 years.

Sentiment Analysis Tools

We used the VADER sentiment analysis tools developed in (Hutto & Gilbert, 2016) to obtain the polarity of each confession. VADER, which stands for Valence Aware Dictionary for sEntiment Reasoning, is a parsimonious rule-based model that assesses the sentiment of content and is well-suited for micro-blog contexts like tweets and short comments. VADER works by extracting the intensity of sentiment through a polarity score that ranges from -1 (most negative) to + 1(most positive). The VADER dictionary of lexical features is particularly well-suited to analyze social media content, such as Scary Mommy confessions, due to its attention to (a) emoticons such as :-) (b) sentiment-related acronyms such as LOL (c) Internet slang such as “nah” and “meh” (d) punctuation marks (multiple exclamation points used to denote intense emotion) and (f)



1a. Hugs with positive polarity | 1c. Likes with positive polarity | 1e. Me Too! with positive polarity

1b. Hugs with negative polarity | 1d. Likes with negative polarity | 1f. Me Too! with negative polarity

Figure 1. Distribution of the Hug, Like, Me Too! reactions as a function of the positive and negative polarity of confessions

capitalization to signal intense emotion. For example, compare, “The food here is great” with “The food here is GREAT!” or “The food here is great!!!”.

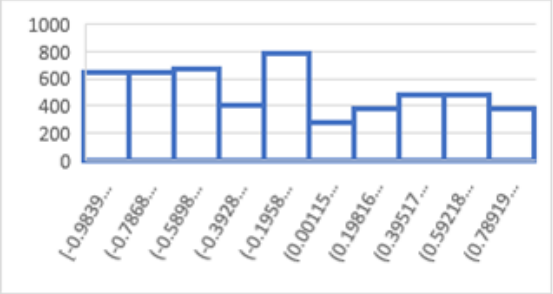
VADER also accounts for modification of inferred sentiment polarity scores found in statements such as “The food here is great, but the service is slow”, where the word “but” reduces the intensity of the overall sentiment. In the next section, we show the distribution of the sentiment intensity in the confessions across the numbers of Hugs, Likes and Me Too! reactions garnered by a confession using VADER.

FINDINGS

Figure 1 shows the distribution of the Hugs and their corresponding positive polarity (Figure 1a) and negative polarity for the confessions (Figure 1b). We see that majority of comments receive less than 450 Hugs, and as the number of Hugs increases, the polarity reduces. The same is true for confessions that receive few Hugs. The highest positive polarity of 0.86 had 4 Hugs. This shows that extreme polarity of sentiment (positive or negative) in the confession was not well-received and did not garner many Hugs. At the same time, confessions that were less positive in sentiment (< 0.5 polarity) elicited maximum Hug response from the confessional readers. A similar effect was observed for the distribution of Hugs with the negative polarity of confessions. The highest polarity of negative sentiment received 23 Hugs, and the confessions receiving the most Hugs (837) had a polarity of 0.05. The maximum Hug response was received for confessions whose polarity was less than 0.4.

We also compare the distribution of Likes, Hugs and Me Too! reactions with the positive and negative polarity of confessions. We see that Likes (Figure 1c, 1d) are the most common reaction, followed by Hugs (Figure 1a, 1b) and Me Too! (Figure 1e, 1f). It should be noted that

Figure 2: Distribution of confession polarity



the Scary Mommy Confessional does not use icons to offer the three reactions and relies on buttons labeled with reaction names. In (Levordashka, Utz and Ambros, 2016), the authors analyzed the motivations of users who clicked the Like button on Facebook and grouped these motivations into categories based on content of the post, acknowledgement, social support and utilitarian responses. Other factors were to acknowledge the source of the post and maintain/strengthen the relationship with the poster. However, unlike (Levordashka, Utz and Ambros, 2016), due to the anonymous environment of the confessions, these other factors have no impact on the motivations of the readers, and hence content of the confession is the primary motivator of the types of reactions it garners. Me Too!, however, is more specific, and conjures images of the reader being in the exact same situation, and hence is not as popular as the Like or the Hug on the Confessional.

Patterns in Anonymous Confessions

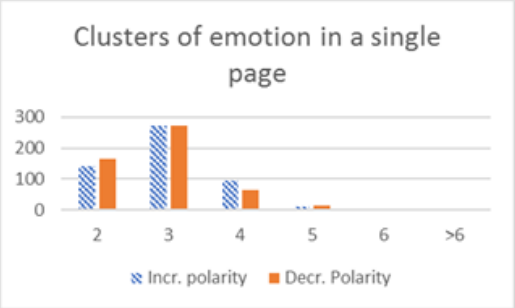
Figure 2 shows the distribution of the compound polarity score of a comment. The compound score is a function of the positive, neutral and negative polarity and lies within the range of -1 to +1. We see that, in general, the confessions tend to be more negative than positive and the highest number of confessions bear polarities that lie in the range of -0.24 to 0.001. Table 1 shows salient statistics of our data set.

Emotional Contagion

Our results in the previous section point to the tendency toward generally negative polarity confessions on Scary Mommy. In this section, we study whether the polarity of confessions on a page affects the polarity of new confessions. For example, if the most recent confession contains mostly negative sentiment, does that influence the intensity of sentiment of an upcoming confession? The phenomenon is widely known as “emotional contagion” (Hatfield, Cacioppo & Rapson, 1962; Schoenewolf, 1984) and has been analyzed for its impact on work dynamics (Barsade, 2002), social networks (Kramer, Guillory & Hancock, 2014), and encounter satisfaction (Pugh, 2001). In (Pugh, 2001), the authors found that emotional contagion can be affected by without direct interaction and occurs even in the absence of verbal cues. This study which was performed on Facebook, by exposing users to the emotions of their friends in their News Feed, found that emotions expressed in online social networks impacted one’s own posts. Our analysis of the Scary Mommy confessions found a similar pattern. We found that emotional contagion existed in clusters. That is, sentiment of the previous confessions had the greatest impact on the sentiment of a new confession. Thus, if the previous two confessions were increasingly negative

Table 1: Key Statistics of Scary Mommy Confessions	
Feature	**Average**
Hugs	53
Likes	125
Me Too!	53
Compound Score	-0.08
Confession length	28 words

Figure 3: Distribution of confession polarity in clusters



or increasingly positive, the upcoming confession had an increasingly positive or negative polarity as well.

Figure 3 shows the clusters of emotion encountered in the Scary Mommy confessions. We see that the largest cluster of emotion occurs for clusters of size 3, followed by clusters of size 4. Thus, confession-posters are heavily influenced by the emotion (positive or negative) expressed in the previous two (cluster of size 3) or previous three (cluster of size 4). Thus, looking at a cluster of size 3, if the previous two confessions had polarities of 0.2 and 0.4 respectively, the next confession had a higher probability of having a polarity that was > 0.4. Our study affirms the emotion contagion theory for the case of anonymous SNSs.

DISCUSSION

This paper provides an overview of interaction mechanisms and their implications on the Scary Mommy Confessional, an anonymous message board that caters to parents, mostly mothers. The study shows how the content of the comment evokes specific reactions from the site's affordances for interaction with the confessions. Our study found that the confessions had a mostly negative sentiment, inspired emotional contagion and were intimate disclosures about parenting, motherhood and family life, in general. We also found that of the three affordances – Hug, Like and Me Too! – the Like was the most commonly used affordance. The Hug and Me Too! affordances are unique to the Scary Mommy Confessional and offer an exclusive one-click tool to model empathy and compassion in a digital framework. The anonymity of the Scary Mommy Confessional ensures that the empathy, compassion and enthusiasm for a confession is motivated solely by the content, since there is no subliminal motivator such as the maintenance of social ties, a concept seen frequently in profile-centric SNSs such as Facebook, Twitter or LinkedIn (Hayes, Carr and Wohn, 2016). However, further research is needed to understand the implications of affordances on SNSs that are used to convey human emotion. Does a Hug on the

Confessional trigger the same benefits as a hug in offline social networks? SNSs offer the benefit of receiving empathy, compassion and enthusiasm, and other emotions that lie on the spectrum of positive and negative psychology, from both strangers and friends. In an anonymous setting such as the Scary Mommy Confessional, a click on any of the three affordances in response to a confession is an endorsement of the confession from a stranger. Does it imply, then, that we are open to receiving empathy, compassion and enthusiasm from complete strangers even in offline social networks? Online disinhibition (Suler, 2004) is a significant factor in this disparate behavior online and offline, and further work needs to be done to determine why we welcome attention from strangers in certain SNSs and are averse to friend requests and profile views from strangers in other SNSs.

Scary Mommy caters to an exclusive demographic: pregnant women, new mothers and mothers of young children. The content of a confession does not require the writer to provide gender information, yet it is generally assumed that most confessions were written by female users. In certain instances, the confession is written with clear phrasing indicating that the writer is a male. The content on sites such as Scary Mommy and our perception of the confessions reveals that our own assumptions about gender roles may have significant implications on our online behavior. For example, the name “Scary Mommy” implies the existence of a forum for mothers, but would fathers be comfortable using the Confessional to seek support and validation about their parenting challenges in an anonymous forum? Research addressing questions such as these will help us understand the gender disparity in the use of technology for niche applications.

CONCLUSIONS

This paper offered an analysis of reactions to anonymous confessions about motherhood, and family life in general on the Scary Mommy Confessional, an anonymous message board. The Confessional offers three ways for readers to interact with a confession, by clicking on buttons labeled Like, Hug or Me Too!. We found that Likes were the most popular reaction, and overall the confessions veered more toward negative sentiment. Extreme intensity of sentiment (highly positive or negative polarity) were eschewed in favor of moderate sentiment value. We also found that the content of the confessions frequently contained intimate content, displaying the Ancient Mariner (passing stranger) effect, where people willingly disclose intimate content to strangers. Emotional contagion was also observed, where the intensity of sentiment affected the sentiment of new confessions and created clusters of emotion with similar sentiment. Among future directions, we hope to understand expression of various emotions in both non-anonymous and anonymous social networks for various niche demographics to better understand user behavior online. Our findings shed further light on anonymity-induced online behaviors of mothers and have potential implications in the design of anonymous networks featuring user interactions for various network demographics.

"ABSTRACT"

We propose an analytical methodology to solve a tri-level mathematical model developed to protect a given number of rail intermodal terminals such that the effect of disruptions is minimized. More specifically, a tabu-search algorithm is combined with a decomposition-based technique to solve the tri-level model. The proposed methodology is used to solve and analyze problem instances generated using the realistic infrastructure of a railroad operator. We also highlight the computational efficiency of the proposed methodology, and compare it to the existing techniques.

KEYWORDS: Intermodal transportation, Mixed-integer program, Fortification, Metaheuristic, Decomposition

INTRODUCTION

Intermodal transportation, which exploits the synergy of at least two transport modes, has experienced phenomenal growth over the last two decades. This has been attributed to competitive pressures on global supply chains, and the increasing demand for new service patterns driven by ocean carriers as well as the globalization of industry. Rail-truck intermodal transportation, which combines the accessibility advantage of road networks with scale economies associated with railroads, is attractive to shippers for two reasons: *first*, the significant reduction in both delivery and lead-time uncertainty because of the schedule-based operation of intermodal trains; and *second*, a more efficient and cost-effective overall movement ensured by combining the best attributes of the two modes.

Intermodal transportation plays a vital role in the economic growth of North America, and hence the associated infrastructure could be deemed critical, i.e., systems and assets whose destruction (disruption) would have a crippling effect on security, economy, public health, and safety (DHS, 2018). Disruptions could be induced by nature such as Katrina and Rita in 2005 that could crippled the nation's oil refining capacity (Mouawad, 2005), or man-made threats such as the 9/11 terrorist attacks in the United States (Scaparra and Church, 2012). One of the ways to mitigate the impact of disruption is to design supply chain configuration, so that it operates efficiently (i.e., at low cost) both normally and when a disruption occurs (Snyder et al., 2006). Alternatively, one could attempt to improve the reliability of existing infrastructures by using fortification models to identify optimal strategies for allocating limited resources. This

study makes use of the latter technique to preserve the functionality of the rail-truck intermodal transportation system. More specifically, we consider disruption only at intermodal terminals and formulate it as a tri-level problem, in which the defender (i.e., network owner) has a limited number budget to protect or harden some of the terminals, an attacker has enough resources to interdict some of the un-protected terminals, and finally the defender (i.e., network operator) attempts to meet demand on a reduced intermodal network.

The rest of the paper is organized as follows. The relevant literature is reviewed in the next section, followed by the problem description and assumptions. We then outline the tri-level mathematical model, and the solution methodology. Finally, the analyses of the realistic problem instances before the conclusion.

LITERATURE REVIEW

Given the focus of this study on fortification and interdiction of rail-truck intermodal terminals, the relevant papers can be organized under four streams: protection and fortification; disruption of networked system; metaheuristic applications in interdiction-fortification; and, rail-truck intermodal transportation systems.

Literature Review on Protection and Fortification

Planning and is an enormous exercise especially given the complexity of a typical intermodal infrastructure, the interdependencies among various components (Liberatore et al., 2012), and the prohibitive cost. A majority of the works has approached the fortification problem, within the facility location domain, as a leader-follower game (Stackelberg, 1952), in which the defender is the leader and the interdictor the follower, and modeled as bi-level programming problems (Dempe, 2002). Furthermore, it is assumed that the attacker is going to make the most disruptive decision, and hence worst-case scenarios are modeled (Scaparra and Church, 2008). To ease the complexity of the bi-level programming problems, Church and Scaparra (2007) and Scaparra and Church (2008) proposed single-level formulations, and an explicit enumeration technique for solving the problems. Uncertainty associated with the attacks has been incorporated by attaching a probability of successful attacks on facilities, and by making use of a probability distribution for estimating the number of facilities that could be attacked (Liberatore et al., 2011). While the concept of investing protection measures to reduce the recovery time of the system has been investigated in Losada et al. (2012), fortification within a system of capacitated facilities has been recently investigated by Scaparra and Church (2008).

Literature Review on Disruption of Networked System

Peer-reviewed works on the disruption of a networked system, on the other hand, have primarily focused on the analysis of risk (i.e., identifying the most critical components of a system) through the development of interdiction models. The effect of interdiction on the maximum flow through a network is studied by Wood (1993), while Lim and Smith (2007) made use of a variant of multicommodity shortest path problem to investigate the impact on revenue from arc interdictions. The concept of fortification against worst-case losses for network models has been discussed in Brown et al. (2006), wherein a tri-level optimization model to represent fortification, interdiction, and network flow decisions (i.e., defender-attacker-defender) was developed. Finally, a number of applications making use of this framework appeared in the literature such as power grid (2014), and water supply (2007). It is important to note that

intermodal transportation is a relatively nascent area, and there is no peer-reviewed work relevant to intentional disruption.

Literature Review on Metaheuristic Applications in Interdiction-Fortification

Though metaheuristic solution techniques have been around for over four decades, we are aware of only three peer-reviewed efforts within an interdiction-fortification setting. Aksen et al. (2013) studied the p-median problem for the planning and protection of critical facilities, and suggested three solution methods including a two-phase tabu search algorithm to solve the resulting bi-level program. Kecici et al. (2012) applied a tabu search-based solution methodology to analyze the design of a public service facility network in the presence of possible terrorist attacks. Finally, Cheng et al. (2016) examined applications of three metaheuristic techniques (i.e., tabu search, genetic algorithm, and simulated annealing) to the interdiction-fortification problems and showed the efficiency of hybrid techniques.

Literature Review on Rail-Truck Intermodal Transportation System

Although rail-truck intermodal transportation has been an active research area over the last two decades (Macharis and Bontekoning, 2004), the discussion about disruption is still in its infancy. We are aware of only two peer-reviewed works. In Sarhadi et al. (2015), an arc-based formulation with no capacity constraints at intermodal terminals was proposed, and it was demonstrated that smaller problem instances could be solved easily using commercial solvers. However, larger problem instances involving path-based capacitated formulations challenged the capability of the existing optimization packages, and thus necessitated the development of a decomposition-based solution technique (Sarhadi et al., 2017).

PROBLEM DESCRIPTION

The protection planning of rail-truck intermodal transportation problem entails interaction amongst three players, i.e., network owner, the interdictor, and the network operator –wherein each is in a different hierarchy (Figure 1). At the highest level, the network owner tries to minimize the cost of using the system by fortifying a limited number of intermodal terminals. Note that this is possible only if the owner knows the cost of the worst-case attack by the interdictor, and hence the latter's problem is a part of the former's. Next, the interdictor wants to maximize the cost of using the system by attacking a limited number of (unprotected) terminals, which is achieved through complete information about the network operator's problem. Finally, following interdiction, the network operator has to meet customer demand using the available intermodal terminals and (reduced) train services.

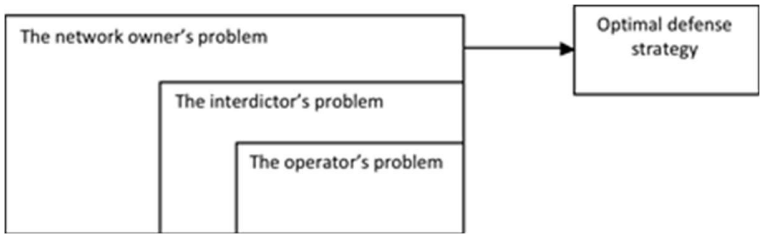

Figure 1: Hierarchical structure for the protection planning

For expositional reasons, we note that a rail-truck intermodal transportation system comprises three processes: (i) inbound drayage, (ii) rail-haul, and (iii) outbound drayage. Thus, the

network operator endeavors to find the minimum-cost way to satisfy customer demand, given the connections between the available intermodal terminals and shippers/receivers, and the pre-defined intermodal trains. In an effort to ensure feasible solutions (i.e., demand is satisfied), direct trucking is permitted between each shipper-receiver. Note that the central question about allocating limited resources such that post-disruption functionality of the intermodal infrastructure is preserved is fairly complex, in large part due to the interaction amongst the three players.

MATHEMATICAL MODEL

In this section, we present the mathematical model of the optimal fortification problem.

Sets

I Set of shippers, indexed by *i*
J Set of receivers, indexed by *j*
P_{ij} Set of intermodal paths between shipper *i* and receiver *j*, indexed by *p*
K Set of intermodal terminals in the network, indexed by *k*
P_{ij}^{k} Set of intermodal paths between shipper *i* and receiver *j* which uses intermodal terminal *k*
V Set of intermodal train services defined on the network, indexed by *v*
L^{v} Set of service legs for train service *v*, indexed by *l*
$S^{l,v}$ Set of intermodal paths using service leg *l* of train service *v*

Variables

X_{ij}^{p} Number of containers using intermodal path *p* between shipper *i* and receiver *j*
XT_{ij} Number of containers using direct trucking service between shipper *i* and receiver *j*
N^{v} Frequency (or the number) of trains of type *v*
$z_k = \begin{cases} 1, & \text{if terminal } k \text{ is protected} \\ 0, & \text{otherwise} \end{cases}$
$y_k = \begin{cases} 1, & \text{if terminal } k \text{ is interdicted} \\ 0, & \text{otherwise} \end{cases}$

Parameters

W Maximum number of terminals that the network operator can protect
R Maximum number of terminals that the interdictor can disrupt
C_{ij}^{p} Cost of transporting one container from shipper *i* to receiver *j* on intermodal path *p*
CT_{ij} Cost of sending a container using truck on the shortest path from shipper *i* to receiver *j*
T_{ij}^{p} Expected travel time from shipper *i* to receiver *j* on intermodal path *p*
T_{ij} Delivery time using truck on the shortest path from shipper *i* to receiver *j*
$\bar{T}_{ij}$ Delivery due date promised by shipper *i* to receiver *j*
D_{ij} Number of containers demanded by receiver *j* from shipper *i*
PC_{ij} Penalty cost per container per unit time between shipper *i* and receiver *j*
α^{v} Capacity of train service *v*
FC^{v} Fixed cost of operating train service *v*
U_k Capacity of intermodal terminal *k*

(P) depict the tri-level optimization model that could be used to make protection planning decision. The *outer* level problem belongs to the network owner whose objective is to minimize total cost by fortifying a given number of intermodal terminals. Constraints sets (3) enforce the binary nature of the terminal fortification decision. The *middle* level problem belongs to the interdictor who intends to maximize the total cost of using the system. Constraints sets (5) depict the finite resources available for interdiction or disruption of intermodal terminals, whereas (6) represents the binary nature of the interdiction decisions. Constraints sets (7) combine the decisions of the network owner and the interdictor by prohibiting the disruption of fortified terminals. Finally, the *inner* level problem belongs to the network operator who intends to minimize the total cost of using the system. Note that this is a variant of the multi-commodity flow problem with capacity, delivery time, and penalty cost considerations. The objective function, i.e., (8), will capture the overall cost of moving shipments using the rail-truck intermodal option, any direct trucking service if applicable, the penalty costs for late deliveries, and the fixed costs of running different intermodal trains in the network. Constraints sets (9) ensure the demand is satisfied either using the intermodal option or through direct truck service. Constraints sets (10) enforce the capacity at various terminals in the network, and states that the interdicted terminals cannot be a part of different paths to meet demand. Constraints sets (11) determine the number of intermodal trains of a specific type needed in the network. Finally, the sign restrictions are imposed through constraints sets (12) to (14).

SOLUTION METHODOLOGY

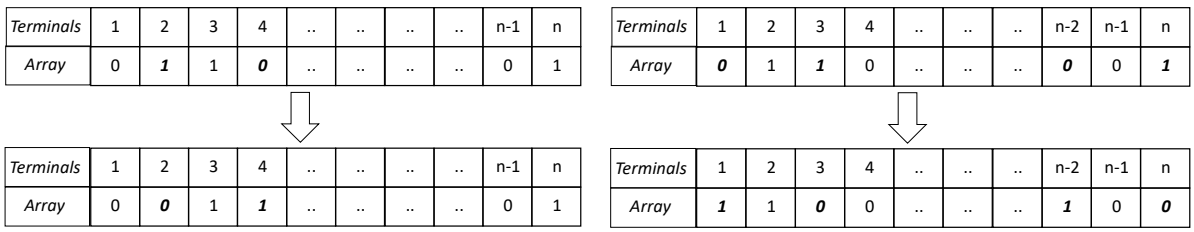
The solution methodology for **(P)** entails a metaheuristic-based technique to solve the outer level problem (i.e., the network operator), and a decomposition-based approach developed earlier in the literature (Sarhadi et al., 2017) to solve the attacker-defender sub-problem (i.e., the interdictor and the intermodal operator).

Tabu Search for the network operator's problem

We chose tabu search (Glover, 1989) over other local searches (such as simulated annealing, variable neighbourhood search) due to its demonstrated success on problems involving dispatching n objects into k sets within a constrained setting, and some recent applications in interdiction-fortification. We invite the reader to refer to Galinier and Hertz (2006), Cordeau and Laporte (2005), Zufferey et al. (2008), and Aksen et al. (2013) for successful applications. We briefly outline the different steps of tabu search adapted for **(P)**, and then explain the execution of the metaheuristic-decomposition algorithm.

a) Encoding: Each feasible solution for the defender's problem is represented by a binary vector of length n, where n refers to the total number of terminals in the network. If a given cell has value of 1, then the corresponding terminal is completely fortified. If the network operator can defend a maximum of W terminals (i.e., receive a value of 1), then the remaining (n-W) positions in the vector will receive a value of 0.

b) Neighbourhood: In order to generate a neighbouring solution of the current solution, we propose two distinct schemes: 1-swap; and, 2-swap. Figure 2a depicts the 1-swap transformation of the current solution, which for a maximum of W fortifications amongst n terminals will require evaluating $\binom{\mathbf{W}}{\mathbf{1}}\binom{\mathbf{n-W}}{\mathbf{1}}$ transformations. Figure 3b shows the equivalent representation of 2-swap transformation, and would entail evaluating a total of $\binom{\mathbf{W}}{\mathbf{2}}\binom{\mathbf{n-W}}{\mathbf{2}}$ transformations.



(a) 1-swap transformation (b) 2-swap transformation

Figure 2: Neighbourhood generation

c) Tabu tenure: The complete exploration of the neighbourhood of the current solution constitutes an iteration. The iteration at which a move is made is noted, and a condition is added to forbid the reverse move for four iterations of the algorithm. It should be clear that when a swap is happening, the most recent swap displaces the oldest swap on the tabu tenure list, and that the latter becomes available for possible transformation. Hence, one could think of the proposed tabu tenure technique as a first-in-first-out queue with a capacity to hold four recent moves.

d) Stopping condition: The algorithm stops either when the number of iterations reaches 10, or if there is no improvement in the solution in 4 consecutive iterations.

Decomposition procedure for the attacker-defender sub-problem

For a given solution generated through tabu-search, all the neighbors are examined by solving the resulting attacker-defender sub-problems. We briefly outline the solution technique for each sub-problem, and invite the reader to consult Sarhadi et al. (2017) for complete technical

details. In the first step, the network operator's problem is solved to determine the routing plan and the optimum number of intermodal train services, wherein the latter are integer valued. The output of sub-problem (SP) becomes the parameters used to build the master-problem (MP), which is a single level interdictor's problem.

SP and MP would be solved iteratively to find the optimum interdiction at each node of the search tree. More specifically, the SP and the MP are determining the upper bound and lower bound of the algorithm, respectively. At the beginning, the upper bound is set to positive infinity and the lower bound is set to negative infinity. Then, the SP is solved and it updates the upper bound and also provides the train flow information to the MP. Subsequently, the MP will be formed and solved thereby updating the lower bound. This process constitutes one-iteration of the algorithm. The algorithm continues until the lower bound and the upper bound become close enough or the maximum number of iterations is reached. However, to make this more explicit, we next outline the general steps involved in building the MP.

Step 1: Define three sets of dual variables corresponding to constraint sets (9) to (11) in **(P)**.

- ω_{ij}, β_k, and θ_l, respectively.

Step 2: Attach the dual of the network operator's problem to the interdictor's problem, and generate the following objective function:

- $Max_{y_k}\left(Max_{\omega,\beta,\theta}\left(\sum_{i\in I}\sum_{j\in J} d_{ij} * \omega_{ij} + \sum_{k\in K} u_k * \beta_k * (1-y_k)\right)\right)$

Step 3: Linearize each non-linear term in the objective function.

Each non-linear term of $\sum_{k\in K} u_k * \beta_k * (1-y_k)$ can take two values depending on the value of the binary variable y_k. It can be $u_k * \beta_k$ if $y_k = 0$, and it is zero if $y_k = 1$. Now, replace each $\beta_k * (1-y_k)$ by a new variable φ_k, and constraints sets (15) to (17) would ensure that φ_k would assume the desired values. Note that M is a large positive number.

$$\varphi_k \leq \beta_k + M * y_k \quad (15)$$
$$\varphi_k \geq -M * (1-y_k) \quad (16)$$
$$\varphi_k \leq 0 \quad (17)$$

CASE STUDY

In this part, we apply the proposed framework to a case study from the existing literature. Figure 3 depicts the intermodal transportation network of a Class I railroad operator in North America, and is borrowed from existing literature (Verma et al., 2012). We first provide the relevant details on the parameters used to solve the problem instance, and then analyze the results using four variants of the proposed tabu-search algorithm. Finally, we provide some managerial insights.

Estimation of parameters

The parameters used in the mathematical model were originally introduced in the literature (Verma et al., 2012; Sarhadi et al., 2015), and were estimated using publicly available information.

Cost: In the United States, trucks can travel at a maximum speed of 50 miles/hour, but due to lights and traffic an average speed of 40 miles/hour is assumed (Verma and Verter, 2010). Normally the drayage is charged in terms of the amount of time the crew (driver-truck) is engaged, and an estimate of $300/hour including the estimated hourly fuel cost is used. A

penalty cost of $40 per hour per container was used. As indicated there are two types of intermodal train services, namely, regular and express. Average intermodal train speed was calculated using the Railroad Performance Measure website (RPM, 2014), and was estimated to be 27.7 miles/ hour for regular, and 36.8 miles/hour for express service. Consistent with the published works, we estimated a rate of $0.875/mile for regular and $1.164/mile for express service. The hourly fixed cost of running a regular intermodal train is $500 per hour, which takes into consideration the hourly rates for a driver, an engineer, a brakeman, and an engine, which are $100, $100, $100, and $200, respectively. The express service is 50% more expensive at $750 per hour (Verma, 2012).

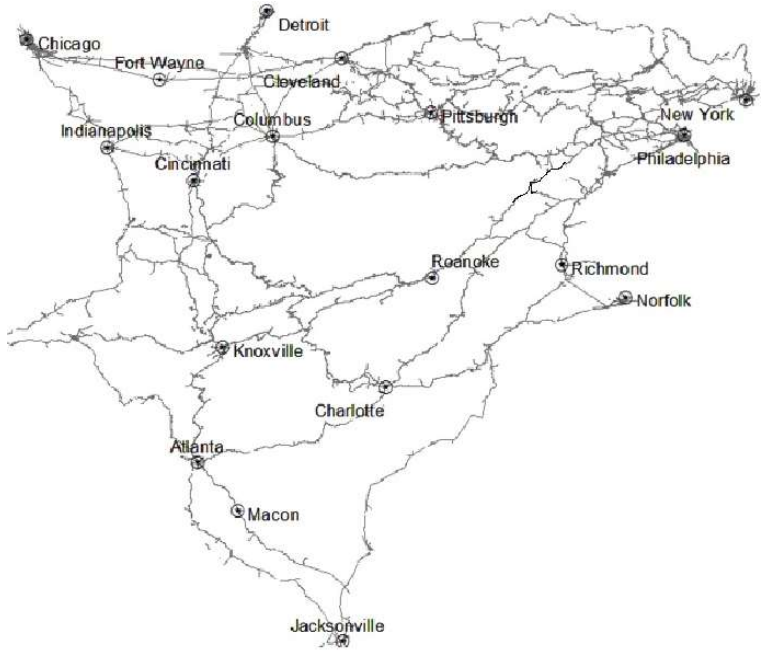


Figure 3: Rail-truck intermodal infrastructure

Due Dates: The distance (d in miles) between each shipper and each receiver was estimated in ArcView GIS (ESRI, 2008). Next, the travel time (in hours) was computed as d/40, where the denominator indicates the average speed of trucks. Finally, a constant of 15 was added to the travel time to obtain the delivery due date for each shipper-receiver pair.

Demand Level and Terminal Capacity: The innermost problem belonging to the intermodal operator was solved in CPLEX 12.6.0 (IBM, 2014) on the dataset used in Verma et al. (2012), and the solution was decoded to estimate the traffic volume through each intermodal terminal. It was assumed that the terminal utilization was 80%, and hence the terminal capacity is 1.25 times (i.e., 1 divided by 0.8) the traffic volume through each terminal. The demand level was set according to the dataset used in Verma et al. (2012). Finally, we set the optimality gap $\boldsymbol{\varepsilon}$ in the decomposition algorithm to 1%, and the maximum number of iterations to 10.

Analysis of the results

In an effort to find the best setting of the tabu search algorithm, we experimented with four variants of the algorithm. Each was coded in C# using CPLEX 12.6.0 concert technology on a PC with Core 2 Quad, 2.4 GHz processor with 4GB of RAM. The four variants are as follows:

- *Variant 1:* The tabu search algorithm starts with the output of the AD problem, i.e., the worst-case attack by the interdictor is the starting point. Under this setting, a 1-swap transformation is used to generate the neighbouring solutions.
- *Variant 2:* The tabu search algorithm starts from a randomly generated solution, followed by a 1-swap transformation to generate the neighbouring solutions.
- *Variant 3:* The tabu search algorithm starts with the output of the AD problem, followed by a 2-swap transformation to generate the neighbouring solutions.
- *Variant 4:* The tabu search algorithm starts from a randomly generated solution, followed by a 2-swap transformation to generate the neighbouring solutions.

To compare the performances of the proposed variants, forty-nine instances of the tri-level problems were solved, and the resulting solutions were analyzed for computational times and objective function values. It is important that, for variants 2 and 4, each problem instance was solved ten times to account for the random starting solutions, and the average results are reported. Thus, a total of 980 problem instances were solved using these two variants, and 98 for the other two variants.

Number of terminals							
Fortified	**Interdicted**						
	3	***4***	***5***	***6***	***7***	***8***	***9***
3	12.75	13.03	13.30	13.58	13.86	14.04	14.35
4	12.45	12.72	12.99	13.28	13.55	13.77	13.91
5	12.22	12.49	12.78	12.98	13.15	13.29	13.32
6	11.88	12.16	12.35	12.57	12.66	12.72	12.86
7	11.58	11.77	11.95	12.09	12.24	12.31	12.38
8	11.26	11.42	11.58	11.72	11.80	11.88	11.91
9	11.18	11.30	11.41	11.50	11.58	11.59	11.60

Table 1: Optimal objective function values ($ millions) using the four variants of tabu search

Table 1 shows the objective function values for the forty-nine problem instances (i.e., different combinations of terminals attacked/ defended) using the four variants of the proposed tabu search algorithm. It is important that each variant is able to find the optimum solutions for all problem instances, and thus any is effective. More importantly, each of the four could find the optimum solution for larger problem instances (i.e., the last two columns), which was not possible using the implicit enumeration technique prevalent in the literature (Sarhadi et al., 2016) where the computational time was capped at thirteen hours, and none of the larger problem instances could be solved optimally. We comment more on this when discussing Table 2.

It is interesting to note that for a given row, i.e., a fixed level of fortification, the cost imposed on the transportation infrastructure increases with higher levels of interdiction. On the other hand, for a fixed level of interdiction, the cost decreases as one goes down a column. The latter could be attributed to the effectiveness of the fortification measures because a higher level of fortification forces the interdictor to disrupt less important terminals wherein the cost of

disruption is not as severe. Table 2 depicts the computational times for the forty-nine problem instances for the four variants, and the exact solution technique.

For brevity, and also for expositional reasons, we report only the computational time to find the best solution for the four variants, and note that the total time until algorithm termination ranged between 700 seconds and 20,860 seconds.

Table 2: Computational time (x 10^3 seconds) for tabu search variants and exact solution technique

In an effort to underline the efficiency of the proposed metaheuristic-decomposition-based methodology to solve the tri-level problem, we note that the combination of the implicit enumeration and the exact solution could not solve larger problem instances in thirteen hours, i.e., 46,800 seconds (Sarhadi et al., 2017). This is also reflected in the Exact Solution Technique block in Table 2, where eighteen problem instances required more than thirteen hours to find the optimum solution. Under this technique the computational time increases both across a row and down a column. More specifically, for a given fortification level, the computational time increases rapidly with the increase in the interdiction budget because a larger number of patterns need to be enumerated thereby requiring more time (Figure 4). On the other hand, for a fixed level of interdiction, the computational time increases more rapidly for larger problem instances because of the explosion in the size of the tree to be searched (Figure 5).

It is encouraging to see that according to Figure 6, without loss of generality, for Variant 1 the computational time is fairly stable for a given fortification level, and exhibits low fluctuations. However, at a given interdiction level, computational time shows an increasing trend with regard to fortification resources (Figure 7), which is due to the fact that with an increase in the fortification budget the size of the network operator's feasible region increases. Consequently, by combining Figures 6 and 7, it is safe to say that the metaheuristic-based methodology is effective in reducing the computational burden of the problem compared to the combination of the implicit enumeration and the exact solution technique since with a fixed fortification budget, a non-increasing trend in the computational time is happening. Furthermore, according to Table 2, each variant beats the exact solution technique easily, and is a definitive improvement over the prevalent techniques to solve tri-level problems. It is clear that Variant 1 outperforms Variant 2 though both are based on 1-swap transformation, which also underlines the significance of the initial solution. The former variant exploited the results yielded by the attacker-defender sub-problem to start the search, whereas the latter made use of random starting points, which often resulted in reaching the best solution very close to the time when the algorithm terminated.

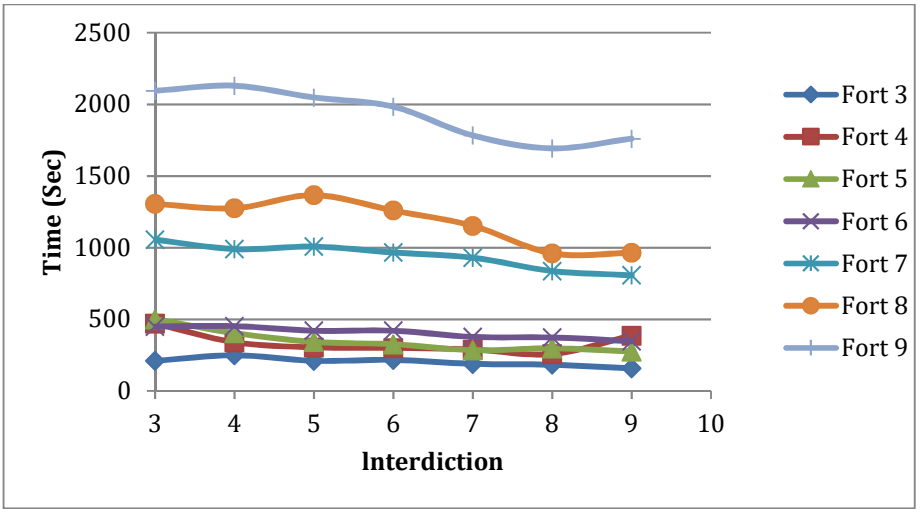

Figure 6: Computational time for Variant 1 at different Fortification levels

This is important, because as mentioned in the fortification-interdiction literature, although the solution to the attacker-defender sub-problem (i.e., critical terminals) may not be the optimal solution to the tri-level problem, we have shown that using the attacker-defender solution to initialize the tabu search algorithm will result in reaching the optimal solution much more quickly

than initializing with a random solution. This phenomenon also explains why Variant 3 outperforms Variant 4, both of which are using 2-swap transformation. Finally, comparing Variant 1 and Variant 3, both of which make use of the same initial solution throws light on the role of the neighbourhood structure on the computational performance. It is evident that 1-swap transformation is outperforming the 2-swap transformation, because the latter forces radical changes in the search process thereby delaying the convergence process. To sum, Variant 1 is the most efficient, and should be used for all computational experiments.

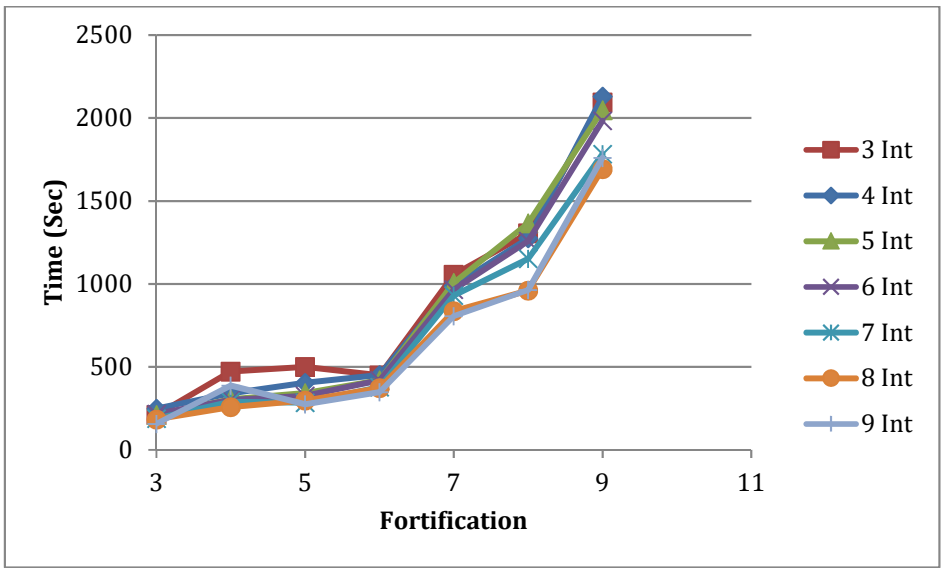

Figure 7: Computational time for Variant 1 at different Interdiction levels

Managerial Insights

Finally, we demonstrate the importance of having a sound fortification plan in place, and highlight the role such a plan plays in the smooth operation of a rail-truck intermodal transportation system. Table 4 depicts the average capacity utilization, the number of terminals at different levels of capacity utilization, and the percentage of demand that lost its connection to the intermodal network. As evident, when there is no attack or defense, i.e., the Base-Case, the average capacity utilization is 80% and all the demands are connected to the network.

For expositional purposes, we report results under two approaches: the optimal fortification (OP) using the proposed metaheuristic-decomposition-based methodology; and, fortification of critical terminals (CP) as identified by solving the AD sub-problems. It is clear that for every fortify/interdict combination, OP would yield a higher average capacity utilization and a lower demand with lost connectivity compared to CP. The results provide additional credence to the notion that the solution to the AD sub-problems will not provide the best protection plan. Note that as the number of terminals fortified/ interdicted increases, both the average capacity utilization and percent of demand that lost access to the network deteriorates under CP, but improves under OP. It is a clear indication that for larger networks, and higher values of fortified/ interdicted terminals, OP will yield significantly better solutions and thus should be the preferred approach for fortification decisions. Also, the percentage of the demand that lost its connection to the intermodal network is always lower in OP compared to CP. For both approaches, with the increase in the number of terminals fortified/ interdicted, the percentage of the demand that

loses the access to the network decreases and especially for the OP the most of the demand could have access to the intermodal network.

Number Fortified	Number Interdicted	Cases	Avg. Cap. Utz. (%)	Number of terminals (utilization)						% loss
				<25	<50	<65	<80	<90	<100	
0	0	*Base-Case*	80.0	0	0	0	10	7	1	0.0
3	3	*CP*	61.0	4	4	2	4	1	3	37.0
		OP	68.0	3	3	1	7	3	1	24.7

CONCLUSION

In this paper, we propose a methodology to solve a tri-level mathematical model developed to protect a given number of rail intermodal terminals such that the effect of disruptions is minimized. More specifically, we propose a tabu search algorithm to more efficiently solve the outer level problem that belongs to the network operator and was until now being solved using the implicit enumeration scheme of Scaparra and Church (2008). We then outline a solution methodology that combines the tabu search process with the decomposition technique developed in the literature (Sarhadi et al., 2017) to more efficiently solve the tri-level model. The proposed methodology was used to solve and analyze problem instances based on the realistic infrastructure of a class I railroad operator. In addition, the computational efficiency of the proposed methodology was highlighted in relation to the existing techniques in the literature.

Through numerical analysis, we can conclude three things. First, it is important to spend the finite resources judiciously to fortify a given number of intermodal terminals, since doing so would improve the post-interdiction performance of the remaining intermodal transportation system dramatically. Second, the proposed metaheuristic-decomposition-based methodology returns optimal solutions much faster than the exact techniques. This is a significant improvement over the existing techniques, including the implicit enumeration strategy proposed in Scaparra and Church (2008). Third, the 1-swap transformation that makes use of the output of the attacker-defender sub-problem yields optimum solutions in the quickest time, and thus should be the preferred variant of the tabu search process. In addition, the identification of the reduction rule facilitates further improvements to the computational performance of the algorithm.

There are a number of future research directions. First, the terminal capacities could be integrated to the model such that the remaining network would have enough capacity to meet the demand. Second, the design of intermodal train services could be explored such that loss in the connectivity, following interdictions, would not be dramatic. Finally, the current model can be augmented by adding uncertainty in the decision making process. For instance, in the absence of perfect information, the attacker may disrupt terminals other than the most important ones. Alternatively, the defender may not know the exact number of disruptions in advance, and may have to fortify the network against the expected number of disruptions.

An Anomaly in Yates' Correction for Continuity in the
2x2 Cross-Tabulation Chi-Square Test of Independence

John R. Dickinson
University of Windsor
Email: MExperiences@bell.net

ABSTRACT

Cross-tabulation and its accompanying chi-square statistical hypothesis test is among the most commonly applied types of analysis. Though not without subtle aspects, the basic analysis is straightforward. A chi-square test statistic is calculated and on the basis of the accompanying p-value the null hypothesis of independence is either rejected or not rejected. For 2x2 cross-tabulations it is commonly held that the original calculation of the chi-square statistic should employ Yates'(1934, 1984) correction for continuity. The present research highlights an anomaly that can occur with that correction.

KEYWORDS: Cross-tabulation, Chi-square, Yates' correction for continuity

Salvador T. Porras
Universidad Autonoma Metropolitana
Email: stp@xanum.uam.mx

ABSTRACT

Electronic commerce represents a very attractive business opportunity for enterprises because of its characteristics and potential advantages. This paper aims to analyze the diffusion of e-commerce in a group of large enterprises in the municipality of Iztapalapa, Mexico. A quantitative and content analysis of the web pages of the enterprises was conducted to establish the adoption and use of e-commerce.
This technological application is a convenient strategy for manufacturing and commercial enterprises. Likewise, the implementation of such a strategy implies an important investment for enterprises. It was found that the use of e-commerce has not been generalized in large enterprises in Iztapalapa.

KEYWORDS: Information technology, on line shopping, Information systems, electronic commerce, large enterprises

INTRODUCTION

Information technology is still in an evolving phase for many reasons, such as the grow of Internet users and broadband subscriptions; the increasing use of mobile technology to access the Internet; the diffusion of Social Networks sites; the need for government to provide services through e-government allowing online transactions; and the spread of cloud computing services (Fredriksson, 2013).
The development of digital economy around the world has been different in speed and level. On the one hand, the economical activities, digitalization and transactions can help to avoid barriers that allow a more inclusive development. On the other hand, it also means a division between well prepared countries to commitment and benefit of the digital economy, facing its risks and causing a digital gap with unprepared countries (UNCTAD, 2017).
In the same sense, enterprises digitalization shows the level of adoption and use of Information Technology (IT). The adoption of IT can be measure through standard indicators such as computer availability, access to Internet and others IT. While more activities within enterprises become digital, the firms will need to be on line and be visible for other consumer enterprises (UNCTAD, 2017).
In particular, Internet has created a new universal technological platform, which has flood the market with multiple applications for domestic and organizational use. Improving the enterprise possibilities to implement technological innovations in different levels and for diverse functions. Concerning electronic commerce (e-commerce), enterprises used patented systems to integrate data from their internal systems to communicate with their customers and commercial partners. Those systems were expensive and based on standard technologies, which only few

enterprises can reach (O'Brien & Marakas, 2007; Stair & Reynolds, 2006). However, this situation has been modified due to IT developments, the creation of web technology in 1992 and the introduction in 1996 of the security encoded SSL 3.0 (Secure Sockets Layer) (Fernandez-Portillo, et al., 2015). Currently e-commerce has been spread because Internet has become as a universal technology used for interchanging products and services, as it is a natural platform choice to develop e-commerce. It also represents an easy way at low cost for connection, business, and users.

E-commerce has evolved from a passive and static activity used by enterprises to show products and services catalogs, to a strategic tool with capacities to develop new businesses, to expand firms and to maintain close relationships with their customers and suppliers.

Because of e-commerce characteristics and the growing number of electronic devices used to search and buy products and services, enterprises have to adopt and implement this technology. The electronic commerce phenomenon continues to generate great interest among researchers. However, the development of e-commerce is uneven and unequal around the world, in particular Mexican organizations present a low level of growth. Attempting to gain an understanding of the adoption of e-commerce, this paper aims, in this first stage, to present the results of the descriptive and explorative research of how enterprise are starting to adopt and use e-commerce in large enterprises in Mexico City.

The paper is divided in various sections. First we present a theoretical framework that includes a definition of e-commerce, its advantages and disadvantages; as well as research topics about e-commerce adoption and multistage model for e-commerce implementation. Next an analysis of the actual situation of e-commerce diffusion in Mexican enterprises is reported, following by the methodology used to develop the research. The following section presents the findings obtained from data collection and an analysis is also included. Finally we present the conclusion of the research.

LITERATURE REVIEW

Electronic commerce

Following UNCTAD (2017:3), e-commerce "refers to purchases and sales conducted over computer networks, using multiple formats and devices, including the web and electronic data interchange and the use of personal computers, laptops, tablets and mobile phones of varying levels of sophistication". E-commerce implies the entire online process of developing, marketing, selling, delivering, servicing and paying for products and services commercialized on Internet (Fredriksson, 2013). E-commerce can include for example interactive marketing, ordering, payment, and customer support process through catalogs and auction sites (Guerrero Cuellar & Rivas Tovar, 2017).

There are different categories of e-commerce (O'Brien & Marakas, 2007; Stair & Reynolds, 2006):

- Business to Business (B2B) in which the participants are organizations.
- Business to consumers (B2C) where business develop electronic marketplaces to sell products and services to consumers.
- Consumer to Consumer (C2C) which involves consumers selling directly to other consumers.
- Business to Government (B2G) where the transactions are between business and government.
- Consumer to Government (C2G), which involves government offering services to consumers.

The advantages of using this technological platform include its universal use and the easy way to employ it, because electronic commerce is based on standards that all enterprises with different characteristics can use it (Fernandez, Hurtado & Peral, 2005). It can be used in any context where documents between organizations are interchanged. The web sites are available 24 hours a day, 365 days per year; products such as software, music, videos, books, for example can be distributed through Internet. Organizations can also use net to distribute information on products or services, for example: price, general characteristics, options, availability or delivering time.

Based on its own characteristics, e-commerce has also had an effect on other areas, such as, developing new channels for sells and marketing; interactive access to electronic catalogs of products and services; price lists; specific characteristics and publicity; uninterrupted technical support; customer support and after-sales services (Rios Ruiz, 2014).

There are multiple advantages for enterprises to use Internet for the buy and sell process; they can reduce transaction costs and delivering time for products, in particular the digital ones, for example, software, text products, images or videos. They can also speed up the flow and information of products, to improve customer support and to coordinate producers, suppliers and customers. Enterprises can also have a global presence, unlimited availability working hours, competitive increase, personalized products and services, remove of intermediaries, to offer products with digital format, new business opportunities, new products and services opportunities, new publicity forms, and a better customers' knowledge and inventory reduction (Guerrero Cuellar & Rivas Tovar, 2017; Fernandez-Portillo, et al., 2017; Rios Ruiz, 2014; Sojo Obando 2001).

Customers can also benefit from e-commerce, for example its more confortable to shop on line, they economize time and resources, there is a broader selection of products and prices; customers also might have enough information about merchandise and easy access to consumer reviews; stores are available 365 days per year; they can have personalize service based on previous purchases and geographical independence; and convenient home delivery (Chang, Kao & Jain, 2014; Sojo Obando, 2001).

However, the adoption of e-commerce can also imply many difficulties for enterprises. It represents a considerable investment in hardware and software; it needs special personal to attend orders; enterprises have to organize special logistic for delivering products; a financial sells cost; management of all site's visits and cost for publicity (Fernandez, Hurtado & Peral, 2005; Sojo Obando, 2001).

When enterprises decide to innovate, for example to adopt e-commerce, they have to realize that market must be ready for such technology; suppliers and customers should get familiar with these tools (McKeen & Smith, 2015). Technological infrastructure and complementary products and services must be available as well, for example, an effective and efficient communication network and associated software to take advantages of this technology. It is important to mention that many innovations fail because an organization's culture cannot sustain or take advantage of them (McKeen & Smith, 2015).

Therefore, before deciding to implement e-commerce, organizations must analyze diverse factors such as the possible benefits; the economical, technical, knowledge and personal requirements for the adoption. Organizations have to consider also, the characteristics of an innovation that influence adoption: relative advantage, complexity and compatibility (Rogers, 2003). Finally, they must to analyze if the decision to adopt a new innovation relates to the business objective, strategies and evaluate the impact that their use will have in the whole organization.

Adoption refers to the decision of individuals or organizations to make use of an innovation, different approaches to IT adoption can be found in the literature. One approach examines the relation between IT acceptance and its impact on the individual user, e.g. the decision made by an individual within an organization (Jeyaraj, Rottman & Lacity, 2006; Rogers, 2003; Venkatesh

et al., 2003). Another approach explains the overall impact of IT adoption within the organization itself (Frambach & Schillewaert, 2002; Jeyaraj, Rottman & Lacity, 2006).

On the stream of research which deals with technology adoption from the users' point of view, we can find a group of diverse factors associated with users' decision to adopt a technology, such as personal's attitude –based o values and beliefs-; personal norms–motivation- (Ajzen, 1991); usefulness and user friendliness (Davis et al., 1989); perceived usefulness (Venkatesh et al., 2003). The analysis of these kind of determinants has been also translated into the studies on individual level adoption of e-commerce, for example: customer perceived value, customer loyalty, perceived risk, perceived benefits, information security, satisfaction purchase intention, perceived usefulness, perceived easy of use (Chang, Kao & Jain, 2014; Jun & Yang, 2013; Lim, Lim & Heinrichs, 2014; Lu et al., 2013; Sharma et al., 2017).

Other studies focus on e-commerce from an organizational perspective. Studies analyze factors related to the adoption of e-commerce such as: organizational, innovation, technical, environment, country level, and knowledge (Kuan, & Chau, 2001; Fernandez-Portillo, Antonio, et al., 2015; Frasquet Deltoro, Molla Descals & Ruiz Molina, 2012; Merhi, & Ahluwalia, 2014; Panda & Das, 2016; Rodriguez-Ardura, Meseguer Artola & Vilaseca i Requena, 2008; Sepulveda Robles, et al., 2016; Thong, 1999; Wymer, & Regan, 2005). Various researchers conclude that some factors related with a successful e-commerce adoption are: firm's size, firm's age, products' characteristics, degree of innovation, degree of internationalization, internet marketing levels, regional economic-cultural differences, communication, industry, financial cost, technical competence.

Another research stream describes the history of e-commerce development (Fernandez Nodarse, 2013; Guerreo Cuellar & Rivas Tovar, 2006). Authors describe the first e-commerce models as the ones to use Internet as a virtual shop window to present their products, the main objective was to assure its presence in Internet. Later on e-commerce evolve to web 2.0 models where the main actor was the customer, in those sites it was possible to do sell and buy transactions through digital media. In a third stage, the e-business is developed; it includes applications and process that allow firms to do the whole commercial process by Internet. Finally some authors posit the idea of a new model, web 3.0, based on web site that uses 3D interfaces and artificial intelligence (Fernandez Nodarse, 2013).

It is possible to find some research focusing on the creation of models explaining the stages through which organizations have to move in order to adopt and implement e-commerce as part of its diffusion (Daniel, Wilson & Myers 2002; Guerrero Cuellar & Rivas Tovar, 2005; Montijano Guardia, et. al., 2002; Veciana Verges & Serrasols Torres, 2001). In that sense Guerrero Cuellar & Rivas Tovar (2005, cited by Andrews 2002) describe three stages as part of the selling process based on telecommunication: the first is the pre-sell stage where customer have access to firm's site and visualize their purchase history and status; the second one is defined as surfing and buying, where users can access the firm's site to search products in catalogs, to find products information, to select products or services and to purchase their merchandise; finally the integrative stage where the firm offers customers the possibility of integrating their buying- selling processes through the use of a complimentary software given by the seller.

Daniel, Wilson and Myers (2002) point stages to adopt e-commerce by SMEs, as they gather experience. In each stage firms develop applications and activities involved with this technology that works as a foundation for the next stage. In the first stage organizations start developing the first e-commerce services, activities related to e-mail communications with customers and suppliers, creating products and services databases to be published in the web site. In the second stage the web site functions with information created in the previous stage, there is electronic interchange of documents within and outside the firm. In the next stage an application has been developed to create and receive on line orders, e.g. the possibility to make digital transactions. In the last stage firms implement the whole e-commerce process allowing to buy products and services electronically, and to provide after-sales services.

Veciana Verges and Serrasols Torres (2001) and Montijano Guardia, et al., (2002) suggest also that firms start adopting Internet technology, including e-commerce by stages. According to Veciana Verges and Serrasols Torres (2001), the first stage includes information in the web site aiming to have presence in Internet; in the second stage firms translate some process to the web site, for example products' catalogs, to recruit personal and for customer service. In the last stage enterprises have the possibility to do transactions on line in their web sites.
In the same sense Montijano Guardia, et al., (2002) establish that enterprise's web presence can be classified in three stages: information web where organizations use Internet to diffuse information of themselves; transactional web, where firms incorporate diverse activities by using e-mail and questionnaires to query customers and to offer their products through this media. Operational web, where firms establish an interconnection with suppliers and customers in order to do electronic data interchange, as well as commercialize their products by Internet.

Multistage model for e-commerce

An e-commerce system requires that firms implement on line all the stages that customers usually experience in the sale cycle of life. That is why firms need to provide the tools for helping users to search and find the products they are looking for, to select the ones they are interested on, to negotiate the price, to choose the type and terms of payment, and to be aware of the delivering date. Once a customer has done the previous stages, firms proceed to complete the purchase order of the products and to make the payment; finally, the buyers receive the product and after-sales services (O'Brien & Marakas, 2007; Stair & Reynolds, 2006). Multistage model for purchasing on Internet includes search and identification, selection and negotiation, purchasing products and services delivery, and after-sales support. According to O'Brien and Marakas (2007) and Stair and Reynolds (2006), firms will be successful only if they include at least next elements in their e-commerce process:

- Access control and security in order to establish mutual trust and secure to make the electronic commerce transaction. Firms should incorporate authenticating users, authorizing access, and enforcing security features in their web site.
- Profiling and personalizing, once customers have gained access to the web site, profiling process can occur obtaining data on customers and their surfing, behavior and choices while on the website; these profiles are used to recognize each customer as an individual user and to offer a personalized point of view of the website, as well as for recommending products or services.
- Search management to help customers finding a specific product or service they want to evaluate or buy.
- Content and catalog management to develop, generate, deliver, update and save files with data and multimedia information of the web sites.
- Payment, usually by using a shopping cart where customers can add their products. Afterwards customers select a payment method and complete the purchasing.
- Workflow management to guarantee that firms' workflow operates properly in order to make the correct transactions, decisions and activities, with the correct data and to deliver the documents to the right employees, customers, suppliers and other business partners.
- Event notification, to respond the diverse activities in the e-commerce process, e.g. new customer's first website access, to payment and delivery processes, customer relationships and supply chain management activities.
- Collaboration and trading are support activities for vital collaboration agreements and trading services needed by customers, suppliers and other partners to accomplish e-commerce transactions.

Electronic commerce context

As we previously mentioned, the development and diffusion of IT have increased the number of Internet users as well as the way business has implemented electronic commerce. According to official UNCTAD statistics (2017) the international level o e-commerce includes business to business (B2B) and business to consumers (B2C) categories, the global electronic commerce in 2015 reach the $25,293 billions. The amount of B2C sells represented $2,904 billons, about ten percent of the global overall estimated. On the contrary B2B sells reached $22,389 billion (UNCTAD, 2017). China still represents the mayor B2C market of e-commerce ($617 billion), closely followed by the United States of America ($612 billions) (UNCTAD, 2017). However, the United States reported the mayor B2B market with $6,443 billions, followed by Japan ($2,382 billions) (UNCTAD, 2017). The ten biggest e-commerce markets reported include: United States, Japan, China, Republic of Korea, Germany, United Kingdom, Northern Ireland, France, Canada, Spain and Australia. No developing country was featured among the top ten lists.
For 2014 the Asia-Pacific market estimated a growth of 23%, been China (65%) and Indonesia (71%) the main sector' actors (Rios Ruiz, 2014). North America and East Europe would growth at 12% (Rios Ruiz, 2014).
In the case of Mexico, according to official data (INEGI, 2016), IT diffusion has had a constant growth, the number of computers users increased from 16.74% in 2001 to 51.25% in 2015; the number of Internet users grew from 7.95% in 2001 to 57.43% in 2015; and the number of mobile phone users were increased from 43.91% in 2009 to 71.46% in 2015.
According to Rios Ruiz (2014), enterprises started to connect to Internet in 1994 in Mexico and the number that has implemented e-commerce has increased constantly; the country is the second in Latin America after Brazil. Data from the Internet Mexican Association shows that the economic flow produced by e-commerce has multiplied by five since 2009 (24,500 million of Mexican pesos) to 2013 (121,500 millions of Mexican pesos) (AMIPCI, 2013). Data also shows that e-commerce has had a positive evolution in recent years (See Table 1), for 2014 the growth passed from 34% to 59% in 2015.

Table 1. Mexican e-commerce evolution (thousand of millions Mexican pesos)

	2009	2010	2011	2012	2013	2014	2015
Estimated value of the e-commerce market	24.5	36.5	54.50	85.70	121.60	162.10	257.09
Source: AMIPCI (2016).							

The AMIPCI (2016) study on e-commerce reports that shoppers from an international retailer have grown from 57% in 2015 to 60% in 2016, the United State was the main source country of enterprises where users buy the most (61%). The same research shows that three mayor categories of products purchased online are cloth and accessories (53% in 2015 an 2016), digital download (49% in 2015 and 46% in 2016), and event tickets (35% in 2015 and 37% in 2016) (AMIPCI, 2016). PayPal (62%), debit cards (51%); and personal credit cards (56%) were the preferred payment methods for online purchases.
Based on the previous data, we can observe that the use of e-commerce in Mexico is becoming more and more popular; nevertheless except for multinational firms or specific sectors few enterprises have taken advantage of this technology. Seeking to understand how enterprises are adopting e-commerce and how is its diffusion in developing countries, this research aims to analyze how firms are adopting e-commerce focusing on the analysis of the web sites and e-commerce sites in large enterprises in Iztapalapa, Mexico City.

METHODS

The research question for this research was ¿how e-commerce is diffused in Mexico through its adoption by large enterprises in Iztapalapa, México City? To answer the research question a descriptive study was conducted in order to determine the properties, characteristic and profile of a set of enterprises located in the region.

According to INEGI (2013), Mexico City is the most important city and the main economic region in the country. It represents the first state in the country contributing the most of the enterprises (8.15%) and the highest contribution to national GDP with 16.7%. Based on the economic census in 2014 (INEGI) the Iztapalapa municipality is the one with more firms established there (73,321), the one with the greater number of employees working there 320,196 and the most important contribution to Mexico City GDP with 4.9%.

The unit of analysis for this research is a group of 273 large enterprises established in the municipality of Iztapalapa, which already has a technological infrastructure that allows them to implement e-commerce. As a general data source for contact firms with 100 or more employees, a database of INEGI (2017) national statistics directory of economic units was used. A content and qualitative analysis of the web pages and e-commerce sites of the enterprises' sample was conducted from May to September 2017. The analysis includes surfing the enterprises' web pages and their e-commerce application already implemented. A static analysis content of both sites was also conducted, in order to review the general characteristics of e-commerce.

The first goal of the content analysis was to determine the level of Internet implementation as foundation of e-commerce adoption. Based on Veciana Verges and Serrasols Torres (2001) stage model to develop e-commerce, we created dichotomous variables to determine the specific stage where large enterprises of Iztapalapa web site are. For the content of analysis the presence or absent of several characteristics of the sites were identified and counted to establish each level o stage.

The first stage corresponds to the Internet presence or absence in the enterprises web sites. Associated with this level we included dichotomous variables related to the firm's inclusion in different electronics directories: corporates, sectorial, and job placement. Variables that show enterprises' general information such as: e-mail address, physical address, phone, age, enterprises' origin, name of the conglomerate, global site, language, kind of enterprise, contact, if the firm is social responsible, if it has any kind of certification, standards or normalization were also defined.

To determine the second stage of web site development we included the following dichotomous variables: general information of products or services, products or services catalogs, specific information about customers, products or services' searching, customer's link, suppliers' link, downloaded information, customer services' link, job placement link and a link for organization recruitment.

The last stage belongs to the possibility to make online transactions in the web page. In the study there are enterprises that have already implemented applications such as intranet, extranet and e-commerce. Thus, we included the following variables: online transactions, intranet, extranet, e-commerce, and category of e-commerce. In this stage enterprises allow users to make online commerce so we reviewed if the web pages include all elements of the multistage model of e-commerce such as search and identification, selection and negotiation, purchasing products and services, delivery and after-sales services. At this level we reviewed variables including: quote or budget solicitude, quote or budget online solicitude, online store access, data and register user, management content, profiling and products personalization, update shopping list, purchase order, payment, delivery method, refund policies and after-sales services.

Data collected from the web and e-commerce sites were coded before the statistical analysis. This analysis was made using JMP software. In order to present the results of this first stage of the research an exploratory statistics based on frequency distributions were used to obtain the characteristics of each variable included in the analysis.

RESULTS AND DISCUSSION

According to the national statistics directory of economic units there are 273 large enterprises registered in Iztapalapa (INEGI, 2015). The majority of the companies were in the manufacturing sector (57%), 27% were in the commerce sector and the remaining 16% in the services sector. In this municipality there were enterprises with more than 100 years old (9), others were established between 1931 and 1950 (25); it was found that the majority of firms were created between 1951 and 1980 (63); 44 firms were established between 1981 and 1997, and only 10 companies were created since 2001. The majority of the companies are Mexican (90%) and more than a half were part of a conglomerate (51%). The majority of them were wholesale firms (86%) and 14% were retailer companies.
It was possible to establish the telecommunication technology foundation related to web site adoption in large enterprises in Iztapalapa, by the number of enterprises with Internet presence in different stages. In relation to the first level of informative web adoption according to Veciana Verges and Serrasols Torres (2001), enterprises adopt this technology aiming to obtain presence in Internet and then include only general information (See Table 2).

Table 2 First stage of electronic commerce adoption: Information Web

Variable	Number of enterprises with	Number of enterprises without	Percentage of enterprises with	Percentage of enterprises without
Web page	227	46	83.15%	16.85%
E-mail	239	34	87.54%	12.45%
Corporate directory	265	8	97.97%	2.93%
Sectorial directory	252	21	93.30%	7.69%
Job placement directory	250	23	91.57%	8.42%
Visitors' register	75	198	27.47%	72.52%
Global site	61	212	22.34%	77.65%
Language	65	208	23.81%	76.19%
Event publicity	112	161	41.02%	58.97%
Contact	243	30	89.01%	10.98%
Certification/Normalization/Standards	160	113	58.60%	41.39%

Source: Own elaboration.

Some characteristics that can be observed in web sites reported that 88% of the firms had an e-mail compared to 83% enterprises that already have their own web site. This shows that organizations start using the Internet adopting an e-mail. Enterprises are interested in having presence in Internet by the development of their own web site or by been part of others' directory that are in Internet, such as corporate (97%), sectorial (92%), or as a job-placement reference (92%).
The majority of web site firms' did not registered visitors, only 27% did, losing the opportunity to have information of organizations or users than can return to the site and would be interested in

obtaining much more information about products or services. Only 22% of the web sites is global, that is they show the branch conglomerate, there are multinational enterprises which their sites show the same information nevertheless the country or region were the visitors are. No matter the origin of the firms the 76% of the sites can display the information in English, probably because is a key element to start internationalizing or reinforcing their presence at a global level.
Firms in their web pages present general information, for example: event publicity (59%), contact information (89%), e-mail' contact information (77%). They also indicated if they have any kind of special certificate, or accomplish some norms (59%). Web sites analysis indicates that more than a half of the firms are socially responsible (53%).
The second stage of the e-commerce adoption process is relates to a procedure web that allow firms to include some elements or processes than can be done in the enterprises' web sites (See Table 3).

Table 3 Second stage of e-commerce adoption: Procedure Web

Variable	Number of enterprises with	Number of enterprises without	Percentage of enterprises with	Percentage of enterprises without
Products or service's description	232	40	85.29%	14.70%
Catalog	192	81	70.33%	29.67%
Search	153	120	56.04%	43.95%
Customer link	144	129	52.74%	47.25%
Supplier link	79	194	28.93%	71.06%
Public link	85	188	31.13%	68.86%
Applications	79	194	28.93%	71.06%
Customer service link	150	123	54.94%	45.05%
Job placement	42	231	15.38%	84.61%
Recruitment solicitude	40	233	14.65%	85.34%

Source: Own elaboration.

The majority of the sites has already included products and services description (85%), as well as an electronic catalog of their merchandise (70%). It is also possible for visitors to search specific products (56%), to show specific communication address to customers (69%), as well as direct link to customers (53%), suppliers (29%), or general public (31%). In the same sense, but with minor percentages of firms, the user can download applications, technical manuals or complement documents of products or services (29%). The sites also have a special link for customer service (55%). Another process that companies are including in the web site is publicity of their job placement (15%), and in some cases a questionnaire for on line recruitment (15%).
In this stage it was visible that firms start establishing some tools to have bidirectional communication with the visitors, in order to have a channel to obtain in particular feedback of their actual customers or potential customers. Also, that allows to make easier some product's searching or selection for traditional commerce or at least to request an online quote or budget.
The third web site stage is related to transactional characteristics, e.g. in this level firms already incorporated process in order to have electronic transactions in the web site (See Table 4).

Table 4 Third stage of e-commerce adoption: Transactional Web

Variable	Number of	Number of	Percentage	Percentage of

	enterprises with	enterprises without	of enterprises with	enterprises without
Transactions	56	217	20.51%	79.48%
Intranet	93	180	34.06%	65.93%
Extranet	69	204	25.27%	74.72%
E-commerce	53	220	19.41%	80.58%
Source: Own elaboration.				

In the third stage of e-commerce adoption, 21% of the sites included the option to make diverse electronic transactions; in some cases they include applications, which imply another level of function such as intranet (34%) and extranet (25%) implementation.

At this level we found 53 enterprises that have already adopted e-commerce, which represents 19% of the sample. The majority makes business-to-business e-commerce (84%) and 26% business to consumers (O'Brien & Marakas, 2007; Stair & Reynolds, 2006).

From this set of enterprises, 51% were in the manufacturing sector, 41% in the commercial sector and the rest 8% in services. Regarding to the age of firms, 7 organizations have more than 100 years operating, and they have already implemented e-commerce. In the web sites that include their foundation year, it was found that 2 enterprises established before 1950, and 17 created between 1981 and 1997 have already adopted e-commerce. It is remarkable that none of the youngest organizations founded after 2001 (10) have adopted e-commerce yet. Analyzing the firms' age, results show that enterprises with more experience, established and with a branch presence will be able to offer their products and services on line, compared with young enterprises.

The majority of this group of enterprises was Mexican (92%) and 19% operate in a global site. Nearly half of the firms were part of a group of enterprises (47), assuring that online selling operations were uniform for all the subsidiaries.

As Sojo Obando (2001) indicates, e-commerce adoption requires an important investment in hardware and software; therefore it could be easier for those firms that have a technological foundation as well as technological innovation expertise the possibility to adopt e-commerce. Research results show that the set of organizations that have adopted e-commerce, they have already adopted other technologies such as intranet (80%) and extranet (74). The previous applications required complements for e-commerce use as the multistage model indicates about the importance of interconnection and communication between different areas of the enterprise involved in the purchase and sale process (O'Brien & Marakas, 2007; Stair & Reynolds, 2006). In the same sense, it will be easier for those enterprises, which are part of a group of companies to share and adopt new technologies.

An electronic commerce system requires that organizations also have an Internet platform to implement a multi stage model, in order to make possible for users to carry out the sale cycle process online secure and efficient. The first element of this model is to have an e-commerce secure site with control access (O'Brien & Marakas, 2007; Stair & Reynolds, 2006). Research results show that 83% of the enterprises require users to register to get access the e-commerce site, and 79% requires visitors to fill a questionnaire. Based on that information, organizations will built the customer profile, and personalize the site for each one of them. This first step implies an important task in order to collect customer data, analyze their behavior and to make recommendations for future visits based on their profile and likes (Rios Ruiz, 2017; Sojo Obando 2001). It is important to have this data, it result a great omission for those firms that do not collect them. Only 8% of enterprises did not have basic tools to make online shopping correctly, for example, they did not have a link to start the buying process or they did not have

the option for register visitors (17%), or neither they ask user's information (21%). These failures generate concerns on potential customers (Fernandez, Hurtado & Peral 2005).
The web site for e-commerce has to include a tool to manage the content of products and services, to allow buyers finding and selecting products and services, as well as to establish the price of the purchase, to look the general characteristics, and eventually update their order. The majority of enterprises (91%) has a management content and a catalog to allow visitors to make the purchase; 58% of the sites allow buyers to personalize products, taking advantage of the e-commerce benefits (Fernandez Portillo, et at., 2017; Sojo Obando, 2001). Once users have selected a product they can add it in the shopping cart (96%). In the same sense in the 91% of the web sites, visitors can modify and update their purchase before they pay it (O'Brien & Marakas, 2007; Stair & Reynolds, 2006).
After that, the system needs to include everything about the payment, e.g. when the customer is ready to carry out the purchase, the 96% of the web sites produce a purchase order and show the payment options, to finish the purchase. In the majority of the web sites the payment is online (97%), with credit or debit card (42%) or by PayPal (55%). The whole process was supervised through the different areas and employees of the company (O'Brien & Marakas, 2007; Stair & Reynolds, 2006). The use of secure payment methods such as, credit or debit card, or pay pal allows customers to purchase having a support of a financial institution and if necessary, to make complaints (Montijano Guardia, et al., 2002; Rios Ruiz, 2017).
An advantage of e-commerce is to avoid the need for customer to buy somewhere else (Fernandez Portillo, et al., 2017; Rios Ruiz, 2017; Sojo Obando, 2001), so one element of the multistage model determines the option for delivery the product; 74% of the enterprises send the order by traditional messenger company and 26% deliver it directly in the enterprise. Results show that 94% of the enterprises only have domestic transactions, wasting one of the e-commerce advantages that allow firms to have a global presence (Rios Ruiz, 2017; Sojo Obando 2001). Maybe because the delivery cost is high, or because of the characteristics of the products or services firms probably consider not financially convenient their internationalization. Another aspect to consider are international regulations, not all products or services are able to be traded internationally some require particular permissions or simply are for internal consumption.
In the e-commerce transactions the possibility to return a product is very important, the 62% of the firms have refund policies, but the rest 38% do not have that option which discourages the use of this application (Fernandez Portillo, et al., 2017; Rios Ruiz, 2017).
The last stage in this process is the after-sales services, which allows enterprises to interact with their customer, establishing a new communication channel (Fernandez Portillo, et al., 2017; Rios Ruiz, 2017; Sojo Obando 2001). This stage represents a key element compared to traditional commerce; 62% of the firms have this option in their web sites. Finally a relevant particularity in the development of this technology is security of the commercial transaction, while the majority of the firms (80%) has a secure web site, 20% did not. This element probably limits the e-commerce because customers more often are paying attention in the secure elements of online transactions (Fernandez, Hurtado & Peral, 2005).
Research results indicate that although adoption and diffusion of e-commerce are constantly growing in developed countries, in countries like Mexico its implementation is still low only 19% of the large enterprises of Iztapalapa are using this technology.
As O'Brien and Marakas (2007) and Stair and Reynolds (2006) posit, e-commerce is general and standard technology that any kind of organization can adopt; we found firms that have adopted e-commerce in the three sectors, practically half of the manufacturing firms have implemented it, a bit less than half of the commercial enterprises (42%) and few services firms (8%). For firms in commerce sector the use of this application could be a natural step to translate their operations to e-commerce.

CONCLUSION

Despite receiving much attention, e-commerce adoption at the global level remains quite low (Merhi & Ahluwalia, 2014). The results allowed us to determine the level of development in the case of web sites of a set of large enterprises in Iztapalapa from e-commerce adoption point of view in this region of Mexico City. Even though the 83% of firms have already an Internet information web site, firms need to continue developing it in order to pass to the next stage of procedure web and transactional web. Firms have to keep working in their web site development in order to include new information and more procedures to achieve the final adoption of e-commerce.

Based on the research results, we obtained a whole outlook of IT diffusion in a group of enterprises, in particular about e-commerce adoption; even though adopting is still low because firms have not yet taken advantages of its multiple benefits. Although e-commerce diffusion in Mexico has grown in the last years according to statistics (AMIPCI, 2013, 2016), its diffusion is still low as the 19% of large enterprises in Iztapalapa have adopted e-commerce. Inclusive in some cases this application has not included the adequate security features, causing that potential customers do not establish commercial relations with enterprises.

For those firms using e-commerce, they are taking advantages obtained benefits such as, the creation of new marketing and sales channels; the opportunity to access new interactive catalogs, price lists, and the alternative to personalize products base on each customers' needs; and have an after-sales services (Rios Ruiz, 2014; Sojo Obando 2001). Benefits that make organizations different from those not using this tools.

Additionally, e-commerce represents for enterprises an always-open window with unlimited timetable available to anyone, because of its permanent presence in Internet; therefore they would be more competitive, eliminate intermediaries and an increase customers' knowledge (Rios Ruiz, 2014).

It is important that before firms make the decision of adopting e-commerce, they have to consider the following key aspects: which one is the strategic objective that leads enterprises to adopt e-commerce; it is important to determine their price policies; enterprises have to reinforce all security features such as, payment, delivery and product characteristics; to know the customer profile; to establish a communication strategy (to have presence in Internet searching and key websites, links and banners, newspaper adds, specialized magazines, radio, television, personalized marketing and public advertising); to develop their web site (reinforce the electronic-commerce strategy with their own personnel, outsourcing others for design and implementation), delivery (sell products by Internet through intermediaries, invest in future) (Sojo Obando, 2001).

The research reported in this paper has allowed achieving its objective obtaining a general outlook of e-commerce adoption and diffusion in large enterprises in Iztapalapa as a first stage of this study; there is also a knowledge base for continuing in depth into the study of these technologies. In the second stage of the research a survey will be conducted to enterprises with e-commerce, aiming to study what are the organizational, technological and environmental factors associated with the adoption of these technologies, and to analyze the organizational experience of e-commerce usage, the benefits and risks obtained for it.

DECISION SCIENCES INSTITUTE

An empirical study of the application of Lean tools in U.S. industry

ABSTRACT"

Lean manufacturing involves implementing a variety of tools and practices for the 6 purpose of reducing waste and increasing an organization's overall productivity. This paper examines the application of lean tools in various U.S. industries to further clarify the impact lean processes may have on an American business's production and efficiency. The analysis of the information collected from the survey demonstrates how lean tools have influenced American industries and allows us to see which Lean practices contribute the greatest to overall company performance, as well as observe patterns in how company characteristics may affect the successful implementation of Lean processes**.**

KEYWORDS: Lean Process, Quality Management, Empirical study, US Industry, Continuous Improvement

INTRODUCTION

Lean Manufacturing

In today's world, high levels of quality and efficiency are essential to maintain a competitive position in both the domestic and global markets. In the mid-twentieth century, Toyota Motor Company developed lean manufacturing techniques to address their specific manufacturing shortcomings during an economic crisis, thus enabling them to remain competitive in the national and international markets (Sharma, Sachdeva and Gupta, 2017). Toyota's successful processes, now referred to as the Toyota Production System (TPM), were direct predecessors to what is now widely known as "Lean." Although Toyota's systems had proven especially successful for the company's individual goals, competitors did not exhibit particular interest in Toyota's processes until the oil crises of the 1970s, during which Toyota managed to remain competitive due to their world-class operating system (Holweg 2006). While many U.S. companies have successfully implemented Lean practices and experienced notable improvement in their processes and significant decreases in waste, many have still not reaped the full benefits of Lean tools.

Research Goal

Our intention with this research is to discover how many organizations are implementing lean practices and to what extent in order to observe the impact these practices are having on organizational performance.

Importance of Study

Considering that business success stories have repeatedly shown that Lean has significant positive impacts on the bottom line (Abdulmalek & Rajgopal, 2006). Lean thinking has proven its status as a significant stepping stone in achieving greater profits and enhancing competitive advantage. Adopting Lean is a culture change for any organization that previously utilized none of the Lean tools; therefore, it represents a greater movement towards a new and continually improving means of carrying out business activities.

The following section summarizes the relevant findings of our thorough literature review, identifying key variables and factors to consider in the questionnaire creation and analysis. Following the literature review, the research questions are posed and supported with evidence

from the preceding literature analysis. Thereafter, the methodology used is explained in detail, to be followed up by our analysis and results. The paper concludes with a short summary and discussion of the implications and limitations of our research.

LITERATURE REVIEW

Lean Manufacturing Variables

During an intensive examination of literature regarding lean manufacturing, we discovered a multitude of variables that earlier research either stressed as a contributor to successful lean implementation or claimed had no notable correlation to such practices. Shah & Ward (2007) identified 48 items, or identifiers, to use when measuring the crucial components of lean production. They produced a set of 10 scales to use for conducting empirical research that will help in the process of analyzing successful lean implementation in a wide array of companies and industries. More importantly, Shah & Ward (2003) identified key variables to take into consideration for lean implementation, including plant age, plant size, and level of unionization. We have incorporated these factors into our questionnaire to further explore the correlation between the variables and group the data according to the strongest correlations. In addition to these easily measurable variables, previous literature also stresses the importance of considering employee involvement, communication, understanding of the tools used, culture change, and education training (Alhuraish, Robledo and Kobi 2017; Marin-Garcia and Bonavia 2014; Prasad, Khanduja, Sharma 2016; Di Pietro, Mugion, Renzi 2013; Fullerton, Kennedy & Widener 2013; J. R. Alves and J. M. Alves 2015). However, the scales and identifiers provide no assistance without a thorough understanding of the concept of lean practices from the start, an issue that arose during the infant stage of lean's existence. Having awareness of the history of lean and its emergence from the Toyota Production System (TPS) gives today's manufacturers insight into the initial intentions for lean and a solid example of lean tools' ability to improve an organization's efficiency (Holweg 2006).

Selecting appropriate lean tools A key issue companies face when deciding to begin lean manufacturing processes is selecting the correct lean tools for their specific problem. Too often organizations choose inappropriate tools for the problem at hand, thus missing their chance to achieve maximum efficiency. Prior research has provided us with various selection processes and criteria to consider when collecting our data to determine whether or not companies have failed to successfully implement lean techniques due to an uninformed selection of tools. A huge component of lean manufacturing research consists of attempts to create a decision framework or formula that increases the likelihood of selecting the most appropriate lean tools for the production problem at hand (Amin & Karim 2013; Ramesh & Kodali 2011; Hines & Rich 1997; Mejabi 2003; Hodge, Ross, Joines & Thoney 2011; Alhuraish, Robledo & Kobi 2017).

Lean Manufacturing and Company Culture Effective lean systems require company-wide implementation in order to produce positive results, in other words, applying lean practices where they did not exist before means a change in a company's culture must take place (Prasad, Khanduja & Sharma 2016; Di Pietro, Mugion & Renzi 2013; Fullerton, Kennedy & Widener 2013; J.R.X. Alves & J.M. Alves 2015). For instance, lean practices often incorporate green ways of thinking to promote waste reduction. A company that previously did not operate

sustainably or “think green” may experience a major 26 culture shift within the organization as a direct consequence of adopting lean principles (Alves & Alves 2015; Prasad, Khanduja & Sharma 2016; Miller, Pawloski & Standridge 2010).
THEORETICAL DEVELOPMENT/MODEL

RESEARCH QUESTIONS

The research questions assessed through our survey are derived from the findings of the literature review. A recurring theme in the collected literature identifies the selection of specific lean tools and techniques as a major obstacle in achieving substantial results from Lean practices; therefore, we deem it necessary to assess the various Lean methods on an individual basis.
Process Improvement Practices

RQ1. Do process improvement practices positively affect organizational performance through elimination of waste?

Manufacturing Planning and Control Practices

RQ2. Do manufacturing planning and control practices positively affect organizational performance through aligning production and demand, eliminating waste and involving the workforce?

Human Resource Practices

RQ3: Do human resource practices positively affect organizational performance through involvement of the workforce and elimination of waste?

Supplier Relationship Practices

RQ4. Do supplier relationship practices positively affect organizational performance through integration of suppliers and elimination of waste?

Customer Relationship Practices

RQ5. Do customer relationship practices positively affect organizational performance through elimination of waste and alignment of production and demand?

METHODOLOGY

Developing the Questionnaire
In order to effectively analyze the implementation of Lean tools within U.S. industries across the nation, we developed a questionnaire intended to evaluate the level of implementation of individual tools and practices grouped together into five meaningful categories.
(1) Pilot Survey: we created and distributed a pilot survey as a means to test the effectiveness and relevance of the research variables we chose to consider, summarized in the five categories of the questionnaire mentioned above.
(2) Random Survey: Similar to the pilot survey, we distributed the final questionnaire to a broad range of organizations working in a wide variety of industries. Out of the 500 responses received, we ruled 236 as invalid due to incomplete responses or notably short completion times, leaving us with 264 valid completed surveys from which to draw our data.

Company Demographics
Collecting specific details of each company is crucial to our research, as it allows us to group the responses according to industry, company age, etc. Our company detail survey questions address

the following aspects of the surveyed organizations: (1) Area of work at the organization; (2) general industry of the company (service or manufacturing); (3) company's annual revenue (USD); (4) company size by number of employees; (5) specific industry of business (i.e. automotive, food, etc.); and (6) the ownership of the company (joint venture, state-owned, etc.) The results from these questions will enable us to analyze the collected data in categories to determine whether any of these characteristics demonstrate an influence over the success of Lean implementation.

Levels of Lean Implementation

To measure the extent of implementation of Lean in each organization, we assessed the 5 categories of Lean practices (PIP, MPC, HRP, SRP, CRP) in individual questions to receive the most specific responses. Each question gauges the level of implementation by employing a Likert scale from 1 to 5, in which 1= "Complete Implementation"; 2 = "Extensive Implementation"; 3 = "Some Implementation"; 4 = "Little Implementation"; 5 = "No Implementation." The following paragraphs detail the tools and practices assessed in each Lean category.

The first category focuses on tools that affect Process Improvement Practices (PIP). This includes 10 different tools and techniques that are intended to streamline and remove waste from any kind of business process. These include: Kaizen/Continuous Improvement, 5S, Setup time reduction, Cellular Manufacturing, Continuous Flow, Equipment Layout, Product Design Simplicity, Error Proofing Equipment (poka-yoke), Total Preventive Maintenance (TPM), and Analysis tools (5Whys, Pareto charts, etc.) The second category of Lean covers Manufacturing Planning and Control practices (MPCP) which includes 10 practices that relate to this area of business operation. These methods include: Levelled production, kanban/pull production, daily schedule adherence, small lot size, visual management, value stream mapping, takt time, statistical process control (SPC), standardized work/qualification, and plant layout reconfiguration.

While the first two categories of practices relate primarily to the efficiency of business processes, the last three categories focus heavily on the human components of any business operation, including internal human resources, suppliers and customers. The third category on the survey corresponds to human resources (HRP), listing five Lean human resource practices for survey respondents to rank. These 5 are: group problem solving, cross training/flexible workforce, cross functional teams, employee involvement/empowerment, and workforce commitment. The fourth category addresses four components of supplier relationship practices (SRP) including: JIT delivery, supplier quality level, supplier involvement in quality improvement program, supplier involvement in product design and development. The last of the five categories considers Customer Relationship Practices (CRP), and is divided into 5 different common practices that promote Lean business operation. These practices include: customers provide feedback on quality and delivery performance, customers are actively involved in current and future product offerings, customer frequently share current and future demand information with marketing department, we (the surveyed company) deliver products to our customers JIT, customers are involved in quality programs in our plant.

Each survey respondent is asked to rank the implementation of each tool/practice of each of the five categories in order to assess the relationships between the tools and methodologies in question and a business's overall performance. As a means to insure that the survey reaches the personnel with adequate skill sets to understand the terminology within the questionnaire, we

require that every recipient first answer a basic question regarding their current position within the organization. Based on their response to this question, they may or may not continue onto the rest of the survey. This question helps guarantee that those in the organization with the greatest knowledge of the company's current processes, as well as the language that accompanies Lean thinking, are the ones to fill out the survey, thus providing the greatest accuracy in response.

Green Supply Chain Management Practices

In addition to the Lean portion of the questionnaire, we included a second major section concerning the stage of implementation of Green Supply Chain practices, in an effort to collect data to both encourage and provide for future research in the field of Green Supply Chain Management. Since Lean is generally considered a "Green" method of conducting business, including this section in the survey may also provide evidence for a relationship between Lean and Green business practices (Prasad, Khanduja & Sharma 2017; Chiarini 2014).

This format of the section mirrors that of the Lean section, in that it is divided into 5 meaningful categories, those being: Internal Environmental Management practices (EMP), Green Purchasing practices (GPP), Green Customer Cooperation practices (GCCP), Investment Recovery Green practices (IRGP), and Eco-Design Green practices (EDGP). Each category lists the most common green practices, of which each survey recipient must rank their stage of implementation on a Likert Scale of 1 to 5, with 1 representing implementing successfully already and 5 representing not considering to implement. While the data collected from this portion of the survey are not considered the foci of our research questions, including these sections in the questionnaire may provide insight into relationships between Lean and Green practices and/or provide a foundation for future research.

ANALYSIS OF RESULTS

Description of the Sample

Survey Respondents: Position & Area of Work

The 264 completed surveys we received cover a wide range of organizations of various industries, ages, sizes, and areas of business. Although our research seeks to assess successful Lean implementation in U.S. industry in general, it is crucial to consider where our results are coming from and how that may shape and/or limit our overall results. Firstly, of the 264 survey respondents, 63% hold managerial positions in their company, 25% are directors, 8% are vice-presidents and 4% hold C-suite positions. These percentages are favorable, as managers and directors are most likely to have the most holistic understanding of the business processes with which they are involved, as well as how those processes fit into the greater context of their organization. Had the bulk of responses come from C-suite positions, their knowledge would mostly relate to the organization's overall strategic position, rather than the day-to-day processes that would have the most direct contact with the Lean practices under study.

In regard to area of work, 45% work in the engineering department, 32% in the quality management department, 15% in the logistics and/or distribution department, and 8% in the supply chain management department.

Organization Specifics

In regard to the demographic details of the organization's surveyed, we asked the size of their company in number of employees, specific industry type (i.e. automotive, food, etc.),

ownership type, and annual revenue to categorize the surveyed organizations and examine each categories relationship to organizational performance. Figure 3 displays the results from the question regarding size of company based on number of employees, showing that the largest portion of surveyed organizations have less than 500 employees, making up 34% of the sample. The next most common size is having greater than 10,000 employees, making up 29% of surveyed organizations.

The results of the question concerning the different specific industry types of each organization, which consisted of a wide variety of answers as the distribution of our survey did not discriminate against industry type.

About the ownership type, the results show that a notable majority of collected surveys come from private ownerships, making up 69% of the responses. This is important to note, as any results and conclusions drawn from the analysis will primarily be representative of organizations of this nature.

The percent distribution of the surveyed organization's annual revenue. The results here are in line with those of the size of industry, in that both ends of the spectrum are covered very well in the sample.

Descriptive Statistics & Measurement Model Testing

For the purpose of assessing the statistical make-up and reliability of our survey and collected responses, we constructed tables of each category of variables that displays the mean and standard deviation of the Likert scale results of each tool under study, the factor loading analysis results, Cronbach's alpha, alpha if item deleted, and the overall mean and standard deviation of all of the tools within that category.

Overall, the factor loading analysis of each tool and practice in all 5 categories indicated a factor loading (extraction) value greater than 0.5, indicating that the factors assessed in the survey have substantial influence over the variables under question. Furthermore, the Cronbach's alpha value for each category of tool is greater than 0.890, indicating that our survey model is reliable in that the factors addressed in each category adequately correspond to the category as a whole. From this, we can conclude that our survey categorizations are sound; therefore, any analysis based on these survey results may be considered reliable.

Regression and Correlation Results

A correlation analysis is used to determine relationships between variables under study to assess any potential multicollinearity issues and eliminate any variables accordingly

The correlation analysis measuring the relationship between LM and GSCM indicated a strong relationship ($r=0.75$) between the methodologies, supporting the notion that the two practices often occur in conjunction with one another. Due to this relationship, the GSCM practices are not part of the following analysis, as their strong correlation presents a multicollinearity problem in regard to impact on performance; therefore, the application of GSCM practices will be the focus of future research. Upon removing GSCM from the variables

under consideration, another correlation analysis examines the relationships between the five categories of Lean tools and PERF.
After removing multi-collinearity issues from the final analysis, we run a regression analysis on the remaining variables to further determine their fitness for the final model and their effect on performance. Upon first glance, the F-value is 0, indicating a 0% likelihood that the regression output is due to chance, thus allowing us to move forward in the analysis.

ANOVA Results

To analyze the relationships between each set of Lean tools (MPC, HR and CRP) or PERF and the demographic makeup of all survey respondents, we conducted ANOVA to evaluate any statistically significant differences (α=5) among the various tools and categories of organizations we surveyed. A Tukey post hoc test revealed even further the unique relationship between each sub-category of the company characteristics under study (i.e. general industry, size, specific industry, ownership, revenue) and the three categories of Lean tools participating in the final analysis.
The ANOVA results regarding ownership type (i.e. state-owned, joint venture, etc.) show that statistically significant differences occur within the categories MPC ($F(3,260) = 5.489$, $p = .001$) and PERF ($F(3,260) = 1.563$, $p = .199$) at α=5, thus indicated that a further look need be taken in regard to these variables through a Tukey post hoc analysis. The Tukey analysis reveals that within the MPC category, statistically significant differences exist between state-owned and joint venture ($p = .020$), state-owned and FDI ($p = .001$), and state-owned and private ($p = .010$). Within the PERF category, differences exist among state-owned and joint venture ($p = .033$) as well as state-owned and private ($p = .032$). It should be noted that two of the significant differences occur among the same relationships in CRP and PERF; therefore, those should receive particular attention in a future study.
The ANOVA results concerning annual revenue of the surveyed companies indicates that statistically significant differences occur in the categories MPC (*$F(5,258) = 5.095$, $p = .000$*), CRP (*$F(5,258) = 3.382$, $p = .006$*), and PERF (*$F(5,258) = 5.429$, $p = .000$*); therefore, the HR category is the only group which may be disregarded in the Tukey post hoc analysis. From the Tukey results, we see that statistically significant difference do occur between groups within MPC, CRP and PERF. Within MPC, these differences occur between $50 million and $51-250 million (*$p = .019$*), $50 million and $251-500 million (*$p = .021$*), $50 million and $501-750 million (*$p = .043$*), and $50 million and >$1 billion (*$p = .000$*). Within CRP, differences occur between $50 million and >$1 billion (*$p = .003$*). Lastly, within PERF, differences occur between $50 million and $51-250 million (*$p = .023$*) and $50 million and >$1 billion (*$p = .000$*). From these observations, it is recommended that further analysis into the relationships of these subgroups take place in a future study.
Notice that the 3rd-level section heading (below the 2nd-level section) is not boldfaced and simply underlined, with only the first letter capitalized.

DISCUSSION

Overall, we may conclude that both human resource practices and manufacturing planning & control practices based on the Lean methodology have a positive impact on organizational

performance, thus providing affirmative answers to RQ2 and RQ3. Although the categories of tools assessed RQ1 and RQ5 had to be removed due to multicollinearity issues, the practices and tools of those categories may be closely tied to those of the MPC category; therefore, a positive impact on organizational performance from those categories may be deduced from MPC's apparent positive relationship. At this time, no final conclusion may be made regarding customer relationship practices on performance, due to the negative slope observed at the 1% confidence level for this variable.

In relation to green supply chain management, an apparent correlation between Lean and Green practices exists, suggesting that the two often operate together; however, future studies need to assess this further. In regard to the ANOVA and Tukey results, the statistically significant relationships among the demographic differences of the companies in relation to the categories of Lean practices under study need be further assessed to determine where and how these differences arise.

An Experimental Study of Croston's Forecasting Method under Cross Correlation Conditions

Matthew Lindsey
Stephen F. Austin State University
lindseymd@sfasu.edu

Robert Pavur
The University of North Texas
pavur@unt.edu

ABSTRACT

Croston's method (1972) and variations have shown promise in forecasting average demand per period for items with intermittent demand. This paper examines how Croston's method and Croston's method corrected for bias performs when demand is correlated with the time between demands. In addition, we assess the performance under two distributions for time between demands. Results reveal the distribution for the time between demands may have a stronger effect on the performance of these methods.

KEYWORDS: Croston's Method, Forecasting, Intermittent Demand, Cross Correlation

INTRODUCTION

Forecasting techniques for intermittent demand or slow-moving products have been explored extensively. Examples of this research are numerous, but most center around applications of Croston's method (1972). This paper assess Croston's method under two conditions that are not assumed in its proposed form. The distribution of the time between demands is allowed to be U-shaped and demand and the time between demands are allowed to be cross correlated. Altay, Litteral, and Rudisill (2011) examined the effect of cross correlation on Croston's method. Our study differs in that the time between demands has either the geometric or a U-shaped distribution.

Improved forecasting methodologies (A. A., 2007; Altay, Rudisill, and Litteral, 2008; Levén and Segerstedt, 2004, 2002; Syntetos, A. A., & Boylan, J. E., 2001, 2005, 2006; Willemain, T. R., Smart, C. N., & Schwarz, H. F., 2004), inventory systems (Chung, K.-J., & Hou, K.-L., 2003), method comparisons (Ghobbar, A. A., 2004) and case studies (Hua, Z. S., Zhang, B., Yang, J., & Tan, D. S., 2007) are many of the areas that have been studied related to slow-moving inventory. However, many of the characteristics of forecasting times series with regular demand have not been thoroughly investigated for items with intermittent or slow-moving demand. Altay, Litteral, and Rudisill (2008) demonstrated that a modification of Holt's method can be used to satisfactorily forecasts when trends are present. Lindsey and Pavur (2008) studied the effect of trends and Altay, Litteral, and Rudisill (2011) examined the effects of correlation when demand is intermittent. Despite studies that highlight its shortcomings, Croston's method (1972) has found widespread use and has been the theoretical and practical benchmark for inventory models and forecasts (Syntetos and Boylan, 2005, 2006; Altay, Rudisill and Litteral, 2008; Teunter, Syntetos & Babai, 2010; Xu, Wang, & Shi, 2012; Ramaekers & Janssens, 2014). Levin and Segerstedt (2004) proposed a technique that handles forecasting items with regular demand and slow moving items.

Leven and Segredst (2004) proposed a procedure with a new estimator for mean demand and for the variance of the forecasted demand rate when the demand rate is modelled as an Erlang distribution. Despite its shortcomings, this approach could provide an opportunity to overcome forecasting issues related to cross correlated data. Furthermore, an item would have a positive cross-correlation when a long demand interval is followed by a high demand size or a short interval is followed by a low demand size. They claim the estimator is unbiased, however, Syntetos and Boylan (2006) shows it is not and the bias is greater than the original procedure and SES. The argument for increased bias in the modified procedure assumes independence and a constant probability of demand. However, we will investigate the application of the modified procedure when cross-correlation is present. The modified procedure may offer advantages over the original method when many of the assumptions are violated.

LITERATURE REVIEW

Croston's method (1972) is one of the most popular techniques when demand is intermittent and is the practical standard for inventory models (Teunter, Syntetos and Babai, 2010; Xu, Wang, & Shi, 2012; Ramaekers and Janssens, 2014). Croston's method has documented benefits by Willemain, Smart, Shockor, and DeSautels (1994), Johnston and Boylan (1996) and others. The procedure generates one forecast for the demand quantity and one for the time between demands and combines them into one forecast. Syntetos and Boylan (2001) provided a modification to correct an identified bias in Croston's method. Studies have compared the bias corrected method with the original without identifying a superior method (Eaves & Kingsman, 2004; Syntetos & Boylan, 2005; Teunter & Sani, 2009; and Teunter & Duncan, 2009).

Croston's Method

See Willemain, et al. (1994) for a succinct review of the methodology. Croston (1972) recommends small alpha values between 0.1 and 0.2. Croston's method is based on assumptions of stationary, identically, independently distribution of demand sizes and intervals, geometrically distributed inter demand intervals and independence of demand sizes and intervals.

Syntetos and Boylan's Bias Corrected Modification for Croston's Procedure

Syntetos and Boylan (2001) identified a bias in Croston's (1972) method. The bias increases as the smoothing constant increases. It can be minimized by using a small alpha. See Boylan and Syntetos (2005) for the formulation. Teunter and Sani (2009) advocate that in cases when limited periods have no demand, Croston's method excels and when most periods have no demand Syntetos and Boylan's correction is better.

Leven and Segerstedt Method

The modified Croston procedure from Leven and Segerstedt (2004) presents two new estimators. The new estimator for mean demand is:

$$\hat{d}_n^{MC} = \hat{d}_{n-1}^{MC} + \alpha\left(\frac{X_n}{T_n - T_{n-1}} - \hat{d}_{n-1}^{MC}\right) \quad (1)$$

The new estimator for variance of the forecasted demand rate is:

$$\hat{d}VAR_n^{MC} = \hat{d}VAR_{n-1}^{MC} + \beta\left(\left(\frac{X_n}{T_n - T_{n-1}} - \hat{d}_{n-1}^{MC}\right)^2 - \hat{d}VAR_{n-1}^{MC}\right) \quad (2)$$

Although this estimator is criticized by Syntetos and Boylan, it should be explored when there is a violation of the standard assumptions used in assessing Croston's method.

EXPERIMENTAL SIMULATION STUDY

Data are generated for demand using a normal distribution with a mean of 200 and a standard deviation of 10. The time between demands is generated under either the Geometric distribution or a U-shaped beta distribution such that the expected time between demands is 5 periods. A normal-to-anything transformation, as described in Altay et al. (2011), is used to incorporate a cross correlation between the demands and the time to demand of either zero, -0.8, or 0.8. 1000 simulations were conducted for each condition. The Geometric distribution has an expected time between demands of 5 for a "p" parameter equal to 0.2. The U-shaped distribution had two high probabilities for the values of 1 and 10 for the time between demands and small probabilities, for the values between 1 and 10. This study uses a normal distribution for product demand.

RESULTS

In Table 1, Croston's performance does not vary much under the three cross correlation conditions. There appears to be a slight uptick in the RMSE for the negative correlation when the smoothing constant is 0.05 and a slight uptick the RMSE for the positive correlation when the smoothing constant is 0.2. A column labeled "Croston Bias Corrected with True Parameter" is included to use as bench mark. This study uses the RMSE to examine the accuracy of Croston's smoothed demand divided by the smoothed time between demands as an estimator of the population ratio of total demand divided by the time investigated.

Table 1. Performance of Croston's Method under Cross-Correlation using a Geometric Distribution for Time between Demands.

Smoothing Constant = 0.05	**SES**	**Croston**	**Croston Bias Corrected**	**Croston Bias Corrected with True Parameter**	**Reduction byCroston PerCent**	**Reduction by Croston BIAS_C PerCent**
Positive Correlation 0.8	12.25	5.32	5.19	5.14	56.58	57.62
Zero Correlation	12.63	5.48	5.35	5.30	56.63	57.66
Negative Correlation 0.8	13.00	5.63	5.50	5.45	56.69	57.68
Smoothing Constant = 0.2						
Positive Correlation 0.8	27.10	13.64	12.47	11.86	49.66	53.99
Zero Correlation	26.56	13.11	11.99	11.46	50.64	54.87
Negative Correlation 0.8	26.01	12.56	11.49	11.05	51.72	55.83

Table 2 serves to contrast the performance of Croston's Method when a U-Shaped distribution is used for the time between demands. The performance is better when a Geometric distribution is assumed. The percent reduction by Croston over the exponential smoothing method is less compared to Table 1.

Table 2. Performance of Croston's Method under Cross-Correlation using a U-Shaped Distribution for Time between Demands.

Smoothing Constant = 0.05	SES	Croston	Croston Bias Corrected	Croston Bias Corrected with True Parameter	Reduction byCroston PerCent	Reduction by Croston BIAS_C %
Positive Correlation 0.8	13.26	5.89	5.70	5.57	55.61	57.06
Zero Correlation	13.20	5.76	5.61	5.53	56.34	57.48
Negative Correlation 0.8	13.27	5.79	5.68	5.63	56.34	57.20
Smoothing Constant = 0.2						
Positive Correlation 0.8	31.03	16.67	15.42	14.35	46.28	50.32
Zero Correlation	31.01	16.59	15.37	14.33	46.52	50.44
Negative Correlation 0.8	31.06	16.63	15.43	14.41	46.47	50.32

DISCUSSION AND CONCLUSIONS

Many studies have investigated the performance of Croston's method and concluded that it is a robust methodology. Altay, Litteral and Rudisill (2011) appears to be the major study that has investigated Croston's method under cross-correlation. Their study did not show a substantial change over the values of the correlation selected. In that regard, their study and this study show agreement. However, this study also considers the effect of the distribution of the time between demands along with the cross correlations. A conclusion is that the distribution of the time between demands appears to have a greater effect of the performance of Croston's method than cross-correlations. The bias correction for Croston's method is clearly more important for larger smoothing constants. Altay, Litteral and Rudisill (2011) explain why it is necessary to used theoretically generated data versus real world data in examining the performance of Croston's method. It is difficult to know the true population distribution of either the demand or the time between demands in real data. The experiment designed here controls for correlations and distributions and make conclusions as to their effects.

ABSTRACT

Exceling in supply chain management (SCM) is a challenge. Businesses struggling with SCM can try to emulate the practices of firms exceling in SCM if they know who these firms are. Information signaling theory asserts that a credential can be a signal of possessing an underlying capability. Gartner annually publishes a list of who they believe are the top 25 companies worldwide in SCM. Being on this list can be viewed as a credential. However, credentials must be examined for their value. We develop a modified form of the event study methodology to see if the Gartner credential has value-relevance.

KEYWORDS: *Supply Chain Management, Information Signaling, Event Study, Value Relevance*

INTRODUCTION

Excellence in supply chain management (SCM) is crucial for firms since it manifests itself in enhanced financial performance (D'Avenzo, Lewinksi, & Wassenhove, 2003; Presutti & Mawhinney, 2007). However, exceling in managing a firm's supply chain is a complex challenge involving different dimensions including strategy, business process, and technology. The role of industry exemplars who have superior SCM capability becomes key as other firms try to emulate the processes, practices, and technologies employed by these leaders. But how do business managers at large find out who these exemplars are? If they incorrectly identify these exemplars, then it could become a case of the blind leading the blind. Information signaling theory states that the possession of an underlying capability by someone can be signaled to the world by the possession of a credential (Spence, 1973, 2002). Information signaling has been used in a variety of contexts such as the job market where a candidate's inner capabilities and competence are manifested by the degree they possess (Spence, 1973, 2002). Of course, the quality of all credentials may not be the same. A degree from a top-tier university is not the same as that from a local college. Hence, before simply taking a credential at face value and acting upon it, the quality or value of the credential must be examined.

In the SCM area, Gartner, an analyst firm, annually publishes a list of 25 firms that it believes are the best firms worldwide in managing their supply chains. We will refer to this list as the SCT25. From an information signaling standpoint, we treat being listed on the SCT25 as the acquisition of a credential that is supposed to reflect superior SCM capability. Whether it truly does that or not is the question that this study addresses. Whether the credential of being listed

in the SCT25 truly correlates with superior SCM capability of course depends on the methodology that Gartner is using in identifying the top firms in SCM. Not much is publicly known about Gartner's methodology because the SCT25 report identifying these top 25 firms is not a document in the public domain as it is available only to its subscribers. Of course, information about the list itself propagates quickly as it generates commentary by other analysts who may have their own views on the best firms in SCM, which could be different from Gartner's. It is to be noted that industry analysts are selling an intellectual product in competition with each other and so there is no reason at all to expect that all these analysts will line up in perfect unison about who the best SCM companies are.

In this article, we develop in this paper a modified event study methodology that has been customized to examine the value-relevance of the SCT25 information. If Gartner is indeed correctly identifying the top players in SCM, which other firms can emulate, then it is providing valuable information which can be expected to have an impact on the capital markets. The standard event study methodology with its short two-day window is however not appropriate for this study. This is because the information that is being disclosed is not factual information, such as an announcement of earnings or a new product release or a corporate acquisition. The SCT25 information is Gartner's opinion about who the best firms in SCM are. Other analysts may well have other opinions that surface in the discussion that occurs in the industry after the publication of Gartner's SCT25 report. We refer to information that is opinion rather than factual as *controvertible* information. When controvertible information is disclosed, the rational investor would naturally want to hear all sides before making a stock market move. Equivalent to waiting, if an investor did make a decision to take a long position on a stock immediately upon the disclosure that it featured high in the SCT25 list, that investor may choose to close or partially close that position upon hearing other analysts challenging Gartner's opinion. As the discussion in the industry takes place in the few days immediately upon the publication of Gartner's SCT25 report, we used a [-1, +7] window in our study. In other words, we accumulate the stock market returns from the previous calendar up to seven calendar days after the day of the announcement. This allows sufficient time for other analysts to weigh in on Gartner's opinion. The accumulation of returns over this long event window allows for the effect of Gartner's opinion together with countervailing views to be captured by our model in terms of the net stock market impact.

Using our modified event study methodology, we find that the SCT25 information indeed has value-relevance. However, a disturbing result that emerges from our study is that if you break up the 2004-2014 period of our study into intervals, or epochs, then the SCT25 information is found to have value-relevance in the earlier epochs, such as 2007-2011, but not in the latter epochs such 2012-2014. This could mean that the methodology that Gartner had successfully applied for many years to identify the best firms in SCM needs to be updated. Clearly, this finding has major implications for both Gartner and the businesses at large that rely on Gartner to identify the best firms in SCM, which they could then emulate.

LITERATURE REVIEW

To excel in managing the supply chain is easier said than done. It is a multi-facetted challenge that embraces strategy, business process, and technology. At the level of strategy, Christopher and Ryals (1999) underline the importance of having a corporate-wide strategy for the supply chain that embraces all the business units. At the business process level, new processes and practices such as collaborative planning, forecasting, and replenishment, or CPFR, must be implemented to ensure that the entire supply chain works in unison (Seifert 2003; Russell and

Taylor 2009). These business practices also include innovations such as vendor managed inventory (VMI) (Nagarajan & Rajagopalan, 2008; Niranjan, Wagner, & Nguyen, 2012), which mitigates the so-called “bull whip” effect (Warburton, 2004; Kok et al., 2005; Panda & Mohanty, 2011) where inventory tends to pile up the further away we move from customers and towards the supplier end of the chain. Excess inventory is of course only one form of inefficiency. Firms must also broadly apply the principles of lean production and management (Womack & Jones, 1996; Holweg, 2007) in all its business processes throughout the supply chain to eliminate all forms of inefficiency and waste. The impact on the environment must also be considered in the operation of the supply chain (Pil & Rothenberg, 2003). Information systems such as supply chain management systems must be used at the operational level to facilitate the execution of strategy and the implementation of best practices (Gunasekaran & Ngai, 2004).

To add to the challenges in strategy, process, and execution, firms must also master a range of complex information technologies (IT) to facilitate the integration of information systems of various organizations in the supply chain. This complex IT includes XML and Web Services (Krafzig, Banke, & Slama, 2005) for integrating software applications such as enterprise resource planning (ERP) and materials requirements planning (MRP) across the various business entities in the supply chain. Firms setting out to improve their supply chains are clearly facing a complex multi-facetted challenge with ramifications for strategy, process, and technology.

Although Gartner’s methodology for identifying the best firms has not been publicly debated, it is possible to make some educated guesses about their methodology. Often in developing these rankings, a panel of experts is constituted who independently rank the firms. The final ranking could be obtained through an arithmetic summarization of the individual rankings by the experts. Other methodologies could be more quantitative in nature where a range of predictor variables, or key performance indicators (KPI) of SCM performance, is used in some sort of a regression model to predict overall SCM performance. It is also possible to develop a methodology of ranking firms using a combination of both subjective and objective elements. Whether a subjective or objective approach, or some combination of the two, is used by Gartner in developing the SCT25 ranking, it is important to recognize is that any methodology does not remain robust indefinitely.

If a panel of experts is being used, and they are very good, what happens when some of those experts leave the panel? If their replacements are not equally proficient in identifying the best firms in SCM, the SCT25 list may not be as spot-on in identifying the best firms as it once was. Even if some objective quantitative model was built to predict the best firms in SCM, the model itself may need to be updated with a newer set of variables to reflect changed business conditions. It should be noted that the SCT25 list was first published in 2004. Since then, there was the financial crisis of 2007 to 2009, a global event leading to a financial meltdown which many people did not see coming. It is arguable that many business models, albeit built for different purposes, may have needed some updating after the financial crisis of 2007 to 2009, which forced a reexamination of basic business assumptions. The financial crisis, even though it originated in the housing and the financial services industry, had lessons for all managers about how to think about risk and how to best manage risk.

As we stated earlier, the value of the SCT25 credential is only as good as the methodology used by Gartner in identifying the firms best in SCM and the same methodology cannot be assumed to be robust indefinitely. This paper addresses the issue of the change in the value of SCT25 credential over time in the 2004 to 2014 time frame of the study. To examine the time-

varying nature of the value of the SCT25 signal, we developed a modified form of the event study methodology. Our modified event study methodology examines the stock market return accruing to the firms that appear on the SCT25 list in a window around the publication date of the SCT25 report in any given year. Like the standard event methodology, we also assume that the strong form of efficiency is a good approximation of capital market reaction to new information disclosures. In other words, all information, public or private, is quickly discounted by the stock market. This fundamental assumption is the basis of using a short event window in the traditional event study methodology of two days, denoted as [-1, 0], where day 0 is the day that the information appears in the mass media and day -1 is the previous day. The previous day is also included because there is generally some leakage of information that occurs prior to the news appearing in the mass media.

Another significant difference between the event study methodology we developed for our study and the traditional event study methodology is that we explicitly account for the occurrence of confounding events. McWilliams and Siegel (1997) lament that many event studies simply fail to account for the fact that there are other value-relevant events happening in the window of the event under study. They report that the results from several event studies would actually *change* if confounding events had been taken into consideration. It can be argued that if you have a short event window of two days, the probability that a major confounding event occurring in the short window that reverses the direction of impact of the event under study is low. While this argument may have some validity for short event window studies, clearly in case of a long event window study such as ours where the window is about a week long, confounding events can certainly occur in a window that long. Hence, we depart from the standard event methodology both in terms of having a long [-1, +7] window and also in terms of explicitly removing the effect of confounding events in that long window.

It should be noted that there was a study done by McCarthy and Nayar (2010) on examining the stock market impact of the SCT25 information disclosure. Our study differs from that of McCarthy and Nayar (2010) in several key respects. First of all, the main goal of our study and theirs is different. Their study was geared towards establishing that there is value-relevance of the SCT25 information, or that the disclosure of the SCT25 information has market-moving impact. They found this result in the 2004 through 2008 time frame of their study. We do not question the basic result of their study. In fact, their result that SCT25 information has value is the basis of our study, which covers the longer 2004 through 2014 time frame, and focuses on whether the market-moving impact of the SCT25 information could in fact be diminishing with time. In other words, is the credential of being listed in the SCT25 still a valid information signal of underlying superior capability in SCM.

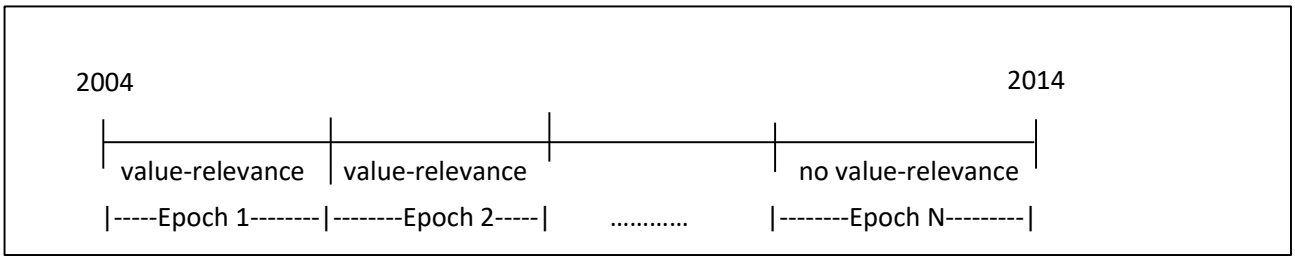
McCarthy and Nayar's (2010) study also had some methodological weaknesses in that they used the standard two-day [-1, -0] short window. Hence, they did not address the controvertible nature of the SCT25 information where other analysts may offer dissenting views and they should be heard as well. To include the impact of dissenting views, we have to lengthen the event window so that they can be heard. McCarthy and Nayar (2010) also did not attempt to make any correction for confounding events. We have developed a more robust and accurate methodology to gauge the value-relevance of the SCT25 information that does not suffer from these shortcomings.

RESEARCH FRAMEWORK AND METHODOLOGY

Hypotheses

The primary research question of this longitudinal study is to examine not only whether the SCT25 information has value-relevance but also if the SCT25, even if it had value-relevance in the past, continues to have value-relevance in more recent years. In other words, we are also searching for chronological patterns of value-relevance. If we break up the 2004 through 2014 period of the study into sub-intervals, or epochs, and we find a pattern as shown in Figure 1 where there was value-relevance of the SCT25 information in the initial epochs but not in the latter epochs, then a significant result would have been obtained. This result would essentially indicate that the methodology that Gartner had successfully used in identifying the best firms in SCM when it first devised this methodology and started publishing the SCT25 list may have become outdated. The methodology may no longer be finding the best firms in SCM in the changed business environment of today. Clearly, such a result would have important implications for Gartner and its subscribers. It would essentially indicate that the methodology needs to be updated to reflect the business conditions of more recent years.

Figure 1: Pattern of Changing Value-Relevance of SCT25 Information



Hence the null hypothesis we are testing is:

> **Hypothesis 1**: Regardless of how the time frame 2004 through 2914 is divided into epochs corresponding to a sub-interval in that time frame, the SCT25 information disclosure remains value-relevant in each epoch.

If this hypothesis is rejected, then there is some basis for a closer examination of Gartner's methodology of identifying the best SCM firms and looking into areas where the methodology can be improved. Hypothesis 1 is actually a family of hypotheses as it depends on how the 2004 through 2014 period is divided.

Addressing Confounding Events

To address confounding events, we first identify the days in the [-1, +7] window when other important information about a firm in the SCT25 list was disclosed, such as earnings, new product launches, mergers and acquisitions, divestments, litigation, key executive changes, competitor actions, and market changes. We used the LexisNexis database to find the major confounding events that occurred in the [-1,+7] event window. To illustrate the procedure, to find key events pertaining to Dell in the time interval 11/14/2004 to 11/22/2004, which is the [-1, +7] interval relative to the publication date of the 2004 SCT25 report of 11/15/2004, the search filter is set as:

LOAD-DATE AFT(11/13/2004) AND LOAD-DATE BEF(11/23/2004) AND HEADLINE(Dell) AND ORGANIZATION(Dell)

The name of the firm is used in both the HEADLINE and the ORGANIZATION search keys to ensure that the news item is principally about the firm in question. The LOAD-DATE AFT and LOAD-DATE BEF search keys are used to define the timeframe of the search. After the dates for the confounding events have been found in the event window, each confounding event is itself assigned the standard [-1, 0] window as its market-move days. The standard [-1, 0] window is chosen because confounding disclosures, such as about earnings, acquisitions, divestments, and product launches, are not controvertible opinion like the SCT25 information. Once the market-move days for the major confounding events have been found, these days are removed from the long [-1, +7] window of the SCT25 information disclosure.

Test Statistic for Longitudinal Value-Relevance of SCT25 Information Signal

We develop a statistic for testing the value-relevance of the SCT25 information over epochs defined in the 2004 to 2014 time frame of the study with a longer than standard event window and correcting for confounding information disclosures in this window. Since the test statistic for the standard event study using a two-day window with no correction for confounding events is clearly not applicable in our study, we develop our test statistic from first principles using Lindeberg's Central Limit Theorem (Feller, 1966). Lindeberg's Central Limit Theorem states that:

$$\lim_{n\to\infty}\left(\frac{X_1 + X_2 + \cdots X_n}{s_n}\right) = Z \quad \text{where } s_n = \sqrt{\sigma_1^2 + \sigma_2^2 + \cdots \sigma_n^2} \tag{1}$$

where the X_i's are zero-centered and independent random variables that are not necessarily identically distributed. The test statistic $\left(\frac{X_1+X_2+\cdots X_n}{s_n}\right)$ converges to a standard normal distribution for sufficiently large *n* provided that the following condition known as Lindeberg's condition is satisfied:

$$\text{For any } \epsilon > 0, \lim_{n\to\infty}\frac{1}{s_n^2}\sum_{j=1}^{n} E\left(X_j^2\, I\{|X_j| > \epsilon\, s_n\}\right) = 0 \tag{2}$$

where $I\{.\}$ is the indicator function or $I\{|X_j| > \epsilon s_n\} = 1$ when $|X_j| > \epsilon s_n$ and 0 otherwise.

To apply Lindeberg's Central Limit Theorem (Feller, 1966) in our context, we define the following variables:

- y = a year in which the SCT25 is published
- y_1 = first year of publication of the SCT25 in this study, which is 2004.
- y_2 = last year of publication of the SCT25 in this study, which is 2014.
- M_y = number of stocks in the SCT25 in year y that are traded on the NYSE or NSADAQ. M_y is not necessarily 25 as some of the firms in the SCT25 in a given year are not traded on the NYSE or NASDAQ. As an example, foreign stocks that don't have an ADR traded on the NYSE or NASDAQ are excluded from the study.
- N_y = M_y plus the stocks which were in the SCT25 list the previous year but were dropped in the current year y. If the SCT25 is correctly identifying the firms that excel in SCM, then we would expect a negative abnormal return for those stocks dropped in year y. Hence, the negative of the abnormal return

for these stocks upon the disclosure of the SCT25 information is included in the accumulation of the abnormal returns that form the test statistic.

D_y = the set of market open days in year y in the event window $[\tau_1, \tau_2]$, which is [-1, +7] for this study. It should be noted that the stock market is not open on all days in the event window.

L_y = cardinality of the set D_y

D_{iy} = the set of market-open days in D_y during which confounding information disclosures for firm i in year y are discounted by the market

K_{iy} = cardinality of the set D_{iy}

AR_{ity} = abnormal return in the event window for firm i on day t and year y, where t is a market-open day in the event window. With regard to the stocks that were in the SCT25 in the previous year but were dropped in the current year y, the negative of the abnormal return is used in the accumulation of the abnormal returns for forming the test statistic

R_{mty} return from the market on day t and year y

T_1 = start of the estimation period

T_2 = end of the estimation period

T = length of the estimation period, $T = T_2 - T_1 + 1$

$\bar{R}_{my}$ = average market return over the estimation period in year y

s_{iy} = residual standard deviation obtained from the estimation of the market model for firm i in year y

C_{ty} = correction factor reflecting increase in variance because of prediction outside the estimation period. The standard deviation of the abnormal return AR_{ity} is $\sqrt{C_{ty}}s_{iy}$. The correction factor is given by $1 + \frac{1}{T} + \frac{(R_{mty}-\bar{R}_{my})^2}{\sum_{t=T_1}^{T_2}(R_{mty}-\bar{R}_{my})^2}$

For large T, the correction factor can be ignored as $C_{ty} \approx 1$.

SAR_{ity} = The standardized abnormal return or $AR_{ity}/(\sqrt{C_{ty}}s_{iy})$

The subscripted X variables in Equations (1) and (2) correspond in our model to the SAR_{ity} terms. Each SAR_{ity} is a Student t distribution with T – 2 degrees of freedom. The total number of SAR's accumulated in the numerator, or the value of n in Equation (1), is given by:

$$n = \sum_{y=y_1}^{y_2} \left(N_y L_y - \sum_{i=1}^{N_y} K_{iy} \right) \tag{3}$$

As indicated in the definition of the AR terms, the number of firms included in a given year y includes the firms in the SCT25 in that year and also any firms that appeared in the previous year but were dropped in the given year. For the firms that were dropped, the sign of the SAR term is reversed when their SAR's are added to the numerator in Equation (1). Also, for any firm to be included in the study, it must be traded on the NYSE or NASDAQ. With regard to foreign stocks in the SCT25, only those that have an ADR that is traded in the US markets are included in the study. The number of firms in our study in any year that the SCT25 is published is not necessarily 25 because some firms in the list are not traded on the NYSE or the NASDAQ. If we denote as L_y the number of stock market open days in the [-1, +7] window in year y, then there would be $N_y L_y$ days in year y for which there would be SAR's in the numerator of Equation (1) before considering the issue of confounding information. Since we exclude the market-move days of confounding information, then with K_{iy} representing the number of market-move days

when confounding information is moving the markets for stock *i* in year *y* in the [-1, +7] window, Equation (3) gives the total number of SAR's in the numerator of Equation (1).
Since each *SAR* is a Student t distribution with T-2 degrees of freedom, the test statistic $\frac{X_1+X_2+\cdots X_n}{s_n}$ is given by:

$$\frac{1}{\sqrt{\left(\frac{T-2}{T-4}\right)\left(\sum_{y=y_1}^{y_2}\left(N_y L_y - \sum_{i=1}^{N_y} K_{iy}\right)\right)}} \sum_{y=y_1}^{y_2} \sum_{i=1}^{N_y} \sum_{t\epsilon\{D_y - D_{yi}\}} SAR_{ity} \tag{4}$$

If the Lindeberg condition is satisfied then the test statistic converges to the standard normal distribution or:

$$\frac{1}{\sqrt{\left(\frac{T-2}{T-4}\right)\left(\sum_{y=y_1}^{y_2}\left(N_y L_y - \sum_{i=1}^{N_y} K_{iy}\right)\right)}} \sum_{y=y_1}^{y_2} \sum_{i=1}^{N_y} \sum_{t\epsilon\{D_y - D_{yi}\}} SAR_{ity} \to Z \tag{5}$$

Since the X_j variables in Equation (2) correspond to the SAR's and each SAR has the same Student t distribution with T-2 degrees of freedom, the expression in the condition can be simplified as follows:

$$\frac{1}{s_n^2}\sum_{j=1}^{n} E(X_j^2\, I\{|X_j| > \epsilon s_n\}) = \frac{nE(X_1^2 I\{|X_1| > \epsilon s_n\})}{n\sigma_1^2} = \frac{E(X_1^2 I\{|X_1| > \epsilon s_n\})}{\sigma_1^2} \tag{6}$$

where X_1 is any SAR in the series of SAR's summed to form the test statistic. Since each SAR has a Student t distribution with T-2 degrees of freedom, we can substitute for s_n in Equation (6) to express the Lindeberg condition as:

$$\text{For any } \epsilon > 0, \lim_{n\to\infty} \frac{E\left(X_1^2 I\left\{|X_1| > \epsilon\sqrt{n\left(\frac{T-2}{T-4}\right)}\right\}\right)}{\sigma_1^2} = 0 \tag{7}$$

Finally, since X_1 is any SAR and thus has a Student t with T-2 degrees of freedom, the condition reduces to:

$$\text{For any } \epsilon > 0, \lim_{n\to\infty} E\left(t^2 I\left\{|t| > \epsilon\sqrt{n\left(\frac{T-2}{T-4}\right)}\right\}\right) = 0 \tag{8}$$

For any fixed ϵ, the limit in Equation (8) is of the form:

$$\lim_{n\to\infty} E\left(t^2 I\left\{|t| > c\sqrt{n}\right\}\right) = 0 \tag{9}$$

where *c* is a constant. Note that the lowercase *c* here is not the same as the uppercase C_{ty} term indicated in the definition of the variables in the model. If we let t_n be the random variable $t^2 I\left\{|t| > c\sqrt{n}\right\}$, then:

$$t_n = t^2 \text{ when } |t| > c\sqrt{n} \text{ and}$$
$$t_n = 0 \text{ otherwise} \quad (10)$$

Equation (10) asserts that t_n is non-zero only when the event $|t| > c\sqrt{n}$ occurs. However, as $n \to \infty$, the probability of the event $|t| > c\sqrt{n}$ occurring tends to 0. Hence, as $n \to \infty$, $t_n \to 0$. This establishes Equation (9) and shows that the Lindberg condition holds and that the test statistic given by Equation (1) has a standard normal distribution for large *n*.

The remaining question is how large *n* should be for the Lindeberg Central Limit Theorem to hold and the test statistic given by Equation (1) to be deemed an approximately standard normal distribution. With regard to the standard form of the Central Limit Theorem (CLT), it is sufficient for *n* > 30 for the standard form of the CLT to hold (Anderson, Sweeney, & Williams, 2010). In our study, when the full timeframe of 2004 to 2014 is considered, the number of *SAR*'s accumulated or the value of *n* is 1340. Even when an epoch is collapsed and reduced to a single year, as was done to explore the time-dependent nature of the value-relevance of the SCT25 information at a granular yearly level, the value of *n* is above 100. When multi-year epochs are concerned the value of *n* is much larger. Hence, there is no issue about the size of *n* when applying the Lindeberg Central Limit Theorem in our context.

Data Set

The list of the Top 25 supply chain companies from 2004 through 2014 produced by Gartner was obtained from McCarthy and Nayar (2010) and also from various vendor web sites. Table A.1 in Appendix A gives the consolidated rankings of the firms in the SCT25 over the 2004 to 2014 time frame. Table A.2 in Appendix A indicates the market-move dates of confounding information about various firms in a given year's SCT25 list in the [-1, +15] window around the nominal publication date of the SCT25 report. We collected data for confounding events for an even larger window than [-1, +7] to test for the robustness of the results if the window was shortened or lengthened from the [-1, +7] window size. These confounding event dates were obtained by searching the LexisNexis database using the procedure described in Section 2.2. The standard two-day [-1, 0] window was allocated for the discounting by the capital markets of the confounding information.

RESULTS

To obtain a hint on how to break up the 2004 through 2014 time frame into meaningful epochs, we examined how the value-relevance of the SCT25 information would change if each individual year is treated as its own epoch. Figure 2 shows the value of the test statistic with each year treated as its own epoch. It is seen from Figure 2 that the value of the test statistic is quite low in the initial years of 2004 and 2005, is high in some of the years in the middle portion of the 2004 to 2014 time frame of the study, and then it goes into a steady decline even reaching negative values towards the tail-end of the time frame from 2012 through 2014.

This suggested a way of segmenting the 2004 through 2014 time frame into the following epochs: Epoch I (2004-2005), Epoch II (2007-2011), and Epoch III (2012-2014). We then tested for value-relevance in each of these epochs and the p-values of the hypothesis of no value-relevance by epoch is shown in Table 1. As Table 1 shows, we did not find any value-relevance of the SCT25 information in either the front end (2004 to 2005) or the tail-end (2012 to 2014)

time frame of the study. But it was strongly value-relevant in the middle portion comprising the years 2007 through 2011.

Figure 2: Epochs of Value-Relevance of SCT25 Information

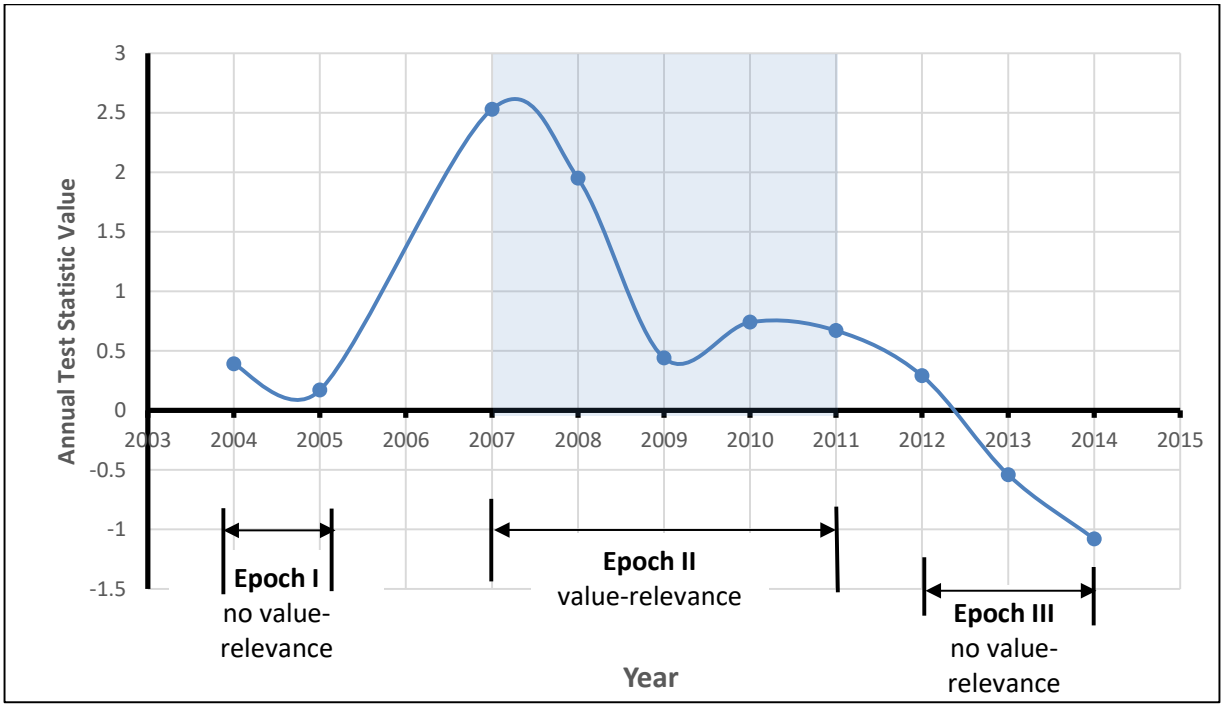


Table 1: Epoch-based P-values

Epoch	P-value
I (2004 to 2005)	0.3504
II (2007 to 2011)	0.0023**
III (2012 to 2014)	0.7808

DISCUSSION OF RESULTS

The conclusion of no value-relevance of the SCT25 information towards the tail-end of the 2004 through 2014 time frame, corresponding to the 2012 through 2014 epoch, implies that perhaps the methodology that Gartner is using to identify the best firms in SCM may need some updating. It is also interesting to observe that there was no value-relevance of the SCT25 information at the front-end of the time frame, or the 2004 to 2005 epoch. This could be explained by the fact that because the SCT25 information is opinion, there must first be credibility built for this type of opinion before rational investors will believe it and act upon it.

The SCT25 report was actually first published by AMR Research, a relatively small research firm, that Gartner acquired in 2009. Gartner is a large well-established analyst firm with $3.3 billion in 2017 revenues and 15,000 employees. In contrast, at the time of the acquisition by Gartner in 2009, AMR Research had a revenue of $40 million and less than 100 employees. The Gartner acquisition gave AMR Research a tremendous amount of visibility and credibility.

But in the early years when AMR Research was on its own and was producing the SCT25 report, the authors would have had to establish credibility for themselves and their methodology before the market would give credence to their opinion.

The lack of value-relevance in the 2012 through 2014 epoch likely implies that the methodology that Gartner has been using for identifying the best companies in SCM may be in need of some updating. In the aftermath of the financial crisis of 2007 through 2009, many business assumptions across-the-board have had to be reassessed. At the heart of the financial crisis was a highly incorrect assessment of the risk of certain financial instruments. The notion of risk and how to best manage it is not limited to the financial services industry. Risk management is an issue in every industry and the fundamental notion of risk pervades many types of business models. Also, many experts did not see this crisis coming at all and were caught on the wrong foot. Regardless of whether Gartner is using a panel of experts or some objective quantitative model or a combination of both, the aftermath of the financial crisis behooves an across-the-board rethinking about risk and the best ways to manage risk.

IMPLICATIONS

Implications for Theory

This article makes two important theoretical contributions. The first is methodological. We have developed a model for assessing the value-relevance of controvertible information. The existing event study methodology is useful mainly for factual information. Facts are not disputable. A report on last quarter's earnings or a corporate acquisition are facts. Controvertible information, such as an analyst pronouncing an opinion on who is best in something such as SCM capability, can be challenged. Other analysts may produce a dissenting opinion. Hence, to find the value-relevance, or market-moving impact, of controvertible information, it is necessary to first have a longer event window to allow for dissenting opinion to be voiced. It is the net market-moving effect of both the original opinion and the dissenting voices that is key in assessing the value-relevance of the original opinion. Hence, a longer window becomes necessary and, given a longer window, the issue of confounding events can no longer be ignored and must be explicitly addressed. This article develops a general methodology for assessing the value-relevance of controvertible information with longer windows and with an explicit correction for confounding information. There are many examples of subjective rankings produced by industry analysts and other gurus in many different walks of life such as yearly rankings of automobile manufacturers or airlines. Our general methodology for examining the value-relevance of controvertible information can be applied by researchers to all these other contexts.

The other important theoretical contribution of this article is that focuses attention on the construct of *credibility* as an important aspect of information, particularly that of controvertible information, as a determinant of value-relevance. If the information is from a source that is not regarded as credible, then it will not move markets. We saw in this study that the AMR Research authors who produced the SCT25 report originally had to first build credibility for themselves and their methodology before investors would believe them and make market moves based on their opinion. That very likely is the reason behind the SCT25 information disclosure not having market-moving impact in the early years of 2004 to 2005, with 2004 being the first year of the publication of the report. We know from past research (Malatesta & Thompson, 1985) that information that is novel has more market impact compared to information that is partially anticipated. This research shows that both novelty and credibility of information play a key role in moving markets. The notion of credibility of information has not been the subject of much research and therefore there is a great deal of room to further explore

the construct of credibility along with that of novelty in future research on value-relevance of information.

Implications for Practice

The main implication here is that Gartner should take a closer look at its methodology of identifying the best companies in SCM and explore areas of improvement. Regardless of whether the identification of the best companies in SCM is done subjectively using a panel of experts or objectively using some kind of quantitative model or a combination of both, a reexamination of the composition of the panel or the predictor variables in a quantitative model is warranted. As stated earlier, in the aftermath of the financial crisis of 2007 to 2009, fundamental notions of risk and how best to manage it are being rethought across the board and not just in the financial services industry. It should also be noted that experts and industry pundits uniformly failed to see this crisis coming. Managers who rely on Gartner's opinion on exemplars in SCM as they make decisions about their own supply chains should ask for more transparency about Gartner's methodology of identifying the exemplars. They should also ask what Gartner has done to update this methodology in the aftermath of the financial crisis which has led to a rethinking about the notion of risk. If the experts in the financial services who deal with managing risk of investments every day could be so wrong about risk, so could managers in other industries.

CONCLUSION

Our article makes a number of notable contributions. We first develop an event study methodology that is appropriate for disclosure of controvertible information or opinion. The staple event study methodology that exists is really appropriate only for the disclosure of factual information. Our new methodology makes feasible the study of the value-relevance of opinion disclosures in many different contexts. We then apply the methodology we have developed to the case of Gartner's opinion about the top 25 companies who excel in managing their supply chains. We validate that Gartner did indeed develop a good methodology for identifying the top companies in SCM. Their disclosure of the top 25 companies in SCM was value-relevant and highly significant when we look at the 2007 through 2011 epoch. However, a concern is that in more recent years, the disclosure of the SCT25 information has not made a statistically significant impact on the market. This may indicate that Gartner's methodology for identifying the best companies in SCM may need to be updated. Particularly, in the aftermath of the 2007 to 2009 financial crisis, the fundamental notion of risk itself is being reassessed by managers in many industries. Risk is a fundamental notion that permeates many business models.

APPENDIX A

Table A.1: Yearly Rank of Firm in Gartner's Supply Chain Top 25 (SCT25)

Company	2004	2005	2007	2008	2009	2010	2011	2012	2013	2014

Walt Disney	26	26	26	17	16	26	26	26	26	26

Notes:

a) Only companies whose stocks are traded on either the NYSE or NASDAQ exchanges are included. Foreign companies included in the study are those that have an ADR traded on either the NYSE or the NASDAQ.
b) The highest rank is 1 and 25 is the lowest rank in the Supply Chain Management Top 25 list.
c) The rank of 26 indicates that the firm was not in the SCT25 list in that year.

TABLE A.2: Two-Day Market Move Dates of Confounding Events

Notes:

a) Firms are listed in the order of their rank in the SCT25 in a given year.
b) The Lexis Nexis database was used to find the dates of other announcements in the SCT25 event window.
c) The media publication date about some major other news about the company is day 0. The market move dates for this confounding news is [-1, 0] provided that both day 0 and day -1 are both stock market open days. If day -1 is a stock market closed day, then the event window is just day 0 provided that this is a stock market open day. If day 0 is a closed day then the event window is day *t* where *t* is the first stock market open day after day 0 if day -1 is also a closed day. If day 0 is closed day but day -1 is an open day then the event window consists of day -1 and day *t*.

DECISION SCIENCES INSTITUTE

An information theoretic approach to treat inverse S-shaped probability weighting problems

Michel Verlaine
Michel.verlaine@icn-artem.com

Abstract

The aim of this article is to provide a decision making approach to treat empirically observed probability weighting problems. We develop an approach to treat empirically documented inverse S-shaped probability weighting problems. We assume that decision makers pick set measures by maximizing entropy under the constraint of the observed dataset. In a sense, the decision maker maximizes uncertainty given the dataset at hand and thus puts more weight on the extremes. The approach is potentially useful to treat many kinds of financial problems when decision makers are uncertainty averse. .

KEYWORDS: Ambiguity, Rationality, Behaviour under risk and uncertainty.

JEL classification: G11, D81, C11

INTRODUCTION

The standard Expected Utility (EU) approach in modelling behaviour under uncertainty has been the paradigm in behaviour under uncertainty since the seminal works of (Von Neumann & Morgenstern, 1953) as well as (Savage, 1954). Yet, (Allais, 1953) pointed out that, Decision Makers when faced with choices under uncertainty, violated the postulates of EU. Later on, (Ellsberg, 1961) also showed that Decision Makers (DMs) faced with ambiguous lotteries do not act according to EU theory. Basically, the DM distinguishes between roulette and horse lotteries (Anscombe & Aumann, 1963). This evidence has led to the distinction between risk and uncertainty, where the latter is also known as ambiguity. Decision theorists thus developed theories of rational decision making when the DM is faced with sets of probabilities.

(Gilboa & Schmeidler, 1989) as well as (Schmeidler, 1989) developed two alternative approaches of decision making under uncertainty. Both approaches relax the independence axiom. (Gilboa & Schmeidler, 1989) show that if independence only holds when risky acts are mixed with constant acts, then the DM's decision problem can be represented as maximizing the EU given the least favourable probability distribution from a set of probability measures. This model is known as maxmin EU (MEU). (Schmeidler, 1989) presumes that independence only holds for so-called comonotonic acts, when acts cannot be used to hedge against each other. The decision problem can then be modelled as maximizing utility with respect to a non-additive set measure, called capacity. This is the Choquet expected Utility (CEU) model.

These decision theoretic models, however, are not consistent with experimental evidence. Since the seminal work of (Kahneman & Tversky, 1979;1991) it is well known that DMs transform probabilities and value deviations with respect to a subjective benchmark. The empirical literature documents that the probability transformation is inverse S-shaped. The probability weighting function (PWF) is extensively discussed by (Prelec, 1998). Prelec suggests that the probability weighting dimension dominates the impact of the value function and that behaviour can be represented with a power utility function and a PWF.

More recently, (Ghirardato et al., 2004) develop an approach known as $\alpha - MEU$ which consists in mixing maxmin behaviour with maxmax behaviour. Within this framework, DMs face a set of probability measures and according to their ambiguity aversion α they choose a certain combination of the most optimistic and pessimistic scenarios. (Amarante, 2009) shows that $\alpha - MEU$ preferences can be modelled with Choquet capacities and there thus exists a mapping between the $\alpha - MEU$ model and the CEU model. Moreover, there are α's for which the capacity is neither globally convex nor concave. This is a very useful property which implies that in principle inverse S-shaped probability weighting could be modelled with $\alpha - MEU$ preferences.

The aim of this article is to develop a decision theoretic approach to treat experimentally documented inverse S-shaped probability weighting problems. Probability distributions are indexed by states of nature. DMs maximize entropy as this maximizes uncertainty given the observed data. We show that we can recover the probability weighting function as maximum entropy implies that the DM puts more weight on the extremes of the probability distribution.

We start by introducing some notations in the next section. We then present the literature on Neo-Bayesian statistics and its relation to capacities. Follows an exploration of the relation between capacities and Cumulative Prospect Theory. We then discuss the empirical features of the probability weighting function. The following section introduces the concept of entropy and imprecise probabilities. We then formulate the statistical decision problem of a DM facing imprecise probabilities and relate violations of the independence axiom to violations of the weak conditionality axioms in statistics. The final section indicates how probability weighting can be deduced from a constrained maximum entropy approach, which can be used for many decision making problems under uncertainty.

PRELIMINARIES AND NOTATIONS

We will consider the following environment. There exists a set of states of the world S and an algebra Σ of subsets of S as well as a set of consequences X. The decision maker chooses elements among a set of simple acts $\mathfrak{I}$. Simple acts are finite-valued Σ-measurable functions $f : S \to X$. The subset of constant acts is identified by elements $x \in X$ such that $x(s) = x \ \forall s \in S$. We will also consider the possibility where X is a set of lotteries like in the (Anscombe & Aumann, 1963) horse-roulette lottery framework. X is then a convex subset of a vector space. Mixed acts can then be defined in the following way:

$$\forall f, g \in \mathfrak{I} \text{ and } \lambda \in [0,1],\ \lambda f + (1-\lambda) g \in \mathfrak{I}. \quad (1)$$

Such a mixed act assigns the outcome

$$\lambda f(s) + (1-\lambda) g(s) \in X \text{ to } s. \quad (2)$$

Preferences are modelled as binary relations $\geq$. Now, consider $B(\Sigma)$ the set of all real-valued Σ-measurable simple functions which is equivalent to the vector space generated by the indicator function 1_A of the events $A \in \Sigma$. A utility function is a mapping from the consequence set X to the real set:

$$u : X \to \Re, \quad \forall f \in \mathfrak{I},\ u(f) \in \mathbf{B}_0(\Sigma) \quad (3)$$

and is defined by

$$u(f)(s) = u(f(s)) \ \forall s \in S. \quad (4)$$

The set of all finitely-additive and bounded set functions on Σ is denoted by $ba(\Sigma)$. A nonnegative element of $ba(\Sigma)$ which assigns proba 1 to S is called a probability measure *P* or *Q*. Elements

$\varphi \in B_0(\Sigma)$ and $m \in ba(\Sigma)$ can thus be combined to give $\int \varphi dm$. We will be interested in the existence of a functional $I : B(\Sigma) \to \Re$. This functional is said:

Monotonic if $I(\varphi) \geq I(\psi)\ \forall \varphi, \psi \in B(\Sigma)\ s.t.\ \varphi(s) \geq \psi(s)\ \forall s \in S$ (5)

Constant additive: if $I(\varphi + a) = I(\varphi) + a\ \ \forall \varphi \in B(\Sigma)\ and\ \ a \in \Re$ (6)

Positively homogeneous: if $I(a\varphi) = aI(\varphi)\ \ \forall \varphi \in B(\Sigma)\ \ and \quad a > 0$ (7)

It is said constant linear if it is constant additive and positively homogeneous.

NEO-BAYESIAN STATISTICS

Following, (Ghirardato et al., 2004) and (Ghirardato & Marinacci, 2001) the following axioms are considered

A1. $\succsim$ is complete and transitive

A2. C-independence: For all $\psi, \varphi \in \mathcal{A}$ and for any constant act γ and all a$\in (0,1)$

$\psi \succ \varphi \ \Leftrightarrow\ a\psi + (1-a)\gamma \succ a\varphi + (1-a)\gamma$

A3. Archimedean property: For all $\psi, \varphi, \gamma \in \mathcal{A}$, if $\psi \succ \varphi$ and $\varphi \succ \gamma$ then $\exists a, b \in (0,1)$ such that $a\psi + (1-a)\gamma \succ \varphi$ and $\varphi \succ\ b\psi + (1-b)\gamma$

A4. Monotonicity: For all $\psi, \varphi \in \mathcal{A}$, $\psi(s) \succsim \varphi(s)\ for\ any\ s \in S \implies \psi \succsim \varphi$

A5. Non-degenerecy: $\exists x, y \in X$ such that $x \succ y$

It is well-known that by adding one of the following axioms one gets the special cases considered in the literature.

A': Subjective expected utility (SEU): For all $\psi, \varphi \in \mathcal{A}$ such that $\psi \backsim \varphi$,

$\frac{1}{2}\psi + \frac{1}{2}\varphi \backsim \varphi$

A'': Choquet Expected Utility (CEU): For all $\psi, \varphi \in \mathcal{A}$ such that $\psi \backsim \varphi$,

$\frac{1}{2}\psi + \frac{1}{2}\varphi \backsim \varphi$ if $\psi\ and\ \varphi$ are comonotonic.

A''': Maxmin Expected Utility (MEU): For all $\psi, \varphi \in \mathcal{A}$ such that $\psi \backsim \varphi$,

$\frac{1}{2}\psi + \frac{1}{2}\varphi \succsim \varphi$

(Ghirardato et al., 2004) show that preferences satisfying axioms A1 to A5 can be represented by a continuous functional $I^*: B(\Sigma) \to \mathbb{R}$ such that $\psi \succsim \varphi$ *iff* $I^*(\psi) \geq I^*(\varphi)$

Where

$$I^*(\psi) = (1 - \alpha^*(\psi))min_{\ P \in C^*} \int \psi dP + \alpha^*(\psi) max_{\ P \in C^*} \int \psi dP \quad (8)$$

$\alpha^* \in [0,1]$

Also, if $\psi, \varphi \in B(\Sigma)$ are linearly related such that

$$(\int \psi dP)_{P \in C^*} = a(\int \varphi dP)_{P \in C^*} + b\ \text{ then }\ \alpha^*(\psi) = \alpha^*(\varphi) \quad (9)$$

The set $C^* \subset ba(\Sigma)$ is typically determined from what (Ghirardato et al., 2004) call an "unambiguous preference relation".

As pointed out by (Amarante, 2009) this representation, however, is not unique. Amarante discusses $\alpha - MEU$ preferences by relating them to Choquet integration.

For $C \subset ba(\Sigma)$, consider $A(C)$ the space of all weak* -continuous affine mappings on C. Weak*-convergence is a measure-theoretic notion which designates convergence in distribution (for further details (Schervish, 1997)). The canonical mapping $\kappa: B(\Sigma) \to A(C)$ then associates to $\psi \in B(\Sigma)$ the function $f_\psi \in A(C)$ defined by $f_\psi(P) = \int \psi dP, P \in C$. Amarante shows that the functional I^* factors as $I^* = V^* \circ \kappa$ where $V^*: A(C^*) \to \mathbb{R}$ is monotone and isotonically additive. Also, a

functional V: $A(C) \to \mathbb{R}$ which is isotonically additive is comonotonically additive. Even though the IBP representation is not unique, all the representations have in common that:

- Any functional I representing IBP can be factorized as $I = V \circ \kappa$, where κ is the mapping $B(\Sigma) \to A(C)$
- The functional V: $A(C) \to \mathbb{R}$ is always monotone and comonotonic additive.

In (Ghirardato et al., 2004) the set $C^*$is interpreted as a description of the ambiguity faced by the Decision Maker whereas the function $\alpha^*(.)$ indicates the DM's attitude towards ambiguity. Amarante, however, points out that the set C^* does not necessarily describe uncertainty faced by the DM as C^* is the set of predictives used by the DM. As α^* depends on the set C^* and as there are many admissible $C's$, α cannot be interpreted as a measure of ambiguity aversion as it is indeterminate. Only, the functional form of V can be used to characterize ambiguity aversion. Thus a concave V would correspond to global ambiguity aversion. Finally, Amarante shows that every $\alpha - MEU$ preference is represented by a functional $I: B(\Sigma) \to \mathbb{R}$ of the form

$$I(\psi) = \int \kappa(\psi) dv \tag{10}$$

For some capacity $v: B \to [0,1]$, *B* being the $Borel\ \sigma - algebra$ generated by the weak*-topology on *C*. As described in the next section, this capacity is mathematical object that can be related to the PWF of Cumulative Prospect Theory.

CAPACITIES AND CHOQUET EXPECTED UTILITY

(Kahneman & Tversky, 1979; 1992) studies show that individuals first rank outcomes and then apply a non-linear PWF. However, their model is just a subcase of the general Choquet Expected Utility (CEU) model which we summarize below. A recent overview of prospect theory is provided by (Wakker, 2010). Let S be a finite set of states of nature. Let *X* be a set of monetary outcomes that includes the neutral outcome 0, all other elements are interpreted as gains or losses. An uncertain prospect *f* (act) is a function from S into *X.* To define the cumulative functional, outcomes of each prospect are arranged in increasing order. The utility that is expected by the individual depends on the ranking of the outcomes and the function is thus called (CEU). A prospect *f* is represented as a sequence of pairs (x_i, A_i), which yields x_i if A_i occurs, where $x_i > x_j$ *iff* $i > j$, and (A_i) are the events of an algebra of S. Now, let's use positive subscripts to denote positive outcomes and negative subscripts to denote negative outcomes. The positive part of *f,* denoted f^+, is obtained by letting $f^+(s) = f(s)$ if $f(s) > 0$, and $f^+(s) = 0$ if $f(s) \leq 0$. As in expected utility theory, we assign to each prospect a value $V(f)$ s.t. $V(f) \geq V(g)$ *iff* $f \geq g$. Now, we call a capacity, a non-additive set function that generalizes the standard notion of probability. More exactly, a capacity *v* is a function that assigns to each $A \subset S$ a number $v(A)$ satisfying $v(\phi) = 0$, $v(\Omega) = 1$, and $v(A) \geq v(B)$ whenever $B \subset A$. CPT asserts that there exists a strictly increasing utility function $u : X \to R$, satisfying

$u(x_0) = u(0)=0$, and capacities v^+ and v^-, such that for $f = (x_i, A_i)$, $-m \leq i < n$,

$$\begin{aligned} V(f) &= V(f^+) + V(f^-) \\ V(f^+) &= \sum_{i=0}^{n} \pi_i^+ u(x_i), \quad V(f^-) = \sum_{i=0}^{0} \pi_i^- u(x_i) \end{aligned} \tag{11}$$

$$\begin{aligned} &\pi_n^+ = v^+(A_n), \quad \pi_{-m}^- = v^-(A_{-m}), \\ &: \pi_i^+ = v^+(A_i \cup \ldots \cup A_n) - v^+(A_{i+1} \cup \ldots \cup A_n), \qquad 0 \leq i \leq n-1 \\ &\pi_i^- = v^-(A_{-m} \cup \ldots \cup A_i) - v^-(A_{-m} \cup \ldots \cup A_{i-1}), \qquad 1-m \leq i \leq 0. \end{aligned} \tag{12}$$

Letting $\pi_i = \pi_i^+ \ if \ i \geq 0$ and $\pi_i = \pi_i^- \ if \ i < 0$, $V(f)$ reduces to:

$$V(f) = \sum_{i=-m}^{n} \pi_i u(x_i) \quad (13)$$

The decision weight associated with an outcome can be interpreted as the marginal contribution of the respective event, defined in terms of capacities. The measure of an event thus depends on it's rank and this model is a generalization of expected utility called (CEU). An individual maximizing (13) is called a Choquet Expected Utility (CEU) maximizer. Under risk, where an objective cumulative distribution function exists, it may be interpreted as maximizing expected utility with respect to the transformed cumulative distribution function $v \circ F$ where *F* is the objective cumulative distribution function. This model is called Rank Dependent Expected Utility (RDEU). *v* is the PWF and it's shape seems to be rather robust across experiments (Tversky & Wakker, 1995) and (Prelec, 1998). Moreover, (Prelec, 1998) derives the functional consistent with behavioral axioms.

EMPIRICAL FEATURES OF THE PROBABILITY WEIGHTING FUNCTION

In the standard CEU model $u(x_0)$ is considered to be the minimal utility that the individual will get in the least favorable state. He then adds the increments in utility weighted by his beliefs on the future states. However, $u(x_0)$ is not necessarily the minimal utility, but may be the reference point with respect to which the individual weights gains and losses. Moreover, the model may be slightly different since the capacities are different on gains and losses. Actually, CEU is a special case where the capacity for losses is the *dual* of the capacity for gains, i.e. $v^-(A) = 1 - v^+(S - A)$. (Kahneman & Tversky, 1992) also considered a special case of CPT where $v^+ = v^-$. This property is based on preference conditions called *reflection*.

There are two possibilities to define risk (or uncertainty) aversion : via the curvature of the utility function or via the functional form of the capacities. Nevertheless, it is generally accepted that risk behavior is described by the functional form of the utility function, whereas the uncertainty (or ambiguity) aversion is given by the functional form of the capacities.

Now, let's rewrite $V(f^+)$ in a different way :

$$V(f^+) = u(x_0) + \sum_{i=1}^{n} [u(x_i) - u(x_{i-1})] v\left(\bigcup_{j=i}^{n} A_j\right) \quad (14)$$

This formula expresses the value of a prospect as a function of changes in utility and a transformation of the cumulative probability, called probability weighting function (PWF). It has been suggested that uncertainty aversion can be analyzed with a CEU model. In fact, (Schmeidler, 1989) gives the following definition of uncertainty aversion. Uncertainty aversion is equivalent to the convexity of the capacity, that is :

$$v(A \cup B) + v(A \cap B) \geq v(A) + v(B) \quad (15)$$

for all measurable events A and B. We have additivity when the right hand side and the left hand side are equal, and the individual is then uncertainty neutral. Now, experimental evidence (Tversky & Wakker, 1995), (Prelec, 1998) shows that the capacity *v* is sub-additive meaning that there exist events *E* and E' s.t.

$$v(B) + v(A) \geq v(A \cup B) \quad whenever \quad v(A \cup B) \leq v(S - E) \quad (16)$$

And

$$1 - v(S - B) \geq v(A \cup B) - v(A) \quad whenever \quad v(A) \geq v(E') \quad (17)$$

The first condition is called lower sub-additivity whereas the second is called upper subadditivity. The certainty effect is characterized by upper sub-additivity, since the increase of a high probability to certainty has more effect than the same increase in probability for a medium probability. This kind of behavior has also been documented under risk.

Empirical evidence (Prelec, 1998), Wu and Gonzalez (1996)) suggests that the probability weighting function has the following properties :

asymmetry - $v(p) = p$ approximately at $p = 1/3$, where p is the probability to get at least a certain amount.
Inverse s-shape - concave on an initial interval and convex beyond
reflectivity - assigns the same weight to a given loss-probability as to a given gain-probability.
If the preference relation satisfies a certain number of axioms given in the appendix A1, the preference relation can be represented by a sign- and rank-dependent utility function. (Prelec ,1998) provides a set of axioms needed to deduce a functional form of the weighting function that agrees with the stylized facts. The most general specification for this weighting function is given by the following form :

$$v(p) = \gamma \exp\left(-\beta(-\ln p)^{\alpha}\right) \tag{18}$$

However, if the preference relationship satisfies certain axioms, notably diagonal concavity, sub-proportionality and compound invariance (see Prelec (1998)), then the specification takes the following less complex form :

$$v(p) = \exp\left(-(-\ln p)^{\alpha}\right) \tag{19}$$

where α indicates the degree of non-linearity of the function. One typically observes risk-seeking for small-probability gains and large-probability losses, and risk-aversion for small-probability losses and large-probability gains. A linear value function would be sufficient to explain observed behavior. However, if the value function is not linear, then the probability non-linearity must dominate the value non-linearity to explain empirical patterns. Such a dominance arises when the above probability weighting function is combined with a power function of the following form :

$$u(x) = x^{\sigma^+} \ \ if \ \ x \geq 0 \ , \ -(-x)^{\sigma^-} \ \ if \ \ x < 0 \tag{20}$$

Concerning the weighting function, the values of the parameters of v can be slightly different across studies, the functional form is quite robust, see Prelec (1998).

ENTROPY AND IMPRECISE PROBABILITIES

Entropy is a concept that stems from information theory. It measures uncertainty as well as the information provided by a probability distribution. The idea behind entropy is that the least likely an event is to occur, the more information is provided by the occurrence of an event. The content of information is thus a negative function of the probability of the respective event. It can be shown that there is a unique function which respects a certain number of plausible axioms, namely, $-\log p$. The content of information in a probability distribution can be evaluated by taking the expectation of this function:

$$E_p(-\log p) = -\sum_i p_i \log p_i \tag{21}$$

This is Shannon's information theoretic entropy measure. (Jaynes, 1957) argues that a way to treat ill-posed statistics problems, is to consider observed functions, typically moments, of the possible events, as part of the available information. He suggests to consider the probability distribution that assumes the less given the data. This is done by maximizing uncertainty given the realized values of the above mentioned functions. Uncertainty is measured with Shannon's information theoretic entropy measure. In fact, even though not the only measure of uncertainty, Shannon's measure is consistent with additivity of independent risks.

The entropy measure is maximum when the distribution is uniform, in the sense that given a range of possible outcomes, we have no information on which event is more likely to occur. Conversely, the entropy is minimum when we know exactly which event is going to occur. If we maximize entropy given constraints in terms of functions of the data, it is as if we take the most uniform distribution consistent with the constraints. Another interpretation is that we get the distribution

that can be generated in the most different ways. Actually, the following entropy optimization postulate given in (Kapur & Kesavan, 1992), generalizes the principle.
Each probability distribution is an entropy optimization distribution; i.e., it can be obtained by maximizing an appropriate entropy measure or by minimizing a cross-entropy measure with respect to an appropriate a priori distribution, subject to its satisfying appropriate constraints.
A rigorous way to be robust, given partial information, is to maximize entropy under the constraint of partial information (Jaynes, 1982)).

We will consider a situation where probabilities are imprecisely known to the decision maker. In the information theoretic literature, those imprecise probabilities are typically analyzed with monotone measures μ which are not necessarily additive. The most recent contributions in generalized information theory (Klir, 2006)) refer to monotone measures as a considerably broader framework than probabilities for formalizing uncertainty. As they can be sub-additive,

$$\mu(A \cup B) \leq \mu(A) + \mu(B) \tag{22}$$

as well super-additive,

$$\mu(A \cup B) \geq \mu(A) + \mu(B), \tag{23}$$

monotone measures are more flexible in capturing different types of uncertainty. For instance, (Klir, 2006) points out that, even though additivity works well for types of measurement under idealized, error-free conditions, it is not really adequate for most measurements under real physical conditions, when measurement errors are unavoidable. When measurement errors are present, observations might provide more evidence for the joint event $(A \cup B)$ than the sum of the evidence for the events considered individually, thus:

$$\mu(A \cup B) > \mu(A) + \mu(B) \tag{24}$$

We will assume that the decision maker views probability distributions as indexed by states drawn from nature. This is the horse-roulette lottery framework developed in (Anscombe & Aumann, 1963). In order to illustrate, consider a statistical decision maker facing densities indexed by random draws of parameters θ. This is typically the way the topic is addressed in the macro-econometric literature on robust decision making. This literature, however, applies max-min behavior which presumes concave capacities and pessimism which is inconsistent with empirical evidence (for a recent discussion (Abdellaoui et al., 2010). In the next section, we describe the decision protocol of a decision maker who maximizes entropy given the observed distribution. This implies that he distorts probabilities by putting more weight on the extremes.

THE STATISTICAL DECISION PROBLEM

We consider a DM observing the multivariate process of variables, called the data generating process DGP. Standard expected utility theory would advocate estimation of a statistical model, usage of that prediction as the objective probability distribution and finally choice of an act that maximizes expected utility. This viewpoint is in line with the classical statistics approach in the sense that probabilities are presumed "objective". We argue in a neo-Bayesian flavor (Amarante, 2009), that our DM cares (and should care) about his precise decision problem and is well aware of his "imperfect view of the world". In that respect, (Al-Najjar, 2009) shows that different models can be consistent with the same empirical evidence, even with infinite datasets. Our DM internalizes the fact that his predictive model is (almost surely) flawed and knows that the estimated density of returns is not necessarily a good representation of the real DGP. We assume that this is due to parametric uncertainty and that it is as if nature drew another parameter θ from the parameter set Θ (see (Blackwell & Girshick, 1965). This is consistent with the (Anscombe & Aumann, 1963) way to model uncertainty. Individuals believe that there is a multivariate Data Generating Process (DGP). Elements θ (vectors of parameters) from Θ are the states of the world. *P* is the set of all simple distributions on the set of outcomes X. Φ is the set of all functions from Θ

to *P*. More exactly, elements of Φ have the following form: $F(X/data,\theta)$ where $F(X/data,\theta)$ denotes the estimated joint density on outcomes as a function of data and the θ drawn by nature.

Acts are thus choices of prospects as well as statistical models. At one point in time the *data* is fixed and observed by the DM. Now, elements of Φ are denoted by φ. The standard expected utility DM would maximize

$$\int u(\varphi(\theta))\pi(\theta/data)d\theta \tag{25}$$

where $\pi(\theta/data)$ is a probability measure over the events of the parameter states Θ given the observed sample *X*. We argue that this would be reasonable if the DM had a perfect knowledge of $(\Theta,\Re)$, where $\Re$ is the $\sigma-field$. However, it is very difficult, even for an expert in statistics, to grasp the underlying process. For instance, regime changes are difficult to detect and regime parameters difficult to estimate. We argue that for some regions the DM has good knowledge to form probabilistic beliefs about the events, while for some yet unseen region the DM has a blurred view and has even difficulty to define the events. In fact, given a finite sample size he has difficulties to get a clear grasp of some parameter values. We will argue later on, in line with (Jaynes, 1957; 1982), that it is rational for such a DM to deduce the posterior by maximizing entropy and that this leads to the functional form of π^* suggested by (Prelec, 1998).
The individual hence maximizes the following function :

$$\int u(\varphi(\theta))\pi^*(\theta/data)d\theta \tag{26}$$

where $\pi^*(.)$ is a (as *v* described in section 4) transformation of *F*(*X*/*data*,θ), which is a function of θ for a fixed data set *data*.

LIKELIHOOD PRINCIPLE, WEAK CONDITIONALITY AND INDEPENDENCE

As we saw in the previous section, a standard Bayesian (DM) would maximize

$$\int u(\varphi(\theta))\pi(\theta/data)d\theta \tag{27}$$

where $\pi(\theta/data)$ is a probability measure over the events of the parameter states Θ given the observed sample *data*. As is well known from Bayes Theorem :

$$\pi(\theta/data)=\frac{f(data/\theta)\pi(\theta)}{\int_{\Theta} f(data/\theta)\pi(\theta)d\theta}\propto \quad f(data/\theta)\pi(\theta) \tag{28}$$

where $f(data/\theta)$ is the density over the respective *data* for a given θ. The latter is given by the likelihood function $l(\theta)$ and this leads to the following expression :

$$\pi(\theta/data)\propto \quad l(\theta)\pi(\theta) \tag{29}$$

$f(data/\theta)$ is now considered a function of θ. Instead of maximizing the likelihood function $l(\theta)$ to recover θ, the Bayesian maximizes the generalized likelihood function $l(\theta)\pi(\theta)$.
However, this presupposes that the Likelihood Principle is not violated. Recall that classical statistics presumes randomization over the sample space. Also, recall that the Likelihood Principle stems from two axioms: sufficiency and weak conditionality. While sufficiency will not be questioned, weak conditionality seems less unquestionable. The idea behind weak conditionality is the following. Each time a statistic is observed, it is an observation of many possible realizations of the process. The Weak Conditionality Principle presumes that a DM, faced with a realization of the sample, abstracts from other possible sample realizations and infers the parameter value by considering only the sample he has observed. Hence, all relevant experimental information is contained in the likelihood function for observed *X*. The following description is given in (Berger, 1985).

The Weak Conditionality Principle. *Suppose one can perform either of two experiments E_1 and E_2, both pertaining to μ, and that the actual experiment conducted is the mixed experiment of first choosing J = 1 or 2 with probability 1/2 each (independent of θ), and then performing experiment E_J .*
Then the actual information about θ obtained from the overall mixed experiment should depend only on the experiment E_j that is actually performed.

Experimental evidence suggests that the independence axiom is systematically violated. Moreover, violations of the independence axiom are responsible for the non-linear probability weighting. As we argue below, violations of the independence axiom imply violations of weak conditionality.
More formally, let S be a general state space with elements s and Y be the set of distributions over S with finite supports

$$\left\{ Y = y : S \to [0,1] : y(s) \neq 0 \ \ for \ \ finitely \ many \ \ s \ \ in \ \ S \ \ and \ \ \sum_{s \in S} y(s) = 1 \right\} \qquad (30)$$

Convex combinations in Y are performed point-wise, i.e. for *f* and *g* in Y and α in [0, 1], $\alpha f + (1-\alpha)g = h$ means $\alpha f(s) + (1-\alpha)g(s) = h(s)$ for $s \in S$.

We can now define the independence axiom.
Definition : The individual respects the independence axiom *iff* for all *f*,*g* and *h* in Y and for all α in (0,1) : $f > g$ implies $\alpha f + (1-\alpha)h > \alpha g + (1-\alpha)h$.
Now, rewrite the problem with $\theta \in \Theta$ (parameters are the states) and the likelihood functions $f(\theta)$, $g(\theta)$ and $h(\theta)$ of experiments *f,g* and *h*. The likelihood function can be considered as the inverse of the statistical loss function. We can thus rewrite the whole axiom with the likelihood notation and parametric uncertainty. The independence axiom can be interpreted in the following way:

Ex-ante there is a probability α to draw experiment *f* (a sample in the frequency interpretation) and $(1-\alpha)$ to draw *h*. This is preferred to the mixed experiment with *g*. Assume that an experiment has been drawn. The Weak Conditionality Principle implies that the DM should not care (for parametric inference) about what could have happened had another experiment (sample) occurred. Hence, if experiment *f* is preferred to experiment *g,* then the DM should not change his preference if those experiments are potentially mixed with another experiment (ex-ante). This implies that the decision maker should not care about how the datasets have been generated. However, since the weak conditionality principle is conceptually the same thing as the independence axiom, violations of the latter imply violations of weak conditionality. Actually, it could be argued that a new random sample could bring more value in combination with one of the observed samples. Here, we will not develop that issue, but point out that this kind of behavior can lead to non-linear probability weighting. We thus discuss parametric inference within such a framework.

ROBUST BAYESIAN POSTERIOR AND ESTIMATION OF THE FORECASTING FUNCTION

From our developments we conclude that the posterior $\pi(\theta / data)$ is calculated using the likelihood function. By acceptance of the Weak Conditionality Principle a realized likelihood function is used to infer θ, without regard of the fact that another value of the likelihood may have been obtained. Nevertheless, according to experimental evidence DM's do not reason that way. We thus advocate a methodology that is consistent with violations of Weak Conditionality and

advocated behavior in terms of robustness. This technique can then be used to infer "robust" parameters. The technique is based on the information theoretic concept of entropy.

Now, we consider a DM that faces an observed likelihood function but knows that he could have drawn another sample and hence another value for the likelihood function. As argued, a rigorous way to choose robust decision rules, given partial information, is to maximize entropy under the constraint of partial information (Jaynes, 1982). We apply this method adapted to our situation, but the general developments are given in appendix A3. We can now prove the following proposition:

Proposition *A DM maximizing uncertainty, given an observed sample cumulative probability to get a certain θ, reasons with a non-additive prior on Θ. Moreover, the latter has the same functional form as the density consistent with the inverse s-shaped probability weighting function.*

Proof : The general problem of a DM maximizing uncertainty subject to constraints given by the sample is :

$$En(\pi) = -\int \pi(\theta / data) \log\left(\frac{\pi(\theta / data}{\pi_0(\theta)}\right) d\theta \tag{31}$$

s.t.

$$E^{\pi}\left[g_k(\theta)\right] = \int_{\Theta} g_k(\theta)\pi(\theta / data)d\theta = \mu_k \quad k = 1,...,m \tag{32}$$

where $g_k(\theta)$ are functions of the parameters and π_0 is a non-informative prior. The solution (see Berger, 1985) is given by

$$\pi^*(\theta / data) = \frac{\pi_0(\theta)\exp\left[\sum_{k=1}^{m}\lambda_k g_k(\theta)\right]}{\int_{\Theta}\pi_0(\theta)\exp\left[\sum_{k=1}^{m}\lambda_k g_k(\theta)\right]d\theta} \tag{33}$$

Now let's consider the following constraint $g_k(\theta) = \left(-\log cdfn\left(l\left(\theta / data\right)\right)\right)^{\alpha}$ which is a function of θ for a fixed data set, hence $l(\theta)$ is the likelihood function. Thus, $g_k(\theta) = \left(-\log cdfn(l(\theta))\right)^{\alpha}$
Notice the relationship of the function with the content of information. In fact, if you rewrite it in the following way :

$$g_k(\theta) = \left(\log\frac{1}{cdfn(l(\theta))}\right)^{\alpha} \tag{34}$$

it is a measure of information content of the distribution with respect to certainty. Now if the DM maximizes the above mentioned program under this constraint, we get the following:

$$\pi^*(\theta / X) = \frac{\pi_{0(\theta)}\exp\left[\lambda_1\left(-\log cdfn(l(\theta))\right)^{\alpha}\right]}{\int_{\Theta}\pi_{0(\theta)}\exp\left[\lambda_1\left(-\log cdfn(l(\theta))\right)^{\alpha}\right]d\theta} \tag{35}$$

Considering a value for the denominator δ (after having integrated), we recover the density in appendix A2 (equation 27), with λ_1=-1 and

$$\pi_0(\theta) = \alpha\frac{l(\theta)}{cdfn(l(\theta))}(-\log(cdfn(l(\theta))))^{\alpha-1}d\theta \tag{36}$$

The robust posterior is the following

$$\pi^*(\theta / X) \propto \alpha \frac{l(\theta)}{cdfn(l(\theta))} \left(-\log\left(cdfn\left(l(\theta)\right)\right)\right)^{\alpha-1} \exp\left(-\left(-\log\left(cdfn\left(l(\theta)\right)\right)\right)^{\alpha}\right) d\theta \quad (37)$$

and the parameter can be estimated in the following way :

$$\theta^* = \arg\max_{\theta \in \Theta} \pi^*(\theta / X) \quad (38)$$

This is consistent with our interpretation in terms of parametric uncertainty. Parametric uncertainty is taken into account in the estimation process.

CONCLUSION

Most of the academic literature in economics and finance has focused on approaches where decision makers maximize a utility function given a worst-case distribution. This implies that the probability weighting function is concave which inconsistent with experimental evidence. Inverse S-shaped probability weighting approaches, however, have been rarely applied in Economics as they are difficult to implement. We develop a tractable approach based on entropy, which could potentially explain the Inverse S-shaped probability weighting as being rational, a topic to be developed in future research.

APPENDICES

A1 :

The appendix collects axioms from (Prelec, 1998). They consist in an axiomatization of the sign- and rank-dependent representation. Let $\geq$ represent a preference relation on the set Π of probability distributions *P,Q,…* on $X = [x^-, x^+]$, with $x^- < 0 < x^+$. The following five axioms are assumed to hold on Π without restriction:

A1. Weak Order: $\geq$ is complete and transitive.
A2. Strict Stochastic Dominance: $P > Q$ if $Q \neq P$ and P stochastically dominates Q.
A3. Certainty Equivalent Condition : $\forall P, \exists x$ *s.t.* $(x) \sim P$.
A4. Continuity in Probabilities: If $(y, p) > (x)$, $0 < p < 1$, then there exists q, r s.t. $q < p < r$, $(y, q) > (x)$, and $(y, r) > (x)$. If $(y, p) < (x)$, $0 < p < 1$, then there exists q, r s.t. $q < p < r$, $(y, q) < (x)$ and $(y, r) < (x)$.
Let's define $S(k, n)$, $0 \leq k \leq n$, as the set of all k non-positive and (n,k) nonnegative rank-ordered n-tuples from X, $S(k, n) = \{(x_1,\ldots, x_n) \in X : x_1 \leq \ldots \leq x_k \leq 0 \leq x_{k+1} \leq \ldots$
A5. Simple-Continuity: For any probability vector $(p_1,\ldots, p_n)$ the preference relation induced on each S(k,n) is continuous.
Let $(x_i, p_i ; x_{-i}, p_{-i})$ denote a prospect with outcome x of rank "i" singled out, and let $\Pi(k, n, p)$ denote the set of all sign- and rank-order compatible prospects that have a p-chance of yielding a negative outcome :
$\Pi(k, n, p) = \{(x_1, p_1,\ldots, x_n, p_n) : (x_1,\ldots, x_n) \in S(k, n)$ and : $p_1 + \ldots + p_k = p\}$
A6. Tradeoff Consistency: There do not exist eight prospects, $(x, p_i; a_{-I}, p_{-i})$, $(x, p_i; b_{-I}, p_{-I})$ $(x_0, p_i)(y, q_j ; d_{-j}, q_{-j})$, such that the first four and the second four belong to the same sign- and rank-order compatible set, and that :
$(x, p_i; a_{-i}, p_{-i}) \geq (y, p_i; a_{-I}, p_{-i})$,
$(x', p_i; a_{-i}, p_{-i}) \leq (y', p_i; b_{-i}, p_{-i})$

$(x', q_j ; c_{-j} , q_{-j}) \geq (y', q_j ; d_{-j} , q_{-j})$
$(x, q_j ; c_{-j} , q_{-j}) \leq (y, q_{-j} ; d_{-j} , q_{-j})$
If A1 to A6 are satisfied, then the preference relationship can be represented by the following functional :

$$V(P) = \sum_{i=1}^{k}\left(v^{-}\left(\sum_{j=1}^{i} p_j \right) - v^{-}\left(\sum_{j=1}^{i-1} p_j \right)\right)u(x_j) + \sum_{i=k+1}^{n}\left(v^{+}\left(\sum_{j=1}^{n} p_j \right) - v^{-}\left(\sum_{j=i+1}^{n} p_j \right)\right)u(x_j) \qquad (31)$$

A2 :

Let's consider the following weighting function $v = \exp(-(-\ln p)^{\alpha})$. If we denote $cdfn(l(\theta))$ the cumulative distribution function v takes the following form
$v = \exp(-(-\ln(cdfn(l(\theta))))^{\alpha})$. We assume that v as well as $cdfn(l(\theta))$ are C^1. Differentiating v leads to

$$dv = \alpha \frac{l(\theta)}{cdfn(l(\theta))}\left(-\log\left(cdfn\left(l(\theta)\right)\right)\right)^{\alpha-1}\exp\left(-\left(-\log\left(cdfn\left(l(\theta)\right)\right)\right)^{\alpha}\right)d\theta \qquad (32)$$

where $l(\theta)$ denotes the likelihood.

A3:

We review the developments of the different Jaynes papers collected in Jaynes Papers on Probability, Statistics and Statistical Physics. First we develop the conceptually simpler discrete case. We then discuss the continuous case. Consider a quantity x that can take n different values ($x_1, x_2, \ldots, x_n$) and functions $f_1(x)$, $\ldots, f_m(x)$ where $m < n$. The idea of maximum entropy is to find a probability assignment $p(x_i) = p_i$ that maximizes uncertainty given a few functional contraints from the data. As we will see later, another interpretation (in terms of frequency) is that the maximum entropy distribution is that frequency distribution which can be realized in the greatest number of ways and hence is the most likely to occur.
More formally the maximum entropy formalism is the following:

$$\begin{aligned} & Max \ -\sum_{i=1}^{n} p_i \log p_i \\ & p_i \geq 0 \\ & \sum_{i=1}^{n} p_i f_k(x_i) = \mu_k \\ & \sum_{i=1}^{n} p_i = 1 \end{aligned} \qquad (34)$$

The solution is

$$p_i = \frac{1}{Z(\lambda_1,\ldots,\lambda_m)}\exp\left[-\lambda_1 f_1(x_i) - \ldots - \lambda_m f_m(x_i)\right] \qquad (35)$$

with the partition function :

$$Z(.) \equiv \sum_{i=1}^{n}\exp\left\{-\lambda_1 f_1(x_i) - \ldots - \lambda_m f_m(x_i)\right\} \qquad (36)$$

The Lagrange multipliers are determined from

$$\mu_k = -\frac{\partial \log Z(.)}{\partial \lambda_k} \quad k = 1,...,m \tag{37}$$

The above density is the "maximum non-commital" distribution given the sample information. Jaynes suggests the application of this method to form prior probabilities in a least ad hoc way. Notice that the above probabilities are not defined as frequencies, but are subjective "maximum non-commital" probabilities. Now, Jaynes also discusses the frequency case. Consider the above random experiment that is repeated *N* times, the result x_i will be obtained m_i times, $i = 1, 2, \ldots, n$. The probability (frequency) p_i is now given by m_i/N and m_i is not uniquely determined. Now we can ask, what is the "best" estimate? Well, in *N* repetitions of the random experiment, there are a priori n^N conceivable results. For observed m_i's, out of the original n^N, how many would lead to a given set of observed m_i's ? The answer is given by the multinomial coefficient :

$$W = \frac{N!}{m_1!.\bullet.m_n!} = \frac{N!}{(Np_1)!.\bullet.(Np_n)!} \tag{38}$$

Hence the set of p_i's that can be realized in the greatest number of ways is the one which maximizes *W* subject to the above mentioned constraints. Now, in the limit, we get, by the Stirling formula,

$$\lim_{N\to\infty} \frac{1}{N} \log W = \lim_{N\to\infty} \frac{1}{N} \log \left[\frac{N!}{(Ng_1)!.\bullet.(Ng_n)!} \right] = -\sum_{i=1}^{n} p_i \log p_i \tag{39}$$

DECISION SCIENCES INSTITUTE
An operational approach to select CEU Portfolios

Michel Verlaine
Michel.verlaine@icn-artem.com

ABSTRACT

Standard portfolio theory presumes that mean-variance optimization is a good approximation for expected utility maximization. Experimental evidence, however, points out that individuals transform probabilities in a non-linear way. This probability weighting behaviour can be viewed as an alternative way to treat risk or uncertainty aversion. The literature has not yet come up with an operational approach to select portfolios for such Choquet Expected Utility (CEU) maximizers. The paper develops a defence of the CEU approach in Finance and then develops an econometric methodology based on the method of moments to select portfolios.

KEYWORDS:: Choquet Expected Utility, Portfolio Selection, Decision Theory.

JEL classification: G11, D81, C11.

INTRODUCTION

Standard portfolio theory presumes that investors maximize Mean-Variance (Markowitz, 1989). Mean-Variance is supposed to be a good approximation of more general expected utility functions. In a recent paper, (Markowitz, 2014) makes the case for Mean-Variance optimization by discussing necessary and sufficient conditions for Mean-Variance approximations. He shows that Mean-Variance is a good approximation for most Expected Utility functions and distributions. Empirical evidence, however, largely documented in (Wakker, 2010), indicates that decision makers are not behaving like expected utility maximizers but transform probabilities. Violations of Expected Utility are well-known in the academic literature, notably violations of the sure thing principle in the Savage framework and violations of the independence axiom in the Von Neumann Morgenstern framework. For an overview of this decision theoretic literature (Gilboa, 2009). Over the last two decades and especially after Kahneman and Tversky's Cumulative Prospect Theory, a huge literature that deals with empirical modelling of probability transformations has been developed. The inverse S-shaped transformations implemented by decision makers are well documented in (Wakker, 2010). (Prelec, 1998) provides an axiomatization and potential parametrizations of the probability weighting model. However, as we will see the axiomatization and parametrization of probability weighting functions (PWF) renders non-expected utility models much more tractable and it is this fact that we exploit.

Strangely the literature on operational portfolio theory as well as professional practice doesn't seem to have developed tools to select portfolios for decision makers maximizing utility with respect to a non-additive probability measure, called a Choquet capacity (Denneberg, 1994). There exists a broad literature, called Behavioural Finance, applying such approaches to financial markets in order to describe so-called financial anomalies (Benartzi & Thaler2003). (Shefrin & Statman, 2000) have also develop a framework called Behavioral Portfolio Theory, but it is not very operational. One of the reasons is probably that non-additive probabilities are viewed as

irrational by many economists trained in the Expected Utility framework. One of the arguments is that a Dutch book could be made against such a decision maker. As (Diecidue & Wakker, 2002) have shown, however, a Dutch book can be made against Mean-Variance maximizers as well. Moreover, as (Wakker, 2010) and more recently (Wakker, 2017) argue, the non-additivity of the weighting function might be used to characterize risk aversion of decision makers.

The finance industry as well doesn't seem to be very consistent in its applications of portfolio theory. Indeed, for operational reasons and due to the portfolio delegation problem stemming from asymmetry of information problems, the industry largely uses benchmarks with respect to which they measure and constrain fund performance. It implies that fund managers' deviations with respect to the benchmark are constrained by what is called a tracking error constraint. However, as shown by (Roll, 1992) such portfolios are generally inefficient. Second, as argued by (Chow, 1995) this renders the utility function de facto state dependent. Third, (Admati & Pfleiderer, 1997) have shown that the tracking error as a control device cannot be supported as an equilibrium by an expected utility function.

This paper aims at analysing those questions and providing a framework to operationally select portfolios for Choquet Expected Utility (CEU) maximizers. We combine experimental approaches in decision making and formulate the CEU maximizers optimization in econometric terms, namely as a method of moments estimation. The first step consists in estimating the preference function by suggesting lotteries to individuals. Their choices will reveal their preference function. Given a multivariate process of asset returns, the individual would then optimize his portfolio by deriving the function with respect to the portfolio weights. This leads to a system of N (the number of assets) optimality relations, namely that the expectation of the derivative of the preference function equals 0. Assuming returns are multivariate i.i.d. the expectation of the function can be estimated by the sample counterpart, and we can use a method of moments method to estimate the portfolio weights.

Section 2 presents the static portfolio selection problem. In Section 3 we describe the tracking error variance approach used in practice. Section 4 presents the main argument and counterargument against non-expected utility models, namely the possibility to construct Dutch books. Section 5 discusses the Rank Dependent Utility (RDU) model. Observed behaviour is described in section 6. In Section 7, we explain how to estimate the preference function. Section 8 derives the optimality conditions of the Decision Maker (DM). Finally, section 9 shows how to estimate the portfolio weights.

THE STATIC PORTFOLIO SELECTION PROBLEM

This section explains the general portfolio selection approach independently of any mean-variance approximation and aims at preparing the general approach for any CEU decision maker analyzed later. Consider a set of n securities, where the one period return of security *j* is denoted by R_j. Any linear combination of these securities that has positive market value is called a *portfolio*. Economic rationality presumes that any individual's aim is to choose a portfolio in such a way that it maximizes his satisfaction, represented by a utility function. The theory imposes some structure on the preferences, namely that the individual maximizes a Von-Neuman Morgenstern expected utility function that is defined on end of period wealth. Beliefs are thus disentangled from the preference functional and such an individual is said to be *probabilistically sophisticated (* Machina & Schmeidler, 1992). The only relevant information is the subjective distribution of returns (assuming that the individual knows his preferences, which is implied by completion). Moreover, it is assumed that there exists a *riskless security* whose future return is known with certainty. The following assumptions are made about the *Capital Market Structure* (CMS) :

A1 : *Frictionless markets*, meaning that there are no transaction costs and that all securities are perfectly divisible.
A2 : The individual is *price taker,* the distribution of returns is given.
A3 : Absence of *arbitrage possibilities.* Implies that the riskless assets have the same rate of return.
A4 : *No Institutional restrictions :* The borrowing and lending rate are the same, there are no short sales restrictions.

Given the CMS and the behavioral assumptions, the portfolio selection problem can be modelled in the following way :

$$\max_{\{\theta_1,\ldots,\theta_n\}} E\left\{U\left[\left(\sum_{j=1}^{n}\theta_j\left[R_j - R\right]+R\right)W_o\right]\right\} \; subject \; to \; \sum_{j=1}^{n}\theta_j = 1 \tag{1}$$

where W_0 and *E* denote initial wealth and the expectation operator of the subjective joint probability distribution. *R* is the riskless rate. The solution to the F.O.C. are then given by :

$$\theta_j \quad s.t. \quad E\left\{U'\left[\left(\sum_{j=1}^{n}\theta_j\left[R_j - R\right]+R\right)W_o\right]\left(R_j - R\right)\right\} = 0 \tag{2}$$

Since the individual maximizes end of period wealth under the constraint that this wealth remains positive, there is another implicit constraint, namely that

$$\sum_{j=1}^{n}\theta_j\left[R_j - R\right]+R \geq 0 \tag{3}$$

at optimal θ_j with *subjective probability* one.

A feasible portfolio is said *efficient* if it respects (2) for an increasing concave function *U*. There are more effcient portfolios and each individual chooses the one that fits his preferences most. The problem is thus to choose an efficient portfolio given individuals preferences.
It has been suggested that the expected utility functional can be approximated by a linear combination of the mean and the variance of returns. Standard portfolio theory is thus based on Mean-Variance (M-V) analysis, meaning that one maximizes the return given a constraint on the variance. Since the problem is dual, one can alternatively minimize the variance under the constraint of a given expected return. This leads to a set of effcient portfolios. However, the investors' problem is to maximize his expected utility (in a general sense), not the return. It is generally accepted that M-V analysis leads to maximum expected utility when all distributions are normal (or when beliefs support a normal distribution) or when the utility function can be approximated by a quadratic function (Levy & Markowitz, (1979)). (Markowitz, 2014) points out that those conditions are sufficient but not necessary conditions and that for most Expected Utility functions, Mean-Variance optimizations are good approximations of Expected Utility. Actually, according to studies M-V analysis gives a good approximation of maximized expected utility (Levy & Markowitz, 1979; Kroll, Levy & Markowitz, 1984). In practice, however, asset managers do not maximize Mean-variance directly, but they compare their results to a benchmark. In order to implement this approach, a market benchmark such as the S&P500 is selected and the manager is forced to track the benchmark by constraining him to minimize the deviations with respect to the benchmark. This is called the tracking error variance (TEV) approach, the drawbacks of which are described in the next section.

DRAWBACKS OF THE TRACKING ERROR APPROACH

In practice, it is not easy to maximize the M-V utility function and practitioners try to find a benchmark (f.i. an index like the SP500) that suites best the M-V function of the customer. Investment professionals then compare their results with the benchmark. The approach based on benchmarks is also the result of a Principal-Agent application to the portfolio delegation model. The benchmark is a constraint that enables the investor to control that the manager does not deviate from objectives in terms of risk. The benchmark to be chosen depends on the aggressiveness of the portfolio, that again depends on the risk characteristics of the costumer. The manager is then told to minimize the variance of the tracking error, that is called the tracking error variance approach (TEV). Notice that the tracking error can be positive all the time, when the manager opts for active asset management.

In that case, the expected tracking error is above the benchmark. This is supposed to be a tractable way to maximize the mean-variance utility. Yet, as (Roll, 1992) has shown, if the benchmark is not an efficient portfolio, then all the portfolios using the TEV approach will be inefficient. Moreover, if the benchmark has greater mean return than the minimum variance portfolio, then the TEV portfolios have larger risks than large market porfolios. The unconstrained TEV managed portfolio thus generally has more market risk than the benchmark. (Chow, 1995) argues that customers care directly about the TEV and that such a term should be included in the utility function. He suggests the following utility function:

$$U(P) = E\big(R(P)\big) - \frac{V(P)}{rt} - \frac{TEV(P)}{tet} \tag{4}$$

where *P* denotes the portfolio, *V* the variance, *TEV* the tracking error variance, *rt* the risk tolerance, *tet* the tracking error tolerance. A customer who cares about the *TEV* can be described by the following behaviour.

A few months later he comes back to see the manager and argues that even though the return is satisfying, while the variance of the portfolio was not too high, the return could have been better since the Dow Jones performed much better. In our opinion, the fact that the individual cares about the TEV indicates that the individual's utility function is not independent of the states. In fact, in a sense the individual is disappointed. As we will see in later sections, non-expected utility has evolved towards modelling such phenomena (regret, disappointment, elation...). Hence, it is this family of functions that we will recommend. However, this kind of models has been questioned on the grounds that such individuals are subject to systematic exploitation. This argument and the counterargument are described in the next section.

BOOK MAKING AND COMONOTONICITY

De Finetti's book making principle implies that preferences should not be such that a linear combination of the latter leads to a loss. It is argued that uncertainty should then be expressed in terms of additive probabilities. The principle serves as a justification for Bayesianism, thus *perception-rationality*.
However, Dutch Books may obtain as the consequence of non-comonotonic random variables (Diecidue & Wakker, 2002) and attitudes to uncertainty (Kast & Lapied, 2003). Consider gambles f_i and g_i (acts) that are functions from the state space to the consequence space. A Dutch book, consists of a number of preferences that, when added outcome-wise, leads to a less preferred situation for each state of nature. More formally :

Definition : A Dutch book consists of a number of preferences $f^1 \geq g^1;...; f^n \geq g^n$ with

$$\sum_{j=1}^{n} \lambda^j f^j(s) < \sum_{j=1}^{n} \lambda^j g^j(s) \quad \forall s \text{ and } \lambda > 0 \tag{5}$$

Diecidue and Wakker (2002) analyze Dutch book making in a static single person decision context. They show that if there exist probabilities $p_1,..., p_n$ such that preferences maximize expected value

$$f = p_1 f(s_1) + ... + p_n(f_n), \tag{6}$$

then no Dutch book can be made.
In a sense, the individual evaluates the subjective likelihood of the states, then chooses the best act in every state and finally aggregates in a linear way. This formulation implies *probabilistic sophistication* and the independence axiom. Yet, when the gambles (acts) are comonotonic no Dutch book can be made and this is the condition for a CEU. Now, if we assume linearity in utility, we get Yaari's Choquet expected Value CEV model. Consequences are thus monetary values. Now consider the example taken from Diecidue and Wakker (2002):

$$\begin{aligned} &(9,9) \geq (20,0) \\ &(9,9) \geq (0,20) \quad but \\ &(18,18) < (20,20) \end{aligned} \tag{7}$$

The reader can verify that preferences are supported by MV. Think of the left hand side as given by the payoff of the risk-less interest rate, and the right hand side by payoff of assets that pay in one of both states. A Dutch-book can be made against such an individual. This kind of preferences are traditionally explained by expected utility with concave utility. However, since for modest gains utility is close to linear, an alternative explanation is plausible. The risky assets serve as a hedge against each other, and this leads to a non-linear sensitivity *vis-à-vis* risk.
The aforementioned authors point out that the Dutch-book effect in the example above is due to non-comonotonicity of acts. They define a comonotonic Dutch book as a Dutch book with the restriction that the set of acts is comonotonic. They show that :
If the binary relation $\geq$ is a weak order, for each gamble there exists a fair price, and no comonotonic Dutch book can be made, then there exists a capacity W (non-additive set function) such that preferences maximize CEV, where CEV is given by

$$\sum_{j=1}^{n} \pi_j f(s_j) \tag{8}$$

π_j are decision weights that depend on the capacities. (Kast & Lapied, 2003) give an interpretation of Dutch Books in terms of uncertainty aversion and the functional (concave or convex)form of the capacity. Capacities are described in the following section.

CAPACITIES AND CHOQUET EXPECTED UTILITY

As already pointed out in the introduction, individuals' behavior is not consistent with expected utility. (Kahneman & Tversky, 1979; 1992) studies show that individuals first rank outcomes and then apply a non-linear PWF. However, their model is just a subcase of the general Choquet Expected Utility (CEU) model which we summarize below. Let Ω be a finite set of states of nature. Let *X* be a set of monetary outcomes that includes the neutral outcome 0, all other elements are

interpreted as gains or losses. An uncertain prospect *f* (act) is a function from Ω into *X*. To define the cumulative functional, outcomes of each prospect are arranged in increasing order. The utility that is expected by the individual depends on the ranking of the outcomes and the function is thus called (CEU). A prospect *f* is represented as a sequence of pairs (x_i, A_i), which yields x_i if A_i occurs, where $x_i > x_j$ *iff* $i > j$, and (A_i) are the events of an algebra of Ω. Now, let's use positive subscripts to denote positive outcomes and negative subscripts to denote negative outcomes. The positive part of *f,* denoted f^+, is obtained by letting $f^+(s) = f(s)$ if $f(s) > 0$, and $f^+(s) = 0$ if $f(s) \leq 0$. As in expected utility theory, we assign to each prospect a value $V(f)$ s.t. $V(f) \geq V(g)$ *iff* $f \geq g$. Now, we call a capacity, a non-additive set function that generalizes the standard notion of probability. More exactly, a capacity v is a function that assigns to each $A \subset \Omega$ a number $v(A)$ satisfying $v(\phi) = 0$, $v(\Omega) = 1$, and $v(A) \geq v(B)$ whenever $B \subset A$. CPT asserts that there exists a strictly increasing utility function $u : X \to R$, satisfying
$u(x_0) = u(0)=0$, and capacities v^+ and v^-, such that for $f = (x_i, A_i)$, $-m \leq I < n$,

$$\begin{aligned} V(f) &= V(f^+) + V(f^-) \\ V(f^+) &= \sum_{i=0}^{n} \pi_i^+ u(x_i), \quad V(f^-) = \sum_{i=0}^{0} \pi_i^- u(x_i) \end{aligned} \tag{9}$$

where the decision weights are defined by

$$\begin{aligned} &\pi_n^+ = v^+(A_n), \quad \pi_{-m}^- = v^-(A_{-m}), \\ &\pi_i^+ = v^+(A_i \cup \ldots \cup A_n) - v^+(A_{i+1} \cup \ldots \cup A_n), \qquad 0 \leq i \leq n-1 \\ &\pi_i^- = v^-(A_{-m} \cup \ldots \cup A_i) - v^-(A_{-m} \cup \ldots \cup A_{i-1}), \qquad 1-m \leq i \leq 0. \end{aligned} \tag{10}$$

Letting $\pi_i = \pi_i^+$ *if* $i \geq 0$ and $\pi_i = \pi_i^-$ *if* $i < 0$, $V(f)$ reduces to:

$$V(f) = \sum_{i=-m}^{n} \pi_i u(x_i) \tag{11}$$

The decision weight associated with an outcome can be interpreted as the marginal contribution of the respective event, defined in terms of capacities (Wakker (2010)). The measure of an event thus depends on it's rank and it is a generalization of expected utility called Choquet Expected Utility (CEU). An individual maximizing *V(f)* is called a Choquet Expected Utility (CEU) maximizer. Under risk, where an objective cumulative distribution function exists, it may be interpreted as maximizing expected utility with respect to the transformed cumulative distribution function $v \circ F$ where *F* is the objective cumulative distribution function. This model is called Rank Dependent Expected Utility (RDEU). *V* is the PWF and it's shape seems to be rather robust across experiments (Tversky & Wakker, 1995; Prelec, 1998). Moreover, (Prelec, 1998) derives the functional consistent with behavioral axioms.

THE EMPIRICS OF PROBABILITY WEIGHTING

In the standard CEU model $u(x_0)$ is considered to be the minimal utility that the individual will get. He then adds the increments in utility weighted by his beliefs on the future states. $u(x_0)$ is not necessarily the minimal utility, but may be the reference point with respect to which the individual weights gains and losses. Moreover, the model may be slightly different since the capacities are different on gains and losses. Actually, CEU is a special case where the capacity for losses is the *dual* of the capacity for gains, i.e.

$$v^{-}(A) = 1 - v^{+}(\Omega - A). \tag{12}$$

(Kahneman & Tversky, 1992) also considered a special case of CPT where $v^{+}=v^{-}$. This property is based on preference conditions called *reflection*.
There are two possibilities to define risk (or uncertainty) aversion : via the curvature of the utility function or via the functional form of the capacities. It is generally accepted that risk behavior is given by the functional form of the utility function, whereas the uncertainty (or ambiguity) behavior is given by the functional form of the capacities.
Now, let's rewrite $\boldsymbol{V(f^{+})}$ in a different way :

$$V(f^{+}) = u(x_0) + \sum_{i=1}^{n}[u(x_i) - u(x_{i-1})]v\left(\cup_{j=i}^{n} A_j\right) \tag{13}$$

It has been suggested that uncertainty aversion can be analyzed with CEU model. In fact, (Schmeidler, 1989) gives the following definition of uncertainty aversion. Uncertainty aversion is equivalent to the convexity of the capacity, that is:

$$\boldsymbol{v(A \cup B) + v(A \cap B) \geq v(A) + v(B)} \tag{14}$$

for all measurable events A and B. We have additivity when the right hand side and the left hand side are equal, and the individual is then uncertainty neutral. Now, experimental evidence (Tversky & Wakker, 1995; Prelec 1998) shows that the capacity *v* is sub-additive meaning that there exist events *E* and E' s.t.

$$\boldsymbol{v(B) + v(A) \geq v(A \cup B) \quad whenever \quad v(A \cup B) \leq v(\Omega - E)} \tag{15}$$

And

$$\boldsymbol{1 - v(\Omega - B) \geq v(A \cup B) - v(A) \quad whenever \quad v(A) \geq v(E')} \tag{16}$$

The first condition is called lower sub-additivity whereas the second is called upper subadditivity. The certainty effect is characterized by upper sub-additivity, since the increase of a high probability to certainty has more effect than the same increase in probability for a medium probability. This kind of behavior has also been documented under risk.
Empirical evidence (Prelec, 1998; Wu & Gonzalez, 1996) suggests that the probability weighting function has the following properties :
asymmetric - $v(p) = p$ approximately at $p = 1/3$, where p is the probability to get at least a certain amount.
Inverse s-shaped - concave on an initial interval and convex beyond. The cumulative capacity is typically above the probability till p=1/3 and below after.
reflective - assigns the same weight to a given loss-probability as to a given gain-probability.
If the preference relation satisfies a certain number of axioms, the preference relation can be represented by a sign- and rank-dependent utility function (Wakker, 2017). (Prelec, 1998) provides a set of axioms needed to deduce a functional form of the weighting function that respects the stylized facts. The most general specification for this weighting function is given by the following form :

$$\boldsymbol{v(p) = \gamma \exp\left(-\beta(-\ln p)^{\alpha}\right)} \tag{17}$$

However, if the preference relationship satisfies certain axioms, notably diagonal concavity, sub-proportionality and compound invariance (Prelec, 1998), then the specification takes the following less complex form:

$$v(p) = exp\left(-\left(-\ln p\right)^{\alpha}\right) \tag{18}$$

where α indicates the degree of non-linearity of the function. One typically observes risk-seeking for small-probability gains and large-probability losses, and risk-aversion for small-probability losses and large-probability gains. A linear value function would be sufficient to explain observed behavior. However, if the value function is not linear, then the probability non-linearity must dominate the value non-linearity to explain empirical patterns. Such a dominance arises when the above probability weighting function is combined with a power function of the following form:

$$v(x) = x^{\sigma^+} \;\; if \;\; x \geq 0 \;,\; -(-x)^{\sigma^-} \;\; if \;\; x < 0 \tag{19}$$

Concerning the weighting function, the values of the parameters of *v* can be slightly different across studies, the functional form is quite robust, see (Prelec 1998). The next section explains how Prelec's probability weighting function can be estimated from customer data.

ESTIMATION OF THE PROBABILITY WEIGHTING FUNCTION AND CEU DECISION MAKING

We now briefly explain how the preference functional of customers can be estimated. The idea is to use the methodology used to test for probability weighting as a tool for estimating investor preferences. If we know the customers' preferences we are able to select their optimal portfolio strategies with the methodology developed in the following chapters.

In the previous section, we saw that the most general form of *v*(*p*) is the following:

$$v(p) = \gamma\, exp(-\beta(-\ln p)^{\alpha}) \tag{20}$$

where *p* is the cumulative distribution function. The certainty equivalent is given by *u*(*c*) ~ *u*(*prospect*). Assume that the utility function is x^{δ}. Since γ generally equals 1, this leads to the following relationship:

$$\frac{c}{x} = exp\left\{-\frac{\beta}{\delta}\left(-\ln p\right)^{\alpha}\right\} \tag{21}$$

Think of *x* as the return of a portfolio. We can then ask the value of the certainty equivalent *c* for different combinations of returns and probabilities. Formally we ask him what *c* were if the prospect were at least a given return with a given probability. Since β is generally equal to 1, we can transform the above relationship in the following way,

$$-\ln\left(-\ln\left(\frac{c}{x}\right)\right) = \ln\delta + \alpha\left(-\ln\left(-\ln p\right)\right) \tag{22}$$

If we are able to elicit the different certainty equivalents for different suggested probability distributions through questionnaires, we can generate sets of points that enable to estimate the

equation by OLS. We are thus able to recover the weighting function for the CEU model. Notice, that we are able to estimate the concavity of the utility function at the same time as the weighting function. In that sense, the utility function is consistent with the weighting function, which would not necessarily be the case if we estimated them in two steps.

We can now formulate the portfolio optimization problem of the investor the same way as in section 2, but for a Choquet Expected Utility decision maker.

$$max_{(\theta_1,\dots,\theta_n)} E^{CEU}\{U[\sum_{j=1}^{n}\theta_j R_j]\} \text{ subject to } \sum_{j=1}^{n}\theta_j = 1 \quad (23)$$

Let's denote the excess return of the portfolio as a function of portfolio weights by $R_s = f[\theta_1, \dots, \theta_n]$. We can now more formally represent the investor's decision problem in integral representation.

$$V(f[\theta_1, \dots, \theta_n]) = \int_{-\infty}^{B} u(R_s)dv^- + \int_{B}^{\infty} u(R_s)dv^+ \quad (24)$$

As pointed out by (Kahneman & Tversky, 1992), dv^- and dv^+ are approximately equivalent and this is the assumption we make from now on. The value function then simplifies to an expectation with respect to a Choquet capacity.

$$V(f[\theta_1, \dots, \theta_n]) = \int_{-\infty}^{\infty} u(R_s)dv \quad (25)$$

With the simplified parametrization, the weighting function takes the following form

$$v = exp\big(-(-lnp^{\alpha})\big). \quad (26)$$

If we denote $F(R_s)$ the cumulative distribution function, then the weighting function takes the following form

$$v = exp\left(-\left(-ln\big(F(R_S)\big)^{\alpha}\right)\right). \quad (27)$$

This function is smooth and differentiable and we can derive it to calculate the "Choquet" density

$$dv = \alpha\frac{f(R_S)}{F(R_S)}\left(-ln\big(F(R_S)\big)\right)^{\alpha-1} exp\left(-\left(-ln\big(F(R_S)\big)\right)^{\alpha}\right) \mathrm{d}R_S \quad (28)$$

Where $f(R_S)$ denotes the density of R_S.
Now we can rewrite the F.O.C. from section 2 in a slightly different way.

$$\theta_j \qquad s.t. \qquad E^{CEU}\{U'[\sum_{j=1}^{n}\theta_j R_j]R_j\} = 0 \qquad \forall_j \quad (29)$$

This is a system of n first order conditions with respect to the "Choquet" density which can be estimated using the method of moments approach explained in the next section.

ESTIMATION OF PORTFOLIO WEIGHTS

Consider a universe of investment of *n* assets. Let's assume that the excess return distribution *R* is drawn from an *i.i.d*. distribution. From the developments in section 2, we have *n* moment

restrictions. We can now use the *n* moment restrictions to estimate the *n* parameters θ_j. This method is called method of moments (MOM) and was originally advocated by Pearson. The values of the parameters are estimated by finding the parameter values that solve a system of equations formed by equating the unknown population moments with their sample counterparts. More precisely, the method replaces the expectation of a function by the sample mean of the function. The parameters are then estimated by solving the system formed by the sample moment counterparts. Since the number of restrictions is equal to the number
of parameters, the model is exactly identified. If our assumption of *i.i.d*. draws
is right, uniform convergence of the sample moments to the population moments is obtained. In fact, in that case the weak law of large numbers makes sure that the sample mean of the function $h(\theta,R_t)$ converges to the expectation in the following sense.

$$T^{-1}\sum_{t=1}^{T} h(\theta, R_t) \xrightarrow{p} E\left[h(\theta, R)\right] \tag{30}$$

For any continuous function *h* the estimated parameter

$$\theta = \arg_{\theta}\left[T^{-1}\sum h(\theta, R_t) = E\left[h(\theta, R_t)\right]\right] \xrightarrow{p} \theta_0 \tag{31}$$

converges in probability to the "true" parameter value θ_0. In our case the problem is somewhat different than in standard econometric identification problems since we are not trying to identify parameters but to find (estimate) the portfolio weights that most closely match the preferences of the investor.
In the standard problems we would have the following (Hamilton, 1994):

$$E(h) = \int_{-\infty}^{+\infty} h(\theta_o, R_t)\, f(R) dR = 0 \tag{32}$$

where $f(R)$ is the density of returns and R_t is the ($n\times1$) vector of returns at date *t*. $E\{h(\theta_0, R_t)\}$ is then replaced by the sample average :

$$g(\theta, R) = T^{-1}\sum_{t=1}^{T} h(\theta, R_t) \tag{33}$$

MOM estimators choose θ such that sample moments are as close as possible to the population moments. In our case the function $h(\theta, R_t)$ is given by

$$U'\left|\sum_{j=1}^{n} \theta_j R_j\right| R_j\,, \tag{34}$$

the marginal utility of the return of the portfolio multiplied by the excess return of asset *j* (from the last equation in the previous section). Since this condition has to hold for *j* assets we actually have a $n\times 1$ vector that has to equal a $n \times 1$ vector of zeros. Now, in order to keep notations simple, we continue to use the general function *h* instead of the marginal utility. Our problem is somewhat complicated by the fact that we have to determine the portfolio weights for a Choquet Expected Utility Maximizer. However, remember that we know the functional form of the S-shaped transformation. Moreover, it can be estimated in the way suggested by (Prelec, 1998).
If we consider the most plausible specification, we get the following Choquet expected utility as a function of the "objective" return distribution of the portfolio $F(R_s)$:

$$E^{CEU}\{h(\theta_0, R_t)\} = \int_{-\infty}^{+\infty} h(\theta_0, R_t)\alpha \frac{f(R_s)}{F(R_s)}(-\ln(F(R_s)))^{\alpha-1}\exp(-(-\ln(F(R_s)))^{\alpha})dR_s \quad (35)$$

In order to use the MOM, we have to transform the above relation to get the expectation with respect to the objective density (Aït-Sahalia & Brandt, 2001). This leads to the following expression :

$$E^{CEU}\{h(\theta_0, R_t)\} = \int_{-\infty}^{+\infty} h(\theta_0, R_t)\alpha \frac{1}{F(R_s)}(-\ln(F(R_s)))^{\alpha-1}\exp(-(-\ln(F(R_s)))^{\alpha}) f(R_s)dR_s \quad (36)$$

We can use the following sample moments :

$$g(\theta, R) = T^{-1}\sum_{t=1}^{T} h(\theta_0, R_t)\alpha \frac{1}{F(R_s)}(-\ln(F(R_s)))^{\alpha-1}\exp(-(-\ln(F(R_s)))^{\alpha}) \quad (37)$$

and minimize the same expression as above. If we normalize $\sum\theta = 1$, then we get the portfolio weights. However, since the DM transforms the return distribution of the portfolio, which depends on the weights we are estimating, we don't know the distribution of the portfolio R_S at once.
We hence have to use the following algorithm. Start with a vector of θ'*s* , deduce the portfolio return distribution and check whether the system is solved. We are looking for a fixed point and the problem can be solved by deriving the portfolio returns for different grids in the parameter space and the one that (almost) solves the system.

CONCLUSION

Standard portfolio theory is based on mean-variance approximations of expected utility functions. For most expected utility functions, this approach seems to be a satisfactory approximation. Most individuals, however, exhibit behavior that deviates from expected utility by transforming probability distributions. Such behavior might characterize a different way to treat risk aversion and leads to so-called Choquet Expected Utility. Portfolio choice with such a behavior has only be tentatively addressed and not in an operational way. This paper addresses the issue in developing a consistent framework to select optimal portfolios for CEU maximizers and argues why mean-variance shares the same methodological drawbacks as non-EU models. This paper focused on the theoretical optimization procedures and a companion paper will focus on the practical implementation steps. Those implementation steps consist in calibration of utility and weighting functions and selection of weights that respect the first order moment conditions. The problem is slightly more complicated than for the standard method of moments approach as the portfolio return distribution that is used to estimate the moments is not known at the beginning. An algorithmic procedure that converges to a fixed point between the moment conditions and the portfolio weights thus has to be developed.

ABSTRACT

This paper is motivated by our observation that research on quality variability amplification across a supply chain has received limited attention. A time series model is developed to identify the influence of throughput time on the quality variability and its expected loss in a supply chain.

KEYWORDS: Quality variability; Throughput time; Supply chain management

INTRODUCTION

A considerable body of literature related to the bullwhip effect emerges with the majority focusing on quantifying the demand-order process through different types of supply chains (Agrawal et al., 2009). However, such variability amplification is not unique to demand-order management. Quality changes in a supply chain exhibit similar behavior. The variance in quality increases as materials move downstream from the supplier through successive stages of the supply chain. The objective of this paper is to conduct the numerical analysis to demonstrate the influence of throughput time on quality variability amplification.

NUMERICAL ANALYSIS

Consider a two-echelon supply chain with a manufacturer and a supplier. Assume the manufacturer receives its raw materials at time period *t*. Let d_{t+i} denote the defective rate of a batch at the manufacturing stage *i*, *i* = 1…T, where T represents the manufacturing throughput time. Let ρ be a correlation coefficient between d_{t+i-1} and d_{t+i} at two successive stages $t + i - 1$ and $t + i$, and we have $0 \le \rho < 1$. Assume that the inventory defective rate is a fixed constant, denoted by *w*. Based on the theoretical model proposed by Li and White (2008), the ratio of variance between output defective rate, *D*, and material defective rate, *d*, is expressed as

$$\frac{Var(D)}{Var(d)} \geq 1+\left(1-\frac{w(T+1)}{2T}\right)^2\left(T+2\sum_{i=1}^{T-1}(T-i)\rho^i\right)+2\left(1-\frac{w(T+1)}{2T}\right)\frac{\rho^2\left(1+\rho^{T-1}\right)}{2}.$$

To gain a better understanding of how some parameters affect the quality variance fluctuation in a supply chain, numerical analyses are conducted for w = 0.05% with different ρ and T values.

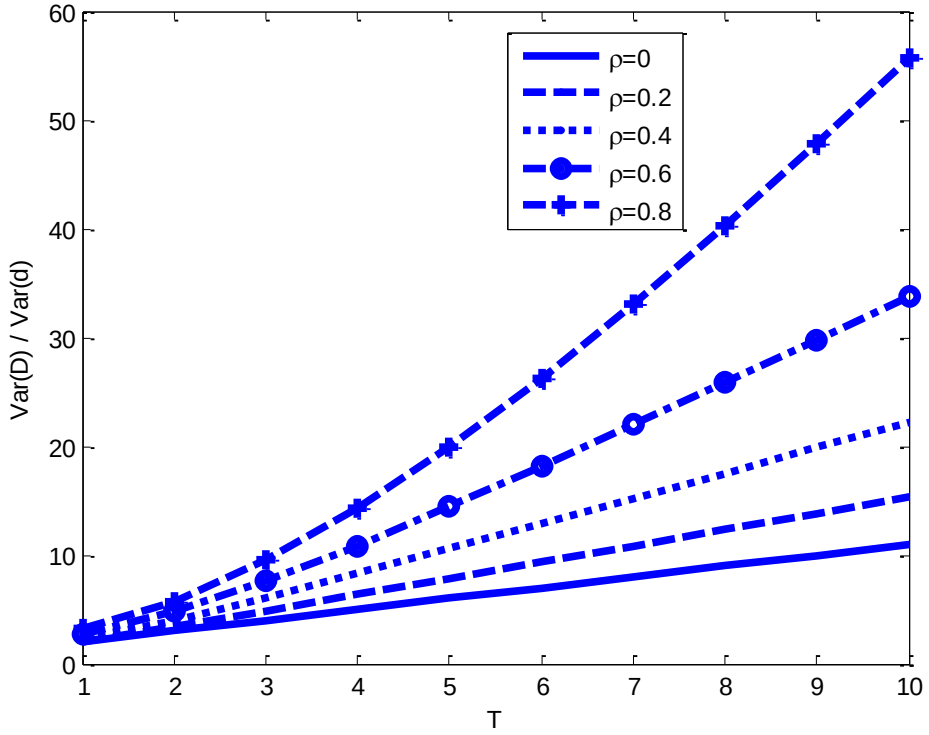

Figure 1 $\frac{Var(D)}{Var(d)}$ vs. T and ρ with w = 0.05%

Several observations can be made in Fig.1. Firstly, for any given values of ρ and w, $\frac{Var(D)}{Var(d)}$ is an increasing function of T. Secondly, for any given values of T and w, $\frac{Var(D)}{Var(d)}$ is also an increasing function of ρ. in a special case with ρ = 0, we have $\frac{Var(D)}{Var(d)} \geq 1+T\left(1-\frac{w(T+1)}{2T}\right)^2$. It suggests that, even when the physical operation activities are independent at two successive manufacturing stages, the variance in the output defective rate is still amplified compared to the variance in the raw material defective rate.

DISCUSSION AND CONCLUSION

Some limitations and future research directions should be mentioned here. First of all, in this paper, we primarily focus on the effect of throughput time on quality variability in a supply chain

for manufactured products whose value will not increase with time. Therefore, products such as wine or cheese which are expected to have higher quality as they age are excluded from this model. Secondly, the present paper may be extended to a more general setting where the manufacturer purchases the same raw material or component from multiple suppliers.

ABSTRACT

Evidence-based decision making seems both desirable and inherently rational. New analytical tools for investigating “big data” promise to provide additional evidence. Concurrently, technological advances for improving decision making reopen issues of epistemology and ontology related to fact and belief. Decision support has aimed to enhance effectiveness of human decision-making processes, foster rational thinking, and avoid biases and errors. Cognitive neuroscience research highlights issues of implicit cognition, physiological and naturalistic processes, and social cues as elements of human thought. Now decision support builders and data scientists must consider epistemological issues, social factors, and technical capabilities when developing cognitive and decision support.

KEYWORDS: Decision Support Systems, Analytics, Collaborative Decision Models, Decision Support, and Cognition and Reasoning

INTRODUCTION

Large data volumes, high data variety, and increasing data velocity have raised hopes for making better informed decisions that use evidence and facts. The flood of data and evidence-based decision making using analytics also raises some concerns for some people. For example, in late 2017, *The Washington Post* reported that “Trump administration” officials had “forbidden” the phrases “evidence-based” and "science-based” in Centers for Disease Control and Prevention (CDC) official budget documents (Sun & Eilperin, 2017). This prohibition was quickly attributed to the current administration’s penchant for “declining to acknowledge scientific findings” (Anapol, 2017). The actual story seems less sensational: career officials worried that these trigger words might draw Republican opposition (Engber, 2017; Levin, 2017). But, the point remains that professional policy communicators acknowledged that evidence-based decision making is not valued in all situations by all audiences.

For many professionals, the descriptor, evidence-based, presumes a noble goal to make decisions based solely on the “facts and information” when determining whether “a belief or proposition is correct, true or valid” (Power, 2018). The term evidence-based decision making

(EBDM) is most often associated with decision-making in education, law, medicine, and science. EBDM has also been promoted for management decision making (Pfeffer & Sutton, 2006). The synonyms for EBDM most used in the business world emphasize a presumption of objective truth: fact-based, data-driven, data-based. The concept of EBDM equates evidence with objectively verifiable truth that is independent of a decision-making process, and hence the process cannot alter or change the evidence.

Management thinkers seem to have embraced analytics and data science, convinced of the value of evidence-based decision making. Many people are surprised that any rational person could question the value of evidence and facts. News reports that link objections to evidence based decision to Republican political strategy (Mooney, 2005) or religious fundamentalism (Pigliucci, 2005) seem reasonable to many as well. This argument over the value, nature and possibility of objective "Truth" is not new and is the subject of several thousand years of Western philosophy. For philosophers, theoretical physicists, and cognitive scientists, the relationships among decision-making, rational thought, evidence and objective reality remain open questions that have been newly energized by advances in computing technology, digitization, and global communication networks.

Ontology, the study of the nature of being, becoming, existence, or reality, might seem unrelated to the concerns of information technology and decision sciences, but business analysts, data scientists, and decision support builders necessarily make assumptions about the characteristics, behaviors and attitudes of those who will use the analyses, systems, outputs and results. Emerging computational techniques appropriate for "big data" exacerbate these concerns in newly unavoidable ways. The big data discussion currently ranges across academic, legal, business, and political venues around fundamental issues of epistemology, technology, methodology, cognition, and aesthetics (Ekbia et al., 2014; Kitchin, 2014). Epistemology investigates what distinguishes justified belief from opinion. Some critics predict these analytical tools will lead to the destruction of clear thinking, reasoned discourse, and moral behavior (Boyd & Crawford, 2012; Ekbia et al., 2014; Gregg, 2015). Decision Support Systems (DSS) are not isolated from the epistemological issues inherent in the decision method and tools used, and DSS builders might offer assistance in an era in which critical thinking has become more valued than data (Mayer-Schönberger & Cukier, 2013).

Management theorists might have embraced an ideal of evidence-based reasoning, but the range of fundamental issues involved in effective implementation of the ideal calls for some attention. Effective decision support must acknowledge biases, preferences, and capabilities of users involved in decision making, as well as the DSS builder's own assumptions about the value of the data and evidence. This article identifies epistemological, cognitive, and social issues involved in designing effective decision support and in applying business analytics. Data Scientists and DSS builders cannot look only at technical delivery of data (big or otherwise) or at facilitation of a decision process. The issues raised by philosophers and cognitive psychologists are important in understanding how people can be supported in decision making most effectively in any given situation.

The next section reviews issues and positions surrounding data, rational argument, and human decision making processes. From that foundation, the following section reviews the implications for effective business analytics technologies that might account for the complex, social nature of decision making, as well as the multifaceted nature of evidence that is an integral part of effective decision making.

EVIDENCE-BASED DECISION MAKING CONTROVERSY

Decision Scientists and DSS builders recognize the value of understanding the biases and limitations of decision makers, which often represent the problems a system attempts to solve. Equally important, however, DSS builders must understand their own assumptions and preferences about alternative decision-making methods or the value of various types of evidence.

Proponents of evidenced-based decision making generally use the term *evidence* to mean facts and information that prove or substantiate an assertion or a conclusion, which may then be used in a comprehensive, systematic and thoughtful decision-making process. The process uncovers and gathers together evidence to inform a reasoned choice among relevant alternatives. Within such a decision process, evidence provides the reasons for concluding that something is true or false. Evidence is not always complete or conclusive, so evidence may be supplemented by reasonable assumptions.

In contrast to judicial settings, where statute and case law define formal rules of evidence, business decision-making processes rarely include an evaluation of forms of proof. Controversies can arise over the validity of evidence because people often disagree about the reliability, value, or relevance of specific data or forms of data. Arguments about evidence are exacerbated by misunderstandings over terminology as well as procedural disagreements.

In a business setting, the term evidence is often used interchangeably with facts or data, which neglects the important process by which observers perceive, interpret, and assign meaning to their observations (Gitelman, 2013). In most cases, decision-makers act as both observers of data and judges of its meaning, value, and relevance, leading to potential disagreement on all three points. Only when all participants in the process agree that a point of fact has been rightly interpreted and holds some relevance for the decision issues at hand can it be rightly considered *evidence*.

Additional disagreements and misunderstandings arise when participants differ in their assumptions about how the decision-making process ought to work. In specialized contexts, rules of law or parliamentary procedure govern the decision process, but otherwise customs and processes vary widely. Considerable research addresses the diversity of rational thinking at a cultural level (Briley, Morris, & Simonson, 2000; Cole, 1996; Cole & Scribner, 1974; R. B. Kaplan, 1976), but even within the relative homogeneity of the Western business community, individuals ignore—and even resist—accepted problem-solving methods.

John Dewey's (1910) prescription for problem solving involved six steps, problem definition, solution criteria, causal analysis, solution identification, and solution evaluation, has since been taught as the basis for critical thinking and problem solving discussions (Keith, 2007). Prescriptions for managerial problem solving reflect the familiar six steps (Young, Wood, Phillips, & Pederson, 2001), although business practitioners typically add a final step of evaluating the implementation of the chosen solution (Drucker, 1973). The model reflects the now widely accepted view of effective, rational, managerial decision making. Despite the agreement on principles, however, wide variations in decision making practice demonstrates that not everyone agrees on the functional meaning of rational thought or a rational process. Furthermore, the era of big data has renewed some seemingly intractable controversies. This

section considers the historical reasons individuals might resist formal, systematic decision making, as well as issues raised by the advances in Big Data.

Contested history of rational decision making

Business users might use the terms *rational* or *analytical* as synonyms for the methodical, evidence-based decision making advocated by John Dewey, but that model is not descriptive of how human beings actually make decisions. Herbert Simon, upon accepting his Nobel Prize in Economics (1979), acknowledged the "strikingly simple and beautiful" nature of the "classical theory of omniscient rationality" along with the penchant of economists for using it to "predict (correctly or not) human behavior without stirring out of our armchairs to observe what such behavior is like" (p. 496). Rhetoric scholar Michael Calvin McGee (1982) classified such theories of public decision making as "idealist" projects based on philosophical presumptions and preferences as to how humans ought to decide, judging them "not theory at all, but a set of technical, prescriptive principles which inform the practitioner while, paradoxically, remaining largely innocent of practice" (p. 24).

Methodical, explicit rules of deductive logic were derived by ancient Greek philosophers (Aristotle and Plato) as a remedy for public decision making contaminated by the emotional intensity of poetry and theater (Havelock, 1968; Lentz, 1989) and the political dangers of cultural relativism (Poulakos, 1995). Prevailing across four thousand years of philosophical alternatives, Western analytical thinking came to define rationality itself—at least in the minds of Western academicians, scientists, and legal theorists—and continues to be taught as the ideal thinking process. Over the past two hundred years, however, breakthrough research in multiple disciplines has demonstrated that the ancient ideal of explicit, deductive reasoning describes just one tool of human decision making—and a somewhat limited tool at that, useful only under specialized conditions.

Some trace the collapse of Western analytics to Gödel's (1931)) momentous proof of uncertainty (Kline, 1980), the discovery of the quantum (Prigogine, 1997) and computing breakthroughs that made nonlinear analysis and complexity science possible (Cilliers, 1998; Scott, 2007; Wolfram, 2002). Others point to the postmodern deconstruction of patriarchal Western political, cultural, and social structures, which maintained power by dismissing the epistemologies of other cultures and communities (Belenky, Clinchy, Goldberger, & Tarule, 1986; Foucault, 1973; Lyotard, 1979/1984; Simons, 1990). Perhaps most tellingly, advances in our understanding of tacit knowledge and implicit cognition (Reber, 1993), physiological factors in decision making (Damasio, 1994; Todo, 1980), and socially distributed knowledge (Cole, 1996; Freeman, 1995; Resnick, 1991; Weick, 1979) demonstrate the erroneous assumption that rational thinking is a well-defined individual endeavor.

Those who seriously study pragmatic decision-making processes have had to set aside the ancient assumptions. Economists were among the first to seriously consider the pragmatic implications of "post-rationality" (Arthur, 2013; Colic-Peisker & Flitney, 2017; Thaler, 2015). Meanwhile, researchers in naturalistic decision-making continue to demonstrate that implicit, non-linear cognitive processes allow people to "quickly match the situation to the patterns they have learned. If they find a clear match, they can carry out the most typical course of action" and thus make "extremely rapid decisions" (Klein, 2008, p. 457). In situations with higher time pressure, higher stakes, or increased ambiguities, experts use intuitive decision-making processes rather than structured approaches with great effectiveness (Gladwell, 2005; Klein,

1998, 2009). Similarly, management studies were quick to adapt to a growing understanding of how groups interactively think, learn, and decide (Engeström, 1992; Weick, 1993, 2000; Weick & Ashford, 2001).

Big data and the "end of rational thought"?

On technical, social, legal, and philosophical levels, big data has been lauded — and condemned — for its potential to change human society on a scale to rival the invention of the printing press (Mayer-Schönberger & Cukier, 2013). These issues are multifaceted and lie far outside the scope of this article, but recent controversies offer insights into the nature of evidence-based decision making and the quest for rationality and help illuminate the significance of technical advances for builders of decision support systems.

For some, big data represents a major advance for evidence-based decision making (LaValle, Lesser, Shockley, Hopkins, & Kruschwitz, 2011; Provost & Fawcett, 2013). Data-driven management yields performance benefits, and with big data technologies, management "can measure and therefore manage more precisely than ever before" (McAfee & Brynjolfsson, 2012, p. 4). Even those who recognize the complications of gathering accurate data and using it effectively conclude that human-kind stands at the brink of a revolution (Mayer-Schönberger & Cukier, 2013). One long-standing criticism of data-driven decision making, of course, has been the potential over-reliance or excessive dependence upon quantification and quantitative data. Two maxims capture the gist of this concern: "What gets measured gets managed," sometimes to ill effect, and, "Not all that counts can be counted." The well-known dangers of relying on financial results to the detriment of society and the environment (Elkington, 1994), the social costs of chasing economic indicators (Karabell, 2014), and the strategic importance of qualitative factors (Kaplan & Norton, 1992) suggest that bigger data might just create bigger problems. Technical advances offer promise, but the excitement over bigger data highlights known dangers of relying too heavily on data in the first place.

Meanwhile, Joel Shapiro (2017) critiques dashboard visualizations, warning that design defaults or choices can draw management attention to data that does not align with business priorities, to neglect information that does not appear, or to infer causality from visual patterns and groupings. The simplicity and elegance of big data visualization can tempt managers to bypass the crucial work of critical thinking. The implicit, intuitive and sometimes mystifying processes of visual analytics demand critical attention (Thomas & Cook, 2005). Concerns that visualization allows quick, intuitive decisions reopens ancient debates about the relationship between "data— what the world presents to us through our senses and instruments" and "knowledge of the world— how we understand and interpret what we get" (Ekbia et al., 2014, p. 1528).

Perhaps most significantly, the technical capacity to process Big Data challenges traditional assumptions of scientific thinking. Chris Anderson (2008), editor of Wired magazine, prompted a firestorm when he proclaimed Google's predictive analytics success as evidence the scientific method is obsolete. In response, critics charge that reliance on big data demolishes or destroys "instrumental reason" (Fuchs, 2017, p. 54) by replacing public discourse with decision algorithms. To be sure, a scientific method designed to maximize the value of evidence when data was difficult and expensive to collect, becomes obsolete and limiting when data are abundant, timely and dynamic (Kitchin, 2014). Yet, when "n=all", the sample size is the entire data set (Kitchin, 2013), decision making requires even more comprehensive analytical support (Driskell & Salas, 2006). Ubiquitous examples of specious uses of big data underscore the

point that critical thinking and instrumental reason are more important than ever (Mayer-Schönberger & Cukier, 2013).

Big data solves no inherent weaknesses in evidenced-based decision making. Nor does big data represent a new challenge to rationality. Rather, the sheer magnitude of available data, coupled with the human capacity for quick, implicit, visual analytics highlight the need for carefully designing decision making processes to account for these new challenges. Further, solutions involve careful attention to the complicated relationships among reality, data, perception, interpretation, knowledge, understanding, and belief.

IMPLICATIONS FOR DECISION SUPPORT

Decision support has been an ongoing effort to enhance, support, and facilitate a rational decision-making process. Working within the familiar frame of logical positivism, DSS developers exhibited an optimistic belief that "human limitations…may be overcome with information technologies and DSS" (Power, 2010). Some observers have questioned the possibility of decision augmentation and decision support. As Ekbia and Reynolds (2007) noted, "Various writers have criticized the classical rational/technical solutions commonly employed in DSS," concluding that "perceived limitations of rational models in contemporary DSS might be more a consequence of our methods or of how we have chosen to employ them" (p.497).

We might, however, describe technological decision support as the continuation of longstanding efforts to help human decision makers in their quest for rationality. The quest for better decision making began with ancient attempts to identify and promote effective methods. Aristotle's treatises on logic functioned as pedagogical tools—guides for those intent on learning the cutting edge thinking processes of the day. Subsequent philosophers, Thomas Aquinas, Francis Bacon, Rene Descartes, among many others, have offered updated advice, models, and guidelines for best practices in critical thinking, logic, rational problem-solving, or decision making. Vocabularies and method have varied over the millennia, but the goal remains the same: help individuals to avoid the pitfalls of human error, emotion, bias, laziness, or confusion to optimize their decision-making effectiveness.

DSS might be understood as a continuation of this effort, albeit with previously unimaginable technological tools to assist in the effort and potentially expanded scope with the assimilation of Big Data.

Some proponents of evidence-based decision making have embraced the promise of Big Data, but "big" does not guarantee better evidence or better evidence-based decision processes. There seems to be no doubt that data has become more abundant and computing technology more capable of analyzing it, but these factors further complicate the issues of evidence-based decision making. Perhaps the most immediate realization has been that evidence and data are not, in fact, synonyms (Hammond, 2013). The ubiquitous adoption of semi-structured and unstructured big data sources highlights the degree to which a complete, accurate understanding of decision making—not merely the idealist presumptions of classical Greek philosophers — must guide decision support efforts.

Data analysts always needed to make certain that any data utilized as evidence would be relevant to the decision question and that facts had been (or could be) verified as true. To the

extent that new data analytic tools like artificial intelligence (AI) and machine learning have begun to emulate, imitate and even surpass the black box of human cognition, these developments give rise to condemnations of Big Data as unsystematic, atheoretical, and dangerous to rational thought (Fuchs, 2017; boyd & Crawford, 2012). Technology advances are making Licklider's (1960; 2001) predicted man-computer symbiosis a real possibility, and the more data analytics are embedded within human systems, the more important an understanding of decision making becomes.

One immediate consequence of technology improvements has been a shift in the locus of decision making. When management both collected and analyzed data, the decision process could be observed as a management activity, but the distributed, fungible, and outsourced processes of advanced analytics (Mayer-Schönberger & Cukier, 2013) distributes decision making across a chain of contributors, from the business analyst charged with wrangling and visualizing the data to the company that monetizes those results by packaging them as information, to the client who buys and ultimately uses the insights. Decision support might provide value or mislead at any point.

For many corporate entities, the concern has been the capacity of an individual analyst to critically and effectively analyze the vast amounts of data that have become available. Business and data analytics require application by a person with sophisticated critical thinking capabilities (Shah, Horne, & Capella, 2012), narrative skills (Brumberger, 2015; Cyphert, 2017; Hammond, 2013; Shoztic, Bible, Nelson, & Stein, 2016) and contextual knowledge (Ernst and Young Foundation, 2015). While the era of digital data can make facts—verifiable data points—more abundant, the path between raw data and rational evidence seems to have grown more convoluted and far more problematic.

Decision scientists, management scientists, and information systems developers had not yet completed the task of predictably and effectively building computerized support systems for the limited, linear steps of logic thinking, classical argumentation, or collaborative group decision making. Now, with advanced analytic tools, virtually infinite data stores, and fast, distributed computing technology at our disposal, we can contemplate scientific advances that will likely demonstrate the vast range of what we still do not understand about human cognition. Cognitive computing is in its infancy. Firm conclusions seem well beyond the scope of this article—or any article, at this moment in time — but we offer a few possible next steps.

First, since the traditional understanding of reason and rationality might no longer represent an appropriate or exclusive goal for decision making behavior, we might redefine good decision making to focus on concrete results rather than idealistic prescriptions of how rational thinking ought or should look to an observer. Decision support designers might focus on imitating decision making processes that yield a desired result rather than presupposing that a specific process will yield effective decision making. Even within this limited scope, there are caveats. Choosing a goal necessarily involves making a decision, and a decision support builder must carefully define a specific system's scope and purpose. Further, effectiveness itself must be contextually understood.

Those who build decision support and analyze data might define their assumptions about targeted decision makers, defining their goals in terms of compiling or analyzing factual data, reconciling diverse stakeholder values, negotiating common interests, developing sustainable goals, and so on. Targeted users of decision support and analytics differ based upon the

specific system that is being built for a specific organization. Some decision support could focus on increasing traditional forms of rationality in a specific situation. Other analytics and systems might foster extended discussions around the interpretation or value of proposed forms of evidence. Some might emulate extended forms of rationality to enhance the rational options of decision makers. Analytic tools and models can be selected for the appropriateness to the type of decision or to supporting a specific element or step of a process. Analysis might uncover patterns, relationships, or correlations that can best be approached with analogy-based reasoning or another implicit reasoning tool? Data may not be relevant to every part of a decision process.

Second, decision support architects, builders and designers might build tools that facilitate broader human decision-making tasks rather than fostering a single, limited type of reasoning. Design of any DSS necessarily encompasses epistemological, social, and human as well as technical design factors. Effective business analytics technologies must account for the complex, social nature of decision making as well as the multifaceted nature of evidence. In general, we cannot and should not design technology decision augmentation and support without a thorough understanding of the broad use case, which is human decision making.

Some support systems might aim to assist just one part of the decision-making process, displaying a certain kind of data more effectively, for instance, or collecting stakeholder perspectives in a systematic way, but the more a designer understands about the overall process, the better the system can support decisions in a real context. Data Scientists and DSS builders should reinforce rational decision making as needed by the targeted user and avoid introducing errors into the analysis. Such efforts depend, however, on presumptions we make about rationality—in all its forms and uses.

Third, and finally, strides in the scientific understanding of the human decision-making process does not imply that all humans are competent decision makers. Decision support arose in response to research and theory of those who recognized systematic failures in the classical decision-making model. If anything, embracing the complexity of implicit and distributed cognitive processes simply introduces more opportunities for failure to occur. Managers, whether they are described as logical data processors, members of a sensemaking organization, or intuitive processors of implicit knowledge, are not infallible decision makers. People, groups and organizations will continue to commit errors in the decision-making process. The goal of decision support remains to help human decision makers avoid the most important biases and errors when possible and to in general minimize the probability that bias and errors of analysis, logic, and reasoning will occur in semi-structured and unstructured decision situations.

Antecedents and Consequences of Blockchain Technology in Food Supply Chains: An Exploratory Study

Meenakshi Jakhar
Management Development Institute
Email: meenakshi.jakhar@gmail.com

ABSTRACT

Blockchain is the new buzzword in business and speculations are rife about its impact on operations. The technology is paving way for novel innovations and challenging the traditional modus operandi. However, blockchain cannot be blindly adopted. This paper explores the antecedents and consequences of blockchain adoption in context of Food supply chains. Since the technology is in nascent stage, an exploratory approach is employed using expert interview technique including experts from blockchain solution providers and supply chains in Food sector. The results highlight the significant factors impacting the Blockchain adoption and paves way for advancement of research in the area.

KEYWORDS: Blockchain, Food Supply Chain, Antecedents, Consequences, and Expert Interview

INTRODUCTION

It is tough to escape blockchain in the current business landscape as it makes inroads in every sector. Each industry is considering the technology as potentially revolutionary. Even though the blockchain revolution started from banking and finance industry (Underwood, 2016), other industries like healthcare, energy, retail, governance, supply chain and agriculture are staring at major disruptions in their operations by blockchain application. The blockchain is a distributed ledger technology that allows all members to record transactions in a decentralised data log maintained on a network of computers, rather than a physical ledger or a single database (Tapscott & Tapscott, 2016). Transactions must be approved through consensus, and everything is secured through cryptography. The data is embedded on the network as a whole and is transparent and incorruptible.

With rising consumer consciousness towards food safety, blockchain application can play a vital role in solving many food-related problems. The global food supply chains have become increasingly complex and it has become almost impossible for food producers and retailers to guarantee the provenance of their products. The Grocery Manufacturers Association (GMA) estimated that food fraud costs the global food industry between $10 billion and $15 billion annually. As per GMA estimates, the cost of one adulteration verdict can be up to 15% of annual company revenues in terms of lost sales, not to mention the damage to organisational reputation and brand loyalty that inevitably occurs. It is becoming apparent that the current food safety and quality management systems are not designed to detect, nor sophisticated enough to prevent fraud occurring in our food (Ruth at al., 2017). Recent food fraud scandals have further increased the need to combat fraud across supply chains (Manning & Soon, 2014). Supply chain transparency is one of the most important and hardest to achieve improvement areas for logistics and SCM (Abeyratne & Monfared, 2016). Hence blockchain provides a transparent, reliable and trustworthy alternative to the current technologies.

The paper aims to explore the antecedents and consequences of adopting the blockchain technology in the context of food supply chain. Since the technology is in a nascent stage, with

a limited number of research papers and use cases available, an exploratory approach employing expert opinion technique has been adopted to unveil the significant factors that influence the adoption of this technology. The rest of the paper is structured a follows: Section 2 provides a brief literature review on the Food supply chain and the Blockchain technology, section 3 discusses the research objective followed by Section 4 and 5 that describe the research methods and results. Section 6 includes the discussion of results and managerial implications.

LITERATURE REVIEW

Blockchain is a digital and decentralized ledger that records all transactions. It is shared with all participants in the network, with each participant holding their own copy through replication. It was first introduced to a larger audience around September 2015 when nine financial companies including Goldman Sachs, Barclays, J.P. Morgan, and others joined forces to build a new blockchain based infrastructure for financial services (Underwood, 2016). The logistics and supply chain management (SCM) community later realized the impact blockchain might have on their industry.

There are three basic pillars on which the blockchain is based: a) Consensus, b) Provenance, and c) Immutability. a) One or more transactions are grouped together to form a new block. All members of the network can verify the transactions in the block. If no consensus on the validity of the new block is reached, the block is rejected. Likewise, if consensus exists that the transactions in the block are valid, the block is added to the chain. b) The transactions, once added to the ledger, cannot be deleted, modified or inserted. Hence each item can be traced back to is source providing provenance. c) A cryptographic hash is generated for each block added to the ledger. Each block not only holds transaction records but also the hash of the previous block. This creates a block interdependency linking up to a chain – the Blockchain. Altering a transaction on the blockchain retroactively would require not only to alter the local records on most of the networks members' devices but also altering the cryptographic hash of every block down the chain. This provides immutability to the ledger.

There are several benefits that the blockchain claims to provide that makes it preferable over the traditional systems. One major promise is to increase trust in the network – by providing transparency in transactions and reduce risk of tampering, fraud and cyber crime. Every member of the network has access to the same data, providing a single point of truth (Tapscott & Tapscott, 2016). The distributed digital ledger of transactions cannot be tampered with due to the use of cryptographic methods (Pilkington, 2016). It also reduces transaction cost and time. The ledger is updated on a real-time basis, thus eliminating the wait times encountered in the traditional systems. Owing to these benefits, some logistics and supply chain experts are considering Blockchain to offer "enormous potential" (O'Marah, 2017), to be a "much-needed platform for economic renewal" (Casey & Wong, 2017), and to "transform the supply chain and disrupt the way we produce, market, purchase and consume our goods" (Dickson, 2016).

The concept of blockchain can prove to be effective in addressing the issues in the Food supply chain. Food Supply Chain Management (FSCM) has been coined to denote the activities from production, distribution, and consumption in order to keep the safety and quality of various foods under efficient and effective modes (Marsden et al., 2000; Blandon et al., 2009). The differences of FSCM from other supply chains are the importance reflected by factors like food quality, safety, and freshness within limited time, which make the underlying supply chain more complex and difficult to manage (La Scalia et al., 2016). Added to this are the issues of food fraud, food adulteration, counterfeiting and food crime. Most organizations in this area, such as the Global

Food Safety Initiative (GFSI), the Grocery Manufacturers Association (GMA) in the United States (US), the US Pharmacopia (USP) and reports of the European Parliament consider food fraud as “an intentional, deceptive misrepresentation of foods for financial gain” (Spink et al., 2017). Current food safety management systems are not specifically designed for fraud control or mitigation. Due to the intentional nature of fraud, it requires an approach that differs from the common safety ploys (Spink et al., 2017). In order to tackle food fraud, the system needs to shift from the safety-based approach to the fraud prevention and vulnerability reduction approach and take into account these deliberate and disguising aspects. This is where the blockchain comes into picture.

RESEARCH OBJECTIVE

The blockchain technology is revolutionizing the way businesses are operating. The technology, though started in financial sector, is exhibiting promising turnarounds in other industries as well. As discussed above, the Food supply chains currently are facing multifaceted challenges in terms of growing concerns over food traceability, safety and quality. The consumers are becoming increasingly aware of the source of the food that they consume. There is a huge scope of improvement in the operations of the food supply chain. Blockchain technology addresses many of these challenges. However, adopting this technology needs a synergy amongst various elements of the system and requires a systems approach. There are certain pre-requisites of adopting the blockchain technology is a supply chain to ensure smooth operation and successful outcomes. The paper is exploring these antecedents of applying blockchain technology in food supply chains. Also, the consequences of this adoption are also explored. So the research objective is *“To determine the antecedents and consequences of Blockchain technology in the Food supply chains”*

RESEARCH METHODOLOGY

The methodology employed in this research was Expert Interviews. Expert interview method is especially useful when historical data is insufficient or a new phenomenon is being explored and is an effective and concentrated method to gather data in exploratory phase (Bogner, Littig and Menz, 2009). The research objective being addressed in the paper is exploratory and the phenomenon is novel. Hence expert interviews were an appropriate method for addressing the objective.

Defining and selecting an expert for collecting data is the most important step in expert interview technique, since the knowledge and experience of the expert can impact the effectiveness of the method. An expert, for this research, has been defined as a person “who is responsible for the development, implementation or control of solutions/strategies/policies or has privileged access to information about groups of persons or decision processes” (Meuser and Nagel, 1991). Experts in this research were Blockchain Solution providers (BSP) and Supply chain professionals in the Food industry. While choosing the experts, the criteria of experience and domain expertise were used. A total of 9 experts were interviewed to gain a holistic view of the phenomenon. Table 1 below provides a glimpse into the profile of the experts.

Table 1: Profile of Experts interviewed

S. No.	Label	Designation	Total Years of Experience
1	EXP1	Supply Chain Manager	10
2	EXP2	Logistics Head	12
3	EXP3	CTO (BSP)	11

4	EXP4	Project Manager (BSP)	7
5	EXP5	CEO (BSP)	14
6	EXP6	Senior Manager	15
7	EXP7	Procurement Manager	13
8	EXP8	Supply Chain Head	12
9	EXP9	AVP, Procurement	16

DATA COLLECTION AND ANALYSIS

Data were collected using semi-structured and open ended in-depth interviews with the experts. An interview guide was developed beforehand for the same (Meuser and Nagel, 1991). Some interviews were conducted in person by visiting the site of the expert and others were telephonic. The interviews were conducted over a period of two months (Mar-Apr, 2018) and the average duration of each interview was about an hour. To secure the contents, the interviews were recorded under the premise of anonymity and transcribed immediately afterwards.

The interviews were analyzed with the aid of qualitative data analysis (QDA) tool NVIVO11. Data analysis was carried out using following steps:

i. *Transcription of the recorded interviews*: The recorded interviews were transcribed from an audio to a text format.
ii. *Reading through the Data*: To understand the overall meaning of the data, multiple readings were given to the transcribed interviews. It also helped in the recognition of pertinent codes and themes.
iii. *Generating Codes and Themes*: Coding may be described as “the process of organizing the material into chunks or segments of text before bringing meaning to information” (Rossman and Rallis, 2009). Relevant codes were identified from the interviews which were then classified to different themes.
iv. *Interpreting the meaning of the themes*: As per Creswell (2009), “qualitative research is interpretative research”. The researcher assigns meanings to the coded data against the background of “her or his own culture, history and experiences” and compares these findings “with information gleaned from the literature or theories”.

Word Frequency search and Text Search queries were used to identify the most frequently occurring words in the data and their corresponding contexts. Table 2 below provides a snapshot of the comments made by the experts.

Table 2: Expert Comments

Experts	Comments	Factors
Project Manager (BSP)	“*As the size of the blockchain grows, the requirements for storage, bandwidth, and compute power required by fully participating nodes in the network also increase.*”	Scalability
Logistics Head	“*The technology that supports the business should have minimal downtime. In this global and fast paced business environment, even small technical failures and glitches may translate into business losses*”	Reliability
Senior Manager	*“In Blockchain, every player along the supply chain holds a complete copy of the data. So it is important to define specific access rights to ensure that confidential*	Privacy

	corporate information is kept private."	
Procurement Manager	"*Supply chains have always been attempting to become more connected and visible. RFIDs, IOT, POS data are a few steps taken in this direction. Blockchain would provide a new dimension to enhancing the supply chain visibility*."	Supply Chain Visibility
Supply Chain Head	*"As a distributed ledger that ensures transparency and security, the blockchain shows promise to fix the current supply chain problems. A simple application of the blockchain to the food supply chain would be to register the transfer of goods on the ledger as transactions that would identify the parties involved, as well as the price, date, location, quality and state of the product and any other information that would be relevant to managing the supply chain."*	Supply Chain Traceability

RESULTS AND DISCUSSION

The agenda of the paper was to identify the significant antecedents and consequences of adopting blockchain for Food supply chains. The first significant antecedent that emerged was Scalability. Blockchain works on the principle of decentralization, which effectively means that the every single node on the network is responsible for securing the system by processing every transaction and maintaining a copy of the entire state. It limits the number of transactions that can be processed to the slowest node of the network. This might lead to low processing capability and slower transaction times. Since typically in a supply chain, the numbers of transactions or data exchanges are quite high, scalability is an issue that needs careful consideration. The supporting infrastructure, nodes with high processing speeds and capabilities, are a pre-requisite of adopting this technology in supply networks. Another important factor was reliability of the system after adoption of blockchain technology. Supply networks, especially global food supply chains, are quite complex and distributed. Transactions happen on a continuous basis and businesses require a high rate of reliability of the underlying system. Any downtime would convert to a loss in the business. Would blockchain be able to provide that level of reliability on a continuous basis need to be explored before taking the plunge? Security of data and privacy are the other two factors that emerged. Data in a blockchain is "final" and "immutable" making it secured against tampering. However, carefully determining the rules of who can access which data is important. In a supply network, there are multiple tiers of suppliers, buyers, distributors, retailers etc. More often than not, there is an overlap of these entities amongst competitors. Having a shared, decentralized ledger with all the transactions visible to everyone in the network would not be desirable for the businesses. Hence protection of data from misuse and restricted access to view the data for different levels are very important features to be taken into consideration while adopting the technology. And lastly, since the technology is new, the businesses would aim at a slow and phase wise implementation rather than a big bang. Businesses would prefer to use blockchain on a limited basis and gradually expand their usage, but there might be challenges with linking one blockchain to another and with coordinating blockchain with the existing systems, which should be taken into account.

On the consequences end, enhanced supply chain visibility and traceability are the most important factors. The items in a supply chain can be accurately traced back to their origin using the blockchain technology. The records are reliable, since they are added to the chain only after

verification or “consensus”, tamper-proof, as they cannot be altered once added and visible to all on the distributed ledger. This provides more transparency to the supply chain operations and the assets become easily traceable. These features of blockchain would help in fighting against the food fraud and adulteration. The authenticity of the food items, tracing them back to their origins has a special significance for the complex and global food supply chains. Since the ledger is shared amongst all the parties in a network, it would lead to inventory optimization and cost savings. The suppliers, given controlled access, would be able to see the actual levels of inventories and plan their delivery schedules accordingly. This would be an advanced stage of Vendor Managed Inventories (VMI) where instead of buyer controlling the centralized database, the suppliers are also a part of the network. Another important aspect is risk management. With everyone in the network having the data backup and visibility, the business and political risks associated with a centralized system are reduced for blockchain. Another important advantage of blockchain is the near real time transaction updates. In a centralized system, it may take days before a transaction is approved and updated in the database. Additionally, there are multiple check points and redundancies. For instance, a purchase order raised from a buyer will go to supplier. The supplier would dispatch the material and send an invoice to the buyer. The buyer in return would send an acknowledgement or receipt of goods. Then the payment would be released. All these transactions would be updated in the central database sequentially. However, with blockchain, the suppliers and buyers can simultaneously access the shared ledger and after consensus, the transactions can be added to the shared ledger on a near real time basis. This eventually leads to enhanced efficiency and cost savings.

Table 3: Antecedents and Consequences of Blockchain in Supply chain

Antecedents	**Consequences**
Scalability	Supply Chain Visibility
Security	Supply Chain Traceability
Reliability	Inventory Optimization
Privacy	Risk Management
Migration to new system	Real time Speed

CONCLUSION

Blockchain is the buzzword in the business and technology space these days. A lot is being said about its tremendous potential to solve a number of business challenges. In the context of food supply chains, blockchain looks promising to address the mounting challenges of food fraud and adulteration. In the light of several recent food scandals, food traceability is becoming increasingly important for the consumers and businesses alike. However, there is no one size fits all strategy as far as technology is concerned. It needs to be carefully evaluated before adoption in any industry or domain. The contributions of the paper are threefold:

a) The paper contributes towards the general understanding of the blockchain technology and discusses its relevance in the context of food supply chains. The fundamental features of blockchain are discussed and how those features contribute in addressing the complexities of the food supply chains are explored.
b) The paper explores the significant antecedents and consequences for the application of blockchain in the food supply chains. Expert interviews with blockchain solution providers and food supply chain experts were conducted to identify the relevant factors. The results help in providing an overview of the significant aspects that need attention while adopting the technology to the food supply chain context.

c) Blockchain is still in its nascent stage with a limited number of research papers and use cases available and the industry is actually leading the academia in the area. The paper is an attempt towards bridging this gap and contributes towards the advancement of the understanding of blockchain technology and its application in the food supply chains.

The paper paves way for further research in the area. Going forward, the factors can be extended and explored in greater detail. Expert's views have been sought to shortlist the most relevant factors, which may have introduced some element of bias. A focus group, with all the experts at one location, could not be organized due to constraints on time and resources. This can be addressed in future research as it would enhance the confidence in the results. Future research can also explore the blockchain adoption in different supply chain contexts, other than Food supply chains.

Appeals to Ownership of Automobiles in Style Magazines of the U.S. and U.K., 1930-2000

Steven Silver
Lucas Graduate School of Business
California State University, San Jose
Email: sds001@calmail.berkeley.edu

ABSTRACT

We report an analysis of attribute and motive content of appeals to automobile ownership in print advertising of style magazines in the U.S. and U.K. Results of the analyses show significant country differences in appeals to technology, status and subcategories of motivation.

KEYWORDS: Cross-national advertising content, automobile advertising, content analysis, consumption artifacts, and time trends in advertising content

INTRODUCTION

A basic difficulty in studying relationships between culture and consumption has been in defining dimensions of consumption (Silver 2002). We will suggest that these dimensions can be usefully defined in attributes or characteristics of differentiated goods (Bajari and Benkard 2005). Among the contributions of studying differentiated goods is the increased likelihood that they include the range of functional and stylistic contrasts in attributes that have been a mainstay in the study of consumption artifacts (Bettinger 1996; Stoetzel 2017).

As has been recognized, that cultural variation in the importance of or preference for attributes of goods and services can meaningful be studies in the content of advertising (Borèus and Bergström 2017). In addressing cultural variation in ad content, there is some advantage to studying countries that have a commonality in language and a correspondence in legal and social institutions but have acknowledged variation in aspects of informal culture that are important to personal consumption. U.S.-U.K. comparisons of the content of print ads provide these conditions. Our interest will be in testing whether measures the importance of attributes of a differentiated good and motive content inferred from advertising content are consistent with oft-cited cultural differences in comparison societies. Following a review of background studies of U.S.-U.K. comparisons in thematic content, we will define the sampling and content analyses methodology. Results of the coding and analyses will then be reported. Finally, results will be interpreted in national contexts for the relevant study periods.

BACKGROUND STUDIES

Available studies of U.S.-U.K. thematic content that relate to culture differ in method, content and dependent variables. While not entirely consistent in their results, these studies offer background for contrasts between countries. Czellar (2003) has studied U.S.-U.K. differences in prestige judgments using a word association text. He found that U.K. respondents were higher in “exclusivity” and “quality” themes but lower in “personal success themes” than U.S. respondents. Caillat and Mueller (1996) in their study of TV beer advertising in the U.S. and U.K. found that American ads exhibited more individualism/independence, modernity/newness, and achievement

content than U.K. ads. Although Tansey, Hyman, Zinkhan and Choudhury (1997) did not find consistently significant differences in work themes they studied in U.S. and U.K. print ad content, they did find that a higher proportion of automobile ads with achievement themes in the U.K. sample than in a U.S. sample. Koslow and Costley (2010) indicate that U.K. ads in general tend to be more focused on overall product quality while U.S. ads tend to have more specific information and price content. Results of these studies suggest composite profiles of the U.S. as a society that is higher in individualism and entrepreneurial "spirit" and aspects of achievement motivation but lower in collectivism, explicit status marking and quality and workmanship orientations than U.K. society.

Benefits of restricting content analysis to a single product category have been noted by Caillat and Mueller (1996); Neuendorf (2016) and Tansey, Hyman, Zinkhan and Choudhury (1997). The functional and symbolic importance of automobiles as a consumer good has been well recognized (Conley 2016; Gartman 1994; Hensher, Barnard, Smith and Milthorpe 1989; Thoms, Holden and Claydon 2016). While available cross-national studies of automobiles have most often addressed country-of-origin effects in communication (Ahmed and d'Astours 1993; Nagashima 1970; Haubl 1996), we study automobiles as a differentiated durable good across a set of representative attributes. Such a more extensive representation of the good can support more definitive identification of societal differences and their interpretation.

Analysis of media content has been a common method used for imputation of cross-national variation in both product attributes and the preferences they imply for a range of products (e.g., Boréus and Bergström 2017, Samiee and Jeong 1994). In this tradition, the study of magazine print advertising can provide data on both cultural and historical variations in attributes of a differentiated good and is unmatched in its continuity and diversity. The significant differences in country comparisons that have been reported in previous studies further indicate that analysis of print advertising can be an important contributor to documenting and interpreting cross-national differences in appeals to the use of consumer goods and motive content in ad copy.

"Efficient market" accounts (e.g., Fama 1998) can support an assertion that competition among producers results in ad content that is shaped to closely reflect consumer preferences. In addition to the importance of attributes to inferring preferences among those who study culture and consumption, attributes that underlie preferences have been of continuing interest to those who design and manage differentiated consumer products (Tai 2004). Although we also recognize that there are intermediary processes that determine how preferences are manifested in choice (e.g., Horsky, Nelson and Posovac 2004), we follow assumptions of previous investigators that the study of attribute content in artifacts and advertising supports inference on the underlying preferences of those who own and use the goods (e.g. Conley 2016). We study what can be designated as style magazines with a readership that has higher education and income than median national levels. The designation of style magazine indicates that they introduce directions for life style and consumption in humor, fiction and reporting.

Magazine Sources and Ad Sample

Unlike the U.S., there are few popular magazines with continuous publication histories that span many decades in the U.K. We will sample ads from the humor, fiction and style or fashion magazine *Punch* in a series for the U.K. The higher mean income and education of the readership of this magazine is likely to allow a wide range of attributes to be manifested in advertising.

Clearly, *Punch* does not have an exact correspondence in a U.S. magazine title. We will study the U.S. magazine that is likely to be most comparable to *Punch* over the study period, *Esquire* magazine has been a publisher of American fiction and an indicator of fashion to the demographic of its readership for much of its history. We designate both titles as style magazines. The demographics of its readership have a direct correspondence to *Punch* in the relative income and occupation/education positions for years in which data is reported. *Esquire* was published in 1933. Punch ceased publication in 2002. Our study period will span the decades of 1930s to 1990s.

HYPOTHESES

We offer the following hypotheses on attributes and motive content in U.S. and U.K. print ads for the differentiated good of automobiles.

h_1: Technology as an attribute is expected to be more frequent in appeals to automobile ownership in U.S. ads than in U.K. ads.

Technology has been often cited as the engine of growth in the U.S. economy in the post-war period under study (Baily 2004; Mundlak 2005; Fernald and Rarnmath 2004). The importance of a technology-based "ethic" in the U.S. in observing the rapid growth of the U.S. economy over most of the post-WWII period (e.g., Litan 2001). In contrast, a decline in technology-related ethic in the U.K. over this time period has been cited (e.g. Collins and Robins 1990).

h_2: Style and comfort as attributes are expected to be more frequent appeals to automobile ownership in U.S. ads than in U.K. ads.

Style and comfort are often considered to be hallmarks of an affluent American society (Cole 1991). The U.S. has been described, as one in which there is more status competition through ownership and use of consumer goods than alternative Western societies. Other authors (e.g., Silver 2015[2002]) have discussed the possible basis for this in terms of differences in the formal status-granting institutions put in place by cultural histories of societies. We expect status competition to be manifested in appeals to style and comfort.

h_3: Quality and efficiency as attributes are expected to be more frequent in appeals to automobile ownership in U.K. ads than in U.S. ads.

Workmanship and its contribution to quality and reliability has also been discussed as a traditional value of British industry (e.g., Collins and Robbins 1990; Greasley and Oxley 1998), although the extent to which it has declined in the post-WWII period and the reasons for the decline (e.g., Collins and Robins 1990; Raven 1989) have been debated. In contrast, the U.S. has been described as an individualistic, entrepreneurial society (e.g., Han nad Shavitt 1994; Sagie, Elizur and Yamauchi 1996) over the study period. There also are bases to expect that differences in income and the prices of fuel and maintenance between countries in the periods under study will result in differences in the importance of the attribute of efficiency.

h_4: Achievement related appeals to meeting or exceeding a "standard of excellence" are expected to be more frequent in U.K. ads than in U.S. ads (e.g., Winter 1984).

h_5: Achievement related appeals of "winning and competing" are expected to be more

frequent in U.S. ads than in U.K. ads.

The importance of workmanship we cite in U.K. history is expected to be reflected in the "standard of excellence" component of the achievement construct. While we consider "standard of excellence" to be a workmanship-related motive, we consider "winning or competing" to reflect individualistic and competitive orientations in American society.

METHOD

Product Attributes and Motives in Ad Content

Our initial pool of attributes is from those that have been identified in a range of previous studies (e.g., Fernandez-Castro and Smith 2002; Hensher et al 1989) or are reported by agencies that compare automobiles (e.g., *Crain Automotive* and *Wards Automotive Yearbook*). We also represent the achievement motive (e.g. Winter 1984) as a motive that relates to workmanship and quality in goods and services in our coding of ad text and have been previously studied in advertising content (e.g. Tansey et al 1997).

Attributes and motives under study are listed and defined in Table 1

Table 1
Coding Attributes of Automobiles in Magazine Ads

Attributes of Automobile	*definition*
Value	mention of quality for Price
Technology	mention of a technology – general or specific e.g., dual diagonal brakes
Style	mention of style/appearance
Durability/Reliability	mention of longevity, durability, consistency, dependability
Efficiency	mention of low cost in operation, maintenance, mileage per gallon
Performance	mention of power, acceleration
Comfort	mention of interior room, comfortable seating or operation
Quality	mention of very high standards; price not relevant
Safety/Security	mention of safety/security – general or specific – e.g., side airbags
Handling	mention of control, responsiveness
Price	mention of low or moderate price, low price as an explicit appeal
Achievement Content	*definition*
1. Standard of Excellence	meets or exceeds certain high standards, can be in mention of brand e.g., Bosch parts, Body by Fisher
2. Winning or Competing with others	favorable comparison to other cars; awards or honors
3. Unique Accomplishment	only brand to offer feature or form; first to introduce it

Sampling Procedure.

For each of the years in which the magazines were published between 1930 and 1999, ten ads of at least half a page were selected from both *Punch* and *Esquire* magazines according to a random procedure. Random numbers between 1 and 20 were drawn for two issues in each year; one closest to the date March 15, the other to October 15. The first five ads in the number sequence were used to select the ads in an issue. If a number in the random sequence was greater than the number of ads in an issue, the next number in the random sequence was drawn.

Esquire did not have automobile ads for World War II years of 1942-1944 in the early 1940s. *Punch* did not have automobile ads between 1941 and 1945. A total of 580 ads for *Punch* and 614 for *Esquire* were used in the analysis.

Coding Procedure.

The ads were coded on the set of attributes and the motive in achievement content listed in Table 1. Two coders each coded more than .7 of the total ad sample with the overlap used to assess reliability. Ads were assigned to each coder following a stratified time sample procedure so that each coder received the same number of ads in a year for each country. Both coders were initially trained with coding of a sample of ads from each magazine that were not part of the sample used in the study we report.

Coding scales.

In pre-study investigation, we found that the difference between low and high importance of an appeal to ownership could be reliably discriminated. Each attribute was consequently coded on a three-point scale of absent, present-low importance and present-high importance. Achievement sub-categories were coded for their presence or absence in an ad following the procedure outlined by Winter (1984).

A recursive partitioning algorithm (CART: Breiman, Friedman, Olshen and Stone 1984; Rutkowski, Jaworski, Pietruczuk and Duda 2014) was used to identify the splits in the attribute and motive coding categories that best classified countries. CART develops a classification or branching scheme that predicts a dependent variable based on the levels of multiple independent variables. Whereas stepwise regression methods pick the independent variable to enter from the reduction in total variance in the dependent variable in the next step, CART has superior procedures to “look ahead” at subsequent splits any candidate split will result in and select the splits that minimize a measure of variation in the dependent variable.

CART constructs a large tree from sample observations by minimizing at each step some “impurity” function for the unexplained variation. The constructed tree is then “pruned” with a penalty criterion in which the penalty is proportional to the number of leaves (nodes) in the tree to obtain more parsimonious specifications of splits in the independent variables. We use CART as exploratory methodology to guide splits in coding categories used in logistic regression.

A classification tree based on a binary classification of the attributes of the presence or absence of technology, comfort and efficiency, the achievement sub-categories of standard of excellence and unique accomplishment, and style-appeals as high importance vs. low importance or absence was found to generate a discrimination of country that minimized the residual variation in CART. Collinearity is unlikely to affect these results since none of the attribute and motive variables evidence a coefficient greater than .24.

Logit Model of Country Attribute Profiles in Print Ads

We use the binary logit model in eq. (1) to predict country of origin from coded attributes and motives.

(1) pr (j = countryA) = F ($\beta_0 + \beta_1$ att$_1$ + … + $\beta_n att_n$)

where F is the cumulative logistic distribution function

F(z)=1/(1+e^{-z}), z = log [pr (j=A)/Pr (j=B)] = $\beta_0 + \beta_1 att_1 + ... + \beta_n att_n$.

β_0 is an intercept and β_k, k=1, ..., n are coefficients for the n attributes in Table 1.

Equation (1) can be estimated with data from procedures that we next describe. The sign and statistical significance of the coefficients for attributes and motives in the estimated model will be used for hypothesis testing.

RESULTS

Coder Reliability

Agreement between coders on a binary categorization of absence or presence of appeals to an attribute were assessed with intra-class correlation methods. These methods as applied in an interval scale by Shrout and Fleiss (1979) have been extended to binary scales (e.g., Ridout, Demetrio and Firth 1999). For the 160 ads that were coded by both coders, the coder agreement on the absence-presence categorization of attributes and motives was between .82 and .94. Coefficients exceeded .85 for all but the status attribute for which they were .81.

Logit Models of Country Differences in Attribute and Motive Content

Estimation of a logit model of country-preferred attributes was undertaken with maximum likelihood procedures of SAS for the binary classification of country. Consistent with the results of the CART recursive partitioning, our backward stepwise procedure of model estimation indicated that only the presence or absence of technology, comfort and efficiency and the binary classification presence of style-appeals-high importance vs. low importance or absence and the motive content of the presence of achievement sub-categories of standard of excellence and unique accomplishment significantly increased model fit.

Measures of overall model fit all show highly significant increases from the attributes and motives we include in the final model (Final -2log likelihood=728.70; Pseudo R^2 =.218, Cox and Snell R^2 =.172, Nagelkerke R^2 =.230). Removal of any of the attributes and motives in the final model all result in a highly significant (p<.001) decrease in model fit (*i.e.,* a significant increase in the -2log likelihood). The absence of a significant Hosmer and Lemshow (1989) statistic (χ^2 = 6.85, df = 7, p>.25) also supports our inference on adequacy of model fit.

Figure 1 shows a profile of the mean proportions in which coded attributes and motives were present in the ad sample for the U.S. and U.K. Table 2 reports the coefficient estimates for the

set of attributes and motives in the final model. Coefficients are for the U.S. with the U.K. as the comparison country.

Figure 1: Overall US-UK Comparison in Attribute and Motive Profiles

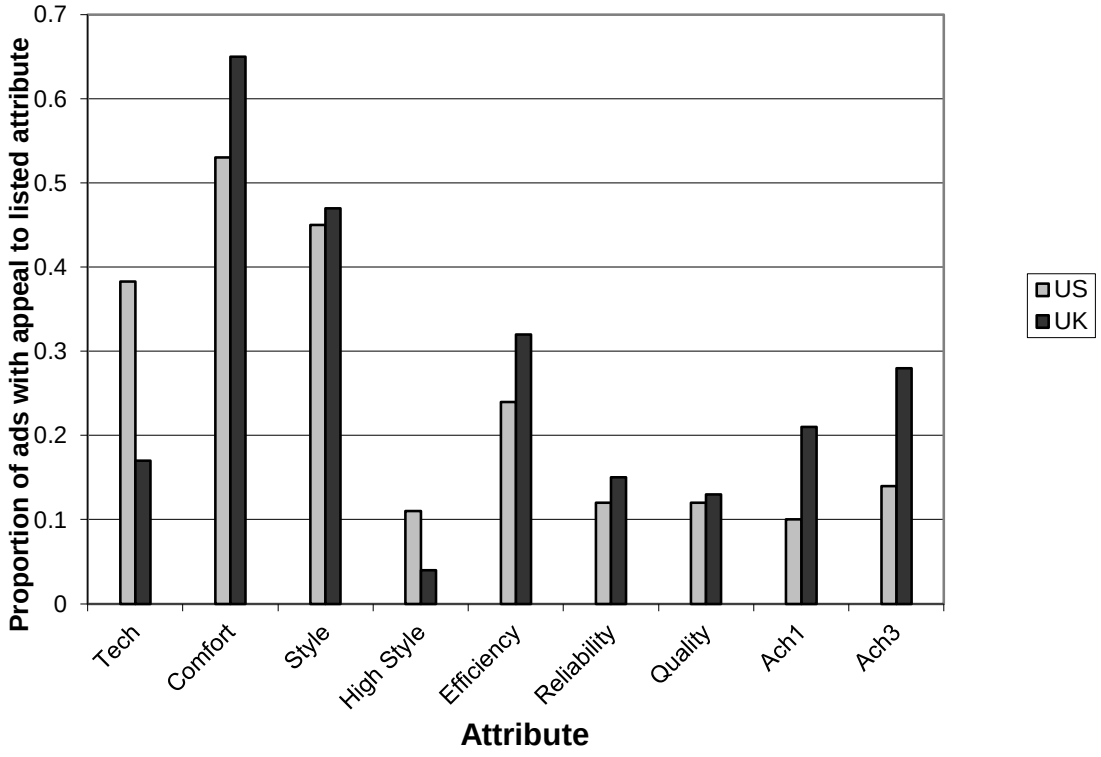

Table 2

Coefficient Estimates for Attribute and Motive Variables in the Model

	B	S.E.	Wald	df	p	Exp(B)
tech	1.692	.165	105.590	1	.000	5.433
style_h	1.119	.272	16.872	1	.000	3.060
comf	-.689	.131	27.661	1	.000	.502
effic	-.462	.142	10.654	1	.001	.630
ach1	-1.206	.195	38.123	1	.000	.299
ach3	-.959	.173	30.541	1	.000	.383
Constant	.039	.351	.013	1	.911	.040

Note: B = logistic coefficient; S.E. = standard error; Wald = Wald statistic; p = significance level; Exp(B) = exponentiated coefficient.

Results for the accuracy of classification of country by attributes and motive in ad content are reported in Table 3.

Table 3
Classification Table: Entire Sample

Observed			Predicted		
			US=1, UK=2		Percentage Correct
			1.00	2.00	
Step 1	US=1, UK=2	1.00	400	214	65.1
		2.00	172	408	70.3
	Overall Percentage				67.7

In addition to the "jacknifed" procedure for results in Table 3, we also cross-validated the classification of country in the logistic regression model with split-sample methodology (e.g., Huberty 1984). Our procedure was to first randomly assign the ads in a sample to a main sample and a hold-out sample with a stratified sample design in which half the ads in each year of the overall sample were assigned to one of the two sub-samples. Results for the analysis and hold-out samples we obtained are presented in Table 4.

Table 4. Classification Table: Hold-out Sample Results

	Predicted Group Membership					
	Analysis Sample			Holdout Sample		
Actual Group	Group 1	Group 2	Total	Group 1	Group 2	Total
Group 1: U.S.	197	115	.63	198	104	.66
Group 2: U.K.	75	214	.73	75	216	.73
Total	272	329	.68	273	320	.69

More than two-thirds of the sample was correctly classified by the study variables in the hold out sample. This is in comparison to correct categorization of .51 by a proportional chance criterion or the assignment of all ads to the country with the larger number of ads in the sample. Press' Q statistic as a measure of classification accuracy yielded a chi-square of 146.67 for the entire sample, 102.95 for the analysis sample and 79.93 for the holdout sample. Each of these χ^2 levels exceeds the critical value for $\alpha = .01$ ($\chi^2 = 6.63$). Thus we conclude that the classifications of ads in both the analysis and holdout sample were significantly better than chance or an assignment of all ads in the respective sample to the country with the larger ad sample.

DISCUSSION

We have reported results of a study of cross-national differences in appeals to ownership of print advertising for automobiles in style magazines of the U.S. and the U.K. over the decades 1920-1990. While previous studies have focused upon content inferred in values and motives from

communication variables, we directly study a set of product attributes that are invoked in appeals to automobile ownership as a differentiated good. In our initial review, we noted bases to hypothesize that U.S. ads would have higher frequencies of technology, style and comfort appeals but lower frequencies of efficiency, quality and reliability appeals than U.K. ads would have. In achievement motive content, a number of previous studies predict higher frequencies of ads with achievement content in U.S. ads. We disaggregated components of achievement and predicted U.K. ads to have higher frequencies of ads with a mention of a standard of excellence but lower frequencies of ads with mention of winning or competing.

Our results indicated that among the attributes we study, the presence of technology appeals was significantly more frequent in U.S. ads than in U.K. ads and was the best discriminator of country in the logit models. Technology has been seen as a dominant theme in the U.S. as commonly designated entrepreneurial society for the period we studied. For the contrast in the attribute of style, we found the high importance of style in an ad to be more frequent in U.S. ads and to also significantly contribute to the discrimination of country. Fewer institutional status contests in the U.S. have been suggested as basis for the increased importance of style in the U.S. consumption ad appeals (Silver 2015[2002]). The above results are consistent with study hypotheses. The presence of appeals to comfort was not found to significantly discriminate countries. This is contrary to our hypothesis for this attribute.

We also found that U.K. ads more frequently had achievement content than U.S. ads. Disaggregating achievement content, both “standard of excellence” and “unique accomplishment” were more frequent in U.K. ads than in U.S. ads. Differences in “competing or winning competition” did not discriminate country. The results we report encourage further comparative study of product attributes for differentiated goods and application of methodology for using historical record for inference on time trends in preferences. As noted in our review, there have been few comparative studies of consumption with the scope in attributes of the one we report. We have also noted the distinct advantages in studying a differentiated good in terms of attributes.

Results do indicate that even countries with high commonalities in language and institutions significantly differ in the attributes that predominate in their market appeals to consumers for differentiated consumption goods with functional and symbolic importance. These results further encourage social theorists to more explicitly include them in conjecture on how culture maps preferences in consumption. They also suggest that multinational companies continue to differentiate product classes by countries of different appeals, attributes and appeals to ownership even when as in the case of automobiles there are substantial correspondences in underlying product forms.

ABSTRACT

Female and male students may have different attitudes toward business statistics class that offer an explanation of some of the differences in their course performance. This study investigates gender effects on attitudes toward statistics among undergraduate students in introductory Chinese and U.S. business statistics classes.

KEYWORDS: Business Statistics, Attitudes toward Statistics, Statistical Instruction and Learning, Gender

INTRODUCTION

Learning statistics requires a different type of thinking as compared to traditional mathematics courses. Student misconceptions in statistical reasoning have been recognized and studied in numerous research papers (e.g., Carmona, Martínez, & Sánchez, 2005; Chiesi & Primi, 2010; Gal, et al. , 1997; Onwuegbuzie & Seaman, 1995; Schutz, et al.,1998; Tremblay, et al., 2000; Wisenbaker & Scott, 2000).

Along with cognitive difficulties in the statistics course, students also suffer from a range of non-cognitive limitations. It is common for students to have predetermined attitudes toward the subject even before the first class session. These attitudes depend on their personal beliefs about statistics as well as expectations about the course, their ability to do well in it, and the usefulness of statistics in their future life or career (Gal, et al., 1997). Previous experience with statistics, or lack thereof, also affect students' attitudes prior to and throughout the course (Schau, 2003a).

Research suggests that attitudes toward a statistics course and student's overall performance and learning may be related, suggesting a link between cognitive and non-cognitive factors (Chiesi & Primi, 2010; Harlow, et al., 2002; Lalonde & Gardner, 1993; Schutz, et al.,1998; Tremblay, et al., 2000). There is also evidence that male and female college students exhibit varying attitudes toward statistics (Bechrakis, et al., 2011; Hilton, et al., 2004).

As one of the required core courses in business curricula, many students find this pre-requisite to be a major hurdle to business school admission. With increasing globalization in business school programs, we were interested in cultural differences and their potential for interactions with gender in attitudes toward statistics. The focus of our study is a comparison of

male and female U.S. and Chinese students' attitudes toward statistics in undergraduate introductory business statistics courses.

LITERATURE REVIEW

Development of Schau's SATS

One popular instrument for research on students' beliefs about statisitcs is the Survey of Attitudes Toward Statistics (SATS) (Schau, 1995, 2003b). The SATS was designed based on Eccles Expectancy-Value Theory as it assesses multiple components of students' attitudes (Vanhoof, et al., 2011). Schau (2003a) states "We need to better understand students' attitudes toward statistics and their interrelationships with achievement and eventual use in life, and we need to find more methods for promoting positive attitudes. I believe that assessing our students' attitudes and creating, considering, and testing models such as the one I've presented here will help us understand the nature of students' attitudes toward statistics as well as their statistics learning".

The SATS-28 uses 28 Likert-scaled questions to measure four different components that make up students' attitudes toward statistics: affect, value, cognitive competence, and difficulty. An extension, SATS-36, has additional questions to measure the two components of interest and effort (Nolan, et al., 2012). The SATS also has pre- and post-versions for use at the beginning and end of a statistics course, respectively.

Cultural effects

A comparison of U.S. and Chinese cultures shows major differences in several of Hofstede's dimensions (Hofstede & Bond, 1984; McFeeters, 2003), such as individualism versus collectivism and power distance. Cultural variations can also be seen between U.S. and Chinese college students. (Lu, 2014) cited six major differences, including more pressure on Chinese students from their parents, more respect for social hierarchy among Chinese students, and more encouragement of independent thinking by U.S. students (Bechrakis, et al., 2011; Hilton, et al., 2004).

Hypotheses

1) There are no gender differences in attitudes toward business statistics among U.S. students.
2) There are no gender differences in attitudes toward business statistics among Chinese students.
3) There are no differences in attitudes toward business statistics among male U.S. and Chinese students.
4) There are no differences in attitudes toward business statistics among female U.S. and Chinese students.

RESEARCH METHODOLOGY

SATS-36 Instrument

There are six components in Schau's survey instrument (Schau, 2003b):

- Affect—students' feelings concerning statistics, with six question items such as "I am scared by statistics"
- Cognitive competence—students' intellectual knowledge and skills when applied to statistics, with six question items such as "I can learn statistics"

- Value—students' perceptions of usefulness, relevance, and worth of statistics in personal and professional life, with nine question items such as "I use statistics in my everyday life"
- Difficulty—students' beliefs about the challenge of statistics as an academic subject, with seven question items such as "Most people have to learn a new way of thinking to do statistics"
- Interest—individual interest in statistics, with four question items such as "I am interested in using statistics"
- Effort—the amount of work students expect to put in to learn statistics, with four question items such as "I plan to work hard in my statistics course"

Data Collection

The instrument was translated into Chinese and pilot tested before data were collected. The original survey instrument and the Chinese translation were approved by the University's institutional review board. Data were collected from undergraduate students in business statistics classes in the U.S. and China during the first week of the semester using paper versions of the instruments.

PRELIMINARY RESULTS

We will present preliminary results from testing hypotheses using structural equation modeling for latent mean differences. Statistically significant differences and their implications for improving instruction and learning in business statistics classes will be discussed.

"ABSTRACT"

Drawn on the capability building mechanism, this research investigates medium firms' flexible capacities on the organizational agility by conceptualizing the IT competencies and IT ambidexterity as lower-order functional capability which enhance the organizational agility as higher-order dynamic capability and organizational performance. To catch up with the dynamism of business environment, IT infrastructure flexibility becomes critical, should play a more sophisticated role in capability building process. Within this research, we propose that IT capabilities and IT ambidexterity enhance the organizational agility; while IT infrastructure flexibility enhances the organizational agility both directly and indirectly as a moderator.

KEYWORDS: IT capability, IT ambidexterity, IT infrastructure flexibility, organizational agility, organizational performance

INTRODUCTION

In today's modern business world, technology is constantly under innovation and business environment is simultaneously changing. Organizational agility thus becomes crucial for building competitive advantage (Neirotti & Raguseo, 2017) and winning competition because it reflects the firm's capabilities to continuously detect and effectively and timely respond to environment changes (D'Aveni, Dagnino, & Smith, 2010). To obtain such ability and agility, firms depend on its IT ambidexterity, which is defined as the firm's ability to flexibly balance the combination of the continuous exploration of new IT resources and practices and the exploitation of current IT assets (Lee, Sambamurthy, Lim, & Wei, 2015). Parallel with IT ambidexterity, firms also need to enhance their IT competency, which is categorized into IT infrastructure and IT capabilities (Chakravarty, Grewal, & Sambamurthy, 2013). When a firm can optimize its resources to sense business opportunities and challenges, outperform its rivals to react to customer demands, business partners, and business operations (Sambamurthy, Bharadwaj, & Grover, 2003), organization agility is reached which in turn will enhance not only the firm's performance but also create a sustainable competitive advantage.

According to World Bank, small and medium enterprises (SMEs) create up to 60% of total employment and 40% of GDP in developing countries. Thus it is natural that SMEs are receiving more and more attention from researchers (Malekifar, Taghizadeh, Rahman, & Khan, 2014; Neirotti & Raguseo, 2017). For medium firms, the balance of IT investments and agility is one of

their biggest competitive advantages. When compared to small enterprises, medium maintain an adequate investment on IT, assuring an adequate IT infrastructure that facilitates its business operation. At the same time, the relatively compact size of a medium enterprise compared to the heavily structured of large firms, make medium firms more agile and flexible in responding to market changes. Thus, it is crucial for medium firms to maintain and enhance their IT competencies to build better IT agility.

Capability-building mechanism (Grant, 1996; Makadok, 2001), is a process where lower-order functional capabilities act as the enablers of the higher-order dynamic capabilities. In IS strategic literature, a number of capabilities is identified as enablers, including IT infrastructure (Lu & Ramamurthy, 2011), IT ambidexterity (Lee et al., 2015), IT alignment (Tallon & Pinsonneault, 2011), IT service climate (Jia & Reich, 2013). According to Chakravarty et al. (2013), IT competencies compromise of IT infrastructure and IT capabilities, whereas IT infrastructure flexibility and efficiency are two most important characteristics of IT infrastructure (Byrd & Turner, 2001). We, however, propose that in today's modern economy, when IT activities are fundamental to all business operations, IT infrastructure is required to be more flexible and IT infrastructure flexibility plays as a catalyst, a "new competitive weapon" (Davenport & Linder, 1994) for the capability-building process. That is why, within this research, we conceptualize the moderating role of the IT infrastructure flexibility of the relationship between IT capabilities and IT agility, as well as between IT ambidexterity and IT agility.

Based on previously mentioned of research background and research motivation, the objectives of this research include: to propose (1) the impact of IT competencies and IT ambidexterity (functional capabilities) on organizational agility (dynamic capabilities) and organizational performance; (2) the moderating role of IT infrastructure flexibility on the relationship between functional capabilities and dynamic capabilities; (3) the mechanism in the context of medium firms where balance between IT investment and IT agility is vital for business success.

The rest of the paper is structured as follows: first, capability-building mechanism is discussed, followed by the discussion of IT capabilities related literature and proposal of research propositions. Finally, conceptual model is presented with proposed construct measurements.

LITERATURE REVIEW

Capability-building Mechanism

Strategic management literature identified two mechanisms that managers can utilize to create economic rents for their enterprises (Makadok, 2001; Teece, Pisano, & Shuen, 1997). The first mechanism is resource-picking. In this mechanism, managers will select and analyze available information so that they can effectively pick resources and outperform their opponents. The second mechanism is capability-building; managers design and set up internal systems and external forces to effectively deploy the firms' resources for better productivity in short run and long term competitive advantages (D'Aveni et al., 2010).

There are two hierarchs of organizational capabilities in the capability building process: functional capabilities at lower hierarch and dynamic capabilities at higher hierarch (Grant, 1996). In information systems literature, ITs, IT competencies, and IT management capabilities were categorized as lower-order functional capabilities; while higher-order of dynamic capabilities were conceptualized as the organizational agility (Grant, 1996; Lee et al., 2015; Sambamurthy et al., 2003). Under the capability building perspective, the functional capabilities are the drivers of the dynamic capabilities, enable firms to identify threats and opportunities, optimize the utility of resources to swiftly react to changes and achieve success (Sambamurthy et al., 2003).

Within this research, we choose to focus on the agility and flexibility aspects of the capabilities that enable the organization agility and performance. Driven on the capability building mechanism and IS literature, functional capabilities are conceptualized as IT infrastructure flexibility, IT capabilities, and IT ambidexterity and dynamic capabilities as organizational agility.

Organizational Agility

Organizational agility has long been an important topic of the IS research and it has rich literature investigating not only the agility concept but also the antecedents that lead to such agility. Because of the rich literature, organizational agility is defined in various ways. Sambamurthy et al. (2003) investigated organizational agility in terms of a firm's responsiveness to its customer demands, its partnerships with other business counterparts, and business operation. Lu and Ramamurthy (2011) identify and conceptualize two types of agility: market capitalizing agility, referring to the ability to quickly capture and capitalize the changes so that it can effectively respond the customer demands (Volberda, 1997); and operational adjustment agility, referring to the ability to adjust its internal process to react to external changes (Sambamurthy et al., 2003).

Fink and Neumann (2007) define organizational agility as "the ability to respond operationally and strategically to changes in the external environment through IT" and conceptualized organizational agility into three varied factors: system, information, and strategic agility. The system agility is defined as "the ability to accommodate change in information systems through activities of system development, implementation, modification, and maintenance". Information agility refers to ''the ability to accommodate change in the way organizational users access and use information resources". And strategic agility is the ''ability to respond efficiently and effectively to emerging market opportunities by taking advantage of existing IT capabilities" (Fink & Neumann, 2007). IT capabilities are important enabler of the organizational agility and also mediate the relationship between IT personnel capabilities and IT agility (Fink & Neumann, 2007). Within this study, we adapted this way of conceptualization of organizational agility to investigate the relationship between capabilities and organizational agility.

PROPOSITION DEVELOPMENT

IT Ambidexterity

IT ambidexterity is defined as a firm's capability to explore new IT resources and exploit current IT resources in managing IT resources and practices (Lee et al., 2015). IT exploration involves with a firm's efforts in understanding and obtaining new ITs, testing them in the firm's systems, and select the most suitable ones to apply in their current and future management and operations; while IT exploitation relates to a firm's capability to control its current IT assets and reuse them in different operational activities to improve their productivity and overall integration (Andriopoulos & Lewis, 2009; March, 1991).

In modern firms where management facing frequent changes, the concurrent utilization of exploration and exploitation, or in other words ambidexterity, is a crucial issue (Raisch & Birkinshaw, 2008). For example, a telecommunication company might need to constantly explore recent technologies and update its IT infrastructure to align with its customers' update; but also need to exploit its current IT infrastructure, e.g. its network, or customer database to improve the services that it provides. Thus, both IT exploration and exploitation are used to improve a firm's performance (Hammer, 2004). IT ambidexterity is considered to be lower-order functional capability and was found to enhance the organizational agility as higher-order dynamic capability (Lee et al., 2015). Thus, we propose the following proposition:

Proposition 1: The ambidexterity of IT infrastructure exploration and exploitation positively shapes the organizational agility.

IT Competencies

IT competencies are widely conceptualized to consist of IT infrastructure and IT capabilities (Chakravarty et al., 2013; Piccoli & Ives, 2005; Sambamurthy et al., 2003). IT capability is defined as "a firm's ability to acquire, deploy, combine, and reconfigure IT resources in support and enhancement of business strategies and work processes" (Lu & Ramamurthy, 2011). IT capabilities are pivotal for firms to shape their business value and long-term competitive

advantage, which is why such capabilities are treated as a source for strategic agility (Weill & Vitale, 2002). IT infrastructure, another core IT competence, is defined as (Broadbent, Weill, Brien, & Neo, 1996):

> "IT infrastructure is the shared IT resources consisting of a technical physical base of hardware, software, communications technologies, data, and core applications and a human component of skills, expertise, competencies, commitments, values, norms, and knowledge that combine to create IT services that are typically unique to an organization. These IT services provide a foundation for communications interchange across the entire organization and for the development and implementation of present and future business applications."

More than IT capability, IT infrastructure receives even bigger attention from researchers and practitioners, especially on the two most important characteristics of IT infrastructure, namely IT infrastructure flexibility and IT infrastructure efficiency. According to (Byrd & Turner, 2000, 2001), IT infrastructure flexibility is defined as:

> "IT infrastructure flexibility is the ability to easily and readily diffuse or support a wide variety of hardware, software, communications technologies, data, core applications, skills and competencies, commitments, and values within the technical physical base and the human component of the existing IT infrastructure."

Within this study, instead of considering IT infrastructure flexibility as a characteristic of IT infrastructure, we propose that it is not IT infrastructure but IT infrastructure flexibility that should be considered as the core competency, in accordance with Davenport and Linder (1994), alongside IT capabilities.

In modern society, IT competencies are crucial for organizations to detect and effectively react to threats and opportunities. A firm's data source and business information are enormous that requires IT competencies to organize and process. If IT competencies can effectively interpret the information, a firm can quickly detect threats and opportunities for quick reaction. IT competence and IT infrastructure have been found to enable and facilitate the organizational agility in terms of entrepreneurial and adaptive agility both directly and indirectly (Chakravarty et al., 2013). Thus, we argue that the higher the IT competencies, the firm will have better ability in response to market forces or enhance the IT agility and propose the first hypothesis:

Proposition 2: IT infrastructure capabilities positively shapes the organizational agility.
Proposition 3: IT infrastructure flexibility positively shapes the organizational agility.

Many research have focused on the IT infrastructure and found that IT infrastructure is the core of IT competence and capability. One characteristics of IT infrastructure, IT infrastructure flexibility is becoming more important nowadays when IT infrastructure presents at every firms but to gain the flexibility, it takes more efforts and management.

IT infrastructure flexibility is measured in terms of scalability and adaptability (Bhatt, Emdad, Roberts, & Grover, 2010; Tallon & Pinsonneault, 2011). Scalability is the extent to which a firm can expand its IT capacity by upgrade or downgrade its hardware capacity, network bandwidth or software licenses. Adaptability is the extent to which a firm can utilize its current IT assets to support different IT needs. Sambamurthy et al. (2003) in their research have conceptualized scalability and adaptability as the reach and richness.

IT infrastructure has long been proven to be the core of IT competencies and influence and IT infrastructure flexibility were found to have direct with agility (Sambamurthy et al., 2003) and moderate the relationship between alignment and agility (Tallon & Pinsonneault, 2011). Within this research, we argue that IT infrastructure flexibility moderate the relationship between IT capabilities and IT ambidexterity with organizational agility. IT infrastructure is the fundamental of IT activities, it might lead to competence and agility of a firm but more importantly, the flexible ability to scale and adapt the IT infrastructure into business operations makes the firm better building the agility based on IT capacities. Thus, we propose as follows:

Proposition 4: IT infrastructure flexibility enhances the relationship between (a) IT infrastructure capabilities and (b) IT ambidexterity and organizational agility

Organizational Performance

Organizational agility can improve a firm's productivity and performance and building the sustainable competitive advantages (Sambamurthy et al., 2003). Firms with good agility have better ability to respond the market's changes and control the uncertainty (Benaroch, Lichtenstein, & Robinson, 2006). Such flexible and agile responses to market changes help firms outperform its rivals and quickly swift away from threats yet grasp the opportunities.

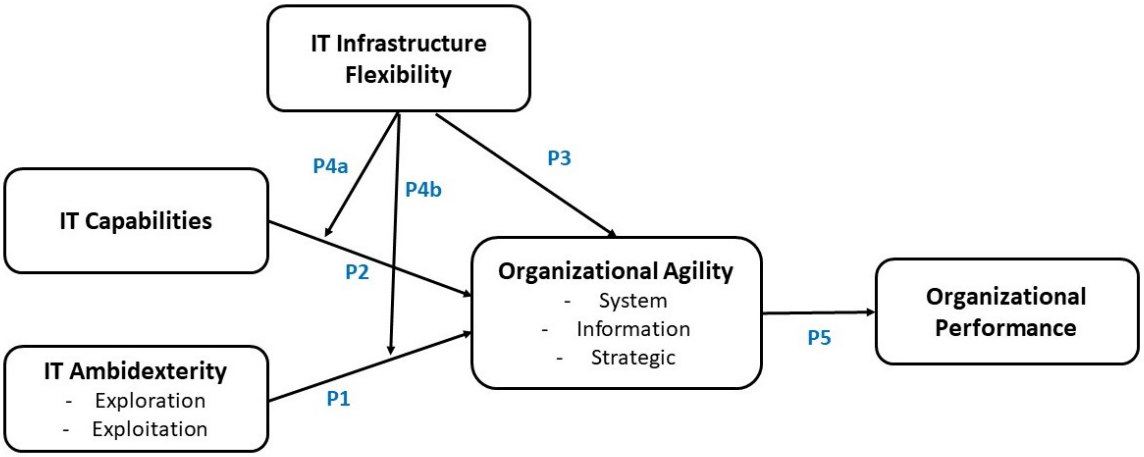
The exploration and exploitation factors of IT ambidexterity are characteristics of a learning and knowledge application process. In their research, Cegarra-Navarro, Soto-Acosta, and Wensley (2016) found that organizational agility facilitates the application of relevant knowledge into operations to improve the firm performance. Based on these arguments, we propose the final proposition as follows:

Proposition 5: Organizational agility has positive influence on organizational performance

CONCEPTUAL FRAMEWORK

Figure 1 below illustrates our proposed conceptual framework, how organizational agility is formed via IT capabilities and IT ambidexterity while IT infrastructure flexibility aside from directly forming the organizational agility, moderates the former mentioned relationships; and increase in organizational agility in turn raises the organizational performance.

Figure 1: Conceptual framework



Construct Measurements

Table 1 below summarizes the proposed measurements for each construct as well as the adopted sources. All question items are measured by 7-point Likert scale with 1 equals to strongly disagree and 7 equals to strongly agree.

Table 1. Construct Measurements

Factors	Items	Source for Adaptation
IT Ambidexterity Relative to other firms in your industry, please indicate the ability of your IT unit(s) to		
	Acquire new IT resources (e.g., new generation of IT architecture, potential IT applications, critical IT skills)	(Lee et al., 2015)

Table 1. Construct Measurements		
Factors	**Items**	**Source for Adaptation**
IT exploration capability	Experiment with new IT resources	
	Experiment with new IT management practices	
IT exploitation capability	Reuse existing IT components, such as hardware and network resources	
	Reuse existing IT applications and services	
	Reuse existing IT skills	
IT Capabilities Relative to other firms in your industry, please indicate the ability of your IT unit(s)		
	We have strong technical IT skills	(Chakravarty et al., 2013)
	We have adequate knowledge about IT	
	Our IT skills are comparable with the best in the industry	
	We invest heavily in our IT human resources	
	We have a good understanding of the possible benefits of IT applications	
IT Infrastructure Flexibility Relative to other firms in your industry, please indicate the ability of your IT unit(s)		
General	Our information systems are scalable	(Bhatt et al., 2010)
	Our information systems are compatible	
	Our information systems are adopted to share information	
	Our information systems are modular	
	Our information systems can handle multiple business applications	
Hardware compatibility	Software applications can be easily transported and used across multiple platforms	(Tallon & Pinsonneault, 2011)
	Our user interfaces provide transparent access to all platforms and applications	
	Our firm offers multiple interfaces or entry points (e.g., web access) to external users	
	Our firm makes extensive use of middleware to integrate key enterprise applications	
Software modularity	Reusable software modules are widely used throughout our systems development unit	
	Legacy systems within our firm do not hamper the development of new IT applications	
	Functionality can be quickly added to critical applications based on end-user requests	
	Our firm can easily handle variations in data formats and standards	
Network connectivity	Our company has a high degree of systems inter-connectivity	
	Our systems are sufficiently flexible to incorporate electronic links to external parties	
	Remote users can seamlessly access centralized data	
	Data is captured and made available to everyone in the firm in real time	
Organizational Agility		

Table 1. Construct Measurements		
Factors	**Items**	**Source for Adaptation**
Relative to other firms in your industry, please indicate the ability of your firm		
System agility	IT shared across the organization saves money by reducing system modification or enhancement costs.	(Fink & Neumann, 2007; Lowry & Wilson, 2016)
	IT shared across the organization allows other applications to be developed faster.	
	IT shared across the organization allows previously infeasible applications to be implemented.	
	IT shared across the organization provides the ability to perform maintenance faster.	
Information agility	IT shared across the organization enables faster retrieval or delivery of information or reports.	
	IT shared across the organization enables easier access to information.	
	IT shared across the organization presents information in a more concise manner or better format.	
	IT shared across the organization increases the flexibility of information requests.	
Strategic agility	IT shared across the organization enhances competitiveness or creates strategic advantage.	
	IT shared across the organization enables the organization to catch up with competitors.	
	IT shared across the organization aligns well with stated organizational goals	
	IT shared across the organization helps establish useful linkages with other organizations.	
	IT shared across the organization enables the organization to respond more quickly to change.	
Organizational Performance Relative to other firms in your industry, please indicate the ability of your firms		
	Our return on investment relative to objective is satisfactory	(Chakravarty et al., 2013)
	Our sales relative to objective is satisfactory	
	Our profit relative to goals is satisfactory	
	Our growth relative to objective is satisfactory	
	Our general success is satisfactory	

Besides the main questionnaire items, demographic information of the respondents and the characteristics of the firms where they are working at should also be collected as control variables for later analysis.

CONCLUSION

In the era of dynamic business environment, flexible and agile capabilities are becoming critical for firms, especially SMEs, to shape the competitive advantage and enhance the firm performance. Thus, instead of considering the static competence such as IT infrastructure, we propose to focus on the agile competences and flexibility as the key drivers in the capability building mechanisms.

ABSTRACT

Business Process Improvement can be a sustainable competitive advantage on the market place. In recent year, technology is the main drive to enable the reengineering process. In this paper, we use a highly competitive car reservation system as an example, to show how Gap analysis can build the links between process improvement and competitive advantage. The goal is to provide a practical case that can be used in graduate level courses for business schools.
KEYWORDS: BPM, Car Reservation Systems, Competitive Advantage

INTRODUCTION

The purpose of this case study is to provide an example of process re-design using BPM techniques and tools to achieve maximum value for the business. The case we studied is MSB Car Rental Company. This company provides a variety of vehicles where a customer can book a rental car online. MSB rental cars provide a unique experience to its customers with its nationwide infrastructure and enormous inventory that permits them to supply rental cars to the customers when booked online. With car rental business being fiercely competitive, the prices offered after considering many factors become extremely crucial for car rental business. To achieve this, the executive team has to showcase great vision, deliver superior products and provides resilience for high-quality service. The goal of this project is to improve the overall sales by 80% when compared to current process. If the sales on an average day is not even 25, our goal is to make at least 40 sales in a day.

THE DYNAMICS OF CAR RENTAL BUSINESS

Rental business or industry is one of the most challenging businesses due to competitions. Car rental systems are one of the most complex processes or business models in the car rental industry. In order to increase the sales and improvising swiftness in car rental websites, Information Systems has a crucial role. The process design of car rental business is a time-consuming procedure because it involves variety of factors such as location, time. It is also a heavily loaded system because many users are constantly trying to find the best prices of good deals for any given day. In this highly competitive market, pricing strategies and service quality

are critical success factors for car rental industry as they offer more and more products to the customer (George & Xia, 2011).

Capacity planning is another challenge in the Car rental business. For any car rental companies, determining the number of fleet of cars and allocating them in the appropriate stores is major operational design issue. Initially many organizations involve in vehicle sharing system, in such system many customers choose to rent car in one store, use the car for certain amount of time and return the car in another store according to their convenience. If the car rental organization has many stores and many vehicles, then managing such huge logistics and making them profitable is huge challenge. One of the primary concerns in enabling those system or program to be profitable is determining the range of fleets that needs to be stationed across all stores (Juan & Ou-Yang, 2004).

Internet reservation systems in Car Rental business has strategic significance, especially for price-sensitive market segment. By using the information provided over the internet, customers can compare the information of one car rental service provider with another and make optimal decision of the choosing the rental provider. Hence it becomes very important for car rental companies to have better customer service as they are looked up on the internet and if there are any negative feedbacks, customers might have reservations about choosing that particular car rental provider (Suriadi et al., 2014).

Subsequently, website and mobile app design become very important. Having a website but not able to navigate easily or not able to provide complete information will do no good for customers and sometimes customers don't even think of specific car rental due bad website and confusing design on their apps. Hence better design features along with easy navigation enhances the online reservation experience and for this to happen latest web technologies and tools must be utilized (Pazour & Roy, 2015; Juan & Ou-Yang, 2004; Suriadi et al., 2014).

Website and mobile app design is usually part of overall business process reengineering initiative. In order to increase the sales, organizations have to clearly understand the process workflow and identify the drawbacks. Integrating the customer requirements and providing additional resources along with present products in rental car business would do wonders to start off with for organizations (Fink & Reiners, 2015).

In car rental business, business process design is constrained by capacity management issues. It is very hard to manage cars and allocate them across various stores since they are all connected and interlinked to multiple groups, store networks and laying out minute details of logistics involves number of varied cases of rental car. At the same time appropriate governance policies and compliance should be in place for all the necessary regulatory requirements from the government (George & Xia, 2011; Pazour & Roy, 2015).

Safety and reliability are two important factors in managing user's expectation toward a web-based system. By providing great experience through website and apps, it creates a sense of safety and reliability among customers. It not only attracts the customers but gains trust among customers and enables them that the site is dependable. This positive experience with customers will increase the brand knowledge among the customers and increases their association to next level (Suriadi et al., 2014).

In addition to the efficiency and effectiveness of the business, process, our design goal also put customer satisfaction as one important evaluating criteria. Customer satisfaction differs from

dealing with online business to that of offline business. In addition to safety and reliability, convenience, ease of use (from the Technology Acceptance Model), availabilities (always online) are all relevant variables. Communication plays a very important role in achieving customer satisfaction at each level. As the customer plays the role of the ruler, the dynamics of the marketplace keep changing accordingly. The market deliberately acts a forum where customers play a dynamic role in creating and challenging for value. The main principle is to encourage customer participation to propose a logic that is service oriented for marketing. Companies need to study from and collaborate with their customers to create and identify values that meet every need. Consumer who undertake the value creation role as prosumers, who consume products eventually and bring out the consumer experiences. Basically, this is a cycle which starts with customers and ends with customers itself which determines the customer satisfaction levels (Chen, 2016).

BPM AS AN INITIATIVE

Business Process Management is a business solution which explains business as a set of processes and workflows. It is a software which enables the business to understand, analyze, execute, implement, monitor and optimize the processes. Implementing the right business process business management tool will always transform the organization. Business Processes is not something which it does to the organization but it is very core of the business. BPM is usually executed through graphical modeling. The graphical notations will help to understand the performance collaboration and business transactions between the organization which will in turn helps the organization to understand themselves and the participants so that they can adjust to the internal and Business to Business acts very quickly (Cochran, 2004).

There are three kinds of BPM frameworks.

1) Horizontal BPM Suite
2) Vertical BPM Suite
3) Full Service BPM

Horizontal BPM Suite: It is a framework which focuses on technology and reuse. It mainly deals with the design and development of business process.
Vertical BPM Suite: The ready to deploy pre-built templates are easily configured and used.
Full Service BPM: It carries all the features of the company where a process is required to achieve the goals.

BPM Model:

BPM Models primarily concerned with the mapping and workflow to enable and understand analysis or the positive changes. The primary step in analyzing the process is to create an outline of the current state. The As-IS map represents what happens, not what should happen or could happen. The main feature of as-is event is to recall the actual event.

Undertaking the Gap Analysis through four steps that is by understanding, and considering the holistic approach to the environment, determining the framework for analysis and finally compiling the data will help to obtain the complete information about the key areas to focus on the process or quality improvement project. Once all the possible reasons are studied and root causes are recognized the next step is to undertake the suitable action which can be identified to remove, fill and mitigate the gap.

The To-Be Process defines the future of the business process. It defines the concept of existing process and identifies if they are effective or need improvement. The analysis is to clarify how the business processes will work once changes are made. The changes made can be technological based or business changes (Estublier, 2003).

To provide better communication between customers and business entities. Customer Relationship Management should be included as part of the TO-BE system. Customer Relationships are strongly subjective to Information and Communication Technology (ICT) (Osterwalder, 2003).

MSB's main business strategy is cost leadership. Organizations who use this strategy has to ensure that their products meeting the minimum requirements of the customers, if not the company is forced to drop the prices of their products eventually loosing profits and slowly losing to the competition (Brown, 2013).

Most organizations misunderstand the concept of Cost Leadership. The problem is many organizations think to work the strategy by charging more for the product and the other by charging less for the product. Charging more works when the company is single mindedly focused on Cost leadership. Many organizations want to pursue this strategy by eventually end up aiming at low cost. With advancements in technology the companies acquire suppliers, parts and distributors but lesser costs than at the initial stages of business. However, they still charge more for their products, while on the other side of the spectrum are companies that take advantage of this technology to deliver similar or better products at a lower cost, thus gaining the market share by Cost Leadership.

To organizations that would like to use the cost leadership strategy for staying competent below are some key strategies to keep in mind.

- Companies need to lead on low price only when they can lead on low cost. This means companies have to make sure they can manage the low costs of production before going with the lost price strategy. If the company cannot manage low price, they need to have a lot of cash lying around to manage the organization standing in the market.
- Step into areas where the employees specialize in. For example, if the organization is packed with innovators, efficient engineers and knowledge workers, it is suitable for such firms to invest into R&D and create innovative products at a lower cost. This will enable the company to charge their customers less and thus attract more customers towards the brand.
- Organizations have to understand that to succeed some markets will force them to be a Cost Leader. In markets where the product yield is low and costs are certain, companies can focus on reducing the costs by making processes efficient and reducing the effort incurred. Suppose the company sells corn, the only way to earn market superiority is to sell corn at a lower price than the competition. There is not much the company can do to innovate with corn being their product and the only thing to do is cost leadership (Jacob, 2014).

GAP ANALYSIS

Gap analysis is an analysis which is helpful in identifying the gap between a company's original performances against the potential performance. In this particular sort of analysis, the association's present state or current state and future state or desired state are initially listed out alongside with the planning which tends to fill out the gapping between both those states. In

general gap analysis is performed to calculate and evaluate the performance differences to conclude and figure out whether the requirements are met or not. For an instance, if the business requirements are not met, then compulsory steps should be taken to make sure that they are met successfully.

State Description:

A. Current State: Each and every single Gap analysis tends to start with a self-analysis approach. Actually, every gap analysis layout is supposed to begin with a division called as 'Current state' and from there you further drill down the attribute that you would interested in. Gap analysis in general can be both quantitative and qualitative or both as well. The very important thing to examine in this analysis is weakness.

B. Future State: The future state in the gap analysis determined the final state or the desired state that you want your company to be in. keeping it short it can be highly specific or highly generic in nature. The table template that you record all the values for the gap analysis should record all the desired attributes that takes current state into picture. Sometimes you may not even have clear idea of the future state in that case just record the values as 'NA'.

Bridging the gap:

A. Gap Identification: The following area in your Gap examination format should record whether a gap exists between the present and future state. A fundamental "Yes" or "No" can suffice (a delineation of the crevice will be made in the following portion).

B. Gap Description: This specific area ought to record all the conceivable components that make a gap between current state and the future state. This specific portrayal ought to be sufficiently clear. This specific area ought to just give a depiction however not a cure

Variables and Remedies:

A. Factors in charge of Gap: This specific segment ought to be next a portion of format and ought to rundown all the capable elements that are in charge of Gap recognized in the past section.

B. Remedies: This is the last stride in the Gap examination and this segment ought to drill down all the conceivable cures that can cross over any barrier between the present state and the sought state or the perfect state. [8]

Improving Current Sales Process:

Since the current process in the company takes 18 minutes for the customer to book a rental car online and because of this time lag and on an average day the company is not even making 100 sales in a day. This is where the Gap analysis comes into picture. Gap analysis helps to

bridge the gap between the present state and the future state where the company has to identify the gap that needs to be filled.

Gap analysis is done in three steps. Notably

1. State description
2. Bridging the Gap
3. Factors and remedies.

As-Is model

The word as-is itself says that it is indicating the “Current figure/situation” and it shows that the results are to be improved. As-is model helps us in identifying the current problem and the following factors. Based on that the problem can be solved and the process can be improved. I would like to give a simple example, Let us suppose there is a manager who is responsible for managing particular project. In order to go forward with the project implementation the manager communicates with the clients and gathers all the requirements in the form of a document. Once the as-is document is ready, based on that the to-be document is prepared.

AS -IS process

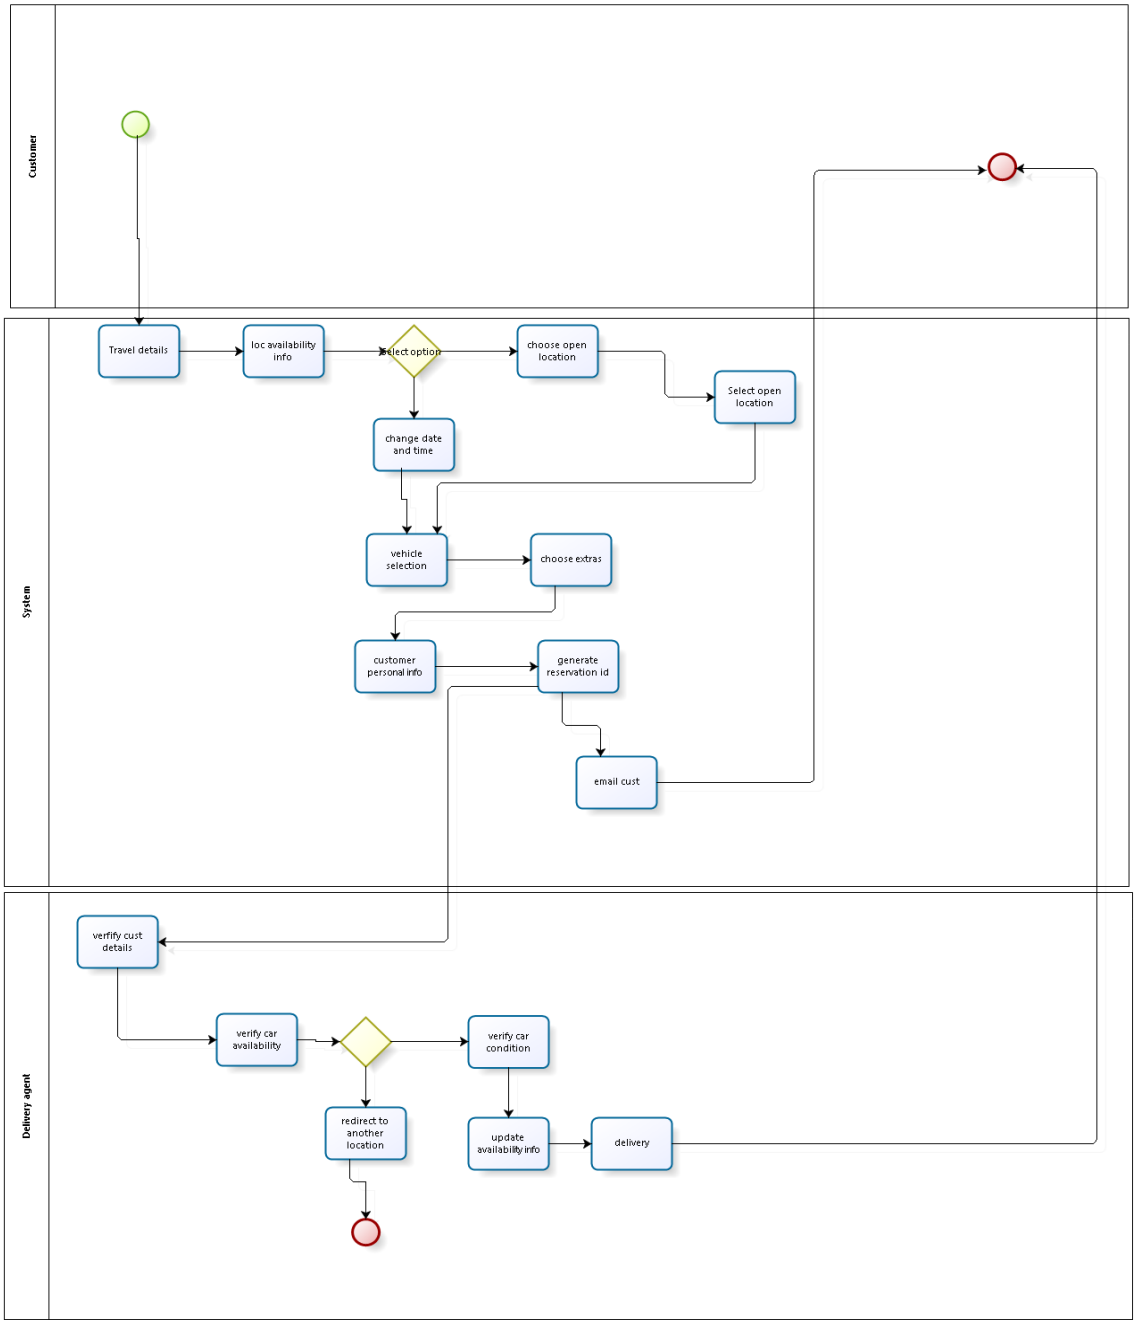
Figure 1 is the process map using BPM 1.0 Notation stating the As-Is model of the design of automated car reservation.

In this process there are three players involved which are Customer, System and Delivery agent. In a typical As-Is model, we capture the existing process which is in the current production. The process initially starts from the customer swim lane, the customer initially enquires the system with desired travel details and then proceeds to the next task i.e. Location availability information. In the next step customer gets a choice to decide between two dimensions whether to choose an open location or change date/time dimensions. If a customer selected an open location dimension then the next step is vehicle selection where the customer can select a vehicle based on their preference and then can select additional accessories by selecting an option “choose extras”. The customer needs to provide personal information and submits the form, a reservation id is created through this process which sends an email to the customer .In the backend, the process flows through the delivery agent .The delivery agent verifies the customer details and then verifies the availability of the car ,verifies the car condition ,updates the availability information and then deliver to the customer .If the car is not available then the delivery agent redirects the reservation to another location which is other sub-process that is to be followed.

To-Be model

The To-Be model integrates the business model into the additional systems that are necessary to get an analysis of As-Is model which optimizes them. The revisions and analysis are done until improvements are resulted from analyzing To-Be model. Numerous organizations are emphasizing "changes" in different perspectives consistently, yet it is unrealistic to accomplish compelling "enhancements" without unmistakably understanding the perfect circumstance and distinguishing issues to be understood to fulfill that objective. To-be precisely implies the focused on perfect circumstance, which is an extreme objective. Then again, As-Is means the present circumstance. Enhancing exercises are characterized as exercises to persuade nearer To-be from As-is.

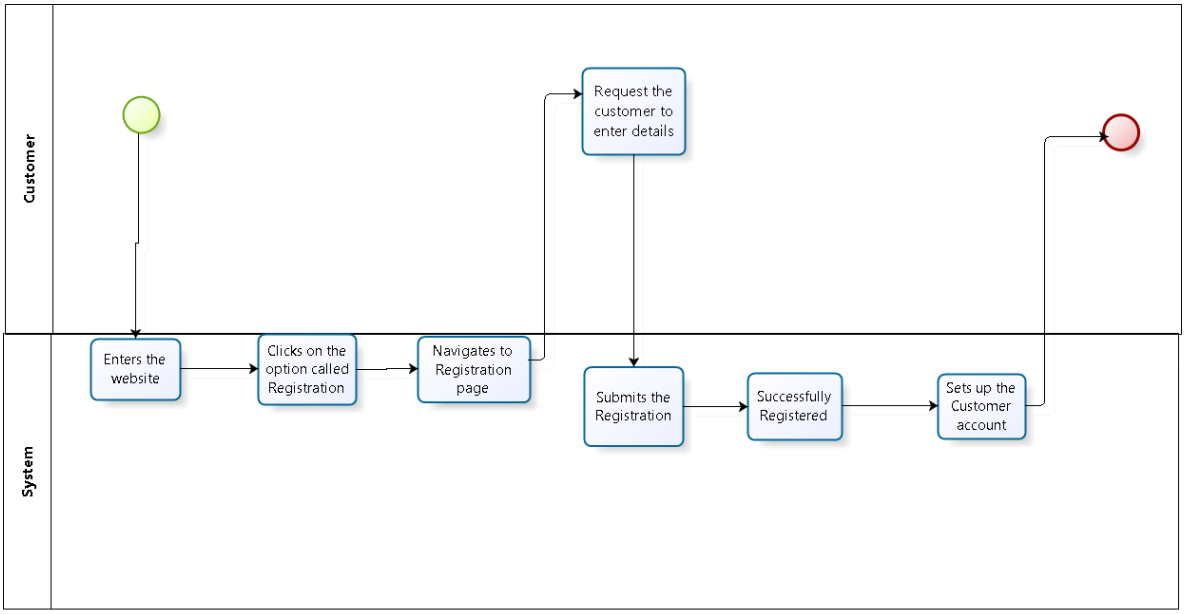
Figure 1. AS-IS Model



To-be solution

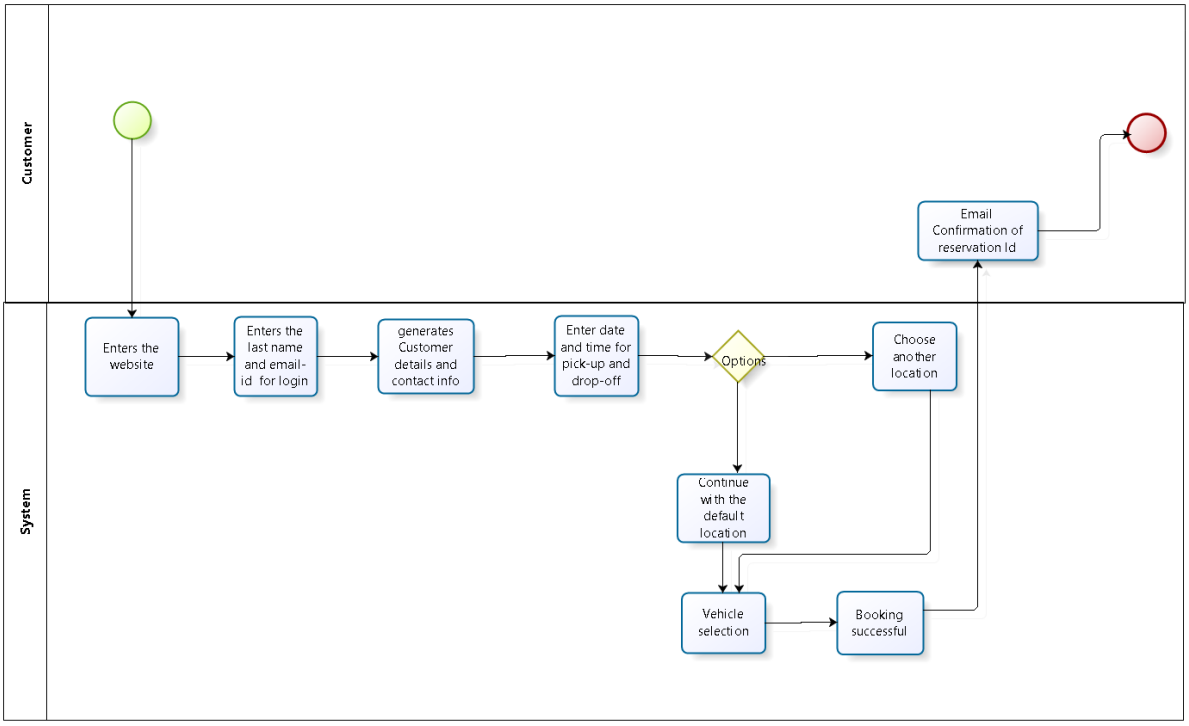
In the To-be solution we are going to introduce a feature called “User Registration”. When a customer enters into the website, person will see the option to register and become as a member of the organization. After the register option is clicked, the person will be redirected to the registration page where his details are asked. The details include primary details, location details, contact information. Primary information includes, first name, last name, license number, date of birth. Location information includes permanent address location of the customer and also the pickup location priorities where the customer is asked to enter his top 4 prioritized pickup locations where he actually rents a car from. Then the third set of details asked for are the contact details which actually include, email address and contact number. Once the registration is done the customer gets his account set up with the organization and he get benefits for being a member. The above approach is going to save ample amount of time for a customer while doing a car reservation. The above process is going to reduce the booking time by not asking customers to enter their personal information and location information. Figure 2 is the process map which depicts only the process which is related to Registration of the customer.

Figure 2. Registration of the customer process



After being a registered customer, it is so easy process to book a car. The customer has to enter his last name and email id to login to the account. Once the customer is logged in the primary details and the contact information is automatically seen. Three things that a customer should choose are, first, pickup and drop off dates. Second one, pickup location from the drop down of preferred locations. If the customer wants a complete new pickup location then he has an option of entering a new location from the drop down. Third one, type of car. After all these steps are completed the customer will receive an email confirmation that the car is booked. Figure 3 is the process map about how the booking process flows when a registered user book a car.

Figure 3. Booking Process



By implementing this process, both customers and organization is beneficial. Customers get good rewards, deals and discounts for being a loyal member and organizations get reputation alongside with good business because of huge members.

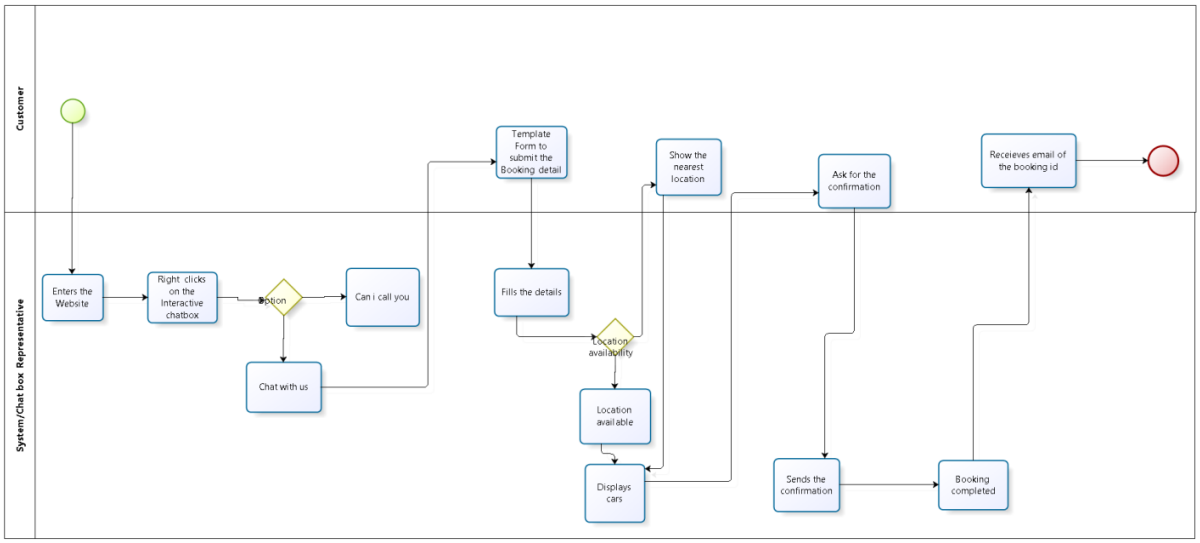
Implementation of a live chat support system:

When a customer visits the website, the person comes across a chat box at the bottom right position called Interactive Box where the customer can talk to the representative to book a rental car. When the customer right clicks on this chat box there will be two options available. One is “chat with us “ and the other options is “can I call you?”. The customer can choose any of these two options where a representative interacts with the customer who books a car on behalf of the customer.

When the customer clicks on Chat with us option, it unveils a rich Textbox where the person can chat with the customer. Here, a pop message is displayed saying that how can the representative assist the customer and answer the questions. The representative sends a template form in the chat box where the customer can fill in the details such as Location, date and time for the pick-up and drop-off and the type of car (Standard/Intermediate etc.). The representative immediately responds to the form, If the requested location is not available then the customer instantly recommends a nearest location and displays a list of cars based on the request .When the customer confirms with the price quoted then the representative will go ahead, submits the request in the backend and confirms the booking.The customer receives a booking id via email and the process flows through the delivery agent as mentioned in the as-Is

process. Figure 4 below explains the process when the customer selects the option called “Chat with us”.

Figure 4. Chat with us process

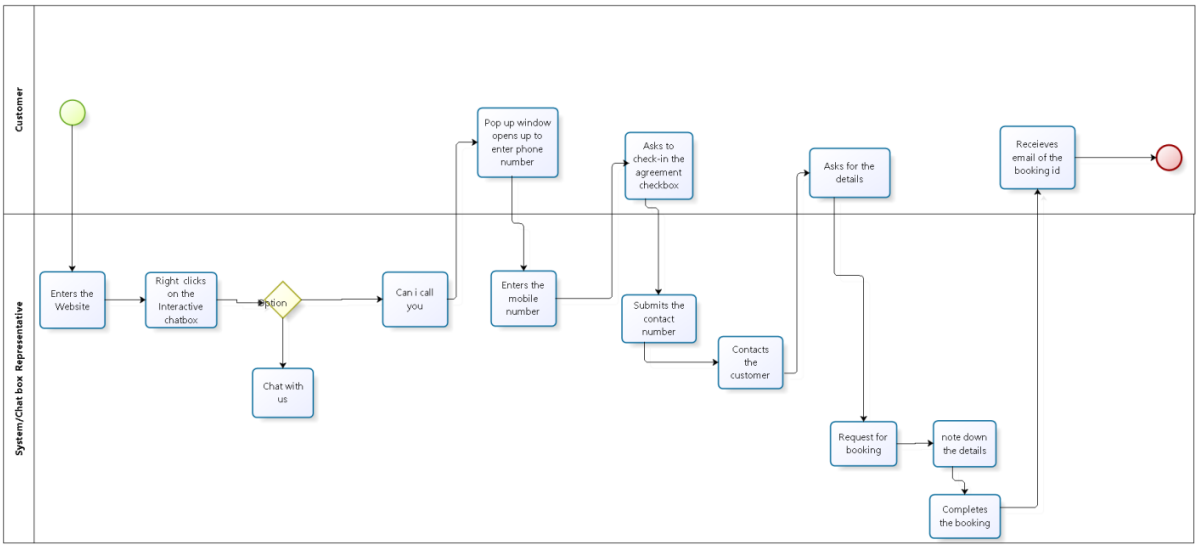


If the customer rights clicks on the option called “Can I call you?” A pop up window opens where the customer has to enter the phone number and click agreement checkbox saying that our company is authorized to make a phone call and then submit the request. The representative contacts the customer over phone, takes the details and does the booking for the customer. The customer receives a booking id via email and rest of the process is same. Figure 5 below explains the process when the customer selects the option called “Can I call you?”

This Interactive chat box can be used both for the new customers as well as the existing customers. By introducing this feature, we are completing the booking process on behalf of the customer where they don’t have to navigate through each and every page of the website to complete a booking.

In all these process maps we haven’t included about the how the flow of events work with respect to the deliver agent since ,it is similar to the As-Is process and there are no changes made with respect to the delivery agent.

Figure 5. “Can I call you?” process



Gap Analysis of the scenario:

Table 1. Gap Analysis

FUTURE STATE	CURRENT SITUATION	REMEDIES/PROPOSALS
1. Sales should be more than 40. 2. The website can be accessed by the prospective users as well as the current users. 3. The booking should be flexible and should not be more than 7 minutes. 4. Recommend a nearest possible location when the requested location is not available	1. Sales are not even close to 25. 2. There is no concept called registered users. 3. It takes 15-18 minutes to complete a single booking. 4. The customer has to go back and navigate the webpages and select another location or change the date/time when the preferred location is not available.	1. Developing a user interface by changing the existing website to a major extent. 2. In order to improve the efficiency and increase the sales on an average day. Providing special discounts to the registered users is a new strategy that can be implemented. 3. Introduce a new feature called live support chart with the help of which a customer can communicate better.
1. A additional cost should be spent on purchasing and integrating the required software	1. Costs are with respect to the existing process. 2. No Proper assessment or	1. Use of Standard help-desk solutions or any other live chat tools should be integrated to communicate with

which will ultimately result in increasing the sales. 2. Improving the customer relationship	customer service provided.	the customer. And also .the live analytics to gain further insights on the visitor's. 2. Technical team is responsible for the flow of events and teamwork is important when working with different departments.

RECOMMENDATIONS

Scope Clarification:

As per our analysis, the process change is a bit difficult as it involves major changes in the user interface and implementing a different approach which changes the way we communicate with the customer's. It is quite difficult to change the entire architecture as there is some cost involved with respect to the enhancements in the existing process. This kind of investment is a must in order to stay ahead of our contemporaries in the market. The additional features that we have presented in our solution will improve the overall efficiency.

In order to add additional features and Redesigning the current process there has to be the required scope to do that. Re-designing the whole process is a bit difficult since it is time consuming and expensive. When the scope is limited, the better way is to change the existing process step-by step by focusing on one particular enhancement at a time.

If MSB organization has to re-design their entire current process, then working on the scope clarification and provided process improvements is the only way to go. Overhauling the entire current process to new process and deploying the new process at once would create lot of disruptions in operations and possibly might not deploy as expected which can also prove to be expensive. MSB cannot afford to lose revenue because of failed process deployment or for any other reasons since their sales progress is as it is very bleak. Having scope clarified incrementally can help MSB organization to address one concern at a time and eventually deployment of re-designed process can be accomplished easily.

CONCLUSION

In our scenario, initially we have identified important elements like the turnaround time and process flow for a single booking reservation to improve the process. We have implemented the Gap analysis model using which the gaps were identified in the current process. While doing the Gap analysis, we have realized that the content of the website should answer all the questions with respect to the customer within a specified time and that is the reason why we have implemented the Live support system in the website using which there will be a two-way communication between the customer and the representatives of the organization.

By implementing the above AS-IS model, the sales target for a day would be considerably increased and even the addresses the concerns of better UI for the website and its content. The

Live support system would also include call option using which the customer can speak to the representative instantly and need not explain the entire scenario to new representative.

CABALONGA AVENTURA ECUADOR: SEEKING SUSTAINABILITY AND SELF-SUFFICIENCY

4 AM, Sunday, November 12, 2017. As Diego Losada-Vasquez, co-owner of *Cabalonga Aventura Ecolodge* boarded the bus to begin his twelve hour commute from the seaside village of Puerto Cayo to the Ecuadorean capital, Quito, he reflected on the past twenty four hours he had spent entertaining his guests. His business partner, Maria-Elena Alvarado-Villon had met a group of university students from Canada at the international airport in Guayaquil around 1 AM Saturday morning, to accompany them on the four hour ride to the beach resort lodge that she and Diego had established in Puerto Cayo. She returned to Guayaquil later that same morning to begin a twelve hour shift with Latam Airlines, where she worked as a flight attendant. Diego arrived at Cabalonga a few hours after Maria-Elena had left and entertained their guests until early Sunday morning when he began making his way back Quito for work. During the four years since Cabalonga was established, it had never turned a significant profit, while occupying 40 to 50 hours of Diego's 90+ hour work week. Diego wondered how to make the business more financially sustainable, and to alleviate the burden on himself and Maria-Elena.

Diego, Maria-Elena and Cabalonga

Diego Losada-Vazquez grew up in Ecuador's largest city, Guayaquil. He had a happy and fulfilling childhood, blessed by his family's relative prosperity in the largely agrarian economy of Ecuador. He attended good schools and graduated from a top university, along the way becoming one of a minority of Ecuadorians fluent in the English language. His mother grew up in the highlands city of Jipijapa, a thirty minute descent from the Andes Mountains to Puerto Cayo on the coast, where her family owned beachfront property. Upon graduating from university, Diego entered the workforce where, in 2007, he met Maria-Elena. Together they decided to start a business based on their shared love of nature, adventure and travel. Perennial entrepreneurs at heart, the pair has several more business ideas in mind, but are not ready to take them forward until their hostel is running without their constant attention.

Like Diego, Maria-Elena Alvarado-Villon (known simply as Ma-Elena by many) was also a native of Guayaquil. As a child she remembers playing happily, and always fantasizing about travel. Her playful and positive disposition is readily apparent, as her effervescent personality constantly bubbles over into exclamations of 'It's really great!' As Ma-Elena grew up, she knew she didn't have the resources to achieve all her dreams, and so she had to plan carefully and commit fully to anything she chose to do. She graduated from university with a degree in Business Administration, intent on one day opening a business. While she had little opportunity to travel when she was younger, it was now her full time job at Latam Airlines, where she works as a flight attendant. Passionate about snorkeling, kayaking and diving, Ma-Elena explains that "Diego brings the nature to our business, and I bring the adventure." She is sociable, loves entertaining and loves spending hours sharing travel stories with her guests at Cabalonga.

The Founding of Cabalonga Aventura Ecolodge

Diego had many fond memories of his time spent on the beach as a child, during summer vacations from school, eating fresh fruit picked from the trees, spending nights by candlelight, watching crabs running about the tranquil beach. He would spend up to three hours with his family in the waters of the Pacific Ocean, followed by lunch at local restaurants. When his father passed away, he inherited part of the family's land in Puerto Cayo. He and Ma-Elena originally planned to build a small vacation house on the beachfront property, but the demands of work and travel left them with little time, and so they decided to build a hostel instead.

While Cabalonga was still just an idea, Diego and Ma-Elena participated in a contest organized by the national government to encourage local entrepreneurship. Cabalonga was one of the 200 winners out of 2,000 submissions. One reason they won was that the government was, and still is, trying to promote tourism in order to build the economy. Moreover, their project was situated in a rural community that did not usually attract tourists, despite being on the popular *Spondylus* seaside route. Winners were to make a payment to the government and receive help developing their business plan, but since Ma-Elena had graduated from a business administration program, she decided to complete it herself. The main value of this competition was that it helped Diego and Ma-Elena realize that the idea was viable and attractive. When reflecting on this experience she says "this was a wonderful idea, it still is. That is why we won."

In 2013, the young entrepreneurs obtained a small bank loan, which they anticipated paying off by the end of 2018, and Cabalonga S.A. was founded, with ownership split evenly between the two. Meanwhile they continue to invest their own money to improve the property, with plants and water saving devices. In Ecuador, the S.A. (Sociedad Anonima) legal designation is typically used by large companies to create private, joint stock companies, but there isn't any similar legal figure yet for smaller businesses. Due to this, Cabalonga must remit several taxes, including a 12% VAT, retain an accountant to audit its books and, as well as meet other legal requirements. María Elena says that it is a huge challenge, but also better positions them for growth.

In April of 2016, a 7.8 Mw earthquake devastated buildings in part of the province of Manabí, and the Minister of Tourism subsequently called Cabalonga seeking help with the relief efforts. Cabalonga received owners of different hostels and hotels that had been destroyed by the earthquake and taught them how to recreate the Cabalonga business model as a means to restore some capacity in the reeling tourism industry. In exchange, photographers were sent to Cabalonga to create promotional material, although more than a year later Diego and Ma-Elena have yet to see the results. As part of the relief effort, the national government raised VAT from 12% to 14% for all businesses in the country, except those in the provinces of Esmeraldas and Manabí, which were to receive the extra taxes to fund rebuilding efforts. Having escaped the earthquake unscathed, mainly due to the simple, resilient design of its structures, Cabalonga did not receive any of the additional tax money.

Mission and Vision

Mission: "We will make your stay a unique ecoadventure experience in Ecuador"[1]

Vision: "Being one of the most innovative eco-tourism hostel franchises of nature and adventure in South America, which offers a comfortable stay, and unique and enjoyable experiences for our visitors.[2]

The founders' *eco-mission* is evident in their design and operation of Cabalonga. Other than the 'furnished' tents used to house guests, the compound is made almost entirely of bamboo and palm leaves, with some concrete pads for the main structures. Rain and used water is recycled to irrigate the plants and trees growing on the property. These include trees such as banana, mango and papaya, along with oregano and mint used to season meals made in the small, quaint, bamboo kitchen. Likewise, kitchen waste is composted to reinvigorate the soil used for growing. Cabalonga runs campaigns such as "save the turtles, no cars on the beach" to gain attention for causes which Diego and Ma-Elena feel connected to. It feels good to do be doing something, and their efforts have created feelings of solidarity amongst the Cabalonga staff, who themselves are able to influence the opinions and behavior of the local community. The many efforts of Cabalonga, especially their policies of hiring workers and sourcing food locally, have earned them an *Eco Lider Bronze* certification by Tripadvisor. They continue to improve their environmental impact with the goal of eventually obtaining Gold certification.

Cabalonga has achieved steady growth in revenues since 2016 (see Exhibit 1). In 2017 revenues grew approximately 22% and the owners expected an equal growth in 2018.

Infrastructure and Operations

The 1350 meter^2 site hosts a bamboo structure comprising the administrative office, storage and utility room, kitchen, bar and two covered patios; one for dining, the other located next to the bar which was housed in the same simple structure as the kitchen. Two bathrooms each for women and men shared the main structure, one of each equipped with warm showers. The bamboo and palm used in construction not only lowered the environmental impact of the structure, but was also necessitated by the entrepreneurs' limited finances.

Lodging consists of four small tents accommodating couples or 'lonely' travelers, and four larger tents with two beds for groups and families. Each tent has hammocks in front, and is protected from the wind and rain by a three-sided, roofed bamboo and palm leaf structure. For guests preferring more privacy, there is also a bamboo guest house with accommodation for up to four, which boasts a private bathroom. In total, there is lodging for 28 guests, plus an additional six travelling with their own tents. Once or twice a year a large group will arrive while touring the coast, forcing the owners to turn away additional guests, but typically the hostel doesn't operate at full capacity.

[1] http://cabalonga.com/index.php/en/about-us-2
[2] ibid

All accommodations include electricity, bedside tables and free Wi-Fi. The compound is fully enclosed within a bamboo fence, with two gates offering a security and privacy. Typically the gates are locked only at night.

All meals are made from locally sourced fish, shrimp and vegetables, especially the ubiquitous plantain. Using local foods is not always cheaper than shopping in grocery stores, but produce grown locally tends to be fresher and is often grown organically. Shrimp in Puerto Cayo is of the highest quality available in the country. Meals are provided to guests, as well as to anyone else stopping in. Sample pricing and costs information for meals is provided in Exhibit 2.

Tours

Cabalonga arranges transportation and/or guided tours of attractions in the surrounding area. It is located close to popular destinations such as Pacoche (30 minutes), Agua Blanca in Machalilla National Park (20 minutes), and the city of Jipijapa in the highlands (30 minutes). Numerous activities can be arranged, including snorkeling, diving at Isla de la Plata, and whale watching tours. Currently a total of 22 programs are offered to guests and other tourists. Since costs are negotiated with guides and tour operators, Cabalonga is able to earn a small margin on the sales, while tourists receive a discount. In addition, taxis in Puerto Cayo meet tour buses to offer rides to Cabalonga for $1.

Due to the extensive use of flat fees, there are significant economies of scale for larger groups, or when accommodating multiple guests. For example, one trail guide charges a flat fee of $20 regardless of the number of guests on the tour. Roundtrip transportation for this particular tour is $35 for a taxi (up to four people) or $60 for a bus to accommodate larger groups. Diego and Ma-Elena have considered operating their own tour boat, but ultimately decided the payback period was too long. They also feel bound to their operators in the region, considering them part of the extended Cabalonga ‘family’. While staff are able to book tours for guests that had not reserved them, standalone prices for tours are not always available, and it is difficult for the staff to therefore come up with a price without consulting the owners. Cost and pricing for tours is depicted in Exhibit 3.

Hospitality

Hospitality at Cabalonga is comprehensive and free, with the proprietors attending to any and all needs of their guests, in person or via email, phone or WhatsApp when not on site. It is not unusual for Diego or Ma-Elena to host karaoke parties, tell fireside stories and play guitar. Following each dinner, a complimentary cocktail is offered, made from local fruit juices and Ecuadorian spirits.

The staff can accommodate most visitors independently, but it is a challenge when they are not Spanish speakers. Maria-Elena and Diego spend about 40% of their time at Cabalonga and hospitality is not quite the same when they are not there. Nonetheless, they are constantly in touch with their guests via phone, text and social media to ensure their stay meets their expectations. Ma-Elena is the primary interface with local suppliers, challenged by her

unpredictable work schedule at LatAm. She accomplishes this by conducting business via text messaging and working with all invoicing 'in the cloud', literally and figuratively.

Sales and Marketing

Diego is primarily responsible for bookings, sales and marketing. He works from 8:30am to 6pm Monday through Friday in Quito. During the workday he takes calls about Cabalonga and in the evenings, manages promotion, publicity and bookings from 7pm to midnight, manages the Facebook (about 15-20 threads with about 100 messages requiring responses daily), Twitter and Instagram accounts, booking guests and so forth. Both owners' cellphone numbers are provided in all advertising and they take business calls and text messages through WhatsApp. Social media is the primary mode through which customer satisfaction is monitored, and Diego will personally respond to all compliments and complaints.

Cabalonga maintains a website (cabalonga.com) that lists pricing information, activities and contact information, as well as links to the Facebook, Twitter, YouTube, Instagram, TripAdvisor and a blog spot pages. Diego takes bookings directly, or they can be completed through Booking.com or Priceline. Tripadvisor rates Cabalonga "#1 of 5 Specialty Lodging in Puerto Cayo" based on ratings posted by guests.

Promotions are rarely used. At one point, Diego offered a free night at Cabalonga but there were no takers. He decided that since discounts are not effective, he focused on creating awareness and curiosity amongst more adventurous travelers. There are no radio or television campaigns and no plans for them. Diego estimates that for $400-500 he could reach about 9,000 to 20,000 people in three days. With Facebook, he reaches the same number of people for a mere $20.

Staffing

The first employee hired by Diego and Ma-Elena did not work out, having made several rather large mistakes that resulted in substantial losses for Cabalonga. They worked with the Ministry of Puerto Cayo to find employees, eventually hiring Johnny, who Diego describes as "a good father, son, fisherman, he is everything!" Johnny selected Nicole and later her sister Yomaira. Together these three are the full time custodians of Cabalonga, cooking meals, entertaining guests, and performing maintenance. There are two part time staff, Diana and Penelope.

Many people from abroad (Colombia, Venezuela, etc.) have acquired about working at Cabalonga, but the policy is to hire only from Puerto Cayo and neighboring communities so as to retain the EcoLider certification. Indirectly, Cabalonga provides income to tour operators, guides and transportation (buses and taxis of various sizes available as needed). In addition to those working directly for Cabalonga, other families in the community have an opportunity to generate small incomes, by purchasing food and running errands, hiring tourist guides from the same region, transportation, maintenance charges and other services which contribute to economic development in Puerto Cayo. The total labor costs for these staff are $2,334 per month, though the salary cost is only totaled at $1,382.50[3]

[3] Cabalonga company documents, 2018

The Ecuadorian Tourism Industry

Tourism is a growth market. Younger generations are more likely to spend their vacation time and money abroad than staying at home. To capitalize on this, many countries, including Ecuador, have invested substantial funds in developing their tourism sector. Ecuador's largest industry is petroleum, at 5.96% ($5.83B), while tourism accounts for 5.1% of GDP ($5.1B).[4] In 2016, Ecuador invested $1.2B into developing their tourism sector. Tourism is forecasted to continue to rise by 4.5% per annum until 2027, topping out at 9.4% of total GDP.[5]

Tourism accounted for about $5.7 billion US, or 5.5% of Ecuador's GDP in 2015. The industry grew from 684 thousand employees in 2007 to 732 thousand in 2015, and revenues have increased over the same period from $626 million US, providing a 12% CAGR.

In 2013, Ecuador tourist arrivals came in at 1.36 million. From 2014 to 2016 this declined from 1.56 million to 1.42 million, with the decline attributed to the devastating earthquake on April 16.[6] The total receipts from tourism in 2014 was 1.25 Billion, peaking at 1.56 billion in 2015 and dropping to 1.45 billion in 2016.[7] International tourist arrivals are forecast to reach 2.8 million by 2027.

In 2015, of the 1.55 thousand tourists visiting Ecuador, 225 thousand were specifically visiting the Galapagos National Park. Seven countries accounted for over 70% of all international tourist: the USA accounted for 37%, UK 8%, Germany 6%, Canada 6%, Australia 5%, Argentina 4%, and France 3%.[8]

One of the ways that Cabalonga stands out is there commitment to being environmentally sustainable. Ecotourism has grown to become a trend worldwide, especially in South America. While lacking a precise definition, ecotourism involves environmentally friendly and sustainable accommodations, and nature-based activities such as fishing, hiking or boating. Most also involve local cultural experiences. The overall philosophy of ecotourism is to leave a site the same or better than you found it.

For Cabalonga, the months of January, May and November are considered low season because in January people tend to have reduced purchasing power after the holiday season and the continuation of the school period. May and November are months in which children return to

[4] AJG Simoes, CA Hidalgo. The Economic Complexity Observatory: An Analytical Tool for Understanding the Dynamics of Economic Development. Workshops at the Twenty-Fifth AAAI Conference on Artificial Intelligence. 2011, accessed May 19, 2018, https://atlas.media.mit.edu/en/profile/country/ecu/.

[6] World Travel & Tourism Council, *Economic Impact 2017 Ecuador*, 1;6;7;9, March 2017, accessed May 19, 2018, https://www.wttc.org/-/media/files/reports/economic-impact-research/archived/countries-2017-old/ecuador2017.pdf.

[7] World Bank, DataBank Ecuador, accessed May 12, 2018.

[8] Juan Carlos Izurieta, "Behavior and trends in tourism in Galapagos between 2007 and 2015," *Galapagos Report 2015-2016* (2017): 83-85, accessed May 21, 2018, https://www.galapagos.org/wp-content/uploads/2017/12/3-GR-2015-16-Tourism-section.pdf.

school, and is the beginning of the rainy season when travel is less desirable. The months of February, April, June, September, October and December are considered medium season because occupancy is higher, at about 20%. This is due to holidays in February and December, the beginning or end of the whale watching season which is also the beginning of summer vacation period in the US (June and July).

The high season results in about 60% of occupancy because it takes time to develop a good market position and there is currently little developed tourism in Puerto Cayo. July and August are considered the high season, due to the highland region vacation time, and the whale and giant stingray sightings. Taking into account the different seasons, the annual occupancy of Cabalonga is 40%.

The monthly number of travellers booking various Cabalonga accommodation and/or tour packages is shown in Exhibit 4.

Hostels in Puerto Cayo

About nine hostels operate in Puerto Cayo (population 5,000) but Cabalonga is the only one which is open all year round, and offers personalized 'high touch' service by the owners. Other hostels are rarely visited by their owners and have been in operation for as many as 25 years. These businesses are neither growing nor contributing to the growth of the local economy.

Diego estimates about 75% of guests are from Ecuador, another 5% from Spanish speaking countries such as Colombia and Venezuela. The other 20% are international travelers from Asia, North America, Europe & Russia. Most international travelers book through Tripadvisor. A lot of the marketing is by word of mouth, primarily in the form of social media.

Conclusion

As Diego's bus wound through the mountains and into the rising sun, he realized there would be little chance for sleep until he arrived back in Quito later that evening. He was in the business of hospitality, with a strong personal touch, but he wondered if there was a way the business could be more self-sustaining so that he and Maria-Elena could squeeze in the occasional vacation for themselves. While creating an enterprise that could be independently run by the staff was his main priority, Diego had to acknowledge that a bit of income also wouldn't hurt, given the amount of time and effort he and Ma-Elena had put into the venture. And then there was always the call of their many other business ideas.

Teaching Note

CABALONGA AVENTURA ECUADOR: SEEKING SUSTAINABILITY AND SELF-SUFFICIENCY

SYNOPSIS

CABALONGA ECOADVENTURE ECUADOR (CABALONGA S.A) is a unique, low-cost hostel located in the small seaside town of Puerto Cayo, Ecuador. The beach-front land on which Cabalonga was established was inherited by one of the two proprietors, Diego Losada-Vasquez. Together, he and his business partner Maria-Elena Alvaredo-Villon built a quaint bamboo and palm structure housing the business office, kitchen and bar, utilities, and two covered open-air dining areas. Accommodations include several tents of various sizes, outfitted with electrical outlets, comfortable bedding, and ubiquitous hammocks, as well as a simple bamboo hut to house guests. The accommodations fill a small, and perhaps somewhat difficult to market-to niche, described variably as eco-lodging, five-star camping, or simply low-cost hostel. The company neither makes nor loses money for its entrepreneurs, but does provide a weekend getaway for its owners, financially maintained by its patrons. However, these weekend getaways have actually become hectic cross-country commutes, with every waking, and most sleeping-hours occupied with attending to guests' every need. While the enterprise is financially stable, Diego and Maria-Elena would prefer it was also a less time-intensive investment.

LEARNING OBJECTIVES

Working through the case will allow students to:

- Learn how to assess revenue streams and asset utilization.
- Learn how to assess options for growth and moving a business from start up to self-sustaining, in an environment of greatly attenuated resources.
- To demonstrate the fundamentals of positioning a start up to seize upon emerging trends in the tourism industry.
- To learn how to assess non-market strategies in emerging industries.

This case works well in a variety of strategic management, international management, entrepreneurship and emerging markets courses, at both the undergraduate and graduate levels of instruction. The simplicity of the company and its products makes this an ideal case for use in strategy capstone courses. At more advanced levels of instruction, the case can be used to analyze non-market strategy (i.e. working with government to promote an industry) and changing macroeconomic conditions. The slower pace of economic development and liberalization of Ecuador, being a very small country, makes it a great 'laboratory' for understanding the opportunities and challenges faced by domestic companies in developing economies, and to formulate strategic options for addressing them. Like many developing economies, Ecuador hopes

to capitalize on its natural beauty and rich culture by attracting tourists to a destination that is often overlooked by travellers.

POSITION IN COURSE

This case is ideal for strategy capstone courses at the graduate and undergraduate level of instruction. Enough information is provided to conduct analyses of the company's strengths and weaknesses, its brand positioning relative to direct competitors, and opportunities and threats emanating from the macroeconomic environment. It also allows more advanced classes to connect the evolution of an emerging market economy with business characteristics and requisite shifts in strategy. The case is designed not only to provide a setting to practice fundamental business strategy and marketing skills, but also to think of creative approaches to addressing opportunities and threats in domestic and international markets.

RELEVANT READINGS

This case works well with nearly any strategy or international business textbook such as:

- Dess, G.; McNamara, G. & Eisner, A. (2016), *Strategic Management: Text and Cases*, 8th edition (New York: McGraw-Hill).
- Navas-López, J.E. & Guerras-Martín, L.A. (2013), *Fundamentals of Strategic Management*, 1st edition (Madrid: Civitas).
- Christopher A. Bartlett & Paul W. Beamish (2018), *Transnational Management: Text and Cases*, (Cambridge: Cambridge University Press).

Additional readings on entrepreneurship in emerging economies an eco-tourism:

- Castaño, M.-S., Méndez, M.-T., & Galindo, M.-Á. (2015). The effect of social, cultural, and economic factors on entrepreneurship. Journal of Business Research, 68(7), 1496-1500.
- Lai, P.-H., & Shafer, S. (2005). Marketing ecotourism through the internet: An evaluation of selected ecolodges in Latin America and the Caribbean. Journal of Ecotourism, 4(3), 143-160.

ASSIGNMENT QUESTIONS

1. What are the possible avenues to achieve sustainable revenue growth?
2. How can Cabalonga increase its bookings and resource utilization?
3. How can the owners reduce their personal time commitment to Cabalonga?
4. How should Cabalonga S.A. position itself to take advantage of tourism trends in Ecuador?

TEACHING PLAN (90-MINUTE CLASS)

The assignment questions are intended to help the students prepare for the in-class session. The instructor can teach the case in one 90-minute session, using the following teaching plan to cover the discussion topics:

- (10 minutes) Instructor should provide a synopsis of the case, discuss the emerging phenomenon of ecotourism, and outline the plan for the analysis. The questions to be answers can be based on the assignment questions, and students can participate in analyses done on the board.

- (15 minutes) Conduct a financial analysis of the company and its product offerings (assignment question #1).

- (30 minutes) Based on the previous discussion, form a set of options to increase revenue streams (assignment question #2). The most logical approaches are to target more lucrative customer segments through marketing initiatives, or to alter the product offering to focus on the highest margin activities. Of course, students will realize that these two analyses are interrelated, in that choosing the customer will essentially make the choice of product a given. During this discussion, the potential of ecotourism in Ecuador should be explored for potential new product offerings aimed at capitalizing on this trend and the marketing efforts of the government (assignment question #4).

- (30 minutes) Making Cabalonga more self-sufficient, in terms of both cash flow and management (assignment question #3), is essentially the implementation of options focusing on specific product-markets students have already discussed at this point. The remaining questions now are a) how to match the product offerings to the skill set of the current staff and systems, and b) what additional resources should be obtained, if feasible, to make the operation run more smoothly.

- (5 minutes) Wrap-up. The instructor can now summarize the discussions, including any conclusions drawn. We have found it useful to emphasize both the opportunities and threats of business in emerging economies. The abundant natural beauty and relatively low cost of travel and accommodations in Ecuador creates a big opportunity. That said, travellers are still going to encounter difficulties communicating if not fluent in Spanish, and are likely to be hesitant about traveling to an area that is not known as a tourist destination. Hence, marketing for Cabalonga must be directed to meeting the needs and concerns of foreign travellers, and perhaps should be most specifically targeted to eco-travellers, given that these are likely to be a more adventurous group.

ANALYSIS

1. What are the possible avenues to achieve stable revenue growth?

Cabalonga has three primary revenue generating activities, which it combines into various forms of 'packages'. These are accommodations (tents and cabin with bedding, electricity, wi-fi internet access and private/shared bathroom facilities), dining, and various adventure tours, such as guided hiking and horseback riding, scuba diving, snorkeling, and so forth. The question that students really need to answer before generating and evaluating alternatives is "where does Cabalonga create the most value?" Answering this question naturally leads to an examination of margins. We suggest doing a quick conversion of the data in Exhibit 1 in the case to percentages of revenue in order to get a rough idea of where to start. This reveals the following:

Revenue	93,869	100%
Direct Costs	40,960	43.6
Gross Margin	52,909	56.4
Overhead		
Employee salaries	28,001	29.8
Managers' salaries	4,800	5.1
Occasional help	3,000	3.2
Utilities & supplies	5,412	5.8
Auditing	3,000	3.2
Maintenance	1,200	1.3
Advertising	3,600	3.8
Total Expenses	49,017	52.2
Earnings	3,893	4.1

The gross margin is quite attractive at 56%. On the other hand, overall earnings is a somewhat dismal 4.1%, although that is after the owners take their meager 5.1% from total sales. The primary portion of overhead, unsurprisingly, is employee salaries which make up nearly 30% of the total revenue. That said, the total yearly salary expense of $28K for two fulltime and 3 part-time employees is roughly in line with Ecuador's government mandated minimum wages. The company does not have much capacity to hire more full time workers, but does pay for occasional help from other community members, amounting to a total of $3,000, or 3.2% of revenues annually. What should be made obvious to students is that Diego and Maria-Elena are actually running a very tightly controlled budget in order to maximize the distribution of the proceeds to the community. They not only hire locally, but also source food locally and provide additional customers for tour operators. Items like auditing, utilities and maintenance are low and

probably not negotiable, and most will agree that marketing budget is quite modest. In many ways, the business appears to be closer to a small charity than a cash cow, but this has earned them recognition as an Eco Leader.

Overall the business appears to be sustainable as is, with positive margins and little threat of unexpected expenses given the simplicity of the operations. Cabalonga's reputation has spread by word of mouth and through social media, with sales growing faster than the tourism industry in Ecuador in general, suggesting that they are enjoying a period of early growth, with ample spare capacity. Of course that is not taking into account the gargantuan time and energy commitment of the owners, who take extremely little of the proceeds for themselves! To increase the profitability of the venture, we must first look for methods to increase revenues. The first step in the analysis is to study the income statements for Cabalonga to determine where the best margins are. By examining these scenarios, we can find the scenario with the highest profit margin, and begin to capitalize on that by gearing the business towards those services.

Revenue on meals is set to 100% of the cost of raw ingredients (Exhibit 2), however most meals 'sold' are actually included in the package costs. Exhibit 3 provides information on the packages, what they include, and the costs for tours, transportation and other supplies needed to provide activities. To these costs, the food and allocation of the overhead costs must be taken into account. From Exhibit 4, we calculate the total number of visitors to be 1,404 for 2017 leading to an allocation of the overhead costs of $28.40 per stay. When average meal costs are taken into account, the margins per stay are shown in Exhibit TN-1. What emerges is that many of the packages appear to be money losers, although they still contribute to paying the fixed overhead costs. Nonetheless, it seems that given the wide variance in margins for each of the packages, either the pricing scheme is not effective or the company is simply too diversified and should scale back to more profitable options. Students should be cautioned however, that any reduction in revenue greatly threatens the bottom line, since the overhead costs are mostly fixed.

Clearly revenue growth and/or simplification will be needed if the owners are to relinquish their control over day to day operations. This leads to the next question of what Cabalonga can do to increase resource utilization, in order to grow revenues without growing assets.

2. How can Cabalonga increase its bookings and resource utilization?

The analyses performed in the previous step lead us to conclude that either prices need to be adjusted, or the company should focus on only those packages which are most profitable. The company has spare capacity most of the time, so increasing assets is probably not an important initial goal. To decide where to focus, students must take into account the demand level for each of the packages (see Exhibit 4 in the case). The forecast for 2018 is based on the previous year's sales which show that the most popular packages are 'Beach' and 'Relax' which coincidentally are the cheapest and amongst the lowest margins (see Exhibit TN-1). Amongst the tours, snorkeling and the boat trip to Frailes Island are by far the most popular, although whale watching is also popular.

It won't take long for students examining TN-1 to realize that packages that include two nights of lodging are the most profitable, but also tend to be less popular than one night lodgings with tours. What this suggests is that there is a fairly sharp division between customers who stay for lodging and those that are interested in tours. Given the small size of Ecuador, the coast is accessible within a day's drive for most residents. Hence, it is quite possible that many of the customers are only using lodging for one night in order to partake of a tour and then get a night of rest before heading home. Indeed, this fits the description of the average middle-class or young single Ecuadorean weekend traveller.

Other options are to try and expand the restaurant sales, which would be worthwhile since the location is on the Spondylus route and many travellers will pass by on their way to their final destination. However, the staff who prepare meals need some idea of how many guests they are going to have in an evening so that they can obtain the right amount of ingredients, most of which require refrigeration, and have adequate time to prepare the meals. At a 50% margin, with no additional costs, it will be very worthwhile to attract a few additional diners each lunch and dinner, which can be done with relatively inexpensive roadside advertising. Perhaps a few of these travelers could be convinced to spend the night to partake in a karaoke session and have a couple beverages, which are also high margin sales. A complimentary cocktail for diners at the appropriate time may be all that is needed in some cases.

By examining Exhibit TN-1, we can see that the most profitable tours are the Romantic, Trekking 2N, Horseback Riding 2N, and Scuba Diving A. There are multiple packages that take a loss, however, the costliest are: Horseback Riding 1N, Relax and both the shared tent and the share room. Cabalonga can either try to fight against the tendency of its customers to prefer shorter stays of one night, or charge more for the tours which seem to be what they value most. However, convincing customers to stay two nights may be possible if packages are combined. That is, have two tours on two days, in order to convince travellers to stay and explore. To do this, Cabalonga should consider simplifying its website (Cabalonga.com) which at present provides the potential with a dizzying array of options which run the risk of producing information overload. They may consider creating a more interactive website which allows customers to build and price their own vacation packages. Eventually the owners may even consider a system to push this information to tour providers so that order fulfillment can be handled more seamlessly, thus requiring less hands-on involvement of the owners. From the current website, it is apparent that Diego has ample technical skills, so this next step in the evolution to a more dynamic website should be achievable within a 6 month time frame. The website change will take a large amount of time upfront and very little after it's completed, the Search Engine Optimization (SEO) will take a constant time commitment to make sure Cabalonga stays up on Google's rankings. Outsourcing this process to a website management firm can cost anywhere from $119-449USD/month[9], on the lower end of the spectrum, basic website updates, designs, security, and SEO is covered. Cabalonga may not

[9] Webpage FX, "Website Maintenance," Webpage FX, 2018, accessed May 29, 2018, https://www.webpagefx.com/websitemaintenance.htm.

need the extensive services that are offered by many website management firms. On top of this there are the current tasks of responding to emails and other digital comments.

Nonetheless, as the case states, prices seem to have little-to-no impact on demand, and so we can probably increase all prices across the board by 20% without turning away many potential customers. By examining this in Exhibit TN-2 and Exhibit TN-3, we can see that this price change increases year end profit from ~$3,900 to ~$22,600, without adding any new resources.

3. How can the owners reduce their personal time commitment to Cabalonga?

Diego and Ma-Elena's time commitments to Cabalonga can be split into three main activities: 1) Managing offsite through social media, electronic documents and messaging, 2) hospitality and 3) traveling to and from the lodge. Item 3 seems to be a rather large *transaction cost* involved with performing the hospitality duties (item 2) and so both should be targeted for reduction.

The simple answer is to increase training to have an employee take on more of the day-to-day management of Cabalonga. However, this will be difficult to do with local employees due to a lack of management education. The full time staff appears to be very committed to the operations, and will likely be able to take on more advanced management duties. Furthermore, a more advanced order fulfillment system as described in the answer to analysis question 2 could automate many of the more complex scheduling and pricing tasks.

To lessen the personal time commitment, Marie-Elena and Diego will eventually need to find qualified help, and spend a great deal of time training them. At minimum, the person would need to be able to speak and read English fluently to help with guests from the United States and elsewhere, as well as manage the personnel, scheduling, replenishment, and so forth. The biggest issue would be finding the right individual to manage Cabalonga, especially when the owners are not at Cabalonga full time, to recognize a qualified person with little to no interaction between them and the customers. They should look to the Universities of Ecuador for young graduates looking for an entrepreneurial challenge. The starting wage of approximately $15K is within Cabalonga's grasp with the 20% cost increase. In addition, the manager could earn a commission for increasing sales, which should also be achievable with someone stationed at the facility full time (see Exhibit TN-4).

4. How should Cabalonga S.A. position itself to take advantage of tourism trends in Ecuador?

From the preceding analyses, it is clear that acting as a tour intermediary is essential for boosting Cabalonga's revenues and profitability. In 2013, Ecuador tourist arrivals came in at 1,364,000 people, from 2014 to 2016 this changed to 1,557,000, 1,544,000 and 1,418,000 respectively. At the same time in the total receipts (USD) from tourism in Ecuador was 1.251 Billion, peaking at 1.557 Billion in 2015 and dropping to 1.449 Billion in 2016. International tourist arrivals is forecasted to reach 2,811,000 by 2027.

The earthquake in 2016 clearly took its toll on the industry, but tourism in Ecuador was certainly experiencing healthy growth prior to this, and Cabalonga's main business attracting mostly Ecuadorean tourists was not greatly affected. Looking to the future the, Cabalonga should prepare to accept more foreign eco-travellers, who have deeper pockets and greater need of the hospitality and the tour arranging services that Cabalonga offers to its guests.

Each year, the split between foreign and domestic tourism increases (see Exhibit TN-5). In 2016 62.60% of tourism spending was from foreign travellers, this increased to 64.80% in 2017, it is projected to be 68.06% for 2018[10]. Long range forecasts are expected to be 4.5% increase per annum between 2017 and 2027, topping out at 2.5% GDP in 2027.[11] In 2017, the USA and Columbia contributed the largest share of tourists to Ecuador. USA: 244,600 tourists, Columbia: 330,671 tourists, total global: 1,608,473 tourists[12] . With this increase in international visitors to Ecuador, Cabalonga should begin to shift it's positioning in their advertising to attract more foreign customers. This can in part be accomplished by created an English version of the Cabalonga's website. Cabalonga may consider the practice of charging higher rates on the English language website, a common practice in developing countries, where the spending power of the local consumer is greatly reduced from that of the international traveller. The prices currently charged are, by American standards, unnecessarily low.

ABSTRACT

The mortality rate in the United States is different for the ethnicities and genders, in such a way that the mortality rates were analyzed and found some important differences that suggest the opportunity of using the unique characteristics of the ethnic and gender groups to reduce mortality on the others. This study focuses on projecting the national mortality data for the future identifying areas of research opportunities by ethnicity groups and gender.

KEYWORDS: regression, mortality, ethnicities, sensitivity analysis and health

INTRODUCTION

The United States is a country that has an amalgam of cultures, ethnicities, races, languages and religions that shape the country as a place for migrants looking for the land of opportunity. The country population of around 325 million people in 2017, and it continues growing by organic growth as well as migration. The composition of the population can be seen in figure 1 that clearly shows that most of the population is in the white persons' category.

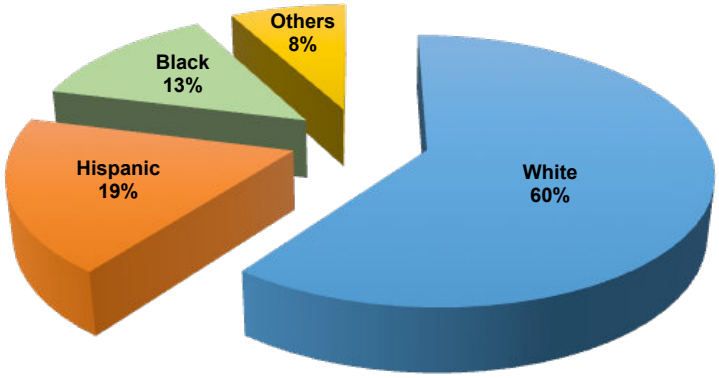

Figure 1: Races and Ethnicities' Composition of the USA Population

An important finding while analyzing the demographics, is that we expected a comparative difference between genders, but this is not true because there are 2.67 million more black women than men, that is 11% more in comparison to males, while in the case of white women,

they are 3% more than men. In the case of Hispanics genders are almost perfectly balanced according to the Census numbers.

Table 1: USA Population by Race and Gender

Male		Group	Female	
29.67%	95,842,609	White	98,885,235	30.61%
9.31%	30,058,779	Hispanic	30,094,010	9.32%
6.17%	19,922,595	Black	22,599,391	7.00%
3.78%	12,212,462	Others	13,381,513	4.14%

The mortality line from 2006 to 2015 shows a R-square of 0.905 with a slope or growth of 28,683 per year at national level, while the population growth is significantly higher with 2,380,488 per year (Census, 2017). This figure shows that there is an aging population in the country as the number of births and migrants is well over the deaths. The cities are growing, and people are living longer, but this study is going to go beyond the surface and into the details of the cause of deaths by ethnicity and gender.

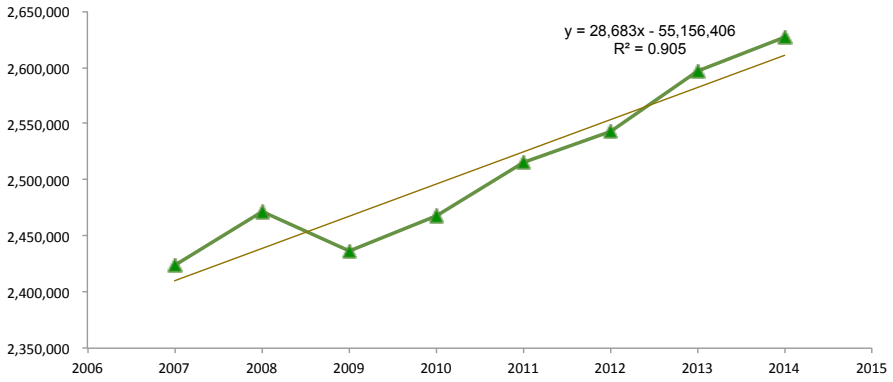

Figure 2: Mortality Numbers in the USA

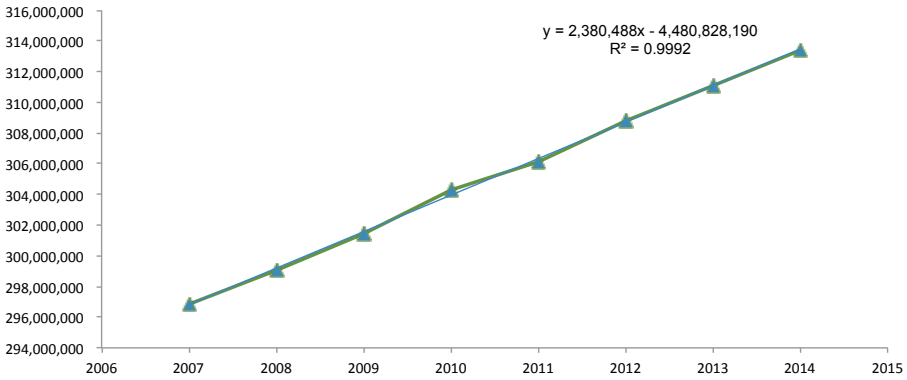

Figure 3: Population growth as Estimated by the Census Office

VIOLENT DEATHS ANALYSIS

We can separate deaths in the United States into two major groups: diseases and violent deaths. The study is based on the available information at the Centers for Disease Control and Prevention (CDC). We are looking at the period between 2007 and 2014 because the County information is not available for comparison, so we will go as far as all three levels of information are available.

The first point to address is the importance of the violent deaths in the country. The percentage of homicides, suicides and accidents is only 7.2% of all deaths, but the behavior of these deaths follows the polynomial non-linear regression with a R-square of 0.937, which is showing an alarming growth of rate on the last four years after a positive trend of reduction. For this particular study, we are only going to separate these statistics by gender and group to have a better idea of where the trend is going.

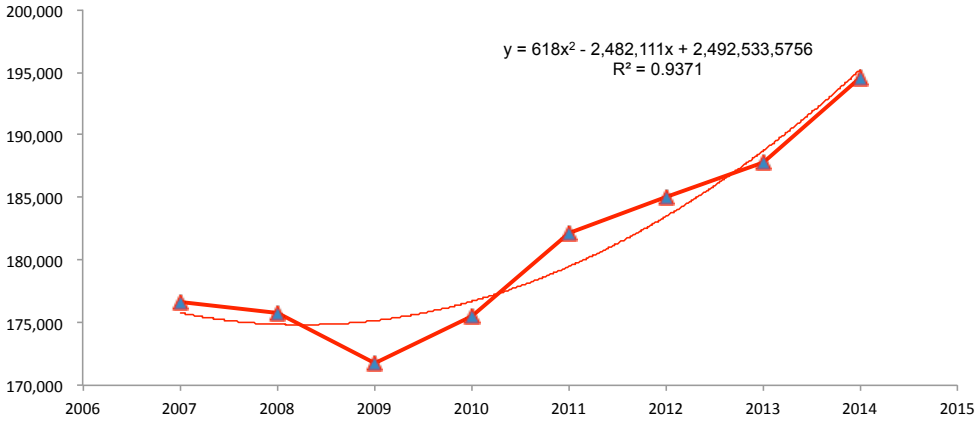

Figure 4: Total Violent Deaths in the USA

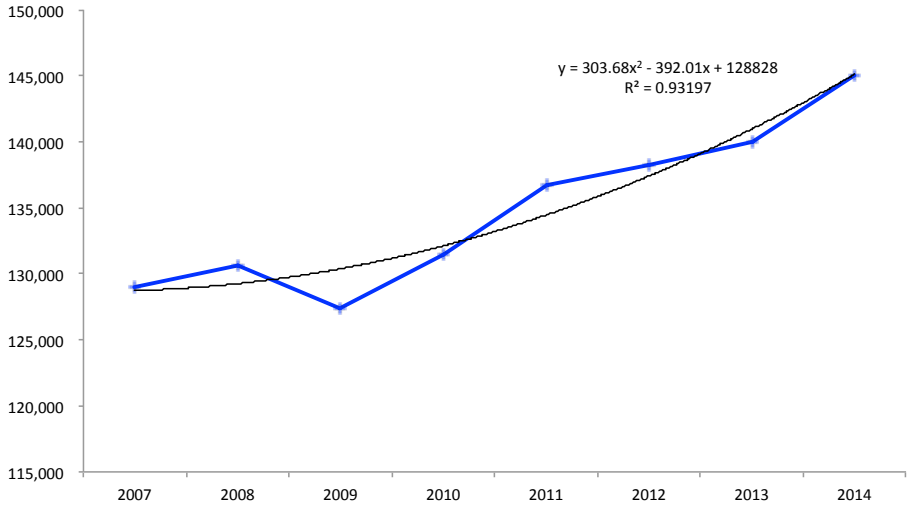

Figure 5: Violent Deaths for White Persons in the USA

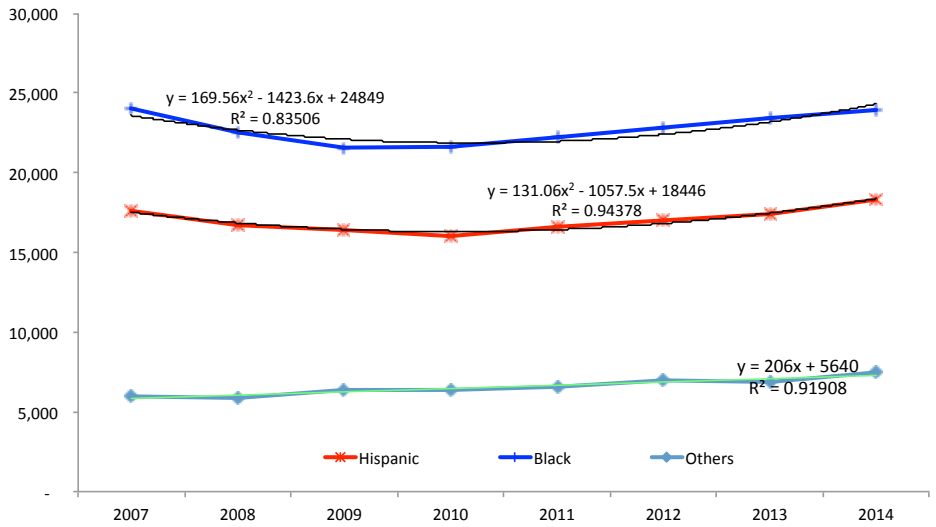

Figure 6: Violent Deaths for Minorities in the USA

The white population definitively drives the curve slope of violent deaths because of its number and proportion. Looking at table 2, we can see that the proportion of violent deaths is almost the same for Hispanics and the others' group, while the black and white groups are higher, being the white people the highest.

Table 2: Proportion of Violent Deaths for Groups to the Group's Population

Group	2007	2008	2009	2010	2011	2012	2013	2014
White	0.066%	0.066%	0.065%	0.067%	0.069%	0.071%	0.072%	0.074%
Hispanic	0.039%	0.036%	0.035%	0.033%	0.033%	0.033%	0.033%	0.034%
Black	0.064%	0.060%	0.057%	0.056%	0.057%	0.058%	0.058%	0.059%
Others	0.033%	0.032%	0.034%	0.033%	0.033%	0.032%	0.031%	0.032%

Table 3: Proportion of Violent Deaths by Gender and Group to the Specific Population

Males	2007	2008	2009	2010	2011	2012	2013	2014
White	0.089%	0.090%	0.087%	0.089%	0.092%	0.094%	0.095%	0.098%
Hispanic	0.060%	0.055%	0.052%	0.049%	0.049%	0.049%	0.049%	0.050%
Black	0.104%	0.097%	0.091%	0.090%	0.091%	0.093%	0.093%	0.094%
Others	0.045%	0.044%	0.047%	0.046%	0.047%	0.045%	0.043%	0.045%
Females	**2007**	**2008**	**2009**	**2010**	**2011**	**2012**	**2013**	**2014**
White	0.043%	0.044%	0.043%	0.045%	0.047%	0.048%	0.049%	0.051%
Hispanic	0.017%	0.016%	0.016%	0.016%	0.017%	0.016%	0.016%	0.017%
Black	0.029%	0.027%	0.027%	0.026%	0.027%	0.026%	0.027%	0.028%
Others	0.021%	0.020%	0.022%	0.021%	0.021%	0.020%	0.019%	0.021%

Table 3 shows the critically of gender while analyzing accidental deaths because females in all groups have a much lower proportion of violent deaths than men. A point to address at this point is that black male violent deaths were going down until 2010, when they started climbing again. It is noteworthy that white and black males have a similar proportion of violent deaths.

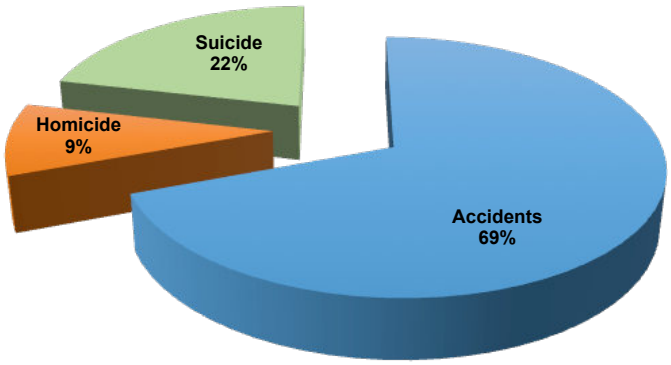

Figure 7: Violent Deaths by Categories in the USA

More than two-thirds of the violent deaths in the country are accidents, while suicides are the second largest contributor with 22% of all violent deaths.

Table 3: Causes of Violent Death by group and Gender in the USA

	White		Black		Hispanic		Others	
Violent Death Cause	Male	Female	Male	Female	Male	Female	Male	Female
Accidents (unintentional injuries)	0.062%	0.038%	0.047%	0.020%	0.033%	0.012%	0.029%	0.015%
Assault (homicide)	0.004%	0.002%	0.038%	0.005%	0.010%	0.002%	0.005%	0.002%
Intentional self-harm (suicide)	0.026%	0.007%	0.010%	0.002%	0.009%	0.002%	0.012%	0.004%

In table 3 we can easily see that the major contributors for accidental deaths are the males, and there is another important fact about the black males being the ones with the largest proportion of homicide deaths. Another subject recommended for further investigation is the higher than normal proportion of suicides from white persons.

DISEASES DEATHS ANALYSIS

The CDC identifies several causes of death due to illnesses, and for this study, we will focus on the major illnesses based on the national mortality data published by the CDC.

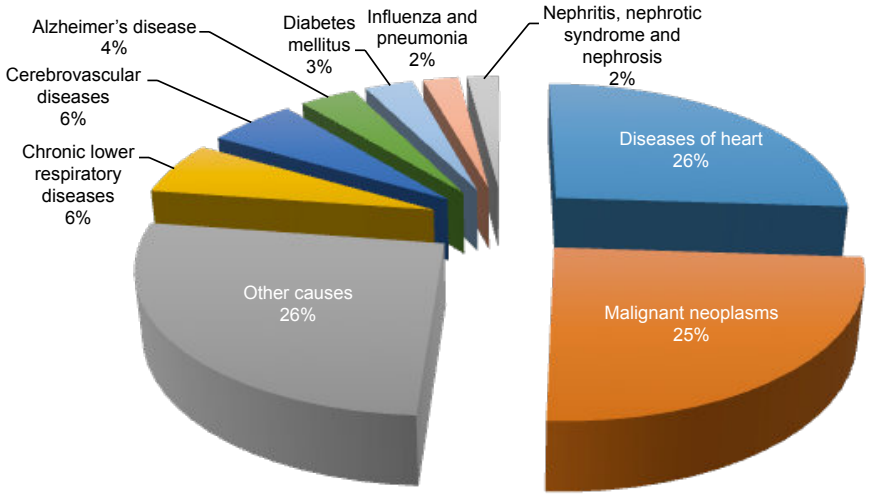

Figure 8: Top Diseases in the USA

The figure shows that Disease of the Heart and Cancers are the top two causes of death by illness in the United States as they add to over 50% of the deaths. The next contributors are much smaller because the following one on the list is the respiratory disease with only 8% of the deaths. Having identified the main causes of death, we now proceed to analyze by gender and then by ethnic group to identify possible trends or differences on the proportions.

Table 4: Causes of Mortality by Gender

Male		Group	Female	
0.209%	312,868	Diseases of heart	293,599	0.189%
0.201%	301,584	Malignant neoplasms	274,242	0.176%
0.166%	248,348	Other causes	300,553	0.193%
0.045%	66,733	Chronic lower respiratory diseases	74,165	0.048%
0.036%	53,276	Cerebrovascular diseases	77,721	0.050%
0.017%	25,139	Alzheimer's disease	58,172	0.037%
0.025%	37,404	Diabetes mellitus	35,039	0.023%
0.017%	25,149	Influenza and pneumonia	28,534	0.018%
0.016%	23,532	Nephritis, nephrotic syndrome and nephrosis	24,039	0.015%
0.011%	16,776	Septicemia	19,461	0.013%
0.014%	21,492	Chronic liver disease and cirrhosis	11,609	0.007%

The table shows that Cerebrovascular and Alzheimer's diseases have a larger percentage in women than in men. The difference is more noticeable in the Alzheimer's disease because the number of deaths is more than twice as much. Aronson et al. (1990) stated that women were over 3 times more likely to develop dementia than men despite controlling for baseline demographic, psychosocial, and medical history variables.

Table 5: Proportions of Death by Group and Gender

	White		Black		Hispanic		Others	
Diseases Causing Death	**Male**	**Female**	**Male**	**Female**	**Male**	**Female**	**Male**	**Female**
Diseases of heart	0.261%	0.239%	0.195%	0.165%	0.067%	0.058%	0.092%	0.068%
Malignant neoplasms	0.251%	0.219%	0.185%	0.154%	0.066%	0.062%	0.095%	0.083%
Other causes	0.199%	0.241%	0.173%	0.169%	0.070%	0.070%	0.076%	0.076%
Chronic lower respiratory diseases	0.061%	0.067%	0.025%	0.021%	0.009%	0.009%	0.015%	0.011%
Cerebrovascular diseases	0.042%	0.062%	0.039%	0.043%	0.014%	0.017%	0.021%	0.024%
Alzheimer's disease	0.023%	0.051%	0.008%	0.019%	0.005%	0.010%	0.005%	0.010%
Diabetes mellitus	0.027%	0.024%	0.032%	0.032%	0.014%	0.014%	0.016%	0.014%
Influenza and pneumonia	0.021%	0.023%	0.014%	0.013%	0.007%	0.007%	0.011%	0.010%
Nephritis, nephrotic syndrome and r	0.018%	0.017%	0.021%	0.022%	0.006%	0.006%	0.007%	0.007%
Septicemia	0.013%	0.015%	0.015%	0.016%	0.004%	0.005%	0.005%	0.005%
Chronic liver disease and cirrhosis	0.016%	0.009%	0.010%	0.005%	0.013%	0.006%	0.008%	0.005%

Looking at the two diseases that were showing higher incidence of women than men, we see now that the Alzheimer disease causing death is showing the same behavior for all groups, because the proportion is more than twice as much as the men. Cerebrovascular diseases seem to be only found for white women because in all other cases the difference between males and females is very close. World studies suggest that CVD are going down in the world for both sexes but the statistics for white women in the USA are still high (Levi et al., 2002).

COMPARING THE RESULTS OF THE USA WITH TEXAS

The population in Texas has a different composition because the white population is still a majority, but closely followed by the Hispanics. If the proportions that we have seen in a national level as impacted by ethnicity, then the numbers should present a different behavior due to the demographics of the state. The idea of Hispanic migrants having better access to health care than the poor native Hispanics could have an improvement effect on the statistics (Gresenz et al., 2009).

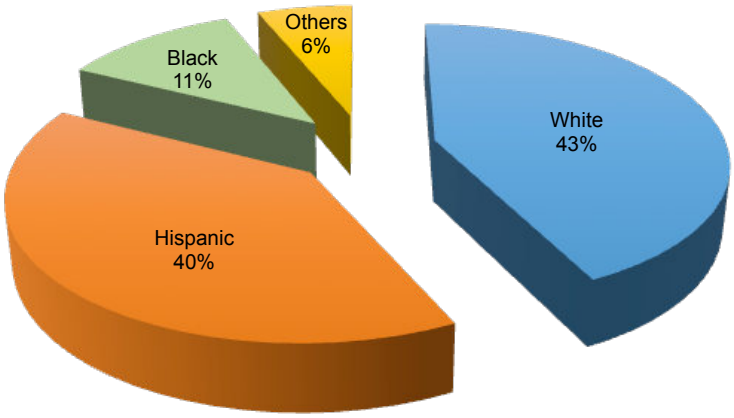

Figure 9: Races and Ethnicities' Composition of the Texas Population

In Texas, all ethnic groups have a close balance between males and females, as their differences on quantities are insignificant

Table 6: Texas Population by Race and Gender

Male		Group	Female	
21.18%	5,753,306	White	5,871,575	21.62%
19.95%	5,417,985	Hispanic	5,322,471	19.60%
5.54%	1,506,024	Black	1,608,163	5.92%
3.03%	821,995	Others	860,423	3.17%

The mortality line from 2006 to 2015 shows a R-square of 0.925 with a slope or growth of 3,204 per year at the state level, while the population growth is significantly higher with 449,629 per year (Census, 2017). These figures show that there is an incredible growth on population with a small mortality rate that is causing a larger than expected demographic growth.

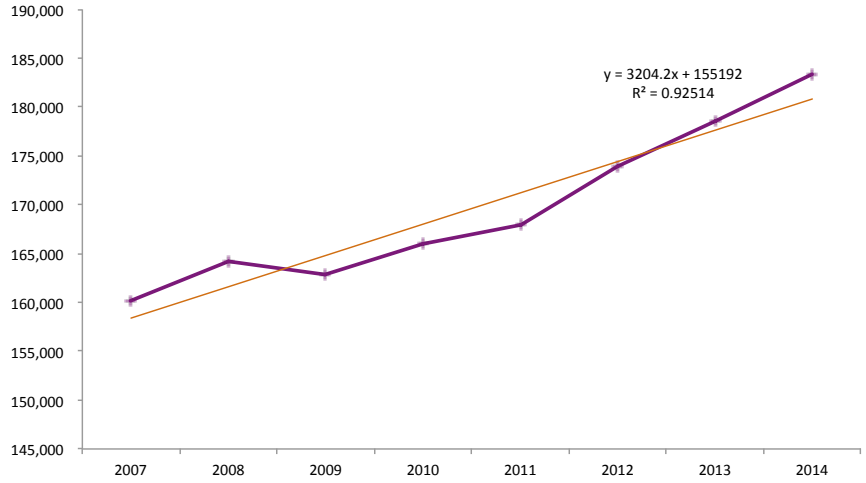

Figure 10: Mortality Numbers in Texas

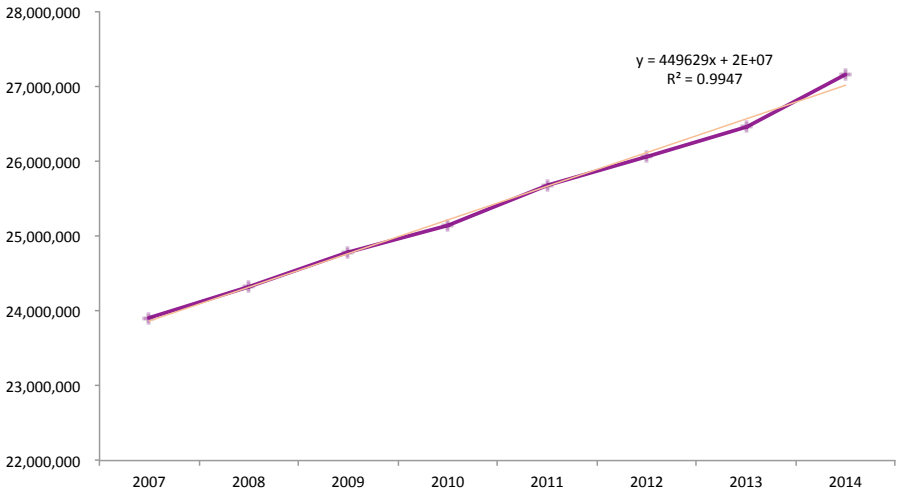

Figure 11: Population growth as Estimated by the Census Office

VIOLENT DEATHS IN TEXAS

The percentage of violent deaths in Texas is only 8% of all deaths, but the behavior of these deaths follows the polynomial of the third order non-linear regression with a R-square of 0.928, which is showing a stable period and the same alarming growth of rate on the last four years as seen in the national chart.

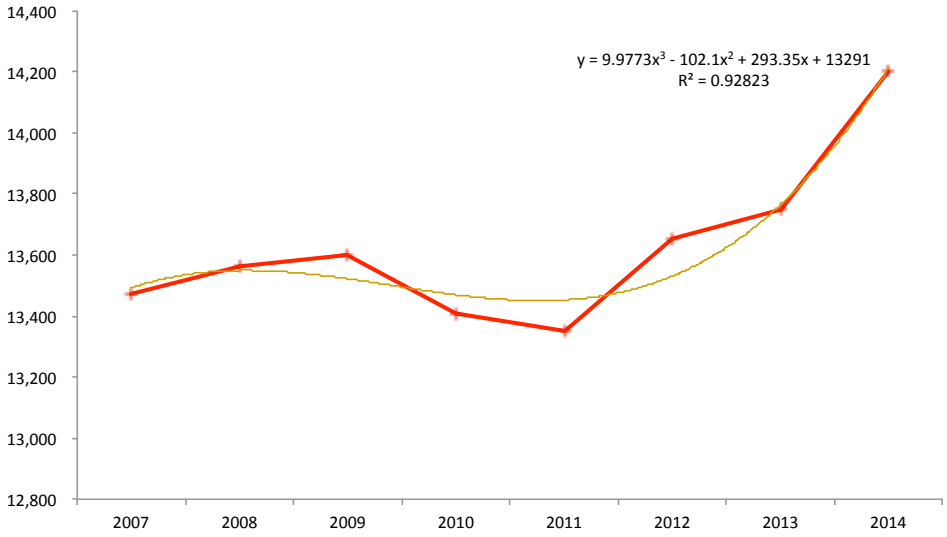

Figure 12: Total Violent Deaths in Texas

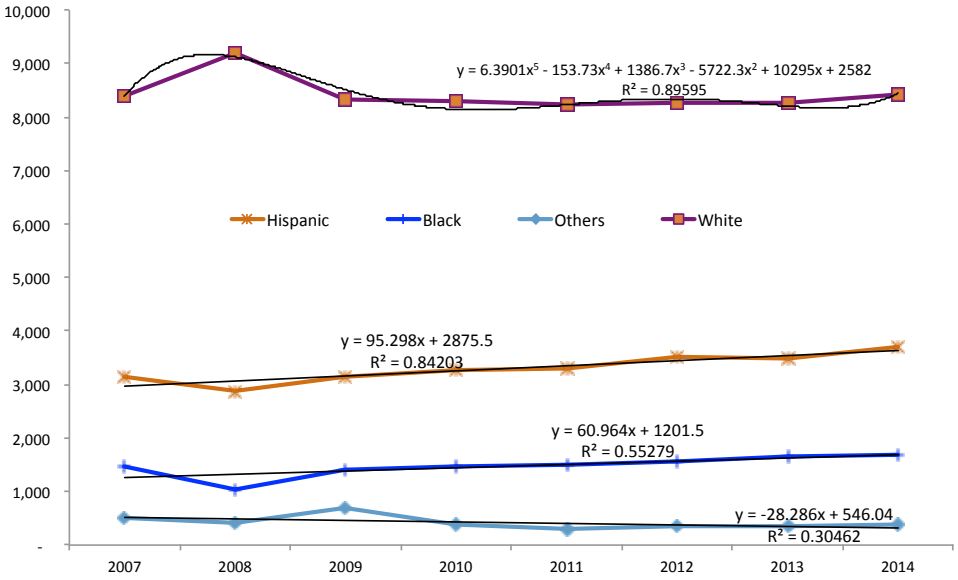

Figure 13: Violent Deaths for All Groups in Texas

Although the white and Hispanic populations are almost the same, the number of deaths of Hispanics is much lower than for white persons, and on regards to the national numbers, the number of violent deaths of Hispanics is comparable to the national proportion.

Table 7: Proportion of Violent Deaths by Gender and Group to the Specific Population

Males	2007	2008	2009	2010	2011	2012	2013	2014
White	0.099%	0.111%	0.097%	0.095%	0.097%	0.097%	0.097%	0.098%
Hispanic	0.052%	0.046%	0.049%	0.051%	0.050%	0.052%	0.050%	0.050%
Black	0.081%	0.054%	0.075%	0.072%	0.075%	0.080%	0.084%	0.083%
Others	0.071%	0.054%	0.091%	0.050%	0.030%	0.032%	0.029%	0.032%
Females	**2007**	**2008**	**2009**	**2010**	**2011**	**2012**	**2013**	**2014**
White	0.049%	0.053%	0.050%	0.050%	0.048%	0.047%	0.048%	0.048%
Hispanic	0.018%	0.017%	0.017%	0.018%	0.017%	0.018%	0.017%	0.018%
Black	0.026%	0.020%	0.026%	0.026%	0.029%	0.026%	0.027%	0.028%
Others	0.029%	0.028%	0.036%	0.018%	0.011%	0.014%	0.014%	0.014%

Table 7 shows the critically of gender while analyzing accidental deaths because females in all groups have a much lower proportion of violent deaths than men. A point to address at this point is that black male violent deaths have been at the same level for the past eight years.

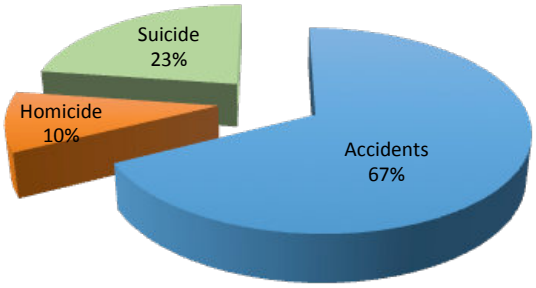

Figure 14: Violent Deaths by Categories in Texas

The same as in the national figures, more than two-thirds of the violent deaths in the state are accidents, while suicides are the second largest contributor with 23% of all violent deaths.

Table 8: Causes of Violent Death by group and Gender in the USA

	White		Hispanic		Black		Others	
Violent Deaths	Male	Female	Male	Female	Male	Female	Male	Female
Accidents	0.064%	0.039%	0.034%	0.014%	0.043%	0.020%	0.028%	0.013%
Homicide	0.005%	0.002%	0.008%	0.002%	0.024%	0.005%	0.008%	0.002%
Suicide	0.029%	0.008%	0.008%	0.002%	0.009%	0.002%	0.009%	0.004%

In table 8 we can easily see that the major contributors for accidental deaths are the males, and there is also the same factor of homicides being the cause of more black males.

DISEASES DEATHS ANALYSIS IN TEXAS

Following the analysis that we did for the diseases as reported by the CDC, we find that the top illnesses are very much the same as for the national level.

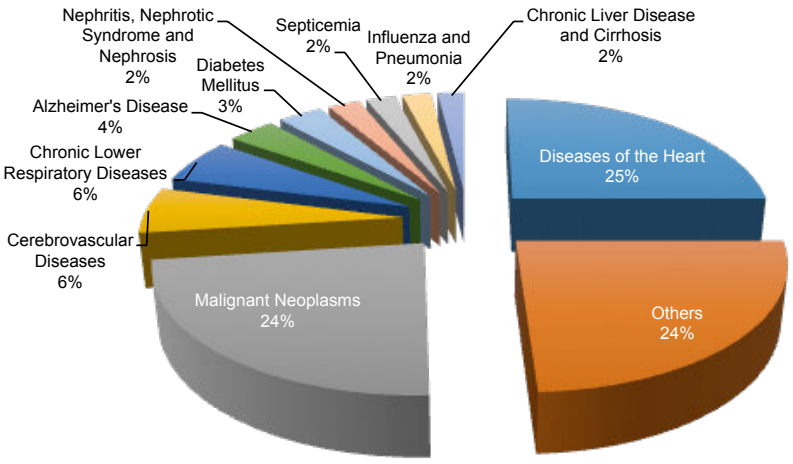

Figure 15: Top Diseases in Texas

The figure shows that Disease of the Heart and Cancers are the top two causes of death by illness in the United States as they add to over 50% of the deaths. The next contributors are much smaller because the following one on the list is the respiratory disease with only 8% of the deaths. Having identified the main causes of death, we now proceed to analyze by gender and then by ethnic group in order to identify possible trends or differences on the proportions.

Table 9: Causes of Mortality by Gender

Males		Diseases causing Death	Females	
0.164%	20,771	Diseases of the Heart	18,258	0.143%
0.137%	17,420	Others	20,508	0.161%
0.156%	19,716	Malignant Neoplasms	17,164	0.134%
0.031%	3,936	Cerebrovascular Diseases	5,406	0.042%
0.035%	4,418	Chronic Lower Respiratory Diseases	4,650	0.036%
0.013%	1,654	Alzheimer's Disease	3,714	0.029%
0.020%	2,586	Diabetes Mellitus	2,496	0.020%
0.014%	1,792	Nephritis, Nephrotic Syndrome and Nephrosis	1,837	0.014%
0.012%	1,581	Septicemia	1,805	0.014%
0.012%	1,535	Influenza and Pneumonia	1,712	0.013%
0.016%	1,996	Chronic Liver Disease and Cirrhosis	1,034	0.008%

The table shows that Cerebrovascular and Alzheimer's diseases have also a larger percentage in women than in men. The difference is more noticeable in the Alzheimer's disease because the number of deaths is more than twice as much.

Table 10: Proportions of Death by Group and Gender

Diseases Causing Death	White		Hispanic		Black		Others	
	Male	Female	Male	Female	Male	Female	Male	Female
Diseases of the Heart	0.250%	0.219%	0.075%	0.062%	0.172%	0.150%	0.069%	0.049%
Others	0.195%	0.238%	0.077%	0.081%	0.153%	0.162%	0.061%	0.059%
Malignant Neoplasms	0.235%	0.198%	0.072%	0.065%	0.165%	0.143%	0.075%	0.065%
Cerebrovascular Diseases	0.043%	0.063%	0.017%	0.019%	0.038%	0.047%	0.016%	0.018%
Chronic Lower Respiratory Diseases	0.064%	0.069%	0.009%	0.007%	0.023%	0.018%	0.009%	0.007%
Alzheimer's Disease	0.023%	0.050%	0.005%	0.010%	0.007%	0.018%	0.002%	0.006%
Diabetes Mellitus	0.024%	0.020%	0.017%	0.018%	0.026%	0.030%	0.009%	0.008%
Nephritis, Nephrotic Syndrome and Nephrosis	0.018%	0.017%	0.009%	0.010%	0.020%	0.022%	0.007%	0.006%
Septicemia	0.016%	0.018%	0.008%	0.009%	0.016%	0.019%	0.006%	0.006%
Influenza and Pneumonia	0.018%	0.020%	0.007%	0.007%	0.011%	0.011%	0.005%	0.005%
Chronic Liver Disease and Cirrhosis	0.018%	0.010%	0.016%	0.008%	0.009%	0.005%	0.005%	0.003%

Some interesting findings on the table 10 are that Hispanic men and women have higher diabetes and lower respiratory issues than white people; white and black women have an alarming rate of Alzheimer disease compared to the other minority groups; and diseases of the heart are predominantly higher for white people in proportion to the other ethnic groups.

CONCLUSION

In this paper, we started the conversation about the ethnicities' differences on the number of deaths by causes. It is our intent that future medical research can answer the above mentioned questions so that developing a health atlas, we can identify the unique cultural and habit practices of people for nourishment, exercise and how do they take care of themselves, so that those practices can be presented to the other groups as a way of reducing the ratios of death by those causes.

Common Omissions and Mistakes in Six Sigma Case Studies

Venkateswarlu Pulakanam
University of Canterbury, Christchurch, New Zealand
Email: venkat.pulakanam@canterbury.ac.nz

ABSTRACT

DMAIC (Define, Measure, Analyse, Improve and Control) problem solving methodology is central to Six Sigma programmes. Hundreds of Six Sigma case studies are being reported in many journals. However, very little in terms evaluating the methodology and its application is published in the literature. Many of the published Six Sigma case studies have several common omissions and mistakes in the application of DMAIC methodology. This research investigated these common pitfalls through an analysis of eight case studies published in different peer reviewed journals. The findings of this research are presented in this paper.

KEYWORDS: Six Sigma, DMAIC, Quality Management, Problem Solving

INTRODUCTION

Six Sigma quality improvement programme is currently widely used throughout the world in many organisation: services and manufacturing, private and public sector (Davis, 2018). DMAIC (Define, Measure, Analyse, Improve and Control) problem solving methodology is central to Six Sigma programmes. Hundreds of Six Sigma case studies are being reported in many journals (including professional and peer reviewed journals) and business management magazines. Almost all of these case studies report process improvements / savings through the application of this methodology.

Six Sigma started at Motorola, but was promoted by Jack Welch at General Electric. It is indeed making a difference to organisations that adopt the programme in a systematic and rigorous way. DMAIC methodology is a standard and rigorous method which consists of several prescriptive steps: Define, Measure, Analyse, Improve and Control. Within each step / phase, there are several sub-steps. Literature consists of numerous problem solving tools (the seven problem solving tools, control charts, design of experiments, etc.) that are applicable to each of the DMAIC steps. While the broader methodology is prescriptive, the selection of tools and the way they are used depends on the quality / process improvement problem that is being solved and the skill and knowledge of the problem solving team. Effective solution to the quality / process improvement problem requires good understanding of the methodology and knowledge of the problems solving tools. Obviously following the methodology correctly and using appropriate data collection and problem solving tools help to achieve desired results in shorter period.

However, in the experience of the author, many of the published six sigma case studies have several common omissions and mistakes in applying DMAIC methodology: some do not follow the methodology correctly; some use wrong problem solving tools; some fail to use relevant tools.

The consequence of these omissions and mistakes in following DMAIC methodology, data collection and the application of the problem solving tools are: failing to identify real root causes,

identifying wrong causes, missed opportunity to further improve / save, delays in solving the quality / process improvement problem and even Six Sigma project failure.
This research aims to study the common omissions and issues in the application of DMAIC methodology. Specifically this research aims to investigate the following**:**

- What DMAIC steps are problematic for the investigator and why?
- What problem solving tools often not used but should have been used? What tools commonly incorrectly used? What could be the potential reasons for this?
- Do these mistakes occur for certain type of quality / process improvement problems? For certain industries? Why?

It is hoped that through the findings of this research organisations and analysts will learn to avoid these pitfalls / mistakes when adopting DMAIC methodology for problem solving and process improvement.

LITERATURE REVIEW

DMAIC stands for Define, Measure, Analyse, Improve and Control. The purposes of the five DMAIC phases are:

Define : to define the problem
Measure : to identify performance measure(s) and establish a current baseline.
Analysis : to identify root causes of the problem
Improve : to implement solutions that address the root causes
Control : to evaluate the solutions and standardize the improved process for sustainable improvement

These five phases are sequentially applied when working on a six sigma quality / process improvement project. Although prescribed to be sequential, in practice these phases overlap. For example, some analysis is often done during measure phase and vice versa. The strength of DMAIC framework is that it guides the analyst to frame the problem and leads to a solution – a solution that is likely to be robust. Six Sigma literature provides several tools that are applicable to each of the DMAIC phases. These are shown in Table 1.
Six Sigma is generally used in two ways:

- As a Strategic approach to productivity and process improvements: Organisations that adapt Six Sigma as a strategy to achieve process and quality improvements throughout the company. These organisations implement tens or hundreds of six sigma projects all of which require DMAIC methodology. Motorola and General Electric are examples of such organisations which have taken this approach. De Maast & Lokkerbol (2012) call this as “project-by-project” approach.
- As a problem solving approach: Ad hoc application of DMAIC methodology for a one-off quality / process improvement problem. The DMAIC framework helps to guide the analyst from starting the problem to solving the problem.

Either way, DMAIC is the recommended approach to problem solving. DMAIC evolved from its predecessor “the seven-step problem solving methodology” which is a prescribed problem solving methodology for TQM (1990s to date) and Quality Circles (1980s) programmes.
Six Sigma projects use more sophisticated statistical tools than is the case with TQM / Quality Circle programmes (Pulakanam & Voges, 2010). The most common tools used with the seven-step problem solving method are: The seven tools of quality (flowchart, cause and effect diagram, etc.), DOE, etc. DMAIC methodology is considered as a far more rigorous approach along with recommendation of far more advanced and simple statistical tools. There are several reasons for this.

Table 1: DMAIC Methodology Steps and most commonly used tools (Ref. Gitlow & Levine, 2005 & De Maast and Lokkerbol, 2012)

DMAIC Steps	DMAIC Tools
Define: problem selection and benefit analysis D1. Make a business case for the project D2. Identify and map relevant processes D3. Identify stakeholders D4. Determine and prioritise customer needs and requirements	**Define Phase Tools** • Process mapping: SIPOC diagram; detailed flow chart (Swim Lane chart); Deployment chart; Workflow diagram (spaghetti chart) • Abstraction Tree (KJ or Affinity) Diagram • Critical-to-quality tree (CTQ) tree • Kano model • Quality function deployment • Stakeholder analysis
Measure: Translation of the problem into a measurable form and measurement of the current situation; refined definition of objectives M1. Select one or more CTQs M2. Determine operational definitions for CTQs and requirements M3. Validate measurement systems of the CTQs M4. Assess the current process capability M5. Define objectives	**Measure Phase Tools** • Histogram • Check sheet & Location plot • Run charts • Control charts • Process capability analysis • Measurement system analysis • Failure modes and Effects analysis • Customer segmentation • Data measurement scales • Basic statistics (Data exploration; graphing data; sample size; ..) • Data stratification
Analyse: identification of influence factors and causes that determine the CTQs' behavior A1. Identify potential influence factors (Xs) A2. Select the vital few influence factors	**Analysis Phase Tools** • Data stratification • Cause and Effect diagram • Scatter diagram and Regression analysis • Pareto chart • Histogram • Runs charts, Control charts • Five Whys • Control charts • ANOVA • Y to X tree diagram • Root cause analysis
Improve: design and implementation of adjustments to the process to improve the performance of the CTQs I1. Quantify relationships between Xs and CTQs I2. Design actions to modify the process or settings of influence factors in such a way that the CTQs are optimized I3. Conduct pilot test of improvement actions	**Improve Phase Tools** • Design of Experiments • Brainstorming • Risk assessment • Control charts • Lean Tools: SMED, Poka Yoke, etc.
Control: empirical verification of the project's results and adjustment of the process management and control system in order that improvements are sustainable C1. Determine the new process capability C2. Implement control plans	**Control Phase tools** • Control charts • Performance dashboards • Poka Yoke (Mistake proofing) • Auditing

Employee participation in TQM and Quality Circle programmes is voluntary. Rarely the project team members work full-time on a project. In most situations, employees are expected to work on quality/ process improvement projects, not a quality engineer or a specialist. TQM / Quality Circles training programmes tend to be short (a few days) and the training is often limited to simple tools such as the seven tools of quality. Advanced tools such as DOE are covered, but these are beyond the capabilities of the shop-floor employees. Use of software is relatively less in TQM / Quality circle programmes as the software programmes in 1980s and 1990s were not that advanced and employees tend be less savvy at using computers or specialist software. In TQM / Quality Circle programmes, there are no specific expectations in terms of the level of improvements to be achieved from a project.

In contrast, six sigma projects are expected to be led by trained Black belts who often work full time on the projects (Harry, 1998). The Black belt training typically is of four weeks duration and the completion of a project that requires the application of DMAIC methodology. The training programmes include advanced statistical techniques and the use of software such as MINITAB. MINITAB and other similar software have become more sophisticated so much so that it is almost impossible to apply DMAIC methodology without such software. Availability of such software obviously encourages the analysts to apply these tools. Each six sigma project may last several months and is expected to save at least $150,000 (Harry, 1998). Many more problem solving tools applicable to different phases of DMAIC methodology are now recommended. These include ANOVA, probability plots, etc. Along with sophistication, it has become complex too, as opposed to the seven-step problem solving approach. For this reason, dedicated resources are needed to work on six sigma projects.

Looking at the number of case studies published in journals and professional magazines, it appears to be popular as a problem solving tool. It is widely used in several industries, including in health, Information Technology organisations even when it is not used as a part of a six sigma programme. A CEO of a local SME likes the approach so much so that he has employed a six sigma coordinator and was putting through some of their employees through A DMAIC training programme that was offered in US.

Nevertheless DMAIC has some weaknesses along with its strengths. De Maast et al. (2012), using scientific problem solving theories, provide an evaluation of DMAIC as a problem solving methodology. They identified several strengths and weaknesses:

- It helps as a problem structure device.
- it is a powerful methodology with advanced statistical techniques, for ‘fact finding and empirical verification’
- it has tools for undertaking testing of hypotheses
- a single authoritative account of DMAIC methodology does not exist
- it is a too generic technique. (In order it to be effective it needs to be specific to industry with specific tools and templates).
- it is not suitable for ill-structured problems.
- It is not suitable for situations with fuzzy objectives.
- it has weaknesses in the areas of problem diagnosis and finding remedies.
- it is not suitable for smaller scope projects

De Koning and de Mast (2006) argue that “ …the descriptions of the steps that these phases are comprised of and the tools that are prescribed for them diverge.” They also comment that definitions of concepts such as CTQ are not precise. Cursory examination of some of the case applications confirms these assertions. Similarly Mandal (2012) argue that “…the manner in which the process improvement is achieved in many DMAIC studies is far from satisfactory.”

In summary, DMAIC methodology is an useful problem solving methodology which is widely used. However, far too frequently the methodology is poorly applied. This research, therefore, aims to evaluate the issues and the causes for unsatisfactory application of the method.

RESEARCH METHODOLOGY

The following methodology was used to undertake this research:

1. Review available DMAIC methodologies and select the one that is robust / widely used.
2. Select peer reviewed journals to select DMAIC application case studies
3. Select a sample Six Sigma case studies that used DMAIC methodology.
4. Deconstruct and analyse the case studies by examining to what extent the standard DMAIC steps have been used correctly.
5. Summarise the findings

The above steps are elaborated further below:

DMAIC methodology and Steps: While there is no disagreement in the sequential application of the five DMAIC phases, there are considerable inconsistencies in the steps and their interpretation within each of these phases. De Koning and de Mast (2006) reviewed the recommended DMAIC steps from 20 sources and came up with their recommendations for DMAIC steps. Gitlow and Levine (2005) provided DMAIC phase steps and demonstrated how to apply these steps with an elaborate but fictitious example that cover all the recommended steps. There is lot more consistency between de Koning and de Mast (2006) and Gitlow and Levine (2005). We used these two references to come up with a set of standard DMAIC steps (Table 1) that we have used to evaluate the case studies.

It is important to clarify that the focus of our research is on the application of the DMAIC methodology. We are less concerned in the order these steps have been implemented in the case studies although we will be making observations on this as well. For example, CTQ is recommended in Define phase and in other cases in Measure phase. For the purpose of this research we will be focusing on whether CTQ was defined or not and not in which phase this was done.

Journal selection: In selecting case studies our initial goal was to include as many different journals as possible.

The journal selection was limited to rank order operations and quality management (including Six Sigma quality) journals listed in Australian Business Deans Council (ABDC) Master Journal list (http://www.abdc.edu.au/master-journal-list.php). Unfortunately, the top raked journals in this list did not have any six sigma case studies. Most of the journals selected were C rank journals. We then decided to select eight case studies form these selected journals. These case studies provided enough data to comment on the underlying issues. The sample is a convenient sample. We have not used any scientific approach to selecting journals or to determine the sample size as our focus at this stage is to assess the nature and extent of the problem rather proving any hypotheses. The selected case studies are shown in Table 2.

FINDINGS

The findings of our case analysis are presented below and a summary of the findings are given in Table 3.

Define Phase

Define phase defines the problem. It consists of:

1. Problem statement and issues and project objectives
2. An explanation of why the project worth considering
3. Process map and SIPOC diagram
4. Identifying customers and their needs VOC Analysis

All cases described the problem and project objectives fairly well. The differences in the level of details are due to the differences in the authors' writing skills and abilities and the requirements of the journal publishers.

Most cases provided an explanation of why the project is worth considering. Cost savings have been the most common reason provided. Just one case argued that the improvement project helps with meeting customer needs.

According to Six Sigma literature, the Six Sigma project goals ideally should be SMART (Specific, Measurable, Achievable, Relevant, Time limited) and the improvements need to be breakthrough improvements (See for example, Gitlow and Levine, 2005). According Harry (1998) an average Black Belt project will save a company $175,000. This makes sense if the project involves some of the team members (like Black Belts) working full time on the project. Besides six sigma training is not cheap! At the same time, it is to be noted that the DMAIC

methodology itself is applicable to almost all projects – weather it is a trivial project or a project that has the potential for savings hundreds of thousands of dollars.
Most cases describe the business cases for implementing a six sigma project only in general qualitative terms and do not provide in quantitative measures. In some cases they have provided the benefits at the end of the case in Control phase. The analysis of the cases does not provide any indication that breakthrough achievements have been made. However, they do demonstrate that the application of DMAIC methodology (rigorously or not) leads to some improvements if not breakthrough improvements.
Almost all cases provided a flowchart of the process and a SIPOC diagram. SIPOC is an appealing diagram, but it is not clear how it was used in the case. SIPOC diagram "helps to define a complex project that may not be well scoped, and is typically employed at the Measure phase of the Six Sigma DMAIC methodology" (iSixsigma). From this point of view, it is worth drawing a SIPOC diagram. However, there is less consistency in the way it is drawn. It may be worthwhile to provide a guide to draw SIPOC diagram to fully utilize its potential?
Six Sigma methodology recommends VOC (Voice of Customer) analysis. According to Gitlow and Levine (2005) this includes, customer segmentation, active and passive data collection and even Kano analysis (Gitlow and Levine, 2005). However, just only one case briefly did customer segmentation, but not followed through in the case analysis. None of the cases undertook Kano analysis. One reason for not undertaking Kano analysis is that most cases considered just one CTQ which is a "must be" otherwise they would not have considered.

Measure: The goal of the measurement phase is to clearly state a performance measure and establish a current baseline. It consists of:

1. Selecting and defining CTQs
2. Validating measurement system of the CTQs
3. Assessing baseline process capability
4. Defining project goals

The CTQs identified, the tools used along with the researcher's comments are provided in Table 4.

Table 3. A summary of case analysis

Phase	Step	What is practiced	Comments
Define	D1. Business case D2. Process mapping D3. Identify stakeholders D4. Determine and prioritise customer needs and requirements	Most cases describe the business case for implementing a six sigma project in qualitative terms, but do not use quantitative measures. Cases that did contain a description of the current process were well defined. Only one of the cases failed to provide any description of the current process.	Why most do not report benefits in measurable terms? Is it difficult to do this for some projects? For what type of projects would that be? Or do they find this an unnecessary step which is not essential to make improvements? Hence is this step necessary? It may be that problem can be solved without a quantitative measure! De we need SIPOC? How is this used?
Measure	M1. Select CTQ M2. Define CTQ M3.validate measurement system M4. Assess current process capability M5. Define objectives	Very few identified CTQ; Only a small number of cases identified what constituted a defect, In some cases the CTQ was poorly defined (For example: “not having too much operating noise”) In many cases there was no description of what is being measured. Most cases skipped validating the CTQ measurement system entirely. Cases with well-defined CTQs are usually the cases that also follow through with well-described baseline measurements. Five out of the eight cases included baseline measurements: A range of measures are used to measure current capacities: Histograms and C_p/C_{pk} and process sigma levels Many cases fail to provide a project goal, or if they do, the goals are often not SMART (I.e., the goal is simply improving X instead of improving X characteristic by a certain percentage within a specified time period).	Is CTQ difficult to define? Poor definition of CTQ is an indicator of poor application of DMAIC which further lead poor improvement results? Is this step difficult? Is it necessary? How critical is this step? Why is this step not done? Dependency on software? Why some case studies have not provided any baseline measurements? Can improvements be achieved without completing this step? What baseline measurements are best? Why have a goal? Isn’t it artificial? Can the problem not be solved without having a goal?

Analyse	A1. Identify potential Xs A2. Select the vital few Xs	Most cases poorly identified / described what the Xs. This has further contributed to the difficulty of measuring Xs. Cases with a very short analyse section were usually preceded by poorly defined define and measure sections.	Why? Perhaps Analysis (i.e. identifying potential influence factors) starts from almost 'Define' phase and continues till Control phase. That is identifying influence factors happens right from the start of the project as there is heightened awareness of the problem. As the saying goes "a problem clearly stated is a problem half solved."
Improve	I1. Quantify relationships between Xs and CTQs I2. Design actions to modify the process or settings of influence factors in such a way that the CTQs are optimized I3. Conduct pilot test of improvement actions	Improve phase was very short for all cases. Cases with a detailed analyse phase didn't necessarily need a detailed improve phase as the information could be viewed as repeating itself. Only two cases adequately described the Xs, with only a single case actually describing the different levels of each X available. Four out of the eight cases didn't describe how the Xs were discovered, nor how the optimal settings were chosen. Many cases only describe a single tool used to arrive at the optimal settings for each X.	How Xs were discovered and chosen seems to be an issue. No specific tools have been described to finding the solution.
Control	C1. Determine the new process capability C2. Implement control plans	Overall most cases presented a good description of the control phase. The cases with the best control phases were consistent with those cases with an effective Analyse/Improve Phase. However, with some categories information needs to be assumed by reading into the case. Some cases did not present any information regarding the level of process improvements.	Again Maast may have provided a good explanation why control phase was general well done

Table 4. Measure Phase: Case study CTQs and tools used to measure baseline capability

	CTQ	Analysis and tools used for baseline capability	Comments
Case 1	Processing time	Histogram	SPC charts would be useful
Case 2	Thickness of Toffee	X-MR chart; Histogram; C_p / C_{pk}	X-MR charts are OK; but Xbar & R charts are more appropriate
Case 3	The ratio of first call resolution	p-chart	
Case 4	Patient Waiting time	Histogram; % not meeting target	SPC charts would be useful
Case 5	Operating noise of car seats (distance between right and left seat frames)	Histogram; C_p	SPC charts would be useful
Case 6	Quantity dispatched; Quantity delayed	Process sigma	SPC charts would be useful
Case 7	Medicine buying time	X-MR chart; C_p	OK; Histogram would be useful too
Case 8	Defective casting / crack propagation in parts (casting density)	Xbar charts; C_p / C_{pk}	Correct type of charts but indicates potential error is the use of the charts

Very few clearly identified and defined CTQs. In many cases it is not clear what is being measured. Because of this it is not clear how the CTQ is measured. For example, how one measures the thickness of a soft toffee? If CTQ is not well defined, then it is difficult to determine what constitutes a "defect". Given accurately defining CTQ is critical to problem solving, it is important to understand why analysts avoid defining or incorrectly define CTQ.
Only two out of the eight cases validated the measurement system. Why?
Five out of the eight cases included baseline performance measurements. Cases with well-defined CTQs are usually the cases that also follow through with well-described baseline measurements. A range of measures were used to measure current capacities: Cp / Cpk and process sigma levels.
Many cases fail to provide a project goal, or if they did, the goals were often not SMART. That is, the goal stated was simply improving X instead of improving X by a certain percentage within a specified time period.
The tools used and type of analysis carried out to measure baseline capability are shown in Table 4. Most cases used histograms (for measurable CTQs) and process capability indices. Some used control charts. Control charts are applicable for almost all of the eight cases, but only three out of the eight cases used control charts! Why? Histograms are useful to understand the process mean and variability, but are inadequate as a tool for process improvement. Linderman et al. (2003) argues that having project goals helps to alter the behavior of organized members and their perceptions about how much change is possible. Eckes (2001) suggests a rule of thumb of reducing the problem of 50% within 120 to 60 day period! In our research only three out of the eight cases set a measurable project goal. Did this help? Did it hinder for the other cases by not setting any project goals? It is not clear.

Analyse Phase: The goal of the Analyse phase is to identify root causes (the Xs). The steps involved are:

1. Identify potential Xs
2. Select vital few Xs.

The following are the finding of the analysis of the Analyse phase:
Three of the eight cases involve reducing time – time to resolve customer enquiry; time taken by the patients to buy medicine and patient waiting time. All these cases rightly identified the component times that adds to the total time (i.e. $Y = Y_1 + Y_2 + \ldots + Y_n$). They then identified the few process steps that significantly contribute to the overall time and attempted to improve these few process steps.
In three cases the original Y (i.e. the CTQ) is different from the final Y that was studied (Table 5). In these cases the original Y is the language of the customer ("too much noise" or "defective casting"). In these three cases the analysts rightly studied the technical causes of the original Y (distance between right and left seat frame, or density of the casting).

Table 5. Analyse phase: Original Y vs root cause Y

Initial Y	**The final Y**
Thickness of sweets	Bubbles in the sweet, which contributes to the thickness of sweets
Car seat operating noise is one of the major contributing factor	Variation in distance between right and left seat frames contributes to car seat operating noise.
Defective casting / crack propagation	Casting density

Most case studies failed to explain how the root causes (well defined or not) were identified and how they have been screened. That is, it is not clear what tools were used to identify the root causes and to select the vital few. Also, many of these cases poorly described the root causes (the Xs) that are being measured.
Brainstorming exercise and Cause and Effect diagrams are the most commonly used methods to identify potential Xs. In one case control chart analysis helped to identify the potential Xs. In our opinion, if the analysts used control charts to assess baseline process capability, they would have found the control charts helpful to identify some of the root causes.
In many cases it is not clear how Xs were shortlisted. Commonly reducing the pool of Xs was done in consultation with team members. Other methods used were: trial and error experiments, multi-voting techniques and FMEA.
In most cases that we studied, the Xs were often inadequate process steps: inadequate maintenance, addition of new step, etc.
Cases with a very short analyse section were usually preceded by poorly defined 'define' and 'measure' phases. The cases that did have detailed Analyse phase with relevant information were usually those that had well defined Define and Measure phases.

Improvement Phase: The goal of the Improve phase is to implement solutions that address the root causes. The improvement steps are:

1. Study relationships between Xs and Y
2. Identify improvement solutions / determine optimal Xs
3. Conduct pilot tests

The following are the findings of the analysis of Improvement phase:

Is X related to Y? This is answered by collecting data. But, establishing relationship (an equation) is difficult in most cases. This was possible when DOE type of experiment was done. Half of the cases didn't describe how the Xs were discovered, and how the optimal settings were chosen. Most cases described just one single tool to arrive at the optimal settings for each X.
In most cases improvements were identified through process flowcharting, "walking" the process and observing the process in action.
Improvements are typically process streamlining (adding / improving a process step), improved maintenance including a measurement system, etc. Such improvements in process steps helped to reduce variation in Y. Many used lean tools: 5S and VSM to make improvements.
Identifying optimal Xs (like optimal production temperature) require trial and error experimentation or design of experiments.
Pilot studies are not undertaken by all case studies. Such studies perhaps are not necessary when improvements are obvious. One case undertook confirmation capability study to assess the true improvements. When one needs a pilot study?
Improve phase was very short for all cases. Cases with a detailed analyse phase didn't necessarily need a detailed improve phase as the information could be viewed as repeating itself.

Control Phase: The goal of the Control phase is to empirically evaluate the solutions, assess if the project goals have been met and standardize the improved process for sustainable improvement. The specific steps are:

1. Determining new process capability
2. Implementing control plans

The key findings of the analysis of this phase are:
Overall most cases presented a good description of the control phase. The cases with the best control phases were consistent with those cases with an effective Analyse and Improve Phases

SUMMARY AND CONCLUSIONS

Six Sigma is a worldwide phenomenon with only a fraction of the actual applications being reported in journals. However, very little in terms evaluating the methodology and its application is published in the literature. In this sense the findings of this research would be most useful to industry. It will add to the Six Sigma literature.
The analysis of the eight cases indicated that the use of DMAIC methodology as a problem solving methodology has been beneficial for organisations, although the improvements are not breakthrough improvements as is promoted by the Six Sigma promoters.
The DMAIC methodology was decidedly poorly applied by the analysts. More research needs to be done to investigate how extensive these findings are. The author thinks that lack of expertise and experience of the analysts may be the main reason for the unsatisfactory application of DMAIC methodology although this need to be further investigated.
There are several limitations in this research, the primary being the sample design: small sample size and the use of convenient sample. Also, the findings are based on what is presented in the case studies. The authors of the case studies most likely have done lot more than what is presented in the case studies. These limitations make it difficult to generalize the research findings. Future research will need to consider these limitations.

ABSTRACT

Community based care coordination is an important strategy for reducing preventable hospital readmissions among the elderly. The purpose of this paper is to discuss the design, development and implementation of an elder care learning community platform aimed at coordinating care and communication between patients, patients' families and caregivers and health care providers. This paper highlights the importance of utilizing design thinking as a strategy for solving complex medical and public health problems and demonstrates how the balanced scorecard model can be used as a foundation for this learning community.

KEYWORDS: Care coordination, elder-care, design thinking, balanced scorecard

INTRODUCTION

According to the Centers for Medicare & Medicaid Services (CMS), national healthcare spending is projected to increase at an average rate of 5.5 percent between 2017 and 2026 and is estimated to reach $5.7 trillion by 2021. The health share of the GDP is estimated to increase from 17.9 percent in 2016 to 19.7 percent by 2026 (CMS, 2018). Reducing preventable hospital readmissions is one strategy that has taken national priority for payers, providers and policymakers to improve quality and health care spending. In 2012, the CMS began to reduce the Medicare payments for certain hospitals that had excessive 30-day readmissions for patients with conditions such as heart attacks, heart failure, pneumonia, chronic obstructive pulmonary disease (COPD), hip or knew replacement and coronary artery graft (CABG) surgery through its Hospital Readmission Reduction Program. In order to lower the rate of readmission, many hospitals have focused on improving the coordination of care and communication between providers and patients and their caregivers, improving discharge planning and education in addition to the use of electronic medical records to improve continuity of care (AHRQ, 2018). In 2013, the national readmission rate fell to 17.5 percent after holding steady at 19-19.5 percent for many years (AHA, 2018) however, the majority of these readmissions are of elderly patients. Hospital readmission among the elderly is a multifaceted and complex issue;

strategies for reducing hospital readmission in elderly patients include comprehensive, multidisciplinary approaches such as patient needs assessment, medication reconciliation, timey outpatient appointments and patient education (Kripalani, Theobald, Anctil & Vasilevskis, 2014).

Care of the elderly is a multi-faceted and multi-organizational service. Some common challenges that are often discussed when dealing with care for the elderly are related to the access, quality, and cost of care. Further, the therapeutic, policy, technological, financial, ethical, and moral issues involved require continuous learning by all the care providers, specifically to help them navigate the interactions between these issues. As such, there is an important need to coordinate and synthesize the fragmented efforts of the many providers and organizations who serve this population. It takes a community of learners to care for a community of the elderly. Florida has the highest proportion of the population age 65 and older (19.4 percent in 2015). Within Florida, some counties have more than 50% of the population age 65 and older as of 2015 (i.e. Sumter, FL.). Meeting the current challenges of elder-care in Florida will provide effective guidelines for managing the challenge at a national level.

The purpose of this paper is to discuss the design and development of a sustainable online learning community for elder-care service providers in Palm Beach County, Florida, to facilitate knowledge sharing, communication, collaboration and coordination of care among providers. This paper contributes to the literature by applying the balanced scorecard design for the online learning community platform as the underlying foundation for care coordination. This paper also provides practical contributions because by addressing the issues facing elder care in Florida, we provide guidelines for implementing similar platforms for elder-care at a national level. In this paper we will begin with a discussion of community-based care and the incorporation of the balanced scorecard framework into the learning community. Then we will provide an overview of the design and build process of the learning community, with a focus on design thinking and provide an overview of the system architecture and components. In the final section, we will discuss the implementation of the learning community and review community efforts along with key outcome measures that will be considered during the implementation phase. We conclude with a discussion of next steps and provide a brief agenda for future research.

LITERATURE REVIEW

Community based care and care coordination

As of 2015, there were 47.8 million adults age 65 and older in the US, which accounted for 14.9 percent of the total population. This population grew 1.6 million from 2014 and is projected to grow exponentially by 105.2 percent between 2015 and 2060 (US Census Bureau, 2018). While the population continues to age, health care providers are tasked with the need to serve more patients while also trying to reduce costs. The central goal of care coordination is to meet the needs of patients and to deliver high quality, high value care by bridging the gaps along the care pathway (AHRQ, 2018).The Agency for Healthcare Research and Quality (AHRQ) of the US Department of Health and Human Services defines care coordination (CC) as "*the deliberate organization of patient care activities between two or more participants (including the patient) involved in a patient's care to facilitate the appropriate delivery of health care services. Organizing care involves the marshalling of personnel and other resources needed to carry out all required patient care activities and is often managed by the exchange of information among participants responsible for different aspects of care."* (AHRQ, 2018).

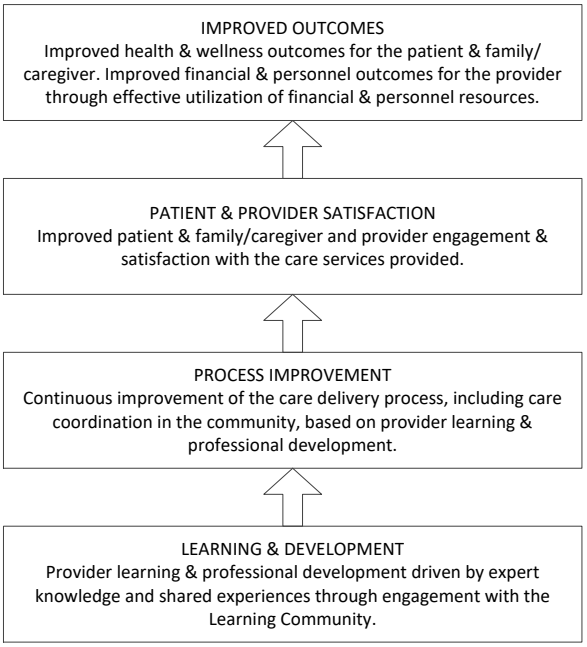
The typical care coordination system focuses on the patient, their health care providers, and their family/friends or designated caregiver while sometimes ignoring the auxiliary services such as social workers and community support that may be available after hospital discharge. Community based care coordination incorporates the services that are provided by non-clinical community organizations which help to supplement clinically oriented care coordination. This care coordination can be provided at different stages of a patient's disease progression or medical condition and has been classified into different stages based on the occurrence or impact of the disease or medical condition. These stages include: acute condition, chronic condition and wellness condition (Dehen et al., 2010). Care coordination can be understood from a system perspective which examines the tasks and processes which are required for coordination of care, a healthcare professional perspective which accounts for the various health care providers and a patient/family perspective which keeps the patient central to the care coordination system. When incorporated with the community perspective which integrates the health and social support networks, this model of care takes a holistic, patient centered approach which is aligned with the Institute of Healthcare Improvement's (2007) Triple Aim framework which emphasizes the need to improve the patient care experience, improve the health of the population and reduce per capita health care costs (Lewis, 2014).

Balanced scorecard

Leaders in healthcare have started to use the balanced scorecard model (Kaplan & Norton, 1990) as a framework for performance measurement and strategic planning in healthcare organizations and the health services sector (Voelker, Rakich & French, 2010). The principle behind the balanced scorecard is that top management should have a balanced set of measures that reveals the interdependency of the critical aspects of the organization. This balanced perspective is then used by top management when designing and implementing strategic decisions in the organization. The balanced scorecard has four perspectives from which they can choose measures and complements traditional financial indicators with measures of performance for customers, internal processes and innovation and learning activities (Kaplan & Norton, 1996). In healthcare the scorecard needs to reflect three categories of interdependent value: the business, employee and patient value and this balance is achieved by considering measures from the patient, internal, learning and financial perspectives (Castañeda-Méndez, Mangan & Lavery, 1998).

Figure 1 illustrates our proposed use of the balanced scorecard model for community-based care and care coordination. Through engagement with the learning community, providers and professionals are able to learn from expert knowledge and shared experiences to facilitate provider learning and professional development. This leads to continuous process improvement of the care delivery process which includes care coordination in the community. As processes are improved, there is subsequent improvement in the engagement between the patient and family/caregiver with the provider and increased satisfaction with the care services that are provided. This ultimately results in improved health and wellness outcomes for the patient and family/caregiver. These improved outcomes are realized through financial and personnel measures for the provider through effective utilization of financial and personnel resources.

Figure 1: Overall Balanced Score Card for the Learning Community



We focus primarily on the outputs and outcomes of the Learning & Development segment of the learning community balanced score card, as that is the primary focus of the proposed care coordination project. The project outputs will be measured in four participation categories: (1) membership; (2) online activity; (3) event activity and (4) engagement. *Membership* will be measured by the number of new members who join the learning community. *Online activity* will be measured by several measures: number of unique participants utilizing the online community, number of unique visits to the online resources/webinars, number of unique contributions or new resources to the online community, number of unique responses to posts by other participants and number of webinars developed. *Event activity* will be measured by the number of participant sponsored small events or site visits and the number of learning community members who participate in large or small events. Finally, *engagement* will be measured by the number of volunteers engaged in the day-to-day operation of the learning community and the tenure of the volunteers involved.

Project outcomes will be evaluated along several key dimensions: (1) network development; (2) technical satisfaction; (3) functional satisfaction; (4) knowledge growth; and (5) efficacy. *Network development* is defined as the growth of the professional network due to participation in the learning community (both quantitatively and in the variety of professional contacts). *Technical satisfaction* is defined as the learning community member satisfaction with system use (e.g. access, ease of use). *Functional satisfaction* is defined as the learning community member satisfaction with learning outcomes. *Knowledge growth* is defined as new topics learned and new resources identified. *Efficacy* will be defined as the improved patient outcomes as a result of learning community participation, contribution to success of others in the learning community and active collaboration in a collective approach to care delivery based on case-based evidence.

Design and build

Design thinking is a human-centered approach to innovation that integrates the needs of people, the possibilities of technology, and the requirements for organizational success. Design is driven by the idea that different perspectives should be analyzed, considered and synthesized to offer solutions to indeterminate problems and has the potential to envision alternative futures for health care (Valentine et al., 2017). Design thinking for social innovation is a collaborative approach that involves everyone rather than just the designer to collectively come together to analyze their usefulness and connections to a given question and collaborate both internally with colleagues and externally with partners (Valentine et al., 2017). This innovative approach to health care encourages the embrace of creative mechanisms of knowledge integration to deliver solutions to complex problems rather than relying solely on a linear approach to problem solving such as the traditional evidence-based practice (EBP) paradigm (Valentine et al., 2017). One such method has been Experience-based co-design (EBCD) which is a participatory co-design method used to improve healthcare practices that integrates the experiences of staff, patients and caregivers to improve health care process. Donetto, Tsianakas and Robert (2014) reviewed a variety of clinical projects however the empirical publications have been limited to support the recommendations developed from design thinking in health care and there has been little formal or systematic evaluation of EBCD projects.

As discussed previously, the primary objective of this online community platform is to facilitate learning and improve the coordination of care for the elderly in the county. This overall model was accomplished by adopting a design thinking approach and through a collaborative process involving appropriate community partners that included clinical, medical, para-medical, social and auxiliary services providers. The direct involvement of elder care service providers in the county, is shown on Figure 2. The elements involved in the design thinking approach included large gatherings in the form of regional conference sand local professional meetings; small gatherings through workshops, classroom trainings, site visits and volunteers in the community; and virtual gatherings through a web presence, social media, a newsletter, webinars and conference calls.

The resulting design was the basis for the development of an online learning community platform that facilitates elder-care coordination in the county. The overall learning system architecture is shown in Figure 3. The key system components include local conversations, announcing events, presenting and sharing webinars on topics of interest to the community of providers, a newsletter to keep the community of providers informed, and established outcomes-oriented tools that community providers can use to improve their services. Specific sub-topics of conversation that were relevant to elder-care in Palm Beach County were identified through the design study.

Figure 2: Elements of the Designed Thinking approach to the learning community

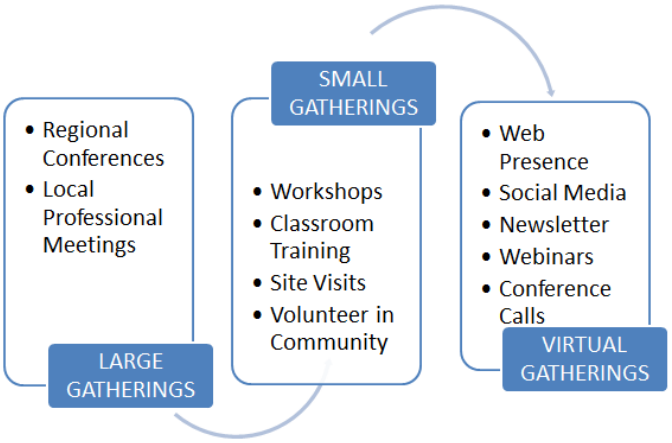


Figure 3: Learning Community System Architecture

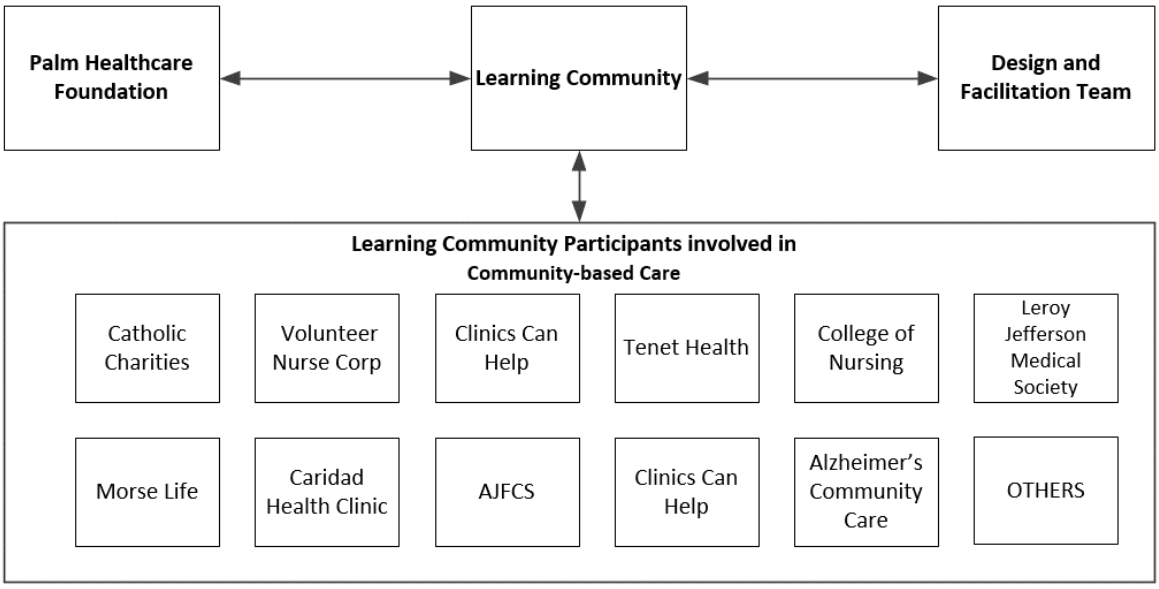
Implementation and community efforts

The Elder-Care Learning Community platform is a system managed by a community of clinical, medical, para-medical, social and auxiliary services providers and the primary purpose of this community platform is to facilitate learning to improve the coordination of care for the elderly in the county, thus implementation involved community efforts. This would be accomplished by developing and implementing a learning community that has both in-person and on-line components. Initial management of the learning community was co-developed with community members to establish a sustainable learning community to support their learning and service efforts. Key system components include: Local Conversations, Events, Webinars, Newsletters, and Tools. At the time of this article, implementation of all components, excluding Tools, are completed. The project structure is shown below in Figure 4. The learning community is supported by the Palm Healthcare Foundation and the authors facilitated the design and implementation of the platform. Some of the participants involved in the community-based care

included: Catholic charities, Morse Life, Volunteer Nurse Corp, Caridad Health Clinic, Clinics Can Help, Alpert Jewish Family and Children's Service (AJFCS), Tenet Help, College of Nursing, Alzheimer's Community Care, Leroy Jefferson Medical Society.

The platform facilitates virtual gatherings, based on which the Learning Community can continue to mature. The system also facilitates the large and small gatherings, which inherently have to be delivered by the Learning Community members themselves. Through these efforts, authors will help the Learning Community reach a level of operational sustainability. The execution of these real and virtual gatherings, and the continued and increasing participation of Learning Community members, will signify the value it provides to elder care service providers through operational, tactical, and strategic information and knowledge that will help care delivery in a rapidly changing healthcare environment.

Figure 4: Project Structure



DISCUSSION AND CONCLUSION

This paper highlights the importance of utilizing design thinking as a strategy for solving complex medical and public health problems and demonstrates how this approach was used to develop a learning community to improve coordination of care for elderly patients in the county. Design thinking has been used and implemented in a variety of healthcare organizations in the last decade around the world, however this field is still in its infancy.

Technically, the system is designed based on the MVC (Model View Controller) architecture on a LAMP Stack using Zend Framework. The Model manages fundamental behaviors and data of the system, the View provides User-Interface element of the application and renders the data from model into a suitable user interface form. The Controller interfaces between user inputs, models and views by making a call to model and view and performing an action. The system is divided into separate modules for all necessary components to implement the various eco-system related activities through components that included discussion groups, newsletters,

webinars, events, tools and permissions. These components are being developed to facilitate learning across members of the learning community. This system was designed with a Role Based Access Control mechanism, where each user is assigned a role and that role is allowed to access various modules. The roles implemented in this application are Super Admin, Admin, Group Coordinator, Newsletters Coordinator, Webinars Coordinator, Events Coordinator, Tools Category Coordinator and Members. These roles were designed so that a small team of volunteers could eventually manage this system with little assistance, thereby driving the adoption and sustainability of the effort.

At this stage, a cloud-based platform has been developed and tested. The main aim of this online community platform is to facilitate learning to improve the coordination of care for the elderly in the county. The key system components include local conversations, announcing events, presenting and sharing webinars on topics of interest to the community of providers, a newsletter to keep the community of providers informed, and established outcomes-oriented tools that community providers can use to improve their services. Specific sub-topics of conversation that were relevant to elder-care in Palm Beach County were identified through the design study. These detailed conversations related to typical cases are being uploaded into the system to provide initial community relevant information before a soft launch of the system later in 2018. In addition, the authors are working with a broader healthcare coalition in the county that will eventually pilot the platform of specific projects involving specific areas of readmission risk for the elderly.

Future work specific to this study is to collaborate with the core team of community volunteers and work to reduce avoidable hospital readmissions among the elderly. The system developed in this study will be the platform on which such efforts will be developed.

ABSTRACT

AACSB (2016) mandated that analytics be integrated into the undergraduate business curriculum. Given that concrete statistical knowledge is necessary to comprehend and learn the discipline of analytics, this paper focuses on selecting data analysis tools that enhance the learning of introductory business statistics in the modern world of big data.

KEYWORDS: Business Statistics, Data Analysis Tools, Excel, R, and R-Deducer

INTRODUCTION

In 2016, AACSB Standard 9 has mandated that analytics be integrated into the undergraduate curriculum. Since a 120-credit curriculum is currently typical across programs, there has been talk at some institutions of subsuming the business statistics course as part of an analytics course. However, there is ample research indicating data-driven decision-making (DDD) is typically superior to intuitive decision making (Brynjolfsson & McElheran, 2016; McElheran & Brynjolfsson, 2016) and that a statistical foundation is necessary to understand advanced analytics concepts (e.g., Logistic Regression). Thus, we contend that strengthening the introductory statistics course will help students to be better prepared for future undergraduate and graduate analytics courses. We believe that students ready to take an analytics course must have a solid foundation in fundamental descriptive methods, a basic understanding of risk and inference, and an introduction to predictive modeling. Therefore, in this study, we re-engineer an introductory business statistics course and explore two data analysis tools to assist in delivering the course content to our students. We choose *Excel*, which is freely available as part of Microsoft Office 365 to all students providing their school e-mail address, and *R-Deducer, which is also freely available to all users*.

LITERATURE REVIEW

In a re-engineering of a modern-day core-required introductory business statistics course, three key pedagogical issues must be addressed:

1. What should be taught? – 2. Why it should be taught? – 3. How it should be taught?

The first and second questions above are reflected in course learning goals while the last question focuses on mode of course delivery. One of the primary goals of instructors is to design an appealing course so that students can be motivated and engaged to learn more about topics. The challenge, however, faced by educators in all disciplines throughout our colleges

and universities is how to achieve this when dealing with current Generation Z student audiences (Bernstein, 2015) who, although clearly more technologically capable than all predecessor student groupings, are often less quantitatively prepared and have seemingly less interest in textbook reading.

With respect to business statistics, Berenson *et al.* (2018) opined that offering discipline-specific introductory business statistics courses (e.g., statistics for marketing) would increase motivation for learning because the course topics and applications would be in career interest to that student audience. Although this appears to be true, the broader question needs to address the teaching of a more traditional statistics course, particularly if it becomes prerequisite to a required course in business analytics. The six key recommendations of the GAISE (Guidelines for Assessment and Instruction in Statistics Education) College Report (Carver *et al*. (2016)) sponsored by the American Statistical Association displayed in Table 1 must be considered when re-engineering a statics course.

Table 1: Six Recommendations of GAISE College Report to Enhance Pedagogical Delivery

***What* to Teach:**
1 – Teach Statistical Thinking
2 – Focus on Conceptual Understanding
***How* to Teach:**
3 – Integrate Real Data with a Context and a Purpose
4 – Foster Active Learning
5 – Use Technology to Explore Concepts and Analyze Data
6 – Use Assessments to Improve and Evaluate Student Learning

The report emphasizes the pedagogical importance of topic and application relevancy in an increasingly data-centered world. In the learning paradigm to be discussed here, not only must topic and applications be relevant, student audience must perceive them as so. With respect to what to teach, the GAISE College Report's focus is on students' understanding that the subject of statistics is a problem-solving process essential for decision making (Recommendation 1) and on students' realizing that many questions require explorations of multidimensional relationships (Recommendation 2). With respect to how to teach, the GAISE College Report's focus on the use of real data with a context and purpose (Recommendation 3) lends itself to classroom projects employing structured data sets that can be used to demonstrate the integration of topics covered throughout the course (Gould, 2010). Active learning (Recommendation 4) can be promoted individually, or in teams, if students can carefully study their data sets and develop the questions they want to address. Assessments for improving and evaluating student learning (Recommendation 6) could be based on written project reports and oral presentations as well as in exam questions that require the students to articulate their key findings. To re-engineer the business statistics course based on our interpretation of the GAISE College Report guidelines, we contend that all the above recommendations relate to its focus on Recommendation 5 – the use of technology to explore concepts and analyze data (Chance *et al.,* 2007). Therefore, the selection of the appropriate data analysis software for such a course will be essential.

THEORETICAL DEVELOPMENT

Any re-engineered introductory business statistics course must first satisfy broader B-school curriculum goals and serve as a prerequisite to learning in the functional areas disciplines. Given the new Standard 9 AASCB (2016) mandate, a redesigned statistics course should also explore the potential for a more seamless transition to a follow-up course or courses in business analytics. An undergraduate business statistics course should provide students opportunities to extract knowledge from data and unveil meaningful association among the variables. After successfully finishing an introductory business statistics course, students should be able to analyze datasets with multiple variables without explicit instructions.

Starting the course with a "prerequisite preparation" that covers basic algebra and fundamental mathematical concepts for business (i.e., indices, ratios, and percentage changes) will help align students with varied mathematical backgrounds and quantitative skillsets. The course then begins with an overview of statistics and stresses the importance of statistical applications in business and business analytics. A paradigm for problem-solving (Levine & Stephan, 2011) that aims at developing statistical thinking and reasoning is then presented and key terms that will be used throughout the course are explained. Learning statistics is in many ways like learning a language. There is an evolving vocabulary that students must develop and continue to use throughout the course. Moreover, in a project-oriented course as proposed here, the structured data set becomes the integrated, unifying course theme, enabling students to expand their knowledge and their overall comprehension as the course topics flow from description to inference to modeling. The selected computational software tools are, of course, integrated into all topics. We opine that such an approach should enhance student learning because they will have the opportunity to develop the parts of a study into a whole project. Business statistics should never be taught as a set of disjoint topics.

Table 2 (on the following page) presents a list of methods covered in a re-engineered project-oriented business statistics course. To compare the *Excel* and *R-Deducer*, we used these tools and conducted analyses for the methods given in Table 2.

Assessing *Microsoft Excel* and *R-Deducer* in Terms of Cost, Platform Capability, and Availability

In general, before deciding to select what data analysis tool to use, three initial issues must be addressed:

1. What will be the cost of the tool?
2. Will it have the capability to equally support both Windows and Mac student users?
3. What is the likelihood of its availability to users in the workplace after graduation?

Addressing the First of Three Initial Issues – Cost

With respect to cost, *Microsoft Excel* (Microsoft, 2013) and *R-Deducer* (Fellows, 2012; Doi *et al*., 2016), are free to students. Thus, the cost will not play a role in our decision-making process.

Addressing the Second of Three Initial Issues - Capacity to Support Varying Platforms

R-Deducer seamlessly supports both Windows and Mac student users. On the other hand, Mac student users are often frustrated in their attempts to obtain some of the charts in *Microsoft Excel*. Currently, *Excel* requires differing instructional sets for the two user groups. At our

institution, for example, where roughly half the students have either PCs or Macs, this would add an unnecessary layer of faculty instruction for teaching the two user groups. In sum, a decision on this issue would be driven by the institutional requirement for the use of *Excel* in all its business courses. If there is no such requirement, as would overwhelmingly be the case, careful consideration must be given for any decision to utilize *Excel* as the appropriate course software tool unless a campus site provides the virtual machines that would enable Mac owners to use their computers as if they were PCs.

Addressing the Last of Three Initial Issues - Likelihood of Workplace Availability

Microsoft Excel and *R-Deducer* provide free access and will readily be available to graduates once they are in the workplace. The only issue with *R-Deducer* could be that employees will not be able to install *R-Deducer* if they do not have administrative privileges on their work computers. Those employees will need to get permission from their employers to install *R-Deducer*.

Table 2: Recommended Topics in Introductory Business Statistics Course

Topics	**Methods**
● Data Presentation for Categorical Variables and Numerical Variables	● Categorical Variables: Summary Table with Bar, Pie, and Pareto Charts for One Categorical Variable; Contingency Table with Side-by-Side Bar Chart for Two Categorical Variables ● Numerical Variables: Ordered Array, Frequency and Percentage Distribution with Histogram
● Numerical Data Characterization	● Summary Statistics, Five-Number-Summary, and Boxplot
● Probability Theory and Distributions	● Applications via Contingency Table ● Normal Distributions: Obtaining Probabilities and *Z*-Scores; Assessing Normality Using a Normal Probability Plot ● Sampling Distributions: Interactive Demonstrations of Central Limit Theorem
● Confidence Interval Estimation and Hypothesis Testing	● Confidence Interval Estimate for a Population Mean and for a Population Proportion ● Hypothesis Test for a Population Mean and for a Population Proportion ● *t*-Test for Differences in Two Population Means; *Z*-Test for Differences in Two Population Proportions

Assessing *Microsoft Excel* and *R-Deducer* in Support of Data Analysis

Once the three initial issues have been pondered, the selection of an appropriate computational software tool for assisting in data analysis should be based primarily on:

- Support of specific course topics being covered
- Correctness of printouts
- Simplicity of access and installation
- Simplicity in data import and data entry
- User friendliness in tool/dialog box design interaction
- Simplicity in exporting printouts to Word files and PowerPoint files

And the selection of an appropriate tool for visual demonstrations aimed at enhancing student learning should be based primarily on its interactive capabilities and through interactive explorations (e.g., "sensitivity analyses that depict how changes in data values affect both numerical results and its graphical display. If not sufficiently provided by statistical software packages, either spreadsheets or web applets can be employed to achieve this purpose.

Using two different datasets (one dealing with a university case study and the other dealing with a retirement funds case study), we were able to assess Excel and R-Deducer by writing instructions and obtaining printouts for the course topics displayed in Table 2.

Assessing Support of Specific Course Topics Covered

When Microsoft *Excel* is used naked without any templates, it falls short in supporting all the course content given in Table 2. For example, *Excel* used along with Analysis ToolPak does not support boxplot diagrams, and its histogram tool is flawed. Additionally, the use of *Excel* without any add-ins burdens students with too many worksheet preparation tasks (such as the manual entry of data and calculation formulas) in addition to numerous editing tasks that distract learning from course content. *Microsoft Excel*, when combined with a properly prepared set of template solutions such as those developed in Levine, Stephan, & Szabat (2017) along with *Excel*'s own Analysis ToolPak add-in program, supports all the course topic methods. However, if instructors want to explore some advanced analytics methods (e.g., VIF scores, logistic regression) in their introductory to business statistics course, *Excel* will not be a good choice as it does not have these capabilities. *R-Deducer* cover all highlighted course topics and many other advanced topics (e.g., clustering, classification, PCA); thus, it becomes a great choice for a program that contains multiple analytics courses in addition to the introductory business statistics course.

Assessing Correctness in Printouts

Using the two datasets, we observe the following: Microsoft Excel incorrectly displays fitted regression lines to a scatter plot in a simple linear regression analysis. The sample regression equation incorrectly uses the symbol *Y*, instead of $\hat{Y}$. This easy-to-fix error has unfortunately not been corrected in the *Excel Template* set proposed by Quintela del-Río & Francisco-Fernández (2017). Additionally, *Microsoft Excel* uses the word *Multiple R* to represent the value of the coefficient of correlation. Should the slope of the fitted line be *negative*, the value for *Multiple R* will, nevertheless, be displayed as *positive*, which would cause confusion to the student user. *Microsoft Excel*'s histogram representing a continuous numerical variable is improperly

displayed with disjoint vertical bars. The word bins, representing the class interval grouping into which the individual numerical data values are assigned, are shown centered on the vertical bars where midpoints should be displayed. This visual presentation causes immediate confusion to students because the bin column which must be entered for developing both the frequency distribution table and the histogram represents the upper boundary of each class interval grouping, not its midpoint. Editing instructions needed to adjust these *Microsoft Excel*-caused errors are time-consuming and unnecessarily detract from the teaching of statistics. On the other hand, *R-Deducer* does not always use the Greek letters to denote the population parameters. For example, the population proportion is denoted using the Latin letter p instead of the Greek letter ∏. Moreover, we observe that the printouts of *R-Deducer*, although correct, can be overwhelming for undergraduate students because it tends to provide more information than needed in an undergraduate statistics course. For example, a linear regression result will generate the Cook's distance plot as well as the partial regression plots, which are not used in an introductory business statistics course.

Assessing Simplicity of Access and Installation

Students can easily access and download a set of *Excel Templates* using textbooks or webpages (such ASQ, 2018). It is also easy for students to access Microsoft Excel and its Analysis ToolPak. Moreover, Installing *R* is easy; however, downloading the *Deducer* package can be sometimes tedious since the package requires several Java dependencies. Once the *R-Deducer* is configured, accessing it again throughout the semester is seamless and does not require any additional work.

Assessing Simplicity in Data Import and Data Entry

Employing the two datasets, data import and data entry are easy to do using Excel and R-Deducer. However, to be able to upload data into *R-Deducer,* users need to save the *Excel* data files as comma-separated values (csv) files, which requires extra instructions and will slow down the pace of the course.

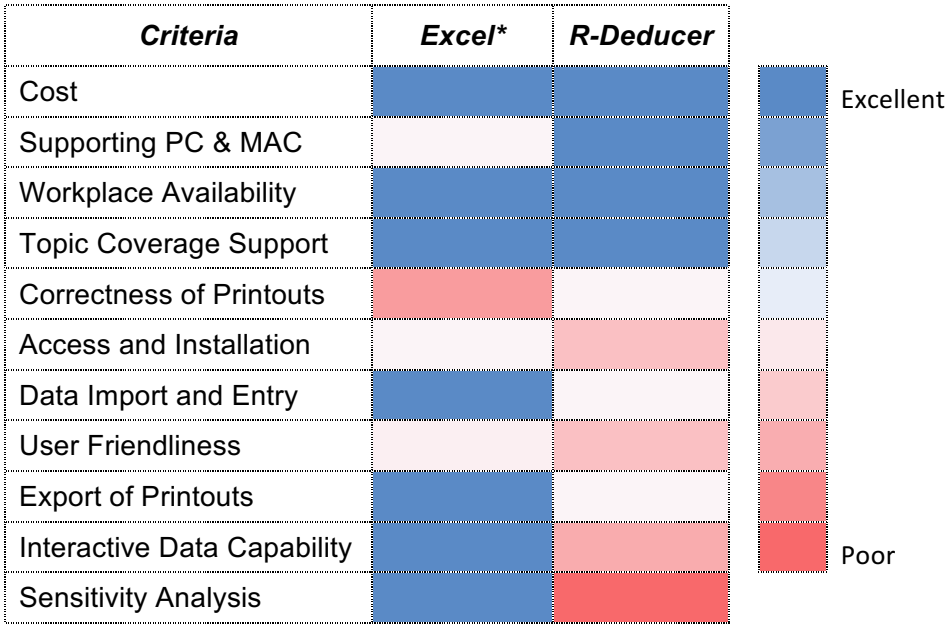
Assessing User Friendliness in Tool/Dialog Box Design Interaction

Our assessment using the two datasets shows that R-Deducer provides a User Interface (UI) where users can easily navigate. However, this interface lacks visual cues, such as icons and pictures; thus, it might take some time for students to locate the commands. On the other hand, students are more familiar with the *Microsoft Office* UI because many students are exposed to *Excel* during high school or in freshmen year in various business schools. Thus, it can take more time for students to learn how to navigate through the *R-Deducer* UI as compared to *Excel*.

Assessing Simplicity in Exporting Printouts to Word and PowerPoint Files

Based on our assessments with the two datasets, we observe that exporting the printouts to Word and PowerPoint files using *Excel* is easy. On the other hand, *R-Deducer* does not allow copy and paste; thus, users must first select images, take screenshots (such as Snipping Tool in PC or Preview in Mac) and then export them to Word or PowerPoint files.

Figure 1: "Quasi" Heat map for a comparison of *Excel* and *R-Deducer*: subjective "report card" grades



* Excel includes its Analysis ToolPak and Templates that can be downloaded online

Assessing Interactive Capabilities

As articulated in the GAISE Report (Carver *et al*. (2016)), in addition to supporting data analysis, it would be useful if the selected computational software tool could also provide appropriate visual demonstrations and enable data exploration to promote conceptual understanding and enhance statistical thinking. Thus, *Microsoft Excel* is strongly recommended for the PivotTable demonstration of data exploration through drill down. R-Deducer, on the other hand, does not offer such capabilities.

Assessing Interactive Explorations (i.e., "Sensitivity Analyses")

Student learning and understanding of concepts can also be enhanced through a computer software tool's capability of demonstrating sensitivity analyses that depict how changes in data values affect both numerical results and its graphical display. Although *R-Deducer* and *Microsoft Excel* are insufficient for such purposes, a properly prepared set of *Excel Templates* are excellent for these sensitivity analyses. Printouts from the *Excel* enable the student user to alter the statistics in the various confidence interval estimates and hypotheses tests and observe how such changes impact on the findings. Besides, the *Excel* enable the student user to alter the parameters and selected values of a random variable when studying different probability distributions.

SUMMARY, CONCLUSIONS, AND RECOMMENDATIONS

In this paper, a comparison of *Excel* and *R-Deducer* intended for use in the introductory business statistics course has been presented and a paradigm for a re-engineered, project-oriented course has been developed. The reason why we analyzed these two software tools is

that they are free for students. Thus, they can be alternatives to paid computational tools (e.g., *Minitab, JMP*) if budget is a concern. Our main conclusions, derived from experimentation with the two tools using two datasets, are summarized as follows:

- Although Microsoft *Excel* is widely used in the workplace and one of the most common tools used in various B-School courses, its pedagogical limitations severely dampen its value for use in an introductory business statistics course. The errors in the printouts of key topics in descriptive statistics and simple linear regression and the omissions in its development of confidence interval estimates are cases in point. And writing formulas in *Excel* to conduct statistical analysis will slow down the pace of the course and puts extra pressure on faculty struggling to finish the course material by the end of the semester.
- If instructors want to use *Excel* as the primary tool, they should use *Excel Templates to facilitate the course instruction.*
- *R-Deducer* is a professional open-source statistical software package. It enables students to spend more time interpreting the results and understanding the concepts rather than formulating the analysis. However, learning to navigate through this software will take some time for our students. Thus, instructors preferring to employ R-Deducer should start using it as early as possible in the semester.
- If the curriculum includes more courses on analytics, we do believe that early exposure to R through R-Deducer will help students in these courses because *R* is one of the primary computational tools in the business analytics field.

The ultimate course goal is the learning of statistics. To this end, we recommend the following if budget is a concern, and the institutions/departments/instructors want to choose a free data analysis tool:

- To support data analysis, particularly in a re-engineered project-oriented business statistics course, *R-Deducer* be selected for use as the computational software tool
- To promote conceptual understanding and enhance statistical thinking, the selected computational software tool be supplemented by interactive applets for visual demonstrations and by *Microsoft Excel* for PivotTable demonstration of data exploration through drill down.

ABSTRACT

A game-theoretical model is designed to study the competition between a company that continuously exploits its established competitive advantage, and an agile company that anticipates and adapts to market changes. We show how the former loses its competition to the latter, when the former could raise the entry barrier to protect its market share, and when such effort would be useless. Practically, we provide guidelines for when firms that are incumbent in the market should prepare to ride a paradigm change, and what firms should constantly look out for the next breakthroughs in order to introduce their next competitive advantages.

KEYWORDS: entry barrier, hybrid product, technology, market invasion

INTRODUCTION

In the present world of business, for a company to remain ahead of the fierce competition, it has to be super vigilant in its pursuit of the next trend or transient advantage (Chan & Chan, 2010). So a natural question arises: How do companies that do not stay alert with market trend lose their shirts in the competition with companies that do? Speaking differently, how can a company really tell whether or not it is losing its market competition?

To address this question, this work treats each market and organization as systems (Lin, 1987; 1999; Senge, 1990; Morgan, 2006), consisting of component parts; and organizations must be adaptable to continuous market and technological changes (Johnson, 1998). Specifically, this paper designs 2×2 and 3×2 games to model the direct competition between two companies named X and Y, where the former honors the once-championed philosophy of sustainable advantages and the latter is of the modern type of transient advantages. Then, the following main results are shown: (1) If Company Y is expected that its expansion will generate profits, which are more than the cost for Company X to take defense, then Company X would move first and take defense against Company Y although the consequence is uncertain; and (2) If there is a much greater market than that occupied by Company X for Y to expand into, then Company Y will definitively introduce its hybrid product.

By considering a customer as the third player who interacts with the two companies, our 3×2 game modeling leads to the following results: (1) If Y's revenue is greater than its cost and its revenue from outside the market base of Company X is smaller than its cost, and Company X does not take any defense to protect itself, then the probability for the customer to purchase X's product is inversely proportional to Y's activities of producing its hybrid product; and when the revenue Y earns from the market of X is equal to its fixed cost of producing its hybrid product minus the revenue generated from beyond the customer base of X, then the probability for the customer to purchase Y's hybrid product is equal to 1. (2) If Y's revenue is greater than its cost and its revenue from outside the market of X is smaller than its cost, and X does take defense to protect itself, then the higher the difference between the cost for Y to produce its hybrid product and the revenue generated beyond the customer base of X, the lower the probability for X's customer to purchase Y's hybrid. (3) If the profits of Y's expansion come mainly from X's market share, then X can successfully delay the deterioration of its territory as long as less than 2/3 of its maximum expected revenue is taken by Y.

There are vast literatures on market entry (Zachary, et al., 2015) and R & D races to develop new products (Jindal, et al., 2016), our focus here is on the interaction between firms that practice the philosophy of sustainable competitive advantages and those that ride the wave of transient advantages. At the same time, there is a large literature of game-theoretical studies of duopoly competition (Puu, 1991; Zhang, et al., 2009; Dubiel-teleszyński, 2011; Fan, et al., 2012; Ma & Xie, 2016; Zhu, et al., 2014; Zhang & Ma, 2016; Pecora & Sodini, 2018). However, for practical purposes, none of these prior models actually fits our needs. So we have no choice but develop a different and straightforward game-theoretical model based on a few very realistic and intuitive assumptions. And instead of optimizing the representative customer's utility function, we maximize companies' profits, which is most likely the practice of relevant companies when they try to decide their courses of action.

Beyond addressing the question posed at the beginning of this section, this paper also attempts to show that other than inductive reasoning, deductive reasoning should be employed to produce scientifically sound theories and conclusions. And, this work also shows the need to enrich the literature of duopoly competition through developing new models that are beyond those established under unrealistic conditions – such as linear price and quantity interactions, linear demand and cost functions, etc. – and processes – such as optimizing customers' utilities.

The rest of the paper is organized as follows. The next section models the competition between Companies X and Y, where X is old-fashioned while Y modern. The following section analyzes the competition between X and Y while the role of consumers is considered. Then the details of the old-fashioned company is analyzed. And the last section concludes this work.

COMPETITION BETWEEN TWO PLAYERS

Assume that companies X and Y operate under two different business models such that X is a successful, old fashioned company that enjoys its time-honored sustainable competitive advantage and that Y also enjoys its traditional success with its unique product(s), its leadership adopts the philosophy of transient competitive advantages. For the sake of convenience, assume that both X and Y each produce only one product. That is, Y is market- and technology-driven (Day, 1994) and fully ready to embrace next fleeting advantage (Kaharuddin, et al., 2017). So, Y considers whether or not to produce a new product that improves the functionality, user friendliness, and the features of the two products produced respectively by X and Y. If it decides "yes, it will produce the imagined hybrid product," then the production of Y's old product will be terminated, and its loyal customers will move on to enjoy the hybrid (better) product at the same price as that of the retired product. And, a portion of X' customers will switch to buy this new

product, which would be considered cheaper and better than the product of X due to the enhanced functionality, user friendliness, and combined features.

Summarizing what are assumed, we have the two-player game in Table 1, where S_X stands for the total sales revenue of Company X without Company Y's invasion of X's territory, S_Y the sales revenue of Company Y generated from the market share of Company X by producing the imagined hybrid product, *C* the cost of Company X for it to take actions, such as raising the barrier of entry, in order to deter the invasion of Company Y, R_0 (respectively, R_1) the cost of Company Y, including risk and opportunity costs, for designing and producing the hybrid product without (respectively, with) Company X taking defensive actions.

TABLE 1. The payoffs of the 2 × 2 game of pure strategies

		Company Y	
		Design/produce	Don't design/produce
Company X	Take defense	$S_X - C - S_Y, S_Y - R_1$	$S_X - C$, 0
	Don't take defense	$S_X - S_Y, S_Y - R_0$	S_X, 0

What is assumed stands for a 'camera' snapshot of the interaction between X and Y. That is, if time is considered, X could still be monitoring what Y is doing and expanding its advantages by investing in resources and capabilities that strengthen its current market position and open up new opportunities. It could still be systematically using these strategic resources and capabilities to respond to the pressures of Y. For example, the rivalry between Montgomery Ward and Sears had been in such a game situation at almost any chosen moment of time since the late 1800s. Montgomery Ward monitored and analyzed what Sears introduced and was planning on doing, while developed itself in a totally different direction (Sobel, 1999).

By the philosophy of transient competitive advantages, it is meant that the leadership of Y, as well as its culture and value system, is more in sync with the technological changes and desires of consumers than X so that Y knows how to excite consumers. In real life, when a company decides to produce a hybrid product, there are many different ways to do it. If a company is in sync with the technological changes and desires of consumers, its product will more likely excite the market than the products of other companies. This end is very well demonstrated by the case of Montgomery Ward and Sears.

A point of notice regarding this game model is that X really stands for the aggregate of all incumbent firms of the marketplace that is in a state of mutual forbearance (Bernheim & Whinston, 1990; Li & Greenwood, 2004; Yu & Cannella, 2012; Fuentelsaz & Gómez, 2006; Haveman & Nonnemaker, 2000). And Y represents the aggregate of all firms that always think about introducing newer and better products.

A second point of notice is that if the additional profits of Y come from the loss of X's market, then X has an incentive to spend an amount equal to this potential loss to create entry barriers; so in equilibrium X would always spend an amount equal to S_Y to eliminate any incentive for Y to introduce a new hybrid product. However, in practice S_Y cannot be known at the time the model is developed and changes over time. And, although S_Y might turn out to be very close to zero, Forrest, Amatucci and Markman (2017) show that Y still has to introduce its new product to just maintain its current customer base. That is, the amount X spends on building entry barriers is not a function in S_Y. In fact, Forrest, Buttermore and Wajda (2017) show that S_Y (less cost) could potentially be greater than S_X (less cost).

All the assumptions imply: (1) For both X and Y, each unit of produced product is sold. (2) When the sales revenue S_Y is > 0, the sales revenue of X is $S_X - S_Y$. That is, S_Y stands for the portion of sales revenue Y takes away from X, assuming that is the total increased sale of Y. (3) When X takes defense to deter Y from invading its territory, the total cost for Y to produce its

hybrid product goes higher so that $R_1 > R_0$. For the rest of this paper, assume that all players establish their best responses by playing the Nash equilibrium through pure self-analyses.

In the following, this game is analyzed in cases.

Case 1: The increased sales revenue S_Y of Y is less than the sum R_0 of the cost of producing the hybrid product and the risk and opportunity cost. So, Y does not produce the hybrid product. And, X does not take any action to deter Y from entering its territory. In this case, (don't take defense, don't design/product) is the Nash equilibrium, although in real life such a situation does not really exist. It is because at least some of the features of X's product can be combined with those of Y's product without breaking the budget by adopting appropriate technologies.

Case 2: $R_0 < S_Y < R_1$ and $S_Y < C$. (Don't take defense, Design/produce) is the Nash equilibrium. That is, if X takes defense against the potential entry of Y into its territory, X has to spend more than its loss in terms of revenue. Due to the high costs, X does not take defense; and Y will enter the territory of X.

Next, if $R_0 < S_Y < R_1$ and $S_Y > C$, then X would decide which strategy to use to maximize its revenue, assuming this company chooses its strategy first. In this case, X is better by taking defense and by expelling Y from entering its market, because the strategy profile (Take defense, Don't design/produce) will give X the maximum revenue. In the subgame for X to take defense, (Take defense, Don't design/produce) is the Nash equilibrium.

TABLE 2. A 2×2 game of mixed strategies

		Company Y	
		Design/produce	Don't design/produce
Company X	Take defense (p)	$S_X - C - S_Y, S_Y - R_1$	$S_X - C$, 0
	Don't take defense $(1-p)$	$S_X - S_Y, S_Y - R_0$	S_X, 0

To make the decision making process more dynamic, instead of using pure strategies, assume that X assigns probability *p* for the event for it to take defense. At the time when the model is established, Y does not really know whether or not X will take defense. So, the payoff matrix is given in Table 2. This game leads to:

Proposition 1. Assume all other conditions are held constant. If Y's revenue from X's territory is greater than its costs when X does not take defense, while less than the costs when X does take defense, and greater than the defense costs of X, then the probability for X to take defense and the sales revenue of Y generated from the market of X by producing its hybrid product are directionally proportional to each other.

Proposition 2. Assume all other conditions are held constant. If Y's revenue from X's territory is greater than its costs when X does not take defense, while less than the costs when X does take defense, and greater than the defense costs of X, then the probability for X to take defense and the cost for Y to produce its hybrid product with X taking defense are inversely proportional to each other.

Next, we consider the case that when deciding on producing its hybrid product, other than the possibility of taking a portion of X's revenue, Y also knows that its new product will appeal to customers beyond the customer bases of X and Y. To study how the incumbent firms in this new market would raise entry barriers to keep new comers from entering, assume that the market the imagined hybrid product will enter competitively is occupied by *m* incumbent firms, *m* = 1, 2, … They provide customers with substitutable products; and these firms enjoy

the backing of their respective loyal customers who only purchase the product of their firms if the price is no more than their reservation value 1. Assume that these firms raise the entry barriers for Y by competing over the price switchers who make purchase decisions based on whose price is lowest only. To prevent Y from entering, assume that these incumbent firms are well aware of their pricing strategies, and that these firms have established their best responses by playing the Nash equilibrium through pure self-analyses. Then, we have the following.

Proposition 3. In the Nash equilibrium, the following two statements are equivalent:

1) B can profitably enter the pre-described market; and
2) The size of the market segment of switchers is greater than zero.

The proof of this result is outlined in Appendix.

What the proof of this result says is that it is impossible for the incumbent firms to stop Y from entering because to counter the pricing strategy of the incumbents Y randomizes its price between the unit cost and the reservation price the incumbents charge their loyal consumers. And, this proof indicates that Y could potentially take all the switchers. That in turn means that if this segment of the market is larger than any of the royal-customer bases of the incumbents, then Y could make more profits than any of the incumbents.

Summarizing what is discussed, it follows that Y expands its market share by taking a portion of X's customers and a portion of the greater market of the hybrid product. So, it is practically possible that the additional revenue Y generates from its hybrid product is more than S_Y, the sales revenue of Y from X's market. Let S_Y- be the revenue Y generates from the market beyond X's market. Then, we naturally have the following case.

Case 3: $S_Y + S_Y- \geq \max\{R_1, C\}$. That is, Y's expanded sales revenue from producing its hybrid product is at least the larger of Y's cost (R_1) of producing the hybrid product and X's cost (C) of taking defense. If, additionally, $S_Y > C$, then X takes defense and the Nash equilibrium is (Take defense, design/produce). If also $S_Y + S_Y- = R_1$, then the Nash equilibrium is (Take defense, don't design/produce). On the contrary, if $S_Y + S_Y- > R_1$ and $S_Y > C$, then (Don't take defense, Design/produce) is the pure strategy Nash equilibrium with payoffs ($S_X - S_Y$, $S_Y - R_0$), Table 1. In other words, X's market share is gradually taken by Y's hybrid product while X cannot do anything about it.

In short, we have the following result:

Proposition 4. Assume that X exploits its sustainable competitive advantages, while Y looks forward to adopting transient competitive advantages (McGrath, 2013), as described above. Then

1. If Y is expected from expansion to generate more profits than the cost for X to take defense, then X would move first and take defense against Y;
2. If Y's decision of whether or not to produce its hybrid product is based on the existence of an expanding market beyond that of X, then Y will introduce its hybrid product.

Result 2 above follows from Proposition 3 and Theorem 5 in (Forrest, Buttermore & Wajda, 2017).

COMPETITION AMONG THREE PLAYERS

The fortune and fate of X and Y are really determined by the consumers. So, let us now include a fictitious customer in the interplay of the X and Y's competition. Assume that X first offers a

product in the market, Y then provides its improved hybrid product, while the customer decide on whether to purchase or not to purchase and which product to buy. Because Y practices the philosophy of transient competitive advantages, it observes X's initiatives and then acts accordingly. On the contrary, X identifies and invests in its determined set of resources and capabilities, believing that they will help the company maintain its current market position and respond to competitive pressures of the market. At this junction, Montgomery Ward was a good example of X described here. So, assume that although the customer is from X's market, she would try the new product by Y if such a product is available. That is, Y closely monitors and follows X, while the customer follows both companies and would try out the new product. So, X needs to increase the consumer confidence on its product and to decide on whether or not to take defense against Y's possible invasion. So we have the following game model:

X chooses whether to take defense (with cost *C*) or not (with cost 0). Y elects between produce its hybrid product (with fixed cost *D*) and not (with cost 0). If X takes defense to deter Y's following, assume that Y will spend additional αC to produce its hybrid product, where $0 < \alpha < 1$. That is because to follow up with X's defense, Y has to push its organization's knowledge envelope outward to incorporate unknown technologies in its production of the hybrid product (Harrigan & DiGuardo, 2016). Ultimately the customer decides whether to purchase or no. If she purchases X's product, her utility is $(-u)$, because after purchasing the product she feels being exploited by a product that is not as innovative as what the market is expected to provide. Such situations of negative utility occur in real life quite frequently and almost surely when the market is controlled by a monopolist. If she purchases Y's hybrid product, her utility is u, because Y's hybrid innovatively reflects the features of both X's product and the old product of Y and more. When the customer decides to purchase, if there is no hybrid product available in the market, X earns revenue S_X. In this case, although the customer does not feel good from the purchase, she does not really have a choice. However, if there is hybrid product in the market, then Y grabs revenue S_Y from X by selling its hybrid to the customer. So, $S_X \geq S_Y$. When the customer decides not to purchase, the revenues of X and Y will both be 0.

TABLE 3. Payoffs of the customer and Y when X takes defense

		Company Y	
		Design/produce (*p*)	Don't design/produce (1 – *p*)
Customer	Buy (τ)	u, $[(S_Y + S_{Y^-}) - D - \alpha C]$	$-u$, 0
	Don't buy $(1-\tau)$	0, $[(S_{Y^-}) - D - \alpha C]$	0, 0

TABLE 4. Payoffs of the customer and Y when X does not take any defense

		Company Y	
		Design/produce (*q*)	Don't design/produce (1 – *q*)
Customer	Buy (ε)	u, $[(S_Y + S_{Y^-}) - D]$	$-u$, 0
	Don't buy $(1-\varepsilon)$	0, $[(S_{Y^-}) - D]$	0, 0

So, the payoffs of Y and the customer are respectively given in Table 3 for the case when X takes defense and in Table 4 for the case when X does not take any defense, where S_{Y^-} is the revenue Y generates from the market of the hybrid product beyond X's market and its expected revenue from its old product.

Proposition 5. If Y's additional revenue from beyond its original territory is less than its cost of producing its hybrid product, then the pure strategy Nash equilibrium is reached when X does

not take defense, Y does not produce its hybrid product, and the customer does not make purchase.

Proposition 6. If Y's additional revenue from beyond its original territory is greater than its cost of producing its hybrid product, then the pure strategy Nash equilibrium is reached when X does not take defense, Y produces its hybrid product, and the customer makes purchase. In this Nash equilibrium, X collects no revenue, Y makes profits, while the customer enjoys her utility u. And, if, moreover, Y's additional revenue from X's market territory is greater than the cost for X to take defense, then when X moves first, the Nash equilibrium is (Take defense, design/produce).

Proposition 6 implies that when Y's additional revenue from its hybrid product is more than the total cost of producing the hybrid product, then Y will move ahead with its production of the hybrid product. In this case, because any defense is useless, X does not even attempt to take any action. However, considering that X is a diehard believer and practitioner of the old school of sustainable competitive advantages, such as Montgomery Ward, it in really life would most likely not passively watch for its market to deteriorate without trying to do something. Because of this, we next consider mixed strategies assuming $S_Y + S_{Y^-} > D + \alpha C$. That is, Y's additional revenue from beyond its original territory is greater than the cost of producing its hybrid product. In this case, assume also $S_{Y^-} < D + \alpha C$ (that is, Y's revenue from outside X's market is less than Y's cost), because otherwise Y will definitely produce its hybrid product.

Because before making its decision, Y has to firstly sense, secondly seize and transform itself, and then acquire the critical capabilities for successful organizational adaptation (Day & Schoemaker, 2016), assume that if X takes defense, the probability for Y to produce its hybrid product is *p*. Let the probability for the customer to purchase be τ. And if X does not take any defense, let the probability for Y to produce its hybrid product be *q*, and the probability for the customer to purchase ε. By solving for mixed strategy Nash equilibrium, we have $p = q = 1/2$, and

$$\tau = \frac{D+\alpha C-S_{Y^-}}{S_Y} \quad (1)$$

$$\varepsilon = \frac{D-S_{Y^-}}{S_Y}. \quad (2)$$

Proposition 7. If Y's additional revenue from beyond its original territory is greater than its cost of producing its hybrid product and its additional revenue from outside X's market is smaller than the cost, and X does not take any defense to protect itself, then

1. The chance for the customer to purchase X's product is inversely proportional to Y's production of its hybrid product; and
2. When Y's revenue from X's market is equal to its fixed cost of producing its hybrid product minus the revenue generated from beyond X's customer base, then the chance for the customer to purchase Y's hybrid product is equal to 1.

Proposition 8. If Y's additional revenue from beyond its original territory is greater than its cost of producing its hybrid product and its additional revenue from outside X's market is smaller than the cost, and X does take defense to protect itself, then

1. The higher the difference between Y's cost of producing its hybrid product and the additional revenue from beyond X's customer base, the higher the chance for X's customer to purchase Y's hybrid; and
2. If, additionally, the α-value is fixed, then the more X spends on raising the barriers against Y's invasion, the lower the chance its customer will buy Y's hybrid.

This result means that X's defense actually works in terms of slowing down the deterioration of its customer base.

COSTS AND BENEFITS

When Y's additional revenue from beyond its original territory is greater than its cost of producing its hybrid product and its revenue from outside X's market is smaller than its cost (or $S_Y + S_{Y^-} > D + \alpha C$ and $S_{Y^-} < D + \alpha C$), it is shown above that to slow down the deterioration of X' customer base the most significant decision is to spend more on building a costly barrier for Y's invasion into X's territory and to increase the customer retention. As part of the most important investment, X could constantly make the features and functionalities of its product better. That would make it difficult for Y to follow. For the comparison of X's deterrence cost C and X's revenue, we have:

Proposition 9. If Y's additional revenue from beyond its original territory is greater than its cost of producing its hybrid product and its additional revenue from outside X's market is smaller than the cost, then

1. If X decides to defend its territory by raising entry barriers, then it can successfully delay the deterioration of its territory as long as less than $\left(\frac{1}{\alpha} + \frac{1}{2}\right)$ of its maximum expected revenue is taken by Y; and
2. If X decides not to take any defense against Y's possible invasion through producing its hybrid product, then X can produce positive revenues. However, this positive revenue decreases with increasing revenue Y generates from outside X's market.

Proposition 9 says that to continuously stay in business, X has no choice except also adopt the philosophy of transient competitive advantages, as pointed out by Dobni and Klassen (2015). And the proof of this result reveals that with improvement of technology and availability of information, the fixed cost D and the cost coefficient α for Y to produce its hybrid product gets lower with time, while the cost C for X to spend on entry barrier gets higher. So, X's expected revenue will be crashed by Y quickly unless X also starts to improve its product by producing hybrid products for the purpose of expanding its market share, as what Y tries to do throughout this presentation. However, Tushman and O'Reilly III (1996) show that this end is a real challenge for X's managers, just as the case of Montgomery Ward.

CONCLUSIONS

Failure to focus on multiple or transient competitive advantages may place a firm in an unenviable deficit with a commensurate serious loss in market share and/or dominance (McGrath, 2013). Accepting that any advantage will be short-lived is critical in a continuous learning and innovative company. Hence, there is a need to show why any company that plans on continuously exploiting its competitive advantages for the long term will disappear from the market place or soon become irrelevant. To this end, this paper employs a simple and

straightforward game model, instead of anecdotes data mining, to show analytically how unresponsively a company that plans on reaping in its profits by exploiting its sustainable competitive advantages is losing its future to those that adopt and practice transient competitive advantages.

To avoid the weaknesses, such as deriving unreliable conclusions from maximizing customers' utilities, developing results from particularly chosen utility functions, and creating beliefs from imposed unrealistic linearities, of the literature of duopoly competition (Singh & Vives, 1984; Zanchettin, 2006), this work establishes thought provoking and practically useful results on the basis of the mathematical formulation of the problem by providing the feasible solutions that incorporate the differences in actions between two companies. The most important conclusion this study produces *analytically* is that to avoid becoming history, any company has to adopt and practice the philosophy of transient competitive advantages.

All results established in this paper suffer from the weakness of missing time variable. In other words, conclusions of this work only describe momentary situations of the competition between Companies X and Y. So, as a theoretical interesting and practically significant research question for future works, one needs to investigate what would follow after X realizes what it needs to do at the next time moment in the competition with Y.

Comparing to the literature of competitive advantages, this study is the first that uses an analytical approach to address issues related to many overriding conclusions – drawn mostly on anecdotes, or data mining, or models developed on limiting or unrealistic conditions. That is why we are able to provide insights into the practically significant question: How do companies of the philosophy of sustainable competitive advantages actually lose their shirts in the competition with companies that ride the current wave of transient advantages? In the meantime, this work enriches the literature of duopoly competition by showing how some of the major weaknesses of the models established to study either Cournot competition or Bertrand competition can be avoided.

APPENDIX

Proof of Propositions 1 and 2. From Table 2, Y's indifference condition is

$$p(S_Y - R_1) + (1-p)(S_Y - R_0) = 0,$$

from leads to

$$p = \frac{S_Y - R_0}{R_1 - R_0},$$

where $R_1 > S_Y > R_0$ is assumed for the analysis here. And when $R_1 > 0$, R_0 will be a nonexistent value. In this case, we assume $R_0 = 0$.

Proof of Proposition 3. Let α stand for the portion of the market of the loyal customers of the *m* firms and $\beta = 1 - \alpha$ be the market segment of switchers, where $0 \le \alpha, \beta \le 1$. Assume that the constant marginal costs of the incumbent firms and Y are set to zero without loss of generality – so in the rest of this proof, revenues are the same as profits. And consider the aggregate of the incumbent firms as one firm, because these *m* firms are in a state of mutual forbearance (Bernheim & Whinston, 1990). So, the market share of this aggregate firm is α so that $\beta = 1 - \alpha$ represents the market size of switchers who base their purchase decisions on which price is lower.

The necessity condition is obvious. Let us now look at the sufficiency condition. Assume that the customer surplus satisfies $\beta = 1 - \alpha > 0$. Let α_0 be a real number satisfying $\beta = 1 - \alpha > \alpha_0 > 0$ and $\alpha = \ell\alpha_0$, where ℓ is a large natural number, indicating that the market has been largely taken by the incumbent firms.

Imagine that the aggregate firm is divided into ℓ many identical "firms", named *i*, *i* = 1, 2, …, ℓ, each of which provides customers with identical products and enjoys the market share $\alpha_0 = \alpha/\ell$ of loyal customers. These imaginary firms compete over the switchers with adjustable prices. Because these imaginary firms are really equal partitions of the same aggregate firm, they have the same constant marginal cost, which is set to zero without loss of generality, the managements of these firms are fully aware of the pricing strategies used by all the firms (because the firms are managed by the same administrative unit), and they establish their best, identical responses by playing the Nash equilibrium through their unified self-analyses.

These ℓ imaginary firms do not have any symmetric pure strategy Nash equilibrium. Because the reservation price of the loyal customers is set to be 1, all the prices (or pure strategies) are values in the interval $[0,1]$. (For the setup here, there is no need to consider asymmetric pure strategy Nash equilibrium, because all these imaginary firms take identical actions). In fact, for any symmetric pure strategy portfolio $(x_1, x_2, \dots, x_\ell)$, where $x_i = x_j$, for *i*, *j* = 1, 2, …, ℓ, a randomly chosen Firm *j* ($\in \{1, 2, \dots, \ell\}$) can slightly lower its price from x_j to x_j' to produce additional profits for all the firms as long as $x_j'\beta > (x_j - x_j')\alpha$, which is possible to do by adjusting x_j' sufficiently close to x_j. So, $(x_1, x_2, \dots, x_\ell)$ is not an Nash equilibrium. Even so, (Forrest, Buttermore, & Wajda, 2017) shows that these ℓ firms do have a symmetric mixed-strategy Nash equilibrium.

For the rest of this proof, it suffices to show that Y will be expected to profit by entering this market through uniformly randomizing its price strategy over the interval [0,1].

Let $F(P)$ be the price distribution of Firm *j*, one of the imaginary firms of the aggregate firm. The aggregate firm or equivalently each of the ℓ imaginary forms sets its price after taking into account the price of Y and those of all other imaginary firms. Hence, the profits for Firm *j* from its loyal customers is $\alpha_0 P$ and those from its share of the switchers is $(1-P)\beta P \prod_{i\neq j}^{\ell}[1 - F(P)] = \beta P(1-P)[1 - F(P)]^{\ell-1}$, where $(1-P)$ stands for the portion of the switchers not taken by Y, and $[1 - F(P)]$ the portion of the switchers not taken by one of the other imaginary and identical firms. Hence, the profits Π Firm *j* generates when the firm sells its product at price *P* are $\alpha_0 P + \beta P(1-P)[1 - F(P)]^{\ell-1}$ and the objective function of Firm *j* is

$$max_{F(P)} E(\Pi) = \int_{-\infty}^{+\infty} \{\alpha_0 P + \beta P(1-P)[1 - F(P)]^{\ell-1}\} dF(P)$$
$$= \int_{0}^{1} \{\alpha_0 P + \beta P(1-P)[1 - F(P)]^{\ell-1}\} dF(P)$$

where $E(\Pi)$ stands for Firm *j*'s expected profits for all possible prices, and the objective for Firm *j* is to maximize its expected profits by choosing its price distribution $F(P)$. The reason why the upper and lower limits of the integral are changed respectively from $+\infty$ and $-\infty$ to 1 and 0 is because when *P* < 0 or when *P* > 1, the profits are zero.

The equilibrium indifference condition of Firm *j* is

$$\alpha_0 \times P + \beta \times P(1-P)[1 - F(P)]^{\ell-1} = \alpha_0 \times 1 \quad (3)$$

So, for the ℓ imaginary firms, solving equation (3) leads to their symmetric equilibrium pricing strategy as follows:

$$F(P) = 1 - \left(\frac{\alpha_0}{\beta P}\right)^{\frac{1}{\ell-1}} \tag{4}$$

From $\beta > \alpha_0$, it follows that $\alpha_0/\beta < 1$. So, for any Price *P*, satisfying $1 \geq P \geq \alpha_0/\beta$, equation (4) is a well-defined probability distribution. This end implies that for the ℓ imaginary firms, or equivalently, the aggregate firm, the lowest allowed price is α_0/β.

From $lim_{P\to 1^-} F(P) = 1 - (\alpha_0/\beta)^{1/(\ell-1)} \neq F(1) = 1$, it follows that the cumulative price distribution function $F(P)$ has a jump discontinuity at the reservation value $P = 1$, where the amount of jump is $(\alpha_0/\beta)^{1/(\ell-1)}$. That is, $F(P)$ has a mass point of size $(\alpha_0/\beta)^{1/(\ell-1)}$ at the reservation price $P = 1$. So, the expected profits of Y are the following:

$$E(\Pi) = \int_0^{\alpha_0/\beta} \beta P dP + \int_{\alpha_0/\beta}^{+\infty} \beta P[1 - F(P)]^{\ell} dP \tag{5a}$$

$$= \int_0^{\alpha_0/\beta} \beta P dP + \int_{\alpha_0/\beta}^{1} \beta P[1 - F(P)]^{\ell} dP + \beta \left(\frac{\alpha_0}{\beta}\right)^{\ell/(\ell-1)} \tag{5b}$$

where the first term in the right-hand side of equation (5a) stands for the expected profits of Y when it charges the lowest price in the marketplace and captures the entire segment of the switchers, and the second term is Y's expected profits when it is in direct competition with the ℓ incumbent firms.

It can be readily seen from equation (5b) that the expected profits $E(\Pi)$ of Y is greater than zero. So, if the customer surplus satisfies $\beta = 1 - \alpha > 0$, Y can profitably enter the market to compete with the incumbent firms.

Proof of Propositions 5 and 6: This result follows from the payoffs of X that are corresponding to the scenarios that X either takes defensive actions or does not take any defensive actions (either Table 3 or Table 4). For details see Tables 5 and 6, respectively.

TABLE 5. The payoffs of X when it takes defensive actions

		Company Y	
		Design/produce (*p*)	Don't design/produce (1 – *p*)
Customer	Buy (τ)	$-C$	$S_X - C$
	Don't buy $(1 - \tau)$	$-C$	$-C$

TABLE 6. The payoffs of X when it does not take any defensive actions

		Company Y	
		Design/produce (*q*)	Don't design/produce (1 – *q*)
Customer	Buy (ε)	0	S_X
	Don't buy $(1 - \varepsilon)$	0	0

Proof of Propositions 7 and 8: To solve for the mixed strategy Nash equilibrium, we solve the following indifference equations:

$$pu + (1-p)(-u) = 0$$
$$qu + (1-q)(-u) = 0$$
$$\tau[(S_Y + S_Y\text{-}) - D - \alpha C] + (1-\tau)[(S_Y\text{-}) - D - \alpha C] = 0$$

and

$$\varepsilon[(S_Y + S_Y\text{-}) - D] + (1-\varepsilon)[(S_Y\text{-}) - D] = 0$$

So, we have $p = q = 1/2$ and equations (1) and (2). Now, Proposition 7 follows from equation (2), while Proposition 8 follows from equation (1).

Proof of Proposition 9: Let π_X represent the expected revenue of X. Then we have

$$\pi_{X,\text{defense}} = p\tau(S_X - C - S_Y) + p(1-\tau)(-C) + (1-p)\tau(S_X - C) + +(1-p)(1-\tau)(-C) \quad (6)$$

and

$$\pi_{X,\text{don't defend}} = q\varepsilon(S_X - S_Y) + (1-q)\varepsilon S_X. \quad (7)$$

So, by substituting the values of $p = q = 0.5$, τ and ε from equations (1) and (2) into equations (6) and (7), we have

$$\pi_{X,\text{defense}} = \frac{S_X(D + \alpha C - S_Y\text{-})}{S_Y} - \frac{1}{2}(D + \alpha C - S_Y\text{-}) - C \quad (8)$$

and

$$\pi_{X,\text{don't defend}} = \frac{1}{2}\frac{D - S_Y\text{-}}{S_Y}(2S_X - S_Y) \quad (9)$$

Because

$$\frac{\partial \pi_{X,\text{defense}}}{\partial C} = \frac{\alpha S_X}{S_Y} - \frac{\alpha}{2} - 1 = \alpha\left(\frac{S_X}{S_Y} - \frac{1}{2}\right) - 1 \quad (10)$$

and α is a constant between 0 and 1, it follows that when $S_X < \left(\frac{1}{\alpha} + \frac{1}{2}\right)S_Y$, we have $\frac{\partial \pi_{X,\text{defense}}}{\partial C} < 0$. That is, when $S_X < \left(\frac{1}{\alpha} + \frac{1}{2}\right)S_Y$, the expected revenue $\pi_{X,\text{defense}}$ of X becomes a decreasing function in variable C. In other words, as soon as the revenue Y generates from X's customer base is greater than X's revenue when X does not experience any challenge from Y divided by $\left(\frac{1}{\alpha} + \frac{1}{2}\right)$, then X can no longer exploit its sustainable competitive advantages by continuously raising its investment in raising the entry barrier in order to prevent B from invading its territory.

On the other hand, equation (9) indicates that when $S_Y\text{-} > D$, the expected revenue $\pi_{X,\text{don't defend}}$ of X will be a loss. In other words, if X decides not to defend itself against Y's

challenge and the expected revenue Y generates from the market except X's territory is greater than the fixed cost of designing and producing the hybrid product, then X's expected revenue will be a loss.

ABSTRACT

Owing to the cost reduction efforts (e.g. reducing inventory and node redundancy), supply chains have become increasingly vulnerable to disruptions. However, it is essential that firms should consider designing robust and resilient supply chains because the world has entered an increasingly volatile era where we observe many disruption risk factors (e.g., recent political atmosphere and natural disasters like Hurricane Maria). Thus, this paper explores the literature and develop a conceptual framework to make supply chains more strong and elastic so that they can survive potential risks they might face in the future.

KEYWORDS: Supply Chain Design, Analytics, Resiliency, Risk, Robustness

INTRODUCTION

Many firms have assumed that volatility caused my financial and political crisis, as well as other disruptions, is generally followed by a return to stability, and markets can recover quickly (Christopher & Holweg, 2011). However, the world has entered an increasingly turbulent atmosphere where this is not the case anymore. Disruptions (e.g., political, natural, financial) in this era have enormous economic impacts and may even lead to a total collapse of supply chain systems. It is interesting that many supply chain leaders and practitioners have focused so much on making supply chains leaner and reducing costs (e.g., removing excess capacity).

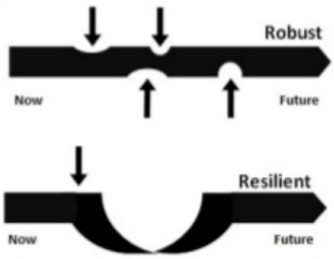
Table 1: Robust vs Resilient Supply Chains

Robust SC	**Resilient SC**
Strong and static	Elastic and dynamic
No excess inventory	Safety stocks and excess capacity
Velocity oriented	Acceleration oriented
Capable of steady output during moderate variability	Capable of responding and adapting to significant variations
Redundancy	Flexibility

However, this attitude, after the recent events (e.g., 2008 financial crisis, Hurricane Katrina, and current global political environment), has started to change, and companies have begun to understand that lean supply chains are more efficient in stable conditions but highly vulnerable in volatile environments (Blackhurst et al., 2005). Thus, business leaders seek methods to identify and manage disruptions in their complex supply chain systems by analyzing the tradeoffs between efficiency, robustness, and resilience (Tang, 2006).

A comparison between the robust and resilient supply chains is given in Table 1. Robust supply chains, when they face disruptions, can function near normalcy (Christopher & Peck, 2004). Resilient supply chains, after they experience disruptions, can quickly return to almost normal operations. The main difference between robust and resilient supply chains is that strategies that help supply chains function near normalcy in robust supply chains have already been defined before disruptions occur. On the other hand, recovery strategies in resilient supply chains are dynamic as they adapt to disturbances.

Figure 1: Resiliency versus robustness



Husdal (2006) states that resiliency is more important than robustness in industry, and his explanation of resiliency vs. robustness is given in Figure 1. A few essential strategies making supply chains robust and resilient are strategic inventory, excess capacity, node redundancy, and multi-sourcing (Pettit, 2008). Although firms might be attracted to the idea of making supply chains robust and resilient to all possible risks and disruptions, supply chains can become costly to operate if they must be robust to all potential threats. Similarly, supply chains can be inefficient if they need to mitigate all the predictable hazards (Johnson & Nagarur, 2012). Therefore, it is essential that field of analytics such as risk quantification, predictive modeling, and simulation must be used to both conceptually and quantitatively design resilient and robust supply chains. In this study, we will review the prominent literate regarding supply chain design and discuss the use of analytics. We will also propose a conceptual supply chain design framework for industry practitioners like ourselves.

THEORY AND LITERATURE

There are several research articles exploring supply chain design from three different perspectives, namely the design of the facility network, distribution system, and transportation system (Chopra & Meindl, 2007). The plan of the distribution network focuses on how and where inventory is stored throughout the supply chain. The transportation system design entails how these inventories are physically shipped throughout the supply chain network. The design of the supply chain network encompasses locating facilities, and then assigning capacities and allocating customers to them.

Quantifying Disruption Risks

Identifying supply chain risk factors is a highly strategic decision and affected by many factors. Deterministic models are not adequate to reflect the dynamism and stochasticity of these ever-changing uncertain factors. Chopra and Meindl (2007) classify these factors into several categories, such as political, technological, and infrastructure. Categorizing supply chain risks is the first step in network design under disruption. Ritchie and Brindley (2007) classify supply chain risks as either systematic or unsystematic. Systematic risks are inherent to a company's attributes and can be controlled (e.g., production yield). Unsystematic risks are impacted by the environment in which the company operates and cannot be controlled (e.g., natural disasters and political instability).

Another risk classification scheme adopted in the literature is endogenous versus exogenous risks (Trkman & McCormack, 2009). The endogenous risks can be controlled whereas the exogenous risks cannot be controlled. While the probability of any exogenous event (also known as an external or unsystematic event as discussed above) occurring may be very low, they often have the highest impacts on the supply chain (e.g., Hurricane Katrina). Therefore, exogenous events, also known as disruptions, must be mitigated to reduce their impact on the supply chain (Snyder & Shen, 2006). Pettit and Fiksel (2010) suggest that supply chain resilience can be assessed in terms of two dimensions: vulnerabilities (e.g., increased outsourcing and centralized distribution) and capabilities (e.g., flexibility in sourcing and capacity). Resilience is defined as the desired balance between vulnerabilities and capabilities.

Applications of Optimization for Designing Robust and Resilient Supply Chains

Sawik et al. (2014), under disruption risks, study single and multiple sourcing strategies, as well as their cost and service levels. In their model, suppliers located in different locations are faced with independent local, semi-global, and global disaster events. They account for potential disruption scenarios and formulate the problem as a mixed integer programming. Their algorithm reveals the outsourcing strategies as those that minimize expected worst-case cost or maximize expected worst-case customer service level. Snyder and Daskin (2005) use linear programming and stochastic modeling to identify location failures due to disruptions. The primary objective of this research is to build resilient and robust supply chains that can work when a facility (a node in a supply chain) fails. Snyder and Daskin (2005) measure the effectiveness of the proposed supply chain system utilizing the distance between the failed facility and the secondary facility that now must meet the customer demand.

Hishamuddin et al. (2013), in case of a transportation disruption, explore a recovery model for a two-stage production and inventory system. Their proposed solution utilizes a heuristic-based approach and can determine the optimal ordering and production quantities during a recovery window after a disruption. Shishebori et al. (2014) consider facility location and network design problems together with a constraint on the maximum allowable disruption cost. The combined facility location and network design problem is essential to public and private facilities; because taking reliability into account with this incorporation becomes an effective way to an effective way to hedge against disruptions in the system. Jabbarzadeh et al. (2014) propose a model that aims to determine the strategic location and tactical allocation decisions for a deterministic four-tier supply chain, then the researchers extend the model to incorporate robustness into the design.

Applications of Simulation for Designing Robust and Resilient Supply Chains

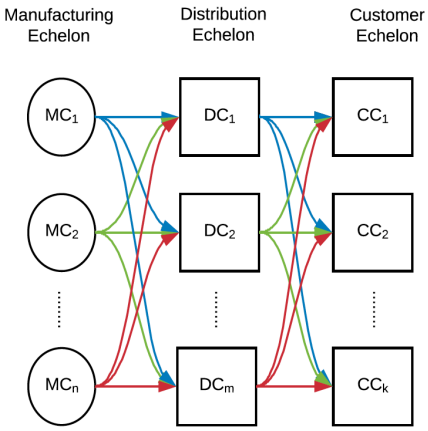
The discrete event, Monte Carlo, and agent-based simulation methods have been used to quantify risk and model the performance of robust and resilient supply chain systems. Strategic inventory at the manufacturing sites and having multiple suppliers of components are two crucial risk mitigation strategies, and Sirivunnabood and Kumara (2009) develop an agent-based simulation model to compare the effectiveness of these strategies. Their results delineated that disruptions with longer durations are best assuaged by multiple suppliers while disruptions with short durations are best mitigated with strategic inventory while. Deleris and Erhun (2005) build a simulation model with four stages. The first stage is to model the risk of specific disruption occurrences and severities with a Poisson process. The second part, which is called operations model, considers the interactions among the network and can be utilized to observe how risks perpetuate through the network. Then, a general semi-Markov process (GSMP) model is used to integrate the disruptions with operations models. In the last element, a Monte-Carlo simulation model is employed to obtain probability distributions of total losses.

Deleris and Erhun (2005) conduct research to measure network vulnerability through loss of volume. They first identify weaknesses by estimating their probability of occurrence and severity of disruptions, then analyze the consequences of these vulnerabilities on the supply chain through a network model. Afterward, they use a Monte-Carlo simulation to quantify the risk and develop mitigation strategies. Discrete event simulation is also used to assess disruption risks using user-defined probability distributions. For example, Schmitt and Singh (2009) propose a research method to determine current levels of disruption risk, test multiple mitigation strategies, and identify redundancies that can be removed without jeopardizing the performance of the supply chain. The disruption risks considered in this model include component shortages (operational), and political instability. Peng et al. (2014) propose a system dynamics model to analyze the behaviors of disrupted disaster relief supply chains. They define and test different replenishment solutions combined with three inventory planning strategies with lead time uncertainties.

CONCEPTUAL DESIGN

In this conceptual framework, we consider a multi-echelon supply chain given in Figure 2 (e.g., manufacturing, distribution, and customer echelons) where disruptions may occur at any stage.

Figure 2: Multi echelon supply chains

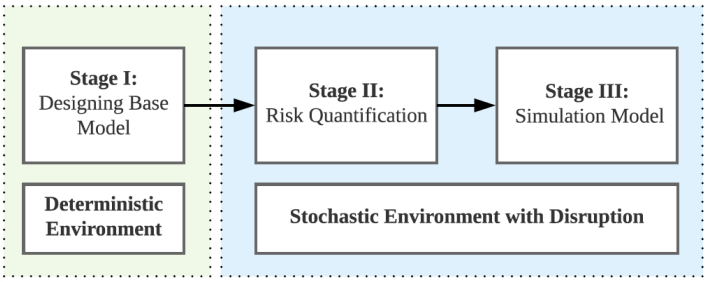


Our primary goal is to design robust (strong) and resilient (elastic) supply chain systems that can mitigate disruptions by adaptively changing the product flow among the centers at various echelons.

General Framework

Although there are multiple ways to design a resilient and robust supply chain (e.g. stochastic programming) systems, our proposed approach is to use deterministic programming and then introduce stochasticity through simulation to model the disruption risk. This approach is simple to frame and easy to solve. The first step to designing such a network is to build a base model using linear programming and then come up with alternative models by incorporating several mitigation strategies (e.g., node redundancy or strategic inventory). Afterward, the performance of these several design strategies can be tested employing discrete event and Monte Carlo simulation methods. We propose that the first stage is to identify a base model using mixed integer programming techniques. It is expected that the base model would require various types of information such as the locations of manufacturing, distribution, and customer echelons, and the transportation times among all these echelons. Then, the base model can determine the best product flow among echelons. However, establishing the base model is just half the equation because disruptions can disable various centers (e.g., manufacturing) located in different echelons. Thus, a mitigation strategy, which will determine the new product flow until the impact of disruption is faded away, is necessary. To be able to decide on the mitigation strategies, one first needs to model to disruptions using probability distributions.

Figure 3: General conceptual framework



Building the Base Model

Supply chain network design has been studied in both supply chain management and logistics fields. The problem entails selecting centers (i.e., node or sites) to install manufacturing plants, distributions warehouses, and assigning customers to customer centers (i.e., serving facilities). The network design problem also determines the optimum connectivity among the nodes at each echelon and identify the best product flow. We think that such a model, which we name it as the “base model” is necessary to determine the initial network design and create the product flow without considering disruptions. Such a base model can be built using mixed integer programming with an objective function of minimizing the total fixed and transportation costs utilizing the estimated demand across different locations where the business has a footprint. We also think that multi-objective optimization that also tries to maximize the customer satisfaction levels can be incorporated into the base model. The base model has one primary constraint, demand satisfaction for the centers located at different echelons. This problem can be sold either using tools like CPLEX or Lingo, as well as meta-heuristics techniques (e.g. genetic algorithms) that can be coded using programming languages such as Python and Matlab. The

output of the base model, which is product flow and the number of facilities in each echelon, can be used to test the mitigation strategies (e.g., excess capacity and inventory).

Quantifying Risks

We suggest that to be able to quantify risk, researchers must collect data regarding the past disruptions in every center located at each echelon. This previous data, then, can be used as an input to several prediction models that can predict rare events (e.g., Bayesian approached) or simulation models such as Monte Carlo. We propose, as implemented by Schmitt and Singh (2009), that researchers model disruptions at each node (e.g. manufacturing center) independently, and that the performance of any downstream nodes may be impacted by upstream disruptions. We propose that there will be different sources of uncertainty that constitute a disruption event (e.g., severity). We suggest that one can incorporate these uncertainties using Monte Carlo simulation. The first thing is to use the past data to decide the distribution of the disruptions and determine its parameters. Keep it in mind that the disruption probability distribution can be different for each node. We propose the following parameters with varying distributions of probability for any disruption:

- Severity
- Duration
- Time to Recovery

After one can determine the probability distributions for each of the above parameters for each disruption using either Monte Carlo simulation or Bayesian approaches, various mitigation strategies can be tested for the base and alternative supply chain designs.

Measuring Effectiveness of Designed Network

We propose that the best performance indicator of any supply chain design will be profits. Thus, we suggest that the data collected through the simulation model must be compared for each robust and resiliency strategies incorporated with the base model. For example, users can integrate postponement and strategic placement capacity at the same time, and compare the overall profits of these two mitigation strategies using ANOVA.

Table 2: Example Mitigation Strategies

Disruption Mitigation Strategy	Description
Postponement	Custom configurations of products should be delayed
Multi-sourcing	Critical components should be supplied using several suppliers
Strategic Inventory	Spare inventory should be placed at different echelons of a supply chain
Strategic Capacity	Spare capacity should be allocated at different echelons of a supply chain
Dynamic Pricing	Shift demand away from product that is disrupted

It is also imperative that users need to account for the cost of implementing mitigation methods. For instance, if the cost of using spare capacity more than using strategic inventory, then this cost must be included in the overall profit calculation. The best mitigation strategies can be selected as those that give the highest profits.

SUMMARY, CONCLUSIONS, AND RECOMMENDATIONS

In this theoretical study, we have emphasized the importance of designing robust and resilient supply chains, especially in this volatile environment where stability is not always guaranteed after disruptions. In our literature review, we have identified the best mitigating strategies to make supply chains both strong and flexible using optimization, simulation, and risk quantification. These mitigation strategies include strategic inventory, excess capacity, and multi-sourcing. In our conceptual framework, we have proposed the following general steps:

1. Build a base model first without the consideration of disruptions
2. Model the probability distributions of disruptions and identify their parameters (e.g., Monte Carlo Simulation)
3. Select several disruption mitigation strategies that will make the network more robust and resilient
4. Use discrete event simulation to test the performance of the proposed network system with mitigation strategies, and employ statistical analysis (e.g., ANOVA) to compare and contrast the candidate supply chain networks

We believe that this literature review and conceptual framework can be employed to build a practical robust and resilient supply chains. As part of our future studies, we plan to use our conceptual design in an empirical study to create a supply chain network to determine the best strategies that will make the system robust and resilient.

ABSTRACT

Social cost is a factor that has been widely considered in social and economic development activities. For any infrastructure projects that has a bearing on the general public, great attention should be paid to any potential social negative effects arising from the mishap thereof. This paper presents a set of social-cost-based attributes for bid evaluation of BOT infrastructure project concession candidates. In case of known weighted attributes, the bid evaluation committee can develop a model for bid evaluation of concession candidates based on interval numbers and grey relational analysis, if it faces uncertainties concerning the attributes themselves and the owner's preference for concession candidates. The ranking of concession candidates can be done by obtaining grey correlation for interval numbers through the distance between interval numbers. This social-cost-based model is set to contribute to less social costs by forcing a concession candidate to work out a more reasonable operational scheme. Meanwhile, uncertain information for decision making is offset by interval numbers, leading to more practical evaluation results.

KEYWORDS: Infrastructure project, concession candidate, bid evaluation, social cost

INTRODUCTION

As a form of project financing for infrastructure construction by way of absorbing foreign capital or social capital, BOT has been widely used. To select a desired BOT concession candidate in the infrastructure project is not only a most important decision the Owner has to make, but also one of the key factors concerning the success of a project (Wang et al. 2012).

In fact, the study on concession candidate selection is a derivative from the mainstream research on project contractor selection (CSn) (Holt 1998). Different in research object, they both in essence deal with typical multi-attribute decision problems involving multiple factors, indexes and levels. The solution to this kind of problems rests with two critical factors, namely,

selection criteria and selection approaches (including the approaches to determine index weight and solve the multi-attribute decision problems). With the enhancement of environmental awareness and sustainable development concept, the concept "social cost" early put forward by some researchers has been attracting the attentions of the public, academia, and government in a great way; especially in Western developed countries, social cost is a factor that has been widely considered in social and economic development activities(Gilchrist & Allouche 2005). For any BOT infrastructure project that has a bearing on the general public, its construction and operation is bound to imposing adverse impacts on ecological, economic and social and other aspects of the surrounding areas, which will evolve into the social cost (the common concern of the project's sponsor, investor and the public) in the end and give rise to social negative effects (Gilchrist & Allouche 2005). Therefore, incorporation of "social cost" into the criteria for bid evaluation of concession candidate is a new issue worthy of studying (Wang et al. 2008). Accordingly, there are still two problems to be solved: on the one hand, how to measure the China's "social cost" in criteria for bid evaluation of BOT project concession candidate, on the other hand, how to deal with the uncertain information. The researches on social cost in recent 20 years in western academia show that, measurement of social cost is complicated and not so accurate.

Social cost evaluation is very necessary for pushing the concession candidates to develop more reasonable project schemes and be more conscious of social benefits of project investment. Moreover, the smooth construction of the project can be assured due to pre-estimation and control of social costs (Wang et al. 2008). Given the above, this research presents a set of social-cost-based attributes for bid evaluation, based on analyses for concession candidate's capacity and quality, as well as evaluation indexes. In case of known weighted attributes, the bid evaluation committee can develop a model for bid evaluation of concession candidates based on interval numbers and grey relational analysis, if it faces uncertainties concerning the attributes themselves and the Owner's preference for concession candidates. The ranking of concession candidates can be done by obtaining grey correlation for interval numbers through the distance between interval numbers.

ESTABLISHMENT OF SOCIAL-COST-BASED ATTRIBUTES

Literature review

Selection of evaluation criteria has always been a hot issue among research topics. A research report titled Infrastructure Concessionary Design and Conferring issued by the World Bank in 1998 points out that: one of critical factors for a successful BOT project is the reasonably designed approach to confer a concession, but criteria selection can be based on two aspects, i.e., technology and financing (Michel et al. 2008). Seen from the time series of researches on criteria for bid evaluation of BOT project concession candidate, Dias, Marcus and Zhang Xueqing made outstanding achievements in this regard. Dias determined the importance of specific indexes by virtue of questionnaire surveys, and suggested evaluating the capacity of the concession candidate based on internationalization characteristics, production capacity, financing capability, team ability, technical competence, and contribution to the project's locality (Dias & Ioannou 1996). Based on a large number of empirical studies for the British Government and private sectors in 2004, Ahadzi believed that, organizational characteristics and advantages, project proposal and financial capacity should be the three main aspects to measure the abilities of concession candidates (Ahadzi & Bowles 2004). The current relevant researches in China basically cited or referred to the research results from Zhang Xueqing. He successively researched the current situation and defects with regard to the criteria and

approaches of Hong Kong Government for selecting the concession candidates during 2001-2005, and put forward detailed and well exercisable criteria for bid evaluation of BOT project concession candidate based on plenty of questionnaires in Hong Kong and the UK, which include financing standards, technical standards, health, safety and environmental standards, and management standards (4 dimensions, 92 elements) (Zhang et al. 2001 2002 2004 2005). Recently, although the social and economic environment has changed greatly, the criteria for bid evaluation of BOT project concession candidate have not yet, which still focused on financial, management, technical, health, safety and environmental project, with the only difference lying in the selection and adjustment of observational variables according to different types of project.
The researches on "social cost" as a consideration for "contractor" selection are numerous in many countries but rare in China. Allouche argues that, the social cost referred to the cost that could not be included into the direct and indirect construction cost according to the contract in the construction process of the project, which included 4 aspects, i.e., natural environment, human society, public property, and regional economy (Allouche et al. 2000). This macro definition covers all aspects to be considered in measurement of social cost, and many relevant specific researches are made within this scope. In conclusion, foreign scholars' researches on measurement of the engineering project's social cost mainly focused on following aspects (Gilchrist & Allouche 2005): (1) Output value loss. This cost estimation largely concentrated on the project's construction process' impacts on normal production or operation of surrounding enterprises and public institutions, which measured the corresponding value loss incurred at current market price by output loss. (2) Human capital. This aspect of researches focused on the human's production capability imposed by the project, which mostly measured the project's adverse impacts on human's health and income, involving currency loss arising from construction accidents, unemployment, as well as decline in income, physical and psychological health and environmental quality. (3) Replacement cost. It refers to the cost to replace the original facilities destroyed by construction of new projects, such as the replacement cost caused by destroying the structure of existing facilities, and increasing the service load of relevant roads due to road occupancy in the process of project construction. (4) Opportunity cost. Estimation of opportunity cost is mainly related to the behaviors violating the rights of citizens, such as loss in social public rights arising from forcible occupancy of cultivated land and illegal demolition and other reasons (the qualitative evaluation generally). (5) Road closure cost. It mainly measures the cost from the adverse impacts on pedestrians due to closure of road under construction, the cost from traffic delays, traffic control and management needs during the construction, as well as the cost lost due to decrease of commercial trading volume thereby. (6) Traffic delay cost. It refers to the value loss caused by traffic jams and decline in travel speed during the project's construction. The aforesaid analyses do not cover all evaluation and measurement of social cost, for example, the social cost value full-prediction model put forward by American Water Works Association (AWWA) also supported the social cost observation. Thus it can be seen that, the observation for social cost can be achieved, and relatively mature foreign research results shall be absorbed and followed.

Establishment of bid evaluation attributes

Based on the above analyses and in order to better link the researches with practices, this research, based on existing research results, classifies the attributes for bid evaluation of concession candidates into five categories: finance, management, technology, health, safety and environment as well as social cost, aiming to determine the observation elements suitable for China's actual situations through discussions with relevant researchers and personnel engaged in this field. Under the comprehensive, scientific and measurable principle, combined

with chrematistics of the BOT project, this research finally builds a bid evaluation attribute set covering 5 bid evaluation attributes and 29 observation elements. See Table 1 below for more details.

Table 1 Attributes for Bid Evaluation of BOT Project Concession Candidates

Bid evaluation attribute	Observation element
Financial position	6 observation elements: Working capital, net capital, project financing amount and financing plan, concessionary price and adjustment program, concessionary period, and the extent requiring government guarantee
Management capability	7 observation elements: Qualification, experience and performance of management organization, project management capability, organizational culture and structure, resource allocation capability, human resources allocation, communication and coordination capability, risk management capability
Technical capacity	7 observation elements: Qualifications, experience and performance of key design and construction personnel, capability of design units and subcontractors, information system, construction scheme and assurance capability, project transfer scheme, operation and maintenance scheme
Health, safety and environment capability	5 observation elements: Qualifications and experience of health, safety and environmental personnel, previous health and safety performance, previous environmental performance, safety and health management measure, environmental protection program
Social cost	5 observation elements: output value loss, human capital, replacement cost, opportunity cost, road closure cost, and traffic delay cost

In Table 1, there are good evaluation approaches for the observations of the first four bid evaluation attributes both in practice and academia. For example, the working capital can be measured by difference value between current assets to current liabilities to further reflect the evaluation object's capability to generate cash; the information system can be measured by information technology equipment rate (total informatization input/fixed-asset investment), so as to judge the informatization degree of the evaluation object; some qualitative indexed such as management capability, guarantee extent, qualification and experience may be determined by score by experts. However, the observation for social cost needs the incorporation of relevant foreign research results into China's actual situations. See details in Table 2.

Table 2 All Observation Elements of Social Cost and Evaluation Approaches

Observation element	Evaluation approach
Output value loss	Number of employer affected by the project × output per hour × production drawdown coefficient × project construction period
Human capital	To evaluate the currency loss arising from construction accidents, commercial loss, unemployment, as well as decline in health and environmental quality and others

Replacement cost	To fully evaluate all replacement expenses related to original facilities with physical accounting
Road closure cost	Road closure time in peak period × Unit cost of road closure in peak period + Road closure time in non-peak period × Unit cost of road closure in non-peak period
Traffic delay cost	Number of passenger per vehicle × Average delay time per vehicle × Average salary per hour × Salary percentage

Note: The production drawdown coefficient and salary percentage may be provided by certain industries.

ESTABLISHMENT OF MODEL FOR BID EVALUATION

In selection of BOT project concession candidates, the evaluation task is very hard (not easy to determine cost frontiers), since it is impossible for decision-makers to provide accurate figures corresponding to the evaluation attributes in Table 1, especially social cost. Therefore, the most effective approach shall be to combine expert's experience and existing research achievements (quantitative and qualitative assessment on observation elements) of bid evaluation committee and use uncertain numbers such as fuzzy number and interval number to conduct fuzzy evaluation for all bid evaluation attributes. In addition, the bid evaluation committee often conducts standard evaluation, but the complexity of objective conditions and the uncertainty of subjective thinking vary the demands of different Owners of projects, resulting in Owners' some subjective preference for concession candidates. That preference information can only be showed by a range instead of certain real number. For this reason, in case of known weighted attributes, the bid evaluation committee can solve the concession candidate selection problem based on multi-attribute decision of interval number and GAR, if it faces uncertainties concerning the attributes themselves and the Owner's preference for concession candidates. The most outstanding characteristic of this method is to be able to address uncertain information for decision making and solve the problem about multi-attribute decision of the Owner's preference for concession candidates.

Agreed symbols

The following symbols and variables shall be applied:

X —Alternative solution set, which is recorded as $X = (x_1, x_2, \ldots, x_m)$; m indicates the number of concession candidates.

U —Evaluation attribute set, which is recorded as $U = (u_1, u_2, \ldots, u_n)$; n indicates the number of evaluation attributes.

W —Pre-determined weighted attribute information set (all are real numbers), which is recorded as $W = (w_1, w_2, \ldots, w_n)$, of which $\sum_{j=1}^{n} w_j = 1, j = 1, 2, \ldots, n$.

a_{ij} —After evaluation of attribute u_j of concession candidate x_i, the bid evaluation committee can obtain the attribute values in interval number and record as $a_{ij} = [a_{ij}^L, a_{ij}^R]$ which shows the subjective preference of the bid evaluation committee for attribute u_j of concession candidate x_i.

θ_i —After the evaluation of concession candidate x_i, the Owner can obtain attribute values in interval number and record as $\theta_i = [\theta_i^L, \theta_i^R]$ $(i = 1, 2, \ldots, m)$ which shows the Owner's subjective preference for concession candidate x_i.

λ_{ij} —Grey relational coefficient, reflecting the level of similarity of objective and subjective preference of decision-maker under concession candidate x_i for attribute u_j.

λ_i —Grey relational degree, reflecting the overall level of similarity of objective and subjective preference of concession candidate x_i for all attributes.

Bid evaluation procedures

Based on above description, ranking concession candidates can be done through using multi-attribute decision and GRA of interval numbers, in accordance with the following specific procedures:

(1) The bid evaluation committee appraises all bid evaluation attributes of a concession candidate in the form of interval number (based on synthetic judgment after collection of observation elements data) and lists an interval decision matrix *A*. The known bid evaluation committee appraises attribute u_j of concession candidate x_i and then obtains attribute value $a_{ij}=[a_{ij}^L, a_{ij}^R]$ in interval number. Therefore, after evaluation of n bid evaluation attributes of m concession candidates, the bid evaluation committee will obtain an interval decision matrix *A*:

$$A=\begin{bmatrix} [a_{11}^L, a_{11}^R] & [a_{12}^L, a_{12}^R] & [a_{1n}^L, a_{1n}^R] \\ [a_{21}^L, a_{21}^R] & [a_{22}^L, a_{22}^R] & [a_{2n}^L, a_{2n}^R] \\ & & \\ [a_{m1}^L, a_{m1}^R] & [a_{m2}^L, a_{m2}^R] & [a_{mn}^L, a_{mn}^R] \end{bmatrix}$$

(2) We normalize the interval decision matrix. Normalizing decision matrix is in order to eliminate the influence of indicative dimension, order of magnitudes and type of attribute on decision results, that is, to normalize attribute values. The normalization methods of interval decision matrix mainly include sum method, vector normalization method and max-min method. This research adopts the vector normalization method to normalize above decision matrix (Goh et al. 1996).

The method of handling profit attribute is

$$B_{ij}^L=\frac{a_{ij}^L}{\sqrt{\sum_{i=1}^{m}(a_{ij}^R)^2}} \quad \& \quad B_{ij}^R=\frac{a_{ij}^R}{\sqrt{\sum_{i=1}^{m}(a_{ij}^L)^2}} \tag{1}$$

The method of handling cost attribute is

$$B_{ij}^L=\frac{\left(\frac{1}{a_{ij}^R}\right)}{\sqrt{\sum_{i=1}^{m}\left(\frac{1}{a_{ij}^L}\right)^2}} \quad \& \quad B_{ij}^R=\frac{\left(\frac{1}{a_{ij}^L}\right)}{\sqrt{\sum_{i=1}^{m}\left(\frac{1}{a_{ij}^R}\right)^2}} \tag{2}$$

The normalized interval decision matrix is recorded as: $A'=([B_{ij}^L, B_{ij}^R])_{m\times n}$.And the attribute value $[B_{ij}^L, B_{ij}^R]$ can be regarded as objective preference of bid evaluation committee for attribute u_j of the concession candidate x_i.

(3) We compute the distance d_{ij} between interval number $[\mathrm{B}_{ij}^{L}, B_{ij}^{R}]$ and interval number $[\theta_i^{L}, \theta_i^{R}]$. Because objective and subjective preference are both uncertain information handled in interval number (subjective preference $\theta_i = [\theta_i^{L}, \theta_i^{R}]$, and objective preference $A' = [\mathrm{B}_{ij}^{L}, B_{ij}^{R}]$), we introduce the formula of distance between interval numbers:

$$d_{ij} = \sqrt{(B_{ij}^{L} - \theta_i^{L})^2 + (B_{ij}^{R} - \theta_i^{R})^2},\ i = 1,\ 2,\ \ldots,\ m,\ j = 1,\ 2,\ \ldots,\ n. \tag{3}$$

With above formulation, we will obtain the distance matrix $d_{m\times n}$ of interval numbers.

(4) We compute the grey relational coefficient between each concession candidate's objective and subjective preference. Grey Relational Analysis (GRA) is put forward by Professor Deng Julong in 1985, with the fundamental principle that: when statistics are showed by curves, the more all curves are parallel, the closer their variation trends are, and the bigger their level of similarity is. For this purpose, the formula of grey relational coefficient λ_{ij} between objective and subjective preference of concession candidate x_i for attribute u_j is

$$\lambda_{ij} = \frac{\min\limits_{i}\min\limits_{j}|d_{ij}| + \rho\max\limits_{i}\max\limits_{j}|d_{ij}|}{|d_{ij}| + \rho\max\limits_{i}\max\limits_{j}|d_{ij}|} \tag{4}$$

In the formula, ρ is an identification coefficient, $\rho \in [0,\ 1]$, and 0.5 is adopted there. With above formula, we will obtain grey relational coefficient matrix $\lambda_{m\times n}$.

(5) We calculate the grey relational degree of objective and subjective preference for all concession candidates, and sort all concession candidates thereof.

$$\lambda_i = \sum_{j=1}^{n} \lambda_{ij} w_j,\ i = 1,\ 2,\ \ldots,\ m. \tag{5}$$

The bigger λ_i is, the closer objective and subjective preference of a decision-maker for concession candidate x_i are, and the better concession candidate x_i is; otherwise, the concession candidate x_i is worse.

ANALYSIS OF NUMERICAL EXAMPLE

Basic information

In a certain city, BOT project selects concession candidates through open tendering. After pre-qualification, five tenders are selected. According to content of bidding documents, the five bid evaluation attributes of evaluation and award of bid during the bid of the project are: Financial position, management capability, technical capacity, the healthy, safe and environmental capacity, and social cost. Known conditions of the numerical example:

(1) the weighted attributes of all bid evaluations have been determined by the bid evaluation committee and the Owner after negotiation and expressed as $W = (0.26,\ 0.23,\ 0.20,\ 0.14,\ 0.17)$ in certain real numbers.

(2) the Owner's subjective preference for all concession candidates are expressed as $\theta_1 = [0.3,\ 0.5],\ \theta_2 = [0.2,\ 0.6],\ \theta_3 = [0.1,\ 0.4],\ \theta_4 = [0.3,\ 0.7],\ \theta_5 = [0.4,\ 0.9]$ in the form of interval number.

At last, the bid evaluation committee appraises all bid evaluation attributes of concession candidates by reference to collected observation elements data. The results of evaluation are given in the form of interval number as showed in Table 3.

Table 3 The results of evaluation of concession candidates by the bid evaluation committee

Bid evaluation attribute / Concession candidates	Financial position	Management capability	Technical capacity	Healthy, safe and environmental capacity	Social cost
T1	[7.2, 8.5]	[8.0, 9.5]	[7.0, 8.5]	[0.5, 1.5]	[7.0, 9.2]
T2	[5.4, 7.0]	[5.5, 8.2]	[6.4, 7.5]	[2.5, 3.5]	[6.5, 8.0]
T3	[6.5, 8.0]	[7.5, 9.0]	[5.5, 7.0]	[2.0, 2.5]	[6.3, 7.5]
T4	[5.5, 9.0]	[4.5, 7.0]	[6.0, 9.2]	[1.5, 2.5]	[8.5, 9.0]
T5	[6.0, 7.5]	[7.0, 8.5]	[5.0, 7.5]	[1.0, 3.0]	[7.0, 7.5]

Computational process

Step 1 According to evaluation values of all bid evaluation attributes of concession candidates in the form of interval number from the bid evaluation committee, the interval decision matrix A is listed as

$$A=\begin{bmatrix} [7.2,\ 8.5] & [8.0,\ 9.5] & [7.0,\ 8.5] & [0.5,\ 1.5] & [7.0,\ 9.2] \\ [5.4,\ 7.0] & [5.5,\ 8.2] & [6.4,\ 7.5] & [2.5,\ 3.5] & [6.5,\ 8.0] \\ [6.5,\ 8.0] & [7.5,\ 9.0] & [5.5,\ 7.0] & [2.0,\ 2.5] & [6.3,\ 7.5] \\ [5.5,\ 9.0] & [4.5,\ 7.0] & [6.0,\ 9.2] & [1.5,\ 2.5] & [8.5,\ 9.0] \\ [6.0,\ 7.5] & [7.0,\ 8.5] & [5.0,\ 7.5] & [1.0,\ 3.0] & [7.0,\ 7.5] \end{bmatrix}$$

Step 2 The interval decision matrix is normalized according to formula (1) and (2).To simply computational process, we select all profit attributes here, handle them and obtain a normalized matrix A':

$$A'=\begin{bmatrix} [0.4009,\ 0.6175] & [0.4218,\ 0.6409] & [0.3923,\ 0.6314] & [0.0833,\ 0.4045] & [0.3784,\ 0.5793] \\ [0.3007,\ 0.5085] & [0.2900,\ 0.5532] & [0.3587,\ 0.5571] & [0.4617,\ 0.9439] & [0.3514,\ 0.5038] \\ [0.3619,\ 0.5811] & [0.3954,\ 0.6071] & [0.3082,\ 0.5201] & [0.3333,\ 0.6742] & [0.3406,\ 0.4723] \\ [0.3063,\ 0.6538] & [0.2373,\ 0.4722] & [0.3363,\ 0.6834] & [0.2500,\ 0.6742] & [0.4595,\ 0.5667] \\ [0.3341,\ 0.5448] & [[0.3691,\ 0.5734] & [0.2802,\ 0.5571] & [0.1667,\ 0.8090] & [0.3784,\ 0.4723] \end{bmatrix}$$

Step 3 After calculations in accordance with formula (3), we can obtain the distance d_{ij} between interval numbers of objective and subjective preference for all bid evaluation attributes of concession candidates, and work out the following distance matrix $d_{m\times n}$ of interval numbers thereof:

$$d = \begin{bmatrix} 0.1549 & 0.1863 & 0.1606 & 0.2369 & 0.1114 \\ 0.1360 & 0.1015 & 0.1643 & 0.4319 & 0.1794 \\ 0.3184 & 0.3608 & 0.2402 & 0.3600 & 0.2512 \\ 0.0781 & 0.2362 & 0.0400 & 0.0566 & 0.2078 \\ 0.3612 & 0.3282 & 0.3692 & 0.2504 & 0.4283 \end{bmatrix}$$

Step 4 After calculations in accordance with formula (4), we can obtain the grey relational coefficient λ_{ij} of objective and subjective preference for all bid evaluation attributes of concession candidates, and work out the following grey relational coefficient matrix $\lambda_{m\times n}$ thereof:

$$\lambda = \begin{bmatrix} 0.6092 & 0.6363 & 0.6798 & 0.5652 & 0.7819 \\ 0.7273 & 0.8063 & 0.6732 & 0.3951 & 0.6474 \\ 0.4790 & 0.4438 & 0.5612 & 0.4444 & 0.5479 \\ 0.8705 & 0.5661 & 1.0000 & 0.9391 & 0.6041 \\ 0.4435 & 0.4704 & 0.4375 & 0.5489 & 0.3973 \end{bmatrix}$$

Step 5 After calculations in accordance with formula (5), we can obtain the following grey relational degree λ_i between objective and subjective preference for concession candidates:

$$\lambda_1 = 0.6738,\ \lambda_2 = 0.6745,\ \lambda_3 = 0.4941,\ \lambda_4 = 0.7907,\ \lambda_5 = 0.4553$$

From value λ, it can be seen that $\lambda_4 > \lambda_2 > \lambda_1 > \lambda_3 > \lambda_5$. And the five candidate concessions are sorted in order: $T_4 \quad T_2 \quad T_1 \quad T_3 \quad T_5$. Therefore, T_4 is judged as the best concession candidate.

CONCLUSIONS

For any BOT project, the degree of the realization of social benefits of the project rather than merely the project construction cost is what truly matters. The evaluation of concession candidates and the award of a concession is a decision-making process involving multiple factors, indexes and levels. This paper creatively includes social cost into the standard for bid evaluation of concession candidates. In case of known weighted attributes, the bid evaluation committee can solve the concession candidate selection problem based on multi-attribute decision of interval number and GAR, if it faces uncertainties concerning the attributes themselves and the Owner's preference for concession candidates. After introduction of distance between interval numbers, we work out the grey relational coefficient of interval numbers, obtain the grey relational degree of objective and subjective preference of bid evaluation committee and the Owner for concession candidates, and thus sort all concession candidates. The feasibility and effectiveness of the model have been proved through analysis of numerical example. Therefore, this model is set to contribute to less social costs by forcing a concession candidate to work out a more reasonable operational scheme. Meanwhile, uncertain information for decision making is offset by interval numbers, leading to more practical evaluation results.

This paper can be extended in the following aspects: (1) we can research the components of social cost in China's BOT project and discuss more accurate social cost observation method; (2) in this paper, the model for bid evaluation is established in case of known weighted attributes of bid evaluation of concession candidates. However, the weighted information cannot be sure in reality. We can consider expressing weighted attribute information in interval number or fuzzy number, and the scientificity of research results must be improved largely.

ABSTRACT

Many models have been built linking supply chain management (SCM) and financial performance. As inputs, these models have used a variety of information about the supply chain, but they have not treated analyst opinion about firm excellence in SCM as an input variable. Opinion is *controvertible* as it can be challenged. Gartner provides its opinion in an annual publication on the top 25 firms in SCM. This article examines the information in Gartner's list and its impact on stock returns of the listed firms. The article thus makes a novel contribution by exploring the SCM-finance link using controvertible information.

KEYWORDS: *Supply chain management, financial performance, event study methodology*

INTRODUCTION

The issue of the relationship between effective management of the supply chain and the financial performance of the firm has been studied from many perspectives precisely because understanding this linkage is very important to business managers (D'Avenzo, Lewinksi, & Wassenhove, 2003). As our literature review demonstrates in the next section, many different models and methodologies using a variety of input variables of supply chain performance and output variables of financial performance have been used to study this relationship. The diversity of models range from survey-based structural equation models where managers are asked about their subjective perceptions of supply chain and financial performance (Kroes & Ghosh, 2010) to time-series analysis of changes in accounting measures such as return on assets before and after the deployment of supply chain management systems (Dehning, Richardson, & Zmud, 2007) to event studies of the impact on capital markets of disclosure of information about disruptions to the supply chain (Hendricks & Singhal, 2003).

Given the effort that has gone into exploring the supply chain and financial performance link over many years, it is somewhat surprising that an important class of information has been largely ignored in studying this relationship. This class of information pertains to analyst opinion about the supply chain performance of firms. Analyst firms such as Gartner annually publish a list of who they believe are the top 25 firms in effectively managing their supply chain. We will refer to this list of the top 25 firms as the SCT25. Event study methodology can be used to examine if Gartner's disclosure of the SCT25 information has capital market impact or not. Our literature review indicates that only one study has been done of the value-relevance of the

SCT25 information using event study methodology (McCarthy & Nayar, 2010). However, as we argue later in this article, their methodology has significant flaws. McCarthy and Nayar (2010) essentially treat the SCT25 information as factual, such as an announcement of earnings or a new product by a firm, rather than as controvertible information. As opposed to facts, controvertible information is opinion which can be challenged by other people who hold a different opinion. Gartner's SCT25 list is their opinion of who they consider are the best firms in managing their supply chain. This opinion may not necessarily be shared by other analysts. Hence, we need to modify the standard event study methodology, which has historically been used to study the value-relevance of factual information, to apply it to that of controvertible information.

This article is the first to do a deep analysis of the information contained in the SCT25 list using a modified event study methodology that is appropriate for studying the value-relevance of controvertible information such as the SCT25 list.

LITERATURE REVIEW

The effectiveness of a firm in supply chain management (SCM) and its financial performance has been studied using a variety of methodologies and input and output variables (D'Avenzo et al., 2003; Presutti & Mawhinney, 2007). Input variables include some aspect of the design of the supply chain or an intermediate performance indicator or a discrete event affecting the supply chain. Thus, input variables could be the design of the supply chain to fit uncertainty, inventory turns, or the disclosure of information about an earthquake that puts a portion of the supply chain out of commission. Output variables include financial metrics such as ROA, ROI, and stock market return. With regard to designing the supply chain, Wagner, Grosse-Ruyken, and Erhun (2012) find that supply chains that are designed to fit uncertainty deliver a higher return on assets (ROA). In their model, the input variable of supply chain fit is managerial perception collected via a survey, the output variable is objective ROA data obtained from Bloomberg, and OLS regression is used to examine the relationship between the two.

The issue of the firm's sourcing strategy and the impact on financial performance is a staple research area and has been approached from many perspectives (Noordewier, John, & Nevin, 1990; Chen, Paulraj, & Lado, 2004; Kroes & Ghosh, 2010). Chen, Paulraj, and Lado (2004) find that having fewer strategic suppliers with whom sensitive information can be shared quickly results in greater customer responsiveness. This is in turn results in improved financial performance. All variables in their model are subjective managerial perceptions and they use structural equation modeling (SEM) as their methodology. Kroes and Ghosh (2010) examine whether the degree of alignment of a firm's outsourcing strategy with its competitive strategy affects supply chain performance, which in turn affects financial performance. Kroes and Ghosh (2010) use various intermediate performance indicators for assessing supply chain performance such as delivery and manufacturing cycle times, on-time delivery performance, and orders filled correctly. ROA and return on sales (ROS) are used as key measures of financial performance. All measures in their study are subjective managerial perceptions and they use structural equation modeling (SEM) to examine the dependence of financial performance on the alignment of outsourcing and competitive strategy. They find that the congruence of outsourcing and competitive strategy does improve supply chain performance and that in turn helps financial performance.

The connection between the use of information technology (IT), such as enterprise resource planning (ERP) systems and information systems for managing the supply chain, and financial performance of the firm has also been examined using different types of information and

methodologies. Vickery et al. (2003) use survey data, or managerial perceptions, to examine this link. Using structural equation modeling (SEM), they find that the use of IT in the supply chain does improve financial performance. It does so mainly indirectly by improving customer service. Unlike Wagner et al.'s study (2012), the financial performance measures of ROA, ROI, and ROS were managerial perceptions of how well the firm was doing with respect to the rest of the industry (Vickery et al., 2003). In another study of the financial impact of information systems such as ERP and SCM systems, Hendricks, Singhal, and Stratman (2007) find that adopters of information systems for SCM experience positive stock returns and improved profitability.

The use of IT to digitally integrate the supply chain allows for the quick transfer of information across the supply chain, which is necessary for just-in-time (JIT) production processes. Fullerton**,** McWatters, and Fawson (2003) show that firms that operate just-in-time (JIT) supply chains reap significant financial rewards. Dehning et al. (2007) also explore the link between the use of IT to manage the supply chain and financial performance. They use a time-series approach where they test for the change in financial performance measures, such as ROS and ROA, one year and two years after the implementation of an SCM information system relative to the financial performance one year before the implementation of the SCM system. They examine how much of the change in the financial performance measures is explained by the change in supply chain performance measures, such as the increase in inventory turns and decrease in selling, general, and administrative expenses (SG&A). They use general linear model (GLM) regression to explain changes in financial performance to changes in supply chain performance measures. Values of variables are based on secondary financial data, such as in SEC filings or other audited external data. They are not managerial perceptions. They find that the use of an SCM information system does improve supply chain performance in terms of increasing inventory turns and reducing SG&A expenses, which in turn improves overall financial measures such as ROA and ROS.

Another approach to study the link between the use of information systems, such as SCM and enterprise resource planning (ERP) systems, and financial performance is to use the event study methodology to gauge the short-term stock market reaction to announcements of the deployment of such systems (Hayes, Hunton, & Reck, 2001). These studies find statistically significant positive abnormal returns to supply chain-related IT investment announcements. Hendricks and Singhal (2003) use the event study methodology to examine the effect of announcements of disruptions to the supply chain on the firm's stock price. In another study employing event study methodology, Hendricks and Singhal (2009) examine how information about inventory build-up in the supply chain can affect stock market performance.
The wealth of studies targeted at exploring the SCM-finance link testifies to the critical importance of this relationship. It underscores the importance to firms of building a distinctive competence in SCM. However, developing a superior capability in SCM is not a simple proposition. It is a complex challenge involving different dimensions such as strategy, business process, and technology. In terms of strategy, Christopher and Ryals (1999) underline the importance of having a corporate-wide strategy for the supply chain that embraces all the business units. At the business process level, new processes and practices such as collaborative planning, forecasting, and replenishment, or CPFR, must be implemented to ensure that the entire supply chain works in unison (Petersen, Ragatz, & Monczka, 2005). These business practices also include innovations such as vendor managed inventory (VMI) (Niranjan, Wagner, & Nguyen, 2012). These new business processes are necessary to ameliorate the bull-whip effect which leads to a pile up of inventory in the upstream portion of the supply chain (Lee, 2010).

Information systems such as supply chain management systems must be used at the operational level to facilitate the execution of strategy and the implementation of best practices (Gunasekaran & Ngai, 2004). Firms must also master a range of complex information technologies to facilitate the integration of information systems of various organizations in the supply chain. This complex IT includes XML and Web Services (Krafzig, Banke, and Slama, 2005; Erl, 2006) for integrating software applications such as enterprise resource planning (ERP) and materials requirements planning (MRP) across the various business entities in the supply chain (Makris & Chryssolouris, 2013). Firms setting out to improve their supply chains are clearly facing a complex multi-facetted challenge with ramifications for strategy, business process, and technology.

Given the daunting challenge of effectively mastering how to manage the supply chain, it should come as no surprise that firms would look to exemplars in SCM and try to emulate their strategies and business practices. But how are these exemplars in SCM capability to be found? Analyst firms who publish their opinion on the best firms in SCM is a source that businesses rely on when seeking exemplars. Gartner, one such analyst firm, publishes the SCT25 list annually where it identifies the 25 best companies worldwide in SCM. But Gartner's list cannot simply be taken as an article of faith. The question must be asked whether Gartner has indeed correctly identified the best firms in SCM. The list after all represents Gartner's opinion of the best firms in SCM. A different analyst may have a different opinion. Gartner's SCT25 list is thus *controvertible* information as other analysts can challenge Gartner's opinion. The methodology of event study can be used to examine if the disclosure of Gartner's SCT25 list indeed pushes up the stock prices of firms listed in the SCT25. If it does, then Gartner's SCT25 list can be said to contain valuable information or that the information has value-relevance.

Our literature review revealed that there has been only one study published of examining the value-relevance of the SCT25 information. This was a conference proceedings paper by McCarthy and Nayar (2010), which perhaps indicates that their research was still at an early stage. There are significant methodological errors in McCarthy and Nayar's study (2010). First of all, McCarthy and Nayar do not treat the SCT25 list as controvertible information. They use the standard two-day window to study the stock market impact of the SCT25 list without taking into account the fact that other analysts can refute or at best partially agree with Gartner's opinion in the industry discussion that occurs in the days following the release of the SCT25 list. But to assess if the SCT25 information is truly value-relevant, it is necessary to consider both Gartner's opinion and those of other analysts, which might indeed be somewhat different from Gartner's.

Gartner's release of the SCT25 list might have initially pushed up the stock prices of the firms featured in that list but as more analysts express their opinion, which might be partially opposed to Gartner's view, the initial stock market bounce that firms received might be reduced or eliminated. As this industry discussion typically occurs in the days following the release of Gartner's report, the event window must be larger than the standard [-1, 0] window typically used in event studies, where day 0 is the day the news appears in mass media and day -1 is the day before that. The day before is included in the window to account for the effect of leakage of information.

Given the controvertible nature of the SCT25 information, a larger window such as a window that is a week-long, which would then pick up the voices of other analysts in the industry discussion in the days following the release of Gartner's report would be more appropriate. It should be noted that Gartner representatives are also actively involved in these discussions. They defend and clarify their positions as they interact with the media and participate in various

industry fora. Hence, a full understanding of the information contained in the SCT25 list and its correctness, or the lack thereof, can only be obtained through having a longer event window and gathering the stock market returns over this longer window.

If a longer event window of several days is chosen, the issue of confounding events can no longer be avoided as it is typically done in the traditional event study methodology. McWilliams and Siegel (1997) have shown that ignoring confounding events can put the results of the study in peril. In fact, they show that in a few cases, the results of the study would actually change if confounding events were to be taken into consideration. In addition to the methodological problems in McCarthy and Nayar's (2010), the time frame of their study covers only the years 2004 to 2008, whereas our study covers the years 2008 to 2014. The SCT25 report was first published in 2004. Also, there was no publication in the year 2006.

The focus of our study is not so much on value-relevance of the SCT25 information, per se, but it is on a deeper analysis of how the information contained in the SCT25 list drives the stock market reaction. Value-relevance is simply about whether the SCT25 information moves capital markets or not. In other words, whether being in the SCT25 list results on average in a positive bounce in the stock prices of the firms in the list. Basic value-relevance is simply a byproduct of the hypotheses tested in this study. The SCT25 list contains more than just binary information of whether a firm is in the list or not. The SCT25 list is also ranking the firms. The change in the ranking of a firm from one year to the next is important information as well. One could hypothesize that the improvement in the rank of a firm from one year to the next, assuming the firm features in the SCT25 list in both years, should result in a positive stock market return. This would be the case if the SCT25 list is indeed doing a good job in identifying the best firms and ranking them relative to each other. One could also hypothesize that getting on the list the very first time, even if it is at the very bottom or at the rank of 25, should create a greater stock market impact than an improvement in rank in a later year. If the list is legitimately identifying the best firms in SCM globally, then being recognized the first time as one of these top 25 firms out of the universe of firms worldwide should be a great achievement that would cause quite a stir in the stock market.

We can thus formulate a set of hypotheses about the total information contained in the SCT25 list. If these hypotheses are indeed borne out in the way they are expected to be, then that lends a great deal of credence to the information in Gartner's SCT25 list. McCarthy and Nayar (2010) also tested a set of hypotheses about the information in the SCT25 list, and we base some of our own hypotheses on those that they tested. However, our hypotheses are tested using data from the larger time frame of 2004 to 2014. Also, as we have noted, there are serious methodological problems in McCarthy and Nayar's study (2010) as they did not treat the SCT25 as a disclosure of controvertible information necessitating a longer event window and a correction for the occurrence of confounding events in the long window. This study assumes a window of [-1, +7] and corrects for confounding events occurring in that window.

THEORETICAL DEVELOPMENT

Hypotheses

Different firms in the SCT25 list experience different stock market returns in any given year in which they feature on the SCT25 list. Clearly, a key driver of the magnitude of the return experienced by a firm should be an improvement in the rank of the firm from one year to the next, assuming the firm appeared in the list in both years. A larger improvement in rank should result in a greater return. The firm at the top of the SCT25 list, or the best firm among the 25,

has a rank of 1 and the firm at the bottom has a rank of 25. The improvement in rank from the previous year to the current year is defined as the difference between the previous year's and the current year's rank.

Hypothesis 1: *The abnormal stock return that a firm receives from appearing in the SCT25 list is positively related to an improvement in the rank of the firm from the previous year to the current year.*

Furthermore, if a firm reappears in a given year in the same position as it was in the previous year, and thus there is no improvement in rank, it is arguable that there should still be some value associated with the reaffirmation of the firm's status as one of the top 25 firms worldwide in SCM. Therefore, we posit:

Hypothesis 2: *There is a positive abnormal stock return associated with reappearing in the SCT25 list in a given year even if there is no improvement in the firm's rank from the previous year*.

We have stated before that Gartner's list of the top 25 companies worldwide who excel in managing their supply chain is opinion and a different analyst can have a different view. Opinion therefore always has a built-in credibility problem. Because there is always some doubt about the veracity of opinion, a rational investor before rushing out and purchasing the stock of firms in the SCT25 list can be expected to also consider other established metrics of SCM excellence, particularly those that are objective rather than subjective measures. A firm's cash-to-cash cycle (CCC) has long been viewed as an important metric of how good firms are at managing their supply chains, at least with respect to the management of cash flows. The smaller the CCC, the better is the firm at managing its supply chain (Hutchison, Farris II, & Anders, 2007; Akgün & Gürünlü, 2010). Large negative values of CCC such as -50 or -100 imply that the firm is even better at managing its supply chain with regard to cash flows. Cash-to-cash cycle (CCC) is defined as:

$$\text{cash-to-cash cycle} = \text{days sales outstanding} + \text{days inventory outstanding} - \text{days payables outstanding} \quad (1)$$

CCC's definition implies that firms should not only delay payment of their accounts payables but should also quickly collect on accounts receivables while maintaining minimum inventory. It should be underscored that CCC is reflecting only one facet of SCM capability and being good at managing cash flows does not necessarily mean that the firm is good at something else, such as the use of IT to digitally integrate the supply chain. Still, a rational investor can be expected to look for other signs of confirmation of Gartner's signal of the SCM exemplars in these other established metrics of SCM excellence such as CCC.

It is arguable that if Gartner's signal of the SCM ability of a firm is aligned with the message that established metrics such as CCC send about a firm's SCM performance, then Gartner's opinion can have a larger impact on the stock return for that firm. Gartner's opinion and the established objective measures are in synchrony and thus have a synergistic effect in boosting the firm's stock price. Similarly, if Gartner's signal and the established metrics were not that well-aligned or were in opposition for a firm, then the stock return for that firm to Gartner's signal could be expected to be more muted. Gartner's signal of SCM excellence in each year is essentially delivered in the form of an improvement in the rank of the firm in that year from what was reported in the previous year. Hence, we are arguing that the impact of the improvement in rank on the stock return for the firm can be amplified or weakened depending on the firm's CCC. The

smaller the value of CCC, the more is the amplification, since small CCC values imply superior SCM capability. Also, as we have mentioned, a negative value for CCC is even better and it fits the definition of being an algebraically smaller number. This results in the following hypothesis:

Hypothesis 3: *The abnormal stock return of an improvement in the rank of the firm in the SCT25 list is moderated by key objective measures of SCM capability such as the firm's CCC. If two different firms in the SCT25 list experience the same improvement in rank, then the abnormal return will be larger for the firm with the smaller CCC or the more negative CCC.*

The next two hypotheses focus on the circumstances of a firm's appearance in the SCT25 list. One could expect a difference in the stock market reaction between a firm's first appearance in the SCT25 list versus a reappearance. There is evidence that the market responds more to information that is novel than to information that is partly anticipated (Malatesta and Thompson, 1985). If news that is novel has more impact, then one could argue that a firm's first-time listing in the SCT25 list should cause a greater stock-market reaction than a continuing listing. Of course, the exception to this would be if the continuing listing were to be accompanied by a large increase in rank, which means that the firm substantially improved its position relative to the other firms in the group of 25 exemplars. But if the continuing listing is not accompanied by a large improvement in rank, and the improvement in rank in the continuing listing was only of one step, then one could argue that the first-time listing even at the bottom of the ladder should be better than the continuing listing. Hence, we posit:

Hypothesis 4: *The abnormal return on a firm's stock upon a first-time entry into the SCT25 list, even at the lowest rank of 25, is better than the return accruing to the firm in a continuing appearance with a one-step improvement in rank.*

Hypothesis 4 stems from the novelty of being named the first time in the very exclusive club of the top 25 companies in the world which excel at managing their supply chains. There is however another aspect of information novelty that plays a role in determining stock market reaction to the SCT25 information. This is the erosion of novelty that occurs as the firm appears again and again in the SCT25 list over the years. The larger the number of times the firm appears in the SCT25 list, the more anticipated its presence on the list becomes thereby reducing the stock market bounce the firm gets from appearing in the list. Hence, to capture this aspect of the gradual erosion of novelty that occurs from repeatedly featuring in the SCT25 list, we formulate the following hypothesis:

Hypothesis 5: *The number of times a firm has previously been on the SCT25 list is negatively related to the abnormal stock return the firm receives from being listed in the SCT25.*

Methodology

These hypotheses are tested using the procedure of hierarchical regression. We introduce the following variables:

$\overline{AR} =$ This is the dependent variable in the hierarchical regression models. It is the average abnormal return over the event window [-1, +7] for a given firm's stock in the SCT25 list in a given year after removing the days in the window when confounding information disclosures are made about that firm. Confounding events correspond to major public disclosures, such as earnings announcements, and these events are given the standard [-1, 0] window.

$\Delta Position$ =	The improvement in the rank of a firm in the SCT25 list in a given year as measured by (previous year rank – given year rank). The firm in the topmost position in the list has a rank of 1 and the firm in the last position has a rank of 25. For this computation, if a firm is not in the SCT25 list in any year, then its rank in that year is deemed to be 26.
CCC =	cash-to-cash cycle for the given firm in a given year. CCC is used as a control variable in the model.
X_{entry} =	1 for the case of a given firm appearing in the SCT25 list for the first time. It is 0 otherwise.
PrevTimes =	the number of times that a firm has appeared in the SCT25 list before the given year.

The first model in the hierarchical regressions that we estimate is:

$$\overline{AR} = b_0 + b_1 \Delta Position + \varepsilon \quad (2)$$

For Hypothesis 1 to be true, the coefficient $b_1$must test as statistically significant and positive in Equation (2). Hypothesis 2 implies that the coefficient b_0 must also positive in Equation (2). To test the moderating influence of CCC on the relationship between $\Delta Position$ and $\overline{AR}$, the second regression model estimated is:

$$\overline{AR} = b_0 + b_1 \Delta Position + b_2 CCC + b_3 CCC.\Delta Position + \varepsilon \quad (3)$$

Hypothesis 3 says that the firm with the smaller CCC will enjoy a greater stock market return for the same improvement in rank as compared to a firm with a larger CCC. From Equation (3), we obtain:

$$\frac{\delta E\{\overline{AR}\}}{\delta \Delta Position} = b_1 + b_3 CCC \quad (4)$$

Hypothesis 3 will be satisfied if the coefficient b_3 in Equation (4) is statistically significant and $b_3 < 0$ as that would indicate that a larger value for CCC reduces $\frac{\delta E\{\overline{AR}\}}{\delta \Delta Position}$. In other words, larger the CCC, the smaller is the increase in the expected average return $E\{\overline{AR}\}$ for the same improvement in position given by $\Delta Position$.

The next model focuses on the role that the specific circumstances surrounding a change in position in the SCT25 play in the magnitude of the stock market return. In other words, does the first-time appearance in the SCT25, even at the lowest rung of the ladder, result in a higher return than a continuing listing with a one-step improvement in rank. This regression addresses the moderating role that the indicator variable X_{entry} plays on the relationship between $E\{\overline{AR}\}$ and $\Delta Position$. Of course, if Hypothesis 3 is true, then we know that the relationship between $E\{\overline{AR}\}$ and $\Delta Position$ is already moderated by CCC. Thus, Hypothesis 4 brings a second moderator, which is the indicator variable X_{entry} into this relationship, where X_{entry} = 1 for a case of first-time entry and is 0 otherwise.

The regression model estimated for the test of Hypothesis 4 is:

$$\overline{AR} = b_0 + b_1 \Delta\text{Position} + b_2 CCC + b_3 X_{entry} + b_4 \Delta\text{Position} * CCC + b_5 \Delta\text{Position} * X_{entry} + b_6 CCC * X_{entry} + b_7 \Delta\text{Position} * CCC * X_{entry} + \varepsilon \quad (5)$$

If this regression is statistically significant, then the difference in the average stock return between getting on the SCT25 for the first time even at the lowest rank of 25 and a one-step improvement in rank in a subsequent year after having been on the SCT25 is given by:

$$E\{\overline{AR}\}_{first-time\ in\ SCT25\ at\ lowest\ rank} - E\{\overline{AR}\}_{one-step\ improvement\ in\ rank\ later} = b_3 + b_5 + (b_6 + b_7)CCC \quad (6)$$

The term $b_3 + b_5 + (b_6 + b_7)CCC$ could loosely be viewed as a measure of the relative value associated with the novelty of being named to the top 25 companies worldwide who excel in SCM.

The value of novelty of being listed in the SCT25 the first time will gradually erode if the firm continues to be listed on the SCT25 year after year. In the fourth regression model, we test Hypothesis 5 of the gradual erosion of the value of novelty by introducing into the model the number of previous times, denoted as *PrevTimes*, the firm has been on the SCT25. Hypothesis 5 would be established if the coefficient $b_4 < 0$ in the following model:

$$\overline{AR} = b_0 + b_1\Delta\text{Position} + b_2CCC + b_3X_{entry} + b_4PrevTimes + b_5\Delta\text{Position} * CCC + b_6\Delta\text{Position} * X_{entry} + b_7CCC * X_{entry} + b_8\Delta\text{Position} * CCC * X_{entry} + \varepsilon \quad (7)$$

RESULTS

The list of the Top 25 supply chain companies from 2004 through 2014 produced by Gartner was partly obtained from McCarthy and Nayar (2010), which had the data from 2004 through 2008, and partly from various vendor web sites. Table A.1 in Appendix A gives the consolidated rankings of the firms in the SCT25 list over the 2004 to 2014 timeframe. Table A.2 in Appendix A shows the market-move dates of confounding information disclosures about the firms in the SCT25 list each year in the [-1, +15] window around the nominal publication date of the SCT25 report for that year. Although we used a [-1, +7] window, we had collected data on confounding events for a larger [-1, +15] window to test for the sensitivity of the results if a shorter [-1, +6] or a longer [-1, +8] window was used. All results remained robust to this marginal change in window size. The confounding event dates were obtained by searching the LexisNexis database. The standard two-day [-1, 0] window was allocated for discounting the confounding information by the capital markets.

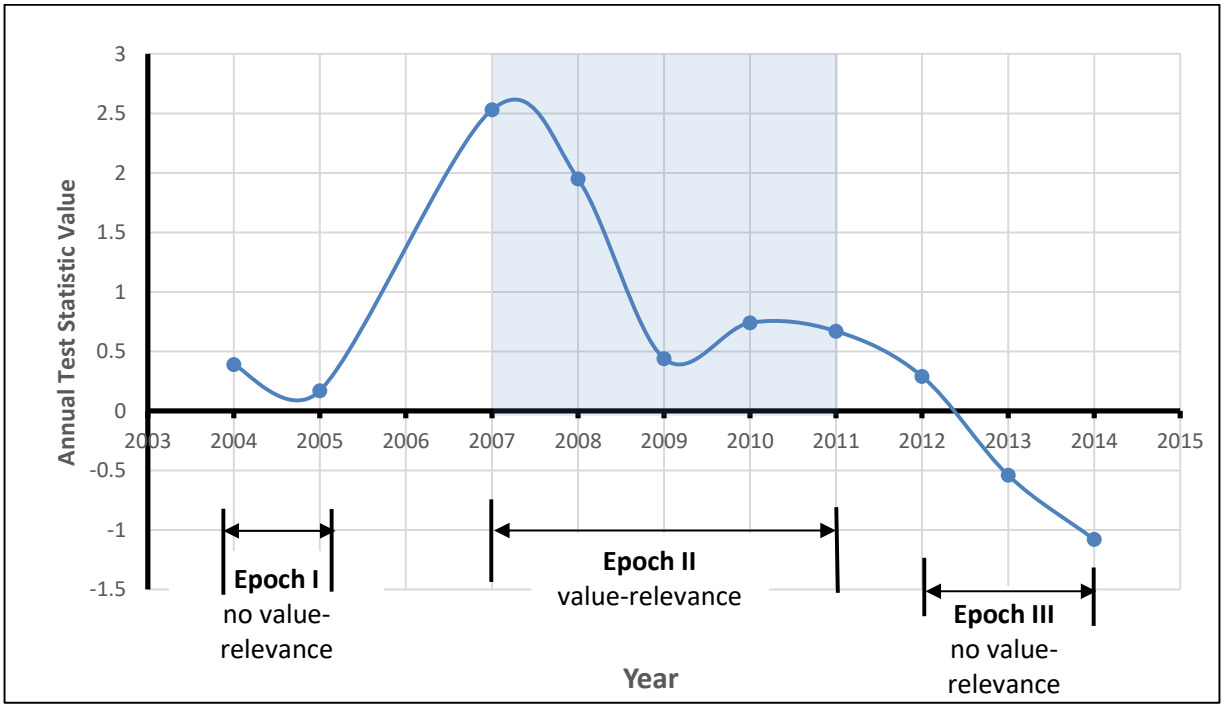
Epochs of Value-Relevance

An interesting result is that if the value of test statistic for value-relevance is computed on a yearly basis on plotted on a graph as shown in Figure 1, we observe that there are certain epochs in the 2004 to 2014 time frame of the study. In the initial two years 2004 to 2005, the value is low, and in the final three years 2012 to 2014, the value is also low and it steadily declines. In fact, if the 2004 to 2014 time frame is segmented into three epochs where Epoch 1 is 2004 to 2005, Epoch II is 2007 to 2011, and Epoch III is 2012 to 2014, the SCT25 information is actually value-relevant only in Epoch II. This result is actually not that surprising. Since the SCT25 information is opinion, clearly the analysts had to first build credibility for their opinion and the methodology used for developing their ranking. It should also be noted that when this report was first published in 2004, the authors were with AMR Research and not with Gartner, which is a larger and better-known analyst firm. Gartner actually purchased AMR Research in 2009 (Supply Chain Digest 2009), which gave the authors of this report a great deal of

credibility. But in the initial years, the authors did not enjoy the instant credibility that the Gartner acquisition brought them. Hence, it is quite plausible that in the initial years of the publication of this report, the market was assessing whether the opinion of the AMR Research analysts of the best firms in SCM actually correlated with reality. Once, the market was convinced that AMR Research's opinion was credible, the disclosure of the SCT25 information began to make a significant impact on the stock market from 2007 onwards.

The lack of value-relevance of the SCT25 information towards the tail-end of the 2004 to 2014 time frame, or in the 2012 to 2014 epoch, could arise from the necessity of updating the methodology Gartner is using to identify the best firms in SCM. Methodologies do need to be updated to account for changing business conditions. In the aftermath of the financial crisis of 2007 to 2009, many fundamental business assumptions have had to be revisited. Although the crisis arose in the financial services industry through an imperfect understanding of the riskiness of mortgage-backed securities, other industries have taken note of the wrong estimation of risk by professionals who should have been experts at doing this. Risk pervades all sectors of the economy and how well it is assessed and managed is certainly an element of superior supply chain management. Hence, many business models and assumptions across the board have had to be reexamined in the wake of 2007 to 2009 crisis. Hence, a plausible reason for the lack of value-relevance of the SCT25 information in the 2012 to 2014 epoch is that the methodology that Gartner is using in identifying the best firms in SCM may need updating. We use this result by focusing on the 2007 to 2011 epoch in examining the drivers of abnormal stock performance upon the release of the SCT25 information in the years in this epoch.

Figure 1: Epochs of Value-Relevance



Hierarchical Regressions

We employed the methodology of hierarchical regression to test Hypotheses 1 through 5. The succession of models tested follows the sequence described earlier in the section on the hierarchical regression models for assessing the differential market reaction to the stocks in the SCT25 list. Table 1 shows the sequence of models tested along with the p-values of the highest-order terms in each model. As shown in Table 1, Model 1 includes only the term $\Delta Position$ corresponding to the improvement in rank. As expected by Hypothesis 1, the improvement in the rank of a firm in the SCT25 list from the previous year to the current year is positively related to the abnormal return as the coefficient of $\Delta Position$ is significant and positive. Hypothesis 2 is also borne out because of the positive intercept in Model 1.

Hypothesis 3 is about the moderating role played by CCC on the relationship between an improvement in rank and the abnormal return on the firm's stock. Small positive or negative values of CCC, which indicate that the firm is doing well in managing its supply chain, would amplify the effect of an improvement in rank in the SCT25 list on the abnormal stock return. Large positive CCC values, which indicate that the firm is not doing that well in managing the supply chain at least with respect to cash flows, would reduce the abnormal return resulting from an improvement in rank. As argued in the section on Methodology, Hypothesis 3 is borne out if the coefficient of the interactive term $\Delta\text{Position} * CCC$ in Model 2 in Table 1 is statistically significant and negative. As Model 2 in Table 1 shows, the coefficient of $\Delta\text{Position} * CCC$ is statistically significant at the 0.01 level and it also has a negative value. This supports Hypothesis 3.

Model 3 addresses the issue of the relative value of novelty of the SCT25 information. In other words, does the first appearance of a firm in the SCT25 list even at the lowest rank of 25 result in a higher stock market bounce for its stock as compared to a one-step improvement in the firm's rank in a subsequent year after the firm has already been in the SCT25? We had argued previously that Hypothesis 4 is true if the coefficients in Equation (6), which corresponds to Model 1 in Table 2, are such that the inequality $b_3 + b_5 + (b_6 + b_7)CCC > 0$. Using the values of these coefficients from Model 3, we see that the inequality is satisfied if:

$$CCC > -9.3 \quad (9)$$

Thus, there is qualified support for Hypothesis 4 in that for firms with CCC greater than -9.3, the first-time appearance in the SCT25 list even at the bottom-most rung creates a greater stock market impact than a reappearance with a one-step improvement.

In the last regression Model 4 in Table 1, we add the final variable *prevTimes* corresponding to the number of times the firm has previously been on the SCT25. Both the coefficient of *prevTimes* and the higher order term $\Delta\text{Position} * CCC * X_{entry}$ remain significant in this final model. The coefficient of *prevTimes* is negative which supports Hypothesis 5 that as the firm continues to reappear in the SCT25, the event of being listed in the SCT25 becomes more anticipated resulting in a progressively smaller stock market bounce. It should be noted that the final significant model has an R^2 of 18%, which means the final model explains a non-trivial amount of the variance in the stock market return resulting from appearing in the SCT25 list.

Table 1: Hierarchical Regression Models

Model No.	Equation	P-values of High-order Terms	R^2	Adjusted R^2
1	$\overline{AR} = 9.11 * 10^{-4} + 2.137 * 10^{-4}\Delta\text{Position}$	$\Delta\text{Position}$ (0.0042**)	0.06574	0.05802
2	$\overline{AR} = 9.166 * 10^{-4} + 2.602 * 10^{-4}\Delta\text{Position} - 2.418 * 10^{-6} * CCC - 3.244 * 10^{-6}\Delta\text{Position} * CCC$	$\Delta\text{Position} * CCC$ (0.008489**)	0.1205	0.09831
3	$\overline{AR} = 9.42 * 10^{-4} + 2.437 * 10^{-4}\Delta\text{Position} + 8.672 * 10^{-7} * CCC + 2.782 * 10^{-4}X_{entry} - 1.072 * 10^{-6}\Delta\text{Position} * CCC - 1.092 * 10^{-4}\Delta\text{Position} * X_{entry} + 2.581 * 10^{-5}CCC * X_{entry} - 7.635 * 10^{-6}\Delta\text{Position} * CCC * X_{entry}$	$\Delta\text{Position} * CCC * X_{entry}$ (0.0151*)	0.1687	0.1181
4	$\overline{AR} = 3.165 * 10^{-3} + 2.007 * 10^{-4}\Delta\text{Position} + 5.746 * 10^{-7} * CCC - 1.945 * 10^{-3}X_{entry} - 7.428 * 10^{-4}PrevTimes - 1.463 * 10^{-6}\Delta\text{Position} * CCC - 6.621 * 10^{-5}\Delta\text{Position} * X_{entry} + 2.61 * 10^{-5}CCC * X_{entry} - 7.245 * 10^{-6}\Delta\text{Position} * CCC * X_{entry}$	$\Delta\text{Position} * CCC * X_{entry}$ (0.01912*) $PrevTimes$ (0.02883*)	0.1802	0.1226

*** significant at 0.001, ** significant at 0.01, * significant at 0.05, ` significant at 0.1

DISCUSSION

The hypotheses all largely tested positive, albeit with one qualification. Hypotheses 1 and 2 tested positive, which lends a lot of credence to Gartner's opinion of the best firms in SCM and their ranking relative to each other. As Hypothesis 1 tested positive, an improvement in the rank of a given firm in Gartner's list results in a positive return to that firm which depends on the magnitude of the improvement in the rank. Given that Hypothesis 2 also tested positive, a firm enjoys a certain measure of a boost to its stock price simply from being listed in the SCT25 even if there is no improvement in its rank from the previous year. In other words, there is value to being reaffirmed in the list of the top 25 companies worldwide who excel in managing their supply chain. That these two hypotheses were established does clearly imply that Gartner's identification of the best companies in SCM and their relative ranking is credible.

Hypothesis 3 also tested positive. This implies that if a firm's SCM capability as reflected by other measures, such as the CCC, is in alignment with Gartner's signal of SCM capability reflected by an improvement in ranking, then the stock market return will be boosted further. On the other hand, if the CCC does not reflect that well on a firm's SCM capability, then the impact of an improvement in rank in Gartner's list on the stock return will be more muted. This result, which addresses the interaction between the information signal from Gartner's list and external measures of SCM excellence, nevertheless continues to support the integrity of Gartner's opinion. It would be reasonable to expect an amplification of the improvement in rank on the abnormal stock return if Gartner's signal and the external measures aligned and vice versa.

Hypothesis 4 can be deemed to have tested positive with one important qualification. Hypothesis 4 is essentially asserting that, since completely novel information creates more impact on the stock market than partially anticipated information, the appearance of a firm in the SCT25 list the first time should have greater stock market impact than a reappearance in the list. To more specifically define the cases of first-time appearance and the reappearance, Hypothesis 4 compares the stock return from a first-time appearance at the bottom of the list to that of a one-step improvement in rank in the case of a reappearance later. Hypothesis 4 tests positive for all firms except those firms whose CCC is less than -9.3. The vast majority of firms that have appeared in the SCT25 list in the 2007 to 2011 epoch have had a positive CCC. Hence, for the vast majority of firms, the first-time appearance does create a greater stir in the stock market than a reappearance, given the specific definitions of the cases of first-time appearance and reappearance.

There is a small number of firms with large, negative CCC's that have featured in the SCT25 list. Two such notable exceptions are DELL and Apple. Apple's CCC in the years it was listed in the SCT25 in the 2007 to 2011 epoch fluctuated from -44 to -82. DELL's CCC in the years it was listed in the SCT25 in the 2007 to 2011 epoch fluctuated from -35 to -47. Companies that have large negative CCCs are typically seen as managing their supply chains well. Therefore, for firms that are viewed as managing their supply chains very well based on other external measures such as CCC, being listed on the SCT25 is not such a surprise. Hence, for these firms, it is the not first-time listing that has a big impact, but it is an increase in the relative ranking of the firm that is of more consequence in terms of the abnormal return to the firm's stock.

Finally, Hypothesis 5 tested positive, which means that the repeated appearance of a firm in the SCT25 list tends to mute the stock market return since the market begins to anticipate more and more the appearance of the firm on the list.

Implications for Theory

The link between superior SCM capability and financial performance of the firm has been examined from many perspectives with different methodologies and different types of information. That so much effort has been expended in studying this relationship speaks to its key importance of this relationship. Models that have been built to study this relationship have used a variety of input variables as indicators of supply chain capability and performance. However, none of these studies have used analyst opinion of the excellence, or the lack thereof, of the supply chain capability of firms and the impact that the disclosure of this information has on the stock market. The lack of treatment of analyst opinion as an indicator of supply chain capability and performance is a key missing piece in the theoretical edifice that has so far been built to support the link between supply chain capability and performance and financial performance.

Our article completes the theoretical edifice of the SCM-finance relationship by examining the impact of analyst opinion of firm capability in SCM and financial performance. In examining this link using event study methodology, certain departures from the traditional event study methodology were necessary. This is because analyst opinion is not like factual information. It is not an earnings announcement or a news flash about a natural calamity that affected the supply chain. Analyst opinion is controvertible in that it can be challenged by a different analyst. Hence, to truly assess the net impact of the disclosure of analyst opinion on the market, such as that of Gartner's SCT25 information, a longer event window must be used to allow for the consideration of different opinions offered by other analysts who may not agree with Gartner. A longer event window of several days also means that the issue of confounding events can no longer be ignored. The occurrence of confounding events should not be ignored even in short event window studies (McWilliams and Siegel 1997), and this factor can certainly not be ignored in event studies where the window is a week or more.

Taking into account the necessity of a longer event window and the correction for confounding events, we show that analyst opinion, such as Gartner's SCT25 list, is indeed a legitimate indicator of supply chain capability and performance, and that this opinion does move capital markets. We have thus made a key theoretical contribution in the research examining the link between SCM capability and performance and financial performance. Analyst opinion of SCM capability and performance was the missing piece in the extensive research done on the link between SCM capability and performance and financial performance. Our article thus finishes building the theoretical edifice of the SCM-finance relationship.

Implications for Practice

This article establishes that Gartner's SCT25 list is important and valuable information. Disclosure of this information does move capital markets. It moves these markets in a way that is consistent with Gartner's opinion. In other words, if Gartner moves a firm up in ranking in the SCT25 list, there is a positive return to that firm's stock which is proportional to the extent of the improvement in the ranking. The fact that Hypotheses 1 through 5 largely all tested positive is actually a validation of Gartner's view of the firms that excel in SCM and how they rank relative to each other. This is very important to the industry as Gartner's list is identifying exemplar firms in SCM. As we stated before, acquiring superior capability in SCM is not easy as there are many facets to SCM capability. The firm has to master strategic sourcing strategies to new business processes such as CPFR to various types of information systems and technology such as ERP and SCM systems and Web Services for digitally integrating the supply chain.

Given this complex challenge, knowledge about SCM exemplars can be of great benefit to firms struggling with managing their supply chains. They can study and emulate the practices of these exemplars. There are many lists and rankings offered by industry analysts, consultants, and gurus. However, not all such rankings are equally good. We provide solid statistical proof that Gartner's SCT25 list has integrity and is a good barometer of companies exceling in SCM. However, while Gartner was able to successfully establish the value of the information in their SCT25 list as evidenced by its impact on the stock market, the concern is that their methodology may need updating. We focused on the 2007 to 2011 epoch in our in-depth examination of the impact of the information contained in the SCT25 list because that is the epoch where this report is value-relevant. Hence, we recommend that Gartner update its methodology of picking the best firms in SCM, so the list continues to be value-relevant in the future as it has clearly been in the past.

CONCLUSION

In this article, we complete building the theoretical foundation upon which the link between excellent supply chain management capability and superior financial performance is based. Although this link has been explored from numerous perspectives using a variety of methodologies and types of information, analyst opinion as an indicator of excellence in SCM has received little attention from researchers. This article fills that gap in the theoretical research that has been done in examining the SCM-finance link. Furthermore, by validating through rigorous statistical analysis that Gartner's opinion of the exemplars in SCM is legitimate, we are providing confidence to the managers who have utilized Gartner's list in the past that emulating the SCM strategies and business practices of the firms in Gartner's list was a worthwhile action. One caveat is that Gartner may need to update its methodology of picking SCM winners so that firms in general can safely continue to look to this list to identify exemplars whose SCM-related strategies and business practices they could emulate.

Notes:

a) Only companies whose stocks are traded on either the NYSE or NASDAQ exchanges are included. Foreign companies included in the study are those that have an ADR traded on either the NYSE or the NASDAQ.
b) The highest rank is 1 and 25 is the lowest rank in the Supply Chain Management Top 25 list.
c) The rank of 26 indicates that the firm was not in the SCT25 list in that year.

Notes:

a) Firms are listed in the order of their rank in the SCT25 in a given year.
b) The Lexis Nexis database was used to find the dates of other announcements in the SCT25 event window.
c) The media publication date about some major other news about the company is day 0. The market move dates for this confounding news is [-1, 0] provided that both day 0 and day -1 are both stock market open days. If day -1 is a stock market closed day, then the event window is just day 0 provided that this is a stock market open day. If day 0 is a closed day then the event window is day *t* where *t* is the first stock market open day after day 0 if day -1 is also a closed day. If day 0 is closed day but day -1 is an open day then the event window consists of day -1 and day *t*.

DECISION SCIENCES INSTITUTE

Decision making: The process is the content in an experience based, autonomy-supportive classroom

Thomas A. Conklin
Georgia State University

Artemis Boulamatsi
Georgia State University
aboulamatsi1@gsu.edu

ABSTRACT

This is a multi-step exercise focused on decision making which helps students understand process issues in decision making in complex and uncertain scenarios. It employs a case and how students often focus on the content of decisions, instead of process issues. Process issues are revealed through the use of various tools such as creating a team contract, a team inventory, and the decisions required in the case analysis. These occur across three 75-minute classes but can be adapted to the time available. The paper's structure is organized according to Wiggins and McTighe's (2005) curriculum development model.

KEYWORDS: decision making; content; process; organizational behavior; experience based learning; autonomy-supportive; andragogy

INTRODUCTION

It is not uncommon for college course material to be sufficiently complex to be both interesting, and hold hidden gems of learning that apply to topics beyond the particular course focus. This is the case with a three-part experiential exercise dealing with individual and group decision making. Decision making refers to the process of generating and choosing from a set of alternatives to solve a problem. This process can be automatic, quick and relatively unconscious which may rely on intuition or it can be systematic and thoughtful relying more on individuals' rationality. In rational decision making individuals go through six steps: 1) define the problem, 2) identify the decision criteria, 3) allocate weights to criteria, 4) develop the alternatives, 5) evaluate the alternatives, and 6) select the best alternative (Harrison, 1999). This model is based on the assumption that the problem is clear to the decision-maker and she has all relevant information to make the best decision, free from biases and with no time or cost constraints (Hardman & Harries, 2002). However, in reality this is rarely the case as people often have very little information at hand, problems are often ambiguous, and biased perceptions and attributions influence their thinking. In addition, when this step-by-step approach to thinking through various alternative solutions takes place in groups, the process of decision making becomes even more complicated. The strengths of one often do not compensate for the flaws of others, and the flaws present in our individual approach can at times become magnified when in groups.

Despite group decision making's limitations, it does contain the advantages of bringing together people of diverse backgrounds and expertise, who combine their knowledge, experiences, ideas and viewpoints to produce novel solutions. This combination of divergent thinking and access to a wider range of information can produce higher quality decisions (e.g. Hollenbeck, Ilgen, Sego, Hedlund, Major, & Phillips, 1995). In addition, group decision making often increases members' commitment to the final decision, as they participate in the process and are more likely to accept the final decision and support its implementation (Brodbeck, Kerschreiter, Mojzisch, & Schulz-Hardt, 2007). Past research has shown that being part of a group decision making process increases participants' perceptions of fairness and identification with the decision (for reviews see, e.g., Moscovici & Doise, 1994).

On the other hand, diversity may serve as a detriment to group decision making if members fail to collaborate and benefit from divergent thinking (Brodbeck et al., 2007; Hollingshead, Jacobsohn, & Beck, 2007; Stasser & Titus, 2003). How members approach information processing within groups can have important negative implications on rational decision making. Members might focus only on dominant or majority opinions, or discuss and repeat information that is brought up first, neglecting unshared information, or be biased on how they evaluate information by evaluating their own ideas or ideas that are consistent with their personal preferences more favorably than others (e.g., Brodbeck et al., 2007; Edwards & Smith, 1996; Harvey & Fischer, 1997; Yaniv & Kleinberger, 2000). These limitations and inherent biases are at the root of this paper's focus on process as something that is often poorly considered in group decision making.

The decision making exercise discussed below aims to help students experience the benefits and the difficulties in group decision making. Through experiential learning students will have the opportunity to identify and understand the issues (e.g. information sharing, conflicts, diverse viewpoints, perception, and attribution biases) that arise within groups when it comes to making collective decisions and become more aware of their own and others' participation in this process. Highlighting these dynamics through this writing is key to more fully understanding the process of decision making in groups, as well as actually making more effective decisions which is poorly addressed in extant literature.

This exercise is designed to highlight the "how" of decision making, and reduce students' tendency to focus on the exercise's content, or the "what" of the decisions to be made. This

tendency can draw students' attention away from the decision making learning points that the exercise is intended to facilitate. The exercise can be used in organizational behavior, leadership, and strategy classes and helps to reveal and underscore the importance of decision making process. With this introduction, the objectives of this paper are to: 1) describe the exercise in sufficient detail to enable instructors to competently and confidently facilitate the exercise in their classes, 2) provide literary foundations that establish this as a worthy exercise in higher education, and 3) provide evidence that this exercise is effective in teaching adults decision making processes. The learning objectives (LO) of the exercise are to enable students to: 1) identify and develop individual and group decision making skills; 2) apply individual and group decision making skills to a case; 3) understand the ubiquity of decision making in work and life; and, 4) understand that decision making is a process, not a discrete event.

The paper contains four major sections. The first section contextualizes the exercise in the larger domain of the Experience Based Learning (EBL) literature (Andresen, Boud, & Cohen, 2000; Dewey, 1938; Kolb, 1984; Kolb & Kolb, 2005; Weil & McGill, 1989) which aids in the creation of an autonomy-supportive learning climate (Reeve, Bolt, & Cai, 1999; Reeve & Jang, 2006). This section includes literature on andragogy (Knowles, 1980, 1984) which is a broad based philosophy regarding the fundamentals of adult education and a set of ideas through which the entire paper takes form. The second section provides a description of the exercise and the three activities that comprise it. It is presented in detail sufficient for other instructors to deploy it. The third section discusses exercise effectiveness as measured qualitatively. The final section of the paper discusses results, limitations, future research and alternatives to the current practice.

LITERATURE REVIEW

Adult Learning

Adult learning is a large research area with many focus areas, including self-directed learning, critical reflection, learning to learn, and experiential learning (Brookfield, 1995; Malinen, 2000). The work on adult learning is closely aligned with experience based approaches.

Experience Based Learning

Experience based learning (EBL) includes writing on autonomy-supportive (AS) classrooms by Reeve, Bolt, and Cai (1999) and others (Reeve & Jang, 2006). Their thinking on AS classrooms serves as a general frame supporting the EBL teaching approach. AS classrooms are characterized by teachers with a more autonomous and facilitative approach rather than a controlled orientation. Students in AS classrooms are provided greater latitude in their behavior as they experiment with ideas and relevant concepts. Here, students are free to engage in volitional behaviors not specifically dictated by the instructor. Research on AS teaching styles has suggested that it increases students' intrinsic motivation and self-esteem (Cheon, Reeve, & Moon, 2012; Deci, Nezlek, & Sheinman, 1981; Furtak, & Kunter, 2012; Haerens, Aelterman, Vansteenkiste, Soenens, & Van Petegem, 2015). An AS teaching style is likely to facilitate greater levels of success in classes characterized by EBL (Andresen, Boud, & Cohen, 2000; Dewey, 1938; Kolb, 1984; Kolb & Kolb, 2005; Weil & McGill, 1989).

The exercise employs numerous elements that reflect EBL frames (Conklin, 2013). Specifically, student experiences in and out of the classroom are treated as focal points for learning and are valued in the EBL tradition. In addition, experiential learning is a cornerstone of the larger domain of andragogy which has been noted as central to constructing meaningful ways to facilitate adult learning (Forrest & Peterson, 2006; Knowles, 1980, 1984; Lindemann, 1926). Andragogy assumes that adults need to: 1) know why they need to learn; 2) learn

experientially; 3) approach learning as problem solving; 4) learn when the topic is immediately valuable; and, 5) become more self-directed in their learning (Knowles, 1980, 1984).

Andragogy bridges to the EBL literature and the power of engaging in activities that require student participation (Andresen, Boud, & Cohen, 2000; Dewey, 1938; Kolb, 1984; Kolb & Kolb, 2005; Weil & McGill, 1989). Particular calls for student participation have come from a broad array of thinkers. Arbaugh (2005) addressed this in his call for less lecture and more interaction. Whetten (2007) did likewise in discussing the need for greater focus on problem based learning, career relevant material, and interaction with practitioners. Boud and Pascoe (1978a, 1978b) believed that: 1) learners must have some control in the activities and process; 2) the learning environment must mirror, to some extent, the real world; and, 3) the learner must be self-involved. These three elements require dialogue and interaction among students which cannot be taken for granted, and likely encouraged in AS classrooms. Gilson (1990) has noted that the proclivity of students' interaction is contingent on the instructor's ability to facilitate an environment that invites such interaction. Given Gilson's words, anyone who adopts these methodologies must also assume the myriad responsibilities that attend that adoption.

Creating a teaching structure and an environment that accomplishes what the above literature describes is at the heart of Wiggins and McTighe's (2005) Understanding by Design (UbD) approach. Their thinking suggests that teachers begin with results in mind. Specifically, determining what students should know, understand, and be able to do is the first step. Second, instructors need to be able to determine if learning has occurred. The authors identify two forms of assessment: performance tasks which require students to apply their knowledge, and the second form of assessment, "other evidence" which includes more traditional elements such as tests, observation, and work samples. The third stage in the UbD model includes decisions about lessons and activities that will result in the outcomes identified. The goal of these activities is to have students be able to make meaning on their own and with teacher support. This requires the teacher to evolve from expert to one who facilitates the learning process and coaches through feedback and advice. These are behaviors consistent with the autonomy-supportive frame described above. The three steps of the UbD model will be referred to as the paper unfolds to tie the stages of the paper to this frame.

THE EXERCISE

The exercise falls into the third element of Wiggins and McTighe's (2005) model dealing with appropriate lessons and learning activities and accomplishes the first and second learning objectives (LO) by engaging with others and with a case. It addresses the third LO in that many decisions must be made regarding the case that often go unnoticed until they are identified in the debrief. The fourth LO is addressed when students begin to see the networked nature of decisions that often conflict with and impact other decisions.

Creating student groups and dealing with the case requires interaction with others as those groups attempt to understand, analyze, and make recommendations. These actions reflect the elements of andragogy cited above - they are relevant and meaningful in students' lives, they are experiential due to the interaction required, there are problems to identify and solve, they have immediate value in learning about and applying decision making processes, and finally, they enable students to discover issues and solutions for themselves rather than be guided strictly by the instructor. Table 1 provides details on where each objective is achieved.

Insert Table 1 about here

The in-class exercise is comprised of three main activities. Each activity takes place during one of three 75-minute class sessions and could be adapted to fit various timing formats. The first activity requires significant out-of-seat interaction as the class forms groups with as much diversity as possible (Coulson & Strickland, 1992). This is followed with the challenges present in the case (Gourville, 2005).

Activity 1. Step 1: The first activity is based on the Diversity game described by Coulson and Strickland (1992). We used this as a sorting mechanism that aided in creating groups with as much diversity as possible regarding thinking styles.

The activity begins with the random distribution of four cards to students (Coulson & Strickland, 1992). They are to trade those cards with others to arrive at a 'hand' that each believes best describes him or her. The 64-card deck (Coulson & Strickland, 1992) contains four color groups reflecting the Hermann Brain Dominance thinking styles (Bentley, 1989; Bunderson, 1989; Herrmann & Herrmann-Nehdi, 2015). Further distinctions are provided in Appendix A.

Each of the four thinking styles contains 16 cards. Each card contains an adjective and description of that style. Examples include helpful, artistic, industrious, etc. and the brief description mentioned. Depending on class size more than one deck may be necessary. When distributing the initial four cards to students we ensure that each card is from a different color group. That is the only criterion for this step.

The cards are used as a convenient means of compelling students to make numerous decisions regarding what adjectives apply to them and which do not. It is important to note that virtually any mechanism that requires a significant amount of decision making could be used to categorize students in some way[1]. Once students have four cards that they believe best describe them they are to take their seats so we can begin step 2.

Step 2: In this step of the activity students are asked to sacrifice the card that is least like them. Groans are often heard around the room. They are then instructed to prioritize the three remaining cards according to which best describes them and rank them as 1, 2, and 3. To ensure they have a record of these three cards we ask students to write down the adjective and description of each in ranked order on the sheet referred to above as Appendix A. They are then requested to return the two cards that are least like them, leaving them with the one card they believe best describes them. Holding only one card, students are asked to form a group with three other students with the stipulation that they maximize the diversity of the adjectives and card colors. Often, students are quite unaware of the numerous decisions they have made at this point in the activity. This provides a rich experience that will be explored in the debrief and reflects the LO regarding the ubiquity of decision making.

Once groups are formed they are asked to construct a team statement and contract (Appendix B) (St. Peter, 2013). This is another activity that compels many decisions. When completed, student groups are asked to stand and share their creations with the class. This can be shortened to a few select questions if the class is large or if time is limited.

Mini-debrief: At the end of this and each activity we ask what they had to do a great deal of in order to complete the tasks. Without fail students offer up good insights such as suspend judgment, collaborate, good communication skills, take leadership, etc. We ask the same question again and finally someone identifies the volume of decisions they had to make. We

[1] For example, using students' Myers Briggs Type Indicator (Myers, 1962) profiles or their Learning Style Inventory (Kolb, 1976) profiles would be suitable sorting devices that create distinctions for students and enable them to construct diverse groups. The cognitive style inventory cited here is simply the one we have chosen. A good review of various instruments can be found in Kozhevnikov, Evans, and Kosslyn (2014).

draw attention to the name of the course (Managerial Decision Making, but the same could be said of many courses which may have a module on decision making or a heavy focus on the roles and obligations of managers and executives) and it dawns on them that this activity has been riddled with decision making from the very start. Usually there is a bit of nervous laughter from the room as this otherwise obvious insight has been missed by most of the students.

Our intent is to draw attention to decision making processes and the subtle nature of decisions that pervade our lives, including the partial awareness we often bring to them. This helps us understand the ubiquity of decision making and the potential contribution to decision quality if we were to increase our consciousness as we craft lives and careers. We close by asking students what decisions create. Here again there are numerous worthy suggestions. Over the course, we have often commented that decisions are what create our reality. This 'truth' is an important element of the course and we want students to understand the significance of decisions in their lives. This debrief provides a pregnant moment to underscore this point.

Activity 2. This activity uses a Harvard Business Review case (Gourville, 2005)[2]. Students are asked to read the case prior to class and come prepared to work in their established groups to identify: 1) the problems and issues in the case that need to be solved; 2) the desired ends (DE) that solving the problems will achieve. DE are the new realities they would like to see the solutions create, or the problems they would like to see the solutions eliminate; and, 3) the criteria by which they will know that the reality is created or the problems are solved. We encourage students to use quantitative means if available as they consider the measurable criteria relative to each DE.

When groups have arrived at their responses to these prompts each is asked to come to the front of the room and describe to the class the issues they identified. Each group usually identifies a unique set of issues in the case that need to be resolved, and what resolving them will create.

Mini-debrief: The diversity of issues identified by each group provides an opportunity for a conversation around the broad variety of possible interpretations that cases provide. This can be further de-briefed by exploring the often hidden values and assumptions behind each group's assessment of what is most salient in the case. To the extent possible, this captures the experience of what happens at the managerial/executive level of organizations. It can be a moment to highlight the attending complexity/ambiguity that must be dealt with at that level when deciding what is most important in creating an organization's future.

Here, as in activity 1, groups have made a number of decisions, often without being fully aware of their process for doing so. To cement the learning it is helpful to discuss decision making issues along the way, rather than saving all discussion for the final event. In that way we have found it beneficial to use similar questions, in addition to new and relevant ones considering the specific activity each time. The students become accustomed to hearing them and as a result begin thinking about them as the three activities occur instead of only considering them once at the end, which would reduce the salience of the issues that they are intended to raise. We ask students what they have done much of (decision making) to arrive at their responses and what that has created (reality). In this step we also ask them to consider the challenges and insights they may have encountered in group decision making, which is a new

[2] While the case cited here is in the healthcare field, virtually any well written case would likely suffice so long as it requires making many significant decisions. For interesting commentaries on this case readers may want to refer to Lutz, R. A., Christensen, C. M., Wittes, J., & Galakatos N. (2005). Holding fast: HBR case commentary. *Harvard Business Review*, June, 40-46.

act for them. Questions that can facilitate the debrief include but are not limited to the following: What went well, what surprised you, where were you challenged, what were the challenges about, did you experience disagreements about what was important or what to do, how did you manage the disagreements around the issues and their relative importance?

Activity 3. This activity also uses the HBR case and requires each group to generate as many potential solutions as possible to the identified problems which will result in the Desired Ends (DE) they identified. They then establish levels of importance for the various DE and the likelihood of each proposed solution achieving each DE. All of this is represented in a Consequence Table (Hammond, Keeney, & Raiffa, 1998) (Table 2) containing the various DE down the left margin and the proposed Solutions across the top row. To be clear, the consequence table is simply a device that reflects the thinking and prior decisions that have been made and offers a structure for analyzing the wisdom of those decisions. It is not the decision making interface itself, only a mirror that helps analyze them. The table simply organizes the DE and the suggested solutions and then aids in the application of quantitative measures to arrive at a weighted score for each proposed solution. While the table construction requires additional decision making, the decisions made at this step are only as good as the intelligence that is reflected through the identified issues contained in the top and left margins of the table.

Each DE in the left margin is assessed with an Importance Score (IS) which is entered in the left margin. This reflects the relative importance of each DE vis-a-vis all other DE. Each proposed solution (contained in the top row) for that DE row is assigned an Achievement Score (AS) that estimates the extent to which that Solution achieves each DE that is found at each column/row intercept. AS are applied to each cell under each proposed solution.

Insert Table 2 here

The range of IS and AS scores selected is an important distinction. These scores should span a broad domain of numbers such as 1-20 or 1-50 and should exceed the raw number of DE and solutions identified. For instance, if a group identifies 10 DE they would like to accomplish, a range of 1-25 for IS would be adequate to reflect the relative importance of each vis-à-vis the other DE identified. This provides an interval ranking which is more meaningful than simple ordinal ranking. As example, on a scale of 1-25, the most desirable end should receive an importance score of 25. This reflects its status as the most important of all DE identified. The next most desirable end should receive an importance score that shows its relative importance compared to the most desirable. So, if the second most desirable end receives a score of 13 it is, apparently, about half as important as the most desirable end. Likewise, if it receives a score of 24 it is very comparable in its importance and desirability to the most desirable end which received a 25. A similar process is undertaken with the AS. As the groups work with each DE, each cell in that row, under each proposed solution is ranked in its likelihood of achieving that DE. When complete, each cell intercept within the table should have an AS.

The IS of each DE is then multiplied by the AS of each cell to arrive at a weighted score for that combination. These weighted scores are then summed to the bottom of each column to provide a total weighted score for each of the proposed solutions. That solution containing the largest sum theoretically identifies the best solution that will achieve the greatest number of DE identified. This step results in a Consequence Table (Hammond, Keeney, & Raiffa, 1998) that reflects the likelihood of desired ends achievement vis-a-vis importance.

When activity 3 is completed groups are asked to come to the front of the classroom and present their consequence table.

Mini-debrief: Once all groups have reported their results we ask the room which group is right. This can lead to lively debate. It is resolved however, when we discuss the idea that they are all correct given the analysis, assessment, and logic they applied to the case data. This often leads to a conversation on the challenges of decision making in general, and especially at the highest levels of organizations where the information is almost always partial and temporary, yet leaders are still required to move ahead despite this ambiguity. In that environment many solutions are likely to be suggested, most of which will achieve some of the DE. This can be a rich moment to discuss the roles of management and leadership and the necessary wisdom that must accompany decisions and which, ideally, informs leadership.

These three activities address Wiggins and McTighe's (2005) first concern focusing on what students should know and understand which would be considered topical questions, and their concern regarding lessons that cement their learning. This also addresses LO 2 which involves using a case as a learning tool, and LO 4 which considers decision making a process that is embedded in the ongoing flow of organizational life.

Final Debrief: The activity closes with groups beginning to understand the complexity and ambiguity of decision making, especially as it moves from individual to group which becomes more encumbered as one ascends in organizations. Closing comments often address the following:

1. All solutions are right and all importance estimates are accurate given the sense making and assessments/judgments of the group. These assessments and judgments are likely riddled with unconscious cognitive biases (Chugh, Bazerman, & Banaji, 2005; Milkman, Chugh, & Bazerman, 2009; Moore & Cain, 2007) which is a central theme reviewed in the course.
2. Group decision making is usually temporary and partial. Access to information and interpretation are often time bound as work and the world continue to evolve/devolve thereby altering current and future interpretations of the reality within which organizations function. It is partial in that apprehending all information relevant to a situation is beyond our reach.
3. Group decision making is difficult. It is not uncommon for group members to conflict with each other and have to debate and concede at some point in order to come to agreement.
4. Decision making tasks require good negotiation skills and a process of collaboration and compromise.
5. Complexity increases in organizations and in groups compared to individual decision making. More people with numerous and complex ideas make management of this process more complicated.
6. Complexity is exacerbated as group size increases and as one ascends into the upper levels of management and leadership. Ambiguity generally increases as one moves into higher levels of management and is exposed to greater amounts of often conflicting data. This creates greater uncertainty regarding the correct path to take.
7. Finally, in some ways it matters little what solutions/recommendations groups identify - this is a decision making course, not a strategy class. Hence, the focus ought to be on group decision making processes, and only partially on the content of the case.

This last issue is worth considerable dialogue. A meaningful and helpful frame through which to make sense of organizational decision making could be that of game models (Elias, 1970) which interprets the "relative strength of the players" (p. 75) regarding the shifting tides of power

in society, and by corollary, organizations. This model may be of some value as students consider their decisions in areas well beyond the narrow band of their careers, thereby bridging the significance of decision making to students' daily lives.

The third activity addresses Wiggins and McTighe's (2005) topical objective regarding what students should know.

EXERCISE EFFECTIVENESS

Wiggins and McTighe's (2005) second concern focuses on measuring achieved results. This section on effectiveness addresses that issue.

To determine student experience of the exercise we surveyed (Appendix C) 104 students after the exercise using two questions rated on a 7 point Likert (1932) scale, and one open-ended, short response question. The first question inquired about the usefulness of the activities. This question received 6.08 for the mean with a standard deviation (SD) of 1.14. The second question asked if students believed that the activities increased their understanding of the decision making process. This question received a mean of 6.01 and a SD of 1.15. These values reflect some consistency within each measure. Both questions were self report measures which have their limitations. These will be discussed below.

Short response

The open ended question asked students to comment on what changes they will make in their decision making going forward. Boyatzis' (1998) three stages of thematic analysis were applied to this data. The first stage regards sampling and design issues and was addressed by surveying all students who had participated in the exercise.

The second stage of thematic analysis requires developing a theme and a code. All student data was hand written and was in phrase or one word responses which was the level of analysis. Data was coded and themes identified following Braun and Clarke's (2006) definition of themes as "something important about the data…and…some level of *patterned* response or meaning within the data set" (p. 82). As a means of increasing the reliability of assessments these coding events were spaced across four weeks. The schedule of events is contained in Table 3

Insert Table 3 about here

The third stage in the analysis required validating and applying the code. Summary themes were shared with the classes of students who provided the data. Students concurred with the analysis and the themes. These themes are supported with response examples in Table 4.

Insert Table 4 about here

Other comments that were present but not thematic, meaning there was no consistent presence and there were no more than two related comments, include things such as "Take more prepared steps in decision making" "Read the case first" "Avoid biases in brainstorming" and "Do more background research." These comments are relevant regardless of their infrequent presence.

DISCUSSION

The purpose of this paper is to illustrate how adult students increase their understanding of the process of group-decision making through an in-class exercise. This exercise helps them identify and develop the necessary skills that can be applied in the work world. In this exercise, students had a central role experiencing the decision making process, while instructors adopted a more facilitative role to help students reflect on their learning experiences throughout the activities. Students were allowed to be autonomous throughout the exercise to maximize their intrinsic motivation and engagement. The design of the exercise required the active participation and interaction of students and was intended to draw students' attention towards the process of decision making rather than to the content of the decisions to be made. This helped them gain confidence on how to collaborate in group decision making, identify their limitations, and develop the necessary tools to apply this process in other domains.

The activities and the dynamics surrounding them stand upon a solid foundation offered by the autonomy-supportive (AS) classroom literature (Reeve, Bolt, & Cai, 1999; Reeve & Jang, 2006). AS classrooms are identified by a more interactive style where teachers are less controlling and often serve as guides and facilitators rather than experts. The three activities also align with ideas related to growth mindsets (Blackwell, Trzesniewski, & Dweck, 2007). Growth mindsets, as compared to fixed mindsets are characterized by a belief that one's abilities can be developed through work and effort. It is contrasted with fixed mindset thinking; one's talents and abilities are fixed, hence, there is little attempt to develop or grow one's capacity (Dweck, 2006). While the activities are compulsory as a course requirement, they bridge to AS in execution as students are provided significant freeboard to interpret the case and apply thinking from the course. Doing so creates a holding environment (Winnicott, 1965) where they are free but not abandoned. This reduces the pressure to be right and centers attention on learning as opposed to performing.

Finally, a recurring theme in the course and the three activities of the exercise is how the decisions of any group are accurate in the moment given their assessment and adjudication of what is and is not salient. Given this foundation we are then able to explore how it is that so many well educated and deeply experienced executives fail so significantly despite these qualifications. While this is a theme in the course material covered over the term, it appears that there is little that so teaches us the significance of an idea as actually experiencing it: a nod to the very essence of this paper - experiential learning.

Limitations and Future Research

This study may be limited by self report data as self determined measures of one's understanding may be easily influenced by cognitive bias (Hilbert, 2012) which, ironically, is a central feature of the course. Further bias may be unwittingly applied by the participants' personality characteristics, motivation, achievement orientation, and locus of control. Future iterations of the exercise could contain a follow-up objective to evaluate students' workplace settings, or perhaps, an application to employees' training programs to determine change in learning. Future research may also include administering the pre- and post-test at times other than just prior to, and following the exercise. Doing so would help establish what learning occurs and when, and enable instructors to determine what elements of the course provide the greatest learning. This could be correlated to learning goals established at the beginning of each course through the use of an appreciative inquiry exercise (Conklin, 2009) that helps identify them. Further distinctions could also be revealed by pursuing the discoveries here, such as the contributions of professional experience.

Summary

This paper has described a set of activities that differ from traditional lecture based teaching models. The insights that often occur are likely to increase retention as they stand outside the typical classroom experience. Still, the challenge is to more fully integrate activities and exercises that leverage the shared power of this form of teaching and learning. We confess, some of the courses used as the source for this paper are modeled on good old fashioned, stand and deliver, sage-on-the-stage (Gibson, 1996) lecture.

APPENDIX A: THINKING PREFERENCES

Four Dominant Thinking Preferences

Analytical (Blue) • Logical problem solving approach • Analytical and quantitative • Rational • Learns by mental analysis	**Conceptual/Strategic (Yellow)** • Imaginative thinker • Intuitive about ideas • Visionary • Holistic/integrating • Learns by experimenting
Structural/Organizer (Green) • Practical, organized, sequential • Likes procedures • Detail-oriented • Cautious about new ideas • Learns by doing	**Social/Personal (Red)** • Intuitive about people • Socially aware • Sympathetic/empathetic • Focused on interpersonal • Learns from others

Communication Styles of Each Thinking Preference

The Analytical wants: • Budget in #'s or graphs • Data • Logical and concise • Credible speaker • Value for time expended • Problem solving orientation • Written info for review later	**The Conceptual/Strategic wants:** • Budget in pictures and graphs • Symbols, metaphors, analogies, myths • Use brainstorming as a tool • Change every 15-20 minutes • Option generation and integration • Overview and summary
The Structural/Organizer wants: • Agenda or outline • Guided discussion and recitation • Practice and feedback • Rules and procedures • Specific information and detail • Dates/times for implementation • An action plan	**The Social/Personal wants:** • Stories and vignettes • Rapport with audience and presenter • To celebrate achievements • To address emotions • A collaborative approach • Information applied to self

1. What was the color, adjective and phrase on your favorite card?

_____

2. Provide an example where something you did in a team setting represented the adjective and phrase on your favorite card:

_____

APPENDIX B: TEAM STATEMENT AND CONTRACT

This is a written statement with the signature of all the team members at the bottom. It should address the following:

1. Team name and team members
2. The expectations about good performance behaviors (core norms) that you are agreeing to hold yourselves mutually accountable for during the next three sessions.
3. The expectations about unacceptable behaviors (core norms) that you are agreeing to hold yourselves mutually accountable for during the next three sessions.
4. The consequences for breaking these core norms.
5. A positive goal for the sessions that all members of the team feel committed to achieve.
6. A description of how your team will address conflicts
7. A description of how your team will celebrate success

APPENDIX C: STUDENT EXPERIENCE SURVEY

Please rate the overall usefulness of these activities.

Not useful Very useful

1 2 3 4 5 6 7

To what extent was this workshop effective in increasing your understanding of the topic?

Ineffective Very effective

1 2 3 4 5 6 7

What changes will you make in your decision making habits based on the exercise?

_____
_____
_____
_____

TABLE 1: LEARNING OBJECTIVES IN 3 PART EXERCISE

Learning Objectives	Exercise sections that address L.O.
Identify and develop individual and group decision making skills.	Activities 1, 2, 3: team formation, use of the Holding Fast HBR case and the variety of problems and solutions groups identify.
Apply individual and group decision making skills to a case.	Activity 2, 3
Understand the ubiquity of decision making in work and life.	Activity1: steps 1 (card sort) and 2 (group formation), 2, 3: All three sections of the exercise are rich with many small decisions that are often unrecognized as decisions at all.
Understand that decision making is a process, not a discrete event.	Activity 3: Achieved near the end of the exercise as students become aware of the networked decisions they have been making in the case that often conflict with other priorities and decision in the case without their awareness.

TABLE 2: CONSEQUENCE TABLE

	Solution 1	Solution 2	Solution 3
Desired end 1; IS	AS X IS = Product	AS X IS = Product	AS X IS = Product
Desired end 2; IS	AS X IS = Product	AS X IS = Product	AS X IS = Product
Desired end 3; IS	AS X IS = Product	AS X IS = Product	AS X IS = Product
Desired end 4; IS	AS X IS = Product	AS X IS = Product	AS X IS = Product
Total	**Sum of Products**	**Sum of Products**	**Sum of Products**

TABLE 3: SCHEDULE OF DATA ANALYSIS

Week 1	Quickly read all comments and make notes of general impression on a separate document
Week 2	Transcribe student comments into a separate file for each question. Read this summary document attending to each word and making tentative thematic notes in the margin
Week 3	Read fresh copy of summary document of student comments and thematized their comments
Week 4	Compared notes on the two summary documents of students' comments from week 2 and 3 to arrive at final themes and supporting student commentary.

TABLE 4: OPEN-ENDED QUESTION THEMES

What changes will you make going forward in your decision making?	
Theme	Supporting Quotes
1. Will consider others' ideas and opinions more fully as they move forward	"I will listen before making decisions. Consult members when in a group. Ask others' opinions."
2. Will consider a broader variety of important factors that impact the decisions they are making	"Weigh many alternatives before making a decision. Think about the value of the alternatives more. Consider alternatives outside the box."
3. The exercise was meaningful and will affect how they make decisions in the future.	"I will add numbers to my decision making process. I will change how I make decisions and use the consequence table more. I will generate more desired ends relative to the alternatives that I am considering."

DECISION SCIENCES INSTITUTE
Determinants of Colleges and Universities Rankings
A Statistical Analysis

Ahmad Vessal
Loyola Marymount University
avessal@lmu.edu

ABSTRACT

This article uses Data Envelopment Analysis to measure relative efficiencies of several universities in three different time periods. Using this technique, it is possible to identify which schools are relatively inefficient compared to the composite school. The efficiency ratings varied from 25% to 100% in 2018 and when compared to 2005-06 and 1998-99 data the index deteriorated for two schools and improved for another. This change in efficiency ratings could be attributed to changes in their inputs and outputs.

KEYWORDS: Linear Programming, Data Envelopment Analysis, College Rankings, Efficiency, Composite School

INTRODUCTION

Every year, US News and World Report releases its famous College Rankings lists. Parents, high school guidance, academicians and college administrators, counselors, and students eagerly await the rankings, so they can impress others with the numbers.
In 2014, for the first time in over two decades, Emory University fell out of the top 20 in the rankings. Although the drop from 20 to 21 is superficially trivial, it is of great symbolic significance given that many students, parents, academicians and college administrators rely on the “top 20” as a rough benchmark for university quality.
According to Lilienfeld and Candler Dobbs (2014) “the rankings drop is indeed a big deal.” Despite the administration unwillingness to admit, “these rankings impart a sobering reality: Emory is a good university, but not a great one.” But compared with MIT, Harvard, Cal Tech or University of Chicago, “cutting-edge discoveries and breakthroughs at Emory tend to be few and far between.” Having followed the rankings of some of these universities since 1998 one is curious to see what factors cause rankings to go up and down.

LITERATURE REVIEW

This article uses Data Envelopment Analysis (DEA) to explore this issue. Since the original introduction of data envelopment analysis (DEA) by Charnes, Cooper, and Rhodes (1978) this technique has been extensively applied to different operating units such as banks, colleges, schools, and others. Ray (1991) used DEA to estimate relative efficiency in the public-school districts of Connecticut. Bougnol and Dula (2006) used DEA to assess performance in higher education. Bates (1997) used categorical variables to measure the efficiency of educational outputs, and Banker and Morey (1986) introduced a case where categorical variables are divided into controllable and uncontrollable by the managers.

METHODOLOGY

In DEA the objective is to identify technical inefficiencies of operating units with same goals and objectives and focus on either saving inputs or increasing outputs. As far as resource conservation is concerned, a decision-making unit (DMU) is considered efficient if it uses less of at least one input and produces same outputs as other units. Alternatively, with respect to increasing outputs a DMU is efficient if it uses no more inputs as other units but produces more of at least one output. Applying Data Envelopment Analysis (DEA) will help measure the relative efficiency of some of the colleges in these states making the decision to enroll in these colleges an informed one. The DEA will point out which colleges to avoid.

The schools of interest in this study are Georgia Institute of Technology (GT), California Institute of Technology (Cal Tech), Massachusetts Institute of technology (MIT), Harvard University, Emory University, and University of Chicago. Therefore, the system is composed of these six schools. The objective is to measure the efficiency of Georgia Tech, Emory University, and University of Chicago and compare them with Cal Tech, Harvard and MIT.

The following five input measures and four output measures are identified to be crucial:

Input Measures:

Acceptance Rate – It measures the percentage of students accepted to the university.

Student/Faculty Ratio – This indicates the number of students per faculty member.

Faculty Resources Rank- This is a measure of school's commitment to instruction. It is obtained as a weighted average of small class size, faculty salary, proportion of faculty with highest degree in their field and proportion of full time faculty.

Financial Resources Rank – It measures that average spending per student on instruction, research, student services, and related educational expenditures.

Student Selectivity Rank – The academic climate of school is determined in part by the abilities and ambitions of the student body. Therefore, schools tend to select those who performed well in high school or who have higher scores on SAT, etc.

Output Measures:

Academic Reputation – The measure is chosen because a diploma from a distinguished college so clearly helps graduates get good jobs or gain admission to top graduate programs.

Alumni Giving Rate – The percentage of alumni who gave to their school is an indicator of alumni satisfaction.

Actual Graduating Rate – This measure captures the effect of the college's programs and policies on the graduation rate of students.

Average Freshman Retention Rate – The higher the proportion of freshmen who return to campus and complete their studies, the better a school is likely to be at offering the classes and services students need to succeed.

QUANTITATIVE ANALYSIS AND INTERPRETATION

The analysis is conducted for three colleges separately.

Emory University:

The general form of the output constraint is:

Output for the best practice school ≥ output for Emory University

and the general form of the input constraint is:

Input for the best practice school ≤ input available to the best practice school

The right-hand side of the input constraint is the fraction of Emory University's input available to the best practice school. If E is used as the fraction, then the input constraint can be rewritten as:

Input for the best practice school ≤ input available to Emory University × E

If E=1 then the input used by the best practice school is the same used by Emory. Therefore, there is no evidence that Emory University is inefficient. However, if E<1 then best practice school does not need as much input as Emory University requires, thus Emory University can be considered relatively inefficient. So, in the linear programming model the objective function is to minimize E, the fraction of resources of Emory University available to the best practice school (composite school).

The objective function and constraints for Emory University are as follows:

Objective Function: Minimize E

Constraints:

$W_c + W_h + W_m + W_e + W_g + W_{ch} = 1$	Weights of Operating Units
$4.6W_c + 4.9W_h + 4.9W_m + 4.4W_e + 4.5W_g + 4.5W_{ch} \geq 4.4$	Academic Reputation
$25W_c + 35W_h + 36W_m + 21W_e + 24W_g + 41W_{ch} \geq 21$	Alumni Giving Rate
$94W_c + 97W_h + 93W_m + 91W_e + 86W_g + 94W_{ch} \geq 91$	Actual Graduation Rate
$97W_c + 97W_h + 98W_m + 94W_e + 97W_g + 99W_{ch} \geq 94$	Avg. Freshman Retention Rate
$8W_c + 5W_h + 8W_m + 25W_e + 26W_g + 8W_{ch} \leq 25E$	Acceptance Rate
$3W_c + 7W_h + 3W_m + 9W_e + 20W_g + 5W_{ch} \leq 9E$	Student Faculty Ratio
$9W_c + 4W_h + 12W_m + 19W_e + 178W_g + 3W_{ch} \leq 19E$	Faculty Resources Rank
$2W_c + 8W_h + 3W_m + 18W_e + 55W_g + 4W_{ch} \leq 18E$	Financial Resources Rank
$1W_c + 3W_h + 3W_m + 23W_e + 22W_g + 1W_{ch} \leq 23E$	Student Selectivity Rank
$E, W_c, W_h, W_m, W_e, W_g, W_{ch} \geq 0$	

Analyzing the Emory University results, it is noted that the objective function shows that the efficiency score for Emory University is 0.3913. This value shows that the composite college can obtain at least the level of each output that Emory University obtains by having available only 39.13% of the input resources required by Emory University. Therefore, it can be concluded that the composite college is more efficient. In other words, Emory University is relatively inefficient compared to the other colleges in the group, namely California Institute of Technology and University of Chicago.

The data envelopment analysis (DEA) revealed that the composite college is formed from the weighted average of California Institute of Technology (W_c =0.7391) and University of Chicago (W_{ch} = 0.2609). The inputs and outputs of the composite college are determined using the weighted average of the inputs and outputs of these two schools.

Outputs/inputs	Emory University	Composite University
Academic Reputation	4.40	4.60
Alumni Giving Rate	21	29.17
Actual Graduation Rate	91	94
Avg. Freshman Retention Rate	94	97.52
Acceptance Rate	25	8
Student Faculty Ratio	9	3.52
Faculty Resources Rank	19	7.43
Financial Resources Rank	18	2.52
Student Selectivity Rank	23	1

The above table summarizes the inputs and outputs of Emory University and composite college. For example, the output "Academic Reputation" of the composite school is determined as follows: Academic Reputation (AR) of the Composite school = W_c (AR_c) + W_{ch} (AR_{ch}) where

AR_c = Academic reputation of California Institute of Technology

AR_{ch} = Academic Reputation of University of Chicago,

= 0.7391 (4.6) + 0.2609 (4.6)

= 4.6.

The Composite school has an academic reputation of 4.6 that is .2 units higher than Emory University. The actual graduation rate for the composite college is determined in similar fashion. The actual graduation rate for the composite college is 94% which is 3% higher than Emory's. The average freshman retention rate for the composite college is 3.52% higher than Emory's rate. Also, the alumni giving rate is 8.17 units higher for composite school than that of Emory University.

Moving to the input constraints, it is noticed that the composite college can obtain at least the level of each output that Emory University obtains by having available no more that 39.13% of the input resources required by Emory University. For example, the acceptance rate of Emory University is 25%. The acceptance rate constraint shows that at the composite college the acceptance rate is at most 39.13% that of Emory University. As a matter of fact, the acceptance rate at the composite college is even lower than the 39.13% of the acceptance rate of Emory. A slack value of 1.78% indicates that acceptance rate at composite college is less than 39.13% of the acceptance rate of Emory University.

The information in the table suggests managerial actions that should be taken to move Emory University toward efficiency frontier. Some actions are feasible and can be carried out in the short term like changing the student faculty ratio or providing more faculty resources

Considering the dual values, the student faculty ratio constraint shows a dual value of 0.0652. It indicates that one unit increase in student faculty ratio at Emory University will increase its inefficiency by 6.52%. According to Lilienfeld and Candler Dobbs (2014) the student faculty ratio climbed from seven to one to eight to one in 2014 and nine to one in 2018. This is "despite the fact that Emory's endowment has rebounded, and its capital campaign has been strikingly successful". Moreover, the dual value of the faculty resource rank is 0.0217. It shows that as the faculty resource rank at Emory increases by one unit the school's inefficiency increases by 2.17%. As a matter of fact, the university has invested much more heavily in Emory HealthCare than in the College, meaning that the hiring of outstanding college faculty has taken a back seat.

This study was repeated using the data for 1998-99 and 2005-06 for Emory university and found out that E=0.5143 in 1998-09 and E=0.6735 in 2005-06, meaning that in 20 years the school's efficiency ratings has become a roller coaster with ups and downs. Interestingly in 1998-99 the composite school was formed from the weighted average of Cal. Tech. (W_c =0.80) and MIT (W_m=0.20) whereas in 2005-06 the composite school was formed from the weighted average of Cal.Tech. (W_c=.5714) and Harvard University (W_h=.4286).

If Emory rankings continue to stagnate or drop, the school will find it increasingly difficult to attract the same quality students and faculty that had kept Emory among the top 20 schools.

University of Chicago:

For the University of Chicago, the objective function and constraints are as follows:

Objective Function: Minimize E

Constraints:

Wc + Wh + Wm + We + Wg + Wch = 1	Weights of Operating Units
4.6Wc + 4.9Wh + 4.9Wm + 4.4We + 4.5Wg + 4.5Wch ≥4.6	Academic Reputation
25Wc + 35Wh + 36Wm + 21We + 24Wg + 41Wch ≥41	Alumni Giving Rate
94Wc + 97Wh + 93Wm + 91We + 86Wg + 94Wch ≥94	Actual Graduation Rate
97Wc + 97Wh + 98Wm + 94We + 97Wg + 99Wch ≥99	Avg. Freshman Retention Rate
8Wc + 5Wh + 8Wm + 25We + 26Wg + 8Wch ≤8E	Acceptance Rate
3Wc + 7Wh + 3Wm + 9We + 20Wg + 5Wch ≤5E	Student Faculty Ratio
9Wc + 4Wh + 12Wm + 19We + 178Wg + 3Wch ≤3E	Faculty Resources Rank
2Wc + 8Wh + 3Wm + 18We + 55Wg + 4Wch ≤4E	Financial Resources Rank
1Wc + 3Wh + 3Wm + 23We + 22Wg + 1Wch ≤1E	Student Selectivity Rank
E, Wc, Wh, Wm, We, Wg, Wch ≥ 0	

Applying the DEA to the University of Chicago inputs and outputs the objective function (efficiency index) E=1. This means that the composite college requires as much input as the University of Chicago does. There is no evidence that the University of Chicago is relatively inefficient. With unit efficiency index the amount of the resources used by University of Chicago is necessary to produce the output of the school itself. In other words, the Composite school is, in fact, made up of the University of Chicago itself.

Using the data for 2005-06, University of Chicago's efficiency index E= 0.6129. This value shows that the composite college can obtain at least the level of each output that University of Chicago obtains by having available only 61.29% of the input resources required by University of Chicago. Therefore, it can be concluded that the composite college is more efficient. In other words, University of Chicago is relatively inefficient compared to the other colleges in the group, namely California Institute of Technology and Harvard University. The data envelopment analysis (DEA) revealed that the composite college is formed from the weighted average of California Institute of Technology (W_c =0.6774) and Harvard university (W_h = 0.3226).

Using the data for 1998-99 University of Chicago's efficiency index is found to be E= 1. Comparing the two periods one can conclude that University of Chicago has become less efficient in 2005-06 and more efficient in 2018. The change in efficiency for the past several years explain why University of Chicago rise from #15 in 2005 to #3 in 2018 in university rankings.

According to Dan Mané (2012), a senior student, "Historically, UChicago has marketed itself for those seeking a totally rigorous intellectual environment at the expense of other niceties like fun, social life, etc. "Where Fun Comes to Die" was our slogan." This policy turned away many great students who wanted a more balanced college experience.

In the past few years the administration has made an effective shift to the brand and perception. One change was to use a common application essay, so more students can apply. Now the university has the intention of achieving more applicant pool and declines higher percentage. Another change was to hire a new admissions director and put more emphasis on career planning. So according to Dan Mané (2012), "UChicago has maintained its quirky and intellectually devoted character while also broadening its appeal and offering a more balanced college experience. (More fun.)"

Georgia Institute of Technology:

The objective function and constraints for Georgia Tech

Objective Function: Minimize E

Constraints:

$W_c + W_h + W_m + W_e + W_g + W_{ch} = 1$	Weights of Operating Units
$4.6W_c + 4.9W_h + 4.9W_m + 4.4W_e + 4.5W_g + 4.5W_{ch} \geq 4.5$	Academic Reputation
$25W_c + 35W_h + 36W_m + 21W_e + 24W_g + 41W_{ch} \geq 24$	Alumni Giving Rate
$94W_c + 97W_h + 93W_m + 91W_e + 86W_g + 94W_{ch} \geq 86$	Actual Graduation Rate
$97W_c + 97W_h + 98W_m + 94W_e + 97W_g + 99W_{ch} \geq 97$	Avg. Freshman Retention Rate

$8W_c + 5W_h + 8W_m + 25W_e + 26W_g + 8W_{ch} \leq 26E$	Acceptance Rate
$3W_c + 7W_h + 3W_m + 9W_e + 20W_g + 5W_{ch} \leq 20E$	Student Faculty Ratio
$9W_c + 4W_h + 12W_m + 19W_e + 178W_g + 3W_{ch} \leq 178E$	Faculty Resources Rank
$2W_c + 8W_h + 3W_m + 18W_e + 55W_g + 4W_{ch} \leq 55E$	Financial Resources Rank
$1W_c + 3W_h + 3W_m + 23W_e + 22W_g + 1W_{ch} \leq 22E$	Student Selectivity Rank
$E, W_c, W_h, W_m, W_e, W_g, W_{ch} \geq 0$	

Another DEA is conducted on Georgia Institute of Technology measures. Efficiency index is at 25% and that the Composite school is formed from the weighted average of California Institute of Technology ($W_c = 0.50$) and Harvard University ($W_h = 0.50$). Similar interpretation to that of Emory's can be stated. The efficiency index at 25% shows that the Composite school can obtain at least the same level of each output that Georgia Tech obtains by having available no more than 25% of the input resources required by the composite school. Obviously, Georgia Tech is relatively inefficient. The actual graduation rate (GR) has surplus of 9.5%. This difference shows that composite college is performing better than Georgia Tech. Another example is the faculty resources rank. The slack of 38 shows that as far as the faculty resources are concerned the composite school is in a position much higher than Georgia Tech.

Applying DEA to this school using previous data revealed that the school efficiency index was 0.2653 in 2005-06. Georgia Tech is a public university and according to Tagami (2016), "Georgia had some of the biggest school budget cuts in the nation during and after the Great Recession. According to the report by the Center on Budget and Policy Priorities, Georgia had the fourth-largest proportional cut in state per-student funding from 2008 to 2014". Comparing the outputs, during this period from 2005-2018 the actual graduation rate increased by 10% and alumni giving rate dropped by 7%.

Finally, for the sake of completeness DEA is performed on MIT, Harvard University, and California Institute of Technology and efficiency index is found to be E=1. It indicates that there is no evidence that above mentioned universities are inefficient. As conventional wisdom goes elite universities usually remain elite and have "sticky" reputations.

CONCLUSION

Based on the findings, there is evidence that Georgia Tech and Emory University are relatively inefficient compared to the schools in the system. University of Chicago relative to the other two Universities is much more efficient. The composite schools can provide the current level of outputs with fewer inputs. It can also be concluded that Emory and Georgia Tech efficiency index deteriorated over this period whereas University of Chicago's index improved from E=0.6129 to E=1. This could be due to increase in alumni giving rate and drop in student faculty ratio.

Other methods like regression analysis are also used in literature to rank efficiency of different operating units. Both DEA and regression analysis methods have their advantages and disadvantages. The advantage of DEA is that it measures the efficiency of a DMU against well performed units not against average performance, which is the case in regression analysis. DEA does not require a functional relationship between output and inputs and multiple outputs

can be used. On the other hand, regression analysis results are more stable and lend themselves to hypothesis testing.

ABSTRACT

This paper examines factors that affect the behavioral intention (BI) towards undergoing a gastric sleeve surgery (GSS). A research model, based on the theory of reasoned action (TRA) and the decomposed version of theory of planned behavior (TPB), was developed and empirically tested using an online survey questionnaire. Antecedent variables are attitude (A), body appreciation (BA), subjective norm (SN), price value (PV), satisfaction with life (SWL), relative advantage (RA), and perceived risk (R). The results showed that attitude toward gastric sleeve surgery, body appreciation, and subjective norm have significant positive effects on the intention to undergo a gastric sleeve surgery.

KEYWORDS: Gastric sleeve surgery, Obesity, theory of planned behavior, decomposed theory of planned behavior, Qatar

INTRODUCTION

Obesity has reached epidemic and disastrous proportions during the 21st century; the worldwide prevalence of obesity is more than 20% (Leitzmann et al., 2006). Obese people could result in disease like type 2 diabetes, hypertension, obstructive sleep apnea, several cancers, depression, diminished average life expectancy and significant impairments in quality of life. Obesity occurs if the energy intake was greater than energy expenditure on the long term and this eventually result in positive energy imbalance. This imbalance can develop from excess in calorie intake and/or a deficit in calorie expenditure (Shepherd et al., 2011). The prevalence of obesity has reached epidemic proportions; nearly 37 % of men and 38 of women worldwide are with a body-mass index (BMI) of 25 kg/m2 or greater (Ng et al., 2014). The obesity in Qatar may have just passed the United States, which was long the world leader. According to a report released by the Qatar Biobank more than 70 percent of the population in Qatar is either overweight or obese (Gichuki, 2017). For that reason, people in Qatar must put more effort to ensure a healthy future, free of diabetes and obesity illnesses, for themselves and their children. According to Katz (2013), the prevalence of diabetes in Qatar is approximately twice as great as in the United States, some 17% of the population as compared to the United States 8.3%. Morbidly obese patients have chosen surgical options like the weight loss bariatric surgeries to lose weight and to maintain the weight loss because diet and exercise alone have been shown to be largely unsuccessful in managing their obesity (Karmali et al., 2012). There are many surgical options that provide significant degrees of weight loss; however, Bariatric surgery is not risk free. Illness and mortality rates resulting from bariatric surgery continue to be a major concern (Habermann et al., 2009). The gastric sleeve surgery (GSS) is considered as the magical solution once done, the ultimate goal of having a thin ideal body is fulfilled. The GSS

also called vertical sleeve gastrectomy or laparoscopic sleeve gastrectomy is a surgical weight loss procedure in which the stomach is reduced to at least 75% of its original size, resulting in a new, tube-shaped stomach or “sleeve” and leads to significant decreases in Ghrelin production, leading to further weight loss. So many people have done it and so many people are willing to do it and more shockingly people who don’t suffer from any overweight issues intend to do it to control their weight. In this paper, we will investigate the factors that would influence the people intentions to undergo a gastric sleeve surgery, which is a weight loss surgery. Knowing those factors will help the health institutions and the society as a whole to control this surgical trend.

LITERATURE REVIEW

Theory of reasoned action (TRA) was developed by Fishbein and Ajzen (1975). This theory posits that the strongest predictor of a volitional behavior is the behavioral intention (BI). And the behavioral intention (BI) is thought to be the result of individual influence or behavioral attitude (A) (attitude towards a behavior) and nominal influence, the subjective norms (SN) of peer influence (Dillard, 2002). Theory of planned behavior (TPB) implied that human behavior is determined by intention to perform the behavior, which is affected jointly by attitude toward behavior (A), subjective norm (SN) and perceived behavioral control (Ajzen, 1991). Attitude (A) refers to a one’s attitude towards a certain behavior; it describes the general feeling of one’s desirability or undesirability of a specific behavior. Subjective norm (SN) expresses the perceived social pressure – pressure of significant people- on a person who intends to perform a particular behavior. On the other hand, Perceived behavioral control (PBC) measures one’s perception of the ease or difficulty of executing a particular behavior. Taylor & Todd (1995) developed the decomposed TPB model which includes additional factors such as relative advantages, compatibility, complexity, and facilitating conditions. The proposed model is based on theory of reasoned action and the decomposed version of (TPB) but with some modifications.

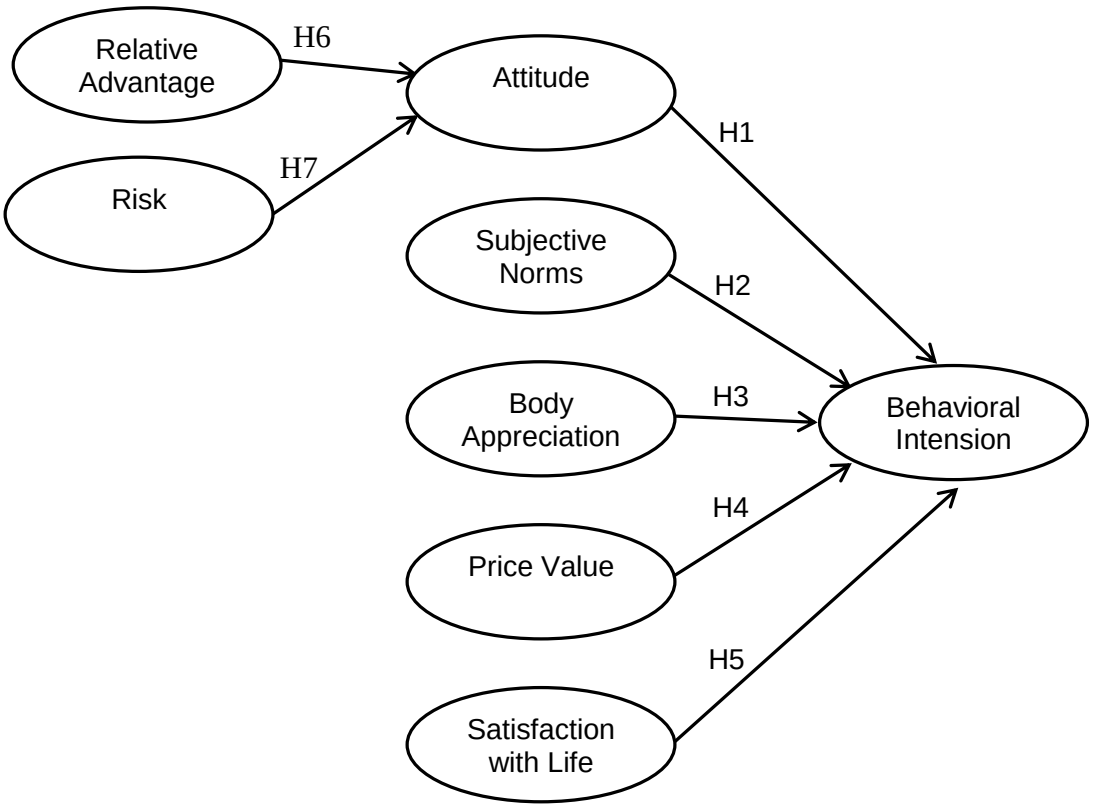
THE RESEARCH MODEL AND FORMULATION OF THE HYPOTHESES

In this study, the dependent variable is the intentions to undergo a gastric sleeve surgery as shown in Figure 1. Behavioral attitude (A) refers to an individual’s acceptance to undergo a GSS. The acceptance or positive behavioral attitude (A) will be affected by the positive influence of the relative advantages (RA) and the negative influence of the perceived risk (R) associated with GSS. This association indicates how important it is for that individual to have specific advantages and risk free surgery. The subjective norm (SN) refers to an individual’s perception of undergoing a GSS by peers (family and friends). The complexity transformed into perceived risk to better suite the study. Some additions were added by the researchers to this model; the effect of body appreciation, price value and satisfaction with life to the behavioral intention as shown in Figure 1.

Behavioral Intention (BI)

Intention is a sign of a person's willingness to do a given behavior, and it is considered to be the direct predecessor of behavior (Ajzen, 1991). In the TRA, The intention is based on attitude toward a behavior, and the subjective norm. In this paper, the following factors will be considered as predictors of the individual’s intention to undergo a GSS. These factors include attitude, subjective norms, price value, body appreciation, and satisfaction with life.

Figure 1: Research Model



Attitude (A)

Attitude is a psychological tendency that is reflected by examining a particular matter with some degree of favor or disfavor (Eagly and Chaiken, 1993). The behavioral attitude in TRA and TPB models refers to the person's attitude towards a certain behavior and in this paper; the behavior is undergoing a GSS. Furthermore, an attitude is an effective response toward performing some behavior and not toward some generalized attitude object (Dillard, 2002). Research on the association between attitudes and intention is extensive, and suggests attitudes toward cosmetic surgery should positively relate to future intention for the practice (Cho & Seong, 2010). Thus, we propose the following hypothesis:

H1: There is a significant positive relationship between attitude toward GSS and intention to undergo GSS.

Subjective Norms (SN)

According to Ajzen (1991), the subjective norm is defined as the perceived social pressure to engage or not to engage in an act or a behavior. In addition, it can be defined as a person's belief whether important people feel that she or he should perform a target behavior (Dillard, 2002). Significant or important people can be characterized as people who influence one's decisions and behaviors such as parents, friends, experts, and celebrities. In this paper, the researchers will examine the influence of significant people on one's intention about whether or not to undergo a GSS. Although no research to date has examined parental and peer influences on positive intention to undergo a GSS, Cafri et al., (2006) has found that there are family influences related to intentions to suntan, which is an activity also aimed at improving physical appearance that just like any bariatric surgery that carries a health risk. We predict that the more an individual parents and friends focused on body appearance, the more positive an individual will be toward undergoing a GSS. We posit the following hypothesis:

H2: There is a significant positive relationship between subjective norms and intention to undergo GSS.

Body Appreciation (BA)

In this paper, the concept of body appreciation is defined as how an individual recognizes and enjoys the good features of his or her body. Avalos, Tylka & Wood-Barcalow (2005) defined body appreciation by holding a positive evaluation of the body, accepting it as it is, respecting and attending to its needs and protecting it by rejecting unrealistic appearance ideals. Based on previous research done by Cash et al., (2005); Henderson-King & Henderson-King, (2005); Sperry et al., (2009); and Swami et al., (2009), it was predicted that individuals with less body appreciation, a higher body mass index (BMI), would report greater consideration of cosmetic surgery (Swami, 2009). Self-perceptions of attractiveness and satisfaction with appearance, which both are under the body appreciation umbrella, have been shown to be substantial predictor of interest in cosmetic surgery (Diraddo et al., 2009). As a contribution to literature, the researchers will study the influence of an individual's body appreciation on the intention towards undergoing a GSS, so the following hypothesis is proposed:

H3: There is a significant negative relationship between body appreciation and the intention to undergo a GSS.

Price Value (PV)

In marketing research, the monetary cost or price is usually hypothesized together with the quality of products or services to determine the perceived value of products or services (Zeithaml, 1988). Price value can be defined as consumers' cognitive compromise between the perceived benefits of the applications and the monetary cost for using them (Dodds et al. 1991). The price value is positive when the benefits of undergoing a GSS are perceived to be greater than the monetary cost and such price value has a positive impact on intention undergoing the surgery. Thus, price value is included as a predictor of behavioral intention to undergo the GSS. Literature suggests that the cost of surgical procedures has decreased as the number of surgeries performed has increased, which makes the option affordable for more people (American Society for Aesthetic Plastic Surgery, 2009). Another contribution to literature is to

measure the influence of price value on an individual's intention to undergo a GSS, so the following hypothesis is proposed:

H4: There is a positive significant relationship between price value of GSS and Intention to undergo GSS.

Satisfaction with Life (SWL)

Life satisfaction can be defined as the cognitive or mental factor of personal wellbeing (Martikainen, 2008). According to Diener (2000), satisfaction with life is a cognitive evaluation of overall quality of the life. Life satisfaction is one of the essential constructs of well-being. There are many potential factors that affect the level of satisfaction with life. These include personality, social expectations, socioeconomic factors, relationships with significant others, physical and psychological health, accommodation, employment and problem with authority (Schimmack et al., 2002). The physical and psychological health factors are definitely negatively affected by obesity, and this may result in low levels of life satisfaction. The level of satisfaction with life could result in high health status (like being fit) or low health status (like being Obese), and commonly when the person is obese he or she will look for solutions reduce their weight (positive intention to have a GSS), so we propose the following the hypothesis:

H5: There is a significant negative relationship between satisfaction with life and intention to undergo a GSS.

Relative Advantage (RA)

In this paper, we investigate the influence of two constructs; relative advantage of GSS and perceived risk on the behavioral attitude of an individual that will result in impacting the intention to undergo a GSS. Relative advantage refers to the case where an invention provides benefits, which surpass those of its predecessor and may incorporate factors such as financial benefits, image, enhancement, convenience and satisfaction (Rogers, 1983). Relative advantages should be positively related to an innovation's rate of adoption (Rogers, 1983; Tan & Teo, 2000). Relative advantage represents the extent to which the innovation is perceived to be superior in both economic and non-economic considerations to alternatives that are already available. And for this paper, the innovation is the invention of GSS. Undergoing a GSS will allow the individual to have a better look, health, and feeling. Therefore, the surgery provides a tremendous advantage and convenience to individuals. People will look for innovations that provide an advantage over the current products or services (Kleijnen et al, 2011). It can be concluded that relative advantage will also play a role in respect to the attitude and intention toward the GSS, so the following hypothesis is proposed:

H6: There is a significant positive relationship between relative advantage of the GSS and the attitude towards GSS.

Perceived Risk (R)

The International Organization for Standardization (ISO) defines risk as the "effect of uncertainty on objectives" (ISO, 2009). Uncertainty is the reason for any risk and uncertainty means not reliable and not identified (Borek et al., 2014). Introducing a new surgical advances may involve both benefits and risks to the patients, and before deciding to undergo any surgical advances, the patient may want to weigh risks and benefits. According (Gutteling et al., 2007), whenever

the perception of the risk is large, the perceived benefits will be less. Undergoing a GSS will have some risks that will negatively affect the attitude towards undergoing it. The perceived risk increases with the higher level of uncertainty or with an increased chance of negative outcomes (Lu et al., 2005). Moreover, it has been found that social risk has a negative impact on attitude for consumers (Yang et al., 2007). The perceived risks of having a cosmetic surgery – risks could be unfavorable physical and psychological outcomes- will negatively influence attitudes toward the practice (Cho & Seong, 2010). Therefore, it can be concluded that perceived risk of having a GSS will influence the attitude and consequently the intention toward undergoing the surgery, so we propose the following hypothesis:

H7: There is a significant negative relationship between the perceived risk of the GSS and the attitude towards GSS.

METHODOLOGY

Data Collection

An online survey was used for data collection. The questionnaire included 37 questions excluding demographics, and distributed in two languages Arabic and English. The questionnaire was distributed through emails and social networks.

Measures

The questionnaire items in this study were adopted from the literature. The scales where modified and tailored to suit the research topic of this study. A five-item Likert scale (ranging from 1-strongly disagree to 5-strongly agree) was used for all measures except demographics. Items measuring body appreciation were adopted from (Avalos et al., 2005). The three items that measure price value were adopted from (Dodds et al., 1991). Perceived risk scale items were adopted from (Featherman & Pavlou, 2003). Intention scale items were adopted from (Cheng et al., 2006); (Venkatesh et al., 2003); and (Taylor & Todd, 1995). Items to measure the relative advantage, behavioral attitude and subjective norms were adopted from (Taylor & Todd, 1995). Satisfactions with life items were adopted from (Diener et al., 1985).

DATA ANALYSIS

Characteristics of the Sample

A total of 256 participants returned the questionnaire; all the respondents complete the questionnaire fully except 10 respondents didn't fill the demographics part. The demographics part of the survey covered: gender, marital status, age, monthly income, education level, nationality, a question asking the participant if he or she had undergone the GSS, body shape, and a question about the influencing factor what might make the participant to undergo the GSS. The sample had 81 percent females. The majority of the participants were Qataris and between 26 and 35 years old. Approximately 60 percent of the participants are married. Almost 45 percent of participants receive a monthly income above 30,000 QAT. The majority (56 percent) has a bachelor degree. Eleven percent of the participant did undergo the GSS and almost 60 percent of the sample described their bodies as plump and overweight.

Reliability and Validity Assessment

It was important to ensure the reliability of the data before examining the factors that influence the positive intention of having a GSS. Cronbach's alpha is used to measure the reliability. According to Nunnally (1978), the standard reliability value of a scale should be above 0.7. In the Appendix, the means, standard deviations, and Cronbach's alpha for all items were reported. The values for all Cronbach's alphas were greater than 0.80 except one construct that is Risk, its' Cronbach's alpha was 0.584 and after dropping one statement (R3), the Cronbach's alpha increased to 0.646; and therefore, they all displayed good internal consistency. The validity was assessed using exploratory factor analysis. Factor analysis was performed on all items that are predictors of the dependent variable, the Intention. The assessment was done including the six predictors. Principle component analysis with varimax was used, the measures of each construct clustered together. All items loaded on their intended factor. A confirmatory factor analysis was performed to assess the model fit. The NFI index was 0.93 and the CFI index was 0.96 both exceeded 0.9 the accepted value as suggested by Comrey and Lee (2013). The other index, the root mean square error of approximation (RMSEA) was 0.07, which is less than 0.08, the accepted value as suggested by Hu & Bentler (1999). Additionally, we employed Harman's single factor test to assess if common method bias exists in this study. Only 31% of the variance was accounted for one single factor, which is less than the threshold value of 50% as suggested by Podsakoff et al. (2003).

RESULTS

Several tests were performed to ensure that the assumptions of the multiple regression models were not undermined. Multicollinearity was not a problem because the variance inflation factors (VIFs) were low 1.566. From the Durbin-Watson statistic test, it was concluded that autocorrelation did not exist (D.W. =2.028). In addition, the plot of the dependent variable against each of the independent variables showed a linear relationship between these respective variables.

Hypotheses Testing

To answer the first research questions (What are the factors that influence the one' intention to undergo a GSS?); the multiple regression analysis was performed to test hypotheses H1, H2, H3, H4 and H5. The dependent variable behavior intentions (BI) was regressed against behavioral attitude (A), price value (PV), satisfaction with life (SWL), body appreciation (BA), and subjective norm (SN). As shown in Table 1, the regression result indicated that H1, H2, and H3 were significant and explained 78 percent of the variance in behavioral intention for the sample. The second research question was (What are the factors that influence the behavioral attitude (A) towards the GSS?), another multiple regression analysis was performed to test hypotheses H6, and H7; the dependent variable behavior attitude (A) was regressed against relative advantage (RA), and risk (R). The regression result indicated that the two factors were significant and explained 45 percent of the variance in behavioral attitude (A).

Table 1: Regression Results

Reg. Model	Dep. Variable	R^2	Independent Variables

Model 1	Intention	0.779	Attitude (H1)	Subjective Norm (H2)	Body Appreciation (H3)	Price Value (H4)	Satisfaction with Life (H5)
			0.705 (0.000)	0.199 (0.000)	-0.143 (0.000)	-0.009 (0.769)	0.049 (0.156)
Model 2	Attitude	0.451	Relative Advantage (H6)	Risk (H7)			
			0.554 (0.000)	-0.281(0.000)			

DISCUSSION AND CONCLUSION

This study examined how factors like (attitude)--the feelings, and behavioral tendencies towards the GSS; (subject norm)--the perceived social pressure to engage or not to engage in undergoing a GSS; (body appreciation)--how an individual recognize and enjoy the good features of his or her body; (price value)--the cognitive compromise between the perceived benefits of the GSS and the monetary cost for it; (satisfaction with life)--the cognitive assessment of one's life, influence the individual's intention to undergo a GSS. The study intended to examine influences of the above-mentioned factors on individuals' intentions to undergo a GSS. The findings of the research showed three significant factors in model 1 and two significant factors in model 2. The results showed compatibility with the theory of planned behavior (TPB) framework as suggested by (Ajzen, 1991). The higher positive attitude towards the GSS, and the higher subjective norm influence, the higher the positive intention of undergoing it will be. In addition, the research findings supported prior research results in which, self-perceptions of attractiveness and satisfaction with appearance, which both are under the body appreciation umbrella, have been shown to be substantial predictor of interest in cosmetic surgery (Diraddo et al., 2009). It should be noted that attitude (Beta=0.705, Sig.= 0.000) towards the GSS had the most significant impact on behavioral intention, followed by subjective norm (Beta=0.199, Sig.= 0.000) and body appreciation (Beta=-0.143, Sig.= 0.000). Since the objective of this study goes beyond finding the major influences on individuals' intention only, the researchers hope once those major factors are identified, they are controlled and get close attention in order to gauge the increase in the number of gastric sleeve procedures.

Since attitude has the highest influence on the intention, a close attention must be paid to it. In this research, attitude was predicted by risk (Beta=-0.281, Sig.= 0.000) and relative advantage (Beta=0.554, Sig.= 0.000), and both factors were significant. These two factors can be controlled to reduce the positive attitude on undergoing a GSS. The risk and negative circumstances of this surgery must be highlighted more than its advantages. Having the relative advantage as the highest influencing factor on the attitude was not surprising. Recently in Qatar, people who were well known for their big bodies and obesity; suddenly transforming into models. This phenomenon made individuals, whether they are overweight or not, to see the GSS as a miracle that offers the ideal body in a very short period, which is a remarkable advantage that overweighs the risk. Thus, few people who know the risks of the GSS or even challenge it.

The subjective norm was also another influencer on the intention, this complies with the theory in general, but more specifically when talking about Qatar, we live in a collectivism or in other words socialism community, so the chances of being affected by parents, relatives, and friends is high. Thus, opposing to individualism society, where individuals pursue their own goals

without being, to some extent, affected by others. In collectivism cultures, people put higher importance on belonging to a group and respect opinion of the other members of the society (McCoy et al., 2007). Body appreciation effect on the behavioral intention was significant. People who appreciate their bodies will have a negative intention towards changing anything in their bodies. It should be noted that price value and satisfaction with life were not significant. The insignificance of price value might be caused by the fact that Qatar income is considered as one of the highest in the world, in addition almost 45 percent of the respondents have a monthly income of 30,000 and above. For the satisfaction with life, the insignificance maybe because the scale used was very general. Satisfaction with body scale might be more appropriate.
The results of this study provide insights for both practitioners and public. Practitioners should raise the awareness of the Gastric Sleeve Surgery in terms of its short and long term risks, benefits, and limitations. With the support of health institutions, they should work harder in changing the unhealthy mindset of people in regards to sport, healthy food and healthy life style. This could be achieved through social media messages about the GSS. In addition, outreaching the school students, who are the future of any society, and involve them in activities that reinforce the importance of healthy diet and sport. Achieving this will build a negative attitude toward any weight loss surgical practice and will shift their actions towards sport, and healthy diet. Same responsibility applies to the individuals themselves. They should be more attentive to their body needs and must try all possible solution before undergoing a surgical procedure for weight loss rather than being hasty and look for the immediate solution, also they should not be directed by the word of mouth of peers.

LIMITATIONS AND FUTURE RESEARCH

Although the findings of the study offer valuable insights into obesity and weight loss surgeries literature; however, these findings should be interpreted in light of the following limitations: The relatively small sample size, and self-reported information. Future research could include more factors such as complexity, perceived behavior control, and facilitating condition. Increase the sample size and conduct a similar study in deferent countries.

APPENDIX: DESCRIPTIVE STATISTICS AND RELIABITITY			
Items	Measures	Statistics	
		Mean	S.D.
Intention: Cronbach's Alpha=0.953			
IN1	Given that I have access to a gastric sleeve surgery, I predict that I would undergo the surgery if I gained weight	2.63	1.31
IN2	I intend to undergo gastric sleeve surgery in the future if I am overweight	2.57	1.336
IN3	I plan to receive gastric sleeve surgery in the future to look better	2.39	1.27
IN4	I will consider gastric sleeve surgery as my first option if I gain weight	2.18	1.221
Price Value: Cronbach's Alpha=0.866			
PV1	A gastric sleeve surgery is reasonably priced	2.75	1.062
PV2	A gastric sleeve surgery is a good value for the money	3.01	1.074
PV3	At the current price, a gastric sleeve surgery provides a good value	2.93	1.058
Body Appreciation: Cronbach's Alpha=0.890			
BA1	On the whole, I am satisfied with my body	3.55	1.197
BA2	Despite its flaws, I accept my body for what it is	3.58	1.195
BA3	I take a positive attitude toward my body	3.75	1.043

BA4	My feelings toward my body are positive, for the most part	3.69	1.019
BA5	I respect my body	4.05	0.85
BA6	I am attentive to my body's needs	3.66	1.031
BA7	I engage in healthy behaviors to take care of my body	3.52	1.036
Subjective Norm: Cronbach's Alpha=0.952			
SN1	People who are important to me would want me to undergo the gastric sleeve surgery if I gained weight	2.21	1.196
SN2	People who influence my behavior would want me to undergo the gastric sleeve surgery if I gained weight	2.27	1.181
SN3	People whose opinions that I value would prefer that I undergo a gastric sleeve surgery if I gained weight	2.25	1.198
SN4	Most people who are important to me would think that receiving a gastric sleeve surgery is a wise idea if I gained weight	2.29	1.169
SN5	Most people who are important to me would think that receiving a gastric sleeve surgery is a good idea if I gained weight	2.34	1.223
Attitude : Cronbach's Alpha=0.919			
A1	I would like to undergo a gastric sleeve surgery if I need it	2.81	1.304
A2	I feel receiving a gastric sleeve surgery is a wise idea	2.62	1.228
A3	I feel receiving a gastric sleeve surgery is a good idea	2.73	1.269
Satisfaction with Life: Cronbach's Alpha=0.848			
SWL1	The conditions of my life are excellent	4.04	0.74
SWL2	I am happy in my life	4.18	0.693
SWL3	I have gotten the important things I want in my life	4.16	0.726
Relative Advantage: Cronbach's Alpha=0.873			

RA1	If I gained weight, receiving a gastric sleeve surgery will make me feel better than before	3.18	1.283
RA2	If I gained weight, receiving a gastric sleeve surgery will make my health better than before	3.11	1.311
RA3	If I gained weight, receiving a gastric sleeve surgery will make me look better than before	3.41	1.316
Risk: Cronbach's Alpha=0.646			
R1	The Gastric sleeve surgery may not be successful and result in sever circumstances	3.82	1.081
R2	It would take me lots of time to cope with a reduced stomach size if I did the surgery	3.86	1.014
R3	If an error occurs during the surgery, I worry that I cannot get the result I wanted (lose weight)	4.02	1.021

ABSTRACT

Over the past decades, data analytics and related applications and technologies have become increasingly important. Accordingly, job postings seeking data analytics specialists abound. In response to the tremendous needs of the job market, higher education institutions have invested millions of dollars to develop data analytics curriculums, minors, majors, and certificate programs. Based on the nature of big data and data analytics, this paper proposes a data analytics course to enhance undergraduate experiential learning in technology entrepreneurship. Course description, learning objectives, pedagogical approaches, faculty team of course development, and supportive entrepreneurial ecosystem for the course teaching are discussed.

KEYWORDS: Data Analytics, Course Development, Undergraduate, Information Systems

INTRODUCTION

Data analytics refers to collect, analyze, and present the user-generated contents and data to gain meaningful insights into organizational practice, processes, and trends (Chen et al, 2012). Over the past decades, data analytics and related applications and technologies have become increasingly important in both academic and business communities, suggesting the ways in which enterprises such as businesses, non-profits, and governments use various data to gain insights and make better decisions. Nowadays, companies and organizations (e.g., Walmart, Google, Capital One, and Disney) are embracing data analytics applications and technologies to reengineer business operations and decision making (McAfee et al, 2012).

Accordingly, in the labor market, job postings seeking data analytics specialists abound. Manyika et al (2004) predicted that by 2018, the United States alone will need 2 million data-savvy workers and managers with analytical skills and education. Business demands are in increase for

employees with skills and training needed to manage the three “perspectives” of decision making: descriptive, predictive, and prescriptive analytics. Boasting a base salary of $110,000 and a job-satisfaction score of 4.4 of 5, data analytics were ranked No. 1 on the “Best Jobs in America” list in 2016 and 2017 (The Market Watch Reports, 2018).

In response to the tremendous needs of the job market, higher education institutions have invested millions of dollars to develop data analytics curriculums, minors, majors, and certificate programs. In the local area, however, our survey shows that the local businesses and companies are still in large need for data analytics workers at the entry undergraduate level. To fill this gap, we propose the data analytics course to enhance undergraduate experiential learning in technology entrepreneurship.

BIG DATA & BIG DATA ANALYTICS

Big data can be characterized with the following dimensions (De Mauro et al, 2016; McAfee et al, 2012; Suthaharan, 2014). (1) Variety. The scope, types and formats of big data extend from traditional structured to semi-structured and unstructured data of all varieties. (2) Volume. The word, big, describes the vast quantity of the data explosion. (3) Velocity concerns both frequency and speed of big data explosion. And, (4) variability refers to the wide inconsistencies of big data. The essential of big data is to collect, analyze, and present the user-generated contents and data to gain meaningful insights into businesses practice, processes and trends. This process has been referred to as data analytics in which the dataset can be so large, various, complex, and ever changing that unique advanced computing technologies and techniques of data management, analysis, and visualization have to be deployed to address the significant impacts (Fan & Gorden, 2014).

DEVELOPING A DATA ANALYTICS COURSE TO BUILD UNDERGRADUATE EXPERIENTIAL LEARNING

Course Description & Learning Objectives

Big data analytics focus on understanding, interpretation, strategizing, and taking action to further business interests. To reflect the characteristics of big data, and map major techniques and technologies of data analytics to the organizational needs for skilled undergraduate learners, we propose the course description as,

> With the increasing availability of broad and various sources of data – so-called “Big Data” that refers to datasets whose size is beyond the ability of typical database software tools to capture, store, manage, and analyze – data analytics is becoming an even more critical capability for enterprises of all types and all sizes. In this course, students will learn to identify, evaluate, and capture data analytic opportunities that create business value. Toward this end, students will learn basic data analytics principles and methods and analyze case studies on organizations that successfully deployed these techniques. Throughout the course, we will explore the challenges that arise in implementing analytical approaches within an organization. Specifically, the course provides an overview of data analytics concepts, principles, procedures, techniques, technologies and applications for business data gathering, storing, processing, manipulating, and interpreting. The course discusses and demonstrates the associated statistical approaches and data mining techniques that arise in the area. Students will learn

key procedures and techniques of data analytics such as parallel algorithms, text mining, social network analytics, machine leaning, data mining, and descriptive, predictive and prescriptive analysis. The applications associated with each technique (such as the fundamental platforms, Hadoop/MapReduce, R, Python, and Tableau) will be hand-on-practice in the form of individual assignments and teamwork project.

Throughout the course, we will emphasize the entire data analytics cycle, which includes the following stages: (1) understanding of business and its opportunities, challenges, and problems; (2) data understanding and preparation; (3) modelling: construct a model to address business interests; (4) evaluating: evaluate possible models and solutions; and (5) deployment and recommendations of data analytics modeling. Accordingly, we have three goals in this course. The first is to help you develop mindset of analytics and think critically about business and data. The second is to enable you to identify opportunities for creating value using data analytics. The third is to help you analyze and estimate the value created using data analytics to address an opportunity.

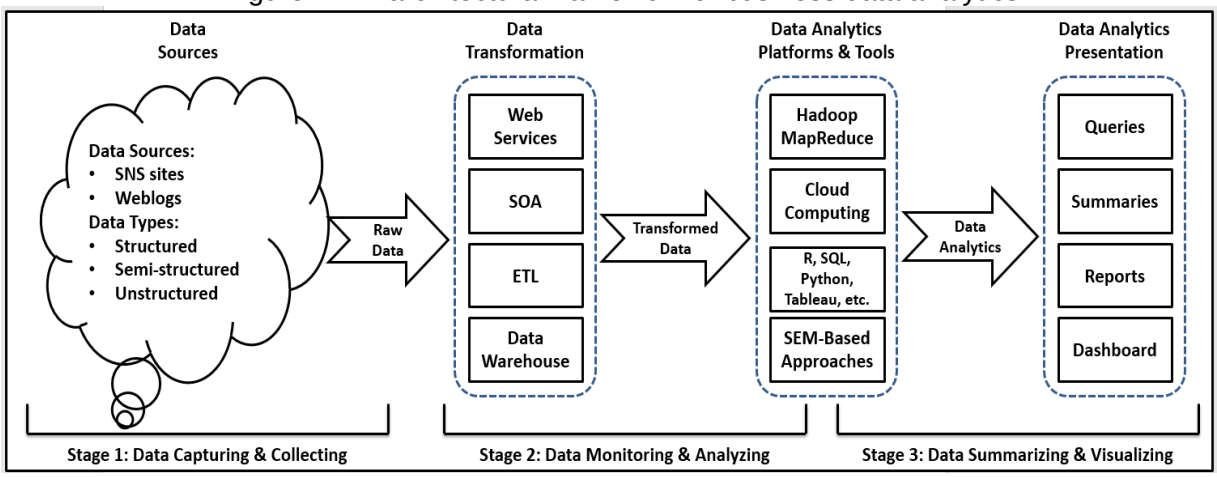
In line with the course description, the prerequisites for the course are required regarding the general understanding of database, information systems (IS) analysis and design, network and data communication (Chen et al, 2012; Fan & Gorden, 2014; Raghupathi & Raghupathi, 2014; Stigelitz & Xuan, 2014; Zeng et al, 2010). Upon the successful completion of the course, undergraduate students should be able to,

- Explain the ideas of data analytics to support business operations and decision making.
- Understand how to determine the appropriate data analytics tools, technologies, techniques for intended business analysis.
- Understand how to extract, transform, load and analyze business dataset upon defining business objectives.
- Design and implement data analytics solutions to address business interests, problems and opportunities.
- Report and illustrate to business stakeholders the procedures, interpretations, and deployment and recommendations of data analytics.

Data Analytics Architecture

We propose a data analytics architecture to facilitate the course teaching. As illustrated in Figure 1 below, the architecture integrates Hadoop/MapReduce, cloud computing, R, SQL, SEM, and other associated technologies and applications of data analytics into the organizational decision making setting (Hu et al, 2018). The content coverage systematically trains students with data analytics skillset and mindset.

Figure 1: An architectural framework of business data analytics



- Hadoop/MapReduce – an open source software framework providing computational capabilities for distributed storage and processing of large, various and complex datasets.
- Python – Python has a powerful data analysis library that provides powerful analytics tools suited to handle big datasets.
- Cloud Computing. Due to the flexibility and effectiveness of cloud computing, many data analytics technologies can be deployed without specific setup expertise.
- R & Tableau. R is an integrated suite of database environment for predictive analytics, data mining and data visualization. Tableau is an interactive data visualization tool. R and Tableau are bundled with an integrated collection of intermediate tools for data analytics.
- SEM-Based Approaches – A diverse set of computing algorithms and statistical methods for factor analysis, path analysis, and latent growth modeling.
- SQL & NoSQL. The SOL is still used heavily as a primary approach to querying big data. Meanwhile, applications of NoSQL and Interactive SQL can be embraced to examine semi-structured and unstructured data.
- Others: For data analytics methods (e.g., content analysis, text mining, opinion/sentiment analysis, social network analysis etc.), many tools provide programing interfaces for business use.

Pedagogical Approaches

The course will be taught in the form of student teamwork modules covering interrelated topics of data analytics technologies, procedures, and techniques. Teaching activities consist of instruction lectures, demos of analytics techniques and technologies, hand-on-exercises, teamwork projects, team presentations and discussions, and invited talks of researchers and business practitioners. The textbooks and materials will be reviewed; requests for review copies will be made to determine the required and complementary readings for the course.

Student Teamwork Projects

Modular teamwork projects will be assigned and used to evaluate student performance in the course; project teams of 3-4 students will be formed. The purpose of the teamwork projects is to

allow students to apply many of data analytics concepts, techniques and technologies to a specific business context. The projects will provide students with significant experiential leaning on which they can develop relationships and enhance technology entrepreneurship with companies. Many skills in data analytics will be learned and reinforced in depth as the student teams work on the projects.

For the projects, student teams will either be provided the open source datasets, or will identify by themselves a company that has a significant business problem or opportunity that can be addressed through the collection and analytics of corporate data resources. The teamwork projects will be conducted based on business procedures, thus it is important that teams are able to define the business characteristics and processes to complete the various requirements of data collection and analytics. Essentially students will follow the stages of big data gathering, storing, manipulating, interpreting, and visualizing to address particular needs of the business.

FACULTY TEAM OF COURSE DEVELOPMENT

By nature, the data analytics course is multidisciplinary in that information systems (IS), computer science, statistics, management, and marketing are involved. It covers organizational behavior, critical analytical thinking, business domain knowledge, and oral and written communications that are critically needed in a complex data-centric business environment (Chen et al, 2012). Thus, IS programs and faculty are uniquely positioned to develop and teach the course and train data analytics workers.

Our team of the course development consists of four full time IS faculty members. Among them, the principal investigator takes primary responsibility to coordinate course development activities, and review teaching materials and textbooks. In the team, one of the faculty members currently serves as the Associate Chair of the Department, and will be responsible for maintaining the institutional support and the entrepreneurial ecosystem for the student teams, and establishing course evaluation criteria and assessing teaching outcomes. The rest of the team provides support for the construction, assessment and management of the course.

SUPPORTIVE ENTREPRENEURIAL ECOSYSTEM FOR STUDENT TEAMWORK TEACHING

The Department, the Business School, and the university, where the proposed course is housed, all have long established a welcoming supportive entrepreneurial ecosystem that focuses on providing students with practical business resources, skills and solid theoretical foundation needed for success in the business environment. The faculty and staff members of the departments, student career center, and college entrepreneurship centers have maintained long term relationships with alumni organizations, and internal and external business communities. The culture of collegiality, community, and commitment within the college largely facilitates students to interact with the real business world and market and commercialize their knowledge, skills and technologies.

CONCLUSION

Given the tremendous needs of both academic and business communities for data analytics workers, and the tradition and commitment of the department and college in establishing the supportive entrepreneurial ecosystem, we have full confidence that the proposed efforts in the construction and teaching of the data analytics course will continue well into the future in developing minor, major, and certificate and graduate programs in the subject matter. We also

have the strong faith that the course will be successful in satisfying the learning objectives, establishing best student teamwork practice, building data analytics skillset and technology entrepreneurship for undergraduate students, and further, helping student teams market and commercialize their skills, knowledge and technologies in data analytics.

DECISION SCIENCES INSTITUTE

Development of a Composite Sustainability Risk Index for Outsourcing Country in Apparel Industry

Gbemileke A. Ogunranti

Drexel University, Philadelphia, PA, USA
Email:gao32@drexel.edu

ABSTRACT

This paper presents the application of the data envelopment analysis cross efficiency method for creating a composite sustainability risk index and ranking of a country in terms of outsourcing production for contract manufacturing in the apparel industry. We consider sustainability-related supply chain risks found in the literature and group them into four major categories, (in use by Nike Inc.) for analyzing country level sourcing risk, namely: political, economic, social/compliance, and infrastructure and climate risks. The results of this study show that this method can be used to identify low-risk countries for making effective outsourcing decisions.

KEYWORDS: Data Envelopment Analysis, Supply Chain Risks, Sustainability, Outsourcing

INTRODUCTION

Global supply chains are complex, fragmented and often influenced by factors beyond the control and purview of individual firms, especially in terms of offshore outsourcing of production. Offshore outsourcing is a common cost reduction strategy in global supply chains but managing such a supply chain is often quite challenging. The U.S. apparel industry outsourced over 40% of its production to low-cost manufacturing countries (VF Corporation, 2016). This makes the supply chain vulnerable to external risks beyond the control of a company outsourcing its production. Such risks differ from country to country. These include: foreign government political risks, legislation and regulation, ethical labor practices such as fair wages, health & safety of workers, maintaining acceptable working conditions at production facilities in different countries, environmental issues such as use and/or disposal practices of toxic or harmful chemicals in manufacturing processes (for example, dyes and softeners), availability and cost of natural resources such as energy, cotton, rubber, and water, among others.

However, the first most important step in offshore outsourcing for global companies is the assessment of its offshore outsourcing countries for the overall risk that might disrupt its supply chain. Therefore, it is imperative to identify countries with low-risk based on both qualitative and quantitative approaches involving multiple criteria. This paper presents quantitative models for measuring and ranking of countries based on the overall outsourcing risk before selecting a contract manufacturer to add to its supply base. Traditionally, most global companies focus on low-cost countries which are not adequate in the current global business environment. Managing risks,

complexity and marketplace dynamics have become crucial for remaining competitive in the current global economy. In this study, we characterize supply chain sustainability-related risks found in the literature into four major categories, namely: political risk, economic risk, social/compliance risk, and infrastructure and climate risk; which are in use by Nike Inc. for analyzing country level sourcing risk.

Based on the unethical practice found in some countries, a factory owner might fail to comply with wage regulations and labor standards. A study by Maplecroft (2012) reveal that supply chains are exposed to the risk of child labor practices in some of the fastest growing economies, including the Philippines, India, China, Vietnam, Indonesia, and Brazil, all of which are classified as 'extreme risk' nations. This might have a negative impact on companies that outsource manufacturing to these countries. For instance, Nike's use of foreign manufacturers has periodically tarnished its image, and its campaign to eliminate such problems hasn't been easy (Banjo, 2014). Bangladesh, the No. 2 exporter of apparel after China is associated with unsafe working conditions, low wages, and persistent fire incidents at many of its garment factories for more than a decade, with hundreds of workers killed over the years (Manik and Yardley, 2012). This country's national economy depends largely on this industry, both as a source of employment and foreign currency because garments constitute about four-fifths of the country's manufacturing exports. Global retailers like Walmart and Sears outsource production to Bangladesh. In 2014, Walt Disney Co. pulled its manufacturing out of Bangladesh in response to a building collapse in the previous year. But retailers, including Wal-Mart Stores Inc., Hennes & Mauritz AB, and 170 others have chose to stay, signing five-year agreements, pledging to draw up safety standards and help fund improvements (Banjo, 2014). There is a need for companies to take a balanced approach to sourcing by taking into consideration environmental, social, quality and cost factors.

The apparel industry is unique and one of the most globalized industries in the world. For example, Nike Inc. value chain has more than 900 contract factories with more than 1 million workers and more than 500,000 different products - each with its own environmental and social footprint (NikeFY10/11 Report, 2011). Also, VF Corporation the world's largest publicly owned apparel company manufactures 21% of its products in China, 40% in Americas, 2% in India, 3% in Egypt, 3% in Indonesia, 11% in Vietnam, 12% in Bangladesh, and 12% in other countries (VF Corporation, 2016). A typical global supply chain comprises of multiple entities such as: a combination of retailers, contractors, subcontractors, merchandisers, buyers, manufacturers and suppliers. The whole supply chain system has become very critical for managing risk in a dynamic, and complex environment (i.e. a supply-driven commodity chain where each player's role is important in the supply network, which spans from fibers to yarn, to fabrics, to accessories, to garments, to trading, and to marketing) (Ramesh and Bahinipati, 2011). Thus, it is difficult in managing multiple priorities of controlling costs, environmental pressures, and maintaining acceptable working conditions. Although there are numerous articles studying the (decision) criteria to be used for the supplier selection process, relatively few papers address criteria related to safety and security issues, which have become extremely important, given the present threats to security and the current 'climate' around the world (Sonmez, 2006).

The remainder of this paper is organized as follows: section 2 gives a brief overview of Data Envelopment Analysis (DEA) model and cross efficiency ranking methodology. Section 3 presents the basic DEA model and solution approach used in this study. Section 4 provides the details of the DEA model evaluation and the analysis results. The last section concludes with a summary as well as some managerial implications of this study.

DATA ENVELOPMENT ANALYSIS (DEA)

Data Envelopment Analysis (DEA) is a linear programming-based method (non-parametric) originally developed by Charnes et al. (1978). Since its introduction, DEA has been extensively studied and applied by researchers in various fields such as management, healthcare, agriculture, environment, transportation, social sciences, public policy, engineering, and education, among others. Unambiguously, this shows DEA's significance and relevance to researchers far and beyond OR/MS, the disciplinary base of the field's founders (Gattoufi et al., 2004). The DEA model allows us to evaluate the relative performance of decision-making units (DMU) by determining a set of optimal weights for each of its inputs and outputs so as to maximize its efficiency. Cook and Seiford (2009) provide a comprehensive review of DEA research covering theoretical developments, as well as "real-world" applications from its inception to 2007 (i.e. the first 30 years of the history of DEA). There are far too many papers on the application of DEA to thoroughly document here. Some works applying DEA in various disciplines include Partovi (2011), Malul et al. (2009), Cherchye et al. (2008), Cook and Green (2004) and many others. We refer interested readers to Cook and Seiford (2009) and Cooper et al. (2000).

The DEA model considers k DMUs that are evaluated in terms of n outputs and m inputs. Let O_{ik} and $I_{jk}, i = 1, 2, ..., n, j = 1, 2, ..., m$, be the output and input values of DMU_k where $k = 1, 2, ..., K$. The CCR (Charnes, Cooper, Rhodes, 1978) model for evaluating the efficiency of e^{th} DMU can be expressed as shown below:

$$Max: \quad E_e = \frac{\sum_{i=1}^{n} w_i O_{ie}}{\sum_{j=1}^{m} v_j I_{je}}$$

Subject to:

$$\begin{aligned} &\frac{\sum_{i=1}^{n} w_i O_{ik}}{\sum_{j=1}^{m} v_j I_{jk}} \leq 1 \quad k = 1, 2, ..., K \\ &w_i \geq 0, \quad v_j \geq 0, \quad i = 1, 2, ..., n, \quad j = 1, 2, ..., m, \end{aligned} \tag{1}$$

In model (1) above, the index i,j, and k refer to a specific sets of outputs, inputs, and DMUs, respectively. The variables w_i and v_j are the relative weights of the output i and input j to be determined by the solution of the model in (1) above.

Output-Oriented Model

Model (1) can easily be transformed to an output maximization linear programming problem as shown in (2) below. This is referred to as the output-oriented model. In an output-oriented model, an inefficient unit is made efficient through the proportional increase of its outputs, while the inputs proportions remain unchanged (Emrouznejad, 2011).

$$Max: \quad E_e = \sum_{i=1}^{n} w_i O_{ie}$$

Subject to:

$$\begin{aligned} &\sum_{j=1}^{m} v_j I_{je} = 1 \\ &\sum_{i=1}^{n} w_i O_{ik} - \sum_{j=1}^{m} v_j I_{jk} \leq 0 \quad k = 1, 2, ..., K \\ &w_i \geq 0, \quad v_j \geq 0, \quad i = 1, 2, ..., n, \quad j = 1, 2, ..., m, \end{aligned} \tag{2}$$

The solution to model (2) gives a dichotomy classification of the DMUs into two distinct groups: efficient and inefficient DMUs. This classification does not provide a way of selecting the best DMU, but rather efficient ones. Several previous researchers have proposed different approaches for ranking and selecting the best DMU. The most widely used ranking methodologies are cross-efficiency, super-efficiency which has proved to be popular in the literature, and the benchmarking approach. For other ranking models in DEA, we refer interested reader to Adler et al. (2002) and Hosseinzadeh Lotfi et al. (2013).

Cross-Efficiency

Cross-efficiency is a ranking method in which the units are self and peer evaluated, resulting in a cross-efficiency matrix. It was first introduced by Sexton et al. (1986). This method simply evaluates the efficiency score k times, using the optimal weights obtained from model (2). Suppose that $w_i^*(i = 1, 2, ..., n,)$ and $v_j^*(j = 1, 2, ..., m)$ are the optimal solution to model (2). Then, the cross-efficiency of any DMU k using the outputs and inputs of a chosen e^{th} DMU can be determined using the following equation:

$$\theta_{ke} = \frac{\sum_{i=1}^{n} w_{ki}^* O_{ei}}{\sum_{j=1}^{m} v_{kj}^* I_{ej}} \quad k = 1, 2, ..., K \tag{3}$$

Where $\theta_{ke} \in [0 - 1]$ indicates that DMU_e is evaluated using the weights of DMU_k.

Note that the results of equation (3) above give the cross-efficiency matrix with the diagonal elements representing the standard DEA efficiency score. If $\theta_{ee} = 1$, DMU_e is efficient, otherwise it is inefficient. Therefore, the cross-efficiency score of DMU_e is given by the average of the θ_{ke} values and can be expressed as follows:

$$\hat{\theta_e} = \frac{\sum_{k=1}^{K} \theta_{ke}}{K} \tag{4}$$

However, averaging is not the only approach; some authors suggest that minimum, median or variance of scores could be applied (Adler et al., 2002). For further understanding of detailed ideas of cross-efficiency, both mathematically and intuitively, see Doyle and Green (1994).

MODEL APPLICATION

This section presents the basic DEA model used in this analysis for creating a single composite sustainability risk index for each country. In this study, we have four major indicators with sub-indicators to evaluate different countries to be selected for the DEA analysis. The indicators are political risk, economic risk, social/compliance risk, and infrastructure and climate risk. The sub-indicators will be referred to as outputs in this study. Similar to Cherchye et al. (2008) and the first model in Malul et al. (2009), our input is standardized to 1. Therefore, the standard DEA model in (2) become the same with DEA model in Cherchye et al. (2008) as shown below:

$$Max: \quad E_e = \sum_{i=1}^{n} w_i O_{ie}$$

Subject to:

$$\sum_{i=1}^{n} w_i O_{ik} \leq 1 \quad k = 1, 2, ..., K \tag{5}$$
$$w_i \geq 0, \quad i = 1, 2, ..., n.$$

Cross efficiency methods in (3) and (4) are applied to the resulting weights obtained from of the model in equation (5). This cross efficiency is referred to as the Sustainability Risk Index (SRI) for each country. To apply the model in (3), we use readily available r-data envelopment analysis package called “Benchmarking" (Bogetoft and Otto, 2015) and the cross efficiency computation method is coded using MATLAB.

DEA Evaluations

We consider forty five (45) countries for the DEA analysis based on three main criteria as follows: countries with cotton yarn production, woven cotton fabrics production (from http://unstats.un.org/unsd/mbs/table_list.aspx) and factory locations of major apparel company such as Nike Inc. In this study, we assume that inputs are standardized to one. The indicators and sub-indicators used for representing outputs in this analysis are: political stability and absence of violence (PSAV), Rule of law (ROL), corruption perception score (CPS), inflation (INF), ease of doing business (EDB), debt to GDP ratio (DTGDP), human development index (HDI) rank, overall logistics performance index (LPI) score, world risk index (WRI) and environment protection index (EPI). Table 1 shows the correlation matrix between DEA outputs and Table 2 shows the data used for the DEA model evaluation.

Table 1: DEA Outputs Correlation Matrix

Outputs	**LPI**	**WRI**	**EPI**	**PSAV**	**ROL**	**CPS**	**HDI**	**EDB**	**INF**	**DTGDP**

We used the inverse of inflation(INF), ease of doing business(EDB), debt to GDP ratio (DTGDP), human development index (HDI) rank, world risk index (WRI) for each country since the lower score is better. Also, we excluded the rule of law (ROL) output in the final DEA evaluation, because it is highly correlated with the corruption perception score(CPS) and Political stability and absence of violence (PSAV) score, as shown in Table 1.

Outputs Definitions

Political Risk

We select three dimensions from the world bank (WGI) world governance indicators to measure the political risk of a country.

1. Political stability and absence of violence (PSAV): This measures the perceptions of the likelihood of political instability and/or politically-motivated violence, including terrorism for a country(Kaufmann et al., 2011). We use the percentile rank score for the countries selected for the DEA analysis. The percentile rank ranges from 0-100 (0 corresponding to the lowest rank, and 100 to the highest rank). A higher percentile rank is more favorable, because it indicates that the country is relatively less likely to be disrupted politically.

2. Rule of law (ROL): This captures perceptions of the extent to which agents have confidence

in and abide by the rules of society, in particular the quality of contract enforcement, property rights, the police, and the courts, as well as the likelihood of crime and violence(Kaufmann et al., 2011).

3. Transparency and corruption: This is measured using the corruption perception score (CPS) of various countries under consideration,which can be found on www.transparency.org/cpi2015/.

Economic Risk

We consider three dimensions relevant to general economic and business & trade environment as a measure of economic risk of a country.

4. Inflation (INF): Data for inflation was taken from World Bank Country Indicators (Available online at http://data.worldbank.org/indicator/NY.GDP.DEFL.KD.ZG). We expect a country with a lower inflation level to be of less economic risk.

5. Ease of doing business (EDB): The ease of doing business ranking ranges from 1 to 189 with a lower value indicating a more desirable ranking. The rankings are determined by sorting the aggregate distance to frontier scores on 10 topics, each consisting of several indicators, with equal weight to each topic (World Bank, 2015). These topics are: starting a business, dealing with construction permits, obtaining electrical power, registering property, credit availability, protection of minority investors, paying taxes, trading across borders, enforcing contracts, resolving insolvency. We only use the country ranking in our analysis.

6. Debt to GDP ratio (DTGDP): Generally, investors use Government debt as a percent of GDP to measure a country's ability to make future payments on its debt, thus affecting its borrowing costs and government bond yields (http://www.tradingeconomics.com/). Data for debt to GDP were collected from http://www.tradingeconomics.com/.

Social/Compliance Risk

This captures how a country deals with issues related to labor and other social well-being of its workers. In order to measure the social/compliance risk, we use the Human Development Index (HDI) published yearly by the United Nation (UNDP, 2015).

7. Human Development Index (HDI): This is a summary measure of average achievement in key dimensions of human development: a long and healthy life, being knowledgeable and have a decent standard of living (from http://hdr.undp.org/en/content/human-development-index-hdi) as shown in figure 1 below.

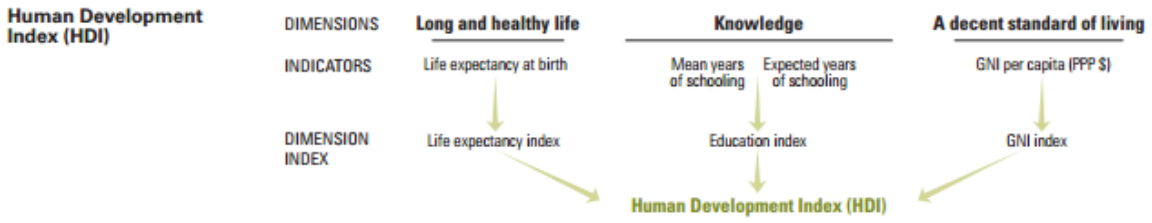

Figure 1: HDI Dimensions

Infrastructure and Climate Risk

The following are the three indicators used to measure infrastructure and climate Risk:

8. Logistics Infrastructure: This is measured through the use of the logistics performance index (LPI) score for countries. Logistics performance is strongly associated with the reliability of supply chains and the predictability of service delivery for producers and exporters (Arvis et al., 2016). The overall score reflects perceptions of a country's logistics based on the efficiency of the customs clearance process, quality of trade- and transport-related infrastructure, ease of arranging competitively priced shipments, quality of logistics services, ability to track and trace consignments, and the frequency with which shipments reach the consignee within the scheduled time. The index ranges from 1 to 5, with a higher score representing better performance.

9. World Risk Index (WRI): This Index calculates the disaster risk for 171 countries worldwide using four components which consist of indicators that capture exposure towards natural hazards such as earthquakes, cyclones, flooding, drought and sea level rise, susceptibility of infrastructure, food, housing and economic framework conditions, coping capacities depending on governance, risk reduction, early warning, health-care, social and material coverage and adaptive capacities related to future natural hazards and the impacts of climate change (WRI, 2015). In this study, we obtained data for the WRI 2015 (from http://www.worldriskreport.org/).

10. Environment Protection Index (EPI): The data for each country EPI was taken from the 2016 report (Hu et al., 2016). A higher score indicates better performance with a range of 0 to 100. The EPI ranks countries based on high-priority environmental issues in two areas: protection of human health and protection of ecosystems.

DEA Results

Table 3 presents the cross-efficiency (CE) values which represent the sustainability risk index and are used for ranking these countries. The higher the index the less is the risk. It can be seen that top five(5) countries are: Germany, Lithuania, Azerbaijan, Russia, and the Korea Rep. with index values greater than 0.85 and the bottom five (5) are: Nicaragua, India, Vietnam, Cambodia, and Pakistan with index values less than 0.62.

Table 3: Sustainability Risk Index (SRI) and Country's Rank

DMU	Country	Code	CE=SR Index	Ranking
15	Germany	DEU	0.9334	1
25	Lithuania	LTU	0.9034	2
3	Azerbaijan	AZE	0.8948	3

27	Malaysia	MYS	0.7669	18
1	Argentina	ARG	0.7589	19
6	Brazil	BRA	0.7513	20
28	Mexico	MEX	0.7482	21
26	Macedonia, FYR	MKD	0.7367	22
44	Ukraine	UKR	0.7361	23
2	Armenia	ARM	0.7308	24
42	Thailand	THA	0.7291	25
9	China	CHN	0.7237	26
19	Indonesia	IDN	0.7236	27
16	Guatemala	GTM	0.7132	28
12	Egypt	EGY	0.7114	29
37	Serbia	SRB	0.7080	30
11	Ecuador	ECU	0.6931	31
21	Jordan	JOR	0.6921	32
33	Philippines	PHL	0.6881	33
41	Tajikistan	TJK	0.6847	34
14	Georgia	GEO	0.6779	35
17	Honduras	HND	0.6541	36
13	El Salvador	SLV	0.6409	37
24	Kyrgyz Republic	KGZ	0.6356	38
39	Sri Lanka	LKA	0.6261	39
4	Bangladesh	BGD	0.6206	40
30	Nicaragua	NIC	0.6167	41
18	India	IND	0.6117	42
45	Vietnam	VNM	0.6076	43
8	Cambodia	KHM	0.5944	44
31	Pakistan	PAK	0.5624	45

It is evident that these results can be easily verified based on the information provided in Table 2. For instance, Germany is ranked number 1 based on the cross-efficiency score, thus, it is the least risky country. This can be attributed to its best logistics performance, lack of corruption, political stability and excellent environmental protection policies.

CONCLUDING REMARKS

In this paper, we adopt the use of the DEA cross efficiency method for creating a single composite sustainability risk index and rank countries in terms of outsourced manufacturing with respect to the US apparel industry. This study explores the application of DEA beyond the standard efficiency

analysis. We show how manufacturing companies can use this technique to create a composite index for assessing a country's overall risk, before making the outsourcing decision. This composite index captures both qualitative and quantitative factors that can pose risks to the supply chain based on the location of the country of the contract manufacturer. In addition, engaging in a proactive and responsible sourcing practices using this approach, may lead to more consistent outsourcing decisions. Eventually, supply chain managers can utilize a more-strategic approach in sourcing, which will significantly reduce the long time required to reach such an outsourcing decision. Finally, this approach can be used to identify low-risk countries with factories that have high quality, as well as social and environmental performance for making effective outsourcing decisions.

Did They Learn Anything? - Learning Assessment in a General Business Analytics Course

Zsolt Ugray
Utah State University
Zsolt.Ugray@usu.edu

Brynja Kohler
Utah State University
Brynja.Kohler@usu.edu

ABSTRACT

There is a projected need for 2 to 4 million of business translators who are not only experts in their business disciplines but also conversant and familiar with the use and limitations of business analytics. Preparing business students to step into the business translator role requires a general introductory analytics course. This paper presents a multi-component learning assessment to evaluate the depth of learning from such a course. This learning assessment is novel in a sense that it uses four distinct tools, both quantitative and qualitative ones, to measure students' improvements in a comprehensive manner.

KEYWORDS: Learning Assessment, Business Analytics, Analytics Instruction, Business Analytics Curriculum

INTRODUCTION

The Need for General Business Analytics Course Learning Assessment

With analytics becoming an indispensable tools for business competitiveness in the last decade (Davenport & Harris, 2011), academic institutions responded to the emerging need of hundreds of thousands of data experts and 2 to 4 million of 'business translators' (Bughin et al., 2016) by developing numerous programs, both at the graduate and undergraduate levels (Wixom et al., 2014.) The majority of academic research and papers target the development of full analytics programs aiming to train data experts. At the same time, a general introductory business analytics course is necessary to address the need to make all future business practitioners at least conversant in the language of analytics so that they could become a member of the predicted million-strong business translator group (Ugray, 2016.) It is hard to underestimate the importance of the success of such a course. This makes it necessary to study the outcome of such a course and to develop a learning assessment mechanism to evaluate the learning that takes place. This paper presents the design and results of a four-piece comprehensive learning assessment effort that took place at an Intermountain university. The assessment utilizes both quantitative and qualitative tools to not only prove students' improvements in knowledge, skills, and comprehension, but to also gain a more granular understanding of students' experiences and their perceptions of the usefulness, advantages, and confidences in what they learnt.

Business Analytics

Data is being generated at an ever accelerating pace. By the year 2025, an astonishing 163 ZB (Zettabytes; 2^{70}, or approximately 10^{21} bytes) of data might be created (Reinsel et al. 2017). Handling this vast amount of data is stretching organizations' abilities (McAfee & Brynjolfsson, 2012). To gain and to keep competitive advantage in today's business landscape, firms need to continuously innovate and become early adopters of evolving technologies, data analytics being one of the most crucial capabilities (Davenport & Harris, 2010; Barton & Court, 2012; Bell, 2013). Knowledge from multiple, often overlapping, disciplines are forming the foundations for the skillset that is in high demand by today's organizations.

For simplicity's sake, in this paper we use the term business analytics to refer to the general collection of related disciplines that include data analytics, data mining, data science, data engineering, machine learning, advanced statistics, and artificial intelligence, among others. As the abundance of discipline names suggests, there are different approaches, backgrounds, and skills that might be necessary to successfully deal with the amount, speed, and variety of data and their analyses. It became a constant challenge to train, keep, and find people with business analytics skills (Davenport & Patil, 2012; Davenport, 2013; Santaferraro, 2013).

Business Analytics Education

Business professionals, consultants, and educators started to study the state of business analytics educational programs no later than a split second after defining business analytics as an emerging field and the identification of its importance. Wixom et al. (2011) referred to 15 full time programs, with 3 at the undergraduate level. Just 3 years later, in another study, Wixom et al. (2014) counted 131 programs, including 47 at the undergraduate level. There is even a website (www.mastersindatascience.org) dedicated to aggregating information about the increasing number of master's programs in business analytics, data science, and related fields. According to Schuff (2018), the website listed 117 graduate level programs at some point in 2017. These programs address the need of training data analysts to fill the large number of missing professionals forecasted: Bughin et al. (2016) posit the number of missing professionals to 250,000 within a decade, updating the 2011 forecast of Manyika et al. from 140,000 to 190,000 missing experts by 2018.

While the number of missing data experts is quite large, the need for business translators, those who serve as the link between data analysts and the business questions that require industry specific expertise and organizational knowledge, is even greater: Bughin et al. (2016) puts that number to between 2 and 4 million for the next decade, updating the forecast of Manyika et al. (2011) from 1.5 million by 2018. What makes these numbers even more concerning is the finding of Wixom et al. (2014) describing how employers find the skills and practical experiences of recent university graduates lacking. Organizations' needs are growing for people with adequate skills for understanding and translating between their domain of expertise and data science practitioners, who can work with the large volumes of data prevalent in more and more business fields. These business translators are essential for companies to effectively compete in their businesses (Davenport & Harris, 2010.)

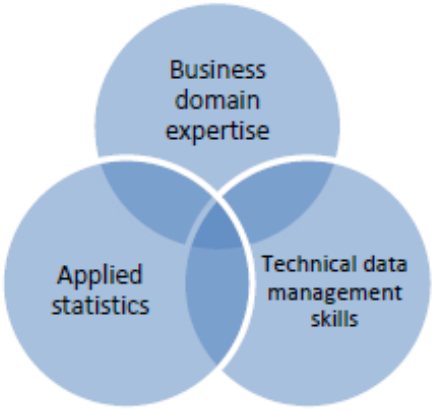
Research into the area of delivering basic data skills to future business translators does not match up to the amount of research addressing curricular needs of data analysts. Some examples include Schuff's (2018) description of a university-wide course in data literacy and Ugray's 2016 report on a general data analytics course for all business undergraduates.

BUSINESS ANALYTICS COURSE FOR ALL BUSINESS UNDERGRADUATES

Course Information

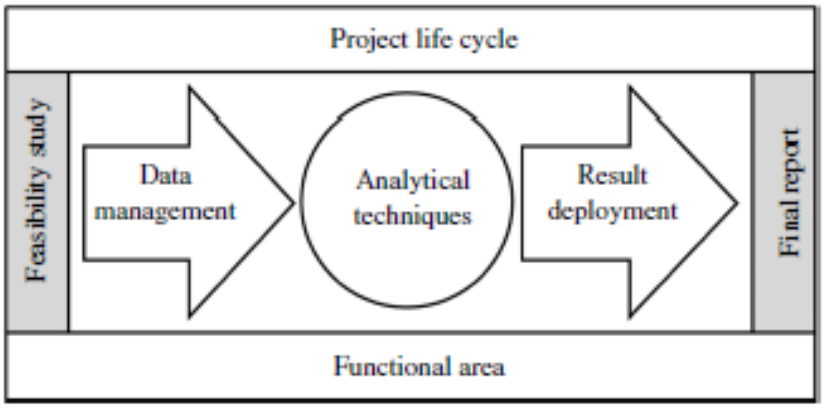
The origins of the course under study at an Intermountain university's Business School go back to 2014, when the approval to develop a college-wide introductory level undergraduate analytics class came from the Dean's office. A group of four faculty, with the help of two graduate students, designed the course in the spring of 2015. All four faculty and the two graduate students had a combination of data management, informatics, analytics, statistics, computer science, or operations research background (Ugray, 2016.) Two sections of the new course were offered in the fall of 2015, 4 in the spring of 2016 and it officially became a required course for all business school undergraduates in the fall of 2016. At this point, there are typically 8 sections offered a semester and an online section is offered once or twice a year as well.
The course outline, after reviewing extant educational research, academic programs, business requirements, and employer expectations, followed the components of business analytics, as illustrated in Figure 1 (Conway, 2013). The domain expertise component relies on student's skills and knowledge acquired from a set of business school acumen courses. Meaningful datasets are selected to demonstrate the relevance of examples to various business domains. Applied statistics concepts are reviewed, refreshed, and introduced throughout the course at relevant times, acknowledging that the amount of statistics remembered by a typical business undergraduate student from her business statistics course is often minimal. Technical data management skills are either refreshed or newly introduced. The course is embedded among other required business courses in a way that knowledge and skills form a synergistic learning surrounding.

Figure 1: Business analytics skillset



Wilder & Ozgur (2015) discussed five knowledge domains of business analytics and described their relations with the chart in Figure 2. While this framework nicely sets up the need for different specialized courses, an introductory course can only tangentially cover some of the knowledge areas.

Figure 2: Knowledge domains



The introductory business analytics course developed consists of three major modules: Data Management (acquisition, querying, cleansing), Data Visualization and Summarization, and Predictive Analytics. Each module consists of conceptual topics and hands-on skill development exercises using appropriate software tools. SQL Server Management Studio (2018), PowerBI (2018) and OpenRefine (2018) are utilized for the Data Management module. PowerBI and RapidMiner (2018) are used for Data Visualization and Summarization, and RapidMiner is the main tool for Predictive Analytics.

LEARNING ASSESSMENT

Data regarding learning assessment included both qualitative and quantitative data. The four assessment tools included the following: 19 pre- and post-test questions administered to students; 12 questions measuring students' perception related to the usefulness, advantages, confidence, and future expectation of task self-execution related to areas of the three major modules of the class, answered twice, once before and once after the course; 3 Short essay questions regarding the value, purpose and usefulness of course topics; and semi-structured interviews conducted with six students after the conclusion of the class.
Data was collected from a total of 68 students from 2 sections in one semester in 2017. There were 65 usable observations for the pre- and post-test question comparisons, with 44 males and 21 females in the sample. For the perception estimates and the short-answer question the 63 usable samples were split between 20 females and 43 males.
Table 1 describes the distribution of majors participating in the class. There were similar numbers of MIS, marketing and finance/economics students, while number of accounting and business administration (including all other business majors) were somewhat lower.

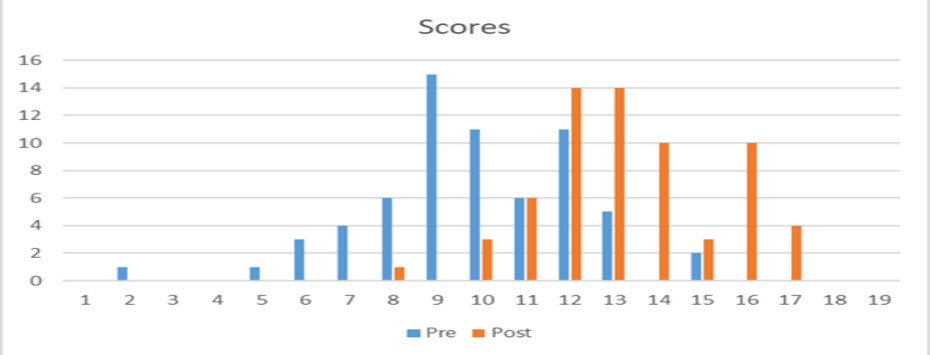
Table1: Distribution of majors in the sample

MIS	ACC	MKT	ECON/FIN	BA
14	7	18	16	10
22%	11%	27%	25%	15%

Pre- and Post-test Quizzes

This part of the learning assessment consisted of 19 multiple choice questions (about 2 per course objectives) administered twice, once at the very beginning of the course and once at the end. The questions aimed to address understanding, critical thinking, and possible application of concepts rather than lexical knowledge. Figure 3 shows the distribution of pre- and post-test scores.

Figure 3: Pre- and post-test scores



The post-test average score of 12.34 was significantly larger ($p<10^{-6}$) than the pre-test score average score of 8.83.
55 (85%) of student had higher scores, 3 (5%) had the same and 7 (10%) had lower scored at the post-test. 14 (75%) of the 19 questions had more correct answers in the post-test (7 questions by 28%-52% more, 7 questions by 2%-25% more), 1 question (5%) had the same number of correct answers, and 4 questions (20%) had lower number of correct answers (3 questions with 1 or 2 respondents lower, and 1 question with 34% lower.) Reviewing this last question reinforces the observation that for more complex questions, as one's knowledge increases, sometimes different answers might appear to be correct.)

Student Perception Questions

For this learning assessment measurement, changes in the answers given to four perception questions related to the three major course topic modules (12 questions total) were calculated. A 5 level Likert scale was used both at the beginning and at the end of the course. Students had to express their agreements with the statements, "strongly agreeing" coded as 5, "agreeing" as 4, "neutral" as 3, "disagreeing" as 2, and "strongly disagreeing" as 1. The four questions were the following:

1. (Useful): Learning about and understanding ____ is useful in my field of study (i.e. major or prospective profession)
2. (Advantageous): Being able to perform ___ will be advantageous in my future job.
3. (Confident): I feel confident about performing ___ tasks.
4. (Expect): I expect that in the future, rather than relying on someone else, I would be able to perform ___ tasks myself.

The three topic modules: 1. (Data): Data querying, cleansing; 2. (Visualization): Data summarization and visualization; and 3. (Mining): Predictive analytics and data mining. Results

of changes in the perceptions are summarized in Table 2, with the significant differences in bold letters.

Table 2. Perception changes (*: p<0.05; **: p<0.01; ***: $p<10^{-6}$)

	Data	Visualization	Mining
Useful	-0.03, (n/s) (3.98,3.95)	+0.03, (n/s) (4.11,4.14)	**-0.44, (**)** (4.35, 3.91)
Advantageous	-0.06, (n/s) (3.97,3.91)	-0.11, (n/s) (4.25,4.14)	-0.10, (n/s) (4.21,4.11)
Confident	**+1.06, (***)** (2.32,3.38)	**+1.19, (***)** (2.43,3.62)	**+1.1, (***)** (2.35,3.45)
Expect	**-0.32, (*)** (3.73,3.41)	**-0.27, (*)** (3.84,3.57)	**-0.52, (**)** (3.85,3.33)

Answers to two questions show significant changes in perceptions after students took the course. Their confidence in performing tasks belonging to the 3 major course modules (data manipulation, visualization, data mining) increased significantly. Interestingly, their expectations about whether they will perform these same tasks showed a statistically significant decrease. While this may seem discouraging at first, this reaction is not irrational: the course is an introductory analytics course with the purpose of making all business students familiar with the broad areas of business analytics. It is not the goal of the course, and it is not reasonable to expect, that student will possess the skills that is expected to perform rigorous data analytics tasks in a real life business setting. If anything, it is encouraging that they seem to realize the limitations of their skills at this point.

The last remaining statistically significant change is the evaluation of the usefulness of data mining. It shows a negative value, meaning that after the course students' perception of the usefulness of data mining is diminished. This artifact could have several explanation. Maybe data mining is too complex of a task at the educational level when students take the course. It is possible that either fewer or simpler examples need to be used. Somewhat relatedly, maybe examples and data sets that are more relatable to the broader set of business majors could be used. Finally, it is not impossible that the instructor needs to sharpen his skills to better convey the usefulness of data mining.

Short Answer Questions

Students were given the opportunity to offer their thoughts to three questions. The questions were asked both at the beginning and end of the course:

- *Why do you think Business Analytics is valuable?* – Answers to this question became more detailed and more sophisticated after taking the course, often referring to the usefulness of predictions that can be gained from analyzing data. Students tended to give examples from their major.
- *How is Business Analytics used in your field?* – More specific examples and benefits gained from analytics were often mentioned in the answers. The most specific examples came from marketing and MIS students who planned to specialize in analytics.
- *What (do you expect to learn / are the most useful things you learned) in the course? What topics will you most likely use later in your career?* – There were many different items listed in

the answers to this questions. Most frequently, gaining general understanding business analytics concepts and the acquisition of the relevant 'language' were mentioned. It was followed by the appreciation of the ability to better interpret data. Many students liked both the opportunity to get acquainted with the software tools and the learning of the concepts behind the tools.

Interviews

After the conclusion of the course a 5 students were interviewed. Selection of the students included a mix of 2 females and 3 males, 3 different majors, and students with final grades ranging from C to A. The direction of the questions focused on students' self-evaluation of their learning and the experiences they had in the course. Among a rich set of qualitative evaluations a few themes emerged. There was a general appreciation of the importance and depth of the fields within business analytics. Even students who described themselves as not particularly number and data oriented developed and appreciation for the insights that can be gained from looking at data from multiple angles. There was a general consensus that the course is one of the toughest and busiest courses within the business curriculum. It resulted in references to many students' strategies to just 'get by' and to just 'successfully pass with a reasonable grade'. Several, often contradictory, suggestions were made to omit or include some topics; to utilize more or fewer example data sets; to spend more or less time on elaborating details of the concepts.

CONCLUSIONS

A comprehensive learning assessment was implemented for a general introductory business analytics course required for all business undergraduates at an Intermountain university. The assessment has quantitative and qualitative components. It utilized quizzes, questionnaires, short answer questions and interviews. Results from the broad assessment convincingly demonstrated that a course addressed to the general business student population can be useful, successful, and it can provide the foundation for many to fulfill the role of the 2 to 4 million future 'business translators' projected by the McKinsey Global Institute. Quantitative assessment tools proved that the knowledge and skill base of students improved after taking the class. Students' confidence and understanding of the importance of their knowledge also improved, complemented with the realization that taking just one introductory course does not make them capable of executing rigorous analytics tasks at a real life working environment. Qualitative assessment tools reinforced the findings of the qualitative tools and brought further nuanced elements to the understanding of the strength and weaknesses present in the course. They revealed improvements in the details and sophistication of how data is looked at, manipulated, and interpreted. They also added more granularity to the particulars of what students learned and what they considered important and useful: the ability to interpret data, the skills to use appropriate software tools, the understanding of the concepts behind the software tools, and a general understanding of the field and the tasks involved.

Diffusion of Generation and Consumption of Energy

Jesus A. Cardenas
University of Texas at El Paso
Email: jacardenas3@uetp.edu

Leopoldo Gemoets
University of Texas at El Paso
Email: lgemoets@utep.edu

ABSTRACT

The electricity generation scenario in the world is changing as countries like China and Germany have started leading the efforts of energy generation moving from the use of non-renewable resources, like fuels, and more into hydro, solar and wind electricity generation plants. Within the United States there are also some effort for this shift, but just a few states are leading the move while others are staying with the traditional contaminant model.

KEYWORDS: energy, electricity, bass diffusion, sensitivity analysis, renewables

INTRODUCTION

In the year 2016, according to the World Bank, 87.35% of the world's population had access to electricity. The region where this access was most restricted is Sub-Saharan Africa (SSA), where only 42.81% of the population enjoyed this service. Considering Latin America and the Caribbean (LAC) as another poverty pole region, the database reports that 97.79% of LAC inhabitants had access to electricity. There was a significant difference between LAC and SSA, as the situation in LAC is comparatively much better. Using numbers from the 2016 census, we deduced that 14 million people in LAC did not have access to electricity, compared to 590 million people in SSA. Because there are definitively more urgent needs at SAA than electricity, this paper will focus on LAC and the implementation of new technologies for the generation and distribution of electricity.

If we focus on the poorest countries, in the year 2000, a little bit over 33% of the population had the chance of accessing electricity; based on these countries' needs companies were overproducing energy. As a result of this decision, losses in transmission and distribution averaged 25% of the total production, so that those firms involved in the electricity sector were operating mostly at significant losses (Kenny & Søreide, 2008).

Another factor affecting the progress in the electricity sector in the LAC was the popular idea, from the 1960's, that reinforced the state as requiring a monopolistic and preponderant role in everything related to energy provision and distribution. The LAC is now facing serious challenges, as it is creating competitive markets while modernizing old institutional structures and national standards and norms (Herrera, 2001). These changes have helped the penetration of energy generation and distribution in the LAC, with a high percentage of private participation in this sector. According to the World Bank database, in 2016 the LAC received 22.263 billion dollars of investments from private companies. This influx of capital into developing countries in the LAC is important for those economies and represents an important push towards

technologies that the public sector could not finance—in some cases due to money supply and technological advancement.

1.1 Global Trends on Generation and Sources

Using the secondary data available at the UN Database, we were able to analyze the sources of generation capacities and trends for the near future.
Combustible Fuels' energy is the generation process with the largest installed capacity and it is also the largest generator of electricity in the world; after the Tsunami in Japan, there was a push back on nuclear energy that is noticeable after 2011, but it has been stable ever since. Therefore, we do not expect all the fuel and nuclear capacity to be uninstalled suddenly, but it will rather continue to function.

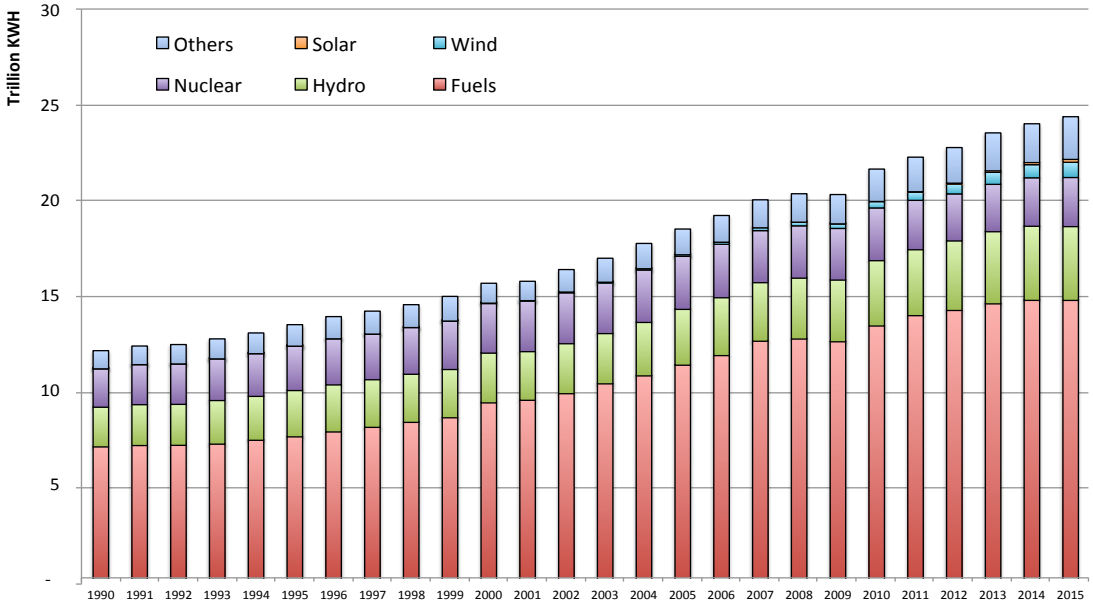

Figure 1: Growth of electricity capacity in KWH per year (source: UN data)

Breaking the production of electricity into the major source of generation, we found that there are some other sources that are not considered in the major categories that the UN database includes, so we added a group named "others".

The installed capacity of electricity generation has been growing way beyond the actual consumption of energy, but we are assuming a perfect world where we will have energy generated and consumed every hour of the whole year. The statistics show an important growth on solar and wind energy generation in the past ten years for the wind and in the last 2 years for the solar panels generation. We found some interesting facts. Namely, China did not report any solar generation until. The plan in China for photovoltaic is so aggressive that it is expected to generate over 1,800 MW by the year 2020, with a stretch goal of 10,000 MW or more (Shen & Wong, 2009).

1.2 Global Sources of Generation Capacity versus Production

The following tables show the comparison of contributions by country for the generation compared to the production of electricity. We shall be careful with the veracity of the data.

Table 1: Hydro capacity and Production in 2015 (KWh)

Country	Installed Capacity	Contribution	Production	Contribution
China	2,278,579,770,000	27.4%	1,130,270,000,000	29.2%
United States	702,381,930,000	8.5%	269,675,000,000	7.0%
Brazil	629,635,500,000	7.6%	338,673,000,000	8.7%
Canada	545,615,400,000	6.6%	349,664,000,000	9.0%
Russian Federation	350,356,260,000	4.2%	168,419,000,000	4.3%
Japan	343,733,580,000	4.1%	74,801,000,000	1.9%
India	277,087,710,000	3.3%	121,377,000,000	3.1%
Norway	215,525,640,000	2.6%	133,525,000,000	3.4%
Turkey	177,713,160,000	2.1%	67,146,000,000	1.7%
France	173,659,860,000	2.1%	58,801,000,000	1.5%
Italy	152,651,400,000	1.8%	46,361,000,000	1.2%
Spain	139,138,110,000	1.7%	30,620,000,000	0.8%
Sweden	112,180,230,000	1.4%	75,428,000,000	1.9%
Viet Nam	107,439,930,000	1.3%	57,174,000,000	1.5%
Others	2,095,863,285,180	25.2%	954,041,955,967	24.6%
Total	8,301,561,765,180	100.0%	3,875,975,955,967	100.0%

Table 2: Nuclear Capacity and Production in 2015 (KWh)

Country	Installed Capacity	Contribution	Production	Contribution
United States	677,876,640,000	25.7%	830,288,000,000	32.3%
France	433,703,100,000	16.4%	437,428,000,000	17.0%
Japan	288,869,760,000	10.9%	9,437,000,000	0.4%
China	186,657,900,000	7.1%	170,789,000,000	6.6%

1.3 Diffusion of Renewable Generation

Figure 2 shows that there are no major trends in the generation of electricity. Wind and solar are going upwards, but their contribution is still minuscule to the total electricity generated nowadays. Focusing only on the renewable resources' generation, we are going to conduct Bass' diffusion analysis only for the wind and solar electricity generation processes by state using the data available at the UN Database.

1.3.1 Wind Generated Electricity

We are seeing Texas as the largest contributor for the electricity generated with wind, with Oklahoma following at a distance with more than one third of the Texas generation; but Oklahoma's growth is important with a very fast diffusion speed, eclipsed only by Illinois which is growing tremendously in a short period of time.

Table 6: Diffusion Indexes for Wind Electricity Generation in the US by States

Wind Energy	Cum. Level (Millions)	Maturity Level (Millions)	Innovation Index	Imitation Index	Diffusion Speed
USA	254.25	311.33	0.0064	0.2977	46
Texas	67.09	362.74	0.0028	0.1475	53
OK	24.40	131.96	0.0007	0.2590	362
IA	20.82	22.22	0.0046	0.4025	87
KS	18.50	40.79	0.0014	0.2981	206
CA	13.97	198.90	0.0039	0.0166	4
IL	11.30	11.30	0.0007	0.6450	969
ND	10.99	16.80	0.0053	0.2412	45
MN	10.88	12.90	0.0138	0.2658	19
CO	9.57	10.56	0.0058	0.3595	62
WA	7.48	7.77	0.0055	0.5115	93

California shows an imitation index of 0.016 which is the smallest one of all, which means that only innovators are implementing wind energy because the curve shows a flattened curve, as this state has been generating electricity using wind mills long before anyone else. Therefore, we do not see as a rapid growth in California as Washington and Minnesota, which will reach maturity much faster.

Table 7: t-test for top 10 States using Wind generated Electricity

Wind	t	df	Sig. (2-tailed)	Mean Difference	95% Confidence Interval of the Lower	Upper
Cum_Level	1.86	10	0.092	40.8409	-8.0107	89.6926
Maturity	2.59	10	0.027	102.4791	14.1507	190.8074
Innov_Index	4.18	10	0.002	0.0046	0.0022	0.0071
Imit_Index	6.14	10	0	0.3131	0.1996	0.4267

Doing t-test for the states' cumulative level is below 10%, but maturity level, innovation and diffusion indexes were significantly below 2%. The top ten states show that the diffusion of wind generated energy will reach maturity around the year 2050, when some scholars are predicting that renewable energy will represent 50% of all electricity in the US (Lehr, 2013).

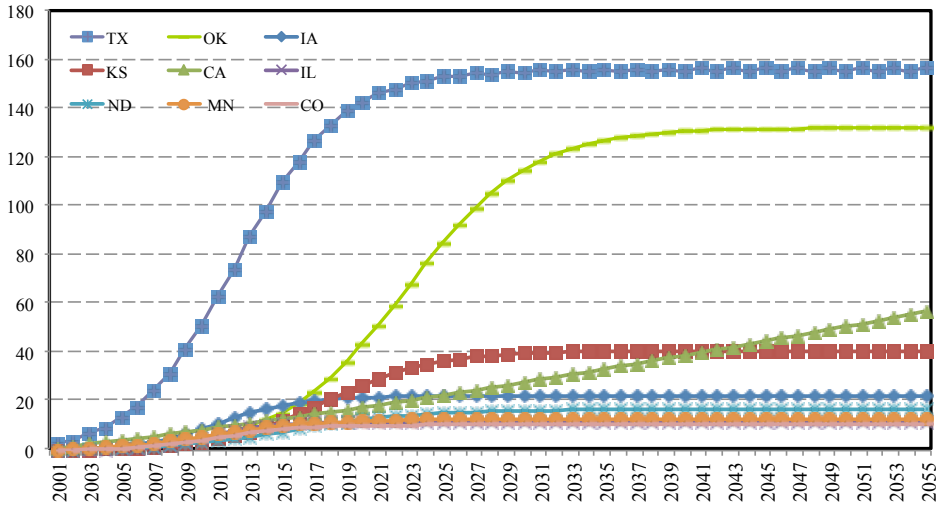

Figure 3: Diffusion of Wind Generation by State

1.3.2 Solar Generated Electricity in the US

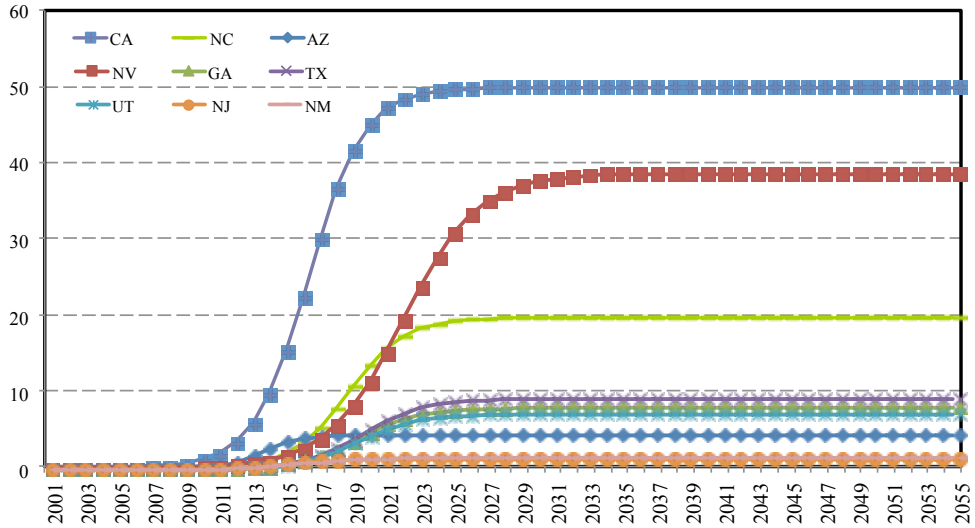

Figure 4: Diffusion of Solar Generation by State

For solar energy, California is undoubtedly the largest contributor with 43.62% of all solar electricity in the country. California has been a pioneer in renewable resources electricity, so we are also seeing an imitation index of zero. This means that the curve is flattened and all the growth is identified as innovator growth that will take much longer to mature. North Carolina is second on order, followed by Arizona and Nevada, but their growth is strongly driven by imitation, which means that they are reaching maturity soon. Nevada's growth is so impressive that the maturity level for this state is expected to be around 38.73 million of Megawatt-hours.

Table 8: Diffusion Indexes for Solar Electricity Generation in the US by States

Solar Energy	Cum. Level (Millions)	Maturity Level (Millions)	Innovation Index	Imitation Index	Diffusion Speed
USA	52.96	99.85	0.0000	0.5937	21,810
CA	23.10	28.46	0.0000	0.7473	74,729
NC	5.58	19.91	0.0000	0.5885	58,854
AZ	4.74	4.62	0.0000	0.8437	84,374
NV	3.83	38.73	0.0000	0.4459	18,024
GA	2.14	8.12	0.0000	0.5672	56,719
TX	2.12	9.33	0.0000	0.5573	55,672
UT	1.97	7.27	0.0000	0.5685	56,852
NJ	1.17	1.42	0.0001	0.6060	7,007
NM	1.11	1.64	0.0002	0.4800	1,930
MA	1.05	1.72	0.0000	0.6786	67,864

For solar generation, the t-tests results are significantly below 10%, with the exception of the innovation index which is the one driving the solar energy generation. The maturity level and the imitation index are the most significant, at below 5%, which demonstrates that the analysis is correct and there will be a quick diffusion process for solar energy in the US.

Table 9: t-test for top 10 States using Solar generated Electricity

	t	df	Sig. (2-tailed)	Mean Difference	95% Confidence Interval of the Difference	
					Lower	Upper
Cum_Level	1.896	10	0.087	9.07	-1.5912	19.7312
Maturity	2.291	10	0.045	20.09727	0.5473	39.6472
Innov_Index	1.399	10	0.192	2.73E-05	-0.000016	0.000071
Imitat_Index	17.726	10	0	0.606973	0.530677	0.683269

3.1.8 Global Prognosis

Coal and other combustible fuels are one of the major concerns in the world for the emission of CO_2 to the environment, as it contributes to the greenhouse effect— the process responsible for global warming. It is concerning to see the tremendous growth of energy generation with the use of coal in China, while in the United States coal use is decreasing, as shown in Figure 5.

Looking at the generation of electricity using hydropower, we see China growing tremendously. China is the number one producer of hydropower and it is still growing strong, while the other countries have remained in a steady state using these natural resources. We also see Brazil growing slowly in this area, after the investments referenced in the introduction, but with a trend down on the last three years.

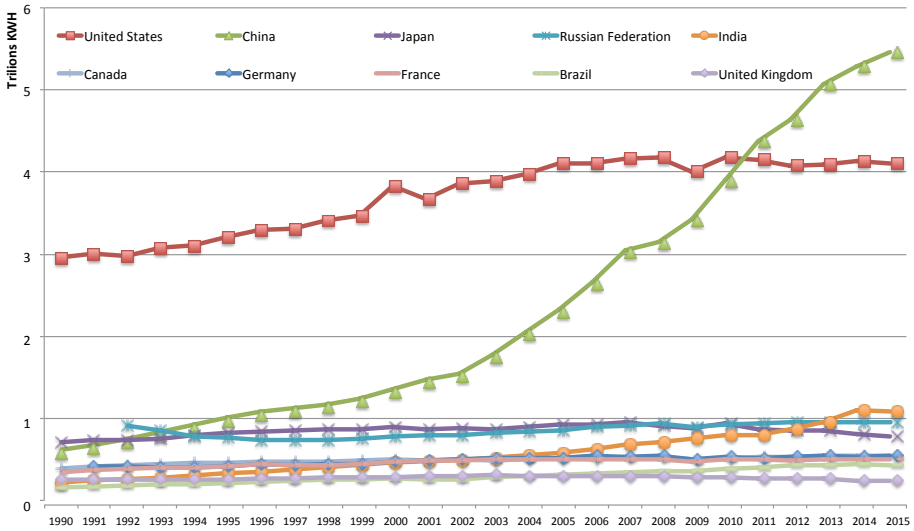

Figure 5: Energy generation burning fuels (source: UN Data)

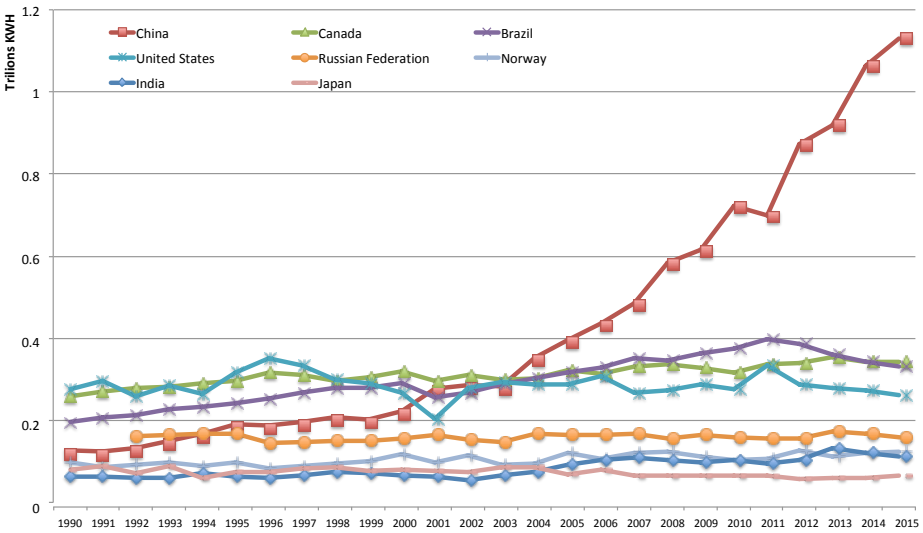

Figure 6: Electricity generated using hydro power (source: World Bank database)

Wind is a renewable resource and has been identified as one of the cleanest sources of energy, causing less harm to the environment; the US is the leader in its implementation. We can see that China is growing in second place and it is about to take the leadership position.

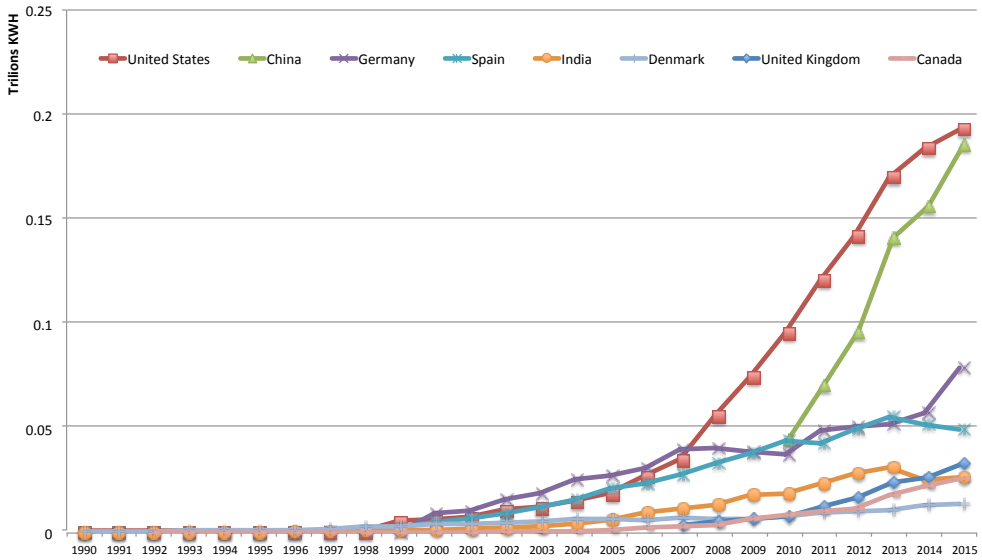

Figure 7: Electricity generated with Wind (source: UN Data)

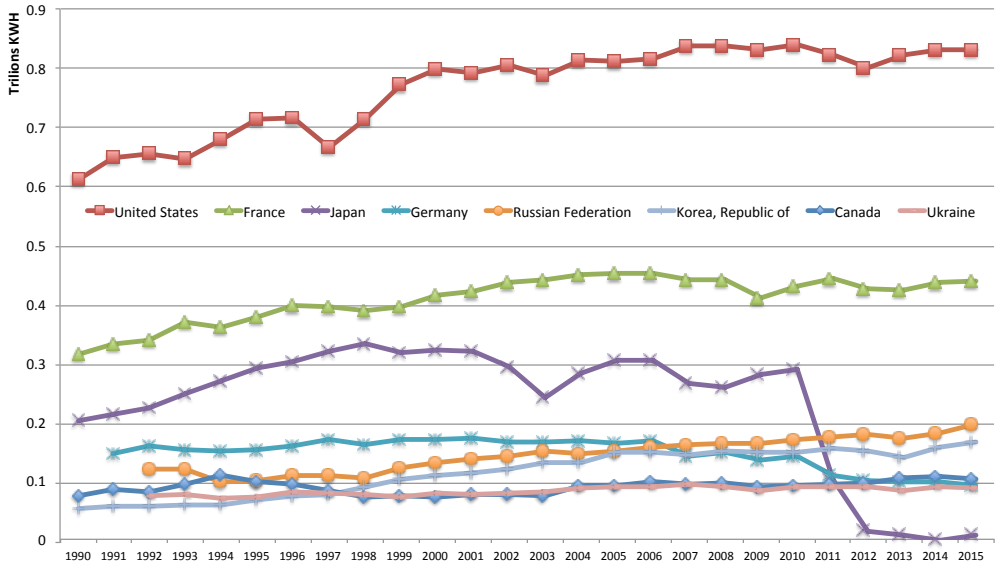

Figure 8: Electricity generated using nuclear plants (source: World Bank database)

Nuclear energy had been steadily growing throughout the world, but following the Fukushima incident there are some countries that are reversing their efforts toward nuclear energy until preventive measures can be implemented to prevent disasters. Japan is the clear example, as it has reduced its nuclear electricity generation to a minimum.

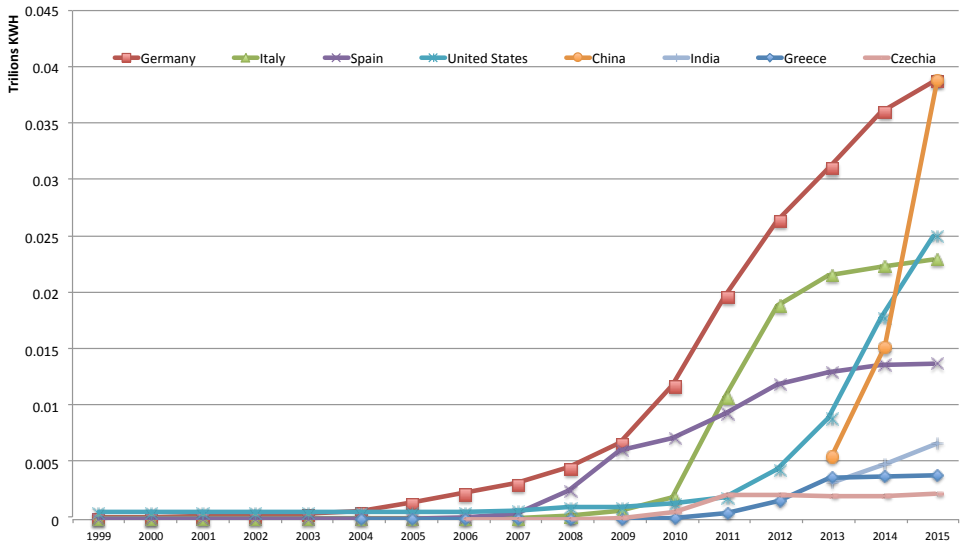

Figure 9: Electricity generated by Solar Energy (source: UN Data)

Another source of energy that it is growing rapidly is the solar energy generation, where Germany is the world leader, but not for long, as China I about to take the leadership position too after only three years of reporting generation of solar electricity. This is the latest of the renewable resources energy coming strong because the generation was almost zero until 1999 when solar energy really kicked in.

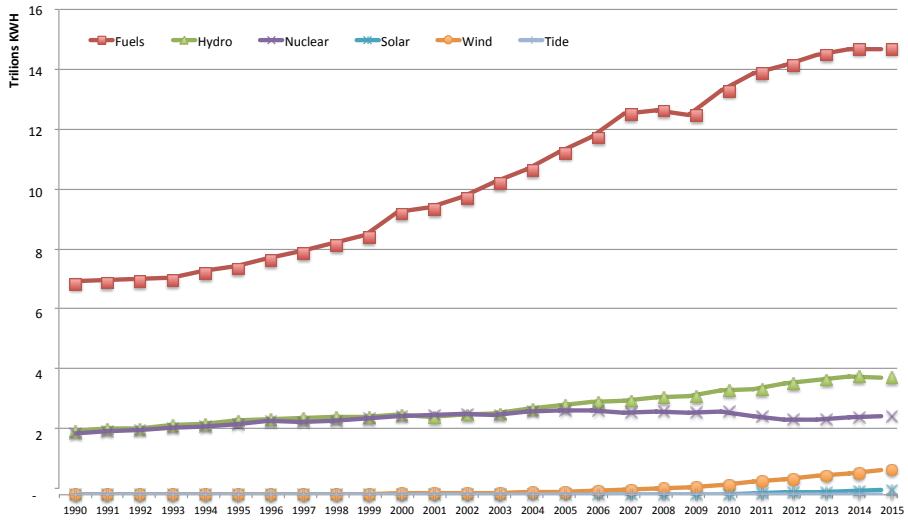

Figure 10: Global energy generation sources (source: World Bank database)

Looking at Figure 5, it is evident that the amount of energy produced using oil, coal and other combustible fuels has been drastically reduced. Figure 5 clearly shows that combustible fuels are the largest source used to generate electricity and will continue to be for a long time, until regulators begin inhibiting its growth. Hydro is clearly second and is also growing, with a big push from China. Nuclear energy will completely change its trend as more countries are prohibiting its use, and oil is also going down. Figure 11 shows that the leadership on electricity generation has changed from the United States to China after 2011 because of the Chinese exponential growth.

The potential of the Chinese market has not been fully understood, as the communist government is investing all necessary capital to electrify the country and allow foreign industries to be located there, while the nationals have access to utilities that can improve quality of life.

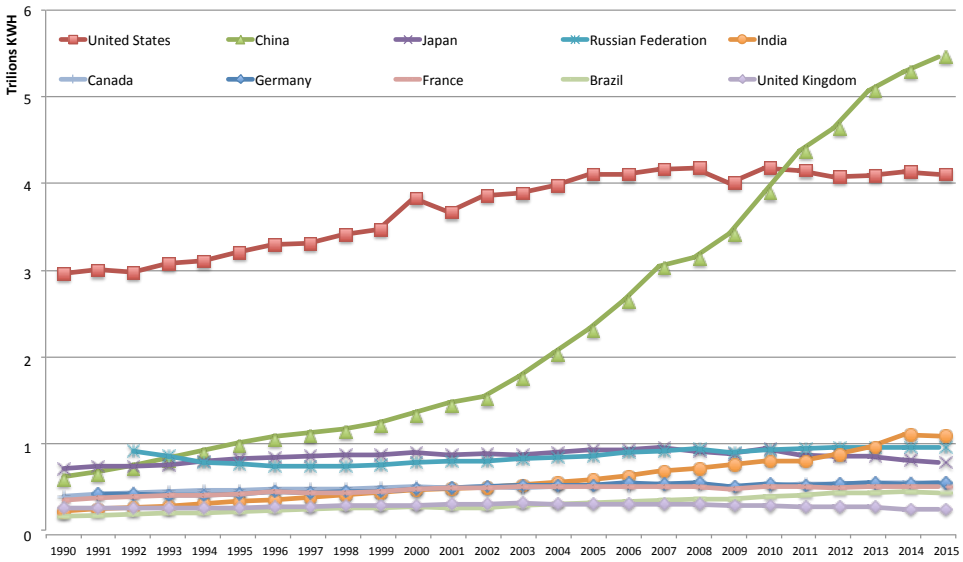

Figure 11: Worldwide top electricity generation producers

CONCLUSIONS

The results of the research present a challenging future for human society as consumption keeps growing and generation is mostly based on generation burning combustibles that emits large amounts of CO_2 to the atmosphere. Consumers, utility companies and governments that are shifting towards the use of renewable resources energy are taking some important actions that are showing exponential growth of wind and solar energy, while nuclear and fuels burning processes still growing but slowly. Unfortunately much of the investment continues to support macro-generation, when one of the possible solutions (distributed generation) is not being supported as much. Maybe solar cells' generation by consumers may also help to revert the trend of contamination and dependency on fuels.

Drivers and Barriers to Sustainability Engagement among NY State SMEs

ABSTRACT

In the extant literature on SMEs' sustainability adoption, relatively fewer research has focused on the US compared to Europe. Our study consists of a larger number of firms (75), from a broader cross section of industries and geographical spreads, investigating major drivers and barriers to SMEs' sustainability. Findings show important internal and external drivers such as owners/managers' sense of moral obligation to reduce negative environmental impacts, lowering costs, market trends of customers who value socially responsible products and environmental audits. However, competitive advantage, regulatory compliance, or financial incentives were not deemed important influencers. Major barriers included cost and limited resources.

KEYWORDS:

Environmental Sustainability, Sustainability in Operations, Small and Medium-sized Enterprise, SMEs, Sustainability in SMEs, NY State SMEs

INTRODUCTION

Awareness of environmental impact is being increasingly studied and investigated at international, national and business levels. Paris Accord, succeeding Kyoto Protocol, has been the most recent effort to treat climate change at global and international levels (Christoff, 2016). In addition, majority of the large corporations have recently made significant efforts to demonstrate their corporate social responsibly and the environmental plans they are committed to through published annual or semi-annual sustainability reports (GRI Sustainability Reporting). Large corporations have been the focus of government policies, regulations and incentives more than Small and Medium-sized Enterprises (SMEs). However, SMEs collectively constitute a larger portion of the economy and are held responsible for a greater share (70%) of the environmental pollution (Parker et al., 2009). On the other hand, SMEs' operations and resources are usually much more limited compared to larger corporations, which leads to more constraints and difficulties for the adoption of sustainable solutions.

A lot of research has been done to explore how and why SMEs develop sustainability strategies and how they implement sustainable solutions. As shown by Parker et al. (2009) and Wiesner et al. (2017), majority of the published work on SMEs' sustainability is focused on Europe, particularly the UK and Germany, with few studies on other countries such as the Netherlands, Sweden, Austria, Australia, Canada, Hong Kong, Israel, Japan, New Zealand, S. Korea, Malaysia and the United States. Lehner and van Eyssen (2017) studied the barriers complicating the adoption of sustainability in businesses. They interviewed ecopreneurs' businesses in Sweden and demonstrated that market demand and partners, as external factors, play a more important role for ecopreneurs to be environmentally sustainable. Aghelie (2017) investigated the drivers

and barriers in SMEs' adoption of sustainability by interviewing businesses in Malaysia. Del Giudice et al. (2017) presented a comparative study of SMEs sustainability adoption between the UK and Italy. They interviewed 10 SMEs in those countries and showed how owner-managers' roles and their collaboration with employees and other stakeholders were different across countries and had key roles in sustainability engagement decisions made by SMEs.

Some sustainability studies have also been done on US SMEs (Theyel & Hofmann, 2012; Langwell & Heaton, 2016). Langwell and Heaton (2016), for example, present the impact of the human resources on SMEs' adoption of sustainability. However, the number of US studies compared to European countries is not adequate or proportional to the size of the SME sector in the US. The scope of studies on US SMEs is also limited in the number of dimensions investigated, the industry that SMEs come from, or in the small sample size of the SMEs studied. In this study, we take a comprehensive approach of investigating major drivers and barriers in SMEs' sustainability adoption through a large sample of SMEs (over 70) in the US. Our pool of SMEs come from small towns (e.g., Ithaca, NY) to big cities (e.g., New York City) and across different industries (manufacturing to services such as food, healthcare, etc.). The purpose of this study is to expand our knowledge of US SMEs' sustainability drivers and barriers. In addition to reviewing the literature during the early development of our study, to validate the potential contributions of our study, we also shared the focal points of our research with four sustainability experts who are very experienced and involved in business sustainability in NY State or at the regional level. These experts were not aware of any previous practice-oriented research similar to ours, which not only integrates several of these dimensions but also focuses on the experience of small businesses in this region. Given their response, we realized that our research could identify both successes and gaps in the sustainability efforts among small businesses in the NY State. These experts believed that our research would provide a baseline data that could benefit both the owners/managers of such businesses, which are the backbone of the local communities in sustaining employment growth and environmental efforts, as well as the state and local government agencies to identify resources and tools that these businesses need for sustainable development.

In the next section, we review the literature on sustainability in SMEs followed by the Methodology section where we describe how we selected SME participants, collected, and analyzed the data. In the Results and Discussion section, we report on and discuss some of our key findings and conclude the paper with a discussion on some of the implications and limitations of our study and suggest directions for future research.

LITERATURE REVIEW

Given the focal point of our study - the examination of drivers and barriers to SME sustainability adoption strategies - this section starts with review of the findings of the meta analyses of such research, followed by the latest published work. In the interest of representation, we have aimed to include studies from developed and developing countries.

In a qualitative investigation of the environmental literature with a focus on business survey evidence, Tilley (1999) identified the following forces that prevented firms from transforming their pro-environmental attitudes into pro-environmental forces: low standard of eco literacy, poor environmental awareness among owners/managers, economic barriers which made reduction of environmental impact costly, and low awareness about the environmental business programs and support offered by governments.

Walker et al. (2008) reviewed 351 publications with a primary emphasis on identifying the main barriers and drivers to environmental management among SMEs. They noted three barriers that prevented such firms from engaging in good environmental practices. First,

characteristics of the SMEs in general (heterogeneous industry nature, size, urban/rural divide, managers' varying educational and ethnic background/gender) which made targeted communication and coordination of technical assistance difficult. Second, resources availability (including financial, human and time) which made perceived cost the single biggest reason why SMEs did not engage in environmental management. Third, owners/managers' knowledge of, interest in, and motivation to adopt environmental management which may have prevented them from viewing environmental issues or the need to act responsibly as significant. Many times, these stemmed from the belief that their adverse environmental impact was small or insignificant.

Parker et al. (2009) reviewed nearly 50 journal articles published between 2003 and 2008 with a primary focus on developing environmental improvement intervention strategies that would be most effective for various subsets of SMEs. Drawn from the literature examined, they listed the following factors as the main drivers/barriers of SME environmental improvement: regulation, environmental commitment, business performance commitment, financial incentives, external demand, environmental knowledge, and assistance/education.

In their analysis of the role of SME suppliers in implementing sustainability, Meqdadi et al. (2012) provided an extensive listing of the literature on SME barriers and drivers in sustainability initiatives by organizing them for SMEs vs. their supply network. As for drivers of SMEs' sustainability, they list commitment and beliefs/values of top management, cost savings and benefits, existence of environmental awareness, availability of financial and technical resources and infrastructure complying with environmental standards and seeking competitive advantage, among others. Among the barriers, they cite lack of top management commitment, time and awareness, perception that their impact on environment is minimal, high cost of environmental programs, lack of financial resources, lack of skills, know-how and technical expertise, among others.

Drawing on 84 journal articles published between 1987 and 2010, Klewitz and Hansen (2014) found SMEs' strategic sustainability behavior to range from *resistant, reactive, anticipatory,* and *innovation based to sustainability-rooted* and identified innovation practices at *product, process,* and *organizational* levels. In their review of literature, they refer to most of the major factors listed by the studies noted above.

Johnson and Schaltegger (2015) reviewed 112 studies to identify the specific sustainability management tools designed for SMEs and reasons why they were implemented or not. All in all, they identified 26 sustainability management tools from the literature applicable to SMEs. They note the following as the normative considerations as to why SMEs should implement these methods: managing legal compliance and stakeholder relationships, performance improvement, organizational learning, and innovativeness. As for barriers to implementation, they divide them into internal and external. The internal barriers include the lack of awareness on sustainability issues, absence of perceived benefits, the lack of knowledge and expertise, and the lack of human and financial resources. The external barriers consist of insufficient external drivers and incentives, the unsuitability of formal management tools in informal SME structures, and the complexity of internationally designed standards and instruments for locally focused SMEs (Johnson & Schaltegger, 2015).

Agellie (2017) explored the drivers and barriers to SMEs sustainable green business practices and uncovered 21 drivers and 35 barriers. The drivers were in turn classified into seven categories among which "social influences" such as improving company's image, having long term relationship with consumers by earning and returning their trust were the most

important driver. “Training and knowledge” (e.g., availability of affordable comprehensive training and education courses) was the least important driver. The barriers, in turn, were divided into six groups among which “government and legislation” was found to be the most challenging barrier for SMEs to implement, that is to say, the absence of government support and enforcement or limited budget/financial incentives to support green sustainable projects. “Suppliers” was found to be the easiest barrier to overcome.

Among studies focused on developing countries, Agan et al. (2013) surveyed 500 Turkish manufacturing firms and found the most influential driver affecting environmental improvement to be the expected benefits resulting from enhancement in companies’ image, reputation, and brand. Chan (2011), surveyed 48 SME hotels in Hong Kong on barriers to the implementation of environmental management systems and found the following factors hindering such adoption: implementation and maintenance costs, lack of knowledge/skills, lack of the sense of urgency, ambiguity of standards, and lack of qualified consultants.

In an interesting twist of research, Chasse and Boiral (2017) explored how decision makers in SMEs explain their lack of commitment to sustainability by conducting 33 interviews in 9 Canadian companies. They grouped responding managers’ rationale for lack of commitment to sustainability into three main justifications. First, prioritization of economic survival, arguing that pursuit of sustainability would possibly lead to layoff, plant closure and risk of bankruptcy, among others. Second, looking for scapegoat, offering such arguments as having little control over suppliers, minimal pressure by consumers to improve their products, not having financial resources to be proactive, inadequate government policies and lack of financial assistance to support SMEs sustainability initiatives. Lastly, denial and minimization in such ways as reject having negative impact, discount sustainability issues and believe that they were in fact running sustainable operations.

METHODOLOGY

We selected the interview method as an exploratory approach in our study. Qualitative methods have been used in many studies of SMEs’ sustainability behavior (Langwell & Heaton, 2016; Aghelie, 2017; Del Giudice et al., 2017). As shown in the literature, many external and internal factors such as government regulations, consumer trends, and businesses’ culture and values are defined within countries, states, and regions. Therefore, studies should focus on certain geographical boundaries to be able to identify the drivers and barriers for SMEs in a region and develop guidelines that are effective for the corresponding areas. We focused on exploring SMEs’ sustainability behavior and strategies in NY State and conducted interviews with SMEs in this area. The interview instrument consisted of six open-ended questions, which were formally developed after reviewing existing literature along with preliminary discussions with several SME experts. Table 1 includes the categories of the questions as well as the questions themselves. Questions prompted interviewees to discuss topics including: their familiarity with sustainability and how they learned about it, their implementation of sustainable business practices (e.g. renewable energy, recycling, local sourcing, etc.), their motivations for being sustainable (e.g. values, regulations, incentives, consumer behavior, competitors, etc.), barriers preventing sustainability in their business (e.g. awareness, cost, etc.), potential future sustainability plans as well as any other relevant information they may have liked to share.

Table 1. *Interview Questionnaire*

Category	**Question**
Familiarity	1. Are you familiar with environmentally sustainable solutions in small businesses (such as energy conservation, reuse and recycling, local resources, etc.)? How did you learn about them?
Solutions	2. Have you implemented any environmental solutions in your business? If yes, please explain exactly what you have done.
Drivers *(Internal)*	3. What have been your motivations in implementing those solutions?
External	a. Have regulations and policies encouraged you in your efforts?
External	i. Did tax incentives help?
External	ii. Did fine or complying with regulation influence your decision?
External	iii. Did your trade/industry association influence your choices?
External	b. Has your consumers' behavior of shopping sustainable product/service influenced your adoption of sustainability?
External	c. Has your competitors' adoption of sustainability motivated you to do the same?
Internal	d. Have you had any business sustainability goal regardless of the external of factors of government policies and consumers' trend?
External or Internal	e. Have you been encouraged by any other factors than the ones discussed above?
Performance	f. Has your investment of adopting sustainable solutions paid off?
Barriers	4. If you have not implemented any sustainable solution, why have you made that decision?
Internal	a. Have you been aware of such solutions?
Internal	b. Have you been concerned with the cost of the adoption of sustainable solutions?
Future Plans	5. Do you have any future plan to start or expand your sustainability efforts?
Other	6. Is there anything else you would like to share with us in this regard?

Interviews were conducted over the phone, in person or through video conference and were up to an hour in length depending on how much information the interviewee wanted to or

was able to share, based on their awareness or knowledge of sustainability or on the amount of sustainable solutions implemented by their business. Prior to the interviews, interviewees were provided a brief overview of the study, the interview questionnaire and the informed consent forms so that they could acknowledge their understanding of the purpose and the voluntary nature of the participation in our research. Utilizing the interview guidelines that detailed potential responses and follow-up questions, interviews were conducted by researchers.

Data Collection

Data was collected via semi-structured interviews with managers and owners of 75 SMEs operating in the NY State. SMEs were defined as small to medium-sized enterprises with 250 or fewer full-time employees. As shown in Table 2, participating SMEs were from the metropolitan areas such as Ithaca (25), New York City (11), Syracuse (9), and Buffalo (9). Of these, 86% were for-profit businesses. To improve generalizability, the interviewed businesses varied across industries, including manufacturing, retail, farming, restaurant, and health.

Table 2. *List of participant locations in NY State*

Location	Number of Participating SMEs
Ithaca	25
Other	21
New York City	11
Syracuse	9
Buffalo	9

Businesses were primarily chosen through referrals or by the researchers' own familiarity with them. Many businesses were also contacted using information provided by the Chamber of Commerce or online business directories and listings, including *the Small Business Administration's Dynamic Small Business Search* database. The SBA's database produced a randomized selection of small business contact information based on location criteria specified by researchers.

Content Analysis

After interviews were conducted, content analysis of the interview transcripts was completed by the researchers. This was done by thoroughly reading through the transcripts and coding the interviewees' responses to each question, which were coded into a spreadsheet, organized into columns for each of the open-ended questions and sub-questions asked in the interviews.

Using the Grounded theory approach, researchers identified several categories in the data as they emerged in the interviews themselves in order to create coded terms (Strauss &

Corbin, 1990; Williamson et al., 2006). When researchers discovered a response within a transcript that did not fit any of the already defined terms, they added a new term to describe the response. Each new term and its definition was recorded in a shared list between researchers to improve the inter-rater reliability of the researchers' coding. Researchers also identified categories and terms by reviewing the terminology used in prior research regarding business sustainability (Robinson & Stubberud, 2013; Wiesner et al., 2017). For instance, the term "feel good" was adopted in the current study to describe sustainable solutions that had paid off for businesses through intrinsic and personal benefits (Robinson & Stubberud, 2013).

Initially, 115 terms were defined to identify recurring concepts within the interviews such as "Family Influence", "Cost", and "Limited Resources". Recognizing the overlap in the definitions of some of the terms, the researchers grouped the related terms into categories, reducing the total number of terms to 86.

FINDINGS & DISCUSSION

As noted in the review of literature section, a variety of internal and external factors such as education, businesses' self-motivation and regulations are among the major drivers behind small businesses' decisions to implement sustainability (Tilley, 1999; Walker et al., 2008; Parker et al. 2009; Johnson and Schaltegger, 2015). At the same time, studies have shown several barriers such as the cost of implementing sustainable solution and resource limitations prevent SMEs from utilizing such solutions. Below we discuss the key findings of this study with respect to the prominent drivers and barriers identified by NY State SMEs against the backdrop of the extant literature.

Drivers

Environmental Awareness

When first considering implementing sustainable solutions in business operations, it is necessary for small business owners or managers to have some level of knowledge, awareness, or understanding as to how. Gadenne et al. (2008) and Giri et al. (2015) demonstrated how environmental awareness, for instance, had influenced SMEs' decision to adopt sustainable solutions. As with typical knowledge-gaining activities, individuals turn towards formal or informal educational outlets such as colleges and journal articles as well as their peers to obtain knowledge. This was evident across several respondents' comments such as the following:

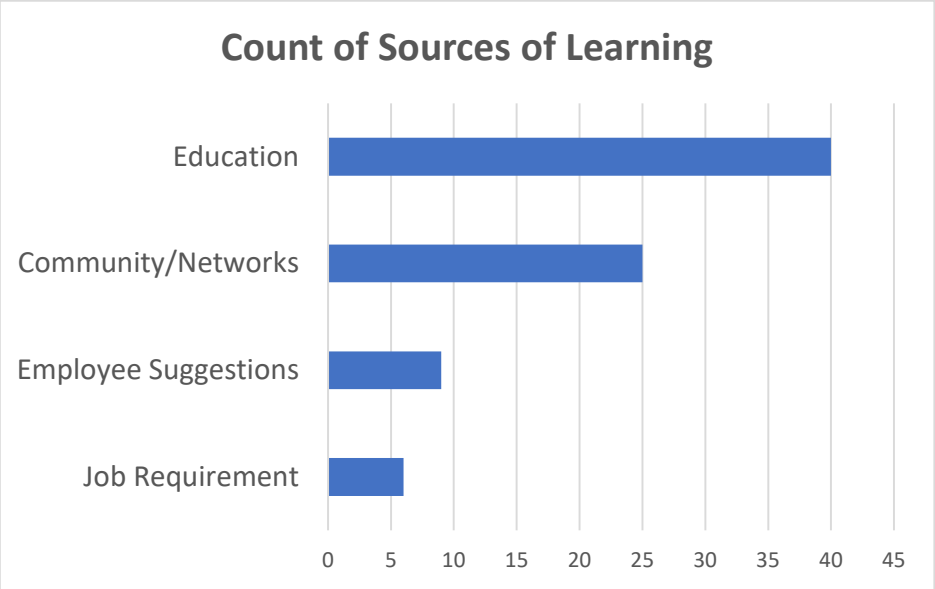
> "I learned about sustainability in class"

> "Because you're subjected to a community of conversation that supports that modality *[sustainability]*, it makes it a lot easier…... We are highly suggestive creatures, and you have to conform with your community."

According to our analysis (Fig. 1), 50% of the respondents noted that education, whether formal or informal (e.g., professional seminars, schooling, journal articles), contributed to their decision to implement sustainable solutions. This aligns with the rise of sustainability-related

courses and educational opportunities offered at colleges and universities around the US, which exposes business owners and managers to the subject (Christensen et al., 2007). In addition to education, 31% of the respondents also noted that their communities or networks allowed them to learn about adopting sustainable solutions. As these social sources have been linked to opportunity recognition, to remain competitive with larger firms, it is plausible to conclude that learned opportunities such as reducing costs or improving customer relations impacted SMEs' business owners/managers' decisions to implement sustainable solutions (Ozgen et al., 2007). Our finding here is in concert with several previous studies which found the extent to which SME owners/managers or employees' knowledge about how to engage in environment improvement was one of the key motivators for adoption of sustainability solutions (Tilley, 1999; Walker et al., 2008; Parker et al., 2009; Meqdadi et al., 2012).

Figure 1. *Sources of learning about sustainability by SME managers / owners*



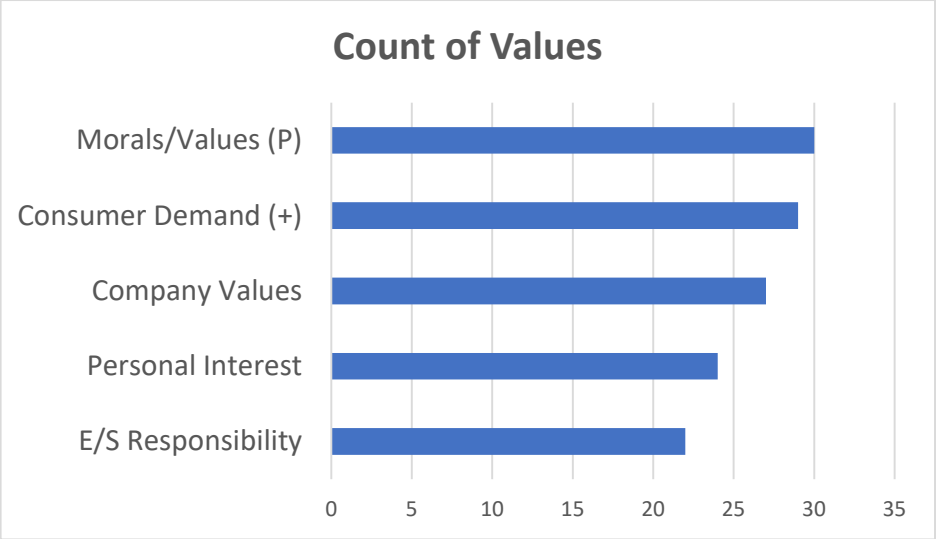
Values

Although businesses may differ in their motivations depending on industry or market segment, their underlying motivations to engage in sustainability are similar. Lozano (2013) notes that SMEs can be motivated by a variety of factors such as internal leadership, customer expectations, and regulations. NY State SMEs appear to be driven by the belief that businesses and individuals hold an obligation to reduce their negative impact on the environment and society. Additionally, SMEs feel as though engaging in such activities will allow them to improve their bottom line in the long term. This can be surmised from transcript excerpts such as the following:

> "I worked with our board of directors to come up with our mission statement which is our triple bottom line mission to enhance community, economy, and environment, through reuse. We saw our core activity to keep stuff out of the landfill, and that it also had other positive impacts."

As per our analysis (Fig. 2), the most common motivators encompassed personal morals or values, general company values and the idea of corporate responsibility, in that order. As the competitive landscape broadens and consumers obtain greater power in influencing business decisions, it has become essential for firms wishing to remain competitive to engage in corporate social responsibility activities such as giving back to the community, sourcing from sustainable suppliers, or providing adequate living wages (Juščius et al., 2008). Coupled with a continuous growth in the environmental movement since the mid 1900's, business owners and managers have become more aware of the necessity of intertwining their operations with sustainability to both limit negative impact while maximizing their operations (Dunlap et al., 2014).

Figure 2. *Values impacting SME sustainable solution implementation*



As it relates to management values, earlier studies have noted both dismissive predisposition by some who do not see environmental issues or the need to act responsibly as significant for their business believing that their impact is small or insignificant, as well as managers who believe they have a responsibility to engage in environmental improvement, proactively undertake such actions and view their business having an environmental impact (Walker et al., 2008; Parker et al., 2009).

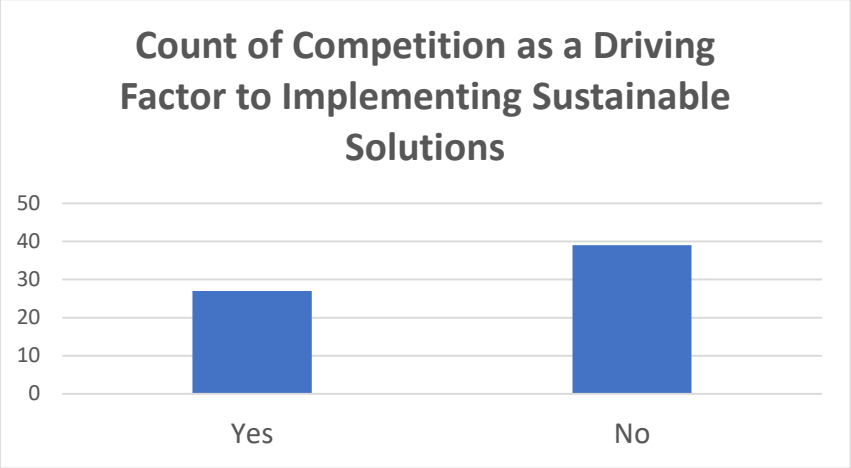
Competitive Advantage

With over 28.8 million SMEs in the United States, individual businesses operate in a vastly competitive environment (SBA Office of Advocacy, 2016). As a result, staying competitive or diversifying one's product line or services is a top priority for business owners and managers. In relation to this research, it does not appear that sustainable solution adoption is impacted heavily by competition, but rather that sustainable solutions are used to inspire the competition. This can be seen through various excerpts such as:

> "No [our competitors' adoption of sustainability has not motivated us], I actually look at it like I hope we motivate other people to start doing more."

According to our results (Fig. 3), of the 66 respondents referring to this factor, 59% noted that competition had no impact on their decisions to adopt sustainable solutions, whereas 41% stated that it did. Although it may appear that the actions of competitors in terms of sustainability does not impact SMEs' decisions to implement sustainable solutions, the concept of maintaining competitive advantage may still apply. As it has been noted, engaging in effective sustainable efforts that help reduce costs, and optimize business operations have led to strong competitive advantages (Meqdadi et al., 2012; Laszlo, 2017). Over the past decade, these advantages have included desirable cultures, improved customer loyalty, improve company's image, reduced operating costs, increased innovation / creativity, improved risk management, and additional value for stakeholders (Fink, 2016; Agellie, 2017).

Figure 3. *Impact of competition on SMEs implementing sustainable solutions*



Regulations, Taxes, and Compliance

Government intervention and involvement in business practices has been prevalent in the US for quite some time. Graafland et al. (2017) argues that direct government regulations and involvement, although helping to improve environmental performance, should be used in conjunction with other factors such as social license pressures to be effective. Although municipal, state, or federal compliance, regulations, or support can impact a business's operations, it appears that it does not have a major impact on NY State SMEs in terms of implementing sustainable solutions. This becomes evident from excerpts like the following:

> "Not at all, I haven't received any kind of specific notice as to plans I should follow or things I can change about my sustainability from the government."

Over the past few decades, there has been an increase in government assistance provided to businesses not only for general economic growth purposes, but also for sustainability activities such as climate investments (Stiglitz, 2016). According to our results, government regulations and incentives did not greatly impact the decision of SMEs to engage in sustainability. Of the 57 owners/managers who responded to this question, about 39% noted government regulations as having an impact on their decision, and 41% of the 59 interviewees who commented on government incentives viewed it as an inducement. In terms of compliance, a resounding 81% of the 54 owners/managers who spoke about compliance stated that it had no impact as well. Overall, it appears that government programs, hold little to no effect on sustainable adoption rates (Table 3).

Table 3. *Government Regulations, Taxes, and Compliance Breakdown*

	Yes	**No**
Government regulations impact on SMEs	39% (22)	61% (35)
Government incentives impact on SMEs	41% (24)	59% (35)
Regulatory compliance impact on SMEs	19% (10)	81% (44)

Findings of the earlier studies on the role of government regulations, compliance and incentives in companies' sustainability decisions have been mixed. For example, in their meta-analysis, Parker et al. (2009) found the extent to which regulations existed and were extensive enough to force SMEs to engage in environmental improvement and the extent to which financial support or incentives were provided to offset the costs or whether taxes/charges/fines were imposed to discourage negative environmental impact to be all impactful on companies' sustainability decisions. Johnson and Schaltegger's meta-analysis (2016) and Agellie's (2017), on the other hand, found that the absence of government support or limited financial incentives offered to support green sustainable projects were among the major barriers to the firms' adoption of sustainability.

Barriers to Implementation

Aside from the various motivations that encourage SMEs to implement sustainable solutions, there also exists barriers that inhibit implementation. Luthra et al. (2015) identified 28 barriers to sustainability for SMEs across seven core dimensions including economical and financial, market, awareness and information, technical, ecological and geographical, cultural and behavioral, and political and government issues. These barriers, though unique to each organization based on size and industry, primarily included costs due to the capital intensity of sustainable solutions such as solar panels, and a general lack of resources such as space or employees for NY State SMEs. This is based on such excerpts as follows:

> "Yes, entirely, it [adopting sustainable practices] is more time consuming and way more expensive, it's often not practical for a small business."

According to our analysis (Fig. 4), among the responding firms, cost rises to the top among barriers to implementation, with 73% noted it as a major concern (Fig. 5). Although still dependent on the financial success of the organization, cost has been noted as one of the leading inhibitors of sustainable solutions in the United States (Meath, 2016). Limited resources was noted as the next barrier to reduce or defer their implementations.

Figure 4. *Barriers impacting SME sustainable solution implementation*

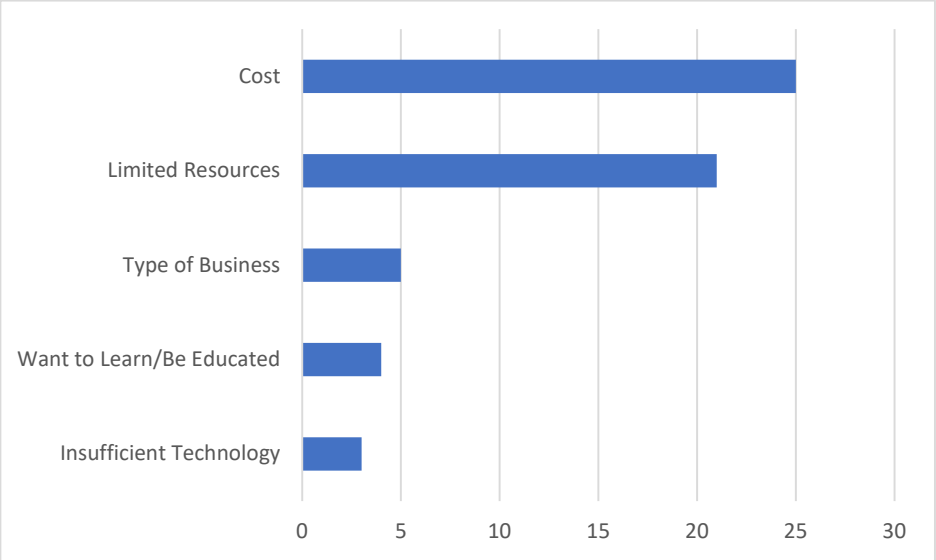


Figure 5. *SMEs concerned with the cost of sustainable implementation*

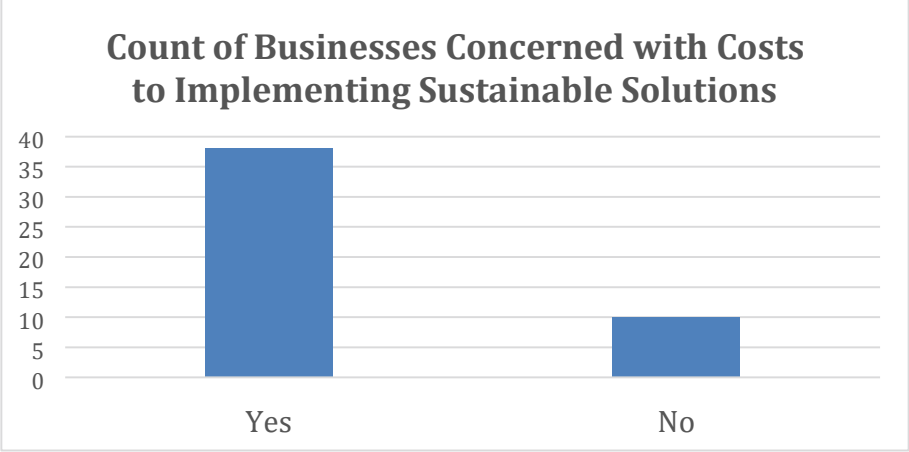


The high cost of environmental programs and lack of financial resources have been among the most frequently cited barriers to the adoption of sustainability programs, particularly among the SMEs making such investment unaffordable and/or highly risky (Tilley,1999; Walker

et al.,2008; Chan, 2011; Meqdadi et al., 2012; Johnson and Schaltegger,2016; Agellie's, 2017; Chasse and Boiral, 2017).

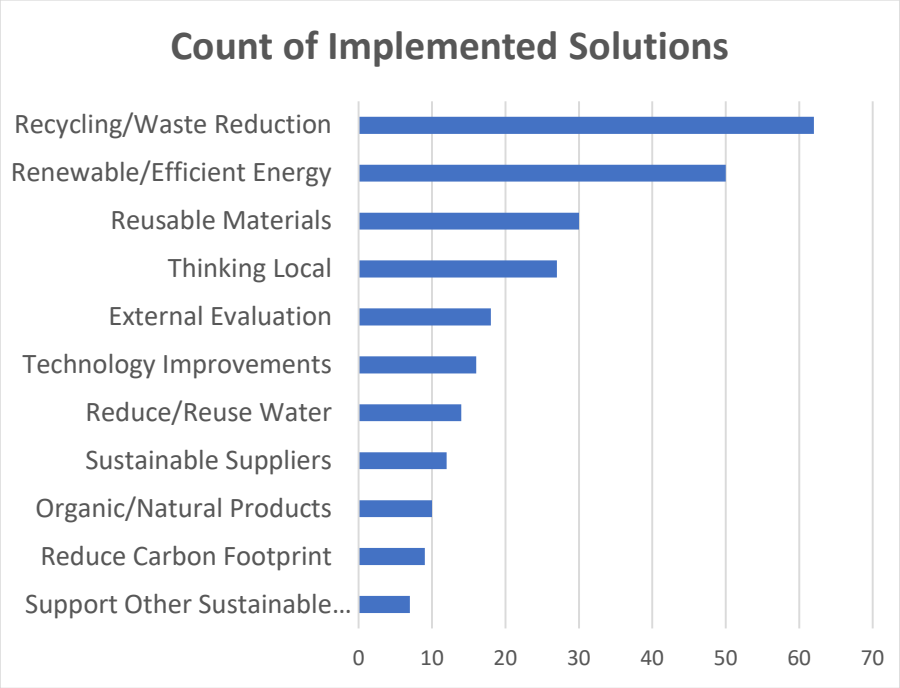
Implemented Solutions

In terms of sustainable solutions that NY State SMEs implemented (Fig. 6), the most prominent was recycling /waste reduction. In total, 78% of respondents (62) engaged in "recycling efforts or took initiatives to reduce waste generation." Ithaca, having the highest number of respondents, held a 96% engagement rate for this solution making it above average for this activity.

The second most prevalent solution was Renewable / Efficient Energy. In total, 63% of respondents (50) noted "utilizing efficient energy technologies such as LEDs, reducing energy consumption, or implementing renewable energy technologies." New York State, excluding Ithaca and New York City, were above average in this category with a 74% (29) engagement rate.

Some other notable sustainable solutions that participants engaged in included Reusable Materials ("using materials or products that can be reused") at 38% of respondents, Thinking Local ("Working to improve local community, sourcing from local suppliers, or supporting local economy") at 34%, and Utilizing External Evaluations ("Utilizing third-party sustainability audits or achieving sustainability-related accreditations") at 23%. Other solutions included such activities as Technology Improvements, Reducing / Reusing Water, Incorporating Sustainable Suppliers into the Supply Chain, and Switching to Organic / Natural Products (Fig. 6).

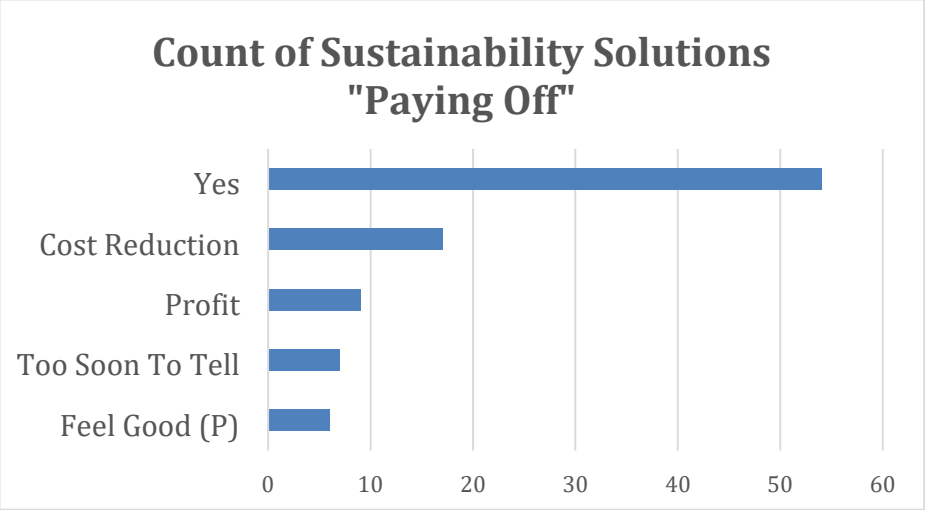
Figure 6. *List of Implemented Solutions for NY State SMEs*



Pay Off

In terms of implemented solutions paying off, 68% of participants noted that their sustainable solution adoption had paid off for their respective businesses (Fig. 7). In some cases, interviewees even went as far as to note that their sustainable initiatives had resulted in reduced costs or increased profitability. However, it was not clear from this preliminary research to what extent this pay off occurred through increasing profits, improving customer relations, or other aspects of business.

Figure 7. *SMEs that have stated their sustainable solutions have paid off*



Relative to other areas (i.e., drivers and barriers to sustainability adoption) fewer research has examined whether such solutions have paid off. Meqdadi et al. (2012) found cost savings and benefits to be one of the motivators among the Canadian firms they studied.

CONCLUSION, LIMITATIONS, AND FUTURE RESEARCH

The results of our research identified important internal and external drivers of the sustainability adoption in NYS SMEs. Internal drivers such as a sense of duty or moral obligation to reduce negative environmental impacts, lower costs and potential future liabilities (cleanup costs), or the possibility of lower long-term operation costs, like the cost of gas or electricity were all positively influencing adoption decision of SMEs. Among external drivers, majority of the participating SMEs did not consider competitive advantage, government regulations and regulatory compliances, or financial incentives as important influencers of sustainability adoption strategies. Further analysis of this finding can help policy makers to either extend the government regulations or make them more effective for SMEs implementation. Social trends, however, such as customers who value socially responsible products are considered important factors. In addition, any formal or facilitated education such

as workshops, seminars, conferences, or environmental audits, as external factors, played a positive role. This result again has implications for planning and developing more formal education at colleges or informal ones at places such as chambers of commerce that can strengthen SMEs' ability to adopt sustainable solutions. Our study also identified the barriers such as cost and limited resources that prevent SMEs adoption of sustainability.

The generalizability of our study is limited due to the methodology and the sample size used. We conducted a qualitative research to explore and understand important factors influencing NYS SMEs' sustainability behavior. Our results are based on analytical and not statistical inference. The results of our study will be the basis for our future research in which we are going to develop an online survey and collect data from hundreds of SMEs across NY State. The online survey obtains more objective and structured data and allows us to conduct statistical analysis of the importance of various factors and their relationships that lead to gaining deeper insights on SMEs sustainability behavior.

Abstract

Despite the growing number of studies on coopetition, research still lacks knowledge about the antecedents and the conditions of inter-organizational coopetition, and this study aims to fill this gap. The results indicate that the interdependence between partners is positively related to inter-firm coopetition, and that this relationship is contingent on the joint occurrence of opportunism (a behavioral condition) and technology uncertainty (a contextual condition). Specifically, highly interdependent firms are more likely to be involved in a coopetitive relationships when both opportunism and technology uncertainty are high. Interestingly, our data also show that opportunism or technology uncertainty alone may not be adequate in moderating the interdependence – coopetition relationship.

DECISION SCIENCES INSTITUTE
Effect of perceived risk in moderating the relationship of PPD and website related to product return

ABSTRACT

In recent years, product returns in internet retailing have shown to be increasing. Among these product returns, large proportions are false failure returns that are not due to functional defects. While it has identified that product return decision influenced by post-purchase dissonance (PPD) among other factors, little information known about which factors in online retailing are responsible for forming the post-purchase dissonance. In the current study, we seek to address this issue of factors influencing post-purchase dissonance. We use a large data set of customers who experienced returns to identify which process attributes influence post-purchase dissonance related to product returns.

KEYWORDS: website information; post-purchase dissonance; attractiveness of alternatives; perceived risk; purchase involvement

INTRODUCTION

Given the liberal return policy in online shopping provided by the new consumer rights protection law in China created the environment for large number of product returns (Ferguson, et al., 2006; Huang, et al., 2011). This happens even before consumers have had enough time to experience the product's performance or evaluate its overall quality (D'Innocenzio, 2011). This high percentage of return rates indicate there must be some factors in E-retail business that make the products' return highly susceptible. In spite of this large occurrence of returns in E-retail, there is very limited extant research on this subject matter within the Operations Management (OM), Supply Chain Management (SCM), and Marketing literatures; specifically, there is a lack in theory-driven investigation (Mollenkopf et al., 2011). According to some recent studies (Powers and Jack, 2013; Lee, 2015), post-purchase dissonance (PPD) is found to be an important driving force for customers to return the purchased products. As a commonly used theory in social psychology, cognitive dissonance has been widely applied to explore consumer behavior. Festinger's (1957) early research suggests that cognitive dissonance could potentially be affecting consumers' attitude towards their purchase decisionAccording to cognitive dissonance theory, customers are motivated to alleviate the anxiety and uncertainty caused by dissonance by taking some actions, which leads to the recovery of psychological balance (Brehm, 1956; Festinger, 1957).

Many researchers are exploring which actions consumers would take to alleviate their negative psychological position. Changing cognition would be a core method to gain the recovery of psychological balance when consumers lack confidence in the success of their actions. Korgaonkar & Moschis (1982) observed that reversibility of purchasing decision has a great influence on consumer's dissonance-reduction process. Therefore, to make the purchase decision undone, the return of purchased product is an efficient dissonance-reduction strategy. In the context of sustainable supply chain Tangpong, Hung, & Li (2014) suggest that human agents need to adapt to the environment in order to reduce the cognitive dissonance to function more effectively. Since cognitive dissonance theory has been widely adopted by researchers to explain the psychological consequences of a purchase decision, it has recently become the theoretical backbone for consumers' post-purchase dissonance (Lee, 2015; Keng and Liao, 2013). With the introduction of the concept of post-purchase dissonance in consumer research, researchers have directed to explore the negative consequences of post-purchase dissonance. If the negative psychological situation could not be alleviated in time, post-purchase dissonance will lead to customer dissatisfaction, which may result in negative behavior that may be harmful to the enterprises, such as negative word of mouth (Grandey et al., 2013) and thus negative publicity.

As a necessary medium for online shopping, E-retailers transfer information about products and services to customers through websites, which helps to attract and guide consumers' purchase (Collier & Bienstock 2006). Therefore, website information provides a strong signal about the product and service quality and widely used in the online market (Hsieh & Tsao, 2013). Online vendors can provide detailed product descriptions in the website, such as product materials, size and function (Park & Stoel, 2005), and can use the image interaction technology to simulate customers' product experience (Kim et al., 2007). Customers can understand the demand of products and other customers' consumption experience by involving themselves on the process and focusing on online customer reviews (Babić et al., 2016), which will help customers to reduce the pre-purchase perceived risk (Ho-Dac et al., 2013). In addition, the availability of attractive alternatives is essential for making choices in product return or buying another product, this will result in cost reduction in switching, which may also have added benefit of decrease in customer's cognitive dissonance during the post-purchase process (Harris and Daunt, 2011; Powers and Jack, 2013). While post-purchase dissonance, website information, perceived risk, attractiveness of alternatives, and purchase involvement have received some attention in the literature separately as discussed earlier, moderating effect of some of these attributes on the core relationship have remained relatively unexplored.

Thus, we direct our attention for the most part on the process attributes of post-purchase dissonance to show that website information is the key predictor of post-purchase dissonance, and that attractiveness of alternatives and perceived risks are influential attributes in their relationship that shows the main functional mechanism of product return system in online retailing. Thus, we integrate the theories of cognitive dissonance along with perceived risk to propose a theory that the association between website information and post-purchase dissonance, although negative, can be strengthen further when customers experience lack of attractive alternatives, but higher purchase involvement. Our results show that post-purchase dissonance, in which attractiveness of alternatives are lower, is impacted more by website information than in which attractiveness of alternatives are higher. Similar results, also observed with perceived risk. While prior research has observed that website information has strong effect on post-purchase dissonance, our findings suggest that the magnitude of this effect is also conditional on the level of other attributes, such as, perceived risk.

LITERATURE REVIEW

PPD is defined as psychologically uncomfortable state following a purchase selected from a set of alternatives, each of which has some desirable attributes (Nadeem, 2007). In general, PPD refers to negative emotions experienced by the consumers, such as doubts, uncertainty, anxiety, regret, etc.; which are results of cognitive confliction shortly after purchase decision (Lee, 2015). Those rejected alternatives can be simulated as a counterfactual in the mind of consumer (McConnell et al., 2000), which would then amplify the existing dissonance (Walchli & Landman, 2003). This may result in product returns for it to help customer to alleviate the uncomfortable state of mind formed by the purchase choice (Gilovich and Medvec, 1995; Zeelenberg et al., 1996). PPD can be influenced by various factors, such as consumer's purchase experience, importance of the purchase decision, customer support service, competitors' product information, the number of alternatives available, consumer's involvement with the purchase, risk perception by consumer, and personality traits (Hawkins, 1972; Murray & Schlacter 1990; Olsen, 2008; Stone, 2003; Lii, 2001; George and Edward, 2009; George and Yaoyuneyong, 2010). Kassarjian and Cohen (1965) noted that comparing the negative attributes of the chosen product, a consumer with decision making difficulty reflects the positive attributes of rejected alternatives, which gives rise to a logical inconsistency between cognitions (Festinger 1957). Hawkins, Best and Coney (2001) measured the PPD's stimulation in terms of purchase decision difficulty. Murray and Schlacter (1990) highlights the association between pre-purchase uncertainty and PPD. Some studies indicate that PPD negatively related to consumer self-confidence (Hennig-Thurau et al., 2002; Nandan, 2005; Szymanski & Henard, 2001) and positively related to consumer anxiety (Keng & Liao, 2009; Liao & Chen, 2008; Soutar & Sweeney, 2003; Sweeney et al., 2000).

ABSTRACT

This research study discusses the Business Intelligence and Analytics (BI&A) evolution, applications, frameworks and emerging trends with the aim to provide a summary of core concepts, a succinct description of the key applications and frameworks, and an account of main recommendations for addressing the Big Data challenges and opportunities. It develops an integrated and organized view on the BI&A evolution process and presents an integrated BI&A application framework to help organizations adopt or develop the appropriate BI&A solutions to derive the desired impact in the Big Data era. The implications for theory and practice are discussed for competitive advantage in the dynamic global business environment in the Big Data era.

KEYWORDS: Big Data, Business Intelligence, Analytics, BI&A Application Framework, Mobile and Sensor-based Content

INTRODUCTION

Welcome to the Age of Big Data and data-drive decision making! Undoubtedly, Big Data represents a new era in data exploration, utilization, and decision making. According to McKinsey Global Institute, Big Data refers to datasets whose size is beyond the ability of typical database software tools to capture, store, manage and analyze (Manyika, 2011). Recent studies show that a majority of employers in the market believe that their organization's need for Big Data skills and support tools will rise in the future (Wixom et al., 2013). With the prominent value proposition, Big Data also brought big challenges for businesses and decision makers across all walks of life. More than often businesses are collecting more data than they know what to do with. Just as the saying goes "*You can't manage what you don't measure*". Successful decision makers must be able to work with the data, make sense of it, and understand the big picture approach to using Big Data to gain insights (Willwhite, 2014; Asllani, 2015).

To put it simply, because of Big Data, business executives and managers can measure, and hence know, radically more about their businesses, and directly translate that knowledge into improved decision making and performance (McAfee & Brynjolfsson, 2012). Modern business analytics has become their weapon of choice. Business intelligence and analytics (BI&A), for instance, have experienced significant growth over the past two decades and have been identified as one of the four major technology trends in the 2010s (IBM Tech Trends Report, 2011). Indeed, organizations have become more competitive through the use

of business intelligence and modern analytics in this Big Data era (Asllani, 2015). Motivated by the emerging opportunities and challenges as well as lack of practical transference of applying BI&A in the Big Data era, we conduct an integrated and selective review (Glass et al., 2004; Webster & Watson, 2002) on the BI&A evolution, applications, frameworks and emerging trends with the aim to provide a summary of core concepts, a succinct but valuable description of main applications and frameworks, and an account of main recommendations for addressing the Big Data challenges and opportunities. The results of this research can help BI&A researchers to count with an updated and integrative summarization of the evolution of the BI&A, and to executives and managers to count with a set of updated recommendations for coping with Big Data challenges and opportunities.

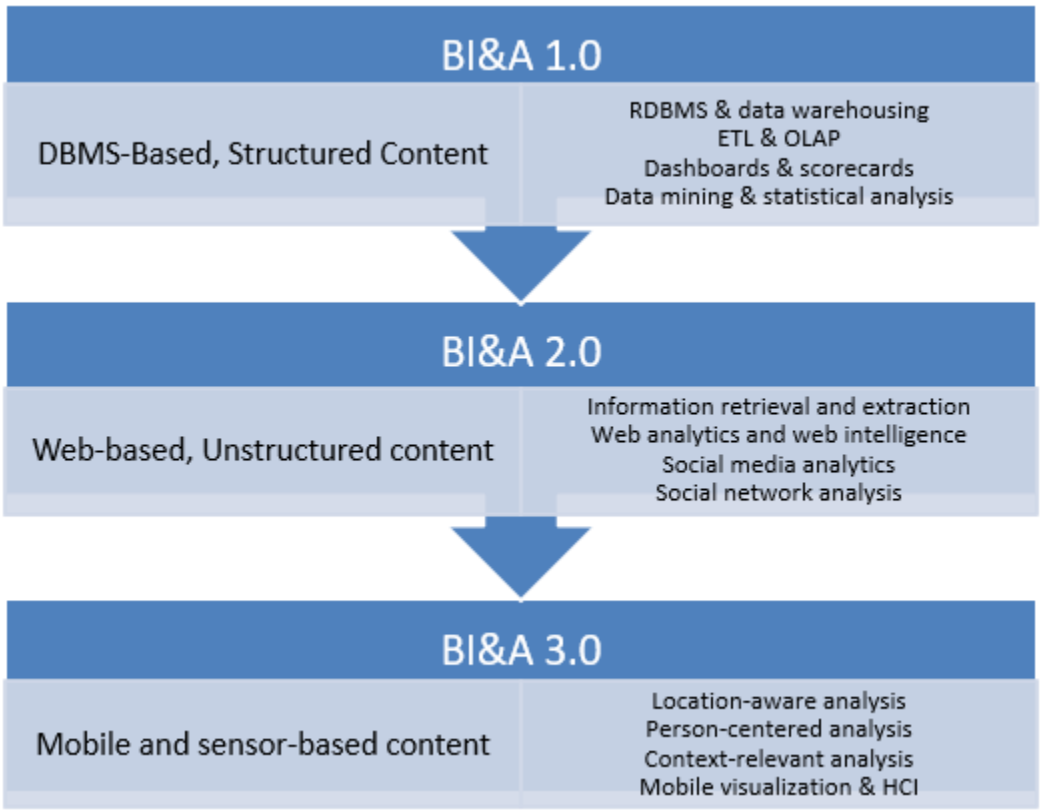
The remainder of this paper is structured as follows: section 2 reports the review of BI&A evolution phases and their key characteristics from core studies; section 3 presents an overview of the Big Data challenges and opportunities for BI&A; section 4 explains an investigation of BI&A applications and framework in the Big Data era; section 5 discusses the implications and insights for addressing the Big Data challenges for BI&A researchers and practitioners; and finally, this paper concludes with the research limitations and recommendations for future studies.

THE EVOLUTION OF BI&A

The term “intelligence” has been used by scholars in the field of artificial intelligence (AI) since the 1950s. Only two decades ago, “business intelligence” (BI) was recognized as a popular trend in the management information systems (MIS) field. Later with the advent and rapid advancement of Internet technologies, business analytics (BA) was introduced within the BI domain and simply defined as “using data for better decision making” (Winston, 2013). More recently, the rise of Internet of Things (IoT) or the Industrial Internet together with improved access to large amount of data is also fueling the Big Data trend. The automation of business processes with information technology has led to the automatic capture of massive data (Asllani, 2015). Accordingly, Big Data and Big Data analytics, considered in this paper as a sub-set of business analytics that offers new directions for BI&A, have been used to describe the unique and advanced analytical techniques that can handle the high volume, variety, value, and velocity of Big Data in business applications.

As a data centric approach that relies heavily on data collection, extraction, and analysis technologies, BI&A has its theoretical roots in the longstanding data management field (Chen, Chiang & Storey, 2012). According to Chen et al (2012), BI&A evolution process can be classified into phases 1.0 (DBMS-based), 2.0 (Web-based), and 3.0 (mobile and sensor-based). More specifically, BI&A 1.0 refers to the BI&A technologies and applications currently adopted in industry, where data are mostly structured, collected by companies through various legacy systems, and often stored in commercial relational database management systems (RDBMS). In the 2000s, Web 2.0-based systems and analytical technologies have led to the exciting era of BI&A 2.0 research, which was centered on text and web analytics for unstructured web contents. Whereas web-based BI&A 2.0 has attracted active research so far, mobile devices and their complete ecosystems of downloadable applications are transforming different facets of society leading to the emerging BI&A 3.0 systems in support of highly mobile, location-aware, person-centered, and context-relevant analysis. Figure 1 below depicts the BI&A evaluation phases and key characteristics.

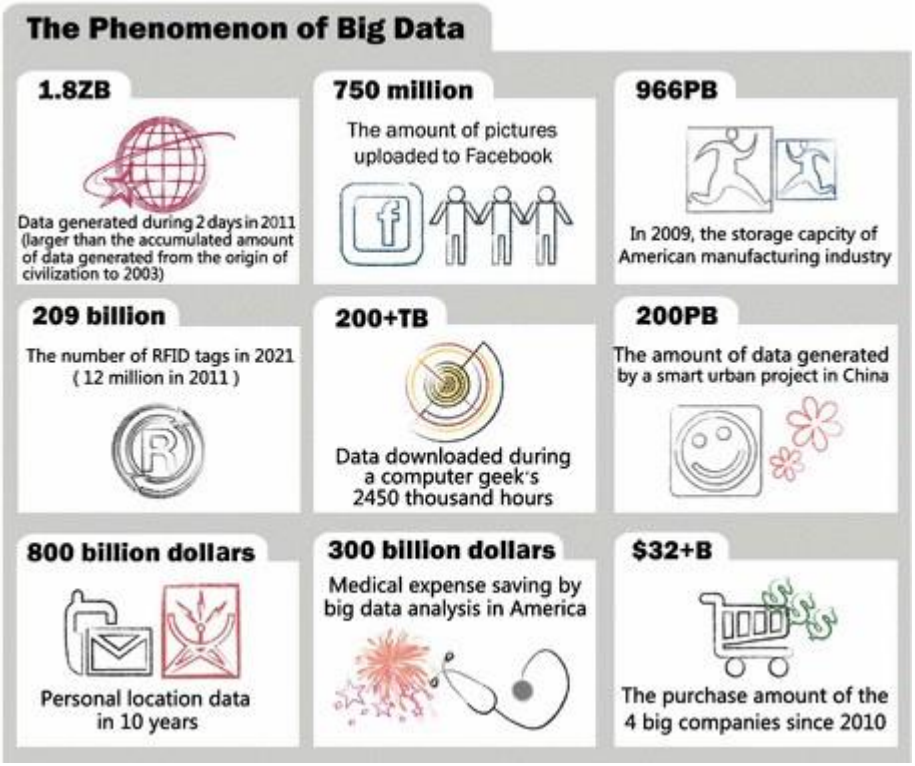
Figure 1: BI&A Evolution Phases and Key Characteristics (adapted from Chen et al. 2012)



THE BIG DATA CHALLENGE & OPPORTUNITY

Modern businesses are now entering the new paradigm of Big Data. In 2010, the total amount of data on earth exceeded one zettabyte (Ackerman & Guizzo, 2011). By end of 2011, the number grew up to 1.8 zettabyte (Reed et al., 2012). Further, it is expected that this number will reach 35 zettabyte by 2020, according to the recent release of 2011 Digital Universe study sponsored by EMC. In 15 of the US economy's 17 sectors, business organizations with more than 1,000 employees, on average, store over 235 terabytes of data—more data than is contained in the US Library of Congress (Brown et al., 2011). Figure 2 below illustrates the phenomenon of Big Data worldwide.

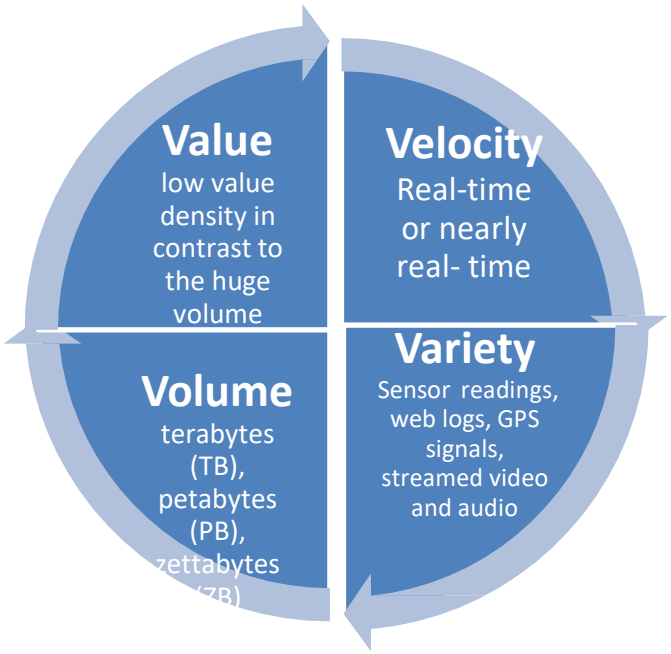
Figure 2: The boom of the global data volume (adapted from Chen et al., 2014)



What is Big Data? Big Data is an abstract concept that refers to massive data sets having large, more varied and complex structure with the difficulties of storing, analyzing and visualizing for further processes or results (Sagiroglu& Sinanc, 2013). Although there are variations about the exact definition, Big Data is typically characterized by three Vs: volume, velocity, and variety. Volume refers to the large size of the data such as terabytes (TB), petabytes (PB), zettabytes (ZB), etc. The volume of Big Data is larger than the volume processed by conventional relational databases in legacy systems. Velocity means how frequently the data is generated and flows into an organization. Real-time or nearly real-time information makes it possible for a company to be much more agile than its competitors (McAfee & Brynjolfsson, 2012). Accordingly, variety refers to the sources, types and formats of data. Different from structured data sets, Big data takes a variety of forms ranging from RFID sensor readings, unstructured social networking messages and web logs, GPS signals from cell phones, streamed video and audio, and more. More recently, many researchers and practitioners proposed one additional key characteristic, namely, the 4^{th} V of Big Data, value (Gantz & Reinsel, 2011; Hashem et al., 2015), which refers to the low value density incontrast to the huge volume of the large data set. It poses big challenges in discovering

huge hidden values from large datasets with various types and rapid generation. Figure 3 below summarizes and depicts the four Vs of Big Data.

Figure 3: The Four Vs Characteristics of Big Data



One of the challenges in the era of Big Data is the increased difficulty of mining enormous amounts of data and information to identify the relevant pieces for effective decision making (Asllani, 2015). The Big Data expansion, similar to the preceding analytics movement, seeks to glean intelligence from data and translate that into business competitiveness. However, to fully realize its potential, Big Data demands new techniques with many of these approaches still in the developmental stages. Asllani (2015) succinctly captures this transformation: "*acquiring the new tools requires a radical change in underlying beliefs or theory: they require a new way of thinking*" (pp. 6). Some of the inherited challenges in Big Data are finding capable ways to capture, store, analyze, and virtualize it in order to support more effective and efficient decision making. More specifically, the volume generally improves the quality and accuracy of BI&A models and solutions. Furthermore, according to Asllani (2015), robust BI&A models can accelerate the flow of information by offering quicker decisions and improving operational business intelligence. Variety, however, presents serious challenges in implementation of BI&A techniques for Big Data. With the right technological framework of the BI&A solution, the negative impact of variety can be mitigated (Asllani, 2015).

Similar to many other technology innovations, Big Data's power does not eliminate the need for human insight or vision. In fact, the managerial challenges are greater than the technical challenges of using BI&A in the Big Data era and reaping the full benefits of the transition (McAfee & Brynjolfsson, 2012).

BI&A APPLICATIONS & FRAMEWORK FOR BIG DATA

In addition to being data driven, BI&A is highly applied and can leverage challenges and opportunities presented by Big Data and domain-specific analytics needed in many high-impact application areas (Chen et al., 2012). In this section, we identified four particular domains to examine the current and potential value BI&A solutions can derive in the Big Data era, including health care in the United States, public sector administration in the European Union, retail in the United States, and global manufacturing. Together these four domains represented close to 40 percent of global GDP in 2010 (Manyika et al., 2011). The data and analytics characteristics, potential impacts, and illustrative case studies within each domain are discussed. By carefully analyzing the application and data characteristics, we can present an integrated BI&A application framework that can facilitate the BI&A researchers and practitioners to adopt or develop the appropriate analytical techniques to derive the intended impact in the Big Data era (Manyika et al., 2011; Chen et al., 2012).

Healthcare

Historically the healthcare industry has generated large amounts of data from numerous patient care points of contact, sophisticated medical instruments, and web-based health communities, driven by record keeping, compliance and regulatory requirements, and patient care (Raghupathi & Raghupathi, 2014). Unfortunately, BI&A for Big Data in health care generally lags well behind BI&A applications in other sectors such as Retail and Manufacturing because it has rarely taken advantage of scalable analytical methods or computational platforms (Miller, 2012). By discovering associations and understanding patterns and trends within the Health care Big Data, BI&A can take advantage of the explosion in data to extract new and actionable knowledge for making better informed decisions (Raghupathi & Raghupathi, 2014).

As Miller (2012) purported, current researchers "*are doing clinical trials using vast troves of observational health care data, analyzing pharmacy and insurance claims data together to identify adverse drug events, delving into molecular-level data to discover biomarkers that help classify patients based on their response to existing treatments, and pushing their results out to physicians in novel and creative ways*". As such, BI&A has the potential to improve the care quality, enable deeper understanding of patient disease patterns, save patient lives, and lower costs in the healthcare delivery system (Miller, 2012; Raghupathi & Raghupathi, 2014). To accomplish so, the current BI&A solutions need to be equipped with advanced techniques targeted at the Big Data challenges, such as machine-learning for pattern recognition, segmentation and predictive modeling, hypothesis-free probabilistic causal approaches (e.g. Bayesian network analysis), symptom–disease–treatment (SDT) association rule mining and clustering, and so on. However, as argued by Manyika et al. (2011), deploying BI&A for Big Data in this sector would need to be accompanied by a range of enablers beyond technology innovation, some of which would require a substantial rethinking of the way health care is provided and funded.

Public sector administration

Similar to healthcare, the public sector is another large sector facing tremendous pressure to improve its efficiency and productivity. In general, governments have access to vast amounts of digital data but rarely take advantage of the powerful strategies in which they could use this information to improve performance and transparency (Manyika et al., 2011). Proper integration and extension of BI&A strategy and technologies that complement the Big Data management would be necessary, such as massive parallel-processing (MPP)

databases, distributed file systems, cloud computing technologies, criminal association rule mining and clustering, criminal network analysis spatial-temporal analysis and visualization, and multilingual text analytics to mention a few.

Successful applications of BI&A in this sector include homeland and cyber security informatics (Chen et al., 2012), in which security agencies are gathering, processing and analyzing large amounts of security-related data (e.g., criminal records of terrorism incidents and cyber security threats); public transportation (Zaslavsky et al., 2013), in which transportation agencies make use of sensor roadways in order to monitor traffic in real-time to optimum traffic management; tax collections or benefit payments auditing (Brown et al., 2011), in which tax agencies apply automated algorithms that perform systematic, multilevel checks on tax returns and automatically flag returns that require further examination or auditing; and construction and public safety (Zaslavsky et al., 2013), in which public safety agencies utilize embedded sensors with monitoring systems to collect variety of different measurements such as a change in temperature and the concrete reaction to that change for further safety analysis.

Retail

In contrast to the first two domains, retail is an advanced, progressive sector where the revolution of Big Data first emerged. The retail sector retail has been leveraging BI&A strategies and techniques for decades. More recently, businesses have been using vast amounts of data for segmenting customers, identifying emerging trends, improving business decision making, driving more sales, and developing new revenue-making strategies. These data are pulled from the web, such as online searches, posts and messages, as well as from local stores, such as customer movement in the store and fitting rooms. Unlike traditional sales transaction records collected from various legacy systems of the 1980s, the Big Data that businesses today collect from various sources are less structured and often contain rich customer opinion and behavioral information (Chen et al., 2012). Along the process, various analytical techniques have been developed for social media customer opinion analysis and customized recommender systems, such as text analysis and sentiment analysis, association rule mining, database segmentation and clustering, anomaly detection, and graph mining (Adomavicius & Tuzhilin 2005; Pang & Lee 2008).

For example, retail giant Walmart, the largest retailer in the world with more than two million employees and annual sales of around $450 billion, has been a data-driven company since the 1990s. The company uses innovative BI&A techniques that allowed the retailer to peer into its massive databases of previous transactions to identify customer buying patterns and predict future buying trends (Mayer-Schönberger & Cukier, 2013). Major Internet firms, such as Amazon, Google, and Facebook, also continue to lead the development of web analytics, cloud computing, and social media platforms that offer substantial opportunities for researchers and practitioners to “listen” to the voice of the market from a vast number of business constituents (Chen et al., 2012). Nevertheless, there is still tremendous potential across the industry for businesses to expand and improve their use of BI&A for Big Data, particularly given the increasing ease with which they can collect information on their consumers, suppliers, and inventories (Brown et al., 2011).

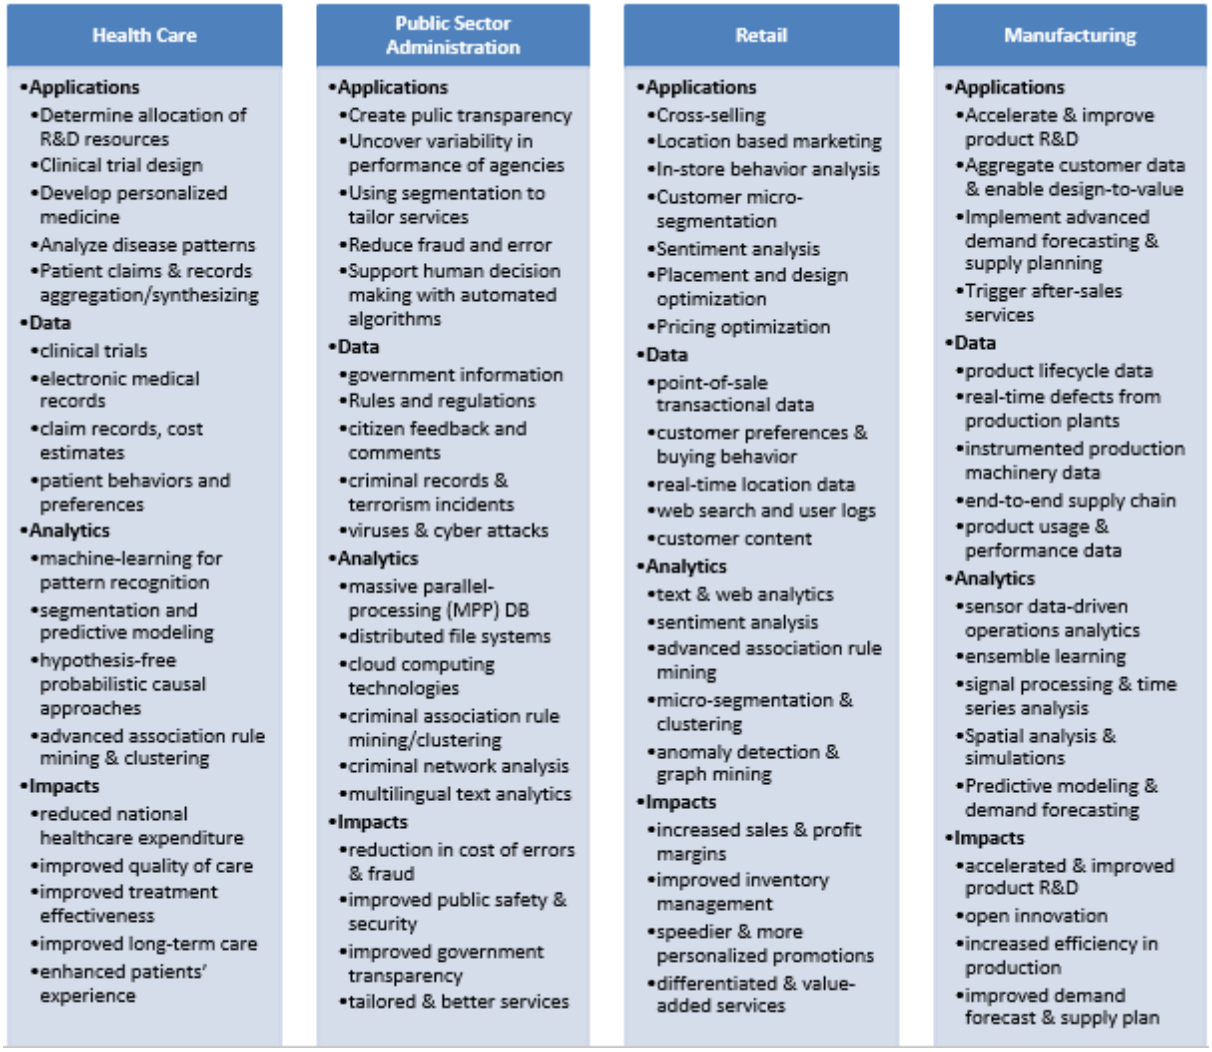
Manufacturing

Increasingly global and fragmented manufacturing value chains have created new challenges that manufacturers worldwide must overcome to sustain productivity growth (Manyika et al., 2011; Lee et al., 2013). As Manyika et al. (2011) purported, manufacturers will need to leverage a significant amount of digital data to drive efficiency across the extended enterprise and to design and market higher quality products in order to continue achieving increased levels of productivity growth. This sector generates the most datasets, more data than in any other sector, from a multitude of sources including instrumented production machinery for process control, supply chain management systems, monitoring systems that observe the performance of products in action (Manyika et al., 2011). Indeed, the amount of data generated will continue to grow exponentially in this sector.

Using a Boeing jet for example, it generates 10 terabytes (TB) of data per engine every 30 minutes and a single six hour flight would generate 240 terabyte (TB) of data (Zaslavsky et al., 2013). In addition, there are about 28537 commercial flights in the sky in United States on any given day. According to Manyika et al. (2011), BI&A for Big data has the potential to enable seven performance improvement areas for manufacturers, affecting the entire value chain: 1) offer further opportunities to accelerate product development and improve product design, through concrete customer input and open innovation; 2) aggregate customer data and make them widely available and enable design-to-value; 3) share data through virtual collaboration sites (idea marketplaces to enable crowd sourcing); 4) implement advanced demand forecasting and supply planning across suppliers; 5) implement lean manufacturing and model production virtually (digital factory) to create process transparency; 6) implement sensor data-driven operations analytics to improve throughput and enable mass customization; and 7) collect after-sales data from sensors and feedback in real time to trigger after-sales services. In short, manufacturers around the globe have tremendous potential to generate value from the use of BI&A with Big Data, integrating data across the extended enterprise and applying advanced analytical techniques to raise their productivity both by increasing efficiency and improving the quality of their products (Brown et al., 2011; Lee et al., 2013).

Figure 4 below summarizes the promising and high-impact BI&A applications to address the challenges and opportunities brought on by the Big Data era in four main domains, namely, healthcare, public sector administration, retail, and manufacturing. This integrated BI&A application framework can facilitate the BI&A researchers and practitioners to adopt or develop the appropriate analytical techniques in each specific domain to derive the intended impact and value in this Big Data era (Manyika et al., 2011; Chen et al., 2012).

Figure 4: BI&A Application Framework for Big Data in Four Main Domains

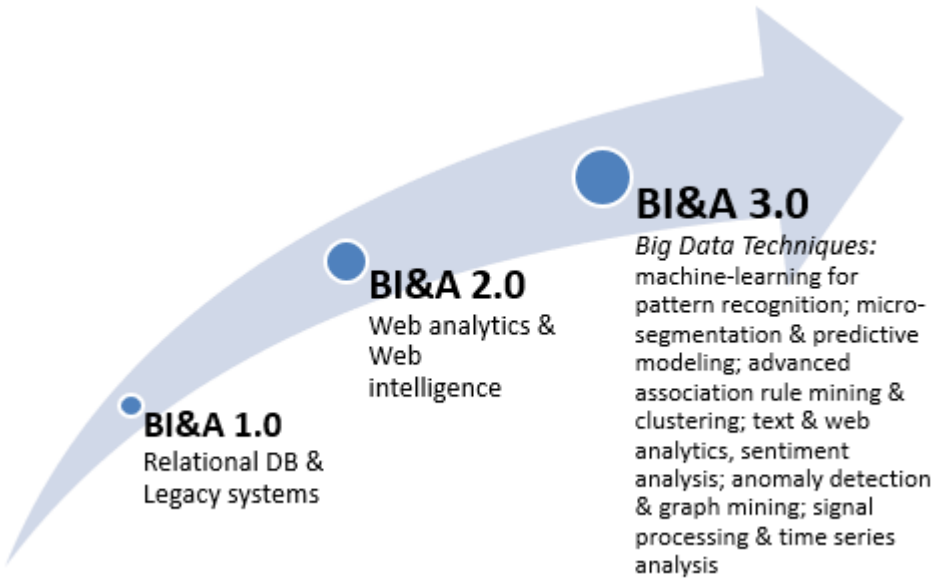


DISCUSSIONS AND INSIGHTS ON BI&A FOR BIG DATA

In this Big Data era, data is not only becoming more available but also more understandable. Recent studies show that a majority of employers in the market believe that their organization's need for Big Data skills and support tools will rise in the future (Wixom et al., 2013). With the prominent value proposition, Big Data has also created new challenges for businesses and decision makers across many different industries and jobs. Businesses are collecting vast amounts of data more frequently yet they are still not grasping the potential of all the data.They do not know what to do with all this data. Consequently, decision makers face the challenge to work with huge datasets from multiple and varied sources, make sense of this data, and process the data with adequate tools to gain insights toward an efficient and effective decision making process. Thus, Big Data needs adequate methods and tools for such an aim (Willwhite, 2014; Asllani, 2015).

The key value promise of Big Data for business executives and managers is to know radically more about their businesses and directly translate that knowledge into efficient and effective decision making processes leading to better organizational performance (McAfee & Brynjolfsson, 2012). For this aim, the Business Intelligence and Analytics (BI&A) methods and tools has become their processing strategy of choice. BI&A evolution process can be classified into phases 1.0 (DBMS-based), 2.0 (Web-based), and 3.0 (mobile and sensor- based). According to some researchers, BI&A 3.0 applied to Big Data has enabled some important international organizations to be more competitive in the global environment (Asllani, 2015). To accomplish this goal, the current BI&A 3.0 solutions need to be equipped with advanced techniques targeted at the Big Data challenges, such as machine-learning for pattern recognition; micro-segmentation and predictive modeling; advanced association rule mining and clustering; text and web analytics; sentiment analysis; anomaly detection and graph mining; and signal processing and time series analysis. Figure 5 below depicts the BI&A evolution process with phase 3.0 techniques highlighted to address the Big Data challenges and opportunities. Figure 6 presents an overview of the Big Data characteristics and corresponding BI&A technology as well as methodology solutions to mitigate the challenges.

Figure 5: BI&A Evolution & phase 3.0 techniques to address Big Data Challenges



From an application perspective, executives and leaders of global organizations are facing these new challenges of effective decision making in the Big Data era and they desire practical BI&A solutions that can help them convert the Big Data into strategic insights and impacts. This integrative review presented in this paper adds to this body of knowledge and helps facilitate additional research and practical endeavors. A logical evolution of the origins and techniques of BI&A for Big Data were identified and presented. Based on the richness and variety of BI&A application and research findings, we present the following recommendations and cautions to executives and leaders interested in such productive yet challenging investments:

- All industry sectors face the challenges of effective and efficient decision making in the Big Data era and the current **BI&A 3.0 solutions can help them become competitive data-driven companies**.
- To effectively address the Big Data challenges, the current **BI&A 3.0 solutions need to be equipped with advanced techniques** depending on the involved data types, sources, structures, and other organizational characteristics.
- Practitioners across different industries can utilize **the presented integrated BI&A application framework** to adopt or develop the appropriate BI&A techniques and solutions to derive the intended impact in the Big Data era.
- BI&A for Big Data brings **a new culture and way of decision making**. Besides technical challenges, managerial challenges of using BI&A in the Big Data era must be addressed to reap the full benefits of that transition.

Figure 6: Big Data challenges and corresponding BI&A solutions (adapted from Asllani, 2015)

Big Data dimension	Challenges to BI&A	Technology-based Solutions	Methodology-based Solutions
Volume	Managing large and rapidly increasing data sources	• Advanced software programs able to process large number of constraints and decision variables	• Standardize the ETL processes to automatically capture and process input parameters • Encourage system-driven versus user-driven optimization programs
Variety	Dealing with heterogeneity of data sources Dealing with incomplete data sets	• Relational database systems and declarative query language to retrieve data input for optimization models • ETL toward specialized optimization driven Data Marts	• Add data structuring prior to analysis • Implement data cleaning and imputation techniques
Velocity	Managing large and rapidly changing data sets Reaching on-time optimal solutions for operational business intelligence	• Advanced optimization software with the capability to reach optimal solutions within a feasible amount of time • Use optimization packages that directly connect to operational data bases	• Consider a trade-off between less than optimal but time feasible and practical solution and optimal but complex and often delayed solutions
Value	Discovering hidden value from large volume data sets Filtering noises and searching for hidden patterns and knowledge through powerful processing	• Advanced cloud computing to address the challenge of processing demand • Scalable implementation of computerized machine-learning for pattern recognition	• Clean and filter noises prior to performing analytics • Adopt scalable solution for data acquisition and analysis through two-phase process, crawling and processing

This study reveals that the BI&A evolution process has experienced drastic changes in its execution by organizations, its theoretical conceptualization by researchers, and its practical implications in the Big Data era. The main shift on the BI&A evolution process can be stated as an evolution from traditional analytical and statistical techniques with structureddata sets in highly predictable and cooperative business environment, to data-driven discovery and highly proactive and creative decision-making utilizing advanced analytical techniques with unstructured and massive data sources to cope with a highly dynamic global business environment in the Big Data era.

CONCLUDING REMARKS

The wealth of Big Data, in turn, accelerates advances in data-driven decision making with advanced BI&A tools and applications. With an aggressive push towards Web 2.0 and Internet of Things (IoT) or the Industrial Internet, data has become more accessible and ubiquitous in the global environment. This Big Data phenomenon and trend necessitates the appropriate techniques and solutions to convert massive data into useful and actionable information. It is a simple formula: Using BI&A for Big Data leads to better predictions, and better predictions yield better decisions (McAfee & Brynjolfsson, 2012). In this paper, we have reviewed the BI&A evolution phases and key characteristics, the Big Data challenges and opportunities for BI&A, and illustrative BI&A applications to address the Big Data challenges and opportunities. Along the process, we have developed an integrated and organized view on the BI&A evolution process and presented an integrated BI&A application framework to help organizations adopt or develop the appropriate BI&A solutions to derive the desired impact in the Big Data era.

On an application level, this paper also elicits a set of practical recommendations to executives and leaders in organizations worldwide for interpreting the BI&A literature and applying the rich body of knowledge for IT practitioners. Given the importance and complexity of BI&A and Big Data phenomenon, we encourage and anticipate continued research efforts to investigate and establish advanced and updated conceptualizations and frameworks to cope with this complex yet critical subject.

ABSTRACT

The focus of this research is to explore a variance estimation for a given population based on quartiles and some other functions of quartiles of the auxiliary variable. The optimum value of the characterizing constant has been obtained ensuring the least amount of MSE of the suggested estimator. Also, we compare the estimator with the competing estimators through the numerical example within the theoretical assumptions. The results of the study show that the proposed estimator yielded the lowest value of MSE among all competing estimators.

KEYWORDS: Population Variance, Estimators, Quartiles, Bias, Mean Squared Error (MSE).

INTRODUCTION

According to natural law, it is well established that no two things are precisely similar. Thus, we can infer that variation is a natural phenomenon, and observed in daily life. For example, a physician is in need to have a complete knowledge of measures and possible variations in pulse rate of human beings, temperature and blood pressure as well for a suitable prescription. An agriculturist will have to have an appropriate understanding of changes in climate factors to have an idea for the planning about when, how and where to plant his crop (Singh et al., 2013). Therefore, it is important to understand the variance or variation of the population to make the optimal decisions.

Sampling is used where it is difficult to collect data on the entire population and to estimate the parameters. The most apparent estimator for a given parameter is the corresponding statistic. Although the sample variance is unbiased for population variance, unfortunately, it can be significantly different from the actual results of variance for another samples. Thus, we search for even a biased estimator with a smallest possible MSE. This goal is achieved by applying the concept of the auxiliary variable. The auxiliary variable is defined as a variable that has either negative or positive correlation with the study variable. Many authors utilized auxiliary information or variable in the form of known parameters for enhancing the precision of

[1] Corresponding Author

population variance estimation. There are several latest research work that have used the similar approach (Khan and Shabbir, 2013; Maqbool et al., 2016; Maqbool and Javaid, 2017).

In this study, an estimator has been proposed for the precise population variance estimation integrating auxiliary information in the form of quartiles and some functions of quartiles at the stage of estimation.

LITERATURE REVIEW

Over the years, several estimators such as sample variance estimator and various improved ratio estimators have been proposed for refining the estimation process of population variance. A summary of recent research work related to estimators is presented in Table 1.

Table 1: Summary of Literature Review of Existing Estimators

PROPOSED ESTIMATOR

The study proposes an improved array of ratio-based estimators using quartiles and some functions of quartiles of auxiliary variable for improved population variance estimation as,

$$t_{p_i}^{*} = \kappa_i \, s_y^2 \left[\frac{S_x^2 + \alpha L_i^2}{s_x^2 + \alpha L_i^2} \right], \ (i = 1,2,3)$$

Where κ_i $(i = 1,2,3)$ are characterizing constants that are determined based on the MSE of $t_{p_i}^{*}$ is the lowest.

The properties of the $t_{p_i}^{*}$ are studied using assumptions given below,

$s_y^2 = S_y^2(1+\varepsilon_0)$ and $s_x^2 = S_x^2(1+\varepsilon_1)$ where $E(\varepsilon_i) = 0$ for $(i = 0,1)$ and up to degree one of the approximation which is ignoring finite population correction factor, defined as,

$E(\varepsilon_0^2) = n^{-1}(\lambda_{40} - 1)$, $E(\varepsilon_1^2) = n^{-1}(\lambda_{04} - 1)$, $E(\varepsilon_0 \varepsilon_1) = n^{-1}(\lambda_{22} - 1)$.

The members of the suggested array of estimators, respective biases and MSEs for the optimum values of the characterizing constants, up to the first order of approximation are presented in Table 2.

Table 2: Proposed estimators, biases and MSEs

Estimator	Bias	MSE
$t_{p_1}^* = \kappa_1 s_y^2 (S_x^2 + \alpha L_1^2 / s_x^2 + \alpha L_1^2)$	$(\kappa_1 - 1)S_y^2 + \Phi \kappa_1 \theta_1^* (\theta_1^* - c)$	$S_y^4[1-(A_1^2/B_1)]$
$t_{p_2}^* = \kappa_2 s_y^2 (S_x^2 + \alpha L_2^2 / s_x^2 + \alpha L_2^2)$	$(\kappa_2 - 1)S_y^2 + \Phi \kappa_2 \theta_2^* (\theta_2^* - c)$	$S_y^4[1-(A_2^2/B_2)]$
$t_{p_3}^* = \kappa_3 s_y^2 (S_x^2 + \alpha L_3^2 / s_x^2 + \alpha L_3^2)$	$(\kappa_3 - 1)S_y^2 + \Phi \kappa_3 \theta_3^* (\theta_3^* - c)$	$S_y^4[1-(A_3^2/B_3)]$

Thus, the biases and the MSEs of the suggested estimators are defined as follows,

$B(t_{p_i}^*) = (\kappa_i - 1)S_y^2 + \Phi \kappa_i \theta_i^* (\theta_i^* - c)$, $(i = 1,2,3)$

$MSE(t_{p_i}^*) = S_y^4[1-(A_i^2/B_i)]$

Where the optimum values of the characterizing scalars are,

$\kappa_i^{(opt)} = \dfrac{A_i}{B_i}$ with $A_i = [1 + n^{-1}\{\theta_i^{*2}(\lambda_{04} - 1) - \theta_i^*(\lambda_{22} - 1)\}]$ and

$B_i = [1 + n^{-1}\{(\lambda_{40} - 1) + 3\theta_i^{*2}(\lambda_{04} - 1) - 4\theta_i^*(\lambda_{22} - 1)\}]$

EFFICIENCY COMPARISON

We present the theoretical efficiency of the suggested estimator demonstrating the enhancement in comparisons with competing estimators and the assumptions where suggested estimator is better than the competing estimators are as follows:

$V(t_0) - MSE(t_{p_i}^*) > 0$, or $\gamma(\lambda_{40} - 1) - S_y^4[1-(A_i^2/B_i)] > 0$, $(i = 1,2,3)$

$MSE(t_R) - MSE(t_{p_i}^*) > 0$, or $\gamma[(\lambda_{40} - 1) + (\lambda_{04} - 1)(1 - 2c)] - S_y^4[1-(A_i^2/B_i)] > 0$, $(i = 1,2,3)$

$MSE(t_i) - MSE(t_{p_i}^*) > 0$, or $\gamma[(\lambda_{40} - 1) + \theta_i(\lambda_{04} - 1)(\theta_i - 2c)] - S_y^4[1-(A_i^2/B_i)] > 0$, $(i = 1,2,3)$

$MSE(t_i^*) - MSE(t_{p_i}^*) > 0$, or $\gamma[(\lambda_{40} - 1) + \theta_i^*(\lambda_{04} - 1)(\theta_i^* - 2c)] - S_y^4[1-(A_i^2/B_i)] > 0$, $(i = 1,2,3)$

NUMERICAL STUDY

We analyzed the efficiency of suggested and competing estimators for the population variance. Data was taken from the study of Singh and Chaudhary (1986) on page 108. The population parameters have been presented in the following Table 3.

Table 3: Parameters of the population

N	70	C_y	0.6254	Q_1	80.1500
n	25	S_x	140.8572	Q_2	160.3000
$\bar{Y}$	96.7000	C_x	0.8037	Q_3	225.0250
$\bar{X}$	175.2671	λ_{04}	7.0952	Q_r	144.8750
ρ	0.7293	λ_{40}	4.7596	Q_d	72.4375
S_y	60.7140	λ_{22}	4.6038	Q_a	152.5875

Where $\theta_1 = 1.00404$, $\theta_2 = 1.008079$ and $\theta_3 = 1.011342$ for above population.

Table 4: Constants θ_i^* for different values of α

α	θ_1^*	θ_2^*	θ_3^*
0.0	1.000	1.000	1.000
0.1	0.969	0.885	0.797
0.2	0.939	0.794	0.662
0.3	0.911	0.720	0.566
0.4	0.885	0.659	0.495
0.5	0.861	0.607	0.439
0.6	0.837	0.563	0.395
0.7	0.815	0.524	0.359
0.8	0.794	0.491	0.329
0.9	0.774	0.462	0.303
1.0	0.755	0.436	0.282

The MSEs of different estimators along with the variance of the sample variance estimator for above population are,

$t_0 = 2043417.072$, $t_R = 1438805.637$, $t_1 = 1449800.126$, $t_2 = 1460902.739$, $t_3 = 1469947.550$
$t_4 = 1458757.621$, $t_5 = 1448737.470$, $t_6 = 1459829.679$

The MSEs of various estimators t_i^* ($i = 1,2,3$) suggested by Singh et al. (2013) and the proposed estimators for different values of characterizing constant α are presented in Tables 5 and 6.

Table 5: MSE of various estimators for different value of α

0.9	857757.5	901611.8	1107006.0
1.0	**849659.8**	926240.6	1143461.0

RESULTS AND DISCUSSION

From Table 5, it can be seen that the variance of sample variance is 2043417.072 and the MSE of rest estimators are lying in the interval 1438805.637-1469947.550. The MSE of estimators in Table 5 is ranging in the interval 1438805.64-885369.73. The MSE of proposed estimators in Table 6 is lying in the interval 998972.5-825861.6. Results show that the suggested estimators are best among other population variance estimators.

CONCLUSION

In this study, we suggested an enhanced array of estimators of the population variance utilizing information on auxiliary variable in the form of quartiles and some functions of quartiles. We derived bias and the MSE of the suggested array. The suggested array is compared with the competing estimators. The assumptions for which suggested array is more efficient than competing estimators have been derived. Finally, the theoretical findings have been verified through the numerical study and shown improvement over competing estimators.

ABSTRACT

Businesses focus on developing business analytics to help gain competitive advantage. Yet skilled individuals are required to perform the analysis. This research project focuses on determining the various stages of task orientation by understanding job postings. The job postings are empirically analyzed using text-mining tools. Using the results of the text-mining analysis, cluster analysis algorithms are used to classify the various types of task orientations. Finally, the relationships among several business characteristics, the tools acquired by businesses, and the identified task orientations are analyzed and then insights into the level of analytic capability of the business are provided.

KEYWORDS: Analytics Tools, Business Characteristics, Cluster Analysis Task Orientation, Text-Mining

INTRODUCTION

Businesses have pursued implementing business analytics to translate real-time insights into competitive advantage, to provide various stakeholders with valuable information for improved problem-solving and decision-making, and to evaluate the massive amounts of unfiltered and unstructured data available for insight generation (Ertemel, 2015; Popovič et al, 2012). Competitive advantage may be achieved by simply using the competencies of analysts performing the insight generation tasks (Trieu, 2017). Yet exploiting the vast quantity of available data becomes a tremendous challenge. Ideally, the insights discovered by the analyst forms the basis for generating actionable insights (Doumpos & Zopounidis, 2016).

Previous research has reported that when businesses are operating in highly competitive markets, the impact from the insights generated on problem-solving and decision-making, produce positive results (Popovič et al, 2012). Yet, the specific analytic competencies required to generate those insights are not well understood and remains an ongoing area for investigation as limited knowledge has been presented in the literature regarding what and how analysts utilize business analytics. Thus, researchers continually question the value of these analytics systems since the academic literature lacks an overarching framework to provide guidance (Agarwal & Dhar, 2014).

Therefore, the focus of this research project is to examine what specific analytics tasks are performed thus providing a contribution to the literature. This research project evaluates the skills required of analysts and the tools used to perform insight generation. In addition, this research project investigates whether the nature of business analytic tasks vary by size and industry type of the business. To accomplish these objectives, a taxonomy containing business analytics task orientations is adopted. Then, this research project empirically validates the different business analytics task orientations using cluster analysis algorithms on job posting data. Finally, the relationships among characteristics, task orientation, and adopted analytics tools are assessed. The results highlight the determinants and nature of analytic tasks performed as well as the adopted tools.

LITERATURE REVIEW

The use of analytics is important as analytics are used to generate insights thus leading to more informed actions. Since many research studies use various analytic terms interchangeably (Bayrak, 2015), it is important to define "business analytics". Davenport and Harris (2007) define this term as "the focus on the extensive use of data, statistical and quantitative analysis, explanatory and predictive models, and fact-based management to drive actions." Watson (2009) views it as "a broad category of applications, technologies, and processes for gathering, storing, accessing, and analyzing data to help analysts". Pape (2016) explicates it as "a set of methods that transform data into action by generating insights used for decision-making". Recently, Wang et al. (2018) incorporates terminology associated with "big data" by including "a combination of skills, technologies, applications, and processes that enables firms to analyze an immense volume, variety, and velocity of data across a wide range of networks to support informed decision-making, and action-taking".

In defining analytics, it is important to recognize the integration of business intelligence and big data terminology along with the focus on analysis, data, models, and an evidenced-based culture. Big data contributes massive volumes of data from various sources which can be used to support different types of actions over varying time-periods. Model creation primarily focuses on providing an explanatory context for business orientation tasks (Goes, 2014). Further, another aspect of analytics involves the analytic culture of the business. The analytics need to be related to the processes used for problem-solving and decision-making (Baesens et al, 2016). It is important that the analytics used for fact-based decision-making and generated insights from the various explanatory, predictive, and prescriptive models are relevant for decision problems (Vidgen et al, 2017).

Conceptual Framework

The conceptual framework that was developed for this research project involves the use of business characteristics, task orientation, and usage of analytics tools. There are a variety of adoption models proposed for integrating business analytics into the problem-solving/decision-making processes. These models include the Healthcare Analytic Adoption Model, task orientation model, the PAIR model, and the simplified taxonomy of big data analytics (Goes, 2014; Sanders, 2012). The task orientation model is adopted for use in this research project.

This research project hypothesizes that business analytics tasks may have four distinct task orientations with differing outcomes. In performing business analytics, four different task orientations that include situation-sensing, making predictions, making evaluations, and making decisions can be used. While these orientations can be used separately or in combination, it is

expected that the business will primarily focus on a certain task orientation while performing analytics tasks. It is also hypothesized that task orientation is influenced by the characteristics of size and industry type. In addition, it is conceptualized that the primary task orientation will have an impact on the specific analytics tools adopted.

Task Orientation

To generate insights demanded by businesses, this study postulates that the analytics tasks being performed may have different task orientations focused on what is to be accomplished by the analytics effort. The task orientation taxonomy indicates that the firm can use one of four specific orientations labeled situation-sensing, making predictions, making evaluations, and making decisions. While firms can adopt any combination of these orientations, it is expected that they will primarily focus on a specific orientation while performing business analytics tasks.

Antecedents: Business Characteristics

It has been argued that business size, skilled personnel, and culture contribute to the successful use of business analytics (Trieu, 2017). Further, a business needs to possess a unique blend of cultural, financial, and human capital to create a business analytic capability which competitors will find difficult to replicate (Gupta & George 2016). To create this essential capability, a business needs to either improve the analyst's business analytic skills or search for individuals who have these skills. Ideally, analysts with required competencies will provide improved insight generation (Ayyagari et al, 2011). To achieve this goal requires that the business has a clear understanding of both the business analytics task and the connection between the expected outcome and the required skills.

It is postulated that size affects the ability of the business to convert business intelligence assets into business analytical impacts (Trieu, 2017). Since larger businesses have the capability of mobilizing greater resources, it is believed that larger businesses are more likely to exploit business intelligence potential. Engaging in business analytics is an expensive, multi-year investment requiring a wide range of skills (Ramamurthy et al, 2008). Yet, small and medium-sized businesses often lack the resources and expertise needed to take advantage of analytical tools (Doumpos & Zopounidis, 2016). Thus, larger businesses may employ the more sophisticated task orientations. Yet, not every business embraces a data-driven culture as businesses in certain industries are more data-driven and may have adopted more advanced business analytics tools leading to different task orientations.

Consequences: Tools

There exists strong connection between the business analytic tool sophistication and the quality of insights generated. Further, Wang & Byrd (2017) report that the effective use of business analytics tools indirectly influences problem-solving and decision-making efficiency and effectiveness. Therefore, it is important to acquire the capabilities of the tools that can facilitate specific business analytics task orientations.

Gartner has classified the business analytic tool platform capabilities into categories labeled analytic, decision, and information. The analytic capabilities contain a collection of various analysis methods, data transformations, and tools including ad-hoc query, content analytics, dashboards, speech analytics, and visualizations. The decision capabilities encompass applications such as scenario modeling and simulation to help analysts learn, share, and

understand the data. The information capabilities focus on the technology infrastructure that ensures proper interfaces thus permitting the exchange of data, documents and other content.

Businesses may combine tool capabilities by establishing a proactive use of the information environment in which insight generation is based on rationality. Analysts with analytical research styles will adopt and use the tools to a greater extent than analysts with conceptual research styles. Hence, a business analytics task orientation with the right analytics culture can help with overcoming the trade-off between reach and richness of the tools.

METHODS

By extracting job postings for business analytics positions, business analytics task descriptions were developed. Then, in late 2017, online job search sites were used to collect business analytics postings. Those posts containing business analytics job titles were selected for this research project. To identify size and industry type, business names of the potential employer in the posting were used. For the identified size, businesses were classified using the 2017 Fortune 500 list. If the business was in the Fortune 500 list, they were classified as Fortune 500 whereas the remaining businesses were classified as non-Fortune 500. By identifying the SIC code and the primary market served, businesses were further classified into consumer products, financial services, healthcare services industrial products, or retail.

Text-Mining Process

Business analytics task descriptions were gathered as the first step in the text-mining process. Over a two-month period in 2017, business analytics postings that were highly relevant were gathered. For the second step in the text-mining process, text-refining and text pre-processing were performed on the collected postings. This was accomplished by clearing the formatting as well as implementing tokenization and stemming for text reduction. The third step in the text-mining process was to perform text-mining analysis using the refined and pre-processed texts. The text-mining analysis process generated intermediate output that contained relevant term concepts related to the four business analytics task orientations. The final step was to perform clustering analysis using the previously generated document-based output. The clustering algorithms created clusters associated with the identified business analytics task orientations.

RESULTS

The k-means clustering procedure was used. The clustering algorithm generated four unique clusters utilizing 27 relevant word-concept terms. These word-concept terms are related to the four task orientations. By examining the cluster centroids, the resulting clusters were classified thus allowing for the interpretation of each cluster grouping.

Cluster 1, consisting of 39 businesses, represented the decision orientation cluster. The word-concept term list showing values greater than .20 include the following nineteen terms: action, analytics, analyze, communicate, decide, define, effect, improve, inform, insight, monitor, problem, report, revenue, solution, strategy, translate, understand, and visualize. Cluster 1 shows large centroid values for concepts relevant to decision as well as prediction, evaluation, and sensing orientation. This suggests that the decision orientation task is a more advanced and sophisticated task orientation driven by the combination of all four task orientations. Cluster 2 consists of 99 businesses and represents prediction task orientation. The word-concept term list showing values greater than .20 include the following fourteen term concepts: action,

analytics, analyze, decide, improve, inform, insight, performance, predict, problem, report, solution, strategy, and understand. These concepts are primarily relevant for prediction task orientation with some overlap with the decision and evaluation task orientation. Cluster 3 consists of 58 firms and represents the evaluation task orientation. The word-concept term list showing values greater than .20 include the following ten term concepts: analytics, analyze, decide, determine, inform, intelligence, performance, report, solution, and visualize. These concepts are primarily related to evaluation orientation task with some decision and evaluation orientation tasks. Cluster 4, consisting of 291 businesses, represents the situation-sensing orientation cluster. The word-concept term list showing values greater than .20 include the following eight terms: analytics, analyze, improve, insight, performance, report, strategy, and understand. These concepts are related to sensing task orientation along with the other three task orientations in a very superficial way. Relatively small centroid values for most of the term concepts characterize this cluster.

According to these results, the largest number of businesses are classified into the situation-sensing task orientation followed by approximately 20 percent of the businesses focused on the prediction task orientation. The remaining 20 percent of businesses were either the make decision or making evaluation task orientation.

Cross-tabulation

This research project evaluated the relationship between business analytics task orientation and business characteristics. Chi-square statistics for cross-tabulations were used to test these relationships. The chi-square test indicates a significant relationship between business analytics task orientation and industry type. The results show that businesses in consumer product, industrial products, and financial services sectors tend to belong to cluster 2 and cluster 4. These two clusters focus on make prediction and situation-sensing business analytics orientation tasks. Businesses in the healthcare services and retail sector more often focus on the situation-sensing business analytics orientation task. The chi-square test is not significant for the relationship between business analytics task orientation and business size. The chi-square test indicates a non-significant relationship between business analytics task orientation and tools used. The selected businesses reported a total of 62 analytics tools in their job posts. Twenty-two analytic tools show reported frequency of 10 or higher. The results show that businesses are using a diverse set of business analytics tools.

DISCUSSION AND CONCLUSIONS

This research project tested a conceptual model that captured the relationships among task orientation, business characteristics, and analytics tool adoption. Text-mining analysis of relevant job postings together with cluster analysis provide insights into the nature of business analytics orientation tasks and adopted tools. Evaluating job postings provides a leading indicator view of the future direction for the business. Each word-concept term used in the job posting belongs, to a certain degree, to a specific cluster. Yet, with cluster analysis, the word-concept terms overlap other clusters as the clustering algorithm optimizes for cluster centers. Thus, cluster analysis partitions the word-concept terms into segments which can then be used to better understand the relationships among the business task orientations.

Using the task orientation model, four types of business analytics task orientation were empirically validated. Text-mining analysis was performed to identify the relevant concepts used to describe the required business analytics tasks. Text-mining output was further

analyzed using clustering algorithms to classify tasks into four unique categories. The cluster analysis results show that the largest cluster containing about half of the businesses focused on the situation-sensing orientation task. The next largest clusters were the prediction and evaluation-oriented clusters with 20.3% and 11.9% of the businesses respectively. The smallest cluster was the decision-orientation cluster which contained 7.8% of the businesses. These results suggest that businesses are using business analytics primarily for sensing tasks, although prediction and evaluation tasks are also important. Yet, the utilization of business analytics for making decisions has not been fully integrated into the business culture. However, the movement toward business analytics is impacting processes, rebalancing the decision-making relationship dynamics, and altering the scope and scale of optimization challenges.

This research project also evaluated antecedents and consequence of analytics task orientation. Two antecedents, size and industry type, were assessed to determine if they were related to task orientation. The results show that task orientation is related to industry type as there exist significant differences in selection of the task orientation for the type of industry. As certain industries require different orientation tasks, unique competencies need to be developed for businesses to remain competitive. The results show no significant relationship between orientation and tools. Interestingly, the results show that there are no dominant business analytics tools used supporting Columbus' (2016) report that the top 10 business analytic providers comprised less than 60% of the market. Yet, by 2026, the demand that drives these business analytics tools is expected to surge with a forecasted 23 percent compounded annual growth rate. These tools are viewed as containing volumes of high quality information in well-designed data stores, user-friendly tools providing timely access, effective analysis, and intuitive presentation thus enabling analysts to develop actions to understand problems and make decisions. These findings are consistent to the reported statistics suggesting that the business analytics tool market is highly fragmented.

These findings provide important implications regarding training as no specific tools are dominantly used thus tool independent training may be required for analytics tasks. Therefore, training should focus on the basic mechanisms of business analytics rather than tool specific skills. The cluster analysis results suggest that business analytics tasks are primarily focusing on the situation-sensing orientation task, followed by the make prediction and make evaluation orientation tasks. These findings shed light on the nature and content of business analytics knowledge and training required. Given that the United States faces a critical shortage of individuals with analytical skills to analyze the volumes of available data and make recommendations based on their findings, the barrier for businesses to incorporate analytics into their processes is the inability to acquire talented individuals. As this research project uses posts from businesses in the United States, managers can gain valuable insights. Yet, given the preliminary nature of this project and the limitations of the sample, the findings may not be generalizable. Future research efforts are required to confirm the results of this project.

Endangered Species International Trade Analysis using Power BI Analytics Tool

Bharti Sharma
Florida Atlantic University
Email: bsharma@fau.edu

ABSTRACT

This paper demonstrates the descriptive analytics method for revealing instant meaningful insights from endangered species international trade using the Power BI analytical tool. The endangered species international trade dataset is analyzed by creating Power BI visualizations that display revelations at a glance. Results display instant plots depicting the levels of exported and imported quantities of endangered wild fauna and flora with respect to several aspects such as their family, class, source, purpose and exporter/importer countries. Use of Power BI visualizations can display faster analysis results and uncover relevant trade insights to benefit the trade volume assessment and restriction monitoring process.

KEYWORDS: Endangered species, Power BI, Visualizations, Insights

INTRODUCTION

International trade analysis for endangered species has been a critical step in regulating the buying and selling of the 'near extinct' wild fauna and flora. Several researchers have been involved in exploring analytical procedures to better investigate the exploitation practices of the endangered species (Bhammar et al. 2016); Clifton, Rastogi, 2016; Jones, 2018). It has been a need of the law enforcement agencies and organizations to employ appropriate tools to analyze the huge amounts of the trade data stored on electronic platforms such as transnational databases (Jones, 2018).

In this research the powerful analytical tool Power BI is used to perform descriptive analytics and produce valuable insights on the endangered species international trade data stored in the Convention on International Trade in Endangered Species of Wild Fauna and Flora (CITES) database (CITES, 2013). This paper is written in sections starting with the literature review explaining the background on the endangered species international trade followed by description of the Power BI analytical tool. The methods section explains the procedure followed in this research starting from data acquisition to creating visualizations. Results and discussion section displays screen shots of the Power BI visualizations and discuss the insights obtained followed by the final closing statements in the conclusion section.

LITERATURE REVIEW

Endangered Species International Trade

Endangered species are the wild fauna and flora that are on the verge of becoming extinct mainly due to reasons such as habitat loss, disease, geographic range, climate change and illegal trade. International wildlife trade has adversely affected the populations of the most iconic fauna and flora such as elephants, rhinos, orchids and many more thereby threatening their survival (Pambo et al., 2016; Jones, 2018). On the other hand, the trade also generates

significant profits for all the consumers thriving in countries throughout the world for example United States has been reported as the largest wildlife trader in the estimated $300 billion international trade (Sheikh & Corn 2016). The presence of a thriving international market for wildlife import and export leads to the necessity of monitoring and regulation of the trade to avoid increase in endangered species.

In 1973, due to the growing global concern over increase in the number of endangered wildlife species, 21 nations united and signed an international agreement called the Convention on International Trade in Endangered Species of Wild Fauna and Flora (CITES) in Washington DC. Since then the main objective of CITES has been to provide a framework to monitor and regulate the trade levels (Sheikh & Corn 2016). CITES follows the procedure of first identifying the species as needing protection and then assessing the risk posed on their survival due to the trade. CITES maintains a database (Oracle RDBMS) that currently holds over 13 million international records of wildlife trade (CITES, 2013). Annual reports are produced from this database and are used for monitoring the trade levels and identify major anomalies in the reporting of imports and exports. In order to analyze a large database like CITES it becomes beneficial to employ a powerful and easy to use analysis tool that can provide instant insights.

Power BI Analytics Tool

Power BI (Business Intelligence) is a user friendly analytical tool created by Microsoft and first released to public in July 24, 2015 (Microsoft, 2015). This tool is built on advanced algorithms and has the ability and power to transform large amounts of data into insightful data visualizations. A visualization is a graphical representation displaying various patterns or trends of the input data thereby helping in the decision-making process.

Ever since its release several researchers have been using Power BI to uncover fast, meaningful visualizations to provide business solutions. It has also been noted that over 200,000 organizations from 205 countries are using Power BI successfully as a platform for data analysis (Krishnan et al, 2017). Power BI can provide results in the form of reports or dashboards which is a combination of more than one visualizations and provides at a glance 360 degree view of the data. There are variety of graphical representations to choose from the Visualization menu where each of them can show further customized view using filtering of the data fields. The uniqueness of the dashboards is their interactive feature where clicking on one visualization displays the related data on all other visualizations along with appearance of tooltips with data displays when mouse is hovered on them.

Researchers have compared Power BI with other tools available and have recommended it to be one of the preferred tools in terms of affordability and adaptability with variety of input sources (Barbulescu et al, 2016; Krishnan et al, 2017; Gowthami & Kumar, 2017).

METHODS

Dataset Acquisition

The dataset used in this analysis was acquired in form of a CSV file from the CITES database (CITES, 2013). It contains 67008 records on the international wildlife trade (import or export) of animal or plant species reported during the year 2016. The columns are as shown in the Figure 1 represent the following: Year column represents the year in which trade occurred; the next column is Taxon denotes the scientific name of animal or plant concerned; Class, Family and

Genus indicate the Taxonomic rank of the species; Importer and Exporter represent the respective country codes that are involved in the trade; Import and Export quantity columns represent the quantity of specimens reported as imports or exports; Term denotes the description of specimens traded; Unit represents the quantity unit in Kilograms (Kg) or Grams (g); Purpose codes represent the intention for the imports/exports such as B-breeding, H-hunting, T-commercial, S-scientific, P-personal etc.; Source column codes represents the original source of the species such as A-plants artificially propagated, C-animals bred in captivity etc. The full form for all the codes is available in the CITES Trade Database Guide (CITES, 2013).

Figure 1: International wildlife trade dataset (sample shown) of animal and plant endangered species exported or imported during 2016

Year	Taxon	Class	Family	Genus	Importer	Exporter	Importer quantity	Exporter quantity	Term	Unit	Purpose	Source

2016	Ailurus fulgens	Mammalia	Ailuridae	Ailurus	JP	US		1	live		Z	C

Import to Power BI

The dataset CSV file was converted into Excel (table) format and then imported into Power BI using the intuitive process of using the web buttons ‘Get data’ followed by ‘Import Excel data into Power BI’. Although any CSV file can be directly imported into Power BI but Excel conversion was done to view the data and clean up any unwanted columns such as serial number.

Visualization Creation

Power BI offers a whole range of visualization designs such as pie charts, scatter charts, line charts, stacked bar/column charts, tree maps, filled maps, funnel maps, gauge maps, multi-row cards (Microsoft, 2015). These options along with extensive page formatting tools, such as shapes and images were used to create visualizations revealing meaningful insights of the endangered species trade.

Procedure to create a visualization included the following:

- Identification of the central question/objective for each visualization
- Selection of data fields that correspond to the central question/objective
- Selection of the appropriate graphical representation. Several visualizations were tried and the ones that produced meaningful revelations were selected

- Further, filtering and drilling down using filtering tools on each visualization to eliminate any unwanted data category selections
- Formatting of each visualization to project results in standout colors and easy readable font style and sizes.

RESULTS AND DISCUSSION

Meaningful insights about the international trade of endangered species were revealed for the following central questions/objectives through Power BI visualizations (screen shots shown in the following figures).

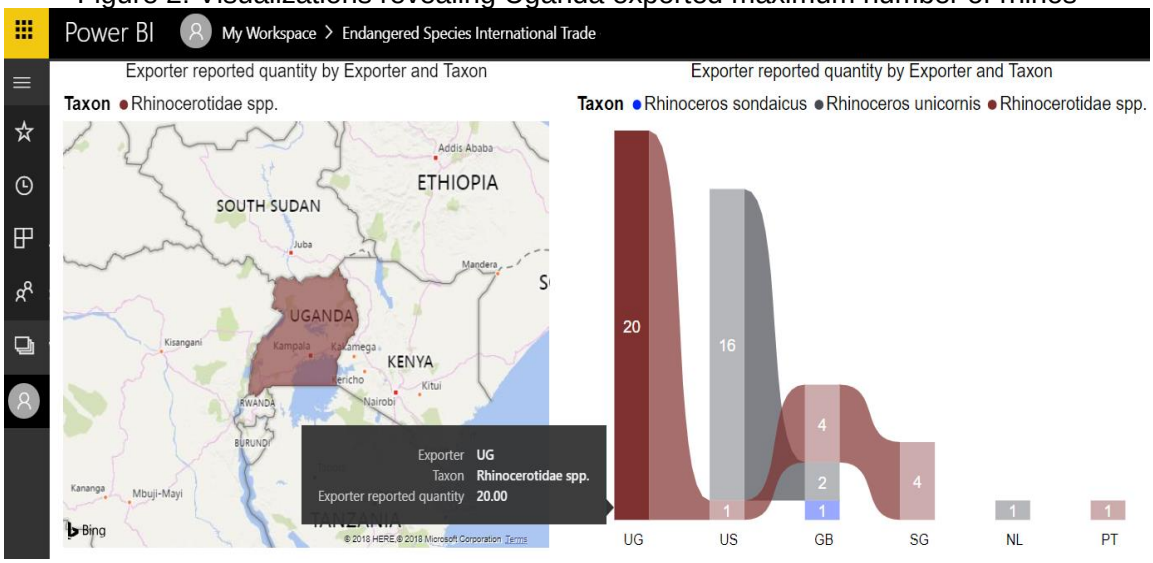
Country that Exported Maximum Number of Rhinos

Figure 2 shows two separate visualizations. The first one (left side) is a 'filled map' visualization displaying the number of species exported categorized by the exporter country and the species taxon. Initially it displayed the whole world map with color markings for each of the species taxon. The second one (right side) was created using the 'ribbon chart' representing the number of rhinos exported categorized by the exporter country and all the taxon representing rhinoceros. The objective was to determine the country that exported maximum number of rhinos. In order to see the exact country geospatially the taxon showing the maximum number was clicked on the right-side visualization and instantly the left visualization automatically zoomed in and displayed Uganda as the respective country.

- The visualizations clearly displayed that Uganda (country code – UG) exported the maximum number that is 20 rhinos followed by USA (US) which exported 16 rhinos and others such as UK (GB), Singapore (SG), Netherlands (NL), Portugal (PT) exported less than 5 rhinos

- The Rhinocerotidae spp. taxon was the maximum exported compared to the other taxon for rhinos.

Figure 2: Visualizations revealing Uganda exported maximum number of rhinos

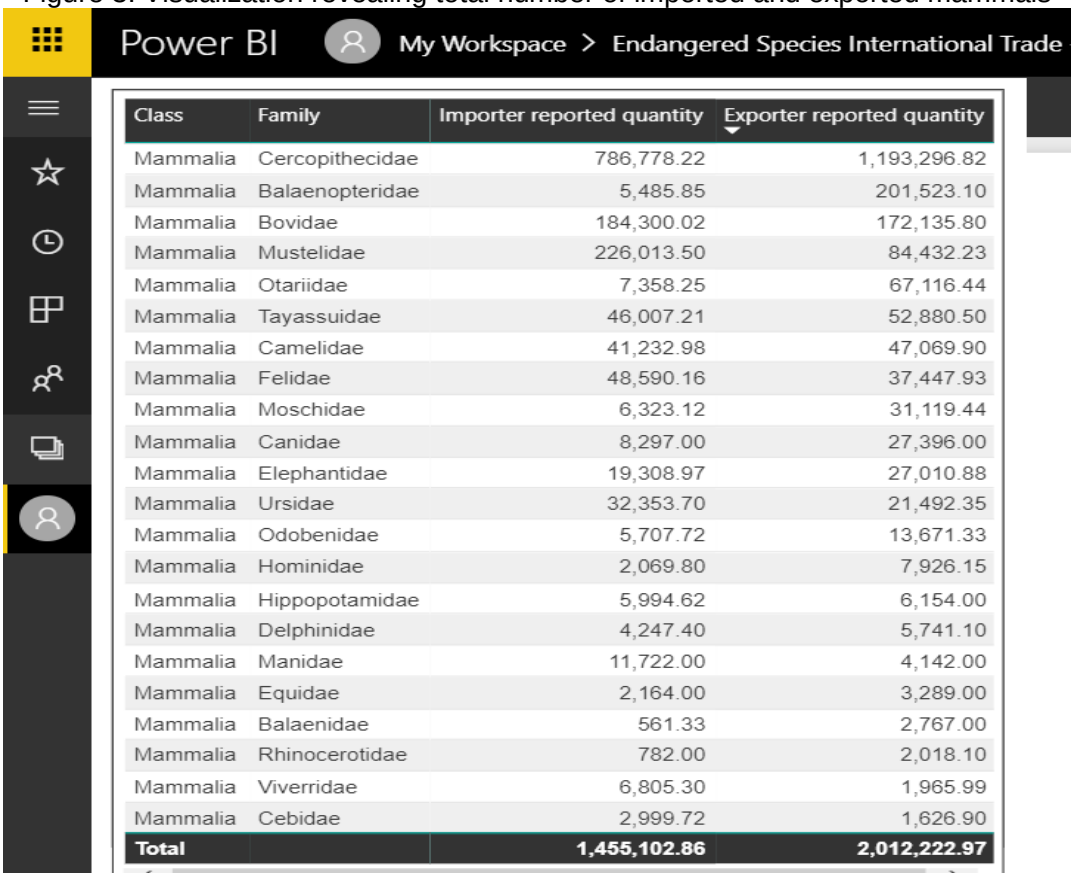


Total Number of Imported and Exported Mammals per Family

Figure 3 displays the 'table' visualization for total number of imported and exported mammals categorized by family.

- It is seen that Cercopithecidae family also known as the old world monkeys are the maximum number of mammals that were imported and exported
- The other species such as Bovidae (bison, African buffalo, water buffalo, antelopes, wildebeest, impala, gazelles, sheep, goats etc) and Mustelidae (carnivorous mammals, including weasels, badgers, otters, martens, mink, and wolverines) are the second highest to be imported and exported
- Rhinocerotidae (rhinos) and Hippopotamidae (hippos) import and export numbers are not as high compared to Elephantidae (elephants).

Figure 3: Visualization revealing total number of imported and exported mammals

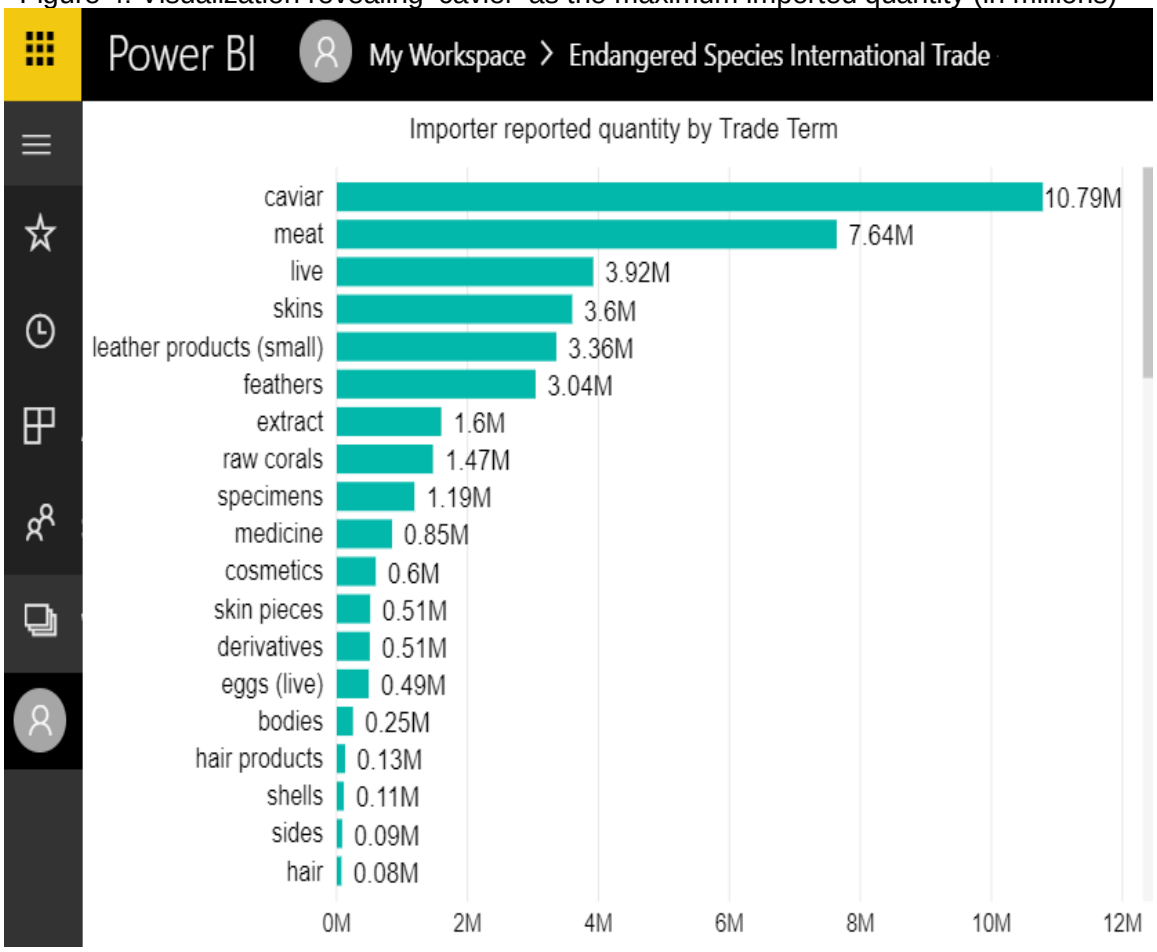


Class	Family	Importer reported quantity	Exporter reported quantity
Mammalia	Cercopithecidae	786,778.22	1,193,296.82
Mammalia	Balaenopteridae	5,485.85	201,523.10
Mammalia	Bovidae	184,300.02	172,135.80
Mammalia	Mustelidae	226,013.50	84,432.23
Mammalia	Otariidae	7,358.25	67,116.44
Mammalia	Tayassuidae	46,007.21	52,880.50
Mammalia	Camelidae	41,232.98	47,069.90
Mammalia	Felidae	48,590.16	37,447.93
Mammalia	Moschidae	6,323.12	31,119.44
Mammalia	Canidae	8,297.00	27,396.00
Mammalia	Elephantidae	19,308.97	27,010.88
Mammalia	Ursidae	32,353.70	21,492.35
Mammalia	Odobenidae	5,707.72	13,671.33
Mammalia	Hominidae	2,069.80	7,926.15
Mammalia	Hippopotamidae	5,994.62	6,154.00
Mammalia	Delphinidae	4,247.40	5,741.10
Mammalia	Manidae	11,722.00	4,142.00
Mammalia	Equidae	2,164.00	3,289.00
Mammalia	Balaenidae	561.33	2,767.00
Mammalia	Rhinocerotidae	782.00	2,018.10
Mammalia	Viverridae	6,805.30	1,965.99
Mammalia	Cebidae	2,999.72	1,626.90
Total		**1,455,102.86**	**2,012,222.97**

Quantities of Endangered Species Specimens Imported

Figure 4 shows the 'clustered bar chart' representation by the Term (description of specimens traded) revealing cavier (internal ovary eggs from wild sturgeon in the Caspian Sea and Black Sea (Davidson & Jane, 2006)) as the maximum imported quantity (10.79 million) followed by meat as the second largest imported quantity (7.64 million).

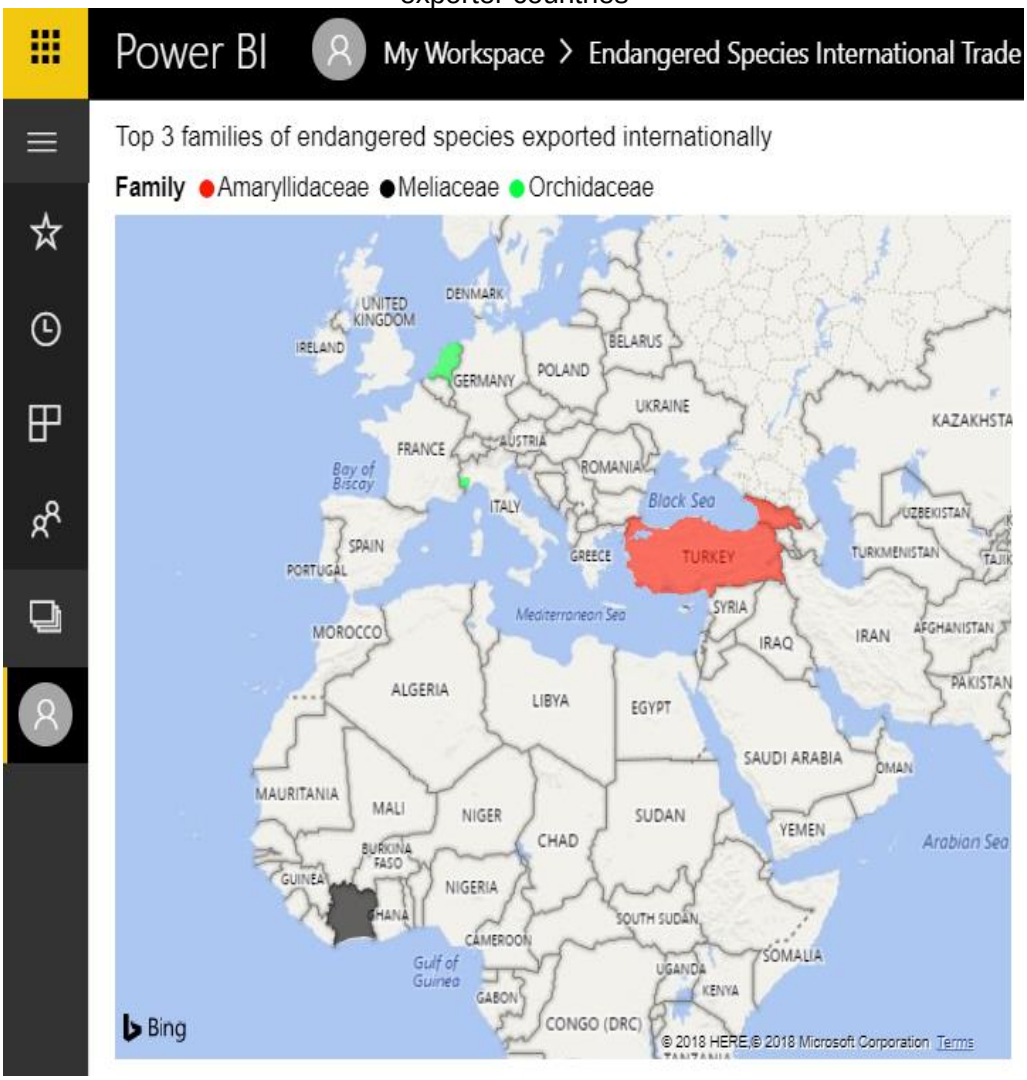
Figure 4: Visualization revealing ‘cavier’ as the maximum imported quantity (in millions)



Top 3 Maximum Exported Endangered Species Family

The ‘filled map’ visualization in Figure 5 reveals the top 3 maximum exported endangered species to be from the family of Amaryllidaceae (perennial flowering plants), Meliaceae (mahogany family flowering plant) and Orchidaceae (Orchids). Further upon hovering over the visualization it displayed the export quantity of approx. 26 million of Amaryllidaceae family plants being exported from Turkey. The second largest were approx. 9 million Orchids exported from Netherlands and third largest were approx. 8 million of mahogany family plants exported from Cote D’Ivoire (West African country). The revelation of the top 3 maximum exported families of species being from the family of flowering plants indicated regulation in the trade of animal species.

Figure 5: Visualizations revealing the top 3 maximum exported species families and their exporter countries



Top 5 Maximum Exported Endangered Species Class

Figure 6(a) shows the countries exporting the top 5 maximum exported species by class. United States was seen to be the largest exporter of Actinopteri (fish) with export quantity of 64,994 and almost all of India was seen to be exporter of 19,424 reptiles.

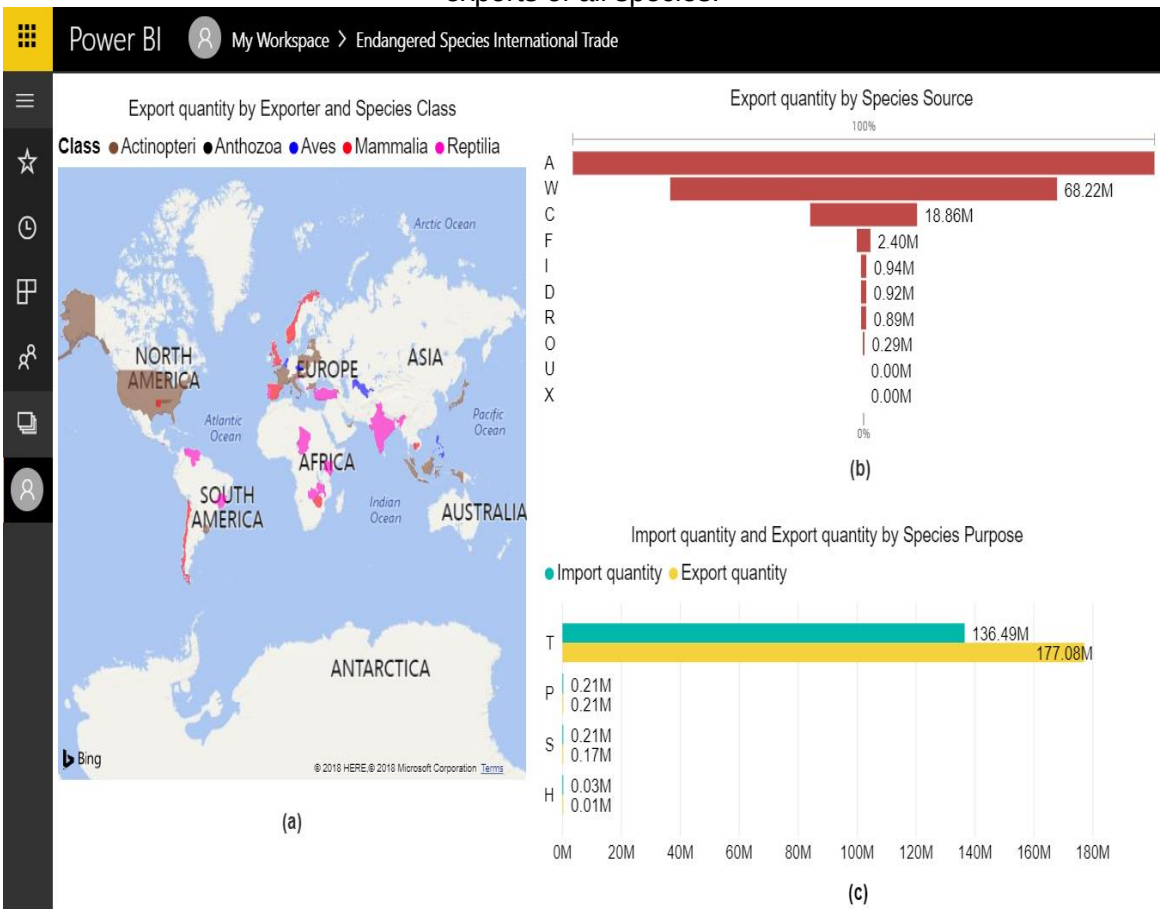
Source of the Maximum Species Exported

Figure 6(b) reveals that approximately 102 million species exported were from the source code A that refers to the plants that are artificially propagated followed by 68.22 million species for source code W referring to taken from the wild. It also reveals that export of animals bred and born in captivity source code C and F respectively are much less than the ones from the wild.

Purpose for the Maximum Species Imported and Exported

Figure 6(c) displays the commercial use (code T) as the purpose for maximum trade occurred. It also shows that number of exported species (177.08 million) were more than imported species (136.49 million) used for commercial purpose. The remaining purposes such as code P (personal), S (Scientific), H (Hunting) had much less trade quantities confirming trade regulation and restriction on the trade purposes.

Figure 6: Dashboard revealing the export quantity; a) Displays the countries exporting the top 5 maximum exported species by class; b) Displays quantity of species exported by their source; c) Reveals the commercial use (code T) as the purpose for maximum number of imports and exports of all species.



CONCLUSIONS

The method of descriptive analytics using visualizations provided instant exploration of the endangered species data and revealed meaningful insights on the international trade that occurred in 2016. It can be concluded that use of analytical tools such as Power BI can be very powerful and faster in analyzing the voluminous data from the endangered species international trade database such as CITES. Visualizations created can reveal meaningful insights and thereby benefit the trade restriction monitoring and import/export volume assessment process.

DECISION SCIENCES INSTITUTE
Evaluating Performance Issues in Local Government
Using the PPP Model

Mohan Rao
Texas A&M University-Corpus Christi
Email: mohan.rao@tamucc.edu

ABSTRACT

Performance evaluation in local governments has proven to be a difficult challenge. This paper focuses on county government performance using the "Profitability = Productivity + Price Recovery" (PPP) model. It describes the application, evaluation of performance, and the challenges in finding solutions to systemic problems.

KEYWORDS: Local government, productivity, profitability, public administration, performance evaluation

INTRODUCTION

Performance measurement is defined as the process of collecting and reporting data which can be used to summarize and assess program implementations (Berenson, 2016). In government, it can simply be interpreted as the achievements made at various levels of government and how the quality of these achievements can promote future projects. Many establishments are using performance measurements to manage and improve programs; as well as ensure desired results are produced. Today, federal government agencies are held to higher standards concerning how information is generated internally and also how this information is revealed to the public (Pollanen, 2011). States and local governments are also recognized for advanced practices related to result-oriented systems (Ralph and Rusdi, 2012). Local governments include cities and counties in which the representing members were elected by the community. During the budget process, governments forecast revenues and expenditures which focus on variability, seasonality, and sensitivity to economic factors (Williams and Kavanagh, 2016). This budgeting process not only helps to prepare the next fiscal year revenues and expenditures, it also assists in visualizing the trends of both revenues and expenditures in order to make appropriate decisions that will fit the organization's goals. Property taxes are the primary source of revenue for the county observed in this study. A significant portion of the revenue from property taxes is allocated to the General Fund, which is then distributed to other funds as needed; for example, the Airport and Parks and Recreation funds. Long-term sustainability of county operations depends on the proper use of property taxes and limited resources. Studying and monitoring how these funds are being used year after year, and the way that they trend, is very important because it allows for a continuity of fiscal efficiency to be seen by the community (Melitski & Manoharan, 2014). Performance issues and inefficiencies may come to light, requiring managerial attention and action. This study focuses on performance measurement using the PPP (model. The rest of the paper is organized as follows: Literature review, data collection/model setup, results/analysis, and conclusion.

There are many performance measurement models such as comprehensive models like the Balanced Scorecard (BSC) which allows managers to look perspectives from; Financial, Internal Business, Innovation & Learning, and Customer in order to understand overall performance.

The other types of performance models are more narrowly focused on single factor productivity that measures efficiency or productivity of labor, for instance, producing a single output. Total-factor measurement models are more appropriate for measuring performance at the organization level. Sometimes they are called multi-factor measurement models. Some of these models link productivity to profitability. One such model is the PPP model (Miller, 1984; Miller and Rao, 1989).

The PPP model is used in revenue-generating organizations. County governments typically do not sell products or services to generate revenue. Although it may manage some properties such as parks and airports, the clear majority of services include public works, law enforcement, and other offices which charges are not levied. Most of the revenues come from property taxes. So, there is no direct relationship between tax collection and major services provided such as the law enforcement service. That is one of the primary difficulties of performance measurement in county governments or governments at any level. County governments use tax funds as the major resource to provide all the services. So, the taxes would be inputs and the services would be outputs. On the other hand, if the services are not provided well, the taxes would dry up. For instance, deterioration in law enforcement and crumbling roads may lead to lower property values and lower tax revenues. In this sense, tax revenues are dependent on the service provided. So, tax revenues could be treated as revenues and the costs associated with providing services as inputs. In this paper, this is how the PPP application is developed for a county in Texas. The main purpose is to uncover and identify performance problem areas so that the administration can take action for a better performance.

DATA COLLECTION AND MODEL SETUP

The application of the PPP model requires quantities, prices and values of inputs and outputs. If two of the three (i.e., quantities, prices and values) are present, the third can be calculated by simple arithmetic. The data is collected, and the application is developed in a spreadsheet. The data is collected from the county's Comprehensive Annual Financial Reports for fiscal years 2011 through 2015. Although the data is public record, it is not easy to acquire, especially because the results may show some unpleasant truths about how the resources are being used. The county government should be commended for providing this data for this research study, and the study's intent is not to embarrass the administration in identifying the problem areas. Moreover, this application does not go into the underlying causes why a specific area may appear to have problems. It may be due to external factors or something that is not in control of the administration. So, the county goes nameless and the data is modified without affecting the major results. The value of the study is (1) to show the readers and researchers how this model and application can be used in identifying problem areas in local governments, and (2) for the county or local government administrators to apply this model internally to discover the problem areas and take timely action, which would be beneficial to the government and the tax payers.

Table 1 shows the county data for five fiscal years. It is important to mention that this study analyzes the data for the General Fund which is the main financial source in the county. Also, expenditures are just those related to the county's operation. The main revenues are property taxes and are calculated based on the tax rate shown in the table. Expenditures are classified into labor, operation, maintenance, energy, telephone and miscellaneous. It is important to mention that the analysis of the data is at the General Fund level; not at the whole government level. The other financial sources are not used in this study, because the purpose is to analyze revenues and expenditures excluding any other extraordinary or non-current transactions like

gain or loss on sale of assets, a premium or discount on bond issues, etc. Note, inter-fund transfers in and out are excluded since these transactions are between funds.

The attraction of the PPP model to the business community is that it uses readily available accounting data and provides performance results in dollars as opposed to abstract indexes (Rao 2000). In the PPP model, current period performance is measured against the actual performances of the previous periods. This paper describes a multi-period implementation of the PPP model for a county government. This application can help many revenue-generating organizations – both public and private – to develop their own applications for performance evaluation.

Once the data is setup for all previous periods until the most current period, we use the information provided by prices to “normalize” the values. The ratio of price-weighted sum of quantities of any input in two consecutive periods provides a deflator that helps “normalize” the dollar value. Table 2 shows all the important calculations thereafter summarized as follows.

1. Determine the dollar value of each input and output in the period prices,
2. Determine implied and “composite” deflator for each input for all periods,
3. Determine input and output profit margins and deflated profit margins,
4. Determine profitability, productivity, and price recovery indices.

An actual multi-period application of the PPP model in Microsoft Excel for a county government is described next. These contributions from the top level, through category level and down to the resource level are plotted so that the trends are easily identified, and the management can zero in on the problem areas.

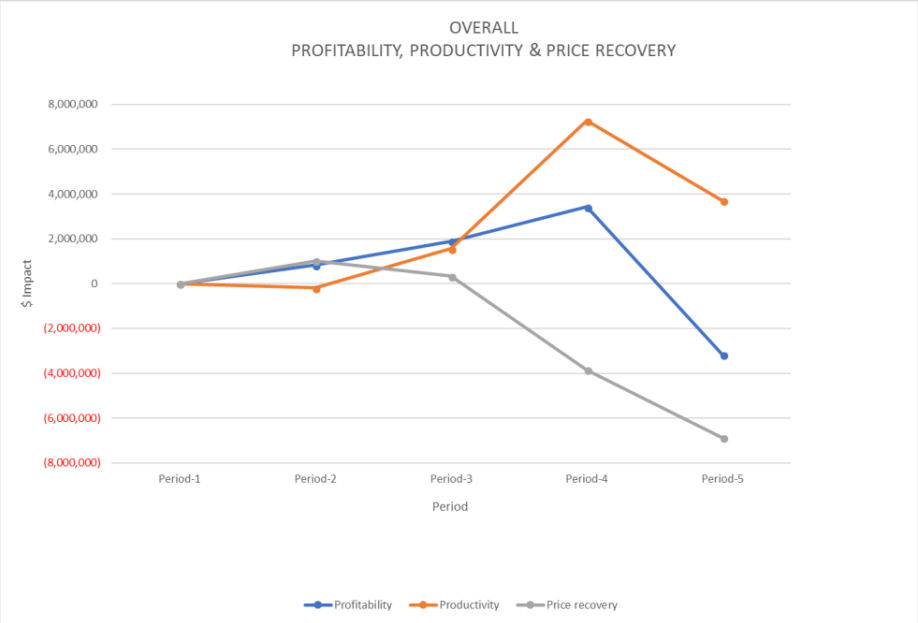
RESULTS AND ANALYSIS

Figure 1 shows the county’s overall profitability, productivity, and price recovery. Productivity contribution shows the performance without any effect of price changes in inputs and outputs.

Basically, it removes any inflationary factors. Price recovery reflects the price changes in inputs and outputs. Profitability is the sum of productivity and price recovery contributions.

In Figure 1, overall profitability of the county looks great until period 4. Apparently, this positive trend is primarily due to productivity. Overall price recovery seems to be a problem. It took a major dive in period 4 and continued in period 5. A negative price recovery contribution of $3.8 million in period 4 and $6.8 million in period 5 is a major problem. This requires drill down into categories and actual resources causing this problem.

Figure 1. County Overall Performance



Like the overall performance chart shown in Figure 1, one could generate charts for each category and each resource. Major problem category seems to be Labor. Figure 2 shows labor performance. In period 5, the overall price recovery contribution was -$6.8 million of which -$5.1 million from labor. This is a serious problem and requires further drill down into resources causing the problem.

CONCLUSIONS

Performance measurement helps organizations perform better. It is important that counties measure performance, identify problem areas and take timely action to improve performance. One model that could be used to develop an application to identify problem areas is the PPP model. This paper described the model setup, the data used, and the results obtained. The analysis has identified that the labor category is a serious problem in terms of price recovery contribution. That is the average expense of labor has been going up relative to average tax rates. Employee overtime, retirement and benefits also seem to be problem areas. The county administration needs to look at these areas and find ways to solve the issues.

ABSTRACT

Children with autism spectrum disorder wander away from care facilities with many reported critical "close calls." This case study presents an evaluation of unmanned aerial vehicle (UAV) and related technologies to help law enforcement develop effective search-and-rescue operations. The study found that deploying these technologies has advantages over traditional operations.

KEYWORDS: Unmanned Aerial Vehicle (UAV), Technology Evaluation, Search-and-Rescue, Case Study

INTRODUCTION

Among children with autism spectrum disorder (ASD), nearly 50% wander away from care facilities, while 32% of the parents report a critical "close call." As the prevalence of ASD rises at an alarming rate to an estimated 1 in 68 children in 2012 from 1 in 150 children just a decade ago, the risks of serious consequence of such incidents have increased significantly. Florida's geography, in particular, poses an elevated threat to children with ASD, due to the pervasive presence of natural and man-made bodies of water—91% of all deaths among wandering and eloping children with autism involve drowning. In addition to prevention, effective search-and-rescue operations, often conducted by law enforcement agencies, are a critical component of the safety of children with autism.

When law enforcement receives a call about a missing person with a mental or developmental disability (which is specified during the initial call and then marked with a special code), the action is swift and extensive. In the case of Palm Beach Sheriff's Office (PBSO), when the initial call is dispatched, it commonly takes 15 minutes for the first officers to arrive. Two or three officers will search the home (or care facility) first to ensure that child is not hiding out, unless an eye witness already reports seeing the missing child outside of the home. If the missing child is not found at home (or care facility), a full search-and-rescue operation is then initiated. A detective will be assigned to the missing child case and, within 20 minutes, four to six additional deputies and a sergeant (for day shift; two to three deputies plus sergeant for night shift) will arrive on scene to join the operation. Depending on the location and terrain, canine (bloodhound), helicopter, and other units may also be called. Altogether, there can be

up to 15 PBSO deputies and detectives, two canines, and a helicopter on one case at any given time. The search can continue for hours until the child is located and positively identified. It is worth noting that Palm Beach County is highly representative for such a pilot project, with a large area and large population of 1.4 million people living in an array of urban, suburban, and rural settings.

In the areas serviced by PBSO, there were 11 reported cases of missing person with autism and/or Asperger syndrome in 2015, and 14 such cases in 2016. When locating eloping children with autism, such search-and-rescue operations have proved to be effective. Even so, as with all operations, there are always limitations to current mode that can see improvements, for instance:

- When the search area is uncertain, a large number of deputies (up to 15 in some cases) is required to fully cover the possible elopement area. To reduce the requirement on PBSO resources, it would be advantageous to limit the perimeter of the search area by either obtaining the latest location of the eloping child (instead of the last seen location reported sometimes hours ago) or having a general direction of search, or both.
- Helicopter use is a critical part of the search team because it greatly expands the search area. However, the altitude and the required motion pattern of helicopters are limiting factors. Also, helicopter deployment may be restricted by weather conditions. In addition, deploying a helicopter is expensive, as it costs $1,000 per hour to operate (with additional personnel cost). It would be advantageous to have another “eye in the sky” that can replace or supplement the helicopter unit in a search-and-rescue operation.

Based on the requirements set forth in *Missing Persons with Special Needs Bill*, a joint pilot study between the authors’ University and PBSO is conducted, seeking to test and evaluate current, latest technologies that can aid the search for missing person with special needs, in particular eloping children with autism.

This project focuses on (1) wearable personal devices, attached to children with ASD that are at risk of elopement, that can track the motion and location of the wearer, and (2) unmanned aerial vehicles (UAVs), commonly known as drones, which can locate or aid the search of an eloping child. The evaluation criteria, which will be discussed fully later in this report, will aim to not only improve on both cost and effectiveness over current search-and-rescue effort, but also to enhance (or at least to impose minimal disruption on) the mode of operations by law enforcement.

This case study is organized as follows. In the next section, we survey and qualify the existing technologies to be considered for this pilot study. Then, an evaluation framework for testing the technologies is provided, followed by a description of the actual scenario-based field tests that we conducted. We conclude this report by summarizing the test results and making recommendations accordingly.

TECHNOLOGY SELECTION

The twenty-first century is experiencing a rapid proliferation of global positioning satellite (GPS) and airborne technologies in the form of drones. GPS is the backbone of recent location-based services, including maps and navigation in cars or small handheld devices. While drones are initially being used by the military, the capabilities of small drones have greatly increased, and their costs have declined rapidly. Combined with wearable devices that are based on GPS or

other technologies such as radio frequency (RF), drones have the potential to significantly improve search-and-rescue operations.

For this pilot project, we have reviewed a number of technologies, as described in the interim report, and selected two combinations of UAV and wearable devices most suitable for search-and-rescue missions involving eloping children with autism. Project Lifesaver is a RF-based tracking system that combines a wrist band and a (dedicated) handheld or UAV-based tracking unit. Keruve, on the other hand, is a GPS-based tracking system, mounted on a wrist watch, with its own handheld control unit. As such, it can work in conjunction with any camera-mounted UAV to locate and identify eloping children with autism. Table 1 below shows a comparison of the two selected technology combinations.

		Project Lifesaver	Keruve + UAV
WEARABLE	GPS	No	Yes (+ cell)
	RF	Yes	No
	Location accuracy	Medium	High (when signals are available)
	Waterproof	Yes	Yes
	Tranceiver wearability	Wrist or ankle band (PAL is watch)	Attached to wrist watch (belt or clothing attachment options also available)
	Battery	Monthly (replaceable)	2 days (rechargeable)
	2-way communication	No	Panic button
UAV	Dedicated UAV?	Yes, Lockheed Martin Indago	No (can use any UAV with camera)
	Camera on UAV	No	Yes
SYSTEM	Training requirement	UAV pilot, Liefsaver operation	UAV pilot, handheld control unit (self-training)
	Control management system	Field managed	Close range tracking and out-of-range alarm (on handheld)
	Costs	Transmitter: $300 Handheld Controller: $749 UAV + PLS Antenna integrated: $47500 + $10,750	Transmitter-Controller pair: $1425 Cost per GPS search: $0.10
	Systems integration	N/A	Allowed

Table 1: Comparison of Project Lifesaver and Keruve Systems

ANALYSIS METHODOLOGY

Drawing on Innovation and Diffusion Theory (IDT, Rogers, 1983) and Technology Acceptance Model (TAM, Davis, 1989), information technology (IT) and information system (IS) researchers identify that the relative advantage, compatibility, and complexity are consistently related to innovation adoption and implementation. Based on these models, we have developed an evaluation methodology for this project, shown in Figure 1 below.

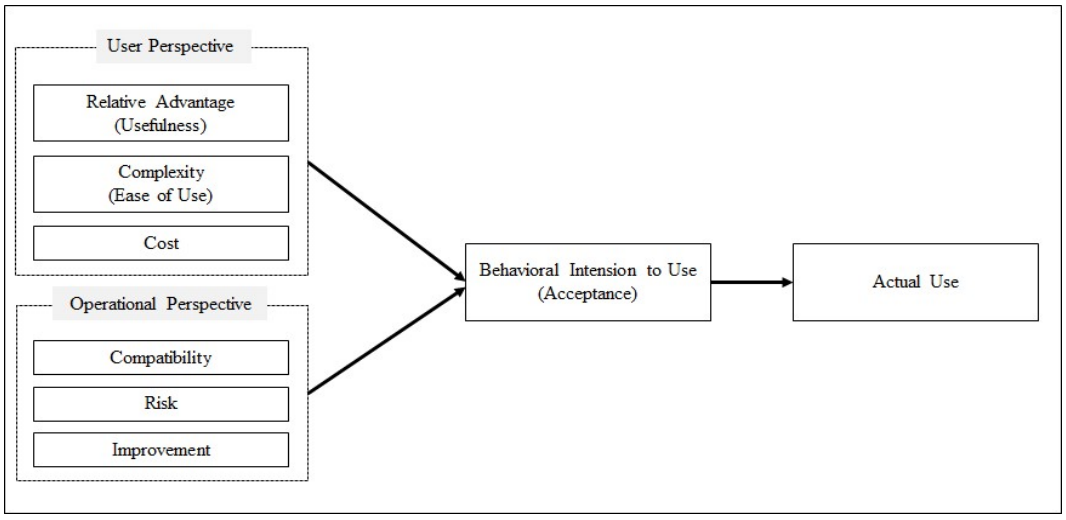

Figure 1: Evaluation Methodology based on IDT and TAM Models

User Perspective: Ease of Use, Usefulness, Cost

Relative advantage is the extent to which a potential adopter views a new technology or innovation as offering benefits over previous, old, or other ways of performing the same task. Because people tend to use (or decide not to use) a technology to the extent they believe it will help them better complete desired tasks, relative advantage is often captured through user's perception of usefulness of that technology to achieving their goals. In addition to the technology itself, its performance and design can greatly affect the perceived usefulness. In the case of tracking systems, factors such as slow location identification, location errors, out-of-date maps, and poor hardware design and software interface have disappointed search-and-rescue users. In a worst-case scenario, such poor performance could even result in a loss of life.

Complexity is the level of difficulty for users to understand and properly use innovations and is often measured through users' perceived ease of use. Even if potential users believe that a given technology is useful, they may, at the same time, perceive that the system is too hard to use and that the performance benefits of usage are outweighed by the effort required to use the application. Therefore, in addition to usefulness, usage is influenced by perceived ease of use.

Beyond usefulness and ease of use, cost concern is another important issue from the user perspective when adopting new technologies. In the context of this project, deploying new technologies to facilitate search-and-rescue efforts will incur non-negligible or sometimes significant cost to users (autism family and law enforcement agency alike). Equipment costs,

subscription fees, and transaction fees are just three important components that may make an innovative use of airborne technologies for search-and-rescue unaffordable, and high cost will be one of the essential factors considered by users when deciding whether to deploy new technologies.

In search-and-rescue operations, “users” are further divided into three parties—child with ASD diagnosis, autism family/caregiver, and law enforcement agency—with possibly different perspectives. Therefore, the current study captures usefulness, ease of use, and cost concerns from all users’ perspectives.

Operational Perspective: Compatibility, Improvement, Risks

While relative advantage, complexity, and cost impact user’s decision on technology adoption and use, operational issues need to be considered when a new technology is actually being deployed. Compatibility is the degree to which innovation is perceived to be consistent with potential users’ existing values and needs as well as with operational routines and systems. High compatibility implies minimal disruption to current operations and thus likely leads to preferable adoption. As such, compatibility of a new technology is a key issue in the operational view of technology adoption and is also used to predict the implementation of new technological innovations.

Improvement in the operational perspective is the equivalent of usefulness in user’s perspective. A new technology can help improve tasks in many ways, such as reducing the complexity of procedures and better communication among parties involved. The level of operational improvement will no doubt impact the decision of technology adoption.

As in all activities, there are potential risks of using wearable and airborne technologies in search-and-rescue operations. To begin with, regulations for new technologies, especially with breakthrough innovations such as drones, always significantly lag the development of applications and use. Operational uncertainties and risks can arise because of changing and unpredictable regulatory requirements. Also, the privacy impacts of civil applications of drones, including law enforcement and community policing, have already been subjected to analysis. Lastly, drone’s safety is of particular concern, because of the wide array of “failure modes” (that is, crash or collision) that may cause harms to property and people. Multiple reasons, such as interruptions to GPS or control-flow transmissions, inadequate fail-safe designs to cope with signal-loss, lack of collision avoidance system in a congested airspace, and a short battery life, may cause such safety concerns. For instance, the FAA has received an average of 250 reports of drones near airports every month, up from 159 for most of last year, and a new study commissioned by the FAA finds a high-speed collision between a drone and an airliner would be worse than a bird strike. This year. These examples highlight the importance of safety risks of using drones in search-and-rescue operations and the need for an assessment of the adequacy of existing regulatory frameworks for public safety as well as the need for proper and extensive pilot training.

PRELIMINARY EVALUATION

Before actual scenario-based field tests of staged elopement were conducted, we examined the two selected technologies based on the analysis framework of the six key dimensions: ease of use, usefulness, cost in user’s perspective and compatibility, improvement, risks in operational perspective. The initial evaluation is summarized in the Table 2 below.

			Project LifeSaver	Keruve (with UAV)
User Perspective	Cost	Child	N/A	N/A
		Family/Caregiver	Average initial cost, high recurring cost	High initial cost, low recurring cost
		Law Enforcement	High (dedicated UAV required)	Cost of shared UAV
	Relative advantage	Child	N/A	User-friendly wrist watch design
		Family/Caregiver	N/A	Knowing child's location at all times; configurable safety zone with visual and audio alarm or cellphone notification when breached
		Law Enforcement	Handheld receiver and deicated drone can identify general location and direction of child	GPS location as starting point of search operation; UAV cheaper and faster to deploy
	Complexity	Child	N/A	Wrist watch needs to be removed and recharged (by caregiver) every 2 days
		Family/Caregiver	Wristband battery needs to be replaced every two months.	Handheld controller relatively easy to use (but currently designed for Europe)
		Law Enforcement	Both UAV pilot training and Project LifeSaver training required	GPS location only shows on paired handheld controller (currently); UAV pilot training required
Operational Perspective	Compatibility	Family/Caregiver	Wristband can only be put on and removed by caregiver	Wrist watch can only be put on and removed by caregiver
		Law Enforcement	Dedicated UAV or handheld receiver needed; no integration with control system	Potential integration with control center; availability of UAV for mission required
	Improvement	Family/Caregiver	N/A	Early knowledge of elopement with location data
		Law Enforcement	Shorter mission completion time; potential reduction of resource requirements	Shorter mission completion time; potential reduction of resource requirements
	Risks	Family/Caregiver	N/A	Data privacy
		Law Enforcement	UAV safety	UAV safety and privacy (due to camera use)

Table 2: Initial Evaluation of Project Lifesaver and Keruve Systems

SCENARIO-BASED FIELD TESTS

Project LifeSaver and Keruve technologies were tested on three different days under different scenarios. The authors' research team and PBSO (command, pilots, and role players) were all present for all three tests. Project LifeSaver and Keruve were used on different days. One role player using the devices was deployed on each day.

Testing Project LifeSaver

This simulation used Project LifeSaver only. Two pilots were needed (project lifesaver UAV and UAV with camera). One role player was deployed with the wristband transmitter. Multiple

environmental conditions were simulated. The test location provides access to test in open areas, enclosed spaces, and wooded areas. Figure 2 below shows the UAV during this test.

Figure 2: UAV with Antenna for Tracking with Project Lifesaver

Scenario A
Missing 7 year old child with moderate autism; the back door was discovered open. The child resides in a gated community; the house is located 1.1 miles from a large community lake in the center of the community. From the time of the call to dispatch, the child has been missing for 15 minutes.

Traditional Response:
The traditional PBSO response to a missing child call involves resource allocation as follows:

- The first 15 minutes: 5 deputies, 1 sergeant and 1 lieutenant, helicopter
- From 20-60 minutes: 5 more deputies, 1 captain, 1 K-9 (bloodhound)
- From 60-90 minutes: Another K-9 (bloodhound), Detective bureau (4 detectives, 1 sergeant)

Expected Response:
With LifeSaver Project UAV, the expected response will be different from the traditional response. Initial responding units after they arrive, determine the child to be missing, request helicopter and UAV (Project LifeSaver/camera). Helicopter and UAV take 15-20 minutes to arrive on scene. UAV unit will deploy two UAVs, maximum 400 feet to help track child wearing project lifesaver bracelet. The whole scenario in this case is expected to play out as follows:

- Phone call comes in to PBSO dispatcher
- 2-3 officers search home first (closet, bed, garage, yard, etc.) except when eye witness reports seeing child.
- Within 20 min: Call for bloodhound (specifically trained for search and rescue), helicopter, and additional units (5-6 deputies); quicker than pulling together UAV (which are all dependent on availability and location and can take another 20-40 min)
- Notify detective specifically assigned to missing children cases (day shift 4-6 deputies/detectives + 1-2 sergeants; night shift is 2-3 deputies/detectives + 1 sergeant)
- 20-30 minutes later: drone unit arrives
    - 20-30 minutes extra if not already on duty
    - First one to get Project LifeSaver drone, the other meets at the site of the report

    - Note: Project LifeSaver drone requires tracker bracelet; commander's knowledge of equipment and asking the right questions may reduce turnaround time from confirming tracker by 50%
- Air assets (helicopter) are supplemented/enhanced by drone search (again, dependent on supervisor's knowledge and request to deploy drone)

Simulation Test:
Weather was Fair skies, Slight drizzle. Role player (with Project LifeSaver transmitter) is walking around community; deputy is on scene in 5 minutes and immediately asks about tracker; confirmed to have Project LifeSaver; reports back to dispatcher; drone deployed in 15 minutes. It took an additional 15 minutes flight time to locate the role player after following up on a second (weaker) signal. It took a total of 30 minutes from decision to deploy the drone to locating the role player.

Summary:
Searching for the role player (with Project LifeSaver transmitter) in the local community with UAV/Project LifeSaver receiver/antenna took a reasonable time (30 minutes) when there was visibility. When searching in areas with heavy vegetation and/or reduced visibility, the search was not possible probably due to signal interference.

Scenario B
Similar to Scenario A, except that the child, 10 years old, is missing for an hour, with no other information.

Traditional Response:
Similar to the scenario in the last section.

Simulation Test:
Weather was fair skies, 86°F, and 6 miles visibility. The role player (with Project LifeSaver transmitter) is about 1.5 miles away; in this scenario, it has been 30 minutes since call was made to PBSO before the drone is launched.

Drone with Project LifeSaver receiver/antenna is deployed at 150/170 feet till a gain of 99 (highest gain setting) is found to hone in on direction; complete 360° rotation to confirm direction (pro: must be done to acquire strongest signal and rule false readings; con: takes times; the faster the drone is rotated, the greater the chance of false positives, because Project LifeSaver receiver/antenna requires time to let band ping settle). After 15 minutes, a second drone with camera only is deployed. (There is no SIM card available for mapping the Project LifeSaver system, hence mapping is not available.) Two drones are used simultaneously in the search at this time. Five minutes later, the first drone with Project LifeSaver receiver/antenna is returned (20 minutes flight time), and a PBSO Deputy is deployed in the field using the Project LifeSaver handheld tracker in the approximate area located. The Deputy located the role player after 5 minutes, 25 minutes after initial drone deployment. The drone with Project LifeSaver receiver/antenna was re-launched with a different strategy of 180 degrees from the role player location. The role player was located within 5 minutes in this scenario, without using the handheld tracker. But it is important to note that in this instance, the exact location of the role player was known. Additional challenge was that the drone with the Project LifeSaver receiver/antenna was in flight for about 35 minutes in both situations, leaving a residual battery life of little over 10 minutes.

Summary:
Searching for the role player (with Project LifeSaver transmitter) about 1.5 miles away with Project LifeSaver UAV took a reasonable time (25 minutes) when an additional drone with camera and a Deputy with handheld tracker was deployed. The drone with camera was deployed because the drone with Project LifeSaver antenna had no mapping capabilities (no SIMS card on the UAV hand controller to provide a map overlay on RF signal) at the time of study. Hence it was necessary to complement the drone dedicated to Project LifeSaver antenna with additional resources (UAV with camera) in this scenario to provide visual support. However, with a known location, the search was possible within 10 minutes when both drones (Project LifeSaver receiver/antenna and camera) were deployed.

Testing Keruve
This simulation used Keruve in lieu of Project Lifesaver. One pilot was needed (UAV with camera only). One role player was deployed with the wrist watch transmitter. The same environmental conditions were simulated. The test location provides access to test in open areas, enclosed spaces, and wooded areas. Figure 3 shows in an image taken during this test.

Figure 3: UAV with Camera for Tracking with Keruve

Scenario C
Missing 7 year old child with moderate autism. The child resides in a gated community, the house is located 1.1 miles from a large community lake in the center of the community. From the time of the call to dispatch, the child has been missing for 15 minutes, the back door was discovered open.

Traditional Response:
Similar to the scenario in the previous section.

Simulation Test:
Weather was partly cloudy 80°F and 6 miles visibility. In this test, a predefined perimeter/geo fence (a built-in option of Keruve) is set. When the role player (wearing Keruve transmitter) breached the perimeter/geo fence, the system notified the handheld tablet (with the caregiver), an app (any family member can use this), and the company website (any family member can access this also).

Summary:
So elopement within the community is immediately recognized and alerts provided with mapping (on the caregiver handheld device), in addition to the app and website. This capability provides

families of children with autism with a proactive approach to stopping elopement before it results in a missing child, negating the need to report in the first instance. Failure of implementing geo-fences would result in no alert being sent, but local community search can still be conducted by family/caregiver using the handheld tablet with mapping to get an immediate (about 2 minute delay in GPS signals) location of the child. Figure 4 below shows the Keruve handheld display with that the role player located.

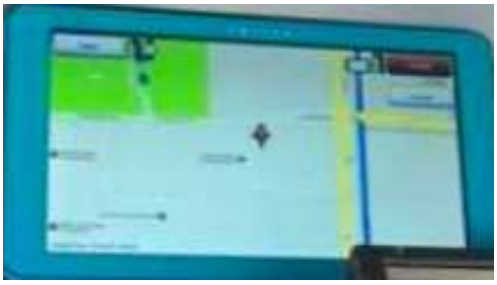

Figure 4: Keruve Handheld Display used for Tracking

The tracking function can also be used to map out the travel path over multiple location identifications (though this uses more battery and higher cost due to frequent GPS location access).

Scenario D
The child, 10 years old, missing for an hour, no other information. This will require for a longer search by placing the tracker about 1.5 miles away.

Traditional Response:
Similar to the above scenario.

Simulation Test:
Weather was partly cloudy 80°F, 6 miles visibility. The role player (with Keruve transmitter) is about 1.5 miles away. The predefined perimeter/geo fence is not set. At the start of the search, the handheld tablet was used and the role player was located within 1 minute on the tablet. Then the drone with camera was launched, and the role player was visually located in 4 minutes.

Summary:
Searching for the role player (with Keruve transmitter) about 1.5 miles away with the Keruve handheld tablet and drone with camera took a total of 5 minutes to have visual on the role player. In this scenario, the drone deployed is commonly used by PBSO with more reserve flight time (about 40 minutes left). A limitation of searching for a child who may have travelled a distance is that current FAA regulations require that the deployed drone should always be visible (in visible range) to the PBSO drone pilot. An advantage is that the Keruve handheld tablet has ability to time stamp and pinpoint last known location (using Live Track functionality that took one minute to activate, it renders location every two minutes, good for tracking moving child), that can also be useful information in PBSO deployment of PBSO Officers.
In addition, the next version of Eagle Eye (Drone with camera system used by PBSO) will include the ability to add coordinates (longitude/latitude). Supplying the coordinates from the handheld tablet to the drone controller will make the visual search using drone with camera much faster, instead of only depending on the drone with camera as “live eyes in the sky” to

assist with location. However, GPS signals could be lost in buildings when there is no available Internet service, which is used as an automatic backup to GPS. (Role player entered a port-a-potty in this field test, and signal was lost as there was no Internet.)

Testing Project LifeSaver and Keruve together

The test location provides access to test in open fields and in a building. Both Project LifeSaver and Keruve would be used simultaneously. Two role players using both devices were deployed.

Scenario E

Missing 7-year-old child with moderate autism. The child resides in a gated community, the house is located 1.1 miles from a large community lake in the center of the community. From the time of the call to dispatch, the child has been missing for 15 minutes, the back door was discovered open.

Traditional Response:
Similar to the scenario in the previous section.

Simulation Test:
Weather was Cloudy, 67°F, 6 miles visibility. In this test, two role players (one with Project LifeSaver and the other with Keruve transmitters) were walking around a corn maze with high hedges. The role player with the Project LifeSaver transmitter was located in 5 minutes. (The drone with Project LifeSaver receiver/antenna likely overshot role player initially, because the role player was actually too close for the airborne antenna to detect signals from the ground). The role player with the Keruve transmitter was located in 2 minutes on the handheld tablet.

Scenario F

Similar to Scenario 1, except that the child, 10 years old, is missing for an hour, with no other information.

Traditional Response:
Similar to the scenario in the previous section.

Simulation Test:
In this test, the two role players (one with Project LifeSaver and the other with Keruve transmitters) drove to park 1.5 miles from the farm market. Both drones with Project LifeSaver receiver/antenna and camera were deployed. The role player with Project LifeSaver transmitter was located in 10 minutes by the drone with the Project LifeSaver receiver/antenna with supporting drone with camera. The role player with the Keruve transmitter was located on the handheld device in 2 minutes and shortly thereafter sighted by the drone with camera. Again, it appeared that low battery levels and software updates may have affected the time it took to enable Live Tracking and Live View on the handheld tablet. But once tracking was enabled, the Keruve handheld device was used to track the role player successfully.

DISCUSSIONS AND CONCLUSIONS

This pilot project is executed and completed as stipulated in *Missing Persons with Special Needs Bill* that was the driver of driver for this project. Based on the initial target for improvement over traditional mode of search-and-rescue operations, we selected the enhancing technologies for testing, created a framework for evaluation, and performed preliminary and

scenario-based testing. In this section, we discuss the findings of this project and present our recommendations based on these findings.

First of all, the addition of location and airborne technologies to the traditional search-and-rescue operations in the case of eloping children with autism is clearly advantageous. Depending on the specific technologies used, compared with traditional methods,

- It is possible to detect elopement earlier and establish an initial search location more accurately;
- Search can be limited to a smaller area and better directed; and
- Positive identification can be made remotely.

And all these result in faster response, lower cost of operation, and better outcome. Using our evaluation framework, from the user perspective, the technologies show relative advantage over traditional methods and are easy to use. From the operational perspective, these new technologies are generally compatible with current organizations and procedures and show improvement in search-and-rescue efforts. There are cost issues as well as operational risks, but we believe, especially in the long run, benefits considerably outweigh the costs when deploying location and airborne technologies in search-and-rescue operations in the case of eloping children with autism.

With that established, the next question is, which technology to deploy? In this pilot project, we selected two most appropriate and promising technology combinations: GPS handset with camera on (generic) UAV and RF tracking with receiver/antenna on (dedicated) UAV. Our tests clearly show strengths and weaknesses of both. In addition to being offered and promoted by different vendors, these two technologies exemplify two distinctive approaches: GPS and generic UAV combination uses state-of-the-art, open-source technologies which may be less robust (subject to bad weather or physical blockage of signals) but are easier to use and customize, while RF with dedicated UAV receiver deploys old, proven technology in a proprietary package that is fool-proof but hard to modify. Based on our preliminary evaluation and field tests, we believe the former is a better fit for this project, because of the following:

- RF may outperform GPS under certain specific conditions (such as indoors without Internet services), but in general, GPS is more powerful and accurate, easier to use, and more likely to see further improvement in the future. Therefore, GPS is a better choice from the user perspective.
- Open-source technologies such as GPS allow additional services (such as geo-fencing, live tracking, and location history, to name a few) to be offered cheaply and quickly, with the potential of integration with other systems (such as law-enforcement command and control).
- When law enforcement can deploy any generic UAV with camera that it has on hand or nearby when it gets the call, the benefit of having an “eye in the sky” is maximized. On the other hand, the need for a receiver/antenna on a dedicated UAV (and properly trained operators) can lengthen the response time and limit coverage area. And it is an additional cost to law enforcement.

Therefore, our findings conclude that GPS with generic UAV is a better choice than RF with dedicated UAV receiver/antenna in search-and-rescue operations in the case of locating eloping children with autism, from both the user perspective (higher level of relative advantage, and lower cost, in particular) and the operational perspective (better improvement potential and compatibility).

In conclusion, based on our overall findings in this this pilot project, we offer the following recommendations:

1. In search-and-rescue missions involving eloping children with autism (or persons with special needs in general), deploying UAV presents many advantages over traditional operations. This is true even in the case when the eloping child has no location devices on him/her; just having an "eye in the sky" can reduce search time, lower resource requirements, and provide better outcomes. This can be an important incentive for law enforcement to have UAVs on the squad.
2. GPS technology is an effective addition to search-and-rescue operation of eloping children with autism. The system we tested (Keruve) is advanced and powerful with many features, but its high initial cost implies that it is probably most appropriate for those with high eloping risk only. But even having a simple GPS device can help greatly, and the cost of generic GPS wearables has come down to $100 or less. It is worthwhile for local community centers or autism advocates to look into funding for such devices for families and caregivers.
3. Finally, search-and-rescue missions are best accomplished when law enforcement and families cooperate and coordinate with one another, and such collaboration extends to the use of technologies. It is advantageous for both parties to jointly decide on a tracking technology that is not only cost effective and easy to use for the families, but also compatible with and beneficial to law enforcement's operations and command-and-control systems. And even with better tracking technologies, it is still very important for the family or caregiver to immediately inform law enforcement in case of elopement.

ABSTRACT

Motivated by bundled payment policies that aim to reduce practice variation, this study examines whether and how lower variation in clinical practice relate to hospital operational performance. Using statistical process control as a theoretical lens, we hypothesize negative impacts of practice variation on operational performance. We also address intervening impacts of hospital quality evaluations on the relationship. We discuss our findings from analyzing six years of inpatient data from hospitals in NY and FL states. We believe better measurement and understanding of practice variation can facilitate healthcare systems to reduce waste and support policy-makers to design bundled payment reform models.

Examining Service Quality in The U.S. Airline Industry by Social Media Analytics

ABSTRACT

Social media has provided a number of online tools that allow people to discuss anything freely. Consumers are sharing their opinions online with others. Electronic Word of Mouth (eWOM) is the virtual communication in use. Customers can choose to complain or to compliment services or products on their social media platforms, rather than to complete the survey offered by the service providers. Compared with the traditional survey, social media offers features that can spread information quickly and broadly. This paper offers a novel methodology that, by utilizing emotional sentiment analysis, can help the airline industry to improve its service quality.

KEYWORDS: social media, service quality, SERVQUAL, emotional sentiment, text mining, natural languages processing (NPL), airline, sentiment analysis, eWOM

INTRODUCTION

With the emergence of the social media online platform, more and more consumers and companies are communicating and sharing experiences and product/service reviews online. Social media provides online tools and allows people to discuss anything freely, with the increase in mobile connectivity. According to research conducted by IBM Big Data, more than 2.5 quintillion bytes of data were generated daily in 2012 (Zikopoulos et al., 2012). Business analysis and big data mining were developed in order to extract insightful information from the collected massive data (He et al., 2015, 2016; Tian et al., 2016). In order to survive in the intense competition of today's business world, business can be based not only on the competition of lower prices, but also on service quality delivery (Zeithaml, Parasuraman, & Malhotra, 2000).

In the traditional way, businesses, including airline companies, use conventional survey-based techniques to conduct the measurements of service quality and customer satisfaction. Those survey-based techniques are AHP, SERVQUAL, and SERVPREF. And the most important technique to study service quality is SERVQUAL. SERVQUAL has been verified by past literatures in Table 1. Tsaur, Chang, and Yen (2002) studied the service quality in the airline service industry, using fuzzy MCDM. Tsaur et al. (2002) found that many intangible attributes are difficult to measure. A survey was conducted and, by applying AHP, Tsaur et al. found that the most critical aspects of service quality are tangible, and the least critical aspect is empathy, in airline service. In addition, Tasur et al. (2002) found, from survey results, that courtesy, safety, and comfort are the most important attributes. Another study performed about service quality in the airline industry identified several SERVQUAL and industry-based items that significantly influence consumers' perceptions of overall service quality and their intention to re-patronize (Young, Cunningham, & Lee, 1994). In addition, the results suggest that the Air Travel Consumer Report has not been properly disseminated, nor has it been used by most consumers (Young, Cunningham, & Lee, 1994). However, survey-based methodology has its limitations, such as sample size, group of participants, and its need for respondents' recall of past events. These limitations can constrain the scalability of the measurements of service quality.

Rather than using a survey-based approach, consumer-generated social media content contains a variety of valuable pieces of information, like opinions, experiences, and viewpoints.

The valuable information makes social media an important source to use in analyzing consumers' decision-making about purchases. Compared to the traditional method of conducting a market survey and social media data analytics, Leung, Lee, and Law (2012) suggest that social media content analysis may be more trustworthy and more reliable than information provided by the marketing departments within a company. Social media has characteristics that include its ability to spread messages more quickly and broadly than the use of any other methods. Thus, examining social media content is becoming important to businesses who want to pursue superior service quality and gain competitive intelligence with improved market performance. Previous studies (Parasuraman, Zeithaml, & Berry, 1988; Ramanathan & Karpuzcu, 2011) have already established multiple dimensions of service quality. Specifically, for airline service quality, Young et al. (1994) measured the service quality of passenger airlines based on SERVQUAL and discussed it in a U.S. Air Travel Report released and published by Department of Transportation (DOT).

This study seeks to develop a framework that uses social media analytics (with an emphasis on emotional sentiment analysis) to help to study the service quality perceived by consumers in the airline industry. According to SERVQUAL, the service quality will be investigated based on a benchmark dataset for each dimension of service quality. Furthermore, emotional sentiment (Lexicon-based) analysis will be applied, in order to examine the tweets for each service quality dimension. Compared with the Air Travel Report published by the DOT, the effectiveness of a social media analysis of service quality will be inspected.

Our research questions are as follows:

What is the relationship between textual social media data and the Airline Consumer Report by DOT?

The following of this paper are organized as follows. In the next section, past research and literatures are reviewed about service quality and social media analytics. The following section introduces out research model and hypotheses. And methodology and results are followed. In the last, we discuss the findings and conclude the paper with research limitations.

LITERATURE REVIEW

Service quality assessment is an important area for multidisciplinary research. Operational management, marketing, and management information systems have had many research articles written about measuring service quality. Prior work about measuring quality has mainly focused on physical products and on tangible goods (Palese & Piccoli, 2016). In the late 20th century, the famous model -- SERVQUAL-- for measuring quality of service was proposed by Parasuranman et al. (1985, 1988). According to Parasuranman et al. (1985), service quality is hard to measure because of intangibility. Most research papers cover the application of SERVQUAL and its ability to conduct a survey to evaluate consumers' perceived service. This method is feasible, but it is limited by the sample size, response rate, and reliability of the responses. With the emergence of social media and the prevalence of mobile platforms (mobile applications), socialized textual data has been found to be a boon to business. Customer experience is the basis for the effective measurement of service quality (Petter et al., 2012). Social media analysis provides the ability to retrieve socialized textual data and to analyze them through text mining, clustering, and sentiment analysis. Competition among airline carriers is becoming intense, and a competitive advantage can be discovered by airline carriers who take service quality into account. Most especially, with the emergence of technology and social media, airline carriers can now communicate with consumers in multiple ways: via online chat, Twitter, Facebook, official websites, phone calls, online surveys, and so on. Airline carriers may change their marketing strategies based on the results of their social media analytics, and can gain a reputation from the opinions of their consumers.

Literature Review of Service Quality in the Airline Industry

Studies about service quality have been done since the 1980s (Grönroos, 1984; Rust & Oliver, 1994; Cronin, Brady, Thomas & Hult, 2000). As defined by Grönroos (1984), service quality is "the outcome of an evaluation process, where the consumer compares his expectations with the service he perceives he has received." Grönroos suggested that, when considering service quality, technical quality, functional quality, and corporate image also must be considered. Further, other researchers have studied service quality and have suggested that customer satisfaction has a positive relationship with service quality (Mukherjee, Nath, & Pal, 2003; Ramanathan & Karpuzcu, 2011). Since service quality is highly related to customer satisfaction and firm performance, it is important for companies of the service industry to measure and to evaluate customer satisfaction. Sasser, Olsen, and Wyckoff (1978) mentioned, back in the '70s, that service quality could be measured by materials, facilities, and personnel. From the 1980s until the 2010s, service quality measurement has been developing, and the research method has improved over these thirty years. In order to measure service quality accurately, the SERVQUAL model is the fundamental model for assessing service quality, since it compares expected service and perceived service from consumers (Parasuraman et al., 1985). Ten dimensions are covered in the SERVQUAL model: access, communication, competence, courtesy, credibility, responsiveness, security, tangibility, and understanding/knowing the customer.

Several years later, Parasuraman et al. (1988) refined the ten dimensions into five major dimensions: reliability, responsiveness, assurance, empathy, and tangibility. Martin (1986) argued that only two main dimensions should be assessed for service quality: service procedure and consumers' conviviality. Martin (1986) considered the managerial portion and the communication with consumers. During the following twenty years, researchers expanded and modified the SERVQUAL five dimensions across different service industries. Ramanathan and Karpuzcu (2011), in their study, suggested using seven metrics to measure service quality: responsiveness, flexibility, availability, assurance, personnel contact quality, reliability, and tangibles (as shown in Figure 1). And Novack, Rinehart, and Langley (1994) argued that personnel of the company and the traits of executives can be used to measure service quality. Another aspect was proposed by Parasuraman et al. (1988), who said that customers' opinions can strengthen the understanding and the measurement of service quality. According to previous research (Parasuraman, Zeithaml and Berry, 1988; Ramanathan and Karpuzcu, 2011), service quality metrics can be defined as follows:

- Reliability: The ability to perform the promised service, both dependably and accurately
- Responsiveness: Willingness to help customers and to provide prompt service
- Flexibility: Flexibility to allow for different transaction options and methods
- Availability: The availability of products in stock
- Personnel Contact Quality: The knowledge and courtesy of employees, as well as their ability to ease communication with customers
- Tangibles: The appearance of the physical facilities, the equipment, the appearance of personnel, and the communication materials.
- Assurance: The ability to convey trust and confidence to customers and to make them feel that they are receiving good service

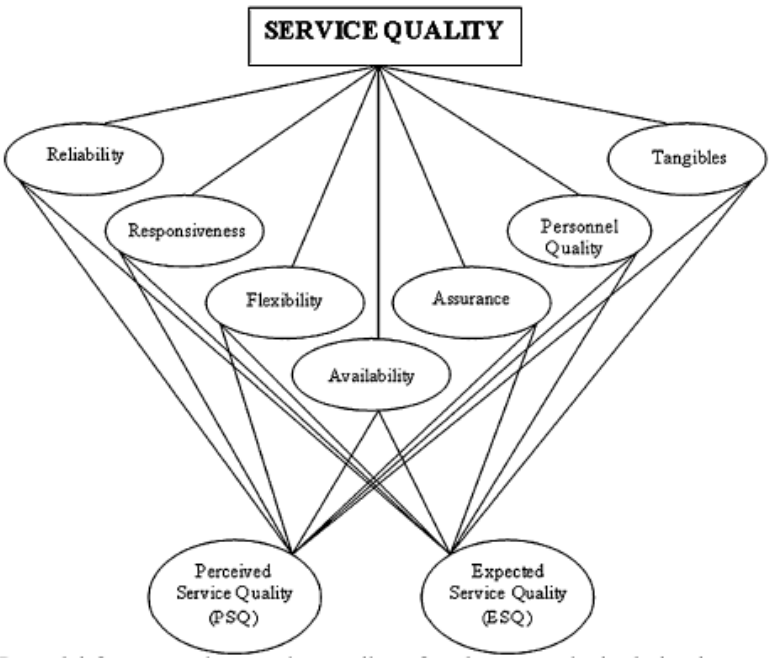

Figure 1. Seven Metrics for Measuring Service Quality
(Adapted by Ramanathan & Karpuzcu, 2011)

The SERVQUAL model has been applied to evaluate service quality in a variety of industries, as among them education, banking, insurance, airline services, and health care. Yang and Fang (2004) identified eight dimensions and sub-dimensions of online service quality. They are responsiveness, service reliability, ease of use, access, system reliability, timeliness, security, and competence. These eight dimensions derive from SERVQUAL; modifications were based on context. In another paper, El Saghier and Nathan (2013) found that only four dimensions (reliability, responsiveness, empathy, and assurance) can influence service quality in banking services. Bansal and Taylor (2015) examined switching intentions, service quality, and customer satisfaction, and argued that service quality is one antecedent to customer satisfaction, while service quality is the key for switching intentions.

To evaluate perceptions of airline service, prior studies were based on survey questions and on the SERVQUAL model. Ostrowski et al. (1993) examined the relationship between service quality and retained preference, which measured customer loyalty in the commercial airline industry. The data was collected from two air carriers; the researchers found a positive relationship between service quality and customer loyalty in the commercial airline industry. And AHP methodology was applied in measuring service quality in the airline industry by Tsaur et al. (2012). Applying the fuzzy set theory to evaluate the service quality of the airline, Tsaur et al. (2012) found that many intangible attributes are difficult to measure. Applying the AHP-based survey showed that the most concerning aspects of service quality are tangible, and that the least concerning aspect is empathy. Courtesy, safety, and comfort were the most concerning attributes for Tsaur et al. (2012). Mazzeo (2003) also found that being on-time plays an important role in service quality in the airline industry; flight delays are significantly related to weather conditions, air congestion, and scheduling decisions (U.S. Bureau of Transportation Statistics, 2000). The time lag is an obvious issue when analyzing service quality in the airline industry. Consumers need a service quality model to evaluate the service quality, and two

dependent variables – perceived service and expected service – are essential for measuring service quality (Grönroos, 1984). To maintain a business' market share, Mazzeo (2003) also argued that when customers have more choices, companies have more incentive to improve service quality by offering lower prices and better service. However, gathering the opinions of consumers is not easy. Surveys can be conducted with limited sample sizes, but the respondents may not represent all of the consumers. This dissertation will bridge the gap in the traditional survey method for service quality measurement in airline industry.

Hussain et al. (2015) investigated the relationships among service quality, service provider image, customer expectations, perceived value, customer satisfaction, and brand loyalty in a Dubai-based airline. Questionnaires were conducted based on the SERVQUAL model and identified six dimensions: reliability, responsiveness, assurance, tangibility, security and safety, and communication. Another research paper regarding service quality in the airline industry was written by Tsaur et al. (2002), who established five aspects and fifteen service quality criteria. We will use both of these research papers to design the benchmark dataset for assessing service quality in the airline industry using social media data. As the special service the airline companies provide, we use dimensions of service quality from prior studies and include security and safety as one of dimensions to measure service quality. Table 1 shows the six evaluation dimensions of airline service quality, as studied in this paper.

TABLE 1 SIX DIMENSIONS OF AIRLINE SERVICE QUALITY

Dimensions of Service Quality	Attributes and Key Words
Responsiveness	Willingness to help passengers; providing prompt service; keeping passengers informed about delivery of service; keeping passengers updated if any modified schedule; quickly response customer's requirements.
Assurance	Providing service actively; language skill or translation help of crew members; pilots' informative announcement in different contexts of culture; employee's skillfulness; courtesy towards customers
Tangibility	Comfortable seats and the cleanliness of the cabin; cleanliness of the aircraft interior and exterior; variety of food, food service and food quality; on-board entertainment: movie and music; the appearance of the crew; complimentary pillow or blankets
Reliability	Efficiency of the check-in process, flight punctuality, timeliness (arrival in promised time), handling of missing luggage complaints.
Security and Safety	Personal safety; luggage safety; animal safety
Communications	communication between cabin crew and passengers; the ability to communicate with passengers in different languages; the communication between pilot and passengers; informative announcement during the flight.

Literature Review of Social Media Analysis

A recent study by Xiang, Schwartz, Gerdes, & Uysal (2015) used a text analytical approach to analyze a large quantity of consumer reviews extracted from Expedia.com and demonstrated the utility of big data analytics to better understand the relationship between hotel guests' experience and satisfaction. Based on the SERVQUAL model and its variations, we can reasonably use big data technology to mine a large volume of social media data in order to potentially identify customer expectations for a service and the perceptions of those customers after they receive that service.

In this paper, we propose a framework for big social data comparative analytics (Figure 2) to help interested businesses to leverage big data solutions mine social media data in order to contextually compare the service quality among peers. The proposed framework adopts the seven service quality measurement metrics proposed by the five dimensions of service quality: reliability, responsiveness, empathy, assurance and tangibility.

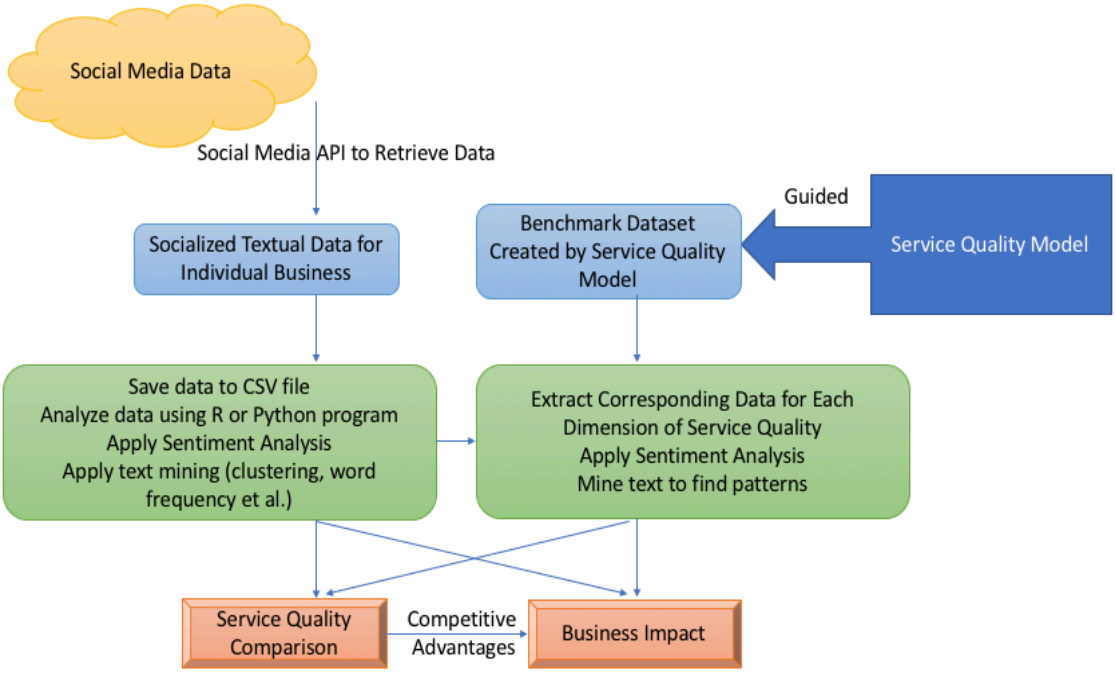

Figure 2. A Proposed Framework for Using Social Media Analytics to Study Service Quality

In the proposed framework, big data technology is used as a solution to analyze social media data from targeted business and their peers, in order to visualize and benchmark comparisons among peers across different service quality measurement metrics that may impact customer satisfaction. Text classification algorithms can be used to mine consumer-generated social media content based on the specified service quality measurement metrics. Then, sentiment analysis, which is the computational detection and study of opinions, sentiments, emotions, and subjectivities in text, can be conducted on the texts associated with each metric in order to identify consumer perceptions, generating a score from -1 (the most negative opinion) to 1 (the most positive opinion). The overall sentiment score of Dimension *i* can be calculated using the following formula provided by Duan et al. (2013):

$$S_i = \frac{N_{pi} - N_{ni}}{N_{pi} + N_{ni}} \quad (1)$$

where N*pi* denotes the number of positive sentences in Dimension *i* and N*ni* denotes the number of negative sentences in Dimension *i*. To make the process of conducting sentiment analysis easier, researchers can use existing popular sentiment analysis tools or services such as Lexalytics, SentiWordNet, SentiStrength, Social Mention, Trackur, Sysomos, and Viralheatto extract positive or negative sentiment scores from text (Pang & Lee, 2004). These sentiment analysis tools mainly rely on machine learning techniques such as Support Vector Machine (SVM), Naive Bayes, Maximum Entropy, and Matrix Factorization to classify texts into positive or negative categories, and they have been used in many studies in the sentiment analysis literature (Pang, Lee, & Vaithyanathan, 2002). Past research has found that a fluctuation in sentiment on social media has been identified to correlate with fluctuations in the stock market (Ranco et al., 2015). For example, the result of the presidential election can be predicted by gauging public opinion on social media when policy announcements are made. Anitsal et al. (2017) investigated the top ten airline carriers in the U.S. using sentiment analysis and found that the customer relationship can be investigated in detail, and that Delta, Southwest, Alaska, and SkyWest Airlines have the most positive sentiments expressed about their cabin crews and their attitude to their passengers. Waguespack and Rhoades (2014) argued that airline carriers have established a social media center in effort to avoid service quality failures, and that viral incidents can significantly affect publicity.

Based on the prior literature, we offer the following hypothesis:

H1: The sentiment analysis results of tweets will align with the DOT Air Travel Consumer Report.

METHODS

This paper will introduce a novel methodology and will utilize emotional sentiment analysis to help the airline industry to improve its service quality and respond to a public crisis in a short time. Bowen and Headley (2017) published the Air Quality Rating (AQR) to measure the service quality of U.S. airline carriers. Alaska Airlines and Delta Airlines were announced as No.1 and 2 in the AQR report in 2017. However, the data used for generating the AQR report was mostly based on that of the 2016 U.S. Airline Consumer Travel Report published by DOT. Bowen and Headley (2017) reported that nine airline companies showed improvement in the AQR report during 2016. In this study, all of the U.S.-based airline companies in the DOT airline consumer report are included: Southwest Airlines, Alaska Airlines, American Airlines, United Airlines, Delta, Express Jet, Hawaiian Airlines, Jetblue, Skywest, Spirit, Virgin America, and Frontier Airlines. The reason for choosing these companies is that each company can represent one type of airline carrier. For example, Southwest Airlines is known to be flexible by allowing passengers to choose their seats and by charging no baggage fee. Frontier Airlines, JetBlue, and Spirit are known by their cheap airfares; United Airlines, Delta, and American Airlines have the largest air route networks, and United Airlines suffered from the incident in April 2017; and Alaska Airlines is listed as No.1 in the AQR report for its excellent service. AQR has been cited to make an airline industry standard and to allow for a comparison of airline companies' performance (Bowen & Headley, 2017). In order to calculate the AQR score, DOT data is used and is applied to the formula, based on the on-time rate (OT), denied boarding (DB), mishandled baggage (MB), and customer complaints (CC). Only the on-time rate has a positive impact; the other three have a negative impact on AQR. The formula to calculate the AQR is listed below:

$$AQR = \frac{(+8.63*OT)+(-8.03*DB)+(-7.92*MB)+(-7.17*CC)}{(8.63+8.03+7.92+7.17)} \quad (2)$$

With its ability to measure service quality in the airline industry, AQR has been designed for the industry, and uses the data from DOT report. The results can be used by airline carriers, can help newly nominated airline services, and can assist DOT in modifying the rules. However, since the AQR is based on the Air Travel Report from DOT, the data in the report has at least a two-month time lag. Consumers cannot get real-time information when they need it to make purchase decisions, and airline companies are unable to improve their service right away.

Sometimes, consumers have reported incidents on their social media platforms and this information has spread rapidly. Then, airline companies can respond to it officially and can regain their reputations using social media tools. To monitor and analyze social media effectively, airline companies need to adapt multiple technologies and to hire data analysts and data scientists to mine tweets from Twitter, reviews on Tripadvisor.com, and comments from their websites and from other social media platforms. The most effective and feasible method is mining Twitter data, since Twitter has a lot of users and it provides an API to connect with the server and to retrieve the specific data. To better use these data, businesses can develop an information system to monitor their mentions on social media. For service companies, emotional sentiment and data mining can be applied to investigate service quality. Since service quality is the backbone of business, the earlier that any negative issues are found, the easier it is to improve service quality. If the sentiment has changed considerably, an alert can be sent to the appropriate person and then the proper operations and responses can be performed. Businesses can then use this information system to improve their service quality, to monitor their market performance, and to adjust their marketing strategies.

Sentiment Analysis

Opinion mining and sentiment analysis contribute to the development of an opinion-oriented information system for service or products providing companies (Pang & Lee, 2008). If service providing companies want to get feedback or opinions from customers, the traditional way is for them to conduct surveys and to distribute the surveys to the customers who have used the services in that company. However, a survey is not enough to get the customers' feedback in this digital world, because a survey needs time to be collected and analyzed. The issues of service cannot be addressed by the company quickly. Fortunately, customers like to post their service experiences on social media platforms rather than completing a survey or complaining to the company directly. Twitter and Facebook are the two of the most popular social media platforms.

Twitter Sentiment Analysis is the process of determining the emotional tone behind a series of words. It is used to gain an understanding of the attitudes, opinions, and emotions expressed within an online mention. Having a solid understanding of current public sentiment can be a great tool for any business. When deciding if a new marketing campaign is being received warmly, or if a news release about the CEO is causing customers to become angry, the people in charge of handling a company's public image need these answers quickly. And social media can deliver those answers quickly. One simple, yet effective, tool for testing the public waters is to run a sentiment analysis.

There are many ways to do sentiment analysis. Many approaches use the same general idea. Here are the three steps to do the sentiment analysis:

1. Create or find a list of words associated with strongly positive or negative sentiment.
2. Count the number of positive and negative words in the text.
3. Analyze the mix of positive to negative words. The use of many positive words and few negative words indicates a positive sentiment, while the use of many negative words and few positive words indicates a negative sentiment.

To perform the sentiment analysis, download the positive and negative words and evaluate the tweets with those positive and negative lexicons. The list of positive words contains 2,003 words and the list of negative words contains 4,782 words (Hu & Liu, 2004; Liu, Hu & Cheng, 2005). These word lists include some misspelled words that are possible appear frequently in social media content.

After having been run through the sentiment words lists, the tweets should be preprocessed before the sentiment scores can be calculated. First, the data must be cleaned. This step involves the removal of stop words, all of the numbers, and all of the white spaces, and the conversion of all of the words or letters to the lower case.

The first step, creating or finding a word list (also called a Lexicon), is generally the most time-consuming. In this study, I use the existing Lexicons and made some modifications to those Lexicons. For example, social media popular acronyms or slang are not included in the existing Lexicons. “omg”, “lol”, “thx”, and “wtf” are very common acronyms on social media platforms. I included these types of words in the Lexicon for in this study. Researchers can edit the Lexicons when they study specific topics. However, some words have double emotional meaning. For instance, “sick" is an example of a word that can have positive or negative sentiment depending on what it's used to refer to. If you're discussing a pet store that sells a lot of sick animals, the sentiment is probably negative. On the other hand, if you're talking about a skateboarding instructor who taught you how to do a lot of sick flips, the sentiment is probably very positive. Sentiment analysis uses machine learning algorithms. In this research, R Studio was used to load the sentiment analysis packages and to analyze the processed tweets for all twelve of the airline companies.

A sentiment analysis works like this: I first take a bunch of tweets about whatever I am looking for. I then parse those tweets out into their individual words, and then count the number of positive words and compare it to the number of negative words. I use the open source R program to calculate the sentiment score of the sentence from https://github.com/exploratory-io/exploratory_func. This function first maps the predefined sentiment type (positive or negative) or the value (how positive or how negative). And then it considers the intensity of the sentiment. If I am using the positive or negative to determine the sentiment, it is not enough to learn the mood or emotion of the customers. For example, here are two tweets in the dataset: “I’m feeling so good!” and “I’m feeling much better!” They are both positive. However, the two sentences express the intensity that influences the different results in emotion. “so” and “much” are the intensifiers in these sentences and score differently.

The Twitter datasets could be described in Table 2. United Airlines was mentioned by the largest number of unique users (135,569 unique users). And American Airlines received the highest number of average tweets per user (2.09). This can be interpreted to show that the customers of American Airlines would like to communicate with the airline company on Twitter. The highest number of tweets was received by Delta Airlines; it was mentioned by Twitter users (or its customers) over 227,000 times during this period (April - June 2017). Table 3 shows the AQR scores for each airline carriers in the period.

TABLE 2 THE DESCRIPTIVE OF PROCESSED TWITTER DATA

Airline Carriers	Number of Tweets from Apr.1 to Jun. 30, 2017	Number of Unique Users	Average Tweets Per User
United Airlines	224,789	**135,569**	1.66
Alaska Airlines	26,616	13,969	1.91
Southwest Airlines	68,522	42,561	1.61
Frontier Airlines	7,301	4,574	1.60
American Airlines	150,454	72,071	**2.09**
Delta Airlines	**227,121**	116,165	1.96
ExpressJet	58	45	1.54
Hawaiian Airlines	3,401	2,025	1.68
SkyWest Airlines	231	141	1.64
Spirit	23,045	13,095	1.76
JetBlue Airlines	49,503	24,693	2.00
Virgin America	11,817	7,270	1.63

TABLE 3 AQR SCORE FOR ALL AIRLINE CARRIERS FROM APR-JUN 2017

	AQR Score		
Airline Carriers	**April**	**May**	**June**
Alaska	**-0.46**	**-0.38**	**-0.45**
Frontier	-1.01	-1.24	-0.94
Southwest	-0.61	-0.81	-0.91
United	-1.10	-0.87	-0.98
Hawaiian	-0.85	-0.76	-0.53
SkyWest	-0.83	-0.65	-0.72
American	-1.20	-1.05	-1.21
Spirit	**-1.89**	**-3.11**	**-2.25**
ExpressJet	-1.47	-1.08	-1.14
Virgin America	-0.95	-1.07	-0.99
Delta	-1.22	-0.49	-0.50
JetBlue	-0.55	-0.57	-0.54

RESULTS

In the following figures showed in Table 4, all of the airline companies' Twitter data are shown in volume and in sentiment scores. I then put them into three categories: large airline carriers, cheap airline carriers, and other airline carriers. "Large airline carriers" comprises those that carry the largest number of passengers, including four airline companies: United Airlines, Southwest Airlines, American Airlines, and Delta Airlines. "Cheap airline carriers" means that the air fares on those are cheaper than on other major airlines. This category includes JetBlue, Spirit and Frontier. Those airline carriers always have their air fare deals online. For example, Frontier Airlines offers one-way air ticket for only $20 from ATL (Atlanta airport) to Orlando, FL. "Other airline carriers" include Hawaiian Airlines, Alaska Airlines, SkyWest Airlines and Virgin America. These airline carriers mostly have limited routes compared with the large airline carriers and the cheap airline carriers. Hawaiian Airlines mainly offers roundtrip fares from the U.S. mainland to Hawaii, and Alaska Airlines offers roundtrip fares from the U.S. Mainland to Alaska, as well as roundtrip fares among major cities in west coast in the U.S. Table 4 shows

the trend of sentiment score and the trend of volume of tweets for each airline carrier in the three consecutive months.

TABLE 1 OVERALL VOLUMES AND MEAN OF SENTIMENT SCORE FOR EACH AIRLINE CARRIERS IN THREE MONTHS

Overall Volume of Tweets	Overall Mean of Sentiment Score
 **Alaska Airlines**	 **Alaska Airlines**
 **American Airlines**	 **American Airlines**
 **Delta Airlines**	 **Delta Airlines**

From Table 4, we can see that United Airlines and Delta Airlines received the most tweets each day. If we look at the volume of the tweets, most of the airline carriers received a high volume of tweets during the period from Apr. 9 to Apr. 12. Since United Airlines had the critical incident on Apr. 9, and news of it was spread widely on social media, many people discussed and mentioned the incident on social media and expressed their indignant emotion and anger towards United Airlines. Southwest Airlines has a much lower volume of tweets compared to the large airline carriers and the other airline carriers. Due to the size of airline

companies and limited airline routes, Spirit and SkyWest Airlines received only fewer than 100 mentioned tweets per day.

Next, we report the results of having used OLS regression to examine the relationship between AQR and sentiment score. The regression results are reported in Table 5. To measure the service quality of airline industry, the dependent variable is the AQR score that is calculated by the formula using the data from DOT monthly report. In column 1, I wanted to test whether the volume of tweets would affect the AQR. The volume of tweets was converted to natural logarithm as log (volume). Other variables were included as control variables, such as the characteristics of the airline carrier and the characteristics of their Twitter account. The number of passengers and the number of scheduled flights are the characteristics of the airline carrier. I used a natural logarithm to convert these two variables, as well. They were converted to Log (passengers) and Log(flights). The number of Twitter followers, months on the Twitter (from the account creation), and whether using online response features on Twitter were the characteristics of Twitter account of each airline carrier. In this model, the R squared value was 0.389, and the p-value was .019, which is less than .05. That means that 38.9% can be explained by this model; this model is statistically significantly in predicting airline service quality - AQR score. The coefficient of log (volume of tweets) was -1.20 and the p-value is .402 which is not statistically significant. Only two variables - months on Twitter and online response feature on Twitter - had a p-value less than 0.1 and 0.05, respectively. However, in this model, I found two high variance inflation factors (VIF). Since the suggested threshold of multicollinearity problem is 10 (by Gefen, Straub, and Boudreau, 2000), the number of passengers (VIF: 25.234) and the number of scheduled flights (VIF: 25.214) were not tolerant in this model. They had the multicollinearity problems. If I included both of them in the regression model, it became problematic. Hence, I decided to eliminate the number of scheduled flights and keep the number of passengers, in this model.

Column 2 in Table 5 shows the model without variable - the number of scheduled flights. The VIFs in the second model were not over 3.5, which is acceptable; this indicates that the model doesn't have multicollinearity problem. The largest VIF was 3.214 of the number of followers on Twitter. In the second model in Column 2, the R squared value was 0.335 and the p-value was .025, which is less than 5%. That means that this model can explain 33.5% and is statistically significant at a level of 5%. After removing the scheduled flights in the model, I found that the coefficient of log (volume of tweets) was - 0.272 with a p-value of .018 (significant at the level of 5%). So, I could interpret that when the log (volume of tweets) increased by 1, then AQR would be negatively affected by that and decrease 0.272. In addition, the coefficient of online response feature on Twitter was 0.775 with a p-value of 0.006 (significant at the 1% level). Using the online response feature on Twitter will significantly improve the service quality of the airline carrier. This feature enables communication with customers on social media and leaves the responses on the airline's official Twitter account. This interaction can be read by other customers and can significantly benefit the airline's service quality. I would recommend all the airline carriers who would like to improve their service quality take advantage of this impressive feature on Twitter. Attracting more followers on Twitter may help to improve the AQR score in this case (p-value is .049). Because the coefficient of the number of followers is fairly small, it may not have a strong association with AQR, but it is still helpful for an airline to attract more followers on Twitter.

Next, we would like to find the association between the sentiment score and AQR. To check whether social media data can be used to measure service quality as DOT consumer reports do, the monthly data of Twitter was used to calculate the mean of the sentiment score that represents the monthly sentiment score for each airline carrier. Column 3 of Table 5 represents that the R squared value was 0.500 of this model with p-value 0.001 (significant at level of 5%). That means that this model can explain 50% and is a statistically significantly

predictor of the AQR score. The coefficient of the average sentiment score was 7.349, and the p-value is .000, which is significant at a 1% level. The sentiment score was positively and highly associated to AQR. This can be interpreted in this way: when the sentiment score increases by 1, the AQR will increase 7.349. The sentiment score can be used to measure the service quality and to predict the AQR score. The online response feature also significantly impacted the AQR, with a coefficient 0.443 at a significant level of 5%. This indicates that the sentiment score of tweets aligned with the DOT Air Travel Consumer Report. Hence, hypothesis was supported.

As shown in Table 5, we found that the number of passengers or the number of scheduled flights did not impact on AQR score. The online response feature on Twitter can be used by airline companies to improve their service quality. Analyzing the sentiment score and the volume of tweets was enough to measure the service quality of the airline industry and to predict the AQR score and complaints on DOT report.

TABLE 5 REGRESSION MODELS RESULTS (VOLUME, SENTIMENT SCORE AND AQR)

Dependent Variable	**AQR (1)**	**AQR (2)**	**AQR (3)**
(Constant)	3.091	-.841	-2.247

DISCUSSION AND CONCLUSIONS

Pang and Lee (2008) pointed out the challenges and opportunities engendered by the growing popularity of opinion-rich resources, such as online comments, blogs, social media platforms, and online forums. By investigating the value of those unstructured data, businesses are able to gather competitive intelligence and improve their products and services in a short time. In order to actively use information technology to seek and retrieve the data and to understand consumer's opinions, computational treatment of subjective texts like reviews, comments, and opinions have suddenly erupted in the past ten years (Pang and Lee, 2008).

With sentiment analysis, the information system could be developed for information retrieval, opinion mining, and sentiment analysis. This new system can provide data visualization and immediate responses to negative comments and can reduce the risk of public crisis. Business practices use the opinion-oriented information system to make decisions and to improve their products and services.

In this case, the airline industry indeed needs such an opinion-oriented information system to monitor the quality of their service to the public. The following steps and technologies can be used for creating the system. The entire system could be integrated, with all of its features, into one piece. Then, each step can be connected to the others, automatically. All of the data retrieved from social media should be saved in a CSV file and then saved to the database for later processing. A script language can be used to create the opinion-oriented system, to mitigate the work load for the employees and to provide the ultimate support from computing 24/7. Keywords can be created for each dimension, in order to track service quality; they can be saved into different tables in a database. And then all of the sentiment analysis and statistical analysis can be performed, in order to support business decision making. The concrete steps are listed below:

1. Use Python code using Twitter API to get the tweets for one's own company or for competitors
2. Gather all of the tweets or parts of tweets from past time or real time. The company can limit the tweets to specified numbers
3. Use the sentiment analysis packages of R to get the sentiment score and the emotion for each tweet
4. Apply the proposed service quality index
5. Save all of the tweets and the sentiment scores to Microsoft SQL Server Databases
6. Manipulate the data and find the pattern of the current data
7. Visualize the date, create report (weekly, monthly, quarterly, annual), respond to the public
8. Make decisions, adjust business strategy, respond to public if necessary.

Table 3 illustrates the conceptual layer of the opinion-oriented information system proposed by this study. With this information system, businesses in service industries can have analyze results every day to help them to better understand and connect to their customers. When something goes wrong, the system will send an alert to the proper departments and will direct them to perform some actions, depending on the type of alert. This information system has good scalability due to its expandable ability. This system should be able to monitor multiple popular social media platforms, such as Twitter, Facebook, and Instagram. When retrieving social media data from those social media platforms, Python can be used to connect the API provided by the social media or to web-scrap the social media data. In addition, the keywords in each dimension of service quality can be modified at any time. Since more customers will use social media platform to communicate and stay tuned with businesses, the keywords may be changed by time. More Internet slang is likely to emerge in the future. For example, "LOL" means "laugh out loud"; it is a popular element of Internet slang. And "bump" is always used in the forums that move the posts or comments to the top on the first page. "Troll" is another word in Internet slang that used a lot today. "Trolls" are the people who want to take pleasure from starting disagreements and angering other people online. "I can't even" is another way to say, "I'm speechless." This phrase is used when you have no words to express to respond to incredible or unbelievable things. There is much more slang that is used on the Internet today, and there is likely to be more and more in the future. Thus, updating the keywords for each dimension of service quality will be necessary.

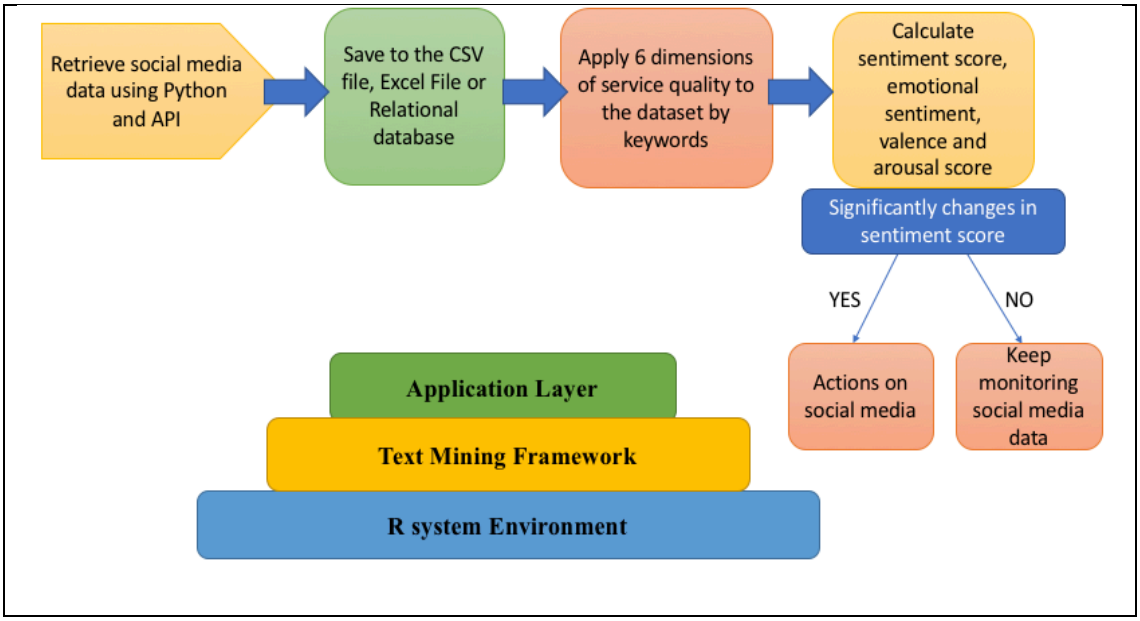

Figure 3. Conceptual Layer of Opinion-Oriented Information System

In this study, we can conclude that sentiment score from social media analysis could be used to predict the service quality in airline industry. Despite of the number of flights or the number of passengers or the size of airline companies, the service quality could be measured by monitoring social media platform and mining the textual social media data. The results can be used by business practitioners and used to adjust the marketing strategy with the marketing survey results. Hiring more business analysts and data scientists in the service-oriented companies are important to keep business advantages in the industry. To understand the customers' opinions, concerns and even their behaviors from the social media, it is valuable for all the business now. Sentiment score and emotional sentiment change were found to be consistent with the conclusion made by Wahba (2017). Negative sentiment could have a short-term effect on company's market value, but in the long run, may not have influence. Analyzing the social media data also can avoid the huge incident affects in public relationship.

ABSTRACT

Based on conservation of resources (COR) theory, this study first examines the impacts of three types of work-family integration activities (i.e., role segmentation, work-to-family integration, family-to-work integration) on employees' job performance and life satisfaction and, then, explores the moderating effects of individual and job characteristics on the relationships between these activities and job performance. Using a sample of 224 MBA students working full-time in China, the hypotheses derived from a proposed research model have been tested.

From Cost To Strategic Focused Offshore Information Systems Investment: The Impact Of Specialized Trainings In The Context Of National Culture

Gorkhali, Anjee
Old Dominion University
Agork001@odu.edu

Shrestha, Asim
Arkansas State University

ABSTRACT

The cost focused offshore Information Systems (IS) investment aims to reduce cost of IS investment, while the strategic focused approach concerns with increasing the rate of innovation in the offshore location. The relationship between specialized trainings and rate of innovation in offshore location was considered to be direct positive. However, this study identifies national culture as a moderator in this relationship and establishes that the trainings provided need to accommodate local culture This study uses the Hofstede's four-dimension model of national culture to examine the impact of cultural differences on individual learning behavior and therefore, trainings needed to address these differences.

KEYWORDS: Information Systems, National Culture, Rate of Innovation, Offshore Investment, and Learning Behavior

1. INTRODUCTION

Offshoring of Information Systems (IS) investment, referred to as the process of sourcing and coordinating tasks and business functions across national borders by Lewin, Massini and Peeters, (2009), has evolved from a risky strategy into a routine business decision (Dossani & Kenney, 2007). However, most of the firms take it as a growth opportunity to gain short-term competitive advantage rather than as an investment on achieving long-term competitive advantage (Lewin & Peters, 2006). This is due to the fact that the firm's aim in offshoring is often to exploit the low cost human resource available in the host countries (Lewin & Peters, 2006).

However, the problem with focusing on short-term gain is that it is, as the name suggests "short-term". As more firms engage in this strategy the competition gets higher and as a result the return on investment becomes smaller. This is the simple economic rule of demand and supply. As established in the field of business, the only sustainable way to gain long-term competitive advantage is by "innovation".

Extant literature explains that firms attempt to increase the rate of innovation by increasing R&D spending (Maskell et al., 2006; Shefer & Frenkel, 2005). Increased R&D investment enhances the ability of the offshore location to spend more in providing in-house work place related trainings as well as hire employees with highly specialized skills (Caramel & Agarwal, 2006). However, only 5% of the offshore location has shown significant increase in generating innovative technologies and products (Caramel & Agarwal, 2006). Therefore, according to Caramel & Agarwal (2006), firms attempt to increase the rate of innovation by providing highly

specialized trainings to the staff in the offshore location. This raises an important question on whether this relationship between rate of innovation and highly specialized trainings is exactly like presented in the extant literature or are there other contextual factors that have been overlooked by previous studies. This study focuses on national culture as an important factor having impact on learning behavior of offshore staff. Trainings provided by the firms are only as successful as the learning capacity of the staff participating.

This paper proposes national culture as an informal institutional factor that moderates the learning behavior of individuals involved in the offshore locations. National culture thus impacts the rate of innovation in the offshore locations and provides a more detailed explanation on why only handful of companies have been successful in achieving the desired rate of innovation. In short, this study aims to fill the aforementioned gap in literature by investigating the role of national culture in the relationship between specialized skills trainings and rate of innovation.

This paper is organized as follows: section 2 includes literature review, section 3 has theoretical development, section 4 discusses data analyses and methods, section 5 is the conclusion and section 6 discusses limitations of this research.

2. LITERATURE REVIEW

Firms try to achieve a long-term competitive advantage by treating the offshoring activity to achieve innovation (Carmel & Agarwal, 2006). Firms offshore core corporate activities including new system and products termed as “proactive strategic focus” (Carmel & Agarwal, 2006, p. 67). The market norm is that firms offshore non-core activities like support and product enhancements termed as “proactive cost focus” (Carmel & Agarwal, 2006, p.67). The difference between these two stages is that the objective during “proactive cost focus” stage is to reduce cost while that of the “proactive strategy focus” is to gain long term sustainable competitive advantage through higher rate of innovation (Carmel & Agarwal, 2006). In this process of shifting from proactive cost to proactive strategic focused phase, the literature available is focused on formal institutional factors such as inter-organizational level information exchange and the economical and financial issues such as increasing R&D investment in the offshore locations which would then be invested in establishing research facilities and providing highly specialized trainings and hiring world class skills (Carmel & Agarwal, 2006; Luo, 2005; Wilhelm, 2011). The current studies operate under a basic assumption that all offshore locations can achieve the status of “proactive strategy focus” stage if world-class talent are hired and provided with highly specialized trainings in the work place, regardless of the environment they are operating in. According to Caramel & Agarwal (2006) only 5% of the firms, that are attempting to increase rate of innovation by increasing number of specialized trainings to their workforce are successful in achieving this target. Their success has been credited to having superior inter-organizational information exchange and past experience in handling offshore activities. This implies that specialized trainings provided at work place do not play a role in increasing rate of innovation of that location. The important question here is, does this result hold true for all environment/host country? The problem is that the above conclusion was based on a finding that there is a direct relationship between specialized trainings and rate of innovation. This direct relationship does not consider impact of any other environmental factors.

The nature of information systems is such that highly specialized skills play an important role in rate of innovation (Black & Lynck, 2001). However, according to Caramel & Agarwal, (2006), highly specialized trainings provided to staff has not resulted in higher rate of innovation in all of

the offshore locations. Learning environment plays an important role in the success of learning program. However, learning is a function of one's individual characteristics and environment, and it is influenced by national culture (Bandura, 1977; Magini, Paolino, Cappetta and Proserpio, 2013). The 5% firms that are successful in achieving their target might have understood the importance of incorporating differences in national cultural dimension in their trainings. This factor has not been examined yet in the literature. Therefore, crediting the

3. THEORETICAL DEVELOPMENT/MODEL

3.1. Training and Rate of Innovation

Extant literature explains that firms attempt to increase the rate of innovation by increasing R&D spending (Maskell et al., 2006; Shefer & Frenkel, 2005). Increased R&D investment enhances the ability of the offshore location to spend more in building better research facilities, providing in-house work place related trainings as well as hire employees with highly specialized skills (Caramel & Agarwal, 2006). The constantly changing requirements and technologies required in IS projects make the option of hiring specialized skills/workforce for every new project less feasible both financially and operationally (Feeny & Willcocks, 1998; Nuseibeh & Easterbrook, 2000). Furthermore, the newly hired workforce will also be provided with workplace related trainings to update them with the required technologies and methods used in the firm. Firms rely on specialized trainings to achieve a higher rate of innovation rather than hire new work force for every new project or upgrade of their system. Trainings therefore, play an important role in the performance output of an employee and impact the rate of innovation (Black and Lynck, 2001).

However, as discussed in earlier section, most firms are unable to generate higher level of innovative technologies and products just through specialized trainings (Caramel & Agarwal, 2006). This raises an important question on whether the relationship between rate of innovation and highly specialized trainings is as direct as presented in the literature or there are other contextual factors that have been overlooked by previous studies. Considering the relationship between training and rate of innovation as a closed system without any interference from the environment does not provide a complete explanation. A detailed analysis will be helpful in understanding the environmental (informal institutional) factors that might play an important role in defining the relationship.

Trainings provided by the firms are only as successful as the learning capacity of the staff participating in the program. Learning ability is a function of one's personality and environment (Bandurra, 1977; Magini et al., 2013). National culture plays an important role in shaping an individual's personality with respect to a social group (Hofstede, 1983). Therefore, the role of national culture cannot be neglected when studying the success of learning program (trainings) regardless of the nature of trainings conducted.

3.2. National Culture as A Moderating Factor

Specialized skills, play an important role in a successful IS project (Black & Lynck, 2001). IS staff working on the project can already have these skills or they can be trained in these skills. A firm expects increased rate of innovation as a result of successful training (Black & Lynck, 2001). The success of the training depends on the ability of a trainee to absorb and assimilate the knowledge learned during the training (Downey, Wentling, Wentling & Wadsworth, 2005). The ability to absorb and assimilate the knowledge gained highly impacts an individual's learning behavior (Magini et al., 2013). According to Bandurra (1977), one's behavior is a

function of one's personality and environment. Personality and environment is in turn is a function of national culture as according to Hofstede (1991), it is "defined culture as the "training or refining of one's mind from social environments in which one grew up" (p.4). Therefore, it has an impact on learning behavior of an individual when studying the individual behavior with respect to a human group. National culture is the collective programming of the mind that distinguishes the members of one human group from another (Hofstede, 1983). In other words, differences in national culture impact the perception of an individual and in turn their perception towards a learning module/method/technique. This difference in individual perception will impact how easily or to what extent the learning module (specialized trainings) will be successful in helping the staff understand and implement the subject matter of the trainings and therefore result in a higher output (rate of innovation in this case). Hence, it can be suggested that national culture plays a moderating role in the relationship between specialized trainings and rate of innovation. If the specialized training modules incorporate the difference in the local cultural norms into its training module, the relationship becomes stronger and should result in a higher rate of innovation compared to training modules that does not incorporate it.

This study will use Hofstede's (1983), four dimension of national culture to present why customized trainings are needed that reflect the difference in local culture. The four dimension of national culture are: individualism/collectivism, uncertainty avoidance, masculinity/femininity and power distance. For example: the perception of individual in an individualistic society is different from an individual in a collectivist society. Trainings that focus on certain characteristic of a human behavior related to individualistic society will positively strengthen the relationship between trainings and rate of innovation resulting in a higher rate of innovation. However, if the same training module is utilized in a collectivist society, the relationship might not be positively strengthened and a higher rate of innovation is not achieved. In a collectivist society a training module designed around the cultural norms of a collectivist society will be more successful. For a list of characteristics of each dimension of national culture, please refer to Appendix A.

3.2.1. Individualism/Collectivism

According to Hofstede (1983), individualism/collectivism pertains to the degree to which individuals are integrated into groups and their feeling of being in a group. According to Straub (1994), perceived social acceptance impacts acceptance of an individual in a collectivist society whereas in an individualistic society, individuals' self-perception triumphs over social perception. The characteristics explained below for both individualistic and socialistic society is based on Hofstede (1983).

One of the major characteristics of a collectivist society is that individuals have close ties with group and value joint efforts and group rewards. They interact in an interdependent, cooperative mode and have strong interpersonal ties. Therefore, group perception triumphs over individual perception. However, for an individualistic society where social ties are not strong and interaction is on individual, competitive basis, trainings that involve group interaction or simulates group working environment will not be perceived to be valuable. Furthermore, individualistic society is characterized by low loyalty to other people and institutions while a collectivist society is characterized by high loyalty to other people and institutions. Similarly, individual opinions and behavior are tolerated in individualistic society whereas in a collectivist

society behavioral conformity is expected. Therefore, as explained in earlier section, due to the difference in characteristics of society that impacts the individual perception towards a certain

learning method/techniques, one single training module/technique can not be successful universally. The difference in characteristics of an individual from different society leads to difference in their learning behavior and therefore, a difference in the impact of workplace training in rate of innovation. An individual from an individualistic society where individual ideas are encouraged will tend to bring in more innovation than an individual from a collectivist society where the group ideas are preferred. Therefore, group agreement is sought out and hence, rate of innovation will not be high. The local individualism/collectivism norm will moderate the outcome of the training and therefore, the relationship between training and rate of innovation.

> **Hypothesis 1:** Individualism/Collectivism dimension of national culture impacts the relationship between workplace training and rate of innovation. Individualistic culture will have a positive moderating effect and collectivist culture have negative moderating effect.

3.2.2. Uncertainty avoidance (UA)

According to Hofstede (1983), it is a cultural trait that determines the risk taking nature of the people in a country. The country where this index is high implies that the population is more risk averse while the country with low uncertainty avoidance index imply that the population is more risk seeking. The reason behind uncertainty avoidance is because of the fear of unknown effects of new technologies or products. This makes people more resistant towards change (Hill, et al, 1998). Specialized education and trainings help alleviate such fear of unknown from people (Veiga et al., 2001), therefore the impact of trainings that provide high specialization will be higher on rate of innovation in a high risk averse society than on a low risk averse society.

The characteristics explained below for both high and low risk-averse society is based on Hofstede (1983). High uncertainty avoidance society is characterized by need for formal structure, in other words, formal rules and regulations while low risk averse society tend to act beyond the structure of formal rules and regulations. Another character associated with high risk averse society is belief in experts and their knowledge. A low-risk averse society has weak faith in people and institutions while a high-risk averse society has strong faith in institutions. As explained in earlier section, due to the difference in characteristics of society that impact the individual perception towards a certain learning method/techniques, one single training module/technique cannot succeed across all different cultures. The difference in characteristics of an individual from different societies leads to difference in their learning behavior and therefore, a difference in the impact of workplace training on the rate of innovation. An individual in low risk averse society is encouraged to bring in ideas of change and therefore aid in generating higher rate of innovation. The local uncertainty avoidance norm will moderate the outcome of the training and therefore, the relationship between training and rate of innovation.

> **Hypothesis 2:** Uncertainty Avoidance dimension of national culture impacts the relationship between workplace training and rate of innovation. Low risk averse societal culture will have a positive moderating effect on the relationship and high risk averse societal culture will have negative moderating effect.

3.2.3. Masculinity (M)

According to Hofstede (1983), masculine societies place greater emphasis on individual achievement and rewards than do feminine societies. Therefore, training modules that emphasize rewards for individual achievement will become more successful in masculine

society whereas it will not impact the success of training in feminine societies. The characteristics explained below for both masculine and feminine society is based on Hofstede (1983).

Masculine societies are characterized by features like emphasis on individual achievement and encouragement of independent thought and action, while societies that are more feminine focus more on solidarity and service as well as cooperation. Furthermore following social norms is a matter of moral obligation for a feminine society while masculine society emphasizes in independent thought and actions. Therefore, the individuals in these two different societies will react differently to different learning environment. For example, an individual from masculine society will put high emphasis on individual achievement and is more likely to work towards achieving individual goals and progress and upon seeing more progress and achievement through innovation is more likely to use the knowledge from trainings to achieve this goal. However, an individual from a feminine society will put more emphasis on solidarity and service. Trainings that focuses on solidarity and service will become more successful in such a society. Similarly, individuals belonging to masculine society will be more inclined to have independent thoughts and action and therefore, a training environment that encourages independent thoughts and actions will be more successful.

As explained in earlier section, due to the differences in characteristics of society that impact the individual perception towards a certain learning method/techniques, a one-size fits all approach to specialized trainings does not work. The difference in characteristics of individuals from different societies leads to difference in their learning behavior and consequently to a difference in the impact of workplace training in rate of innovation. Individuals from masculine society will be encouraged by the environment to work towards achieving individual goals and achievements and if rate of innovation is tied to individual goals and achievements, then they are more likely to turn in more innovation. Local masculinity/femininity norm will thus moderate the outcome of the training and therefore, the relationship between training and rate of innovation.

> **Hypothesis 3:** Masculinity/Femininity dimension of national culture impacts the relationship between workplace training and rate of innovation. Masculine societal culture will positively moderate the relationship while feminine societal culture will have a negative moderating effect.

3.2.4. Power distance (PD)

According to Hofstede (1983), power distance index represents importance of hierarchy, vertical communication patterns, centralization of power, resistance to change and control over subordinates. The characteristics explained below for both high and low power distance society is based on Hofstede (1983). The society with high power distance is characterized by norms for differential prestige, power and wealth, whereas in a low power distance society egalitarian relationships prevail. Therefore, while organizing a training module that include staff in different hierarchy of power will become more successful in a society with low power distance, such

training modules are less likely to succeed in a society with high power distance. Furthermore, low power distance society is characterized by norm for cooperation, interdependence, solidarity and affiliation, group trainings and sharing of information.

The norm of conflict in high power distance society is a part of national culture and innovation requires cooperation at individual and higher levels. Thus a high power distance culture in society negatively affect rate of innovation. However, Hasan & Dista (1999), argue that when employees have or gain highly specialized skills, they gain more equity with managers and thereby reduce the effect of power distance. Providing staff with specialized skills will help in reducing power distance resulting in a positive impact on rate of innovation. However, local managers may be wary of such trainings that reduce power distance. Therefore, in these societies, trainings designed for managers and employees that are conducted in group is more likely to reduce the power distance and therefore have higher positive impact on the rate of innovation. A low power distance society is more encouraging to innovation due to its collaboration and open to discussion characteristics while comparatively a high power distance society that is characterized by closed-door discussion is not encouraging of innovation. The local power distance norm will moderate the relationship between training and rate of innovation.

> **Hypothesis 4:** Power distance dimension of national culture impacts the relationship between workplace training and rate of innovation. A low power distance societal culture will positively moderate the relationship while a high power distance societal culture will negatively moderate the relationship.

A model representing the impact of all national culture on the relationship between training and rate of innovation is presented in Appendix D and E.

4. RESEARCH DESIGN

4.1. Sample

This study uses a sample of the top 25 largest U.S. Fortune 500 firms. Out of the 500 firms listed in the Fortune 500 magazine, the 25 largest firms that have at least 10 offshore IS investments are selected for this study. The list of the largest U.S firms is selected from Fortune 500 list that is compiled and published by Fortune magazine. It ranks 500 of the top U.S firms on the basis of total revenues reported. The firms selected are from both technology and non-technology groups. The assumption behind choosing both technology and non-technology firms is that technology firms might be more active in offshoring and so behave differently than non-technology firms. The firms selected have U.S based headquarters. To select firms amongst the Fortune 500 that have at least 10 offshore IS investments, event study is carried out, where the event (announcement by firms to invest in offshore location) is collected from firms monthly/annual reports which is publicly available on Bloomberg and or company website. Furthermore, a survey questionnaire is sent out to the executives in the headquarters to verify the total number of their offshore subsidiaries.

The total number of offshore subsidiaries studied, from the top 25 firms selected above, is 250. The time frame of study is between January 2014 and December 2015. The total number of executives in headquarters that were surveyed is 50 and the total number of managers surveyed in offshore subsidiaries is 500. The response rate from this survey is 14.3%.

4.2. Variables & Measures

4.2.1. Dependent Variable

Number of innovation/year (NumOfInno): The number of innovation per year is measured as the total number of new product and process introductions, Rothaermel and Hess, (2007) describe

it as firm's innovative capability. New product/process introductions are those products/process that have a significant design change (Parente & Geleilate, 2015). Therefore, this variable consists of the total number of incremental and completely new products/processes introduced in a given year, as not all product/process introduction can be considered as innovation. In the first phase, offshore managers were surveyed to provide the total number of new product/process introduced in the past year. The survey questionnaire is presented in Appendix B. In the second phase, the same questionnaire is sent to managers in headquarters. This step is carried out to verify the numbers provided by the managers in both offshore subsidiaries and headquarters. The questionnaire was back translated to avoid translation errors. There are 4 items in the scale.

4.2.2. Independent Variable

Total Number of Trainings (NumOfTrainings): This variable is adapted from the eight item scale presented by Gallivan, Spitler and Kufaris (2005). It measures the total number of training sessions attended by a staff in a particular offshore subsidiary. Each session is measured by number of hours and each session can range between 2 to 4 hours. Traditionally, this variable is supposed to have a direct positive impact on rate of innovation. However, this study proposes that the impact of this variable on rate of innovation is moderated by Hofstede's four dimension of national culture. The eight scale measure in presented in APPENDIX B.

4.2.3. Moderating Variable

Individualism/Collectivism (IC): This study adapts the Individualism/Collectivism measure proposed by Hofstede, 1980, pp. 403-410 and further validated by Yoo, Donthu and Lenartowicz (2011). This new set of questionnaire has 6 items that measure the collectivism of the society and present that high score in this dimension pertains to collectivist society while the low score pertains to individualistic society.

Uncertainty Avoidance (UA): This study adapts the Individualism/Collectivism measure proposed by Hofstede, 1980, pp. 403-410 and further validated by Yoo, Donthu and Lenartowicz (2011). This new set of questionnaire has 5 items that measure the uncertainty avoidance norm of the society and present that high score in this dimension pertains to high risk averse society while the low score pertains to low risk averse society.

Masculinity (M): This study adapts the Individualism/Collectivism measure proposed by Hofstede, 1980, pp. 403-410 and further validated by Yoo, Donthu and Lenartowicz (2011). This new set of questionnaire has 4 items that measure the masculinity/femininity norm of a society and present that high score in this dimension pertains to masculine society while the low score pertains to feminine society.

Power Distance (PD): This study adapts the Individualism/Collectivism measure proposed by Hofstede, 1980, pp. 403-410 and further validated by Yoo, Donthu and Lenartowicz (2011). This new set of questionnaire has 4 items that measure the power distance of the society and present that high score in this dimension pertains to high power distance while the low score pertains to low power distance.

All items in the questionnaire and source and validity is presented in APPENDIX C. 4.2.4. Control Variables

Firm Structure: According to Teece (1994), a firm's structure (formal or informal) has a direct impact on rate of innovation of the firm. As we want to study the moderating role of national culture on the relationship between trainings and rate of innovation, firm structure is controlled so as to remove the potential impact that can be caused by this variable on the relationship.

Firm Age: According to Sorensen and Stuart (1999), firms that have been in existence for longer period of time will have higher rate of innovation than the firms that are newer. Furthermore, they mention that this is due to firm learning from their experience and knowing the patterns to achieve higher rate of innovation. Therefore, in this study firm age is controlled. This is done to exclude the potential impact of firm age on rate of innovation for firms that have been in existence longer than other firms in the sample.

4.3. Data Collection

The data was collected in two separate sets of interviews. One was conducted on executive level in headquarters and next on the executive level in offshore subsidiaries. The executive level interviews were conducted in two steps: one for the executives at headquarter that was conducted on 50 executives from 25 firms. The second phase of executive questionnaire survey was sent to the 500 managers in the offshore subsidiaries. These interviews were supplemented with follow-up messages and conversations. The respondents were "head of global software engineering", "head of enterprise development services", and "director of global IS planning". Questionnaire data was supplemented with publicly available data about the firms and was analyzed utilizing qualitative methods. In the first analysis, factual answers to questions were analyzed, such as the extent of offshoring, decision drivers and rationale for site decisions. In the second analysis, more concrete answers were analyzed such as the extent of customization of trainings provided to different locations for both staff and local managers.

4.4. Data Analysis

A pilot study was conducted on a sample of 4 executives from offshore subsidiaries and 2 from headquarters. The necessary adjustments were made to the questionnaires. The sample survey was then used to conduct a confirmatory factor analysis to validate the developed model and once the validity of the model was established, the final survey is conducted. The chi-square fit, RMSEA and CFI fit were checked for model validity. The RMSEA value is desired to be below 0.8 (Browne and Cudeck, 1998) and CFI above 0.9 (Bagozzi and Yi, 1988). The final survey will be conducted by sending the adjusted questionnaire to all of the potential respondents (50 executives in headquarters and 500 managers in offshore subsidiaries). The result of the survey is then used to run the regression model, the first model consists of the main effects variables only and is shown below:

$$N\text{umOfInno} = \beta 0 + (\beta 1 * T\text{raining}) + \varepsilon \quad (1)$$

Then the interaction effects will be introduced in the second step. The reason behind this is to check whether the moderation effect introduced by the four dimension of national culture are significant or not. The regression equation to analyze hypothesis 1 through 4 in this study is presented as:

$$NumOfInno = \beta 0 + (\beta 1 * Training) + (\beta 2 * (Training * IC)) + (\beta 3 * (Training * UA) + (\beta 4 * (Training * M)) + (\beta 5 * (Training * PD)) + \varepsilon \quad (2)$$

The R^2 value for both models are noted and compared to reach a conclusion regarding whether the hypothesis are supported or not. The expected result from this test is that all the interaction effect is significant, thereby supporting all the hypothesis and therefore suggesting that national culture does moderate the relationship between trainings and rate of innovation.

5. CONCLUSION

IS investment can be considered different from other types of business investment, since technology is same worldwide. However, it is people who use the technology, therefore neglecting the "human behavior" out of the environment may not be able to project a complete picture. The results expected from this study will highlight the importance of "people" factor in IS investment. This study supports national culture as an informal institutional factors that impacts the learning behavior of an individual. Any relationship that studies an individual learning behavior with respect to a group without considering the impact of national culture will not be able to properly address the complete phenomena. Therefore, taking "national culture" into consideration, this study will be able to explain some of the reasons behind only some firms being able to achieve the desirable level of innovation while others lagging behind.

6. LIMITATIONS

6.1. Data Sample

The sample included are divided into technological and non-technological firms and has not been further categorized into manufacturing or service firms, therefore, a detailed analysis of the moderating impact on different kinds of firms is not possible. It is difficult to check whether firm characteristics play any role in the relationship.

6.2. Method

This study uses Hofstede's four dimension of national culture that was established in 1980. The more newer version that has six dimension has not been included in this study therefore, this limits the ability of this study to predict other dimensions in national culture that might impact the relationship between rate of innovation and trainings.

6.3. Model

The only moderating effect that has been examined here is that of national culture and therefore, this study is not able to analyze whether it is just the national culture that has the moderating effect on the relationship or there are other factors that moderated the relationship along with national culture. For example: Would Composition of Top Management moderate this relationship, how about the role of a firm's experience in offshore IS investment? These factors might be able to negate the moderating role of national culture on the relationship, but this study does not venture into studying these additional factors.

APPENDICES
APPENDIX A

Individualism	Collectivism
• Value individual accomplishment • Tolerate individual behavior and opinion • Interact on an individual competitive basis • Loose interpersonal ties • Low loyalty to other people and institutions	• Value joint efforts and group rewards • Norms for behavioral conformity • Interact in an interdependent, cooperative mode • Strong interpersonal ties • High loyalty to other people and institutions
High Risk Averse	Low Risk Averse
• Need for formal rules and regulations • Norm for compromise • Strong faith in institutions • Belief in experts and their knowledge	• High tolerance for deviance • Norm for conflict • Weak faith in people and institutions
High Power Distance	Low Power Distance
• Norms for differential prestige, power and wealth • Norm for conflict • Authoritarian norm	• Prevailing egalitarian relationship • Norm for cooperation • Norms for interdependence, solidarity and affiliation
Masculinity	Femininity
• Value individual achievement • Norms for independent thought and action	• Norms for solidarity and service • Norm for cooperation • Social norms honoring and moral obligation

Total Number of Trainings	• Over the past year, how many trainings were conducted on the following topics? a) An updated word processor applications program such as the Word? b) An updated spreadsheet application program such as Excel? c) A special purpose application system (for example: case tracking or development) d) The local Area Network e) Any updated internet browser For each item in this section, response choices were: 1) None at all 2) One session (2-4 hours)	(Gallivan, Spitler and Kufaris, 2005)

	3) Two sessions (4-8 hours) 4) Three sessions (8-12 hours) 5) Four sessions (12-16 hours) 6) Five sessions (16-20 hours) More than five sessions	

APPENDIX C
Power Distance

People in higher positions should make most decisions without consulting people in lower positions.
People in higher positions should not ask the opinions of people in lower positions too frequently.
People in higher positions should avoid social interaction with people in lower positions.
People in lower positions should not disagree with decisions by people in higher positions.
People in higher positions should not delegate important tasks to people in lower positions.

Uncertainty Avoidance
It is important to have instructions spelled out in detail so that I always know what I'm expected to do.
It is important to closely follow instructions and procedures.
Rules and regulations are important because they inform me of what is expected of me.
Standardized work procedures are helpful.
Instructions for operations are important.

Individualism/Collectivism
Individuals should sacrifice self-interest for the group.
Individuals should stick with the group even through difficulties.
Group welfare is more important than individual rewards.
Group success is more important than individual success.
Individuals should only pursue their goals after considering the welfare of the group.
Group loyalty should be encouraged even if individual goals suffer.

Masculinity/Femininity
It is more important for men to have a professional career than it is for women.
Men usually solve problems with logical analysis; women usually solve problems with intuition.
Solving difficult problems usually requires an active, forcible approach, which is typical of men.
There are some jobs that a man can always do better than a woman.

Reliability Of This Scale:

- .91 (power distance) for Americans
- .89 (collectivism) for Koreans
- The five-dimensional measurement model exhibited an excellent fit.
- The model's χ^2 with 289 degrees of freedom is:
  - 496.27 for Americans
  - 416.34 for Koreans.
- RMSEA is:
  - .058 for Americans
  - .039 for Koreans.
- CFI and TLI are:
  - .91 for Americans
  - .94 for Koreans
- The item loadings to their constructs ranged from:
  - .43 (t-value = 5.97) to .85 (t-value = 15.10) for Americans
  - .56 (t-value = 4.71) to .87 (t-value = 14.24) for Koreans.

ABSTRACT

The single-machine flow-rack automated storage and retrieval system (AS/RS) has high storage density, high floor space utilization, low investment cost and low operational cost. Unit-loads in each bin of the single-machine flow-rack follows the first-in-first-out (FIFO) rule, which implies that inappropriate stored sequence of unit-loads brings extra travel time for restoring blocking unit-loads. In duration-of-stay (DOS) storage policy, the arrivals and departures of all unit-loads within a whole planning horizon are determined in advance. Therefore, a grouping-matching heuristic assigns FIFO unit-loads to the same group in the grouping step and matches group with most unit-loads to the bin closest to the pick-up/drop-off (P/D) station in the matching step. Simulation experiments are conducted to evaluate the performance of the grouping-matching heuristic.

KEYWORDS: single-machine flow-rack, AS/RS, duration-of-stay, storage assignment

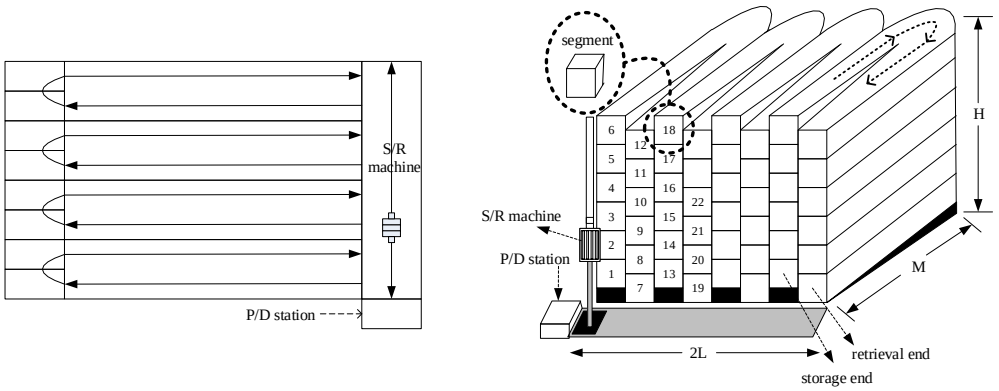
INTRODUCTION

Single-machine flow-rack AS/RS (Sari & Bessnouci, 2012) has high storage density and low implementation and operational costs since the depth movement of unit-loads in each bin is driven by the gravity. A single-machine flow-rack consists of multiple columns and rows of U-shaped bins as illustrated in Figure 1. Each bin has two adjacent ends, one is the storage end and another is the retrieval end. Unit-loads are stored to the storage end of a bin, slide to the retrieval end driven by the gravity and retrieved from the retrieval end. Since storage and retrieval ends located on the same face, one S/R (storage/retrieval) machine can perform storage and retrieval operations for a single-machine flow-rack AS/RS. Unit-loads in each bin follow the FIFO rule, which requires the appropriate stored sequence to avoid blocking unit-loads in each bin.

In DOS storage policy (Goetschalckx & Ratliff, 1990; Chen, Langevin & Riopel, 2010), arrivals and departures of unit-loads are known, based on which proper sequence of stored unit-loads can be generated in each bin to avoid blocking unit-loads. As well, to store as many unit-loads as possible to bins near the P/D station can save the total travel time of warehouse operations.

In this paper, a grouping-matching heuristic is applied for the storage assignment in a single-machine flow-rack AS/RS with DOS storage policy. In the grouping step, FIFO unit-loads are assigned into the same group based on the arrivals and departures of unit-loads. In the matching step, groups are matched to bins based on the number of unit-loads in a group and the travel time between the bin and the P/D station. A greedy-based heuristic is designed as the benchmark in this paper. Simulation experiments are conducted for the performance evaluation.

Figure 1: The structure of single-machine flow-rack AS/RS



PROBLEM DESCRIPTION

Assume a single-machine flow-rack AS/RS consists of L-column and H-row of bins as shown in Figure 1. There are a total of K bins where $K = LH$. Each bin can simultaneously store at most $2M$ unit-loads. The storage end of bins in the x^{th} column are labeled as $(2x – 2)H + 1$, $(2x – 2)H + 2$, …, $(2x – 2)H + H$ from the P/D station to the highest row where $x = 1, 3, …, L$. As well, the retrieval ends of bins in the x^{th} column are labeled as $(2x – 1)H + 1$, $(2x – 1)H + 2$, …, $(2x – 1)H + H$ from the P/D station to the highest row where $x = 1, 3, …, L$. An S/R machine performs the storage and retrieval operations. Let t_h and t_v be the travel times between horizontal and vertical adjacent ends, respectively. The travel times from the storage end and the retrieval end to the P/D station of a bin locates at x^{th} column and y^{th} row are $\max\{(2x – 1)t_h, (y - 1)t_v\}$ and $\max\{2xt_h, (y-1)t_v\}$, respectively. Blocking unit-loads are restored to the storage end of the same bin, which implies that the travel time of restoring a blocking unit-load is $2t_h$. Based on above estimations, the travel times of storage and retrieval operations can be easily calculated.

For the DOS storage policy, a planning horizon is divided into a number of T periods, which are denoted as 1, 2, ..., T. Let {1, 2, ..., N} be the set of unit-loads. A tuple of $[a_i, d_i]$ represents that a unit-load i is stored at period a_i and retrieved at period d_i. It can be known that $1 \le a_i < d_i \le T$. The length of a period is much longer than the total travel time of warehouse operations in the period, which ensures that all warehouse operations can be finished within the period. As well, the number of simultaneously existing unit-loads is less than or equals to the number of segments to let all unit-loads can be stored to the single-machine flow-rack. For period t, let $S^t = \{i_1, i_2, …, i_n\}$ be the sequence of incoming unit-loads where $a_{i_1} = a_{i_2} = . . . = a_{i_n} = t$ and $d_{i_1} \le d_{i_2} \le . . . \le d_{i_n}$. Correspondingly, the set of outgoing unit-loads is $R^t = \{j_1, j_2, …, j_m\}$, where $d_{j_1} = d_{j_2} = . . . d_{j_m} = t$.

In each period, outgoing unit-loads are retrieved before storing incoming unit-loads. In other words, the S/R machine performs retrieval operations then conducts storage operations. The primary aim of storage assignment in a single-machine flow-rack AS/RS with DOS storage policy is to minimize the average travel time of storage and retrieval operations.

PROPOSED METHODS

Greedy-based heuristic

Greedy-based heuristic is a simple and straightforward way to solve the optimization problems. It can get a feasible solution in a short time. For outgoing unit-loads, greedy heuristic generates retrieval operations based on the ascending order of bins. Blocking unit-loads are directly restored to the storage end of the same bin. After all outgoing unit-loads have been retrieved, storage

operations are generated. Assuming an incoming unit-load i with $[a_i, d_i]$, there is a bin k has a number of b unit-loads where $0 \le b \le M$-1. For a unit-load i stored to bin k, the number of blocking unit-loads of i is the number of unit-loads depart after period d_i stored in bin k. Therefore, the greedy-based heuristic chooses a bin closest to the P/D station from a bin set, in which all bins have empty segments and minimal blocking unit-loads of i. The Greedy heuristic is detailed in Algorithm 1.

Algorithm 1 Greedy

Input: N
Output: storage and retrieval operations
$t \leftarrow 1$;
while ($t \le T$) **do**
  Build S^t and R^t;
  while (R^t is not empty) **do**
    Let j be an outgoing unit-load in R^t;
    Restores blocking unit-loads, retrieve j, $R^t \leftarrow R^t - \{j\}$;
  while (S^t is not empty) **do**
    $i \leftarrow$ head(S^t), $S^t \leftarrow S^t - \{i\}$;
    Build a bin set B, in which all bins have empty segments and minimal blocking unit-loads of i;
    Select bin k closest to the P/D station of B;
    Store i to bin k;
  $t \leftarrow t + 1$;
  return.

The Grouping-matching heuristic

To store FIFO unit-loads to the same bin can avoid blocking unit-loads. Two grouping heuristic, the forward-grouping heuristic (FG) and the backward-grouping heuristic (BG), have been proposed to assign FIFO unit-loads to the same group (Chen, Li & Gupta, 2016).

FG selects a unit-load with minimal sum of a_i and d_i as the seed of a group and appends FIFO unit-loads with smallest d_i one by one to the end of group. The number of simultaneous existing unit-loads in each group is less than or equals to $2M$. Based on above mechanism, a total of K groups are generated at most. However, it cannot guarantee that all unit-loads are assigned to a certain group. In this case, FG must re-organize some of groups to let all unit-loads be assigned to a certain group. So, the remaining unit-loads are appended sequentially to the group containing the smallest number of unit-loads. The FG is detailed in Algorithm 2, in which o(G, j) represents the number of unit-loads in group G simultaneously existing with unit-load j.

Algorithm 2 FG

Input: N
Output: groups
for (g = 1**..**K) **do**
  $i \leftarrow \arg\min_{i' \in N}\{a_{i'} + d_{i'}\}$, $G_g \leftarrow \{i\}$, $N_G \leftarrow \{j | a_j \ge a_i, d_j \ge d_i, \text{o}(G_g, j) \le 2M-1\}$
  while ($N_G \ne \{\}$) **do**
    $j \leftarrow \arg\min_{j' \in NG}\{d_{j'}\}$, $G_g \leftarrow G_g \cup \{j\}$, $i \leftarrow j$, $N_G \leftarrow \{j | a_j \ge a_i, d_j \ge d_i, \text{o}(G_g, j) \le 2M-1\}$
  $N \leftarrow N - G_g$
  if (N = {}) **then**
    return.
while ($N \ne \{\}$) **do**
  $g \leftarrow \arg\min_{k \in \{1,\ldots,K\}}\{|G_k|\}$, $N \leftarrow N \cup G_g$, $G_g \leftarrow \{\}$
  sort $N = \{1, \ldots, n\}$ where $a_1 \le a_2 \le \ldots \le a_n$ and $d_i \le d_{i+1}$ where $a_i = a_{i+1}$
  for (i = 1..n) **do**
    if (o(G_g, i) ≤ $2M$–1) **do**

13: $G_g \leftarrow G_g \cup \{i\}$
14: $N \leftarrow N - G_g$
15: **return.**

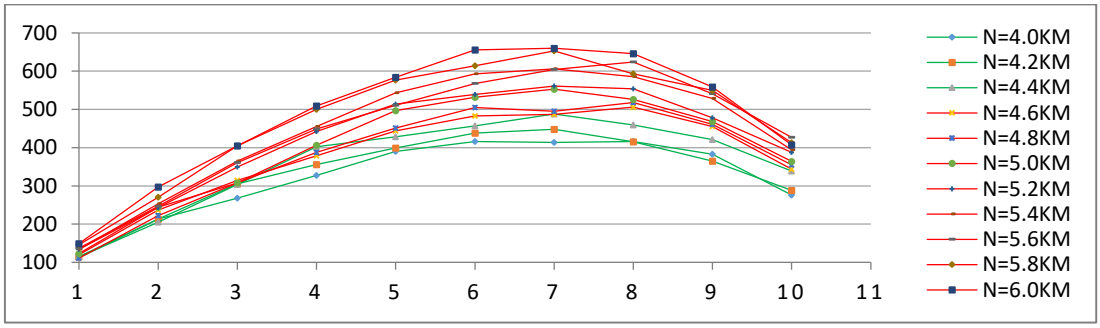
BG selects a unit-load with maximal sum of a_i and d_i as the seed of a group and appends FIFO unit-loads with maximum d_i one by one to the head of group. The number of simultaneous existing unit-loads in each group is also less than or equals to $2M$. Based on above mechanism, a total of K groups are generated at most. However, it also cannot guarantee that all unit-loads are assigned to a certain group. In this case, BG applies the same mechanism of FG to let all unit-loads be assigned to a certain group. In short, BG applies "$i \leftarrow \arg\max_{i' \in N}\{a_{i'} + d_{i'}\}$, $G_g \leftarrow \{i\}$, $N_G \leftarrow \{j | a_j \le a_i, d_j \le d_i, o(G_g, j) \le 2M-1\}$" and "$j \leftarrow \arg\max_{j' \in NG}\{d_{j'}\}$, $G_g \leftarrow G_g \cup \{j\}$, $i \leftarrow j$, $N_G \leftarrow \{j | a_j \le a_i, d_j \le d_i, o(G_g, j) \le 2M-1\}$" to replace Step 2 and 4 of Algorithm 2.

After the grouping step, groups are matched to bins. To maximize the number of unit-loads allocated in the first one, the first two, …, the first K bins can minimize the total travel time for storage and retrieval operations (Goetschalckx & Ratliff, 1990). Therefore, a group with the most unit-loads is matched to a bin closest to the P/D station. The aim of matching step is to let as many unit-loads as possible be stored to bin near the P/D station.

EXPERIMENTAL RESULT AND ANALYSIS

In simulation experiments, 50 bins in the single-machine flow-rack AS/RS were set, where $L = 5$, $H = 10$, $t_h = 2.0$s and $t_v = 1.0$s. The number of stored unit-loads in each period must be smaller or equal to the number of segments, i.e., $2KM$. Let $M = 5$. It can be known that the number of segments is 500. Therefore, the maximum number of stored unit-loads in a period must be smaller than or equal to 500. Figure 2 illustrates the average number of stored unit-loads for each period under different values of N. The curves reveal that when $N \ge 4.6$KM, the number of stored unit-loads easily exceeds the limitation of 500. Therefore, let $N = 4.4KM$ in simulation experiments. Let $M = \{10, 14, 18, 22\}$ and $T = \{11, 13, 15, 17\}$. It needs to analyze 16 combinations of M and T and generates 100 instances for each combination.

Figure 2 The number of unit-loads stored in AS/RS under different *KM* coefficients for each period



The number of incoming unit-loads in each period is randomly generated. For unit-load i arrives at period a_i, let d_i be uniformly distributed in the interval of $[a_i + 1, T]$. All simulation experiments are coded in C++ and executed on a laptop with 2.5GHz CPU and 8GB CPU.

Table 1 demonstrates the experimental results of the greedy and the grouping-matching heuristics. "*Cost*" represents the average travel time to store and retrieve a unit-load, "*Block*" indicates the average number of blocking unit-loads, "*ARPD*" is the performance measure of of the algorithm ($Z_{min} = \min\{Z_G, Z_{FG}, Z_{BG}\}$, $ARPD_G = (Z_G - Z_{min}) / Z_{min} * 100$, $ARPD_{FG} = (Z_{FG} - Z_{min}) /$

Z_{min} * 100, $ARPD_{BG}$ = (Z_{BG} - Z_{min}) / Z_{min} * 100) where Z is the total travel time of storage and retrieval operations within the whole planning horizon and "*CPU*" is the efficiency performance of algorithm (in seconds). Table 1 clarifies that FG obtains the lowest average travel time to store and retrieve a unit-load. Although the differences between FG and BG are not obvious, the values of ARPD show that FG can gain better solution than BG does. The values of *CPU* clarify that the computation speed of the greedy is faster than FG and BG, since greedy checks the departures of unit-loads and grouping-matching heuristic considers arrivals and departures of unit-loads.

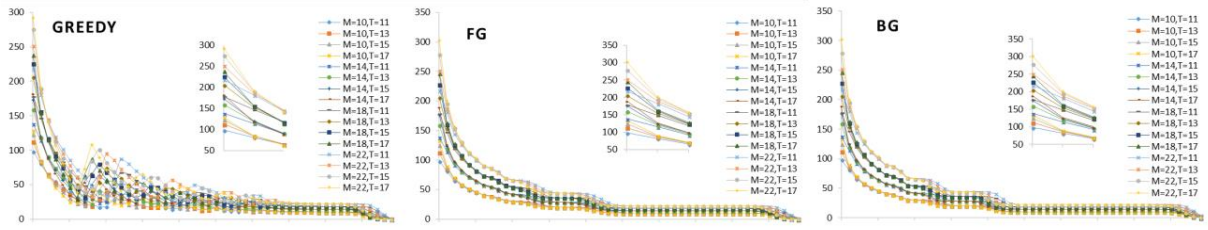
The average numbers of unit-loads assigned to bins with the ascending travel time to the P/D station are illustrated in Figure 3. The horizontal axis in Figure 3 is arranged in ascending sequence according to the travel time between storage end and P/D station. Figure 3 illustrates that FG and BG can simultaneously maximize the number of unit-loads allocated in the first one, the first two, …, the first *K* bins. However, the greedy cannot simultaneously maximize the number of unit-loads allocated in the first one, the first two, …, the first *K* bins. Therefore, greedy has the longest average travel time of storing and retrieving one unit-load among all three methods, as represented in Table 1. Therefore, the grouping-matching heuristic is suitable for the storage assignment in single-machine flow-rack AS/RS with DOS storage policy.

Figure 3 The number of unit-loads stored in AS/RS under different KM coefficients for each time period



CONCLUSIONS

In this paper, the effectiveness of the grouping-matching heuristic for the storage assignment in a single-machine flow-rack AS/RS with DOS storage policy is analyzed by simulation experiments. In the grouping step, FIFO unit-loads are assigned into the same group based on the arrivals and departures of unit-loads. FG appends FIFO unit-loads at the end of group and BG appends FIFO unit-loads at the head of group. In the matching step, groups are matched to bins based on the

number of unit-loads in a group and the travel time between a bin and the P/D station. FG and BG can simultaneously maximize the number of unit-loads allocated in the first one, the first two, …, the first K storage bins. According to simulation experiments of performance evaluation, the grouping-matching heuristic is an effective and efficient method. FG has better performance than BG does.

Since grouping-matching heuristic only generates storage and retrieval operations, novel heuristic should be designed to generate DC (dual-command cycle) operations based on the storage assignment results obtained by the grouping-matching heuristic to further reduce the total travel time of warehouse operations.

ABSTRACT

This study examines the relationship between health information technology (HIT) practices and patient care quality characteristics for acute care hospitals. More specifically, using a sample from Pennsylvania hospitals using econometric analyses we examine the impact that HIT functionalities such as electronic health record and health information exchange have on quality of care measures such as risk adjusted mortality and risk adjusted readmission rates; hospital efficiency measures such as cost per inpatient day and cost per inpatient admission, and on patient flow measure such as average length of stay. Our findings indicate a mixed bag. Implications of the study are discussed.

KEYWORDS: Hospital efficiency, quality of care, health information technology, electronic health records, health information exchange.

INTRODUCTION

The United States spends far more per person on healthcare than other industrialized nations but fares worse on most of them on several health indicators even though comparatively Americans use fewer medical services (Lee, 2014). Setting aside factors like fraud, human error, inflated prices, or prevention failure, this waste can be attributed to money spent on inefficient care delivery, and the slack in system elements such as unnecessary services or administrative staff. In fact, inefficient care delivery and unnecessary services are explanations often offered for higher healthcare costs, which could be avoided with better health information management. Proponents of health information technology (HIT) claim there are tremendous benefits such as reduction in length of hospital stays, reduced readmissions, greater information exchange, improved patient safety, improved quality of care including reduction in medical errors, among others, for the U.S. health care system. Despite these apparent benefits, the U.S. lags other developed countries in HIT use (Blumenthal, 2009). In order to promote HIT use in hospitals and clinics, the American Recovery and Reinvestment Act of 2009 allocated $19.2 billion (Prasad, 2014).

Previous researches have produced mixed results pertaining to the benefits of HIT. For instance, Devaraj and Kohli (2003) found that HIT usage is associated with a reduction in patient mortality rates and greater hospital productivity measures as revenue generated per admission. Menon et al. (2000) provide evidence of a positive impact such as of medical information technology (IT) capital on hospital output as well as marginal hospital revenue. Zhivan and Diana (2012) demonstrate that hospitals with more cost inefficiency were more likely to introduce electronic health record (EHR). More recently, Bardhan and Thouin (2013) show positive association between HIT usage and quality of delivery and reduced operating expenses. However, there are several studies that have found little or no positive association between HIT usage and hospital performance. For instance, Furukawa et al. (2010) examined the impact of EHR adoption on hospital cost-inefficiency in medical-surgical units and found that the presence of an EHR was associated with significantly higher inefficiency. Kazley and Ozcan (2009) found no significant improvement in efficiency over time due to EHR usage. Agha (2014) analyzed the impact of HIT on the quality and intensity of medical care and found no evidence of cost savings even five years after adoption; and HIT adoption appeared to have little impact on the quality of care. Thompson et al. (2015) found that HIT had no substantial effect on mortality, length of stay, or cost in the inpatient and ICU. Most scholars have empirically chosen to investigate a lot of hospital variables in conjunction with HIT, some of which may be inter-related and thus, there may have been compounding effects. Given that the impact of HIT on organizational-level variables such as hospital efficiency and the quality of care has been mixed, we wanted to take a slightly different methodological approach by adopting econometric analyses with longitudinal panel data to investigate the link between HIT and hospital efficiency measures; and between HIT and hospital quality. In this research we investigate the following question: *what is the link between health information technology (HIT) practices and the quality of care and between HIT practices and other quality of care-related hospital level variables—hospital efficiency measures and patient flow?*

This study extends the existing literature in several ways. First, we include a broad spectrum of HIT functionalities to study its impact on hospital performance. Second, our recent data set provides us an excellent opportunity to determine HIT's impact due to the long gestation period that may be necessary before the effects of learning curve with HIT implementation can set in throughout the organization/hospital. Finally, this study specifically focuses on Pennsylvania, which is a compelling target state for this study for several reasons: first, it captures national trends toward increased HIT use; second, due to its patient demographics, Pennsylvania (PA) is the home to the nation's third-largest rural population and it has the third-largest population of elderly in the United States; and finally, the level of uninsured Pennsylvanians as of 2013 were roughly the same as that of the national average.

The remainder of our paper is structured as follows. First, we draw from tenets of the Theory of Swift, Even Flow (TSEF) to theoretically ground our expected relationships among the variables, expressed in propositions. Second, we present our regression models that we would use for our study, explaining the variables in detail. Finally, we discuss the implications of our model, address the limitations of the study, and conclude with future directions.

THEORETICAL BACKGROUND AND HYPOTHESES

The Theory of Swift, Even Flow (TSEF) (Cf. Devaraj & Kohli, 2013; Deming, 1986; Fredendall et al., 2009; Schmenner, 2004; Schmenner & Swink, 1998; Venkatesh, 2006) notes that the swifter and more even is the flow of materials through a process, the more productive that process becomes. Thus, productivity of any process—labor, machine, materials, or total factor productivity—increases with the speed by which materials flow through the process, and decreases with increases in the variability associated with the flow—variability associated with the demand on the process or with steps in the process itself.

TSEF has been applied to the healthcare context in extant literature. Devaraj and Kohli (2013) empirically demonstrated that HIT is associated with swift and even patient flow, which in turn is associated with increased hospital revenues. Their 2013 study demonstrated the differential effects of swift flow and even flow on various measures of hospital performance and noted that although swift flow affects financial performance, even flow primarily affects quality performance; and taken together, they have a mutually reinforcing overall impact on hospital performance. Applying TSEF, Yeow and Goh (2015) examined how resources are allocated to healthcare tasks and processes and their study suggested that the gains in allocative efficiency for a few processes are associated with improved organizational outcomes.

In the following sections we draw from the tenets of TSEF to support our hypothesized relationships among the variables in the study. We first discuss quality of care and then introduce HIT and other associated variables that help improve the quality of care delivered in hospitals.

Quality of Care

Quality of care in U.S. hospitals has been a growing concern ever since the Institute of Medicine's (IOM's) quality chasm report revealed widespread incidence of medical errors and substandard care. Because of preventable medical errors, hospitals incur an estimated total cost of between $17 billion and $29 billion per year (Kohn, Corrigan, & Donaldson 1999). Hospitals have been continually working on improving all three measures of quality of care: *structural*–-by adopting HIT and improving staffing ratios; *process*–-the generally accepted recommendations for clinical practice such as providing preventative services or conducting tests; and, *outcomes*–-hospital-acquired infections, risk-adjusted mortality, and risk-adjusted readmissions, among others. Previous literature has frequently cited several measures pertaining to quality including risk-adjusted mortality, risk-adjusted readmissions, average length of stay, registered nurse per bed, and risk-adjusted morbidity (Hvenegaard et al., 2011; Needleman et al., 2006; Pai, Hosseini, & Brown 2017). In this paper, we use two commonly cited measures of quality of care: *readmission index* and *mortality index*.

Preventable hospital readmissions constitute a significant part of avoidable medical spending. In 2013, nearly 18 percent (or roughly two million) of Medicare patients who had been hospitalized were readmitted within a month, costing Medicare $26 billion, an estimated $17 billion of which came from potentially avoidable readmissions (Rau, 2014). These hospitals faced a penalty rate as high as 3 percent for readmissions and additional penalties for hospital acquired conditions. In 2015, 72 percent (or 126 hospitals) of the Pennsylvania hospitals were penalized for excessive readmissions, with an average penalty of 0.63 percent of Medicare reimbursements (Rau, 2014). Prior research suggests that large hospitals, teaching hospitals, and safety-net hospitals are more likely to be penalized for excessive readmissions under the HRRP due to both medical complexity and socioeconomic mix of the patient population (Joynt, Orav & Jha, 2011; Joynt & Jha, 2013). For instance, teaching hospitals are generally resource-intensive and may incur higher operating expenses because they are affiliated with medical schools, located in urban areas, treat the most complex patients' cases and the urban underserved population (Shahian et al., 2012). Furthermore, safety-net hospitals treat large numbers of low-income patients, who face financial and access challenges that may deteriorate their medical condition after discharge compared with others. Joynt and Jha (2013) observe that there is less evidence that differences in readmissions with their smaller, nonteaching and non-safety-net counterparts are related to quality of care. Prior research as well as anecdotal evidence suggest that HIT systems may help prevent readmissions by improving access to clinical data across hospital systems, especially after discharge from hospital (Walker et al., 2005; Jones, Friedberg, & Schneider, 2011). The second quality of care indicator, *mortality*

index, measures to what extent a hospital's inpatient mortality rate is higher or lower than expected for a group of diagnoses and procedures given the risk factors of the patient population, where an index of 1.00 indicates that the actual mortality rate equals the expected rate.

Health Information Technologies and Hospital Efficiency

Health Information Technology (HIT) has impacted hospital operations in many ways. First, HIT help providers with easy access to patient health information such as diagnosis, lab results, list of medications, among others, so they can focus more on patient care activities. Second, coordination, quality, and cost of patient care may be improved as technologies are used to exchange patient information with external providers. For instance, the ability to electronically send patients reminder notices for preventive or follow-up care (e.g., computerized reminder system) may reduce in hospital costs and increase life expectancy (Shekelle et al., 2006). Finally, administrative costs, which accounts for 25 percent–-or over $200 billion–-of total U.S. hospital spending (Himmelstein et al., 2014), are expected to fall as new technologies are adopted that enable paperless transactions.

This study focuses on two types of health information technologies: *electronic health records (*EHR*)* and *health exchange information (*HIE*)*. An EHR is a digital version of a patient's medical records that can be accessed by authorized providers and staff across more than one health care organization. Health Information Exchange allows healthcare providers including doctors, nurses, pharmacists, and other healthcare providers to electronically access and share a patient's clinical information that are constantly updated on demand at the point of care.

The EHRs used by the hospitals in this study has some or all of the following capabilities: electronic clinical documentation (e.g., demographics, vital signs, provider notes, medication lists, allergy lists), results viewing (e.g., lab reports, radiology reports), computerized provider order entry (e.g., lab tests, radiology tests, consultation requests), closed-loop medication tracking system, population health management, medication management, automated quality measures reporting, and public health reporting. King et al. (2014) in their study argue that most physicians reported EHR use enhanced patient care overall, helped them access a patient's chart remotely, and alerted them to a potential medication error and critical lab values. Furthermore, the authors found that between 30 and 50 percent of physicians reported that EHR use led to clinical benefits related to providing recommended care, ordering appropriate tests, and facilitating patient communication. Anecdotal evidence suggests that the use of an EHR eliminates the potential for confusion and medical error, and shortens the average work-up time from weeks to less than a day. In an integrated, multi-specialty medical group, for example, the average work-up time from lung cancer diagnosis to surgery dropped by more than half: from 40 days, the U.S. average, to just 16 days (Pearl, 2016). Thus, there is reason to believe that the adoption of EHR may contribute to overall healthcare productivity.

The health information exchange (HIE) functionalities used by hospitals in this study have the ability to electronically exchange or share patient information with one or more of provider types: with hospitals and ambulatory providers in the system, and with hospitals and ambulatory providers outside of the system. The following information could be shared by the hospitals' HIE - patient demographics, laboratory results, medication history, radiology reports, and clinical and summary care records, among others. Anecdotal evidence suggests that use of HIE has resulted in improved quality and efficiency of healthcare by allowing healthcare providers to access and share patient clinical information. Hersh et al. (2015) review the available literature on health information exchange. The authors observe that the use of HIE has risen over time, and is the highest in hospitals. They also find evidence that the use of HIE has led to reduced use of some specific resources and improvements in quality-of-care measures. The authors, however, claim that the full impact of HIE on healthcare outcomes,

especially clinical outcomes, is inadequately studied and future studies are needed to advance understanding of HIE. Jung et al. (2015) find positive association between HIE use and cost savings attributable to repeat imaging. Carr et al. (2014) investigate the ability of an HIE to decrease health services use for patients at an urban emergency department (ED). Clinicians participating in the study reported that the use of HIE resulted in reduced use of hospital resources, cost savings, decreased LOS, and improved quality of care.

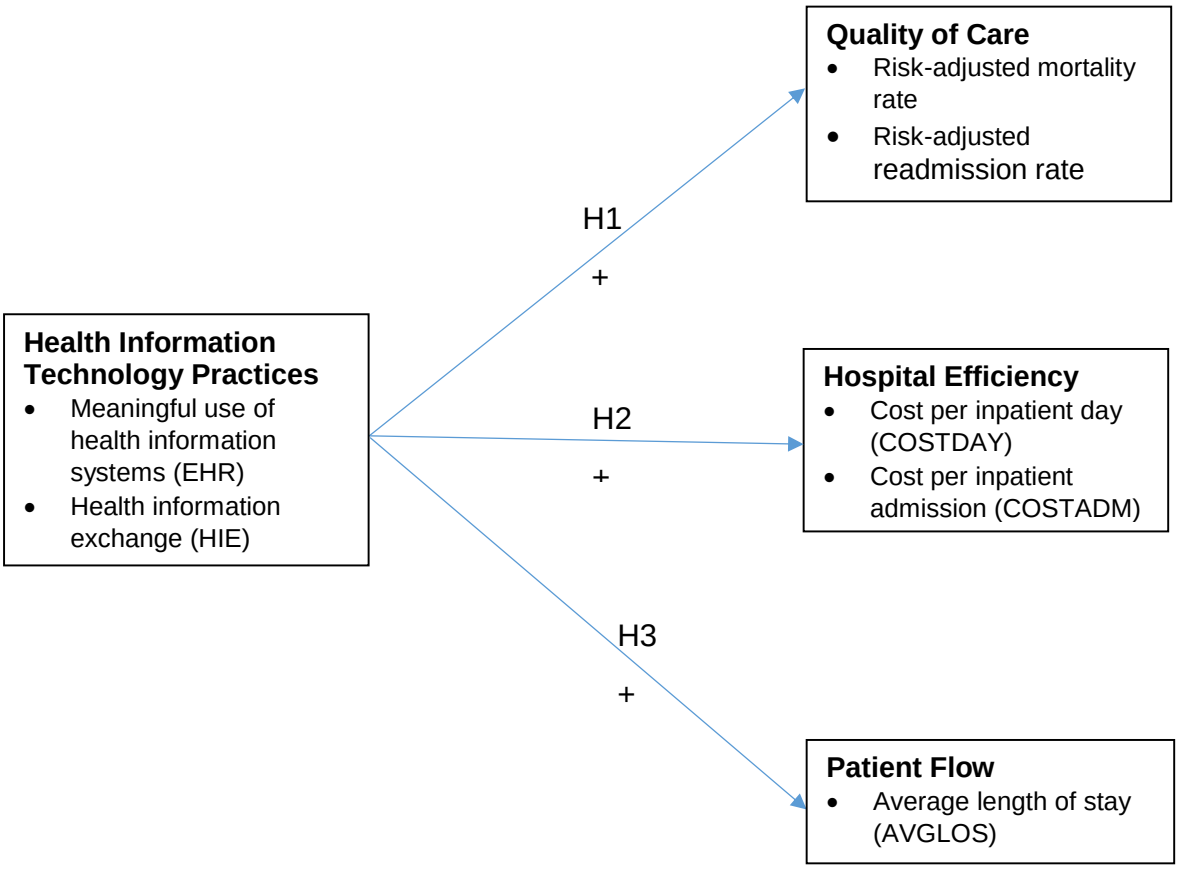
Now taking all the above variables together and drawing from the tenets of TSEF we suggest that if hospitals can smoothen/even out their patient flow in the hospitals, the day-to-day tasks related to patient care in the actual departments such as the operating rooms, blood banks, X-rays, CT scan, radiology and testing labs can all be done quickly and efficiently. This will consequently result in better time utilization of the healthcare team members (physicians, nurses and support staff) and with the advantage of receiving the correct and up-to-date information regarding the patient from the health information technology, better quality care can be delivered to the patients, on time, and their needs can be addressed by the healthcare team members. As a result, readmission and mortality rates should decrease over time. In sum, based on the above discussions, drawing support from TSEF we hypothesize three aggregate relationships among the variables:

> *Health information technology (HIT) practices are positively related to: (1) quality of care (**H1**); (2) hospital efficiency (**H2**); and (3) patient flow (**H3**) in the hospital.*

The research model being empirically tested is presented below. Although each of our hypotheses has a few sub-parts—one each for the indicators of the predictor and criterion variable combinations, for brevity we have numbered the hypotheses only at the aggregate variable level.

FIGURE 1

Health Information Technology Practices and Quality of Care, Hospital Efficiency and Patient Flow



METHODS

Procedures

The data for these analyses come from four different sources: (1) the Pennsylvania Health Care Cost Containment Council (PHC4) Hospital Performance Reports (HPR) provide data pertaining to financial analysis, health performance, utilization, among others; (2) the CMS cost reports provide data pertaining to case mix index and average hourly wages; (3) the demographic data come from the County Health Profiles; and (4) the HIT functionalities data are obtained from American Hospital Association.

Variables

Quality of care variables. We considered two quality of care indicators: *readmission index* and *mortality index*, which measure outcome quality by taking a weighted average of risk-adjusted readmissions rate and risk-adjusted mortality rate, respectively, for 11 common medical procedures and treatments identified by the International Classification of Diseases, Ninth Revision, Clinical Modification (ICD-9-CM) codes for hospitals in Pennsylvania. The following procedures and treatments were used: abnormal heartbeat, chest pain, chronic obstructive pulmonary disease, congestive heart failure, diabetes, gall bladder removal, heart attack, hypotension, kidney failure, pneumonia, and stroke. The weighted outcome quality index was computed as follows:

$$Mortality\ Index_{ht} = \frac{\sum c_{pht} RAM_{pht}}{C_{ht}}\ \ \forall h; Readmission\ Index_{ht} = \frac{\sum c_{pht} RAR_{pht}}{C_{ht}}\ \ \forall h$$

where RAM_{pht} captures the risk-adjusted mortality rate from the p^{th} procedure for the h^{th} hospital in year t. Similarly, RAR_{pht} captures the risk-adjusted readmission rate from the p^{th} procedure for the h^{th} hospital in year t. c_{pht} captures number of cases in p^{th} procedure for the h^{th} hospital in year t. C_{ht} captures the total number of cases across all 11 procedures.

Efficiency variables. We considered two measures of efficiency: *cost per patient day* and *cost per adjusted admission*. Regardless of the reimbursement methodology used, lower costs—cost per patient day and cost per adjusted discharge—lead to higher profitability, *ceteris paribus*.

The efficiency measure—*cost per patient day* (COSTDAY) is computed by dividing the total operating expenses by patient days, whereas, the other efficiency measure—*cost per adjusted admission* (COSTADM) is computed by dividing the total operating expenses by total admissions adjusted for case-mix index.

Other variables. As a proxy for smooth patient flow, we used the average length of patient stay (AVGLOS) in the hospital. Based on an extensive literature search, quite a few key control variables were identified and incorporated. The choice of the variables included in the study is consistent with existing literature in the healthcare and operations management areas (Ciliberto & Lindrooth, 2007; Deily, McKay, & Dorner, 2000; Kim, 2010; Mullner et al., 1982): *beds set up and staffed*, a better indicator of hospital capacity compared with licensed beds; *occupancy rate*, a measure of hospital utilization, which past literature suggests may have frequently been the cause of financial distress in many hospitals and their eventual closure; *case mix index*, used to capture the complexity of operation of a hospital; *ownership*, by which hospitals are categorized as either for-profit and not-for-profit; *teaching status*, as teaching hospitals are generally resource-intensive and may incur higher operating expenses because they are affiliated with medical schools, located in urban areas, treat the most complex patients' cases and the urban

underserved population, train physicians and other health professionals, and advance research (Shahian et al., 2012); *location*, which the empirical evidence shows impacts hospital performance (Younis, 2003; McKay, Lemak, & Lovett, 2008); and *year*, which accounts for possible trend effects.

Payer mix, which in this study refers to the percentage of revenue coming from Medicare and Medicaid was controlled for in this study. Payer mix is important because Medicare and Medicaid typically pay hospitals less than what it costs them to treat. *Percentage of bad debt* and *charity care* were also controlled for as both are known to inflate hospital operating expenses and to be highly correlated with not-for-profit status (Ding, 2014). In the PHC4 data set, both bad debt and charity care were combined; hence, bad *debt and charity care* were treated as a single variable.

In addition, two demographic variables were included that provide information about the county in which the hospital is located: *percentage population below poverty line* (BPL) and *percentage of residents who are age 65 or older*. Also included were the variables *operating margins* and *number of general acute care hospitals* in the county. Operating margin is one of the most popular metrics for determining hospital profitability.

Regression Models

We examine the relationship between HIT adoption and hospital efficiency, quality of care and patient flow using ordinary least squares model with hospital random effects. We intend to use a continuous measure of hospital HIT adoption based on the proportion of functionalities implemented.

$$COSTDAY_{it} = \beta_0 + \beta_1 (EHR_{it-1}) + \beta_2 (HIE_{it-1}) + \beta_3 (Beds_{it}) + \beta_4 (Case\ Mix_{it}) + \beta_5 (Operating\ Margins_{it}) + \beta_6 (Charity_{it}) + \beta_7 (Medicare_{it}) + \beta_8 (Medicaid_{it}) + \beta_9 (Ownership_{it}) + \beta_{10} (Teaching_{it}) + \beta_{11} (Location_i) + \beta_{12} (\%\ Population\ Aged\ 65\ Years\ or\ Above_{it}) + \beta_{13} (\%\ Population\ Below\ Poverty\ Line_{it}) + \beta_{14} (Number\ of\ Acute\ Care\ Hospitals_{it}) + \beta_{15} (Years_t) + \varepsilon_{it} \quad (\textbf{\textit{Model 1}})$$

$$COSTADM_{it} = \beta_0 + \beta_1 (EHR_{it-1}) + \beta_2 (HIE_{it-1}) + \beta_3 (Beds_{it}) + \beta_4 (Case\ Mix_{it}) + \beta_5 (Operating\ Margins_{it}) + \beta_6 (Charity_{it}) + \beta_7 (Medicare_{it}) + \beta_8 (Medicaid_{it}) + \beta_9 (Ownership_{it}) + \beta_{10} (Teaching_{it}) + \beta_{11} (Location_i) + \beta_{12} (\%\ Population\ Aged\ 65\ Years\ or\ Above_{it}) + \beta_{13} (\%\ Population\ Below\ Poverty\ Line_{it}) + \beta_{14} (Number\ of\ Acute\ Care\ Hospitals_{it}) + \beta_{15} (Years_t) + \varepsilon_{it} \quad (\textbf{\textit{Model 2}})$$

$$READMIN_{it} = \beta_0 + \beta_1 (EHR_{it-1}) + \beta_2 (HIE_{it-1}) + \beta_3 (Beds_{it}) + \beta_4 (Case\ Mix_{it}) + \beta_5 (Operating\ Margins_{it}) + \beta_6 (Charity_{it}) + \beta_7 (Medicare_{it}) + \beta_8 (Medicaid_{it}) + \beta_9 (Ownership_{it}) + \beta_{10} (Teaching_{it}) + \beta_{11} (Location_i) + \beta_{12} (\%\ Population\ Aged\ 65\ Years\ or\ Above_{it}) + \beta_{13} (\%\ Population\ Below\ Poverty\ Line_{it}) + \beta_{14} (Number\ of\ Acute\ Care\ Hospitals_{it}) + \beta_{15} (Years_t) + \varepsilon_{it} \quad (\textbf{\textit{Model 3}})$$

$$MORTIND_{it} = \beta_0 + \beta_1 (EHR_{it-1}) + \beta_2 (HIE_{it-1}) + \beta_3 (Beds_{it}) + \beta_4 (Case\ Mix_{it}) + \beta_5 (Operating\ Margins_{it}) + \beta_6 (Charity_{it}) + \beta_7 (Medicare_{it}) + \beta_8 (Medicaid_{it}) + \beta_9 (Ownership_{it}) + \beta_{10} (Teaching_{it}) + \beta_{11} (Location_i) + \beta_{12} (\%\ Population\ Aged\ 65\ Years\ or\ Above_{it}) + \beta_{13} (\%\ Population\ Below\ Poverty\ Line_{it}) + \beta_{14} (Number\ of\ Acute\ Care\ Hospitals_{it}) + \beta_{15} (Years_t) + \varepsilon_{it} \quad (\textbf{\textit{Model 4}})$$

$$AVGLOS_{it} = \beta_0 + \beta_1 (EHR_{it-1}) + \beta_2 (HIE_{it-1}) + \beta_3 (Beds_{it}) + \beta_4 (Case\ Mix_{it}) + \beta_5 (Operating\ Margins_{it}) + \beta_6 (Charity_{it}) + \beta_7 (Medicare_{it}) + \beta_8 (Medicaid_{it}) + \beta_9 (Ownership_{it}) + \beta_{10} (Teaching_{it}) + \beta_{11} (Location_i) + \beta_{12} (\%\ Population\ Aged\ 65\ Years\ or\ Above_{it}) + \beta_{13} (\%\ Population\ Below\ Poverty\ Line_{it}) + \beta_{14} (Number\ of\ Acute\ Care\ Hospitals_{it}) + \beta_{15} (Years_t) + \varepsilon_{it} \quad (\textbf{\textit{Model 5}})$$

Where, the subscript i = 1…N represents each hospital and t = 1, 2, …T represents each year from 2014 to 2016.

RESULTS

Health information exchange (HIE) had a negative but statistically significant impact on efficiency measure—COSTDAY, whereas it had a positive and statistically significant impact on patient flow measure—average length of stay (AVGLOS). Surprisingly, HIE also was positively associated with mortality index. Contrary to our expectation, electronic health record (EHR) was positively associated with readmission index; however, it did not significantly impact mortality index, efficiency measures and ALOS. The detailed results are presented in Table 1.

In line with the major findings in extant literature on impact of HIT on hospital quality-related variables, a summary of all the hypotheses tested in our study, presented in Table 2, indicate only partial support for hypotheses. While two out of four hypotheses under ***H1*** were supported (one with each of our predictor-criterion combination), only one of the four hypotheses under ***H2*** were supported and similarly only one of the two hypotheses under ***H3*** were supported. Thus, with statistical significance of only the four out of the 10 regression coefficients we can only claim partial support for the hypotheses tested in this study. Like several other past studies, our research too reveals mixed impact of HIT on quality of care, efficiency and patient flow.

TABLE 2

Hypotheses Testing Summary

Hypothesis	Predictor	Criterion				
		Quality of Care		Hospital Efficiency		Patient Flow
		Mortality Rate	*Readmission Rate*	*Cost per inpatient day*	*Cost per inpatient admission*	*Average Length of hospital stay*
H1	*EHR*	No support	Supported			
	HIE	Supported	No support			
H2	*EHR*			No support	No support	
	HIE			Supported*	No support*	
H3	*EHR*					No support*
	HIE					Supported

Notes. EHR-electronic health record; HIE- health information exchange. *Regression coefficient is negative, contrary to our expectations.

Based on the extant literature discussed earlier, we incorporated as many as 14 controls in our study. Quite a few of them turned out to be significant, as indicated in Table 1. First, the number of beds (proxy for the hospital's size) was significant with both criterion for quality of care and mortality index, patient flow indicator (AVGLOS) but not with any of the two criterion variables for hospital efficiency. As already noted in healthcare literature, this indicates that bigger sized hospitals having more resources at their disposal can benefit more and deliver improved patient care to their patients but there may be an optimal hospital size only beyond which, hospitals are able to enjoy the improved hospital efficiency. Second, the case mix index was found to be significant with both hospital efficiency measures, with the patient flow indicator and only one of the quality of care characteristics (mortality index) thereby indicating that choosing the right case mix is important for hospitals to improve their patient flow and efficiency measures. Third, the operating margin was found to be significant with only one of the hospital efficiency measures, with both quality of care measures and with patient flow thereby indicating similar importance of having high operating margins for hospitals. Fourth, bad debt and charity care are found to be significant only with the quality of care indicators, thereby indicating their effect on the quality of care. Fifth, Medicare as a percentage of net patient revenue is significant with each of the two quality of care characteristics, each of the two hospital efficiency measures and the patient flow indicator thereby indicating the importance of Medicare reimbursement for hospitals. In comparison, Medicaid as a percentage of net patient revenue is significant with each of the two quality of care characteristics and with patient flow but not with hospital efficiency indicators. Sixth, the other commonly used controls in the healthcare literature such as hospital ownership, teaching status and location are significant with both the hospital efficiency indicators indicating that the hospital efficiency may be impacted by these three factors. Seventh, the demographic factors used as controls—percentage of population over 65 years and the % below poverty line are not consistently significant with the indicators of hospital efficiency, quality of care and patient flow. Similarly, the number of acute care hospitals

did not have any significant effect except on mortality index and on patient flow. Finally, the 2015-year indicator has a significant effect on only one of the hospital efficiency indicators and on mortality and patient flow. Similarly, the 2016-year indicator has a significant effect on both hospital efficiency indicators, on patient flow and only on mortality index. In sum, it is truly a mixed bag with some of the controls having a significant effect on the relationships hypothesized in the study.

DISCUSSION AND CONCLUSION

In this paper, drawing support from the tenets of TSEF and based on extant literature we tested a research model using econometric analyses wherein health information technology (HIT) practices such as the meaningful use of systems (EHR usage) and health information exchange (HIE) were hypothesized to be positively related to: (1) the hospital's quality of care characteristics such as risk-adjusted mortality rate and risk-adjusted readmission rate; (2) hospital efficiency measures such as cost per inpatient day (COSTDAY) and cost per inpatient admission (COSTADM); and (3) patient flow measures such as the average length of stay (AVGLOS). Our findings indicate a mixed bag with only partial support for the hypotheses.

Our study contributes to advance the knowledge in the healthcare information technology domain. This research demonstrates that HIE has partial positive effect on patient flow, hospital efficiency and consequently, on quality of care. With recent data from hospitals in PA, the study once again, reiterates the positive effects of smooth and even flow (TSEF) in the hospital context. There are several reasons why our results may have turned out a mixed bag. First, we used only a sample of hospitals from the state of Pennsylvania (PA). Although we know that the PA healthcare data captures national trends toward increased HIT use it is possible that currently, the average EHR usage in the state's hospitals may be quite low. This may explain why we could find a significant relationship with EHR as a predictor only with one out of all five criterion variables—with one of the two quality of care measures (readmission index). Second, perhaps as a related effect of the low extent of HIT usage in the state of PA, the total cost of implementing newer technologies has not yet reach the optimal level; hence it is likely that hospitals in the state are not yet able to reap all true benefits of HIT including optimal hospital efficiency. This is indicated by the negative regression coefficient or the negative relationship among HIT practices (HIE) and hospital efficiency measures such as cost per day and cost per inpatient admission that we found which indicate that the costs are actually increasing now. In comparison, HIE is significant with at least one indicator of each of the three criterion variables—quality of care (readmission index), hospital efficiency (cost per day) and patient flow (AVGLOS). Our study should spur more replication studies with these variables with data collected from hospitals all over the country.

The study has the following implications for medical practitioners and hospital leaders. First, the results of the study should re-emphasize the positive relationship between health information exchange (HIE) and hospital efficiency measure such as cost per day, quality of care indicator such as mortality index and the patient flow characteristic such as the average length of patient stay in the hospital. Hospital leaders may need to invest more in HIE systems such as EHR; and also pay more attention to propagation and use of EHR across their hospitals and all their internal departments. Second, our study results from PA data should also demonstrate to the hospital leaders across the rest of the country that HIE is the way of the future. The business press still routinely publishes articles detailing problems due to incomplete information available to the physician/nurses while making patient-related decisions, which arises due to inappropriate integration of health information systems in many hospitals across many small and big cities across the country. It is time that hospital leaders clearly understand that investing in health information systems are a way of the future as they help improve the patient flow, hospital efficiency and ultimately help in delivering higher quality of care to patients.

Like in most studies, this study too suffers from several limitations. First, we used secondary data from only one state (PA) for our study. While PA healthcare data is truly reflective of the emerging population trends of this country and PA has many big and small hospitals, the extent of healthcare technology usage is still low when compared to some of the western states of the country. Future studies would do well to collect more data from hospitals across the country so as to spread it over the other regions. Second, only three years (2014-16) data was available and used for this study. While this period is certainly long, future studies may want to extend over more number of years to clearly identify trend effects. Third, one of the possible reasons for the lack of clear and consistent effects of HIT in our study may be that the effect on the outcomes studied in this research may generally take a very long time, in general, in most hospitals. Although we have captured this dimension of the problem already by considering lagged effects by considering the t-1 period for both EHR and HIE, it is possible that other spurious and compounding variables, not identified in this research may have also played a part in partially affecting our outcomes. Future research may also consider much-more short-term effects of health technology usage such as study of the improvement in healthcare team level coordination and patient care delivery measured by the reduction of inpatient complaints related to physicians and nurses after technology usage.

In closing, we would like to place our results in the context of the findings in extant literature. Quite a few studies have already demonstrated mixed results with HIT and other quality of care-related hospital outcomes. Our study too, using a different methodology than most studies that use surveys (econometric analyses) could still find partial effects of HIT on quality of care, hospital efficiency and patient flow. In the future, we hope more replication studies with even longer periods of data and spread across more hospitals in more U.S. states will be able to clearly demonstrate all positive effects of health information technology usage for hospitals.

ABSTRACT

With the rise of social media such as blogs and social networks, these interpersonal communication expressed by online reviews has become more and more important as an influential source of information both for the managers and consumers. In-depth purchasing related information is made available to markers. Now we can utilize this new source of information to understand how consumers evaluate hotels. In this paper we not only examine the contents of attributes of hotels consumers value when they stay but also attempted to categorize a number of key areas by the level of importance as measured from consumers' online reviews also. Moreover, the means-end chain theory was used as a theoretical framework to analyze the attributes of the hotels with the dimensions of the key areas in evaluating hotel qualities.

KEYWORDS: Online reviews, Text-mining, Key areas, Evaluate, Means-end chain theory

INTRODUCTION

With the rise of social media such as blogs and social networks, these interpersonal communication expressed by online reviews has become more and more important as an influential source of information both for the managers and consumers. With the rapid growth of comments by consumers over the Internet, in-depth purchasing related information is available to markers. The wide availability of lengthy and numerous text-based online reviews provides a treasure trove of information that can potentially reveal a much wider set of variables that determine the consumers' attitude/evaluation towards the products. With the large amount of information, data-mining methodologies are needed to uncover the hidden information from the unstructured text/data (Lee & Siau, 2001; Hoontrakul & Sahadev, 2008).

However, as there has been ample research on text mining, they mainly aim at improving the methodology it self a lot like classification performance of text classifier, feature selection methods, etc. (Ng et al. 2006; Pang, Lee, & Vaithyanathan, 2002; Bast, Kuzey, & Delen, 2015). Or data mining is used as a tool for the prediction power of the words itself (Rickman &Cosenza, 2007; Ghose, Li and Ipeirotis, 2012; Mostafa, 2013) and are missing the diagnostic aspect of using reviews, which is of important use to marketers. The identification of attributes can be used to help marketers in understanding what contribute to the evaluations by consumers toward the products; or even at a more abstract level.

In our research, instead of using the traditional experiment/survey method, we extract attributes from online text reviews through pre-processing and indexing et al. standard natural language processing algorithms. . We partnered with orbitz.com, a leading hotel booking websites with

ample true consumer reviews about their stay at the hotel. The importance of the attributes is also developed through online review analysis instead of surveys. This way, we not only examine the attributes of hotels, but also attempt to categorize a number of key areas by the level of importance. Moreover, the means-end chain theory was used as a theoretical framework to analyze the quality of the hotels.

The rest of the paper is organized as follows: in section 2 we discuss the fundamentals of text mining approach and means-end theory. In section 3 we discuss the details how we implement this for our research. In section 4 we analyze the results we get and provide the insights of our discussions. Section 5 provides a summary of our findings and suggests future directions for research.

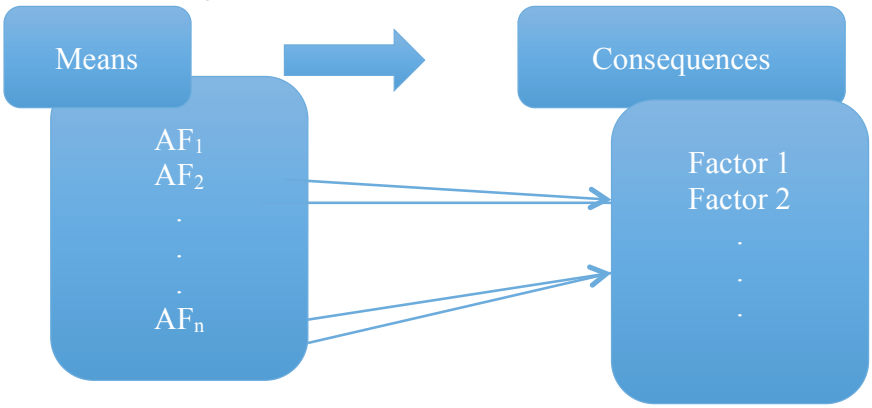
LITERATURE REVIEW

Means-end Chain Theory

We adopted means-end chian theory as the conceptural framework. This conecptural cognative model suggests that conusmer decision-making process is a series of cognitive developments through linkages between product attributes, consequences, and value (Gutman, 1984). In the context of product usage, product it self is the “means” and the value of the products is the “end”. The product attributes are retained in the minds of consumers at abstract level and can influence the evaluation of the product by the consumers. Means-end theory has been used a lot e-service quality research (Ladhari, 2010; Rowley, 2006; Wolfinbarger & Gilly, 2003). Parasuraman et al. (2005) applied this theory as the theoretical foundation to develop and conceptualize e-service quality delivered by websites.

In our research, the means are the attributes of the hotels extracted from online consumer reviews while the end (consequences) are the key areas categorized by factor analysis based on the importance of the attributes also extracted from online consumer reviews through text mining.

Figure 1: Proposed Theoretical Framework



Text Mining Review

In this section we describe the overall approach that we use for analysis of text content. In the following sections, we will explain the complete process of how we used text mining.

Preprocessing and Text Representation

Before a learning method can be applied, several preprocessing steps are required to get the data in ready format for further analysis. Raw text is divided into tokens (single word, special symbols, etc.), converted to lower cases, remove stop-words (eg: the, a, etc.), stem into word-root, and represent the text value by indexing into a term-by-document matrix. The columns of the matrix represent terms (words), and the rows represent documents (reviews for example). Jones (1972) showed that there is a significant improvement in retrieval performance by using weighted terms vectors. The term weight is generated by multiplying Term Frequency (TF) with the Inverse Document Frequency (IDF) (Jones, 1973; Coussement & Van Den Poel, 2008; Salton & Buckley, 1988). Now this term-by-document matrix becomes a structured table with numerical values, which can be analyzed using standard statistical method.

Dimensionality Reduction

So far this weighted term-by-document matrix is a high dimensional matrix due to the many distinct terms. Moreover, it is very sparse with many zeros since not all documents contain all terms. Large attribute dimensionality incurs high computational cost and more seriously cause over-fitting problem on many classification methods. We choose Gini-index as our method for attributes selection since it is base upon the distinguishing ability of the word as well as importance of the word.

Gini-index was proposed and sudied by Aggarwal & Chen (2010). It aims to decide which feature variables are decision variables for a decision support appication. In the training data the key decision variables are identified and trained to predict the decisions classes. Training dataset D_{trian} contains n reviews and each review q belong to a predefiend class with lables s which is drawn from the set {1…k}. Overall we have a dxn feature-review matrix with each feature is denoted i with i range from 1 to d and each review is denoted by q with q range from 1 to n. In our case since the lables will be a binary situation of reconmend or not. Now the Gini index is calculated to define the level of class dscrimination among the data points of each feature as follows:

$$G(i) = \sum_{s=1}^{k} f(i,q,s)^2$$

Then we can use gini index to help us find the key features that are important to the decisions. With a bigger Gini index, it indicates a higher discriminating abillity of that word. So we set a threshhold of choosing higg value Gini-indexd attributes. In previous research the frequency of occurrence of an indexed word has been used to indicate term importance for content representation (Baxendale, 1958; Luhn, 1957; Salton & McGill, 1983). So we set another threshold of selecting attributes based on the frequency.

Classification

We use the Support Vector Machine (SVM) approach for classification purposes. SVM was invented by Vapnik and Chervonenkis (1962) and has been used a lot in various areas (Pang, Lee, & Vaithyanathan, 2002; Bast, Kuzey, & Delen, 2015). SVM are supervised learning models that can classify data into the groups. Given a set of training examples, each data record is marked as one or the other of two categories. An SVM training algorithm builds a model that

can assign new examples to one category or the other. In our case, we have categories of class: recommend or not recommend the hotel to others.

Classification performance is measured by the percentage correctly classified. If *TP*, *FP*, *TN*, *FN* are respectively the number of correctly predicted positive reviews, the number of negative reviews predicted as positive, the number of correctly predicted negative reviews, and the number of positive reviews predicted as negative, accuracy is defined as $\frac{(TP+TN)}{TP+FP+TN+FN}$.

DATA AND ANALYSIS RESULTS

Data Collection

In our study, we used data obtained from orbitz.com, which is one of the leading websites in the travel industry. On the websites, consumers can only leave their reviews, ratings, and recommendation choices after they stayed in the hotel and registered with the hotel. We collected the data of a high quality hotel in Las Vegas: 5-star hotel "Venetian". We chose Las Vegas among the various cities across the whole nation because it is one of the most popular tourist cities in the U.S., and attracts a large number of hotel consumers staying and leaving reviews. We pick a 5-star hotel because as in Las vegas, in order to attract visitors, lots of high-level hotels were built and also because of the low price comparing to other locations, 5-star hotels are very popular among consumers. Table 1 represents the summary of the review data of the two hotels.

Table 1: 5-star Venetian Descriptive Statistics

	All	Business	Couple	Family	Friend	Other
Overall ratings	4.5	4.5	4.5	4.4	4.4	4.4
Recommendation (actual)	92%	92%	92%	87%	92%	87%
# of reviews	2286	188	1109	296	342	351

Analysis Results

After preprocessing of the raw reviews we get the term (attribute) by document matrix. For each attribute, we calculated the Gini index of that feature and select only the ones with a Gini value higher then 0.75 (Aggarwal et al. 2009) and also frequency is higher than the average frequency of the words appearence. Through this we are able to find the major attrbiutes that are both important and distingushing in the evalutions of the hotel. List of feature is shown in table 2.

From the table we see, around 40 features which are both important and distinguishing were extracted from the consumers online reviews. For each feature, we calculated the tf-idf value to reflect the frequency of occurrences of the word features, which indicate the importance of the features for representation of the content of the reviews. The evaluation of importance of features was usually determined by consumer surveys in the past.

79248drink	0.124056133	0.760623902

Next, we performed classification (SVM) using the sleeted 38 features as the predictive variables. The accuracy is 91.6%. The high accuracy indicated text reviews can be used to represent the true thinking of the consumers towards the hotel, which can be fatherly used to identify the factors that consumers value as when they evaluate the hotels.

Last, we conduct factor analysis using principal axis factoring in order to identify the underlying factors of the two hotels. The principle axis factoring analysis with a Varimax rotation showed 14 factors with an eigenvalue of one or greater for the functions of apps. As stated in Table 3, total

variance explained by each factor of apps' functions was also revealed. Specifically, the first factor has an eigenvalue of 3.48, which is 21% of the total variance of 7 items. The second factor has an eigenvalue of 1.74, which is 16% of the total variance of 7 items. Then the next five factors have an eigenvalue bigger then 1.3. The rest has too small values (either below 1 or close to 1) so we didn't include them. Normally, eigenvalues greater than 1.0 are recommended as a criterion. We pick the first 7 factors.

Table 3: Total Variance Explained				
Component	Eigen Value	% of Variance	Cumulative %	SS loadings
1	3.48	21%	21%	1.53
2	1.74	16%	37%	1.13
3	1.57	15%	53%	1.10
4	1.51	13%	66%	0.95
5	1.41	13%	79%	0.91
6	1.32	12%	91%	0.86
7	1.30	9%	100%	0.66

The factors are labeled as: 1) room, 2) value, 3) Las Vegas specific hotel amenity-casino, 4) other amenities, 5) location, 6) staff, 7) Las Vegas specific hotel amenity-entertainment. Among the 38 items, three items were deleted for appropriate data reduction for future statistical analysis. As you can see in table 4, AF5 (beautiful), AF13 (experience), AF25 (weekend), AF30 (close), and AF33 (expense), were eliminated because they had no significant loading on any of the factors above (factor loading less than .20).

Table 4: Summaries of Features and Factor Loadings									
		Factor Loadings							
	Features	1	2	3	4	5	6	7	Communality
1)	AF1-room	.46							3.0
	AF14-comfort	.52							1.1

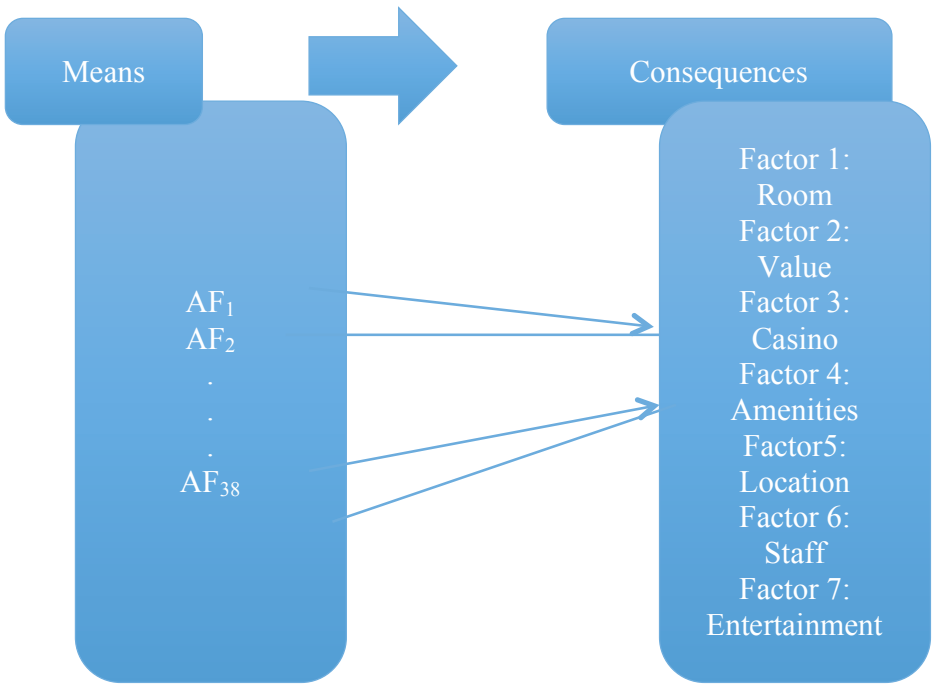
	AF8-strip					.70			1.2
	AF21-view					.34			2.3
6)	AF3-staff						.60		1.1
	AF15-friendly						.63		1.0
7)	AF4-time							.29	3.0
	AF11-pool							.32	2.5
	AF19-show							.19	4.8
	AF23-getaway							.22	1.3
	AF29-fun							.23	1.8
	AF31-couple							.31	1.2

As revealed in Figure 2, there are 38 features (means) of evaluations of the hotels by consumers that were categorized by 7 factors (consequences) in the given framework.

Figure 2: Theoretical Frameworks



On the website, there are already separate ratings by consumers towards 5 aspects: room, value, location, staff and amenities. In our results, we also identified the same dimensions except that for amenities, due to the uniqueness of Las Vegas, hotel amenities contain more meaning than usual hotels in other places. Therefor, we identified three categories of amenities: regular, casino, and entertainment. Also the hotel we analyzed here is the 5-star hotel venetian. For Venetian, and also many other high level hotels in Las Vegas, besides the regular hotel amenities, casino is a big area to draw attention and entertainments is another like show/pool etc. People especially couple come here for a getaway.

DISCUSSION AND CONCLUSIONS

A major finding of our research is that we can utilize the great volume of reviews online to help us identify the key aspects of hotel industry. Online reviews of products and services are present all over the Internet. Potential consumers value these greatly. Marketers can also get valuable information from reading these reviews. These reviews predominantly contain text-based information. In our present research we utilize text-mining methodology to show that consumers' attitudes can be accurately predicted by text mining.

In addition to making predictions of recommendations, marketers would benefit tremendously if they can identify key information from many thousands of reviews; we suggest a framework by which companies can get this important *diagnostic* information. This framework consists of reliance on the importance of words based on frequency of occurrence and a new way to look at how certain words have greater power to discriminate/distinguish between existence and non-existence of recommendations (Gini index). Factor analysis is conducted to extract the key dimensions for hotel evaluations.

While the contribution of this research is clear, there is still limitation of it. In this research we studied one hotel-venetian, it will be beneficial to include more hotels to see the generality across hotels and also across cities.

The potential future directions for this research stream are numerous. The overall methodology designed in this paper is a foundation that can be applied to a variety of marketing situations. In today's digital era consumers freely express their opinions about products and services on many websites. This provides numerous information sources that can help academicians and practitioners in analyzing consumer attitudes. We can extend this methodology to study a tremendous variety of research questions that would benefit from the analysis of text content posted by web users all over the Internet. Advertisers and marketers would be among the prime beneficiaries once they can glean the appropriate information from text-based reviews. The identified information can either be strongly used in advertising or to improve the business.

ABSTRACT

How do customers make selections from among millions of smartphone apps? In this study, we analyzed the relationship between icon attributes and choice of apps. Based on the literature, 5 icon attributes were identified: active, balance, complexity, depth, and organic. 12 app categories were explored. Explicit policy implications were exploited for icon design. For example, for arcade games, icons should be active or organic. For brain games, icons should be balance. For social, organic is the top choice. It is proven that meaning and dominance are two decisive factors for design dimensions as top choices for downloading.

KEYWORDS: Icon attributes, Meaning, Dominance, Download, Wilcoxon test

INTRODUCTION

Today's smartphones are full of apps – mini software applications designed to run on smartphones, tablet computers, and other mobile devices. Two prominent app markets are Android's Android Market (Google Play) and Apple's Apple Store (Annie, 2017). Since its opening on July 14, 2008, Apple Store has received 75 billion downloads as of October 2014 (Statista, 2015a), and 180 Billion in 2017 (Apple Inc, 2017). Google Play reached 50 billion downloads in July 2013 (Statista, 2015b) and 64 billion in 2017 (Sensor Tower Inc, 2017) with more than 1 billion monthly active users (Protalinski Emil, 2017). Our question is: Given millions of apps to choose from, how do customers make their selections? Most of these apps are free. Techcrunch (Perez, 2015) reported that 90% of Apple apps are free in 2013. This number may rise to 93% by 2016 (Gartner Newsroom, 2012) Although, the market share of free APPs is shrinking in 2018 (Dinsmore et al, 2017; Ying et al, 2017).For app developers, "free" is a strategy (Arora et al, 2017; Finkelstein et al, 2017). Making the software free increases the user base, which is especially useful if the software demonstrates "network externality". These developers make their profits by applying "In App Purchase" (IAP).

How can a single product attract attention in a sea of millions of "free" software apps? In our study, 159 of 208 survey respondents acknowledged that they chose apps based on their icons – the small graphical squares which deliver the messages the software apps are intended to deliver. The literature also demonstrates that logos, typefaces, package designs, and other exterior designs can affect customer loyalty, brand impression, and purchasing behavior (César Machado et al, 2012; Fu, 2016; Henderson and Cote, 1998; Machado et al, 2015; van der Lans et al, 2009; Zhu et al, 2014).According to pattern recognition theory (Selfridge & Neisser, 1963), features such as attributes function as stimuli that provide a foundation that viewers can use to decode the meaning of the icons.

In their pivotal work, Henderson and Cote (Henderson & Cote, 1998) identified certain design principles for logos. Our study shifted the focus from “what makes good logos” to the causality between the adoption of apps and icon attributes and between the icon attributes and meaning and dominance of icons. We wanted to explore which icon attributes improve the adoption of a given app category, if an icon’s meaning and dominance affect app downloads, and how meaning and dominance affect app downloads through icon attributes.

LITERATURE REVIEW

Research has identified the effectiveness of images (including icons, logos, and packages) in product recognition, corporate identification, marketing, brand impression creation, etc.(Bresciani and Del Ponte, 2017; César Machado et al, 2012; Chiu and Lee, 2018; Henderson and Cote, 1998; Hyeyeon, 2018; Machado et al, 2015; van der Lans et al, 2009). Peters (Peters, 1999) recognized the importance of a visually strong logo: “Humans think visually. A picture is really worth a million words. And great brands have readily identifiable icons – just ask Nike or Apple or Shell – strong simple images that connect with customers.”

However, there have been only a few recent published studies on the relationship between logos and the choice of products/services. Prominent among these, Henderson and Cote (1998) and Henderson, Giese, and Cote (2004) proposed guidelines for good design of logos and typefaces. Orth and Malkewitz (2008) developed a holistic package design that creates a better brand impression for consumers. Pham, Pallares-Venegas, and Teich (2012) delineated relationships among logos, storytelling, and customer loyalty. Kang believes that the user will choose to have a good icon design in the APP that has been downloaded and has similar functions. To increase the user's download quantity and frequency, it is necessary to increase its icon features and brand (Kang, 2017). Burgers et al. used APP online reviews and visual features to analyze users and developers and thought that user reviews and developer designs have a strong influence on APP downloads (Burgers et al, 2016). Machado, Vacas-de-Carvalho, Costa, and Lencastre (2012) and Hagtvedt (Henrik Hagtvedt, 2011) analyzed the effect of logo designs in specific circumstances. Although these studies have paved the way for logo research in the field of management, they provide little guidance for choosing the best logo design for a particular product/service. We believe this guidance is important to have, especially when customers must choose from a large number of logos. As noted by Pham et al. (2012), logos tell stories. But if the logo doesn’t catch the customer’s eye, the story has no place to start. Due to the proliferation of software packages, a tempting research question is how to apply these logo studies to research on software adoption.

Based on Henderson and Cote (1998) and Nemett (Nemett, 1992), we distinguished 5 different attributes of icons and predicted which of these would draw the most attention for which app categories.

(1)Organic
According to Henderson and Cote (1998), “Organic designs are those that are made up of natural shapes such as irregular curves. Graphic design literature suggests that organic designs are more meaningful (Dondis, 1973)” (see Table).
(2)Balance
According to Henderson and Cote (1998), “Balance captures the notion that there is a center of suspension between two weights or portions of the design. Graphics design literature has suggested that imbalance is more upsetting to viewers (Dondis, 1973).”

(3)Complexity
According to Henderson and Cote (1998), “Complexity can arise from many different design features such as irregularity in the arrangement of elements, increases in the number of elements, heterogeneity in the nature of elements, and how ornate the design is ((Berlyne, 1971; Schmitt, Simonson, & Marcus, 1995).”
(4)Active
Henderson and Cote (1998) defined active designs as “those that give the impression of motion or flow. This flow is the basis for the design notion of rhythm (Bevlin, 1989).”
(5)Depth
According to Henderson and Cote (1998), depth “gives the appearance of perspective or a three-dimensional design.”

Table 1 Attributes of logo designs

Table 1 Attributes of logo designs		
Attribute	High	Low
Organic		
Balance		
Complexity		
Active		
Depth		

Henderson and Cote (1998) also described symmetric and representative designs. Symmetric designs are those that “appear as reflections along one or more axis. That is, the elements on one side of the axis are identical to the elements on the other side.” A “representative design and its opposite endpoint, abstract, capture the degree of realism in a design.” “Symmetric designs are normally considered balanced.” In the same vein, they cite other researchers (Block, 1969; Clark, 1988; Durgee & Stuart, 1987; John Peter, 1989; Keller, 1993; Kropp et al, 1990; Masten, 1988; Siegel, 1989; Vartorella, 1990; Yeung, 1988), claiming that the “logo strategy literature frequently suggests using representative logos.” We thus incorporate the symmetric

design as a subset of the balance design and ensure that all our logos have the representative design feature.

In addition to the above design dimensions, there are response dimensions. One is dominance. Dominance through emphasis of one or more particular elements creates a focal point in a design. It's where most people will instinctively go when first looking at a work ((Vanseodesign,2010). Goonetilleke ((Goonetilleke, Shih, Kaion, & Fritsch, 2001) believed that the dominant element will result in shorter response times than single-element representations with the non-dominant (redundant) element. We expected that icons with higher dominance level would generate more downloads.

Another response dimension is meaning. (Horton, 1994) argued that icons alone are meaningless without a particular context (meaning). If a logo has a clear meaning, it can be linked more easily to the company or product ((Hazarika and Nath, 2017; Johannessen, 2017; Kelly, 2017; Park et al, 2017). We expected that icons with higher levels of meaning would generate more downloads.

THE SURVEY

To evaluate how icon attributes affect the choice of apps, we designated 15 icons for each app type, with each attribute represented by 3 icons. To guarantee that the icons represent the attributes well, we first interviewed domain experts to understand the design principles for each of the 12 app types.

Then, 9 designers were invited to design the icons for all the apps. Initially, 480 icons were drawn, representing 40 icons for each app or 8 icons for each app /attribute combination. Because all the icons were designed exclusively for this experiment, there is little chance that the participants had ever seen them. The next step was to assure that the icons represent the attributes well. This is said to happen if and only if a significant number of respondents agree that the representation is valid. To achieve this objective, we needed to set a threshold value. A value of 6 means that the icon can be considered to represent the attribute only if 60% of the respondents agree that this is so. The Delphi method (Dalkey & Helmer, 1963) was employed to determine the appropriate threshold value. 7 experts, including 2 professors, 2 designers, and 3 MIS professionals, participated in the Delphi session. A web-based GDSS tool, TeamSpirit, was employed (Chen, Liou, Wang, Fan, & Chi, 2007) for the session. The experts started brainstorming in the first round; the main topic was, "What makes an icon a good representation of an attribute?" In the second round, the discussion was routed to the determination of "reasonable threshold values for an icon to represent an attribute well." The proposed values were 6.0, 7.5, and 9.0. In the last round, the participants voted for the final threshold value of 7.5.

Next, all 480 icons were presented to 50 pilot study participants. They observed each one and selected which attribute or attributes it represented. An icon was considered well represented if 38 (50*0.75=37.5) or more participants identified 1 and only 1 attribute. An icon was labeled as over-represented if it was considered by 75% or more of the participants to represent 2 or more attributes. It was labeled as under-represented if it failed to represent any attribute. All over- or under-represented icons were discarded. The 3 best well-represented icons then were chosen to represent each app/attribute combination (total 12*5*3 = 180 icons).

The above procedure guarantees the reliability and validity of the icons' attribute representations. It assures that each set of 3 icons represents one and only one attribute. Similar icons are joined in single sets. Thus, reliability, convergent validity, and discriminant validity are all achieved.

During the main test, each participant was given an imitation smartphone with cardboard icons attached to its screen and covered by glass. Both the phone and icons were the same size as their real counterparts. To avoid fatigue (van der Lans et al, 2009), each participant was given only 1 of the 3 icons for each app/attribute combination. The participant was then asked to rank the 5 icons for each app category based on their preferences: a rank of 1 represented the greatest desire to download the game app when observed and 5 represented the least.

The experiment was conducted in Taiwan near the university campuses we believed had the highest likelihood of many smartphone users. Those who had previously downloaded apps with smartphones were asked to participate. The experimenter gave them the instructions and recorded their answers.

In the meantime, the respondents were asked if each icon has unique meaning. A respondent wrote down the meaning if any, or kept the answer box blank if there was none. They were also asked if an icon had an identifiable dominant subject. A respondent circled the subject if any or kept the answer box blank if there was none.

THE ANALYSES

The collected data were then undergone a series of analyses. First, Friedman tests were employed to investigate if there truly existed ranking of download preference among the 5 icons for each app category. It was employed because once one design dimension was selected, it could not be considered again so events are not independent from one another. The results showed that ranking did exist for all the 12 app categories.

Then, Wilcoxon tests were employed to actually uncover the ranking. For example, in arcade games, the Wilcoxon test showed the results as in (Table 2). It showed that the ranking is Active = Organic > Complexity > Depth > Balance

Table 2 Wilcoxon test for the arcade game

Attribute	B - A	C - A	D - A	E - A	C - B	D - B	E - B	D - C	E – C	E - D
Z test	-11.361[a]	-6.581[a]	-9.532[a]	-.522[a]	-5.450[b]	-3.915[b]	-10.443[b]	-2.190[a]	-6.399[b]	-8.921[b]
asymptotic Significance (two-sided)	0.000	0.000	0.000	0.602	0.000	0.000	0.000	0.029	0.000	0.000

a. negative rank b. positive rank (A: Active, B: Balance, C: Complexity, D:Depth, E:Organic)

Such practice was repeated for all the 12 categories and the results are summarized in (Table 3).

Table 3 Attribute ranking for app downloads					
	Active	Balance	Complexity	Depth	Organic
Arcade Game	1	5	3	4	1
Brain Game	2	1	4	3	5
Casual Game	1	3	5	3	2
Entertainment	4	2	2	5	1
Tool	1	1	5	1	1
Communication	1	4	5	3	2
Productivity	1	3	5	3	1
Personalization	2	5	2	4	1
Music & Audio	1	3	3	3	2
Social	2	2	5	4	1
Media & Video	1	5	3	3	2
Travel & Local	1	5	3	3	2

The results of the Wilcoxon tests allow us to further analyze the impact of the demographic variables on the rankings of attributes. We need to answer two questions. First, do demographic variables have an effect across all respondents on the ranking of a specific attribute for each type of game? For example, do males consistently rank the active attribute of arcade games higher than females do? An ordered probit was employed because the dependent variable is ranking data, and the regression of gender on the ranking of the active attribute for arcade games is as follows:

$$Y_i=\alpha_0 + \alpha_1 X_{1i} \quad (1)$$

where Y_i is the ranking (from 1 to 5) that respondent i assigned to the active attribute for the arcade games and X_{1i} is i's gender. X_{1i} was coded 1 for males and 0 for females. For example, $Y_i = 4$ and $X_{1i} = 1$ means that a male respondent ($X_{1i} = 1$) ranked the active attribute as the second highest ($Y_i = 4$) for arcade game.

We followed the same convention for the other demographic variables and the other 11 app types. After conducting the ordered probit regressions using SPSS and verifying the results using Stata, we found no impact of the demographic variables gender, age, education, profession, and number of downloads in the past year on the rankings of the active attributes for arcade games. We applied the same technique to other attributes for other apps and found no impact of the demographic variables on the rankings of any of the attributes for any app. Second, do demographic variables affect the rank order generally for each type of game across all respondents? For example, to assess if there is a gender difference in the general rank order for arcade games, we apply the following formula:

$$Y_{ij}=\beta_0 + \beta_1 X_{1i} + \beta_2 X_{2j} \quad (2)$$

where Y_{ij} is the specific ranking that respondent i assigns to attribute j, X_{1i} is i's gender, and X_{2j} is the overall rank order (assigned by all respondents) of the j^{th} attribute for arcade games. This overall rank order was determined by a Wilcoxon test. For arcade games, $X_{2j} = 5$ when the attribute is active (because active attribute is #1 ranking for downloading), $X_{2j} = 5$ when it is organic, $X_{2j} = 3$ when it is balance, $X_{2j} = 2$ when it is depth, and $X_{2j} = 1$ when it is complexity. Rank number 1 is the highest and was thus given a score of 5. For example, $Y_{ij} = 4$, $X_{1i} = 1$, and $X_{2j} = 2$ means that a male respondent ($X_{1i} = 1$) ranked the depth attribute ($X_{2j} = 2$) as the second highest ($Y_{ij} = 4$) for arcade games.

On the other hand, we suspected that the relationship between Y_{ij} and X_{2j} would prove to be asymptotic instead of linear, so we also tested the following regression:

$$Y_{ij}=\beta_0 + \beta_1 X_{1i} + \beta_2 X_{2j}^2 \quad (3)$$

If Equation (3) has higher explanatory power than Equation (2) (by observing adjusted R2), it demonstrates that the relationship is asymptotic.

For the three regressions, we found that, first, any value of a demographic variable did not have more significant effect on ranking than other values for all 12 app categories. For example, we did not find that males consistently rank the active attribute of arcade games higher than females did.

Second, we could not find impact from any demographic variables on overall ranking for the 12 app categories either. For example, we could not find that males showed different rank order for arcade games than females did.

Third, we could not prove that the relation between the attributes and the rank orders was asymptotic. We also tested X_{1i} and X_{2j} for multicollinearity using ordinary regression and found it not to be significant for all 12 categories. There also was no significant heteroscedasticity or autocorrelation, because the error terms for probits or ordered probits are always standard normal.

The next analyses were testing the impact of meaning and dominance on ranking. Another series of ordered probit regressions similar to Equation (1) were employed. Here, X_{1i} is a dummy variable. When it is one, it means that a respondent believe that an icon contains meaning or it has a dominant subject. We concluded that having meaning or having a dominant subject could increase the chance of an icon to be downloaded.

CONCLUSIONS

It is important for practitioners and scholars to know why an app is more likely to be downloaded than others. We found that icons were important. How can an icon foster the downloading? We believe its attribute is the key. For example, for arcade games, if an icon demonstrates active or organic attribute, its app can be more likely to be downloaded than that of depth, complexity, or balance attributes. Likewise, for entertainment apps, organic can be a better design dimension than active. From Table 3, we can tell that active attribute in general is a good design principle. Although active attribute can be the best design dimension for many app categories, it is not always true. For example, following active design principle for entertainment apps can be a wrong decision because Table 3 shows that apps with active icons are ranked number 4 in downloading preference. Therefore, our research is valuable because it clearly shows the ranking of design dimensions for each app category and it tells us that an optimal design choice for one type of app might be a bad design choice for another app type.

A more sophisticated question to ask is why a certain design dimension may foster the download. The key is response dimensions. In this paper, we suggested two response dimensions – meaning and dominance. Our results shows that not only having meaning or having a dominant subject could increase the chance of an icon to be downloaded, but also the impact of design dimensions is by way of meaning and dominance because there exist causality from response dimensions to. Meaning was studied in previous research (Henderson & Cote, 1998; van der Lans, 2009) but dominance was studied first by us.

Regarding the research limitations and future study, one can be the limit of research domain. We conducted our research in Taiwan. Although logo recognition can be universal (van der Lans et. al, 2009), authors have suggested that managers “can optimized logos for specific countries if desired.” Thus, extending our research from Taiwan to other cultures can be beneficial.

In addition, as Henderson and Cote (1998), we examined only logo recognition (Have you seen this logo before?) as opposed to recall (What company does this logo belong to?). Further research can focus on providing managers with guidelines to achieve high recall. Though, this issue may not be significant in mobile app business at this moment because most app providers are too small to make brand recognition important. After mobile app business reshuffles and enter a new era of competition, brand recognition may become an issue.There are more response dimensions as listed by Henderson and Cote (1998).

ABSTRACT

Rapid increase of technology usage combined with limitedness of capital resources technology managers are forced to come up with optimal strategy for technology implementation. To maintain their competitive superiority managers are expected to increase productivity through reduced technology downtime with improved performance in a limited resource environment. To best achieve this, one option is to replacement of older technologies with current and improved versions in every few years. However, the primary challenge for an organization is to understand and measure the replacement timing for optimum outcomes. To this end, a comprehensive two step statistical process is proposed.

KEYWORDS: Technology changeover, Leading indicator, piecewise regression, technology operations, technology management

INTRODUCTION

Technology is essential in accomplishing the primary organizational operations (Croteau & Bergeron, 2001; Mithas, Ramasubbu, & Sambamurthy, 2011; Tallon, Kraemer, & Gurbaxani, 2000) and has become a tangible resource utilized by organizations to enhance their capabilities. Researchers (Bharadwaj, Bharadwaj, & Konsynski, 1999; Devaraj & Kohi, 2003; Sabherwal & Jeyaraj, 2015) have provided evidence suggesting substantial returns are attained through technology investments along with being a method some organizations have used to create a strategic advantage (Mithas, 2012). Subsequently, investments in technology have been made by organizations' managers with the defined purpose of using technology to attain a competitive advantage (Kohli and Devaraj, 2003; Melville et al., 2004; Piccoli and Ives, 2005). More embedded technology means dependence on technology, and technology dependence challenge managers to address the risk to their company's operations when technology goes wrong. To overcome these challenges increasing interest in finding ways, to promote optimal use of technology, its updates, and the timing of changing technology over to its updates.

Educational technology in the classroom, similar to business organization's use of technology, has become an avenue university administrators use to facilitate innovations (Xu & Meyer, 2007).

Organizations create procedures to address technological disruptions that include analytical practices that assist in continuous monitoring, evaluation, and support services of the technology to minimize technology related interruptions to the operations of businesses and universities. Both types of organizations from time to time make additional technology investment decisions associated with replacing or updating technology. For managers, this is a complicated decision making process, as the producers of the technology make frequent changes and the managers try to accomplish strategic goals for the organization in a constrained resource settings.

As the underlying goal of technology resource management is the optimal usage of technology, determining the best timing of technology changeover becomes the core issue. Technology changeover, the main focus of this study, is different from the replacement of individual technology unit. Technology changeover is a large scale replacement of a technology system adopted by an organization. To implement a technology changeover many organizations rely on historical information and data that is usually subjective in nature. The length of time a technology remains valuable to an organization during the technology's life cycle is uncertain (see, Aytac and Wu, 2013) and therefore predicting the precise timing of changeover is challenging. This difficulty is primarily due to differences in the products' life cycles of various products and integration of multiple technologies in the system that reduces the likelihood a manager could, through subjective means alone, effectively predict the appropriate timing. Analysis of objective data taken from the operations of the technology should make it feasible to determine if the technology changeover adhere in the past fit into a recurring cycle and, if it does, it must also be possible to effectively predict when the organization's technology needs a changeover. To this end, this research contributes by determining if a technology changeover, that has already happened, is able to document through objective analysis and also investigates if any leading indicator(s) exists to identify the changeover timing in advance. Furthermore, this two-step approach combines the information from a leading indicator with an intervention model to predict the timing of technology changeover before it becomes essential. Operations managers could use this process to become more knowledgeable on the dynamics of advance planning for technology changeover to project necessary capital requirement.

LITERATURE REVIEW

Putting technology in the hands of employees where employees have a world of information at their fingertips, collaborate with colleagues across the globe, and deliver products also means employees are dependent upon a certain level of performance from the technology (even as it ages). Strategic standouts with technology, therefore, achieved a level of proficiency that allows them to construct, implement, maintain, changeover, and sun setting technology. Yet, of these areas, a proficiency in determining the timing for technology changeover is among the least researched. Given what we know about the landscape of the digital workforce and the increasing deployment of technology at work, the state of installed technology eventually reaches an operational state where it needs replacement or becomes surpassed by updated versions of the technology. Individual component repair or replacement of a broken unit is indicative of a traditional technology maintenance program, but this does not necessarily represent a state, where much of the organization's technology needs a changeover as discussed in this paper.

Changeovers here represent the replacement of technology and the continued use of this technology in an operationally improved form, and the changeover is a wholesale replacement of the technology. Hence, replacement *en masse* of the technology to newer version that possessed additional features is indicative of a technology changeover. Hallmarks of a technology changeover are an upgrade of a technology system by replacing incompatible units, replacement

of units on an enterprise-wide scale to improve efficiency, and stay current with the technological innovations. Timing this replacement can be a challenge as completing a changeover too early could provide additional improved technology at a higher cost to the organization, but the improvement may provide no additional strategic value. Changeover, instead of repair at a later time, might be beneficial to an organization with some number of aging technologies (e.g., computers) when the updated technology is a better option than the combination of downtime and maintenance costs associated with not updating the technology. Another option might be to delay changeover until the technology cannot effectively meet the expected performance need of users, when it stops working, replacement parts are hard to find, or it becomes totally outdated.

ABSTRACT

We develop an approach for the evaluation of interrelated risks that could compromise a pharmaceutical supply chain's ability to serve patients, whereby experts conduct pairwise-comparisons through an online gamification-enabled platform. Risks categorization based on structural modelling elevates their consideration beyond the single instance in which they are normally evaluated.

KEYWORDS: Multi-method research, Pharmaceutical Supply Chains, Supply Risk Management

INTRODUCTION

The literature on risk management in supply chains has developed substantially in recent years demonstrating the importance of taking a systems perspective on risk. For example, since the seminal work of Craighead, Blackhurst, Rungtusanatham, & Handfield (2007) increasing attention has been paid to the network characteristics of supply chains, and how these characteristics may affect system-wide disruptions. In a similar fashion, the World Economic Forum (2018) highlights that global risk perception should take into account how different risks might influence each other, as if forming a network, rather than evaluating each risk in isolation in terms of frequency and magnitude. Interdependencies between individual risks are sometimes acknowledged (for example, Chopra & Sodhi 2004), but not generally considered. The pharmaceutical sector provides an ideal context to address this methodological gap. Pharmaceutical Supply Chains (PSC) are increasingly exposed to disturbances such as the contamination, adulteration and substitution of pharmaceutical ingredients throughout increasingly global sourcing processes; the intentional and fraudulent production of drugs (counterfeiting); and the manifestation of arbitrage behavior through speculative inventory build-up in secondary distribution channels (Marucheck, Greis, Mena, & Cai, 2011). Due to the fragmented nature of PSCs, it is not common practice to analyze the identified risks in terms of possible interdependencies between them. Rather, the industry's approach to risk management is predominantly concerned with Good Manufacturing Practice (GMP) and regulatory compliance (Friedli, Basu, Bellm, & Werani, 2013, p. 63). Whilst relationships between risks are sometimes defined in hierarchical terms as in Fault Tree Analysis (Rees, 2011, p. 403), these approaches lack consistent analytical counterparts.

Considering the above mentioned gaps, we develop an approach for identifying and evaluating risk interdependencies that could compromise a PSC's ability to serve patients. This is achieved by answering the following research questions:

- RQ1: How can PSC risks be categorized and prioritized while systematically taking into account the interdependencies between them?
- RQ2: Which areas of interventions become more prominent when risk interdependencies are taken into account?

The proposed approach is meant to inform the formulation of mitigation strategies by elevating the consideration of risks beyond the single instance in which they are normally assessed. The reminder of this paper provides an overview of the relevant academic literature; outlines key methodological aspects for the elicitation and analysis of expert knowledge on risk interdependences; and illustrates an initial implementation through a sector case study in the UK pharmaceutical industry. This is followed by a discussion of some preliminary findings, and the expert feedback on how such findings may inform a critical appraisal of current and perspective risk mitigation practices.

LITERATURE REVIEW

Compared to the vast academic literature on Risk Management in Supply Chains (Heckmann, Comes, & Nickel, 2015 provide an overview), relatively little work has investigated the nature and prevalence of risk in pharmaceutical supply. For example, Huq, Pawar, & Rogers (2016) surveyed senior PSC executives on 20 'disturbance factors' in three global pharmaceutical network configurations differing for outsourcing location policy; Panzitta et al. (2017) propose a simplified risk assessment procedure to help regulators to quickly assessing medicine shortage risk in relation to 10 factors potentially affecting manufacturing complexity; Breen (2008) mapped out the PSC underpinning the UK National Health Service and identified 35 aspects of the current 'state-of-the-world' that could negatively affect the movement of medicines and materials, and hence compromise the treatment of patients. Jaberidoost, Nikfar, Abdollahiasl, & Dinarvand (2013) identify 50 vulnerability areas of a PSC by reviewing the literature. While a comprehensive overview of the literature is left outside the scope of this paper for brevity, it is possible to outline broad trends from both a conceptual and a data-driven modelling perspective:

- From a conceptual perspective, a common trait across research carried out to date, regardless of specific applications to PSC, is that the emphasis is placed on identifying and categorizing disturbances, chiefly uncertain and adverse triggering-events and outcomes, which are aggregately addressed with the blanket term 'supply chain risks'.
- From a modeling perspective, there seems to be three incumbent perspectives on data-driven supply chain risk management in PSC, namely:
  - *Statistical inference and predictive analytics*: empirical observations such as time-series or longitudinal data are mined to detect regularities in the occurrence of specific events. With regards to the pharmaceutical industry, regulatory agencies provide public domain datasets regarding, for example, medicine shortages and recalls. The analysis of such data with the aim of identifying trends and developing predictive analytics has received little attention in academia (Aschenbrücker, Löscher, & Troppens, 2013);
  - *Simulation and optimization*: probabilistic and 'snapshot' data (i.e. not historical) concerning the occurrence of identified scenarios are commonly taken into account when optimizing supply network configuration or simulating inventory dynamics in the form of stochastic programming and chance constraint. Applications may include avoiding medicines shortage by optimizing the build-up of buffer inventory as a mitigation strategy. For example Bam, McLaren, Coetzee, & Von Leipzig (2017) apply Systems Dynamics to model shortage risk for tuberculosis medicines;

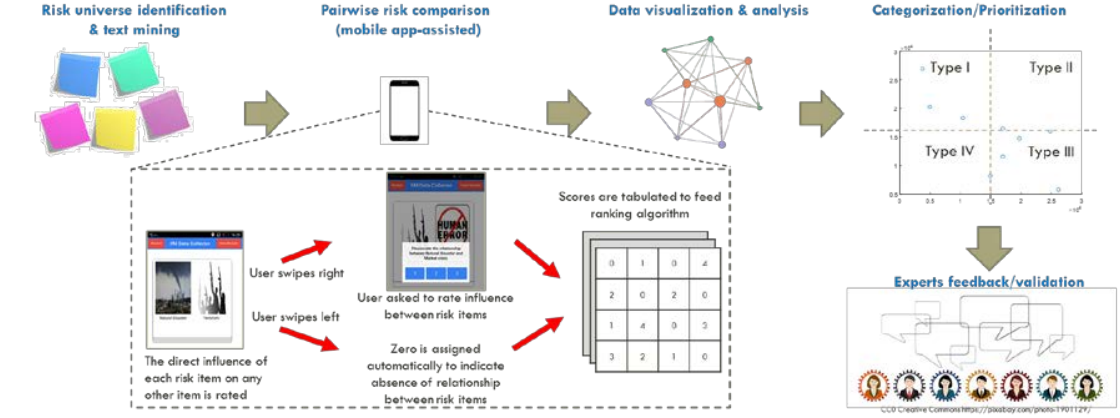
- *Expert judgment*: In the absence of precise quantitative data about specific product supply chains, the two approaches mentioned above cannot be applied. Often, the only source of empirical evidence is the expertise of those 'in the know', which then needs to be appropriately elicited and processed to provide some aid to decision making. Expert judgment may be elicited in the form of qualitative data, as in interviews or panel studies (Breen, 2008); or semi-quantitative data such as scores on ordinal scales as in surveys (Huq et al., 2016) and pair-wise comparisons (Raka & Liangrokapart, 2017).

The last perspective is of particular relevance for this paper, since empirical evidence is gathered chiefly through expert judgment. The reason for this choice is twofold. First, the necessary data for simulation and optimization is often company and product-specific: while providing greater accuracy, this approach may limit *a priori* the possibility to gather a broader, multi-stakeholder perspective on the topic of risk in PSC. Second, most statistical datasets available in the public domain have geographical coverage limited to the United States, and lack an end-to-end supply chain perspective. Rather, these datasets focus on the occurrence and duration of specific events such as shortage and recall of pharmaceutical products, sometimes accompanied by the indication of a single cause for its occurrence (for example, 'manufacturing delay', 'demand variability' etc.).

MATERIALS AND METHODS

The multimethod research approach adopted in this paper for modeling PSC risk is illustrated schematically in Figure 1.

Figure 1: Visual summary of proposed approach



The following sub-sections illustrate the key methodological aspects of the proposed multi-method research approach with regards to terminology and conceptual assumptions; techniques for semi-quantitative analysis; and data gathering process.

Theoretical perspective

In the context of this research, the notion of PSC risk is chiefly associated with the ability or inability to provide patients with the 'right' medicines.

While risk is relatively straightforward to formulate mathematically, it is more difficult to reach agreement on contextual definitions that enable the effective management of risk in supply chains (Kumar, Srai, & Gregory, 2016). A widespread attitude towards the concept of risk is to place the emphasis almost exclusively on what can go wrong, and hence on what supply chain organizations need to worry about (Olson & Wu, 2010). Underneath this common understanding of risk is the belief that unacceptable outcomes must have unacceptable causes, and that these

must be distinct from the causes of acceptable outcomes, thus reflecting an implicit moral codex in which good deeds are rewarded and bad deeds are punished (Hollnagel, 2018). This belief is implicitly endorsed in PSC through commonly adopted managerial practices such as root cause analysis – see for example Friedli et al. (2013). The main methodological implication of this terminological habit is that hunting for broken components within complex socio-technical systems continues to equate with 'good analysis' (Dekker, 2011).
A more nuanced view is that undesired outcomes typically associated with the notion of 'risk' emerge from the behavior of a complex socio-technical system, hence making 'things that go wrong' hardly separable from 'things that go well' (Hollnagel, 2018). Fewer works have brought to the fore the role of structural elements reflecting the system-like nature of supply chains in general, and PSC in particular. For example, Craighead, Blackhurst, Rungtusanatham, & Handfield (2007) associate the occurrence of supply chain disruptions, as well as the ability to respond to such disruptions through mitigation capabilities with structural elements of supply chains across several industries, including pharmaceutical, such as density, complexity, and node criticality.
The terminological caveats examined above lead to the following conceptual assumptions, which are adopted henceforth:

1. The term 'risk' more appropriately describes the exposure to the chance of loss or gain by choice rather than fate: in this way the attention is shifted towards managerial aspects for which decision support tools are needed (Emblemsvåg, 2011);
2. Supply chains being complex socio-technical systems (Pathak, Day, Nair, Sawaya, & Kristal, 2007), focusing on linear cause-effect relationships to understand adverse and disruptive outcomes can be misleading. Rather, it is necessary to pay greater attention to both the relevant system's elements, and the contextual relations among them;
