3. Higher-order interactions between ill-defined elements of a complex system are difficult to grasp relying on the individual's bounded rationality. To explore these interactions, experts need to sharpen their perception of the relationships between the system's elements through a formalized structure (Bolaños, Fontela, Nenclares, & Pastor, 2005).

Techniques for semi-quantitative analysis

The theoretical perspective presented above is addressed here through Structural Modeling (SM). A common principle across various SM techniques is to enable a group of experts to formally articulate an ill-defined problem in terms of elements and relationships within a system using the principles of graph theory, while allowing each expert to contribute diverse data, skill, and knowledge – see Lendaris (1980) for a comparative overview.
Specifically, two closely related techniques will be considered here:

- the structural problematique analysis developed within the DEMATEL (Decision Making Trial and Evaluation Laboratory) project (Fontela & Gabus, 1974), and
- the MICMAC (Matrice d'Impacts Croisés-Multiplication Appliquée à un Classement) technique (Godet, 1977).

Both approaches take inexact, subjective inputs with the aim of producing a meaningful, but not precise output by ranking, categorizing, and visualizing the elements included in the system of interest based on how they relate to each other. In both cases, the system's elements are typically qualitative structural variables of memory and experience, anticipation and foresight, or needs and goals; the relationships between such elements are typically relational statements can be definitive, comparative, influential, or mathematical in nature.
The key difference between MICMAC and DEMATEL is in the classification/prioritization and visualization of the elements of the system based on their interrelationships. In particular:

- Visualization facilities: both MICMAC and DEMATEL generate classification planes with specific interpretations for different areas of the plane;

- Computational structure: DEMATEL is based on solving a convergent series the elements of which are powers of a normalized cross-impact matrix. Conversely, MICMAC is based on raising a cross-impact matrix to consecutive powers following specific stopping criteria;
- Procedural consistency: DEMATEL is probably the approach more accurately described since the outset from a computational perspective. The consistent application of MICMAC is difficult to verify, as most works in the literature do not disclose the analytical details of the steps followed (see for example Jain, Kumar, Soni, & Chandra, 2017).
- Synthesis of multiple responses: DEMATEL explicitly provides analytical devices to combine multiple responses obtained from different experts, and to deal with the uncertainty deriving from such variety. In principle, also MIMAC and ISM may involve multiple experts, but it is unclear how this is analytically taken into account.

Based on our literature review, neither DEMATEL nor MICMAC have been applied to evaluate risk interdependencies in PSC. While System Dynamics qualifies as an SM tool (Lendaris, 1980), its applications to PSC are either product-specific (Bam et al., 2017), or purely schematic representations of causal paths and feedback loops (Narayana, Arun, & Rupesh, 2014).

Data gathering process

The identification of relevant risks with specific regards to the PSC was carried out through an iterative process involving multi-stakeholder workshops; qualitative data analyses through text mining; and online collection of semi-quantitative data (ordered-category rating items) through gamification-enabled structural modelling. Workshops were deemed a suitable format to gather reliable data through the active participation of a selected group of individuals sharing common expertise in the domain of interest (Ørngreen & Levinsen, 2017).

The steps of the knowledge elicitation process can be summarized as follows:

- Identification of risk elements to generate a 'risk universe' for a generalized PSC using a standardized PSC configuration map (Srai & Gregory, 2008) within a semi-structured workshop process involving input from multiple experts with extensive experience on risk analysis across the sector. Experts included individuals from two of the largest UK-based medicine manufacturers; a leading specialist healthcare distribution logistics providers; the major pharmacy retailer in the UK; a healthcare consultancy practice providing analytical tools for risk management; and a financial institution specializing in pharmaceutical risk insurance and reinsurance.
- Over 120 hours of expert deliberations on risk events informed the development of a 'universe' or risks, generating 121 risk items (statements) across the end-to-end PSC. In line with the incumbent risk management practice and academic literature alike, the risk universe thus obtained represented a comprehensive list of 'things that can go wrong' in a PSC, each accompanied by a definition and supporting statement of possible root causes. The potential relationships between these items were not identified at this stage;
- Textual data analysis: standard text mining techniques (Provost & Fawcett, 2013 Ch.10) were deployed to evaluate wording similarity and discover possible latent topics across items included in the workshop's risk universe, as well as in relation to 13 similar lists published in the academic literature. Through multiple iterations informed by the text mining results, 74 risk items aggregated in 17 categories were selected as elements of the system of interest to be further analyzed through SM. The items and categories included in this subset of the risk universe are listed in the Appendix;
- Pair-wise comparison of selected risk item: a second data-gathering process involved a group of five experts representing primary and secondary manufacturing; distribution and retail pharmacy, and institutional sector risk consultancy. The experts were required to provide $N = n(n-1)$ scores on a scale from 0 [no influence] to 5 [very strong influence], were $n = 74$ is the number of risks included in the final list. A gamification-enabled online

platform for structural modelling (MATRisk: https://remedies-ifm.azurewebsites.net/) was specifically developed to enable the assessment of the level of interdependence between risks by pair-wise comparison.

Elements of gamification were specifically introduced to incentivize users to engage in the process of collecting data of greater quantity and quality (Seaborn & Fels, 2015). In particular, through the online platform, each respondent scored remotely and in their own time the N pairs of risk items. Each pair was presented on screen as a 'card' containing an iconic representation and textual description of each item. The pairwise comparisons between these items was operated either by simply 'swiping left' to indicate that no association between the items exists, or 'swiping right' otherwise – in which case the respondent is asked to score the magnitude of the association on a 5-point ordinal scale. To expedite the process, experts could swipe groups of items simultaneously by using top-level cards corresponding to the 17 categories previously identified. The second process step in Figure 1 provides an iconic representation of the proposed gamification-enabled pair-wise comparison.

The preliminary data gathered process was carried out over 20 days throughout April 2018, following a webinar organized by the researchers to illustrate the purpose and use of the online platform to the enrolled respondents. At the end of the time window, data was gathered in the form of cross-impact matrices, analyzed by the researchers and the results presented to the respondents for feedback in a follow-up validation workshop.

RELIMINARY FINDINGS

To address RQ1 and RQ2, this section provides insights into the process of generating a classification and prioritization of PSC risks from experts-generated interdependencies scores. For the sake of clarity, the analysis is illustrated through a streamlined example first, and later on applied to actual data obtained from one respondent through the MATRisk online platform. For illustration, assume the risk universe consist of 7 items; then a hypothetical expert response corresponds to a 7 × 7 cross-impact matrix $\mathbf{X}$ like the one depicted in Table 1. (An actual table gathered through MATRisk would have 74 × 74 = 5,476 cells: due to space limitations, such table is not reported in full here, but is available from the authors on request)

Table 1: Hypothetical response numerical example: values are randomly generated for illustrative purposes only

EXP	Influencing risk item	Influenced risk item						
		1	2	3	4	5	6	7
A	1 Critical findings during Quality Audit	0	0	1	0	0	0	5
D	2 Process variability and quality deviation	0	0	0	0	2	5	0
A	3 Final product contamination/degradation	0	0	0	0	0	0	5
B	4 Supplier's understanding of regulatory constraints	3	0	0	0	0	0	0
C	5 Strategic/commercial decision by supplier to discontinue product	0	0	0	0	0	0	0
B	6 Lack of process robustness/process failure/variability of product	0	3	4	0	0	0	0
E	7 Shelf life insufficient for product lifetime/distribution timescales	5	0	0	0	0	0	0

EXP: expert classification by cause/responsibility (A - Failure in Focal Company Quality; B - Failure in Contract Manufacturer quality; C - Inability of supply; D - Process complexity/variability; E - Regulatory Change);

Table 1 shows an example of how most SM techniques, such as DEMATEL and MICMAC, formally articulate the relationships of direct influence between any pair of constituting parts of the problem situation. Each cell in the cross-impact matrix records the expert's assessment of the influence of the item listed row-wise on the item listed column-wise. Hence, the generic element of a cross-impact matrix $\mathbf{X}$ can be interpreted as follows:

$$\mathbf{X} = \left[x_{ij}^{k}\right] = \begin{cases} l, & \text{expert } k \text{ believes that } i \text{ exerts direct influence of magnitude } l \text{ on } j \\ 0, & \text{otherwise} \end{cases} \quad (1)$$

In equation (1), each row and column of $\mathbf{X}$ (hence, each risk item) is indexed as i and j, respectively. The estimate l of the magnitude of a relationship between elements of a problem situation is typically expressed using ordered-category rating items. Unfortunately, there is no consistent use of rating items in the literature. Depending on the individual study, the rating items range from [0, 1], indicating just the absence/presence of an influential relationship (see for example Jain et al., 2017), and up to 5-points ordered-category rating items to indicate very low [1] to very high [5] influence (see for example Rajesh & Ravi, 2017). The latter type of rating item is not be confused with Likert-type scales used in survey research, since it lacks the characteristic of being a bipolar and symmetrically balanced response set, and it is not meant to indicate degree of agreement with a stimulus attitude statement.

For example, $x_{2,5} = 2$ denotes that, in the expert's opinion there is a direct influence between risk item 002 ('Process variability and quality deviations') and risk item 005 ('Strategic/commercial decision by supplier to discontinue product'). While this is not the case the other way round, since $x_{5,2} = 0$. Mutual influences are allowed, but the relationship is not symmetrical i.e., 'A influences B' does not imply that 'B influences A'. In terms of the MATRisk online platform usage, this means that the respondent has 'swiped right' when presented with a the pairwise comparison card stating 'Risk item 002 influences risk item 005', but they 'swiped left' when presented with the card stating the relationship the other way round. Consequently, along any row of matrix $\mathbf{X}$ one reads the direct influence exerted by the corresponding risk item on any other item; along any column, one reads the dependence of the corresponding risk item on any other item. In the example, item 002 directly influences items 005 and 006 ('Lack of process robustness/process failure/variability of product'); and it directly depends on items 005, hence 002 and 005 are said to form a cycle. Matrix $\mathbf{X}$ can, in fact, be interpreted as the incidence matrix of a weighted directed graph. For an actual response, Figure 2 shows the network visualization and descriptive analysis generated using Gephi (Bastian, Heymann, & Jacomy, 2009).

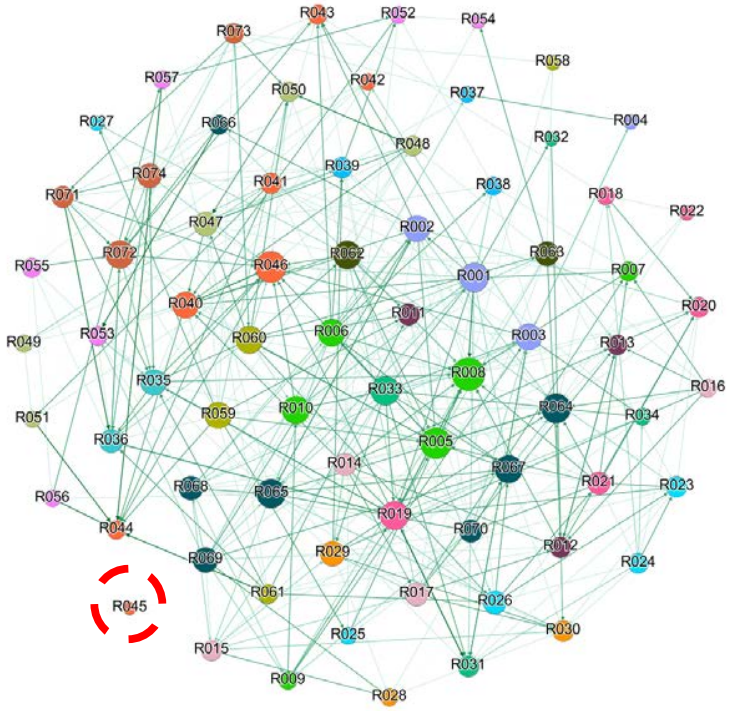
The use of graph-theory to interpret the cross-impact matrix $\mathbf{X}$ is a key principle of SM in general (Lendaris, 1980), and of techniques such as MICMAC and DEMATEL in particular. Both techniques take $\mathbf{X}$ as input, but then process it in a slightly different fashion:

According to the MIMAC technique, $\mathbf{X}$ is raised to successive powers $p = 2,3,\ldots$ to unravel paths of influence beyond the direct connections represented in the corresponding graph. For example, making reference to the hypothetical example in Table 1, risk item 002 does not exert a direct influence on item 003 ("Final product contamination/degradation") but it does so indirectly through item 006, which it directly influences and, in turn, influences item 003. This is known as transitivity. This path can be discovered through the Boolean operation of raising $\mathbf{X}$ to the power $p = 2$, and checking that $x_{2,3}^{(2)} \neq 0$ – here the notation $x_{i,j}^{(2)}$ denotes the element in row i and column j in the Boolean matrix associated with $\mathbf{X}^2$, not $\left(x_{ij}\right)^2$. This leads to the following general formulation:

$$\mathbf{T}^{*} = \lambda \mathbf{X}^{p^{*}} \quad (2)$$

Where $\mathbf{T}^{*}$ is the normalized matrix of total connections, p^{*} is the highest power to which matrix $\mathbf{X}$ is raised; and λ is a normalization factor. Unfortunately, there is no agreement in the literature with regards to the parameters λ and p^{*}.

Figure 2 Network visualization, descriptive analysis of initial response (risks list in Appendix)



Network summary:
- Avg. degree: 5.9
- N = 74; L: = 443
- Density: 0.08
- Avg. path length: 4.12

- Arcs color-coding: weight (the higher the score the darker the arc color)
- Nodes color-coding: categorization in risk universe

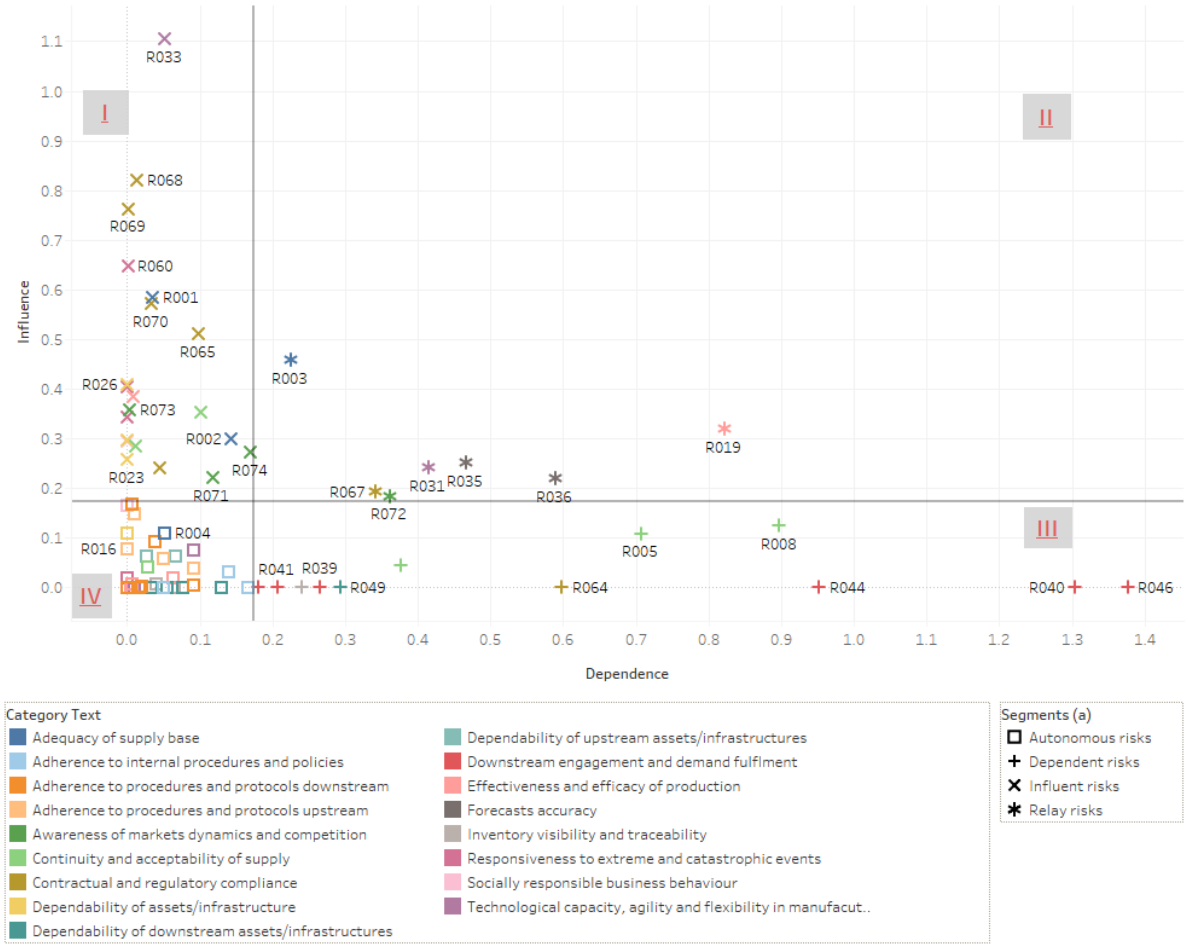
For example, Godet (2007) suggests that p^* is such that greater powers no longer affect the ranking of the vector sums across the columns and rows of $\mathbf{T}^*$, whereas Lendaris (1980) implies that $p^* = n$; in either case $\lambda = 1$. Conversely, (Hachicha & Elmsalmi, 2014) use $\lambda = 10^{-p^*+1}$ but do not provide a general rule. Other applications do not disclose the computational procedure followed in implementing MICMAC. In the simplified example considered here, $p^* = 4$ is found iteratively. It follows that $\lambda = 10^{-3}$ and:

$$\mathbf{T}^* = \begin{bmatrix} 0.625 & 0 & 0.025 & 0 & 0 & 0 & 0.250 \\ 0.500 & 0.225 & 0.300 & 0 & 0 & 0 & 0 \\ 0.625 & 0 & 0 & 0 & 0 & 0 & 0.125 \\ 0.075 & 0 & 0.075 & 0 & 0 & 0 & 0.375 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0.100 & 0 & 0.090 & 0.225 & 0.800 \\ 0.125 & 0 & 0.125 & 0 & 0 & 0 & 0.625 \end{bmatrix}; \mathbf{d}^* = \mathbf{1}' \mathbf{T}^* = \begin{bmatrix} 1.95 \\ 0.22 \\ 0.62 \\ 0 \\ 0.09 \\ 0.22 \\ 2.17 \end{bmatrix}; \mathbf{r}^* = \mathbf{T}^* \mathbf{1} = \begin{bmatrix} 0.90 \\ 1.02 \\ 0.75 \\ 0.52 \\ 0 \\ 1.21 \\ 0.87 \end{bmatrix}'$$

Vectors $\mathbf{d}^*$ and $\mathbf{r}^*$ are obtained, respectively, as the column and row sums of $\mathbf{T}^*$, providing for each item in Table 1 a measure of its overall power of influencing or being influenced, directly and indirectly, by any other items. The elements in $\mathbf{d}^*$ and $\mathbf{r}^*$ that correspond to a specific risk item are used as coordinates to graphically represent the item on a Cartesian plane. For an actual respondent, Figure 3 (next page) shows the risk items scatterplot on the influence/dependence plane.

In Figure 3 the risk items are categorized as they fall into specific quadrants of the plane based on whether their coordinates are above or below the average dependence and influence. Proceeding clockwise, each quadrant is interpreted as follows (Godet, 2007):

Figure 3 MICMAC risk categorization for initial response (risks list in Appendix)

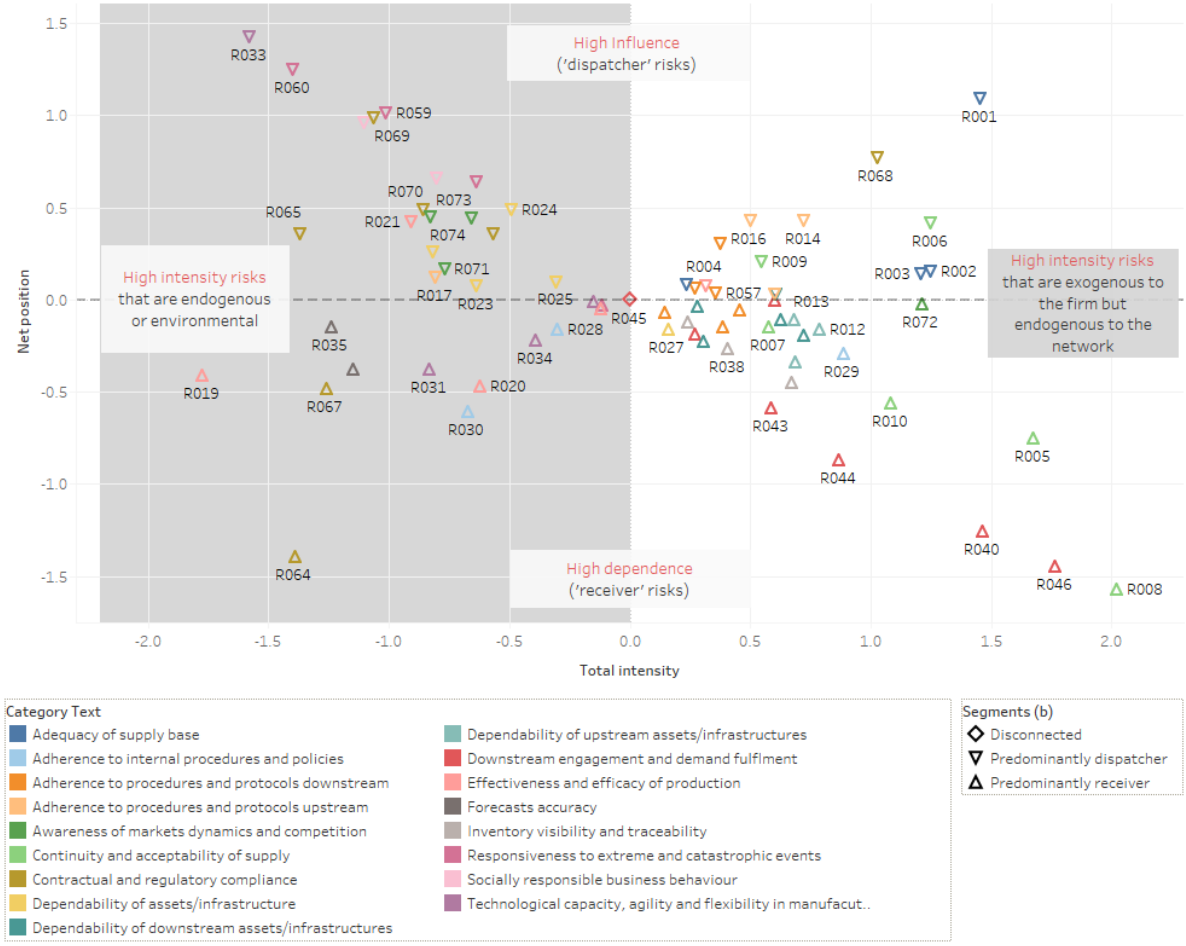


- Quadrant I (upper-left): mostly *influential* items, potentially conditioning and explaining the behavior of the whole system;
- Quadrant II (upper right): gate-keeping or *'relay'* items showing instability, characterized by being both influential and dependent on other items in the system;
- Quadrant III (lower right):mostly *dependent* items, largely resulting from the interactions between those items in quadrants I and II;
- Quadrant IV (lower left): mostly *autonomous* items, that may be expected to have little or no influence on future developments having fewer relationships with the rest of the system. These can be safely discarded from further analysis.

The segments corresponding to each quadrant are visually codified as shapes in Figure 3.
The same matrix-structured dataset gathered through the MATRisk app was analyzed through the DEMATEL technique. A distinguishing feature of DEMATEL is that the total connections matrix $\mathbf{T}^*$ is the result of a convergent series, the element of which are powers of a normalized cross-impact matrix $\mathbf{A}$ obtained by multiplying the raw data gathered in $\mathbf{X}$ by a scalar equal to the reciprocal of the largest row sum of the cross-impact matrix (Fontela & Gabus, 1974):

$$\mathbf{T}^* = \lim_{p\to\infty}\left(\mathbf{A} + \mathbf{A}^2 + \mathbf{A}^3 + \cdots + \mathbf{A}^p\right) = \mathbf{A}(\mathbf{I} - \mathbf{A})^{-1} \quad (3)$$

Figure 4 DEMATEL risk categorization of initial response (risks list in Appendix)



In equation (3), $\mathbf{I}$ is an identity matrix of adequate size, and the superscript "-1" denotes matrix inversion. The aspects of normalization and convergence criteria when computing the total connection matrix as shown in equation (3) are less ambiguous in the literature than in the MICMAC case. As in the MICMAC case, the key metrics of dependence and influence are obtained by summing the elements of the total row and column-wise, respectively. Using the simplified example in Table 1, from equation (3) one obtains:

$$\mathbf{T}^* = \begin{bmatrix} 1.39 & 0 & 0.34 & 0 & 0 & 0 & 1.95 \\ 0.71 & 0.44 & 0.69 & 0 & 0.41 & 1.20 & 1.01 \\ 1.22 & 0 & 0.17 & 0 & 0 & 0 & 1.71 \\ 1.02 & 0 & 0.14 & 0 & 0 & 0 & 0.83 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 1.01 & 0.61 & 0.96 & 0 & 0.17 & 0.44 & 1.41 \\ 1.71 & 0 & 0.24 & 0 & 0 & 0 & 1.39 \end{bmatrix}; \mathbf{d}^* = \mathbf{1}' \mathbf{T}^* = \begin{bmatrix} 7.09 \\ 1.06 \\ 2.57 \\ 0 \\ 0.58 \\ 1.47 \\ 8.32 \end{bmatrix}'; \mathbf{r}^* = \mathbf{T}^* \mathbf{1} = \begin{bmatrix} 3.69 \\ 4.30 \\ 3.12 \\ 2.01 \\ 0 \\ 4.62 \\ 3.36 \end{bmatrix}$$

The elements are visualised and categorized by combining the corresponding values in vectors $\mathbf{d}^*$ and $\mathbf{r}^*$ as follows:

- $\mathbf{y} = \mathbf{r}^* - \mathbf{d}^*$: is the "net position" of the risk items. A positive entry in $\mathbf{y}$, indicates that the corresponding risk item is predominantly a "dispatcher", strongly influencing other risks. Whereas, if negative the item is predominantly a "receiver", strongly influenced by other risks.
- $\mathbf{x} = \mathbf{d}^* + \mathbf{r}^*$: is the "total intensity" of the risk items. Similarly to the concept of weighted node degree in a network, larger-valued entries in $\mathbf{x}$ denote risk items of greater overall relevance, considered simultaneously as a dispatcher and receiver.

With reference to the data gathered for an actual respondent, Figure 4 (above) shows an alternative scatterplot of the same risk items according to their net position and total intensity indicators computed according to the DEMATEL procedure described above. In Figure 4, risks regarded as endogenous and environmental are shown with total intensity increasing from right to left (greyed area), whereas risks regarded as exogenous to the individual firm but endogenous to the PSC are shown with total intensity increasing form left to right.

DISCUSSION

Although derived from a limited respondent base, the results illustrated in the previous section already provide some structural insights into the propagation of risks in a generalised PSC when possible interdependencies between risks are explicitly taken into account.

Joint examination of Figures 3 and 4 leads to the following observations:

- Dependent risks (items falling in Quadrant III of Figure 3; bottom half of Figure 4) are mostly located downstream, reflecting a linear upstream-to-downstream flow of influence. For example, almost all the risk items included in the category "downstream engagement and demand fulfilment" exhibit high dependency (bottom-right quadrant in Figure 3; and bottom half of Figure 4). Most of these items are perfectly dependent (nil influence). Those items that more closely reflect the overarching PSC risk concept defined in the theoretical perspective section, namely R046 ("Product shortage prevents patient getting product") and R040 ("Delays in delivery to patient"), exhibit the highest dependence in Figure 3. Whilst these items are still prominent in Figure 4, risks belonging to other categories, namely R008 ("Late or incorrect delivery of materials "") and R064 ("Loss of license to operate") exhibit higher rank in terms of receiver net position and intensity;
- Influential risks (items falling in Quadrant I of Figure 3; upper half of Figure 4) belong to heterogeneous categories. The highest ranking risk in this segment, R033, is technological in nature and related to the increasing complexity of medicines portfolios. Most contractual/regulatory compliance risks, and risks in the category "responsiveness to catastrophic and extreme events" fall in this segment (upper-left quadrant in Figure 3; upper half of Figure 4);
- Relay (unstable) risks (Quadrant III in Figure 3; middle-right/left in Figure 4): the presence of seven items in the upper-right quadrant in Figure 3 suggests some instability in the system, although none of these items scores simultaneously as high in influence and dependence. Relay items are either endogenous to the firm or environmental in nature, including categories such as: process complexity/variability; forecast accuracy; and inability of supply;
- Ambiguous risks: some risks are located in close proximity to the x or y-axis in Figure 3, such as R067 ("Failure/inability to comply with regulatory change") and R072 ("Product diversion e.g. product not being sold in target market in the presence of price differentials"). These risks are more difficult to categorize and require further analysis (Godet, 2007).
- Independent risks (Quadrant IV in Figure 3; close to the centre in Figure 4): Almost half (~46%) of the risk items evaluated falls into the "autonomous" category and hence could be dismissed, as they exhibit weak influence and dependence. For example, two downstream risks have neutral net position, with R045 ("Extended applicability of GDP to handling points in the distribution chain") being perfectly autonomous (graphically positioned at the point of origin in Figure 3 and 4; and a disconnected node in Figure 2).While relevant in terms of risk

identification, these risks might not propagate as pervasively as others, rather, they can be regarded as mostly self-contained and hence not a priority.

Preliminary findings such as those discussed above provided the grounds for an expert-panel discussion in a follow-up workshop. Visual analytics analogous to those shown in Figure 3 and 4 were presented to the participants through interactive dashboards on multi-user touch-screen surfaces to enable further interrogation and exploration of the data as part of a small-group learning activity.

From a mitigation strategy perspective, the analysis lends itself to network theories on contractual relationships and their implications for supply chain management (Kim, Choi, Yan, & Dooley, 2011). More specifically, proposed risk management for networked risks (54% of those identified in our study) would be informed by the identification of influential, informational dependent, and relational mediation characteristics of risks. For independent risks (46% in our study) conventional approaches to manage and mitigate risk such as those prosed by Chopra & Sodhi (2004) and Kumar et al. (2016) would remain appropriate and relevant.

From a computational standpoint, similarities and differences between MICMAC and DEMATEL and the visual-analytical insights they generate are rarely pointed out. Rather, either technique is chosen upfront by individual studies without acknowledging the other. This reflects a more general lack of comparative research on SM approach since seminal works such as Lendaris (1980). For similar reasons, only few works to date address the issue of assessing the reliability and validity of the results obtained through these techniques (e.g., Shieh & Wu, 2016).

CONCLUDING REMARKS

This paper has presented an approach for the evaluation of interrelated risks that could compromise a pharmaceutical supply chain's ability to serve patients. The approach was developed in line with multi-method research, and it encompassed the elicitation of expert knowledge on risk events across the PSC; the development of an online gamification-enabled platform for experts to conduct pairwise-comparisons; and the use of structural analysis methods to categorize and prioritize risks based on their identified interrelationships. These steps have been illustrated throughout the paper with reference to some preliminary results gathered from actual survey responses with a focus on the UK pharmaceutical landscape. Feedback and validation of preliminary findings through industry experts' engagement confirm the utility of the approach in determining risk category clusters where interdependencies elevate their consideration beyond the single instance in which they are normally evaluated.

While existing techniques are employed as part of the proposed approach, its novelty lies in the broader process of expert judgement elicitation, from the identification of a sector-specific universe of risks, through to the analytical evaluation of the possible interdependencies between the identified risks, and up to bringing the analytical insights gathered from individual respondents back to the group for discussion and validation.

The proposed approach promotes the innovative use of gamification-enabled structural modelling, thus explicitly addressing the challenges of engaging experts in a potentially cumbersome data gathering process. The panel discussion provided initial feedback on the respondents' overall experience with the data gathering process, visualisation of results insights on ranking. Overall, the MATRisk app was found to be easy to use, and serving its purpose of expediting a comparison process potentially involving 5,000+ pairs of items.

An obvious limitation of the research presented in this paper is that it relies on preliminary results gathered from a limited set of respondents. However, similar works often present aggregated view through a single super-respondent, or are vague with regards to whether single or multiple experts are involved in a study. Other limitations include the absence of a consistent approach on assessing the reliability and validity of the results obtained through SM techniques. Addressing these limitations calls for further research on this topic.

ACKNOLWEDGEMENTS
Support from the Advanced Manufacturing Supply Chain Initiative (Grant No. 35708-233529, ReMediES – Reconfiguring Medicines End-to-end supply) is gratefully acknowledged. The authors would like to thank Catherine Geyman and Yong Bang Xiang for their invaluable technical support in developing and deploying the MATRisk online platform. Comments from two anonymous reviewers greatly helped to improve the paper.

Impact of Game-Based Classroom Response System as a Persuasive Technology on Students' Perception of Their Learning Experience:
Case study of Information Systems course for Business Student

ABSTRACT

This survey study measured the effect of game-based classroom response system as a persuasive technology on the students' perception of their learning experience. A group of 108 Business students enrolled in one of the introductory courses of Management Information Systems was selected as a convenient sample. Based on Fogg Behavioral Model, three independent variables were selected, which are Ability, Motivation, and Trigger factors. The effect of these factors on the dependent variable, students' perception of their learning experience, was measured. Multiple linear regression test was used to determine the best-fit models between the independent and dependent variables.

KEYWORDS: Game-based classroom response system, Persuasive technology, Gamification, Fogg behavioral model (FBM), Motivation

INTRODUCTION

There are different types of classroom response systems (CRS) in the new educational era such as Turning Point, Poll Everywhere, Top Hat, Socrative, Clicker, and Kahoot. Mahon (2012) defined classroom response system as "technology that allows an instructor to present a question or problem to the class; allows student to enter their answers into some kind of device; and instantly aggregates and summarizes students' answers for the instructor". The features of game-based learning such as competitive practices, immediate feedback, and classroom monitoring are supported by the newer type of classroom response systems. The purpose of this study is to address the impact of game-based classroom response system (Kahoot) as a persuasive technology on the students' perception of their own learning experience.

Problem Statement

MIS101, Introduction to Information Systems for Management, is the mandatory lower level course for all business students in the College of Business in one of the large-size public universities of northeast California. Two sections of 55 students were assigned to me for the first time to teach in Spring 2018. More experienced colleagues who taught this course in previous semesters informed me that there is a student lack of interest in this class and it is difficult to engage large number of students in the non-specialized courses for their major.
For increasing students' engagement, motivation and learning, we decided to use Kahoot, a multiplatform game-based classroom response system. Kahoot has several advantages compare to its competitors and the most important one is that it's free and can run in a browser without installation. The Kahoot platform was new for me and for the students. Some of them used Clicker or Hat, but almost none of them had the experience of working with Kahoot.
As an instructor of MIS101, my main goals and strategies for using CRS in this class were classroom monitoring, game-based learning, formative assessment, immediate feedback, and equal participation. Monitoring student attendance and participation in large-size classes are not easy tasks (Lander and Stoeckel, 2012). According to Martyn (2007), CRSs support some principles of game-based learning, such as competitive practices and scoreboard system. The game strategy that the instructor used in this class was to ask students to read the assigned

chapter for the class session, then listen to the lecture in the class and take a multiple-choice quiz on Kahoot to stabilize their learning.

LITERATURE REVIEW

Game-based classroom response system

The benefits of CRS according to Martyn (2007), are immediate response and display as well as data analytics for assessments and evaluations. Fies and Marshall (2006) described that the appropriate pedagogy combined with the classroom response systems can promote learning. Other studies such as those of Simpson and Oliver (2007) and Stowell and Nelson (2007) disclosed that classroom response system by making an interactive and dynamic environment could make the class more fun and enjoyable for both students and instructor. Lander and Stoeckel (2012) and Caldwell (2007) discussed the disadvantages of CRS. Based on their studies, making quality questions which are aligned with learning objectives of the course, unfamiliarity of instructors and students with the CRS interactive environment, and the unstable or disconnected internet connections are some of the disadvantages that need consideration before applying CRS in the classroom.

Kahoot is one of the game-based classroom response systems (GCRS) that for the first time was introduced in 2013 (Wang and Zhu, 2016). While Bring You Own Device (BYOD) and technology tools have been widespread in the modern classroom, the classroom response system (CRS) has shifted from Clickers or Zappers to more game-based classroom response system (GCRS), such as Kahoot or Socrative (Wang, 2015). With Kahoot, students can use their cellphone or tablet to open the web browser, connect to the Kahoot game landing page, enter the game pin and start answering the questions in a game-show like situation. Instructor is the game show host and students are the competitors. Question will be displayed on the classroom screen with different graphical user-interface, audio, and time limit. The instructor can control the pace of play. If students answer the question correctly, they will be awarded points and students' points will be displayed on the screen and this could be exciting for the students.

THEORETICAL FRAMEWORK: GAMIFICATION AND PERSUASIVE TECHNOLOGY

Huotari and Hamari (2012) defined gamification as "a process of enhancing a service with affordances for gameful experiences in order to support user's overall value creation". In gamification, the game elements are applied in an unlikely context, such as education, health, management, or marketing. According to Gartner, gamification motivates a target audience to higher and more meaningful levels of engagement. The stimulating elements of gamification, such as immediate feedback, feeling of achievement, and challenge make it valuable in the field of education (Kapp, 2012). Because of these stimulating features, game-based response systems can be used as "persuasive technology" within the classroom environment.

Fogg (2002) defined persuasive technology, as a technology that is designed to change user attitude and behavior through persuasion and social influence. Fogg (2009) explained that persuasive technologies are ubiquitous. People can experience them through the web, video games, mobile phones applications, and consumer electronic devices. He introduced the best practices for developing new digital experiences that could influence people. Furthermore, he described the eight-step design process for creating successful persuasive technologies. He believed that three factors, lack of motivation, lack of ability, and lack of a well-timed trigger to complete the task may result in an unpleasant digital experience (Fogg, 2009). Also, the lack of these three factors could prevent audience from performing the target behavior. In this study,

the Fogg model was applied to the game-based classroom response system (Kahoot) and its users (students here).
In this study, the Ability, Motivation, and Trigger factors were used as independent variables. Therefore, Ability, Motivation, and Trigger scales were designed for the purpose of this study. Here each of the three factors as defined in the Fogg Behavioral Model (FBM) are explained.
In Fogg Behavioral Model, Ability is sometimes replaced by Simplicity. Based on his model, if persuasion designers focus on Simplicity of the target behavior, they will increase the Ability. Fogg (2009) defined Simplicity as "the minimally satisfying solution at the lowest cost". Also, he mentioned that time, money, physical effort, brain cycles (think a lot for the long time), social deviance (going against the norm), and non-routine tasks are the elements of Ability.
Fogg (2009) observed that the core motivators are central to human experience. Three core motivators in his study are sensation, anticipation, and belonging. Each of these has two sides--pleasure/pain, hope/fear, and acceptance/rejection. Fogg's keynote at Health User Experience Design Conference clarified that when motivation is high, you can get people to do hard thinks (Fogg, 2012). Also, his model shows that by motivating people, we can facilitate changes in their behavior.
Fogg (2009) gave different names to Triggers such as cue, prompt, call to action, request, and so on. Based on his study the target action sometimes needs an internal or external trigger, such as, a ringing alarm. There are three types of Triggers--facilitator, signal, and spark. The designers should use the Trigger type that best matches their target user's context. Further information of these constructs as applied in this study will be provided in the methodology section.

METHODS

This study used cross-sectional methodology. Cross-sectional is a subset of survey research methodology in the quantitative strategy category [16]. This study investigated the extent to which differences in students' Motivators (Motivation), Simplicity factors (Ability) and different types of Triggers (Facilitators) are related to differences in the students' perception of their learning experience.

Population and sample

A convenience, non-probability-based sampling method was used in this research (Creswell and Creswell, 2017). The sample comprised business students who were enrolled in the Introduction to Information Systems (MIS101) course in Spring 2018 at one of the large-size public universities in northeast California. All students in this study are business undergraduate students with different concentrations such as accounting, business, management, marketing, finance, management information systems, human resources, and entrepreneurship.

Data collection and response rate

The tool for collecting data in this study was an online questionnaire. The total number of questions was 30 plus 11 demographic questions. Students took 5-10 minutes to fill out the questionnaire. As an instructor of the course, I explained in the face-to-face class that this is the first semester that I am using mobile-based response system (Kahoot) in MIS101 and would like to know how this technology tool affects their learning experiences. It was mentioned in the class that survey is located on the Google Form. The link to the survey was provided in Canvas (Student Learning Management System) and was also emailed to them. Participants were informed about the subject of the study and could ask any questions regarding the research.

Their participation was voluntary, and they were offered an extra credit if they filled out the survey. At the end of the semester, they were assigned two different types of extra credit activities and they had an option to choose between them. Since the survey was anonymous, there was no fear of revealing the participants' identity. The data collection process took two weeks. A sample survey will be provided upon the request of the reviewers.
Out of 108 face-to-face registered students in two different sections, all of them filled out the online survey. Therefore, the response rate was 100%.

Descriptive Sample Information

Table 1 shows the sample demographic information. his includes gender, age, international/domestic student, ethnicity, class level, full-time student, major, studying and working per week.
Most of the sample members are male (66.7%); the female population is 33.3%. Students' ages are between 19-above 42 but most students are in the age range of 19-24 years old. Three main ethnic groups are Asian (26.9%), Hispanic or Latino (20.4%), and White (28.7%). Around 75% of the sample populations are in their junior year at college and 94.4% of them are full-time students. Finance concentration has the highest rate of enrollment, business administrative with 21.3% stayed in the second rank and accounting with 17.6% placed as a third popular concentration. Also, around 45% of them are working full time and 40% of the students are studying between 6-20 hours during a week.

Instrument Validity and Reliability

The validity of the instruments was examined by content validity. After extensive literature review and consulting with experts in the field, the main scales for Motivation, Ability, Trigger, and perception of learning experience factors in this study were designed. Two experts from the School of Business and two experts from the College of Technology at the large-size public university in northeast California reviewed the questionnaire and gave their professional opinions. Furthermore, Forgg (2002) study provided a comprehensive viewpoint and applicable guide to develop the scales. Several items of Motivation and Trigger scales were adapted from Bicen and Kocakoyun (2018) and Zarzycka-Piskorz (2016) and modified for this study. All four scales are based on a 5-point Likert scale and five anchors (1=strongly disagree to 5=strongly agree).
Perception of learning experience scale included seven items and was intended to measure the student's perception of their learning via the mobile-based classroom response system. The Cronbach's alpha for this scale was solid and 0.94. The students' perception of their learning experience construct included the following questions:

1. Information can be recalled more easily thanks to Kahoot
2. Use of a learning method blended with a Kahoot help me to understand the lesson better
3. Playing Kahoot improves my learning
4. Kahoot enables active learning
5. Kahoot provides permanent learning in classroom activities
6. Playing Kahoot made me think more during
7. Playing Kahoot makes my learning process faster and easier
8. Overall, how would you rate your learning performance playing with Kahoot?

The simplicity (ability) scale in this study was intended to measure how easy or simple it is for students to work with Kahoot. In another word, how simple setup of Kahoot can increase the ability of students to work with. This scale included seven items. When students see Kahoot

application easier to setup and use, the scale values are more positive; if they find Kahoot application difficult to set up and hard to use, the direction tends to be negative. The Cronbach's alpha for this scale with the value of 0.717 was meaningful. The Ability construct included the following question:

9. It is fun to compete against other students
10. I like to see myself on the Kahoot Podium at the end of the game
11. The Kahoot music on the background while I am answering a question, makes me nervous
12. I like to put funny avatar for my Kahoot nickname
13. The color harmony of the buttons in the application is nice
14. Kahoot point-system makes me excited for playing it
15. I think my reputation in the classroom improves with the badges I win through Kahoot

The motivation scale in this study was intended to measure the students' motivation for using Kahoot in the classroom. This scale included eight items. When students are motivated to use Kahoot, the scale values are more positive; if they don't have enough motivation, the direction tends to be negative. The reliability test for this scale was solid and 0.88. The motivation construct included the following questions:

16. Playing Kahoot decreases my stress for taking other quizzes (such as midterm and final exam)
17. My fear of taking exams decreases by playing Kahoot in class
18. Seeing the answer of the test immediately increases my motivation to focus
19. Playing Kahoot can increase my class attendance rate
20. I wish Kahoot! Was used in other lectures
21. I enjoy playing Kahoot
22. I engage more in class while playing Kahoot
23. Each question I correctly answer improves my self-confidence

The Trigger (Facilitator) scale in this study was intended to measure the Kahoot's facilitator tools to attract students to engage in the class. This scale included seven items. If facilitator tools could engage more students in the class, the scale values are more positive and if they don't, the direction tends to be negative. The reliability test for trigger scale was 0.74 and acceptable.

The Trigger construct included the following questions:

24. It is fun to compete against other students
25. I like to see myself on the Kahoot Podium at the end of the game
26. The Kahoot music on the background while I am answering a question, makes me nervous
27. I like to put funny avatar for my Kahoot nickname
28. The color harmony of the buttons in the application is nice
29. Kahoot point-system makes me excited for playing it
30. I think my reputation in the classroom improves with the badges I win through Kahoot

Data analysis

Multiple linear regression was utilized for analyzing quantitative data in this study to determine the strength and direction of the relationships between the motivation, ability, and trigger scales and students' perception of their learning experiences. Scale reliability was examined by the Cronbach's alpha. Multiple linear regression was used to build a model and discover the best predictors for the students' perception of the learning experience; statistically-insignificant

variables were not included in the model. All statistical procedures were performed using SPSS (Version 25).

Table 1: Demographic Information		
DEMOGRAPHIC	FREQUENCY	PERCENT
Gender		
Female	36	33.3
Male	72	66.7
Age		
19-24	71	65.7
25-30	16	14.8
31-36	7	6.5
37-42	4	3.7
Above 42	10	9.3
International/Domestic		
International	3	2.8
Domestic	105	97.2
Ethnicity		
American Indian or Alaska Native	2	1.9
Asian	29	26.9
Black or African American	6	5.6
Hispanic or Latino	22	20.4
Native Hawaiian or other Pacific Islander	2	1.9
White	31	28.7
Other	2	1.9
I prefer not to respond	14	13
Class Level		
Freshman	2	1.9
Sophomore	1	0.9
Junior	81	75
Senior	24	2.2
Full-time Student		
Yes	102	94.4
No	6	5.6
Major		
Accounting	19	17.6
Business Administrative	23	21.3
General Management	10	9.3
Marketing	8	7.4
Finance	24	22.2
Information Systems	14	13
Human Resources/Entrepreneurship	9	8.3

RESULTS AND DISCUSSION

The two important questions that were studied in this research are:

1. How game-based classroom response system (Kahoot) as a persuasive technology can affect the students' perception of their learning experience?

2. What are the most important factors that change students' perception of their learning experience? Motivation, Ability, or Trigger?

A multiple linear regression was used to determine the best-fit models between the dependent and independent variables. The R square value of 76.2% of the observed variability in students' perception of their learning experience is explained by the three independent variables. The R with the value of 0.873 shows the good correlation coefficient between the observed value of the dependent variable and the predicted value based on the regression model. The observed value of 0.762 is large enough and indicates that the linear regression model predicts well (Table 2). Table 3 shows that the coefficient for ability and motivation scales are not zero ($p<0.05$); therefore, the null hypothesis is rejected. However, the null hypotheses for trigger scale cannot be rejected and the coefficients for the scale may be zero. In fact, this result does not mean that Trigger is a not good predictor alone or in combination with other variables, it just does not contribute significantly to the model being considered (Norusis, 2006).

Table 2: Model Summary

R	R Square	Std. Error of the Estimate
0.873[a]	0.762	2.645

Table 3: Coefficient

Model	Unstandardized Coefficients	Standardized Coefficients	Sig.
	B	Beta	
Constant	-4.763		.056
Ability	.476	.310	.001
Gamification	.131	.119	.084
Motivation	.469	.508	.000

LIMITATION AND FUTURE RESEARCH

This study has several limitations that are worth considering for future studies. One of the limitations was the sample. The selected population included 108 Business students, enrolled in MIS101 in Spring 2018 at a public university in northeast California. Providing a bigger sample with more variety of students in different majors and courses may affect the results of this study. The impact of aforementioned independent variables on the students' perception of their learning experience in this study may be different among different course subjects and students who are using Kahoot.

We acknowledge that this is only a preliminary study. We did not examine the extent to which students' gender, age group, and ethnicity affect the relationships between the ability, motivation, trigger factors and the students' perception of their learning experience. Also, the influence of the study and work hours per week as a moderator variable is worth examining in a future study.

Certainly, different factors may affect the students' perception of the learning experience by Kahoot application. These factors could be reviewed in future studies. Also, the comparison of Kahoot, Top hat, and other classroom response systems and their effects on students' learning experience is worth studying in the future.

ABSTRACT

Over the past several decades, Information Systems have become a vital component for organizations to operate and compete in the industry. The design, development, and use of Information systems are also influenced by governmental regulations. For example, Sarbanes-Oxley (SOX) Act that was enacted in the year 2002 had a widespread impact on the IS field. This study systematically reviews existing research on SOX and its impact on the field to present the results. Findings of the study will be useful in seeing the role of government regulations and provide pointers on how regulations may impact other areas of the IS field.

KEYWORDS: SOX, Laws, regulation in IS, and Review

INTRODUCTION

Information systems have become the cornerstone of modern organizations, and are used in a multitude of ways by organizations functioning in diverse areas. Owing to its impact, sporadically we see regulations to impact the field. For example, airline reservation systems in the 1980s (Copeland & McKenney, 1988) and computer operating systems in the 1990s (Economides, 2001). In these cases, the effect of the action was on the organizations involved alone. In some other cases such as the copyright laws (Elkin-Koren, 2007), or healthcare information/privacy the impact was on select sectors of the economy. Likewise, the data protection regulations (Cornock, 2018) in Europe is geographic specific. However, unlike other fields such as finance, accounting, the field of information systems is not under the purview of widespread regulations. The lack of regulations has enabled the field to rapidly grow (Anderson, Block, DiLorenzo, & Mercer, 2001) unfettered in the various areas impacting the society in a wide range of ways.

Promulgation of SOX Act of 2002 had a widespread impact on the public corporations and required robust internal controls that many times were effected by the information systems. SOX impacts various aspects of the information systems discipline, such as project management, software development, IT governance, and data/information (Dhillon & Mishra, 2006). Owing to this SOX had a major impact on the way organizational information systems are designed, developed, and operated. IS researchers have been exploring ways in which SOX regulations are affecting the use of information systems in organizations. In the past Cleven and Winter (2009), carried out a literature analysis of regulatory compliance in information systems. This

study extends this line of work by not limited to one area alone but to the broader aspects of SOX on IS. Focusing on the wider ramifications of the regulation will helps us to understand the impact of it in a more holistic manner.

Findings of this study are important in many ways. First, it has been 15 years since SOX was introduced and it is an opportune time to take stock of the research on it in the IS field. Second, with more widespread use of technologies in our daily life, there will be calls for regulations in other areas of IS (e.g., data privacy/protection in the US, artificial intelligence, self-driving cars, etc.) and the research on SOX can shed light on the kind of impact new regulations can have on the IS field. Third, research on the compliance with regulations effected by IS is not that frequent, and this study will help in identifying gaps and future research directions for research.

The rest of the paper is organized as follows: The next section presents SOX act its provisions that affect IS area. Next, we discuss the methods used in this study to gather research on SOX and Information Systems. We then summarize the findings of the past research and present results. The final section provides directions for future research and concludes the study.

Sarbanes-Oxley Act 2002

Sarbanes-Oxley (SOX) Act was enacted in 2002 after the prominent financial scandals came to light in Enron, WorldCom, Adelphia, and others. The Sarbanes–Oxley legislation, officially called the Public Company Accounting Reform and Investor Protection Act of 2002, was designed to fix auditing of U.S. public companies (Coates & John, 2007). SOX is aimed at strengthening the internal controls and ultimately increase accountability. SOX has sets of mandates that increase the role of auditors in enforcing laws against at public companies (Coates & John, 2007). Eleven sections of SOX define auditor and corporate responsibilities in various areas (Brown & Nasuti, 2005). For example, Section 302 requires the CEOs and CFOs to certify the financial statements filed with the SEC. Likewise, Section 906 specifies the accountability/liability for the accuracy of the financial and the officers' knowledge about it (Volonino, Gessner, & Kermis, 2004). Section 404 deals specifically with the management's assessment of internal controls. Section 401 and 409 deals with the disclosure of information that may have a material effect on the financial health of the company (Volonino et al., 2004). Section 201 restricts organizations auditing organizations from carrying out non-audit services such as the design and implementation of financial systems for their audit clients (Levy, 2016).

Since financial reporting processes are driven by information systems, they too need to be assessed, documented, and tested to achieve compliance with SOX (Damianides, 2004). Some of the sections of the law had specific implications on the information systems used by the organization or the information systems field itself. Section 802 requires authentic and immutable record retention and IT plays a major role in data management, system security and business recovery practices(Brown & Nasuti, 2005). These requirements necessitate IS professionals to design, develop, and adopt systems that can provide accurate, visible, and timely information while ensuring that company's information assets are secure (Damianides, 2005).

METHODOLOGY

Following the prescriptions of Webster and Watson (Webster & Watson, 2002) in reviewing the existing research, as the first step, we searched EBSCO's Business Source Complete and ABI-Inform database for research on SOX and Information Systems. We used the search string "Sarbanes-Oxley" and "Information Systems" to retrieve relevant research articles. We restricted

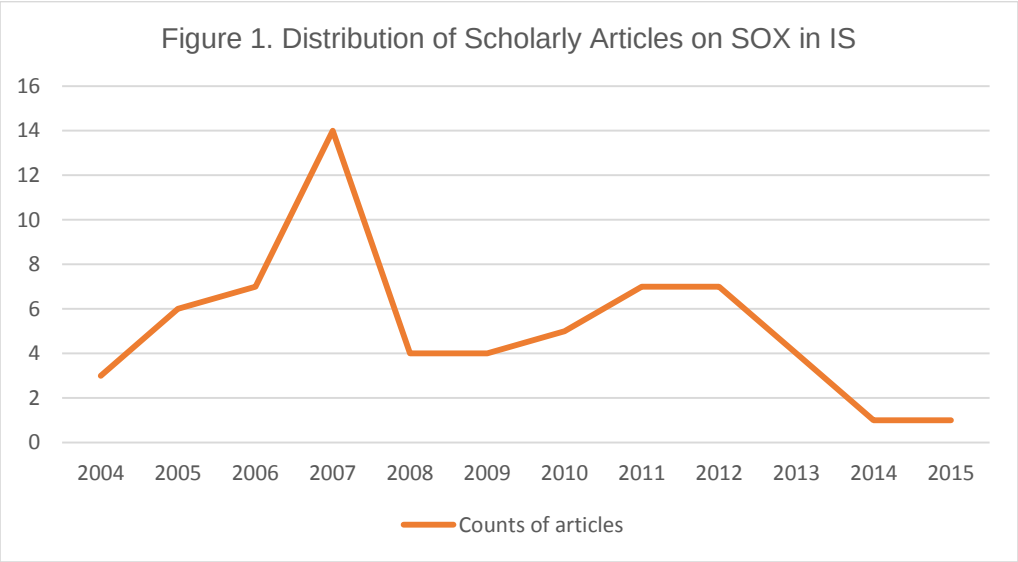
the study to focus on the peer-reviewed scholarly journals and included research until 2017. As the second step, we scanned the search results and selected the articles that focused on the information systems areas and its domains. This step eliminated articles that made passing reference to either SOX or Information Systems. We also excluded pedagogical related articles.

Table 1 presents the distribution of SOX-related research in IS from various journals. As can be seen, two journals specializing in Accounting Information Systems are namely the International *Journal of Accounting Information Systems* and *Journal of Information Systems* has published a greater number of research on SOX in IS. However, a variety of IS journals have also published research on SOX but to a lesser extent.

Table 1. SOX-related IS articles in Journals

Journal Title	Number of articles
Communications of the ACM	3
Communications of the Association for Information Systems	7
Information Management & Computer Security	2
Information Systems Management	6
International Journal of Accounting Information Systems	10
Journal of Information Systems	9
MIS Quarterly	3
Other journals	23
Total	63

Figure 1 presents the distribution of SOX-related research in IS from various journals during the period in review. Though the SOX act was promulgated in 2002, research on it in the IS area took a while to peak in 2007. From then on, there is a steady stream of research that has tapered in the recent times.

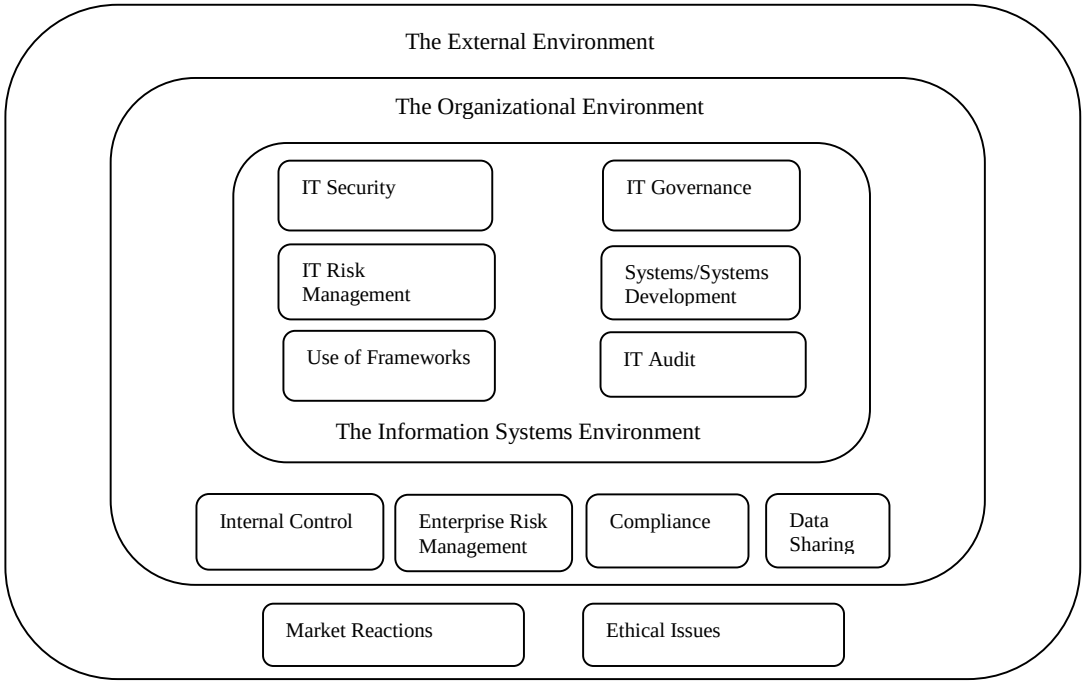


The selected articles were individually examined and categorized into various focus areas of research. Then using the IS research model(Ives, Hamilton, & Davis, 1980), these categories were classified into IS environment, organizational environment, and the external environment to understand the nature of research done in the field.

FINDINGS

Ives et al. (1980) developed a comprehensive framework for understanding and classifying research in Information Systems. According to the authors, IS research is the systematic investigation of the development, operation, use, and impact of an information (sub) system in an organizational environment and an external environment. This framework allows us to classify the various research in the SOX-related information systems research and also find gaps in the existing research. Figure 2 presents the key areas of research on SOX and Information Systems.

Figure 2. Scholarly Research on SOX and Information Systems



The Information Systems Environment

IS environment is concerned with the development, management, and use of information systems in organizations. Since this study focused on IS area, obviously found this domain to have the bulk of the studies included in the review. Various dominant themes within the IS environment explored by the researchers are indicated below:

IT Governance

This area is widely studied in the context of SOX and its need for prudent governance of IT. Studies have explored the use of IT Governance frameworks to facilitate the compliance needs of SOX. Damianides (2005) describe how Control Objectives for Information and related

Technology (COBIT) for IT governance provides the necessary information for management to provide reasonable assurance of the IT control structure for complying with Section 404 of SOX and also provide an illustration with a case study on a financial institution. Trites (2004) examine the director's responsibility for IT governance in light of the SOX and state that the directors, in general, do not have an understanding of IT. Hence they provide a list of considerations for various areas of IT in an organization. Bowen, Cheung, and Rohde (2007) stress the importance of IT Steering committee in fostering SOX compliance and use a case study to examine specific propositions.

IT Security and Risk management

SOX has requirements for the external reporting of adverse events an organization faces and hence IT security and risk management is also a focus of attention. For example, the security control activities and user participation is the focus of one of the studies (Spears & Barki, 2010). Likewise, the most and least used controls, and the variations in the type and size of the organization have also been studied (Wallace, Hui, & Cefaratti, 2011). Since the Committee on Sponsoring Organizations (COSO) considers security as a critical variable in enterprise risk assessment, the effective security governance is important for SOX compliance (Brown & Nasuti, 2005).

Systems and Systems Development

Development of systems is impacted owing to the need for internal control. There are studies that examined the use of frameworks such as COBIT in the systems development process so that the SOX compliant needs could be met (Mishra & Weistroffer, 2007). Likewise, the impact of SOX on outsourcing systems requirements have been examined. Hall and Liedtka (2007) discuss the implications of large-scale IT outsourcing and the weakening of financial controls and reduction in accuracy and clarity of financial reports. Systems such as enterprise resource planning have been shown to reduce the reported internal control weakness of firms (Morris, 2011).

IT Audit

SOX regulations had an impact on internal audit and consequently on the IT audit. For example, auditor independence and the audit quality has been explored (Wright & Capps, 2012). Use of appropriate technology for internal audit to increase the efficiency and effectiveness is also highlighted (Weidenmier & Ramamoorti, 2006). Likewise, systems development for audit using simulations for the audit objectives has been proposed (Borthick & Bowen, 2008). Chang, Wu, and Chang (2008) describe the development of a computerized auditing system to comply with SOX Section 404 and validate it using an ISO model.

Frameworks

Frameworks help in implementing compliance mechanisms for the regulations. Haworth and Pietron (2006) highlight how an organization implementing the ten categories of IT control provided by ISO 17799 will be compliant with SOX. Likewise, Wallace et al. (2011) study how well the controls suggested by ISO 17799 framework has been incorporated in internal control environments of organizations. COSO is also explored in the context of the weakness of IT and non-IT related components of an organization (Klamm & Watson, 2009).

The Organizational Environment

Organizational environment pertains to the internal environment of the organization. Compliance with SOX required a focus on the organization's internal processes and requires necessary organizational structures. Information systems play a major role in creating such a compliant environment. Following topics were explored by IS researchers in the past.

Compliance

Many studies have explored the aspect of organizational compliance with the requirements of SOX. For example, institutional pressures such as coercive pressure, mimetic pressure, and normative pressure have been found to influence compliance with Section 404 of the act (Braganza & Desouza, 2006). Further, Braganza and Hackney (2008) highlight the role of senior authorities, financial and resource subsidies, and standards in complying with the Section 404 requirements. Also, patterns for enforcing compliance in the business processes has also been explored (Elgammal, Turetken, & Van Den Heuvel, 2012).

Internal control

SOX has called for better internal control mechanisms and IS plays a major role here. Perceptions about IS reliability in the section 404 disclosure has been explored on analyst stock price predictions (Arnold, Bedard, Phillips, & Sutton, 2011). IT is also proposed to be used to identify internal control weaknesses in organizations (Boritz, Hayes, & Lim, 2013). Li, Peters, Richardson, and Weidenmier Watson (2012) mention about the importance of IS controls and the reporting of material weakness and found evidence that management forecasts were less accurate for a firm with information technology material weakness in their financial systems.

Enterprise Risk Management

Apart from IT risk management, enterprise risk management has also been studied as there mandated SOX requirements on it. Organizations with stronger strategic enterprise risk management experienced less difficulty in meeting the SOX mandates (Arnold, Benford, Canada, & Sutton, 2011). Integrated information systems have also been shown to increase strategic flexibility and performance through enterprise risk management (Arnold, Benford, Canada, & Sutton, 2015). Likewise, an enterprise risk management system is also claimed to improve compliance with SOX (Kusserow, 2007).

Data Sharing

SOX regulations require data/information sharing with the stakeholders on a timely basis. These data/information sharing may use information systems or the information sharing itself is about information systems. This has prompted research on the data models for data sharing (Kim, Fox, & Sengupta, 2007) as well as the sharing of financial information with stakeholders (Biot-Paquerot & Hasnaoui, 2009). Moreover, the quality and reliability of the data itself is also a focus of a study (Krishnan, Peters, Padman, & Kaplan, 2005). There also studies that have explored information sharing as a result of cyber-attacks (Hausken, 2007).

The External Environment

External environment pertains to the factors that are outside of the organization and may have a bearing on the functioning of the organization. As with any regulation, SOX and its compliance by the organization had an external impact, and explored by various researchers as shown below:

Ethical issues

The act itself was brought to improve corporate governance and ethical business practices in organizations. Mingers and Walsham (2010) state that the relevance of ethics in IS is not restricted to SOX and highlight the need for IS professionals to understand the ethical imperatives of SOX in their work. Likewise, the ethics of dissemination of financial information with the stakeholders is subject of a study that states that typically this aspect is missed by research with focusses only technical and technological issues in information sharing (Biot-Paquerot & Hasnaoui, 2009).

Market reactions

Some of the studies have examined on the market reactions to internal control weakness, and some studies have found negative effects of it (Stoel and Muhanna 2011). However, there seems to be an influence based on the type of investors used in the study as not all may have information on the internal control weakness reports(Arnold, Benford, et al., 2011). Benaroch, Chernobai, and Goldstein (2012) conceptualized IT operational risk evens as an internal control weakness and examined the market reactions to IT failures. They found that investors to penalize firms more strongly for events compromising the availability of systems. Market reactions regarding bid-ask spread have been found to reduce with compliance (Dobre, 2011).

Discussion and Future Research Directions

This study systematically reviewed the SOX-related IS research that appeared in the scholarly journals. Findings of the study provide a glimpse of the areas that are of focus when researching SOX in the context of IS. SOX had a profound impact on the public corporations in general and IS in specific areas. Review of the research shows some of the unique IS aspects considered in compliance with SOX.

Findings of this research could be used to examine the impact of future regulations in the IS area. For example, in the IS environment, IT governance will play a major role in light of any future regulations as the compliance with the law/regulations will require more directed efforts in the development and use of information systems. Likewise, frameworks that aid in the adherence to the laws/regulations could be developed or used by organizations to facilitate the requirements of such regulations. In the organizational environment, compliance will be a major area of research. Organizations should have to evolve adequate mechanisms/processes to comply with the requirements of the law/regulations. In a similar fashion, data sharing with the organizational stakeholders (e.g., customers, suppliers, regulatory bodies, etc.) will be vital as the organization tries to meet the requirement of the new law/regulations. In the external environment area, ethics play a major role as a particular segment of operation is regulated. Usually, the laws take time to get enacted and till then the ethics play an important part in evaluating and determining appropriate actions by organizations.

This study also found some gaps in the existing research. For example, the issues surrounding non-compliance with the provisions of SOX and the role of IS is not much explored. Sometimes, IS/IT itself may create issues in the compliance of SOX mandated requirements. Likewise, the effects of regulations on the IS systems design/development is not that much examined in the past. Requirements of the regulations are taken into account in how a system is designed and developed.

In the future, research could be undertaken to examine the impact of SOX on some of the under-explored areas such as the role of regulations and the requirements for compliance with systems design and development. Moreover, the study sample could be enhanced to include

conference publications. This study used SOX as an avenue for studying the impact of regulations on the IS field. Findings of this study could be used to frame research questions for future regulations in the IS field. For example, many of the themes found in the SOX research such as compliance, security, systems development, and frameworks could be used in studying the effects of future regulations.

Conclusions

Research on the impact of SOX on Information Systems is found in both Information Systems as well as accounting journals. SOX had a multi-level (IS, Organizational and Environmental) impacts on organizations and the extant research highlight this. Compliance and internal control were some of the major themes in the research done in the past and IS role is often stressed. Many IS specific areas such as IT security, IT audit, systems development also focuses of the studies.

SOX and its provisions had an impact on the IS field in many ways, and it provided a classic example to study the impact of regulations on the IS area where regulations are only sporadic. (Smith & McKeen, 2006) claim that the IS field of the future will be increasingly controlled, standardized, and bureaucratized due to regulations. Already, we see calls for regulations such as on privacy on the Internet, artificial intelligence applications, and self-driving cars. Examining the research themes in the advent of SOX will afford us with the opportunity to see the impact of regulations on the IS domain. This study highlights some of the dominant areas that were impacted and future research and practice can use it as they navigate through regulations in any specific IS area.

Sadaf Aman
Information Technology University
Email: sadaf.aman@itu.edu.pk

ABSTRACT

Need for creation of inclusive business opportunities while considering base of the pyramid (BoP) markets makes it a sound starting point for evaluating how supply chain practices impact the firm's purchasing performance in business-to-business (B2B) markets of BoP. A structured questionnaire was used to collect data from indigenous micro-entrepreneurs operating in a BoP setting while factor analysis and linear regression are used to investigate the findings of the empirical research. (S)SCM construct of supply chain partner development is found to have the significant positive impact on the purchasing performance of indigenous firms in B2B supply chains. With earlier empirical works in BoP literature mainly focused on business-to-customer linkages, this paper while aiming at business-to-business interactions in emerging economies will enrich the understanding of the base of the pyramid business environment.

Keywords: Base-of-the-Pyramid, (Sustainable) Supply Chain Management, Empirical, Regression Analysis, Supplier Development, Buyer-Supplier Interaction.

INTRODUCTION

Emerging economies are increasingly considered as sources of learning and innovation for driving firm performance(Kaplinsky, 2011; Murphy, Perrot and Rivera-Santos, 2012). Novel solutions are required in milieu of their unique and predominantly informal business environment (Poetz and Prügel, 2010). In this context, the supply chain practices which contribute to the achievement of new performance and innovation frontiers need to be explored carefully. Since its emergence in a little more than the past decade, base of the pyramid (BoP) literature has been dominated by two debates: first, a more conceptual debate contemplating BoP business strategies either from a consumer, producer, or partner oriented perspective (Prahalad, 2006; Karnani, 2007; London *et al.*, 2010). Second, a more strategic BoP debate "focused on product and distribution strategies tailored to consumers in these markets" (Arnould and Mohr, 2005). This paper tries to explore the operational dynamics of BoP supply chains which advance indigenous firms' purchasing performance. While following a partner oriented BoP approach, the paper presents results of a quantitative survey conducted in Pakistan, focusing on business-to-business (B2B) supply chains.

The unique business environment of informal markets requires a reconsideration of the contemporary supply chain knowledge to fulfil the exclusive demands of BoP supply chains (Sesan *et al.*, 2013). Furthermore, the call for the development of inclusive business models

(Halme *et al.*, 2012; Kolk *et al.*, 2014) for BoP, necessitates the examination of purchasing issues in greater detail. In this context the core research question of the study can be stated as: Which of the respective (S)SCM constructs substantially affect the purchasing performance of micro-firms in B2B supply chains at the BoP? The (S)SCM constructs have been derived from published (S)SCM literature deductively. The respondents of the study were selected from manufacturing and retail sectors without specifying any industry in particular. The constructs representing both process and strategic dimensions of supply chain management have been employed to assess their effect on purchasing performance of BoP entrepreneurs. Furthermore, in line with the arguments of (Ahlstrom, 2010) for the crucial nature of integration in BoP, this paper, while contemplating work of Chen and Paulraj (2004) and Vachon and Klassen (2006), further explores *supplier* and *customer* dimensions of technological integration in driving the BoP supply chains. The strategic part of BoP supply chains is signified by constructs of supply chain partner development and supply network structure constructs (Chen and Paulraj, 2004). The process part of the supply chain is represented by such constructs as strategic purchasing and communication and coordination with suppliers.
Concerning the organization of this paper, the next section presents a brief literature review on the subject matter and introduces BoP and the core (S)SCM constructs used in the paper. Section three elaborates the research methodology. The succeeding section four presents findings of the empirical survey followed by a discussion presented in section five. The conclusions are drawn in the last section.

LITERATURE REVIEW

Base of the Pyramid (BoP)

Potentially lucrative informal markets of developing world have started gaining attention of intellectuals and practitioners (Kolk *et al.*, 2014). The informal markets of developing countries in particular, and the respective societies served by these markets in general are referred to as base of the pyramid (BoP) in contemporary management literature (the word pyramid implies ‘world income pyramid’). The apparent little consensus on a concrete definition of the base of the pyramid (BoP) in literature is quite in line with the argument by Gladwin *et al*. (1995, p. 876) who maintains “definitional diversity is to be expected during the emergent phase of any potentially big idea of general usefulness”. While some scholars used an income yard stick for defining BoP (Arnold and Williams, 2012), the authors of this paper follow the arguments of Hart (2010) and London and Hart (2011) and consider all the participants of informal markets who are “generally excluded from the current system of global capitalism” as part of BoP.
“Ingrained in notion of inclusive capitalism”, the BoP literature argues for an enterprise-driven strategy for the creation of economically viable business models to kick start economic activity in BoP markets (Ansari *et al.*, 2012). From a strategic perspective BoP literature can be generally divided into three sub-streams. First, a *consumer centered* BoP approach presents BoP markets as a long forgotten potentially lucrative market of billions of “value conscious consumers”(Prahalad, 2006; Weidner, Rosa and Viswanathan, 2010; Arnold and Williams, 2012). Second, a *producer centered* BoP strategy, while appreciating the BoP population as potential suppliers, producers, co-owners and/or customers, considers BoP markets as a “hot bed” for future innovations (Karnani, 2007; Agnihotri, 2013). Third, a recent *partner oriented* BoP strategy contemplates a holistic perspective while calling for taking on-board all the traditional and non-traditional stakeholders to formulate economically viable business strategies for the BoP which aim at poverty elimination (London *et al.*, 2010). Nevertheless, there remains

a consensus in the BoP literature concerning the centrality of the business in designing poverty alleviation strategies.

BoP research contemplates business operations on the integration of disadvantaged parts of societies as part of production or distribution processes. This highlights the criticality of a sustainable management of the respective supply chains (Gold *et al.*, 2013). Calls for the creation of inclusive business opportunities by considering BoP as potential source of suppliers in the respective literature highlight the crucial role of purchasing in informal markets (Halme *et al.*, 2012). "The growing importance of supply chain management has led to an increasing recognition of the strategic role of purchasing, which has recently evolved and expanded from buying to procurement and supply management" (Paulraj *et al.*, 2006). The involvement of BoP actors in upstream (as producers) or downstream (as distributors) supply chains in informal markets of developing countries is particularly challenging from a supply chain management perspective, as it implies dealing with a "large number of small transactions", thereby tremendously increasing the transaction costs (Sodhi and Tang, 2014). Devising a mechanism to ensure fair distribution of supply chain surplus among the disadvantaged supply chain actors on account of illiteracy and poor market power is yet another steep hill to climb for supply chain researchers (Sodhi and Tang, 2016). These obstacles to inclusive business opportunities in the BoP, however can be tackled by formulating strategies of "establishing cross-sector partnerships" and taking a wide array of traditional and non-traditional stakeholders on board (Hill, 2010; Matos and Silvestre, 2013). (S)SCM with a rich tradition of stakeholder focused research can help to provide useful insights for the development of inclusive business models to address social, economic and environmental issues on sustainable basis at the BoP (Meixell and Luoma, 2015). While (S)SCM research can potentially provide viable answers to certain challenges faced by BoP scholars, a research gap is evident since "… current research on the interface between supply chain management and BoP business operation is lacking" (Gold *et al.*, 2013).

Furthermore, in the context of the relationship based business environment of the BoP (Kistruck *et al.*, 2011; Ansari *et al.*, 2012), the accumulation of relational capital (Kale *et al*., 2000) should be seen as a crucial part of the firms' long-term business strategy in BoP. Earlier BoP-related studies suggested the firms who remain successful in building their relational capital in BoP communities would reap benefits in the long run (Galariotis *et al.*, 2011; London and Anupindi, 2012). Therefore relationship building not only remains a business qualifying criteria, but also has strategic implications for focal firms' sustainable performance in BoP supply chains (Hall and Matos, 2010).

Additionally, the relationship based business environment of BoP can be explained by acknowledging the resource scarce nature of BoP. One should also keep in mind the fact that the BoP firms have to interact with their external environment not only to fulfil their operational resource requirements but also for compensating the evident institutional voids (Rivera-Santos, Rufín and Kolk, 2012; Van den waeyenberg and Hens, 2012). While the relationships with traditional business stakeholders can fulfil the operational needs of businesses, effects of institutional voids can be counterbalanced by engaging with non-traditional stakeholders (Reficco and Marquez, 2012).

In such a backdrop the extent paper intends to explain the impact of supply chain practices on the purchasing performance of the BoP organizations.

Core (S)SCM constructs

Supply chain management (SCM) appreciated as the management of all the various actors and processes involved in the movement of products and services from an ultimate supplier to an

ultimate consumer (Chen and Paulraj, 2004), has certain contingencies with the BoP related literature (Khalid and Seuring, 2017). Correspondingly, the sustainability part of supply chain management dealing with the integration of triple bottom line concepts in the supply chain management discourse also speak about many issues apparently part of the traditional BoP debate (Gold *et al*., 2013). While defining sustainable supply chain management (SSCM), Pagell and Wu (2009) argue that a sustainable supply chain is "one that performs well on both traditional measures of profit and loss as well as on an expanded conceptualization of performance that includes social and natural dimensions". Since this paper discusses constructs taken simultaneously from SCM and SSCM literature and because of the evident overlaps in both of the concerned theories (e.g. in case of constructs of supply chain integration), the paper for sake of convenience refers to both of the respective theories together as (sustainable) supply chain management (S)SCM.

The (S)SCM constructs used in the paper have been selected considering their relevance to the propositions of relationship building with various supply chain actors. Furthermore, the respective constructs are defined as they have been presented in the respective key papers which are presented in Table 1. It is worthwhile to indicate here that the supply chain partner development construct in this study is a cumulative construct representing the respective constructs of long term relationship development (Chen and Paulraj, 2004), supplier operations (Carter and Rogers, 2008), and investment in human capital (Pagell and Wu, 2009). The supply chain partner development concept is further enriched based on the arguments by Wagner (2011) and considered in this study as a buyer-supplier relationship management paradigm. The strength of a buyer-supplier relationship is therefore taken as a moderator impacting a focal firm's supply chain partner development activities to increase its purchasing performance. Furthermore, buyer – supplier interaction is signified by the construct of communication and coordination with suppliers. *Appendix B* indicates that the construct connotes an exchange of business related sensitive information among the interacting partners.

.

Table 1**:** Brief explanation of (S)SCM constructs taken up in the study

(S)SCM CONSTRUCTS	SOURCE	DESCRIPTION
Strategic purchasing	Chen and Paulraj, 2004	The construct is "conceptualized by its proactive as well as long-term focus, its contributions to the firm's success, and strategically managed supplier relationships".
Communication and coordination with suppliers	Seuring and Müller, 2008; Chen *et al.*, 2004	The efficient exchange of critical and sensitive information related to operational and strategic issues and collaborative relationship maintained by the focal firm with its various suppliers
Technological integration	Vachon and Klassen, 2006	The construct represents "the tacit knowledge sharing taking place between a buying and a supplying organization in strategic areas like product development, process reengineering, and technical training".

Supply chain partner development	Chen and Paulraj, 2004; Carter and Rogers, 2008; Pagell and Wu, 2009 and Wagner, 2011	The process by which buying firm strives to develop its suppliers as strategic partners by developing their operational and human capabilities based on intensity of mutual business relationships
Supply network structure	Chen and Paulraj, 2004	The construct explains "non-power based relationships and inter-firm coordination as well as the informal social systems that are linked through a network of relationships".
Purchasing performance	Wagner, 2011 and White, 1996	Performance indicates purchasing performance of focal firm in a dyadic buyer-supplier relationship context.

THEORY AND HYPOTHESIS

Relationship between SCM Practices and Purchasing Performance in Context of BoP

The relationship based business environment of the BoP demands firms to invest heavily in building and maintaining relationships (Ansari *et al.*, 2012). Though trustworthy long-term relationship development with indirect supply chain actors has also been emphasized in related literature, efficient connections with direct supply chain partners in the context of the social nature of business in BoP remain business qualifying criteria in the BoP (Calton *et al.*, 2013). Extensive relationship building evident in BoP, therefore is a consequence of its special indeterminate external business environment (Ghauri *et al.*, 2014). Furthermore, one can infer that with increasing uncertainty in the firm's external business environment, an increase in width and breadth of inter-organizational relationships will be evident (Pfeffer and Slancik, 1979). The highly social nature of business in BoP thereby is also an indication of its extreme uncertain business environment. BoP firms in order to build and maintain these relationships can therefore be anticipated to become actively engaged in activities that foster long term relationship development (Khalid *et al.*, 2015). Practices like joint product development, supplier integration, partner development by investing in ones' human and operation capabilities and other related activities, can therefore assumed to be evident in BoP business relations (Elaydi and Harrison, 2010). Business performance of BoP firms is thereby highly dependent upon the extent to which a firm engages in activities related to fostering relationship development with other supply chain actors (Arnould and Mohr, 2005).
In line with the aim of the study and focusing on purchasing performance, we can anticipate that indigenous BoP firms will actively engage in relationship development related activities in order to decrease uncertainty in their purchasing related practices. Uncertainty reduction in purchasing activities will thereby help respective firms to boost their purchasing performance (McMullen, 2011). As mentioned in section 2.2, the supply chain partner development construct in this paper represents various relationship development related practices. We can therefore say:

> ***Hypothesis 1:*** *A BoP firm's engagement in inter-organizational relationship development related activities (represented by the supply chain partner development construct in this study) significantly influences respective firm's purchasing performance.*

The volatile business environment tends to lure firms to manage their supply lines on strategic basis. Operating in highly uncertain markets, BoP firms thereby take efforts to strengthen their relationships with their immediate suppliers in order to decrease the supply related uncertainty (Carter and Rogers, 2008; Gold, Seuring and Beske, 2009). Strategic purchasing has been conceptualized by Chen and Paulraj (2004) in context of supplier relationships. Trust based carefully managed supplier relationships remain a precondition to pursue purchasing activities on strategic basis (Hahn and Gold, 2014). A strategically managed, secure, and dependable supply line not only helps firms run their internal business operations more smoothly but may also be a source of competitive advantage in its own right in volatile markets (Busse, 2016). By helping reduce supply related uncertainty strategic purchasing can be envisioned to have a direct impact on purchasing performance of BoP firms. In backdrop of such an association between strategic purchasing and purchasing performance second hypothesis of the study can be stated as:

> ***Hypothesis 2:*** *Strategic purchasing significantly influences purchasing performance of micro-entrepreneurs in BoP.*

Chen and Paulraj (2004) refer to supply chain management as a study that involves "collaborative advantage". In other words, collaborative advantage involves building a strong correspondence between buyer and suppliers in order to get benefit from one another's strengths. Within this collaborative paradigm, the firms need an efficient communication and coordination framework at place within their buyer-supplier relationship. Moreover, the communication and coordination is essential to increase the performance of the firms (Prahinski, & Benton, 2004).
Volatile business environment makes it crucial for indigenous BoP firms to actively communicate and coordinate with their suppliers (Webb *et al.*, 2010; Kistruck *et al.*, 2013). Through active engagement BoP firms also intend to retain the suppliers of critical products. This supplier retention strategy through active coordination also helps firms strategically managing their supply base (Chen and Paulraj, 2004).
Furthermore, due to their capricious nature, information related to both operational and strategic issues needs to be shared among the dyadic actors. Efficient exchange of information leads to mutual trust in the buyer-supplier dyad (Reficco and Márquez, 2012). Accordingly, maintaining good communication and coordination will help foster the purchasing activities of the firm. Therefore, it can be hypothesized that:

> ***Hypothesis 3:*** *Active communication and coordination with suppliers significantly effects purchasing performance of micro-entrepreneurs in BoP.*

Relationship based business environment of BoP also highlights the need of prudent flow of tactical information between various actors of supply chain. Vachon and Klassen (2006) defines the concept as technological integration. Technological integration includes "strategic knowledge sharing between the buying and a supplying organization in areas like product development, process reengineering, and technical training" (Vachon & Klassen 2006). The extent paper looks into both supplier and customer dimensions of technological integration, while working with two separate constructs i.e. technological integration with suppliers and technological integration with customers. Technological integration with customer includes involvement of customers into the process. On the other hand, technological integration with suppliers accentuates the knowledge sharing with the key suppliers of the firm.

Researchers have shown that a positive relationship exist between technological integration and performance of the firm (Prajogo, & Olhager 2012). The inconsistent business environment of BoP firms call for the tactical knowledge sharing, which will further enhance their purchasing performance. In this backdrop we propose that:

> ***Hypothesis 4:*** *A BoP firm's technological integration with suppliers significantly influences its purchasing performance.*
>
> ***Hypothesis 5:*** *A BoP firm's technological integration with customers significantly influences its purchasing performance*

Supply chain network concept in BoP entails how non-power based relationships, inter-organizational coordination, and informal social systems are linked within a supply chain (Calton *et al.*, 2013). Supply network structure highlights the firm's relationship with traditional and non-traditional stakeholders, and explains how flourishing them impacts the overall performance of the organization. However, within the BoP business environment, establishing such relationships require craftsmanship. Personal ties with key personnel and institutions like local political leaders, banks, tax officials, local administration, NGO's etc. are fruitful for a firm in long run (Ghauri, Tasavori and Zaefarian, 2014). These relationships can impact the purchasing performance of the respective firm as they account for the alliances with institutions and personnel making up the social capital that remains vital for doing business in BoP markets. Networks by helping respective firms bridge institutional voids in BoP and securing their supplies can potentially have a direct impact on purchasing performance (Webb *et al.*, 2010). Within the horizon of this study, we therefore propose that:

> ***Hypothesis 6:*** *Supply network structure significantly influences respective firm's purchasing performance.*

RESEARCH METHODOLOGY

The BoP research has mainly dealt with business-to-consumer issues (Kolk et al., 2014). The evolving state of BoP research in general and novelty of focusing on B2B issues in BoP in particular, allows to employ exploratory research techniques to generate new ideas or hypotheses (Neuman, 2012). Furthermore, since the primary data of the study is collected from indigenous micro-entrepreneurs by administering personal interviews, the study follows an exploratory research approach.

Survey Instrument

A seven point Likert scale structured questionnaire was used to collect the data for this research in face-to-face personal interviews. While administering the interviews, other relevant information was also sought and recorded by taking field notes. The side line information gathered like this, helped to reveal a clearer picture of the subject matter and thus further enriched the survey findings.

Survey Design

Concerning the sampling design, the data for this study was gathered from micro-entrepreneurs operating in Pakistan without specifying any particular industry to focus on. An employee size of

less than 15 was one defining criteria for the inclusion of firms in the sample. However, it is worthwhile to mention here that in most of the cases the employee size of sample firms was less than 10. The data was collected between November 2015 and March 2016. In absence of any reliable and up-to-date databases of indigenous SMEs in the country, a snowball sampling technique was employed to collect data. The sample was drawn from the micro-entrepreneurs having their operations in three cities of Pakistan i.e. Lahore, Rawalpindi and Islamabad. A total of sixty interviews was conducted with entrepreneurs in manufacturing and retail sectors. The respondents interviewed for this study represented such industries as garments, home appliances, auto spare-parts, steel, wooden furniture, marble tiles and electrical equipment. A typical interview lasted for about 30-45 minutes, with the interviewee filling in the questionnaire and interviewer assisting him for clarifying any ambiguities.

Data Analysis

After completing the data collection phase of the study, the interview results were first coded and later analyzed using SPSS. First of all, the reliability of the constructs used in the study was tested by calculating Cronbach's alpha (α) value for individual constructs. Constructs with α-values greater than 0.6 were taken as being significant (Table 2) (Hair, 1998, pp. 207-219). Following this, an exploratory factor analysis was conducted for respective significant constructs to check the reliability and validity of the items formulating individual constructs used in the survey. A threshold value of 0.450 was used and all the items with factor loadings less than the threshold value were considered as insignificant and therefore discarded (in total twelve items were rejected). The two purification procedures left us with *seven* constructs (one *dependent* and six *independent*) and *twenty-six* items (Table 2).
Finally, correlation and regression analysis being "statistical tools for the investigation of relationships between variables" (Sykes, 1993) were used. In line with the aim of this study, purchasing performance was taken as dependent variable while conducting regression analysis. The effort helped to identify the particular (S)SCM constructs which have the most significant impact on and are responsible for the considerable variation in purchasing performance of firms in a BoP setting.

Reliability and Validity

"Reliability is the degree of dependability, consistency or stability of a scale" (Wen-li *et al.*, 2003). As mentioned above the internal reliability of the study was ensured by calculating α-values. Only the particular constructs with α-values greater than 0.6 are used in the study (Bagozzi and Yi, 1988; Cohen, 1992) . Furthermore, Composite reliability was calculated to confirm the consistency of the scale. The results of Cronbach alpha and composite reliability are presented in tables 2 and 3 below.

Table 2: Internal Reliability test results

CONSTRUCTS	CRONBACH ALPHA
Strategic Purchasing (SP)	0.835
Tactical Purchasing (TP)	0.697
Supply Network Structure (SNS)	0.711
Communication (COMM)	0.768
Technological Integration with Supplier (TIS)	0.782

Technological Integration with customer (TIC)	0.667
Purchasing Performance (PP)	0.951
Supply chain Partnership Development (SCPD)	0.944

Table 3: Convergent Validity and Composite Reliability test results

CONSTRUCTS	AVERAGE LOADING	VARIANCE EXTRACTED	CONVERGENT VALIDITY ESTABLISHED	COMPOSITE RELIABILITY VALUE
Strategic Purchasing	0.9264	0.8583	Yes	0.9237
Tactical Purchasing	0.7905	0.6249	Yes	0.8363
Supply Network Structure	0.6748	0.4553	Questionable	0.9062
Communication	0.7674	0.5888	Yes	0.8519
Technological Integration with Supplier	0.8346	0.6965	Yes	0.8734
Technological Integration with customer	0.7932	0.6292	Yes	0.8391
Purchasing Performance	0.9340	0.8723	Yes	0.9654
Supply chain Partnership Development	0.9272	0.8597	Yes	0.9609

(Acceptable values = AVE > 0.5, Average loading > 0.7, Composite reliability > 0.7)

Convergent validity was established for the constructs having average loading greater than 0.7. Similarly, composite reliability was established for the constructs having values greater than 0.7 (Fornell and Larcker 1981). Only supply network structure had values of AVE and average loading below the threshold of 0.5 and 0.7 respectively.

TABLE 4: DISCRIMINANT VALIDITY TEST RESULTS

AVE	SP	TP	SNS	COMM	TIS	TIC	PP	SCPD

SCPD	0.0095	0.0586	0.0103	0.0539	0.0015	0.0005	0.8501	-

The validity of the results presented in this paper are confirmed by assessing the *content*, *construct, and discriminant* validity. The content validity of the study was ensured first by collecting all the different supply chain constructs used in the paper via conducting a comprehensive literature review and second by consulting two experienced researchers to avoid any ambiguities in items and in the questionnaire (Chen *et al.*, 2004). The construct validity was assessed based on the factor loading values of the items used to collect the data related to individual constructs. Not only the items with cross-loaded values but also those having factor loadings less than 0.450 are not taken into account while cumulating results of the study. Similarly, discriminant validity was calculated to ensure that the constructs used in the study are statistically unrelated. Average variance extracted AVE and squared correlation were calculated to establish the discriminant validity between constructs, the results are presented in table 4 and 5 above. The discriminant validity was established as the Average variance extracted between all the constructs is greater than their squared correlation.

FINDINGS

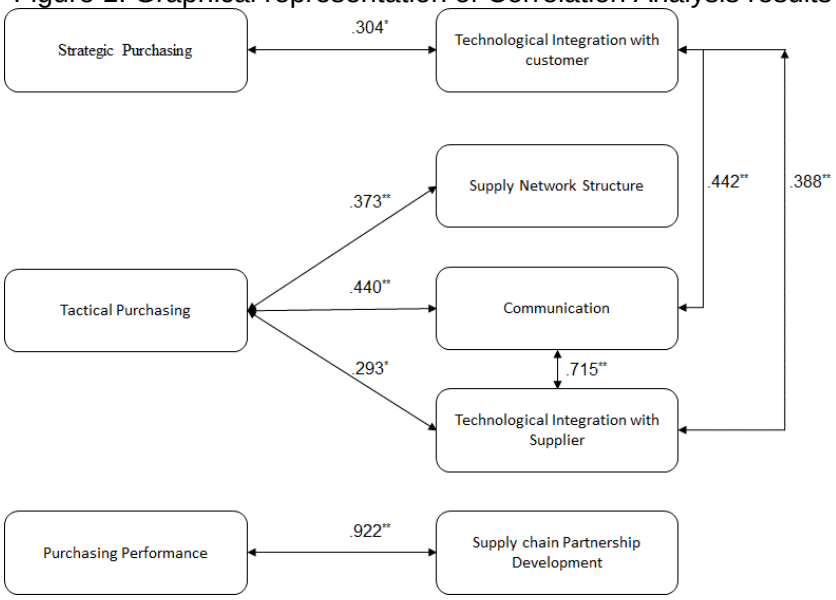
"The BoP approach, … can be thought of as an emergent 'metanarrative'— a grand synthesizing framework which provides scholars and practitioners at diverse sites with a template for future research and action aimed at creating market based solutions for poverty eradication" (Chatterjee, 2014). This section of the paper presents the results of the correlation and regression analysis and comments on the hypothesis presented earlier.
The correlation of the constructs is presented to find the degree of associations between them. Positive correlation indicates a reciprocal association and vice versa.

Table 6: Correlation Analysis

	SP	TP	SNS	COMM	TIS	TIC	PP	SCPD
SP	1							
TP	.020	1						
SNS	-.080	.373**	1					
COMM	.060	.440**	.222	1				
TIS	.120	.293*	.164	.715**	1			

TIC	.304*	.102	-.028	.442**	.388**	1		
PP	.082	-.152	-.065	-.176	.013	-.039	1	
SCPD	.098	-.242	-.101	-.232	-.038	-.022	.922**	1

Figure 1: Graphical representation of Correlation Analysis results



* Correlation is significant at the 0.05 level (2-tailed)
** Correlation is significant at the 0.01 level (2-tailed).

Table 6 presents the correlation analysis results. Supply chain partnership development and purchasing performance have highest correlation of 0.922, which is also statistically significant at 0.01. However, strong correlation between two constructs can raise the issue of multicollinearity, however, discriminant validity was established between two in previous section. Therefore, it can be concluded that, BoP firms which are engaged in partnership development activities are more likely to get benefit in their purchase related activities. A positive correlation exists between strategic purchasing and purchasing performance, however, the value remains statistically insignificant. Besides, the association between other independent variables and purchasing performance has not been established as has been anticipated.
As far as correlations among other constructs are concerned, positive and significant associations have been analyzed between tactical purchasing and supply network structure, communication, and technological integration with suppliers. Similarly, another positive association has been observed between communication and technological integration. The positive correlation signifies that the BoP firms who communicate and coordinate with their suppliers are more likely to practice tactical knowledge sharing. Though the results are beyond the scope of this study, however the correlations established among the constructs remain constructive and offer useful foundation for further research on the topic. Further, the results are analyzed in light of regression model.

The regression model has brought forth the construct of *supply chain partner development* (the process by which buying firm strives to develop its suppliers as strategic partners by developing their operational and human capabilities based on intensity of mutual business relationships) as the one responsible for significant variation in the purchasing performance of BoP micro-entrepreneurs in dyadic buyer – supplier interactions (Table 3 and Table 4).

Table 7: Model Fit Summary

Model	R	R Square	Adjusted R Square	R Square Change	Sig. F Change
1	.926[a]	.857	.838	.857	.000

a. Predictors: (Constant), Supply Chain Partner Development, Technological Integration with Customer, Supply Network Structure, Strategic Purchasing, Technological Integration with Supplier, Tactical Purchasing, Communication

Table 7 elaborates the model fit summary. The prominence of the (S)SCM practices in explaining the variation in a focal firm's performance is indicated by the respective values of R. As shown in Table 7, all independent variables account for 86% of variation in firm's purchasing performance. The model presented above is also statistically significant, thus the model is a good fit.

As indicated in Table 8 only supply chain partner development construct shows a significant association (positive) with the purchasing performance of micro-entrepreneurs in BoP. The association between the two constructs denotes the fact that more a firm engages in supplier development related activities more it will benefit in terms of improvement of its purchasing related activities.

The regression analysis results signifying correlation between purchasing performance and supply chain partner development lead to acceptance of Hypothesis 1. We thereby conclude that supply chain partner development significantly effects the purchasing performance of BoP firms. The construct is also therefore responsible for significant variation in the purchasing related performance of indigenous micro-entrepreneurs.

Having said that the statistical results lead us to reject Hypothesis 2,3,4,5 and 6, since significant influence of none of the other constructs upon the purchasing performance could be established. The results are interesting as some of the otherwise seemingly relevant constructs appeared to become irrelevant as far as their association with purchasing performance is concerned.

Table 8: Regression model

Model	Unstandardized Coefficients		Standardized Coefficients	t	Sig.
	B	Std. Error	Beta

a. Dependent Variable: Purchasing Performance

DISCUSSION

"Purchasing has increasingly assumed a pivotal strategic role in supply-chain management", and today is considered as a seminal pillar of a firm's business strategy (Chen et al., 2004, p. 505). Relationship based business environment renders indigenous BoP firms largely dependent on other supply chain actors for getting their supplies; may they be small scale producers, wholesalers or manufacturers. Evaluating the factors effecting the purchasing performance of these indigenous micro-entrepreneurs therefore becomes crucial if one has to develop respective supply chains on a sustainable basis while creating inclusive business opportunities for BoP communities.

Earlier BoP literature has dealt with the issues mainly falling within B2C domain of supply chain (Kolk, Rivera-Santos and Rufín, 2014). The extent paper by focusing on the B2B interactions in BoP will help in further advancement of knowledge and understanding of BoP business environment. The survey methodology employed in the study will also aid in bridging the apparent research gap, since the BoP literature mainly comprises of case studies and conceptual articles (Kolk, Rivera-Santos and Rufín, 2014; Khalid and Seuring, 2017). Furthermore, the subject of the paper also seems justified and timely when seen in context of calls for creation of inclusive business opportunities for BoP (Halme, Lindeman and Linna, 2012). The results of the study contribute towards evaluating the factors contributing towards integration of BoP micro-entrepreneurs in regional and global supply chains.

In such a context the results of the study depict a reciprocal relationship between the constructs of *supply chain partner development* and *purchasing performance*. The result indicates that the indigenous micro-entrepreneurs in BoP, by capitalizing on their relational capital and partner development related activities can increase their purchasing performance (Arnould and Mohr, 2005). BoP micro-entrepreneurs are normally devoid of capital, technological and human resources enabling them to optimize their business processes. Investing in developing the manufacturing and technological capabilities of these micro suppliers enable them to upgrade their manufacturing processes (Elaydi and Harrison, 2010; Hahn and Gold, 2014). Since supply of inconsistent quality products remains one among the major obstacle hampering the smooth

integration of BoP suppliers in global supply chains. The up-to-date manufacturing technology enables micro-entrepreneurs produce quality products with the specifications aligned with what their customers demand. Such supplier development activities thereby have a direct positive impact on purchasing performance of businesses in BoP. Furthermore, involvement in such supplier development related activities also fosters relational capital of respective firms by nurturing trust based relationships (Pagell and Wu, 2009).

Importance of developing human resource of suppliers to strengthen management related capabilities have also been highlighted in the empirical research (Lim, Han and Ito, 2013). Illiterate personal managing the micro-businesses usually lack proper training and knowhow of advanced process management techniques. Coaching and efficient exchange of information related to process management techniques help in joint development. Micro-entrepreneurs were found not capable enough to hold formal training sessions for their suppliers, therefore, most of the supplier development initiatives falling under the realm of human resource remain of informal nature. Frequent visits of each other's facilities and informal discussions between the buyers and suppliers help the dyadic actors explore avenues of further improvement and knowledge sharing (Murphy, Perrot and Rivera-Santos, 2012).

Knowledge sharing by helping sort out the human and process related deficiencies of interacting actors, fosters innovation capabilities (Murphy, Perrot and Rivera-Santos, 2012). Though the product related innovation capabilities remain very frugal in nature. However, better than nothing, the meager innovations help keep the businesses running by enabling them offer final customers with an assortment of products (Esko, Zeromskis and Hsuan, 2013). It was learned during the course of the empirical research that the innovation in BoP markets mainly centers products/services, with business processes largely considered an out of bound area for the subject. Micro-entrepreneurs were found to be apt with traditional ways of doing businesses and consider no need of bringing any change in the way they are running their business operations. Innovation related partner development endeavors therefore remain focused at nurturing product development capabilities among the interacting actors.

Logistics, particularly inventory management appeared as another area benefiting from partner development activities. Efficient exchange of information among buyers and suppliers enable them to establish a smooth flow of products characterized by short replenishment times and low levels of inventory. Usually 3PLs are hired for physical transport of products from supplier's premises to buyers' facility. Respondents of the study noted that developing manufacturing and human capabilities particularly aids in reducing replenishment times.

The results of the study thereby conclude that partner development practices related to and by ensuring consistent quality of products purchased, fostering management, innovation and logistics related capabilities have greatest impact on purchasing performance of micro-entrepreneurs in BoP.

CONCLUSION

Considered as a notion advocating for "privatisation of poverty reduction" (Arora and Romijn, 2012), "the BoP approach, … can be thought of as an emergent 'metanarrative'—a grand synthesizing framework which provides scholars and practitioners at diverse sites with a template for future research and action aimed at creating market based solutions for poverty eradication" (Chatterjee, 2014). The paper presents the results of a survey aimed at highlighting the supply chain practices which have a significant impact on indigenous micro-entrepreneurs purchasing performance in B2B supply chains of the BoP. The supply chain partner development construct (signifying long term relationship and supplier development related activities) is found to be the construct having a significant impact on the purchasing

performance of the firm. A reciprocal relationship between supply chain partner development and purchasing performance is revealed by the results of the regression analysis. Correlation analysis results also highlight potential areas for future studies in B2B domain of BoP. For example, positive and significant relationship between communication and coordination with supplier and technological integration signifies that the firms who communicate and coordinate with their suppliers are more likely to practice tactical knowledge sharing. Though the relationship is beyond the scope of this study, it is more appropriate for future studies to explore the area in detail.

Consistent with earlier studies, empirical results of the extent paper highlight the frequent informal interactions among buyers and suppliers a distinguishing characteristic of business in the BoP and a prerequisite of establishing long term relationships. The interest in building trust worthy relationships is mirrored in firm's urge of long term commitment and investment in supplier development. The interactions not only intensify mutual business relationships but also serve to improve business processes. The results remain also crucial from practitioner's point of view as they provide a holistic view of enhancing purchasing efficiency when considering BoP firms as suppliers.

The study results also enable us to explore how potential win-win situations can be achieved while working in a dynamic business environment like BoP. Incorporating these synergic impacts into the goals of the firm may then serve as starting point for adequate business process improvements.

APPENDIX A

Strategic Purchasing

SP1	Purchasing for critical products is done from selected group of suppliers
SP2	Non-critical items are purchased from wherever we get quality products at competitive price

Communication and coordination

CM1	We share sensitive information (financial, production, design, research, and/or competition) with our suppliers
CM2	Suppliers are provided with any information that might help them improve their performance
CM3	We keep each other informed about events or changes that may affect the other party
CM4	We exchange business performance feedback with our suppliers

Technological integration with customers

TIC1	We involve key customers in product design and development stage
TIC2	Our customers assist us in improving our operational technology (machines etc.)
TIC3	We involve our key customers in business and strategy planning

Technological integration with suppliers

TIS1	We involve key suppliers in product design and development stage
TIS2	We involve our key suppliers in business and strategy planning
TIS3	We collaborate with our suppliers in improving mutual operational technology (machines etc.)

Supply chain partner development

Our firm has undertaken supplier development through

SPD1.1	Giving manufacturing related advice (e.g. processing, machine process, machine setup)
SPD1.2	Giving technological advice (e.g. materials, software)

By improvement of supplier capabilities through development of supplier

SPD2.1	He was able to strengthen his management capabilities
SPD2.2	He was able to strengthen his manufacturing capabilities
SPD2.3	He was able to strengthen his logistics capabilities
SPD2.4	He was able to strengthen his product development capabilities

Supply chain network structure

SNS1	We consider doing business in networks more productive
SNS2	I think I will be helped in difficult times by other business owners in vicinity
SNS3	We try to establish trust based long term relationships with our suppliers
SNS4	Our relationship with other business players can be termed as supportive instead of competitive

To what extent do you think you have maintained any personal relationships with following

SNS5.1	Buyers
SNS5.2	Suppliers
SNS5.3	Competitors
SNS5.4	Logistic service providers

To what extent do you think you have maintained any personal ties with following

SNS6.1	Local political leaders
SNS6.2	Banks
SNS6.3	Tax officials

SNS6.4	Local administration
SNS6.5	Local communities
SNS6.6	NGOs

Purchasing performance

Improving product and delivery performance through development of supplier has improved/reduced

PP1.1	The quality of products purchased from supplier
PP1.2	The replenishment lead time of the products purchased from supplier
PP1.3	The service of supplier deliveries
PP1.4	The reliability of supplier deliveries

ABSTRACT

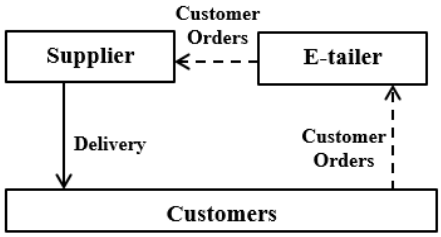
Using simulation methodology, our research is the first study to investigate the impact of equal stockout compensation strategy (E-SC) compared to no stockout compensation strategy (N-SC) on supplier's profits and etailers profits in a dropshipping supply chain. Results from our study shows that on average, the profit difference in E-SC compared to N-SC is less than 4.0 percent of overall profits for both the supplier and etailer. Also, this study shows that demand variability, production capacity and service level have a significant impact on both the supplier's profits and etailer's profits in E-SC compared to N-SC.

KEYWORDS: E-Commerce, Dropshipping, Stockout Compensation, Variable Demand, Simulation Modeling

INTRODUCTION

In recent years, due to ease of online shopping, there is significant increase in online sales and continues to increase. Market research firm eMarketer estimates online sales of $1.91 trillion in 2016 and projects to exceed $4.00 trillion by 2020 (eMarketer 2016). However, many online retailers have realized that the integration of front-end order taking process with back-end order fulfillment process is challenging, with order fulfillment process being regarded as the weakest link. To overcome this challenge, many online retailers have adopted dropshipping strategy, solely or in combination with their in-house order fulfillment strategy (Khouja 2001, Netessine et al. 2002, Gan et al. 2010, Chen et al. 2011, Cheong et al. 2015). In drop-shipping order fulfillment strategy, as shown in Figure 1, the online retailer (here on referred to as etailer) takes on-line orders from their customers and requests their supplier (manufacturer or distributor) to ship these orders directly to their customers. For example, eBags.com carries very little inventory and use dropshipping extensively to sell more than 12,000 different bags online which are shipped directly by their suppliers to their customers. Large online retailers like Amazon and eBay also use dropshipping to fulfill some of their customer orders (Cheng et al. 2015). In dropshipping strategy, the etailer benefits by transferring inventory management and shipping responsibilities to the supplier, while the supplier benefits with increased demand and the ability to charge higher wholesale prices.

Figure 1. Drop Shipping Supply Chain



However, in a variable demand environment with production (and/or supply) capacity constraints, there are risks to this zero-inventory order fulfillment strategy for the etailer. They are usually vulnerable, especially when the dropship supplier is unable to fulfill customer orders due to stockout situations. As etailers are in direct contact with their customers, they are ultimately held responsible for any unfulfilled customer orders. If orders are not fulfilled on time, customers may cancel their orders or leave negative reviews that will impact the etailer's current and future business. (Kim and Lennon 2011). In a recent study, using 14 months of empirical sales data for an online retailer selling non-perishable items, Jing and Lewis (2011) found that approximately 25.4% of all online orders were imperfectly filled due to stockouts. Similarly, another study by Accenture found that despite best efforts to improve online order fulfillment during the busy season, more than 12% of the orders were not delivered on time (Enos 2010). When online retailer Value America declared bankruptcy, it cited the inability of its dropship suppliers to fulfill their customer orders on time. Similarly, in its early days, online retailer Zappos.com carried very little inventory and used dropshipping extensively to fulfill their customer orders. However, they soon stopped using dropshipping due to poor order fulfillment by their suppliers (Hsieh 2010). As most dropship suppliers do not pay any penalty for late orders, there is less incentive for them to improve their inventory management and order fulfillment rates (Yao et al. 2008, Gan et al. 2010).

So, in a dropshipping supply chain, unfulfilled customer orders during stockout can be a huge obstacle for etailers to pursue dropshipping strategy. In an online retailer setting (without dropshipping), Bhargava et al. (2006) analyze stockout compensation policy during inventory stockouts and conclude that it helps to increase customer retention, improve demand rate and decrease average inventory costs. However, to the best of our knowledge, there are no research studies that investigate the impact of stockout compensation on supplier's profits and etailer's profits in a dropshipping supply chain. In our research study, we propose that both the supplier and etailer share the risk of stockout and equally pay stockout compensation in a dropshipping supply chain. The etailer generates continuous demand and therefore the supplier should consider sharing the risk of stockout to avoid losing future business with this etailer. So, if stockout compensation is to be considered in a dropshipping supply chain, some of these questions arise. What will be the impact on supplier's profits and etailer's profits when both equally share stockout compensation (E-SC) compared to no-stockout compensation policy (N-SC)? In E-SC stockout compensation strategy, what will be the impact on supplier's profits and etailer's profits under different supply chain parameters? Using simulation modeling, our research aims to answer these questions by investigating the impact of E-SC compared to N-SC on the supplier's profits and the etailer's profits in a dropshipping supply chain.

LITERATURE REVIEW

Academic research in online retailing has largely focused on the marketing aspect, and is mostly qualitative in nature (Gulati et al. 2000, De Koster 2003, Jiang et al. 2005, Anderson et al. 2007, Baier et al. 2010, and Rafiq et al. 2013). Academic research in online retailing with operations consideration (production, inventory, dropshipping, etc.) is relatively new and growing in importance. Many online retailers have realized that the integration of front-end order taking process with back-end order fulfillment process is quite challenging, where order fulfillment is regarded as the weakest link.

First, we will review the studies related to dropshipping in online retailing. Next, we will review the studies related to stockout compensation in online retailing. The following studies are related to our research in online retailing using dropshipping. Using a single period model framework, Khouja (2001) formulate a model to identify the optimal mix of in-house inventory and dropshipping to meet customer demand, where capacity of drop-shipping option is unlimited. Using empirical data, Netessine et al. (2002) discuss the advantages and disadvantages of dropshipping for the etailers (they use the term virtual order fulfillment for dropshipping). Netessine and Rudi (2004) develop a model to analyze the interaction between a wholesaler and an online retailer in a dropshipping supply chain. They propose a profit sharing contract where both the wholesaler and online retailer should share the profits and expenses of acquiring customers and fulfilling customer orders. Bailey and Rabinovich (2005) develop an analytical model for an internet book retailing, where both in-house inventory and dropshipping option can be used to fulfill customer orders. They discuss how the product's popularity or frequency of ordering affects the decision of either using in-house inventory or dropshipping option. Netessine and Rudi (2006) model a supply chain with multiple retailers and a wholesaler with dropshipping contract. They provide recommendations where dropshipping or a traditional channel should be preferred from the perspective of inventory risk pooling. Using Monte Carlo simulation, Ayanso et al. (2006) determine a threshold level of inventory for online retailers to switch from internal inventory stocking to dropshipping option for different demand priorities and different lead times. Using a Stackelberg game, Yao et al. (2008) explore how an online retailer (leader) can give the supplier (follower) appropriate incentive to improve the level of delivery reliability in a dropshipping supply chain. Khouja and Stylianoua (2009) develop two (Q, R) inventory models for an online retailer with both in-house inventory and dropshipping option. Their results suggest that dropshipping should be used in case of inventory shortage during the lead time. Chiang and Feng (2010) consider an EOQ game model with pricing and lot-sizing decisions to investigate the advantages of dropshipping over the traditional shipping channel. They identify conditions under which the dropshipping channel produces more profit than traditional shipping channel.

Gan et al. (2010) propose a commitment penalty contract in a dropshipping supply chain with three different parameters under asymmetric demand information. They propose that the supplier should receive demand information from online retailer to maximize the expected profit. Cheong et al. (2015) develop an analytical model for a two-level supply chain to study impact of information discrepancies on both the drop-shipper and online retailer. Their study concludes that both parties can achieve substantial cost reductions if information discrepancy is eliminated. Using mathematical models, Cheng et al. (2016) investigate different order fulfillment strategies for an e-tailer and show that dropshipping model and hybrid channel with inventory rationing model are optimal choices for the e-tailer. Yu et al. (2017) consider a dual-channel supply chain with a manufacturer selling a product through a traditional retailer and online retailer using dropshipping. Their study show that dropshipping benefits both the manufacturer and online retailer, when the online retailer has relatively low market power compared to the traditional retailer.

There are some studies in online retailer setting that consider consumer behavior during stockouts. However, there are limited studies in online retailing that consider some form of financial compensation during stockouts. Using EOQ type inventory modeling framework with deterministic demand in an online retailer setting (without dropshipping), Bhargava et al. (2006) analyze profit difference between stockout-compensation backorder policy and no-stockout-compensation backorder policy. They conclude that stockout compensation policy results in more efficient operation which helps to increase customer retention, increase demand rate and lower average inventory costs. Breugelmans et al. (2006) investigate the impact of an online retailer's stock-out policy on the consumer's category purchase and choice decisions. Their results from an online grocery shopping experiment reveal that suggesting a replacement item during stockout helps to substantially increase consumer's probability of purchasing the suggested item. Kim and Lennon (2011) investigate how consumers respond to online apparel stockouts and found that negative emotions evoked by stockouts create a depressed perception of store image, lowered decision satisfaction, and reduced behavioral intent of buying. They show that financial compensation was most effective in mitigating the negative impact of stockouts.

Previous studies in online retailing using dropshipping have identified some factors that help the supplier and etailer to pursue dropshipping strategy, where most studies consider unlimited capacity for dropship supplier. However, the literature related to stockout compensation in online retailing is relatively small and to the best of our knowledge, there are no studies that consider impact of stockout compensation on supplier's profits and etailer's profits in a dropshipping supply chain. Using simulation modeling, our study is the first paper to consider impact of equal stockout compensation strategy (E-SC) on supplier's profits and etailer's profits compared to no-stockout compensation strategy (N-SC) in a variable demand dropshipping supply chain. These are the two different scenarios considered in our research study.

Scenario 0 (N-SC): This is Base Scenario. During stockout, the customer orders are backordered with 'no stockout' compensation. Customers are willing to wait for their orders to be delivered.
Scenario 1 (E-SC): During stockout, the customer orders are backordered with a 'stockout' compensation. Both the supplier and etailer 'equally share' stockout compensation, and the wholesale price is the same as in the Base Scenario (N-SC).

We investigate the following research questions in this study.

1. On average, what is the impact of E-SC compared to N-SC on the supplier's profits and etailer's profits?
2. What is the impact of E-SC compared to N-SC on the supplier's profits and etailer's profits under different supply chain parameters?

Our research will expand the existing literature (Netessine and Rudi 2004, Bhargava et al. 2006, Yao et al. 2008, and Gan et al. 2010, Kim and Lennon 2011) in the area of online retailing and dropshipping by investigating the impact of stockout compensation in a dropshipping supply chain. The contributions of our research to the literature are three-fold. First, our research is the first study to consider impact of stockout compensation on the supplier's profits and etailer's profits in a dropshipping supply chain. Second, using simulation modeling we consider the impact of equal stockout compensation strategy (E-SC) compared to no stockout compensation strategy (N-SC) on the supplier's profits and etailer's profits in a dropshipping supply chain under different supply chain parameters. Third, our study aims to provide managerial insights for both the supplier and etailer on the impact of E-SC under different supply chain parameters.

RESEARCH METHODOLOGY

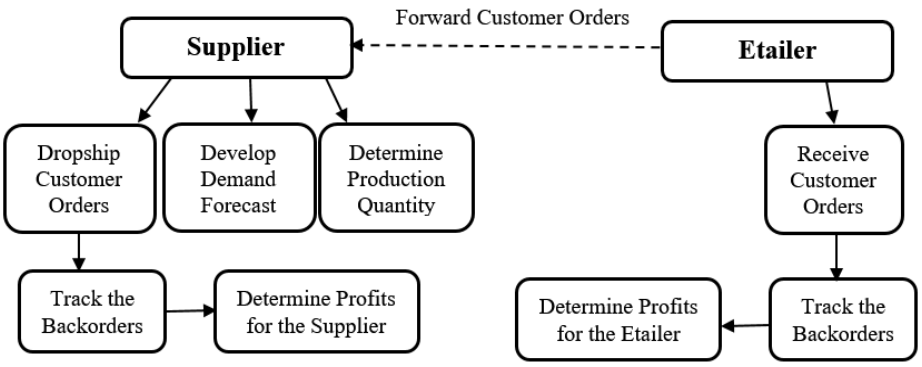
Discrete event simulation (Arena software from Rockwell automation) is used to develop the simulation model for the dropshipping supply chain. Simulation method is appropriate to study the dynamic and time varying behavior of a dropshipping supply chain in a variable demand environment with production capacity constraints. Simulation helps to provide insight into the cause and effects of different supply chain parameters on the performance measures. Simulation approach has been used in many studies for analyzing supply chain systems, including dropshipping and online retailing (Ayanso et al. 2006, Mathien and Suresh 2015).

Simulation Modelling

The conceptual model used to develop the simulation model for dropshipping supply chain is a two-echelon production-inventory system with a make-to-stock manufacturer (i.e. supplier) and an online retailer (i.e. etailer). Periodic review policy is used where all decisions by the supplier and etailer are made at the end of each period, where review period is one week. Demand forecast for supplier is developed using exponential smoothing forecast technique and smoothing parameter is selected based on minimizing forecast error. Periodic review order-up-to policy is used to determine production quantity during each period. Safety stock for supplier is determined using service factor (based on service level) and standard deviation of demand. The supplier uses lot-for-lot production policy with a lead time of one week and has production capacity constraints.

During each period, the customers place their orders online and the etailer forwards these orders to supplier at the end of each period. The supplier's warehouse receives shipment from their production plant at end of each period and their inventory level is updated. From this available inventory, the supplier dropships the customer orders received from etailer, and any demand not met is backordered. In N-SC, customer orders are backordered without a stockout compensation, and in E-SC they are backordered with a stockout compensation. Next, the supplier forecasts demand for next period, calculates order up-to inventory level to determine production quantity. The production quantity during each period is the difference between order-up-to inventory level and current inventory position. The production starts at the beginning of next period and the production quantity along with current inventory is available for dropshipping at the end of next period. Finally, the revenues and expenses are calculated to determine the supplier's profits and etailer's profits during each period. The decisions made by the supplier and etailer during each period in the dropshipping supply chain are shown in Figure 2.

Figure 2. Drop Shipping Supply Chain Setting



Model Notations

P	Retail price per unit (paid by customer)
W	Whole sale price per unit (paid by etailer)
T	Dropshipping cost per unit (paid by etailer)
E	Etailer cost (website, marketing, etc.) per unit
F	Fixed cost of production per period
C	Variable cost of production per unit
H	Inventory holding cost per unit per period
S_s	Supplier stockout compensation cost per unit per period
S_e	Etailer stockout compensation cost per unit per period
d	Customer orders per period
q	Production quantity per period
i	Average inventory of supplier per period
b	Backorder quantity (due to stockout) per period
EP	Etailer profits per period
SP	Supplier profits per period

Profits for Supplier and Etailer in N-SC strategy

$EP = (P - W - T - E)*d$
$SP = W*d - (F + C*q) - H*i$

Profits for Supplier and Etailer in E-SC strategy

$EP = (P - W - T - E)*d - S_e*b$
$SP = W*d - (F + C*q) - H*i - S_s*b$

Experimental Design

The purpose of an experimental design is to develop a methodology to track changes in performance measures by varying factors under study during the experimental runs. According to Law and Kelton (2000), “One of the principal goals of experimental design is to estimate how changes in input factors (control variables) affect the performance measures (response variables) in the experiment.” The main motivation for this research is to investigate the impact of equal stockout compensation strategy (E-SC) compared to no stockout compensation strategy (N-SC) in a dropshipping supply chain under different supply chain parameters. So four independent variables (control variables) with three levels each and two dependent variables (response variables) are considered for this study. All factor combinations of these independent variables are used to investigate impact on dependent variables in N-SC and E-SC stockout compensation strategies.

Table 1. Control Variables for this Research

Control Variables	Details for Variables
Demand Variability (DV)	Low Demand Variability, σ = 100 Med Demand Variability, σ = 200 High Demand Variability, σ = 300
Production Capacity (PC)	Low Production Capacity, 1.10 Med Production Capacity, 1.25 High Production Capacity, 1.40
Service Level (SL)	Low Service Level, 90.0 % Med Service Level, 95.0 % High Service Level, 99.0 %
Inventory Holding Cost (HC)	Low Inventory Holding Cost, $1 Med Inventory Holding Cost, $2 High Inventory Holding Cost, $3

Table 2. Response Variables for this Research

Response Variables	Details
Etailer Profits per Period (EP)	Etailer Revenues minus Expenses
Supplier Profits per Period (SP)	Supplier Revenues minus Expenses

As shown in Table 1 and Table 2, four control variables and two response variables are used to investigate the impact of E-SC compared to N-SC on supplier's profits and etailer's profits in a dropshipping supply chain. Variable demand, production capacity, service levels, and inventory holding costs are used as control variables, as these are important factors that will impact profits for both the supplier and etailer. In this study, auto-correlated demand pattern with three levels of demand variability is considered. The customer demand during each period of the simulation run is generated as shown: $D_t = d + \rho D_{t-1} + \varepsilon_t$ where ρ = correlation factor, d = initial mean, and ε_t = error that is normally distributed with mean zero and standard deviation σ. The initial mean is 500 units with a correlation factor of 0.5 to generate an average demand of 1000 units per period. Three levels of demand variability are generated by varying σ in the above equation.

To investigate the impact of production capacity, three levels of production capacity with different levels of capacity cushion based on average customer demand are considered. Additionally, three levels of service levels to determine the safety stock inventory and three levels of inventory holding costs for supplier are considered. The retail price is assumed to be $100 per unit and the wholesale price per unit is as follows: When demand is less than 900 units per period, the wholesale price is $61 per unit; when demand is 900 to 1100 units per period, the wholesale price is $60 per unit and when demand is more than 1100 units per period, the wholesale price is $59 per unit. The shipping cost charged by supplier to etailer for dropshipping the item is as follows: When inventory holding cost is $1 per unit per period, shipping cost is $5.00 per unit; when inventory holding cost is $2 per unit per period, shipping cost is $5.50 per unit and when inventory holding cost is $3 per unit per period, shipping cost is $6.00 per unit. The stockout compensation cost is assumed to be 10% of retail price and no customer order returns are considered in this dropshipping model. Most studies in dropshipping use retail price minus wholesale price as profit

measure for etailer (Netessine & Rudi 2006, Chiang & Feng, 2010) and do not consider any expenses incurred by the etailer. However, the etailer incurs some expenses for online retailing such as cost of website, marketing, etc. and so our study considers etailer's expense as $3 per unit to generate the customer demand.

Table 3. Production Capacity and Unit Production Cost

Production Capacity	Fixed Production Cost per Period	Var. Production Cost per Unit	Avg. Production Per Period	Avg. Production Cost Per Unit
1.10	$4,000	$22.00	1000	$26.00
1.25	$5,000	$20.00	1000	$25.00
1.40	$6,000	$18.00	1000	$24.00

Generally, the production cost per unit decreases as production capacity increases, so our study considers the production cost details as shown in Table 3. Initial inventory of 2000 units (2 times average demand) is used for supplier at start of simulation run. The supplier profit and etailer profit are used as performance measures and calculated based on revenues minus expenses during each period.

To eliminate the impact of random variations of input data, the same random number sequence is utilized in simulation model to generate the same customer demand data in N-SC and E-SC strategies for all factor combinations. In addition, to reduce variance of output data, a sample size of 60 replications is considered in this study. Generally, stochastic processes for most real systems do not have a steady state distribution, since parameters of the system may continue to change over time. In this research, customer demand for etailer varies from period to period, and therefore the steady state parameters are not well defined or do not exist. In this situation, there will be a fixed amount of data describing how the input parameters can be varied over some time duration. This in effect provides a terminating event for simulation and thus analysis techniques for terminating simulation will be appropriate (Law and Kelton 2000). To determine performance measures for a terminating simulation, the initial conditions should be representative of the actual system. In our study, the simulation model for all factor combinations is run for a total of 1144 periods, with the first 104 periods used to initialize the system (warm up period), and remaining 1040 periods (equal to 20 years) is used for analysis. Increasing warm up period will not have a significant impact, as output values from the simulation model are relatively stable for different warm-up periods. Microsoft Excel and statistical software "Minitab 18" are used for results and discussions.

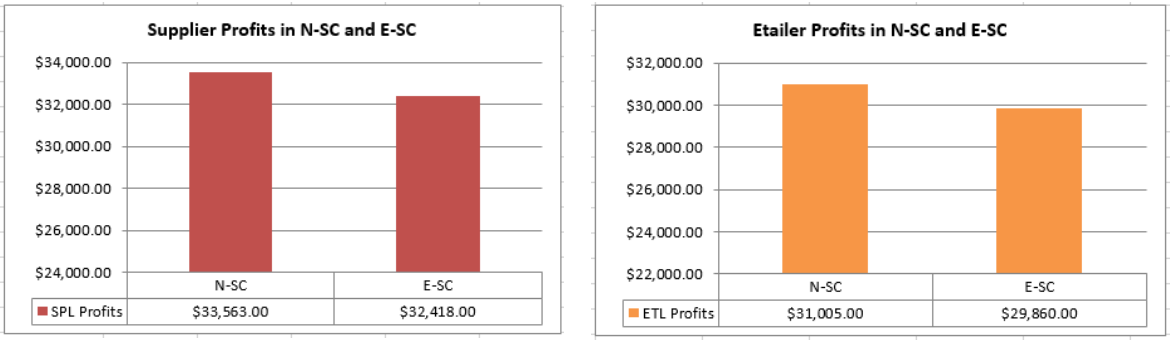
RESULTS AND DISCUSSION

The output data (supplier's profits and etailer's profits) from the simulation model is analyzed to determine the impact of equal stockout compensation strategy (E-SC) compared to no stockout compensation strategy (N-SC). First, the impact of E-SC compared to N-SC on the supplier's profits and etailer's profits for all factor combinations is investigated. Next, the impact of E-SC compared to N-SC on the supplier's profits and etailer's profits under different supply chain parameters is investigated. Some of the main results of this research study are shown below.

Impact of Stockout Compensation Strategy

To determine the impact of E-SC compared to N-SC on supplier's profits and etailer's profits in a dropshipping supply chain, the output data from the simulation model for all factor combinations are plotted as shown in Figure 3. When both the supplier and etailer pursue E-SC, on average, the supplier's profits decrease from $33,563 to $32,418 (i.e. by 3.42%) and etailer's profits decrease from $31,005 to $29,860 (i.e. by 3.69%) compared to N-SC. So, based on the dropshipping supply chain considered in our research study, on average, the profit difference in E-SC compared to N-SC is less than 4.00% for both the supplier and the etailer. This amount of money, which is less than 4.00% of overall profits is surely worth spending to keep the customers happy, which in turn can help in maintaining or even increasing the overall demand and overall profits for both the supplier and the etailer.

Figure 3. Impact of Different Stockout Compensation Strategies

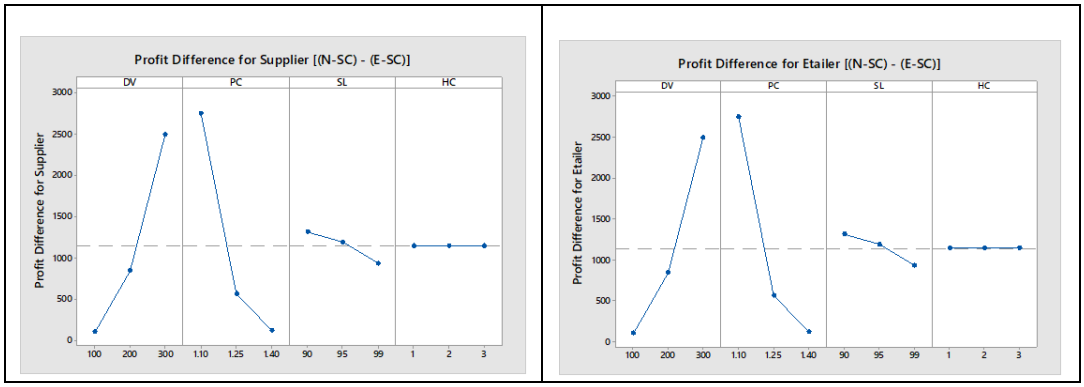


To determine if the difference between means for supplier profits and etailer profits in E-SC and N-SC are statistically significant in a variable demand environment, we use ANOVA to compare p-value to significance level ($\alpha = 0.05$) as shown in Table 4. In E-SC, both the supplier and etailer equally pay stockout compensation, and so the profit difference for both the supplier and the etailer between E-SC and N-SC will be the same. In addition, profit difference for the supplier and etailer between E-SC and N-SC for different supply chain factors is shown in Figure 4.

Table 4. ANOVA of Profit Difference between N-SC and E-SC

Source	DF	Sum of Squares	Mean Squares	F	P
DV	2	80845559	40422780	2398.78	0.000
PC	2	106221592	53110796	3151.71	0.000
SL	2	2026614	1013307	60.13	0.000
HC	2	0	0	0.00	1.000
DV*PC	4	65954297	16488574	978.47	0.000
DV*SL	4	1172861	293215	17.40	0.000
DV*HC	4	0	0	0.00	1.000
Error	60	1011084	16851		
Total	80	257231736			

Figure 4. Profit Difference for Supplier and Etailer between N-SC and E-SC

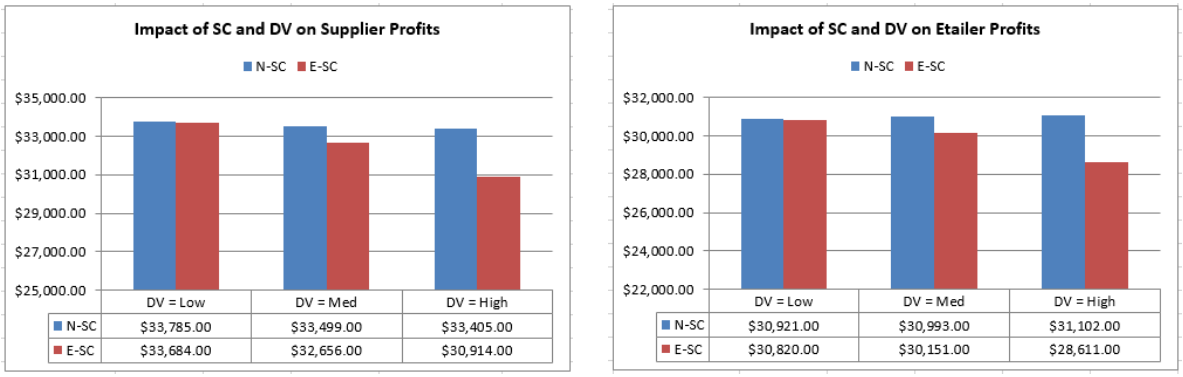


From Table 4, the p-value is less than the significance level, and so we conclude that there is a statistical significant difference for the supplier profits and the etailers profits between N-SC and E-SC for different DV (demand variability), PC (production capacity) and SL (service level). However, it is interesting to see that there is no statistical significant difference in supplier profits and etailer profits between N-SC and E-SC for different HC (inventory holding cost). The likely reason is that same amount of inventory is held by the supplier in both the N-SC and E-SC strategies under different inventory holding costs. Also, only the supplier holds inventory in a dropshipping supply chain, and so inventory holding cost does not impact the etailer's profits.

Impact of Stockout compensation (SC) and Demand Variability (DV)

Demand variability can play an important role on impact of E-SC compared to N-SC on both the supplier profits and etailer profits in a drop shipping supply chain. In this research, the customer demand for etailer is varied during each period of the simulation run. The supplier profits and etailer profits under different demand variabilities and stockout compensation strategies in a dropshipping supply chain are shown in Figure 5.

Figure 5. Impact of Stockout Compensation (SC) and Demand Variability (DV)



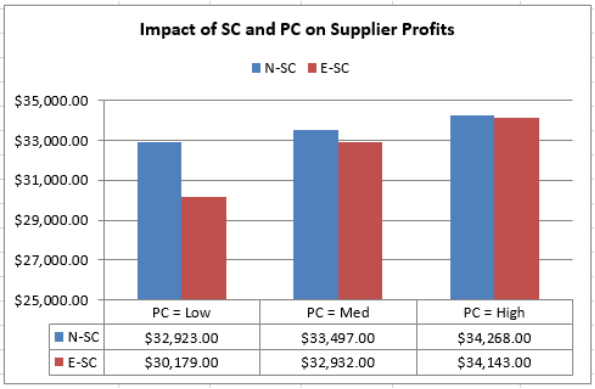
When demand variability is low, the supplier's profits decrease only by 0.30% and etailer's profits decrease only by 0.33% in E-SC compared to N-SC. It means that when demand variability is low, the profit difference for E-SC compared to N-SC is less than 0.50% for both the supplier and etailer. This is because when demand variability is low, the supplier is able to accurately forecast

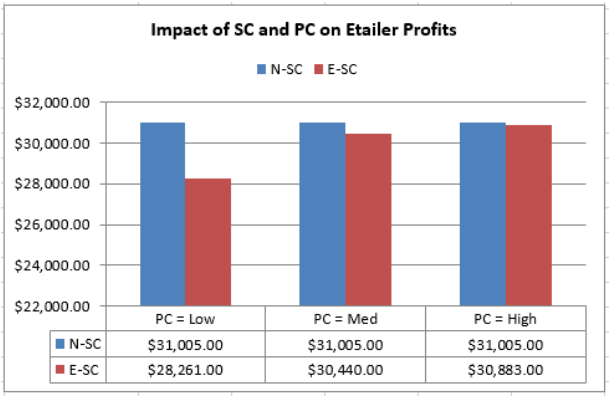
demand and have enough production capacity to fulfill almost all customer orders with very little stockout. However, when demand variability is high, the supplier's profits decrease by 7.46% and etailer's profits decrease by 8.01% in E-SC compared to N-SC. When demand variability is high, the supplier may not be able to accurately forecast demand and may not have sufficient production capacity resulting in higher profit difference in E-SC compared to N-SC due to higher stockout. Our results are similar to the study by Bhargava et al. (2006) who show an increase in profit difference for an online retailer with stockout compensation (without dropshipping) when demand rate increases. The results from this study show that demand variability does have a significant impact in E-SC compared to N-SC on both the supplier's profits and the etailer's profits. If feasible, the etailer should try to reduce demand variability to help increase the profits in E-SC for both the supplier and the etailer.

Impact of Stockout compensation (SC) and Production Capacity (PC)

Production capacity helps to determine if the supplier has enough capacity to produce during each period to meet the customer demand. So, production capacity can play an important role for both the supplier and etailer in E-SC compared to N-SC. The supplier profits and etailer profits under different production capacities and stockout compensation strategies in a dropshipping supply chain are shown in Figure 6.

Figure 6. Impact of Stockout Compensation (SC) and Production Capacity (PC)



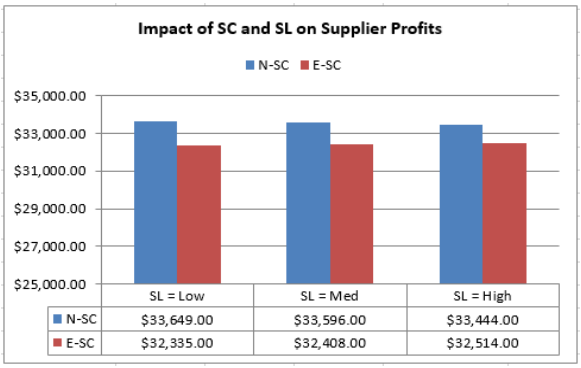


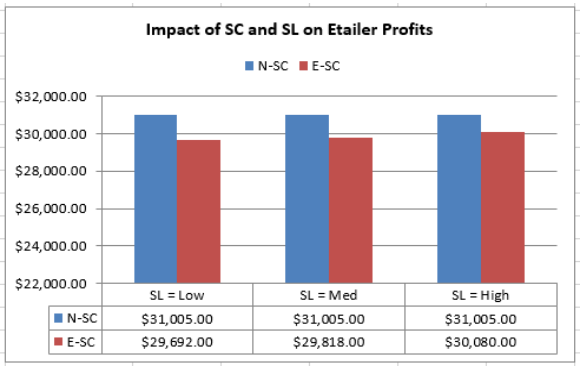
When production capacity is high, the supplier's profits decrease only by 0.36% and etailer's profits decrease by 0.39% in ESC compared to N-SC. It means that when production capacity is high, the profit difference in E-SC compared to N-SC is less than 0.50% for both the supplier and etailer. This is because when production capacity is high, the supplier may have enough capacity to produce and fulfill almost all customer orders with very little stockout. However, when production capacity is low, the supplier's profits decrease by 8.33% and etailer's profits decrease by 8.85% in E-SC compared to N-SC. When production capacity is low, the supplier may not have enough capacity to produce and fulfill the customer orders resulting in higher stockout. The results from this study show that production capacity does have a significant impact in E-SC compared to N-SC on both the supplier's profits and the etailer's profits. So, in a variable demand environment, the supplier should increase production capacity which will significantly reduce cost of stockout compensation in E-SC and increase overall profits for both the supplier and etailer.

Impact of Stockout compensation (SC) and Service Level (SL)

Service level used to determine the safety stock for supplier can play an important role on the impact of E-SC compared to N-SC for both the supplier and etailer in a drop shipping supply chain. The supplier profits and etailer profits under different service levels and stockout compensation strategies in a dropshipping supply chain are shown in Figure 7.

Figure 7. Impact of Stockout Compensation (SC) and Service Level (SL)



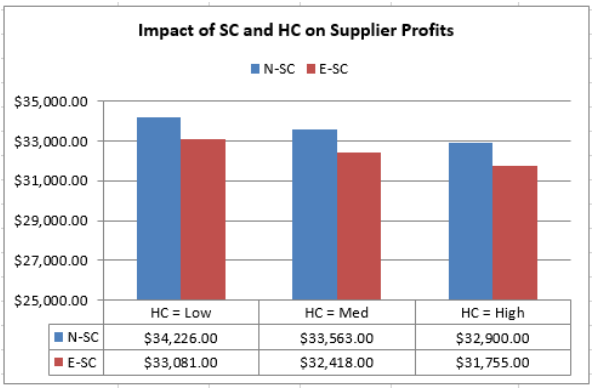


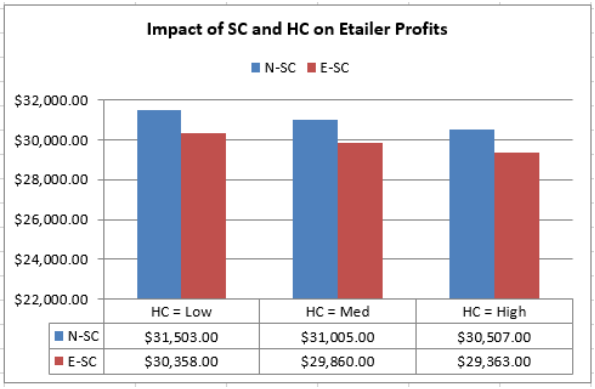
When service level is high, the supplier's profits decrease by 2.78% and the etailer's profits decrease by 2.98% in E-SC compared to N-SC. It means that when service level is high, the profit difference for E-SC is less than 3.00% for both the supplier and etailer. With higher service level the supplier carries more safety stock inventory which helps to fulfill customer orders with less stockout. However, when service level is low, the supplier's profits decrease by 3.91% and the etailer's profits decrease by 4.23% in E-SC compared to N-SC. It means that when service level is low, the profit difference for E-SC compared to N-SC is more than 3.00% for both the supplier and etailer. With lower service level the supplier carries comparatively less safety stock inventory which increases the stockout rate. The results from this study show that service level does have a significant impact in E-SC compared to N-SC on both the supplier's profits and the etailer's profits. Ideally, in a variable demand environment the supplier should maintain higher service level to help reduce the stockout compensation in E-SC which will help to increase the overall profits for both the supplier and the etailer.

Impact of Stockout compensation (SC) and Inventory Holding Cost (HC)

Even though the profit difference for the supplier and etailer is same between N-SC and E-SC strategies under different inventory holding costs, however the supplier profits and etailer profits are not the same in E-SC compared to N-SC under different inventory holding costs. The supplier profits and etailer profits under different inventory holding costs and stockout compensation strategies in a dropshipping supply chain are shown in Figure 8. In this study, for every dollar increase in inventory holding cost per unit per period, an additional cost of $0.50 per unit is charged to etailer for dropshipping the customer orders, which will help the supplier to offset their higher inventory holding cost. In a dropshipping supply chain, only the supplier holds inventory, and so they should be able to charge slightly higher price to etailer which will help to offset their higher inventory holding cost.

Figure 8. Impact of Stockout Compensation (SC) and Inventory Holding Cost (HC)





When inventory holding cost is low, the supplier's profits decrease by 3.35% and etailer's profits decrease by 3.63% in E-SC compared to N-SC. It means that when inventory holding cost is low, the profit difference for E-SC compared to N-SC is less than 4.00% for both the supplier and etailer. Similarly, when inventory holding cost is high, the supplier's profits decrease by 3.48% and etailer's profits decrease by 3.75% in E-SC compared to N-SC. It means that when inventory holding cost is high or low, the profit difference for E-SC is less than 4.00% for both the supplier and etailer. So, the results from this study show that inventory holding cost does not have a significant impact in E-SC compared to N-SC on both the supplier's profits and the etailer's profits. This is because, the supplier is able to charge higher dropshipping cost to etailer, which will help the supplier to offset their higher inventory holding cost.

CONCLUSION

In a dropshipping supply chain, unfulfilled customer orders during inventory stockout can be a huge obstacle for online retailers (i.e. etailers) to pursue dropshipping strategy. Using simulation modeling, our research is the first study to consider stockout compensation in a dropshipping supply chain. We investigate impact of equal stockout compensation strategy (E-SC) compared to no-stockout compensation strategy (N-SC) on supplier's profits and etailer's profits in a variable demand dropshipping supply chain. The conceptual model is a two-echelon production-inventory system with a make-to-stock manufacturer (i.e. supplier) and an online retailer (i.e. etailer).

The results from this study suggests that on average, the supplier's profits decrease by 3.42% and the etailer's profits decrease by 3.69% in E-SC compared to N-SC. So, based on the dropshipping supply chain considered in our research study, on average, the profit difference for both the supplier and etailer is less than 4.00% of their overall profits in E-SC compared to N-SC. This amount of money, which is less than 4.00% of their overall profits, is worth spending to keep the customers happy which in turn can help in maintaining or even increasing the overall demand and profits for both the supplier and etailer in a dropshipping supply chain. Demand variability, production capacity, and service level have a significant impact on both the supplier's profits and the etailer's profits in E-SC compared to N-SC. When demand variability is high, production capacity is low, service level is low and inventory holding cost is high, the impact on the supplier's profits and etailer's profits in E-SC compared to N-SC is higher (i.e. decrease in profits is higher in E-SC compared to N-SC). However, when demand variability is low, production capacity is high, service level is high and inventory holding cost is low, impact on supplier's profits and etailer's profits in E-SC compared to N-SC is comparatively lower.

Limitations and Future Research

Although valuable insights can be gained from this research study to understand the impact of equal stockout compensation strategy (E-SC) compared to no-stockout compensation strategy (N-SC) on the supplier's profits and etailer's profits in a variable demand dropshipping supply chain, however, it is recognized that the conclusions provided here is limited to the dropshipping supply chain setting considered in this study. In this research, a single supplier and a single etailer with periodic review policy (R, S) is considered for the dropshipping supply chain. Demand variability, production capacity, customer service level and inventory holding costs are used as the control variables. A fixed retail price and one set of stockout compensation cost is considered in this study. So, there are many opportunities to evaluate and strengthen these insights by investigating other parameters to determine the impact of E-SC compared to N-SC on the supplier profits and etailer profits in a dropshipping supply chain. Future studies can investigate the impact on supplier's profits and etailer's profits when only the supplier pays the stockout compensation (S-SC) and in addition, determine the appropriate wholesale price the supplier can charge in the S-SC strategy to offset their stockout compensation cost. Also, future studies can investigate how different sets of stockout compensation costs, retail price and profit margins will impact supplier profits and etailer profits in E-SC and S-SC compared to N-SC. Another area of future research is to consider the impact of E-SC and S-SC on supplier profits and etailer profits with multiple suppliers and/or multiple etailers. In addition, it would be valuable to extend this study to investigate the impact of E-SC and S-SC on the supplier profits and etailer profits by considering other inventory management policies like (s, S) and (R, Q) policies in a dropshipping supply chain.

Impacts of Stimulation Approaches on Online Learning Achievement: A Case Study

San Yun (Nancy) Tsai
California State University, Sacramento
Email: sytsai@csus.edu

ABSTRACT

This study has adopted academic motivation theory to implement a stimulation strategy with a teacher-stimulated approach and a teacher-guided approach in an online undergraduate computer literacy course. Hypothesis testing utilizes the performance records of 2,500 students to exam students' learning performances and achievements of each approach in two consecutive semesters.

KEYWORDS: Online learning; Learning motivation; Learning achievement

INTRODUCTION

The affordable of advanced information and communication technologies have nourished the popularity of online learning in the current digital age. Organizations and higher education institutions have permanently incorporated this into its traditional classroom learning approach. It is a cost effective for having the ability to communicate and educate vast number of distance students at anytime and anywhere in the universe. The limited resources and funding constraints have also prompted the College of Business Administration (CBA) to transform a high enrollment undergraduate computer literacy course (MIS 123) from the traditional face-to-face classroom teaching to a student self-pulled online learning.

Under the new learning approach, students have the total control and freedom of their studying time, place, and pace to access a courseware over the Internet. The course instructor acts as a course administrator to define structure, prepare syllabus, submit grades and solve problems. Students have to pull themselves together to figure out the entire learning process without any push from the instructor. Unfortunately, this approach has produced a high dropout rate and a low passing rate as revealed by numerous academic researches. It is due to some students lacking self-managed and self-motivated ability to study as required in an isolated online learning environment. An urgent responsibility of the instructor is to figure out a stimulation strategy that utilizes academic motivation theory to persuade students to engage in the online learning process.

MIS 123 adopted a stimulation strategy of 20 extra reward points based on ARCS motivation model and self-determination theory (SDT). It utilized two implementation approaches for a stimulation strategy including teacher-stimulated and teacher-guided to motivate students in their learning process and reducing online learning pitfalls. Every student received the same lessons, assignments, and final exam via a commercial online courseware. Hypothesis testing utilizes the performance records of 2,500 students to exam the effectiveness of each approach in two consecutive semester.

LITERATURE REVIEW

In general, the student satisfaction is a critical successful factor to improve learning effectiveness, passing rate and dropout rate as suggested by many researchers and educators (Allen & Seaman, 2013; Castillo-Merino & Serradell-Lopez, 2014; Eom & Ashill, 2016; Jung, Choi, Lim & Leem 2002; Collins, Deck & McCrickard 2008; Manochehri & Young, 2006; Mashaw, 2012; Wu, Tennyson & Hsia, 2010; Zhao, Lei, Yan, Lai & Tan, 2005). A well-designed courseware and instructor's motivation strategy are the two major determinants for fabricating students' satisfaction. An effective courseware should have multiple course delivery formats such as reading, watching and practicing to fit student's learning style. Its structure has to be easy navigating, interactive and multimedia presentation for reducing the isolated learning feeling. In addition, it should provide instant learning feedback for quick performance improvement (Nemanich, Banks & Vera, 2009; Neuhauser, 2002; Ozdemir & Abrevaya, 2007).

The instructor's stimulation strategy utilizes academic motivation theory to persuade student in the learning process for a better learning outcome (Deci, Vallerand, Pelletier & Ryan, 1991; Guay, Morin, Litalien, Valois & Vallerand, 2015; Herath, 2016; Keller, 1987; Ryan & Deci, 2009). One motivation theory is ARCS model that proposes four elements including attention (A), relevance (R), confidence (C) and satisfaction (S) to design a motivation strategy for achieving better learning outcomes by students (Keller, 1987). The attention focuses on persuading students to put in effort in acquiring knowledge. The relevance makes students to realize that knowledge is a useful and valuable tool for their study and professional career. The confidence helps students to build self-assurance for completing learning tasks. The satisfaction stresses a desired learning outcome for students by finishing their course assignments.

The SDT includes autonomous motivation and controlled motivations (Deci, Vallerand, Pelletier & Ryan, 1991; Ryan & Deci, 2000). An autonomous motivation comprises intrinsic motivation and extrinsic motivations that give reward to students as a stimulation strategy for their learning accomplishment. A controlled motivation builds rules and guidance to put pressure and requirement on students for their achievement.

The instructor can establish a stimulation strategy based on ARCS model to motivate and inspire students for mastering course knowledge. The implementation of the stimulation strategy can utilize either an autonomous motivation or a controlled motivation as stated in SDT. The studying efforts and outcomes of students are according to their assessment value of a stimulation strategy. The instructor can identify an appropriate and effective stimulation strategy approach.

COURSE BACKGROUND

MIS 123 is a prerequisite requirement for students before declaring a major in CBA. There are two objectives of this course. First, it is to provide students with advanced microcomputer software knowledge and skills for helping their studying in other courses and/or facilitate their work in professional areas. Second, it is to initiate their lifelong self-learning ability. Course materials include Microsoft Office for its popularity usage in the business world and availability in the form of commercial online courseware. The course includes three one-unit, credit/no credit, and sequenced five-week long sub courses in a semester. Windows, Internet Explorer and Outlook are subjects for MIS 1. Comprehensive Excel is the only subject for MIS 2 due to its complexity and usefulness in the business field. Comprehensive Word and PowerPoint are two subjects for MIS 3. Results of a student survey regarding MIS 1 is the easiest and least useful one. MIS 2 is the hardest one but most valuable to find a job. MIS 3 is the most usefulness in other courses for writing papers and conducting presentations.

Only one instructor was responsible for administrating MIS 123. Each sub course's homepage had a detailed syllabus to provide students with information including learning objectives, contents, learning methodology, technical support, course materials, final exam (date, procedure and regulations), grading policy, office hours and communication with instructor.

There was no class meeting on campus. Same lessons and assignments were available (except final exam date) for students via an online courseware 24x7 during every semester. Students could take each lesson in three different learning methods at their own preferences. "E-text" word-by-word online lessons describe tasks, "watching video" online step by step demonstrations show tasks, and "hand-on practicing" step-by-step allows students to complete tasks. Each chapter had a comprehensive assignment for students to study and prepare for final exam. Students could view the correct assignment question answer after entering three wrong entries. Consequently, students could obtain a high assignment correction rate if they put in adequate studying time and effort.

Students took the same online final exam in an executing format that was scheduled from 8 a.m. to 4 p.m. Pacific Standard on the last Friday of the fifth week for each sub course. Exam parameters were 50 minutes, 1 attempt, 30 random sequenced questions, 30 attempts for each question and no makeup. Grading policy was at least 70 points for receiving one unit credit.

Students could take final exam at any remote location via their own computer facilities and Internet connection without supervision. To reduce misconducts, lessons and assignments were not available to students on the final exam date. Access to the courseware using the same student identification number via different computers at the same time was disabled. A study has revealed that there is no significant difference of average final exam score between a supervision and no supervision testing environments (Tsai; 2016).

STIMULATION STRATEGY IMPLEMENTATION

As suggested in the ARCS motivation model, an effective strategy ought to include tactics such as granting reward to persuade active participation, give learner control, and perceive present worth. In addition, two critical elements to increase passing rate and dropout rate are encouraging students to carefully studying lessons first, then correctly completing assignments on time. Accordingly, a stimulation strategy gives extra 20 points reward to students if they could achieve 90% correction rate for every assignment within five weeks of each sub course. This stimulation strategy might motivate students to improve their learning behavior and achievement for several reasons. First, students could view reward value as an incentive to study harder. Second, students had control to complete assignments for the reward. Third, students would assess reward as an attainable value and compliment to pass a sub course with 20 points less. Finally, students would be better prepared to pass their final exams.

Teacher-stimulated Approach

In the first semester, students in each sub course had five weeks to study lessons and drill assignments at their choices of learning method, time and place. There was no learning guidance from the instructor except syllabus and offering a reward motivation to students. Earning extra 20 points was an option for students if they can complete every assignment on or before the last Friday of fifth week of each sub course. Students could earn one unit credit if their sub course score (sum of final exam score and extra points) was 70 points or higher. The entire studying process solely depended on students to motivate, discipline, and commit to their

own education for achieving their own learning objectives. This was a teacher-stimulated online learning approach that offered a reward opportunity to students without any instructor's push as an implementation of autonomous motivation stated in the SDT.

Teacher-guided Approach

In the second semester, the syllabus of each sub course included two weekly lesson and assignment completion schedules defined by the instructor. The assignment correction rate (90% or higher) was 20% (20 points) of sub course grade. Students received a weekly announcement with an email that urged them to do their weekly lesson and assignment on Monday. Furthermore, instructor generated a correction rate report of assignment on every Thursday night. The report always showed that less than 25% of students would complete their assignment for every sub course. Based on the report, students without a 90% correction rate received a warning email that served as a reinforcement to complete assignment within the next three days. The second report generated on deadline (midnight of Sunday) that indicated 80% of students with 90% correction rate. Around 55% of students would put in their studying efforts during the last three days. This was a teacher-guided online learning approach that instructor employed rules and encouragements to push students completing their assignments for getting the reward. It was an implementation of controlled motivation stated in the SDT.

DATA ANALYSIS

The statistical analysis of collected data for these two stimulation implementation approaches reveals the degree of impacts on students' learning behavior (lesson completion rate and assignment correction rate), achievement (final exam score) and engagement (passing rate and dropout rate). It uses two tails hypothesis testing at 99% (2.58 Z value) and 95% (1.96 Z value) confidence levels for the analysis (Spurr & Bonini 1973). The independent variables are the reward stimulation approaches to detect changes in the three dependent variables including lesson completion rate, assignment correction rate, and final exam score. Last, a descriptive discussion addresses changes of learning engagement via passing rate and dropout rate.

Hypothesis 1: There is no statistical significant difference of student's online learning behavior measured by the average lesson completion rate between two approaches.

Table 1: Z-value of the Average Lesson Completion Rate between Two Approaches

Class Name	Teacher-stimulated			Teacher-pushed			Z-Value
	No. of Student	Average Completion Rate	Standard Deviation	No. of Student	Average Completion Rate	Standard Deviation	
MIS 1	420	89.37	28.99	390	89.33	28.78	-0.02
MIS 2	421	88.72	28.39	404	85.49	32.65	-1.51
MIS 3	394	89.46	20.76	362	88.22	30.49	-0.64

Outcomes: Accept the no difference hypothesis at both 99% and 95% confidence levels for every sub course as illustrated in Table 1.

Findings: The average lesson completion rates of every sub course are slightly higher under the teacher-stimulated approach. According to ARCS model, students will not put in extra efforts to complete lesson since their lesson assessment value is less than their time and efforts. The students' learning behavior measured by the average lesson completion rate stays the same

regardless the reward implementation approaches (either an autonomous motivation or a controlled motivation).

Hypothesis 2: There is no statistical significant difference of student's online learning behavior measured by average assignment correction rate between two approaches.

Outcomes: Reject the no difference hypothesis at both 99% and 95% confidence levels for every sub course as illustrated in Table 2.

Table 2: Z-value of the Average Assignment Correction Rate between Two Approaches

Class Name	Teacher-stimulated			Teacher-guided			Z-Value
	No. of Student	Average Correction Rate	Standard Deviation	No. of Student	Average Correction Rate	Standard Deviation	
MIS 1	420	73.06	36.83	390	83.88	30.05	4.59
MIS 2	421	39.72	41.07	404	78.89	31.96	15.32
MIS 3	394	40.78	41.36	362	76.31	34.68	12.83

Findings: It is interesting to note that average correction rates of every sub course are much higher under teacher-guided approach. Clearly, this is due to the assignment score is a part of the course grade and students either are willingly or forced to put in the extra efforts to correctly complete the assignment under teacher-guided approach. According to ARCS model, students will finish assignment since their assignment assessment value is worthwhile of their time and efforts. The students' learning behavior measured by the average assignment correction rate does change significantly under the teacher-guided approach (a controlled motivation).

Hypothesis 3: There is no statistical significant difference of the students' online learning outcome measured by the average final exam score between two approaches

Outcomes: Reject the no difference hypothesis at both 99% and 95% confidence levels for every sub course as illustrated in Table 3.

Table 3: Z-value of the Average Final Exam Score between Two Approaches

Class Name	Teacher-stimulated			Teacher-guided			Z-Value
	No. of Student	Average Score	Standard Deviation	No. of Student	Average Score	Standard Deviation	
MIS 1	420	77.66	16.24	390	80.23	7.86	2.90
MIS 2	421	62.76	23.84	404	67.29	22.83	2.79
MIS 3	394	69.60	20.06	362	73.96	18.82	3.08

Findings: Students in every MIS 123 sub course have achieved a higher average final exam score under teacher-guided approach. Obviously, these results closely related to its superior average assignment correction rate. Students have well prepared for the final exam by finishing the required assignment under teacher-guided approach. The students' learning achievement via average final exam score does show a significant improvement under teacher-guided approach (a controlled motivation).

Table 4 presents the statistical summary of the total number of enrollment, the total number of student taking the final, the total number of student passing the final, the final passing rate and

the drop rate for both approaches. The final passing rate is the total number of student receiving "credit" divided by the total number of student did take the final exam. The drop rate is the total number of student did not take the final exam divided by the total number of enrollment.

Clearly, there is a substantial higher final passing rate increased ranging from 24% to 10% among the three sub courses under teacher-guided approach comparing with teacher-stimulated approach. MIS 1 passing rate has a 10% increase from 78% to 89%. MIS 2 passing rate has a 22% increase from 54% to 76%. MIS 3 passing rate has a 20% increase from 63% to 83%. MIS 2 and 3 have generated 20% or higher increasing for the passing rate. These results indicate that students require more learning guidance for harder and useful subjects as MIS 2 and 3 under teacher-guided approach.

Table 4: Drop and Passing Rate of Two Approaches

	Student Enrollment	Student Took Final	Student Passing Final	Final Passing Rate	Drop Rate No Final
MIS 1. Operating Systems and Electronic Communication					
Teacher-stimulated	464	420	330	0.79	0.09
Teacher-guided	462	390	346	0.89	0.16
MIS 2. Spreadsheets					
Teacher-stimulated	503	421	229	0.54	0.16
Teacher-guided	495	404	309	0.76	0.18
MIS 3. Word Processing and Presentation Graphics					
Teacher-stimulated	488	394	250	0.63	0.19
Teacher-guided	491	362	299	0.83	0.26

However, the drop rate is higher under the teacher-guided approach. MIS 3 has the highest drop rate that 26%. In addition, the drop rate is higher toward the mid and end of the semester (MIS 2 and MIS 3). It is also interesting to note that the average drop rate of the three sub courses is around 20% that is corresponding to the overall 20% of students do not put in their time and effort to do the assignment for preparing their final exam. There are four factors related to this drop issue. First, students would drop if they could not meet the deadline of the weekly assignment requirements. Second, each MIS 123 sub course is a 1-unit independent "Credit" and "No Credit" course. Receiving a "No Credit" will not affect a student's grade point average (GPA). Third, a student will neglect the MIS 123 when there are more studying pressure from other courses between the 2nd five weeks of MIS 2 and the last five weeks of MIS 3. Last, a student will more likely to drop a sub course such as MIS 3 if it has two major subjects including Word and PowerPoint.

CONCLUSION

The students' online learning behavior measured by assignment correction rate, the achievement measured by the average final score, and final exam passing rate have sufficiently supported that teacher-guided approach (a controlled motivation) is a more effective and promising motivation approach comparing with teacher-stimulated approach (an autonomous motivation). These positive and fruitful results reveal a successful online learning approach required not only reward strategy for persuading students' learning engagement, but also an instructor's heavily involvements in the isolated, distance and virtual Internet learning environment as in the traditional face-to-face classroom. In general, the instructor's guidance,

encouragement, and motivation strategy do positively increase students' satisfaction and results a better online learning behavior and a higher achievement.

As online learning becomes an important part of higher education system in the current digital era, educators need to conduct further researches in order to refine the online learning experiences for students. It is a critical success factor for an instructor to design a sound stimulation strategy with proper implementation approach based on educational motivation theory under isolated online learning environment. Students can then perform well under the instructor's learning motivation, regulation and guidance. The future researches can extend to other areas. First, how to reduce the high student drop rate in the online learning. Second, how to virtually encourage and guide the student mastering and completing the course material when there is some studying pressure from other classes. Third, the most suitable course subject using the online teaching/learning. Last but not the least, the best student classification (freshman, sophomore, junior or senior) in the higher educational system to adopt the online learning.

Importance of Course Relevance to Enhance Learning in Business Statistics

Katherine Ashley
Montclair State University
Email: ashleyk@montclair.edu

Mark Berenson
Montclair State University
Email: berensonm@montclair.edu

ABSTRACT

Although the American Statistical Association's guidelines for instruction stress the importance of topic and application relevancy, the traditional business statistics course covers a broad spectrum of topics with applications across functional areas. This paper questions whether a discipline-specific focus would enhance learning by increasing the perceived relevance of course material.

KEYWORDS: Business Statistics, GAISE College Report, Learning

INTRODUCTION

Over the years, too many undergraduate students have found their core-required introductory business statistics class to be anxiety-producing, and this feeling detracts from proactive engagement and learning (Simmons, 2014). Therefore, if students can perceive the course to be more appealing, it will likely enhance motivation, proactive engagement, and opportunities for learning.

The recently updated Guidelines for Assessment and Instruction in Statistics Education (GAISE) College Report (Carver et al, 2016), sponsored by the American Statistical Association, once again stresses the pedagogical importance of topic and application relevancy. Not only must topics and applications be relevant, the student audience must perceive them as so. With respect to *how* to teach, the GAISE College Report's focus is on the use of real data with a context and purpose; this lends itself to classroom projects employing structured data sets that can be used to demonstrate the integration of topics covered throughout the course (Gould, 2010).

Current Practice

In schools of business, the content of the introductory statistics course is typically more general, covering topics and applications across all business disciplines. A literature review of available text titles reveals a near absence of discipline-specific offerings; the only undergraduate-level text that we find with a true single-discipline focus is one book in marketing (Mazzocchi, 2008). The question that needs to be addressed is whether the current, traditional delivery of the introductory course is best practice.

A Proposed Solution: Offering Dedicated Discipline-Specific Statistics Courses

Berenson et al. (2018) opine that offering discipline-specific introductory business statistics courses would increase motivation for learning because the course topics and applications would be in the area of career interest to that student audience. A course dedicated specifically to finance majors is thoroughly described, and the hypothesis is put forth that such students would have more motivation to study and come to class because they would feel the course is more important and more relevant to their future goals.

To test the hypothesis that dedicated course delivery will enhance learning in introductory business statistics, two studies were conducted simultaneously: one study assessed overall performance across chosen majors in finance and accounting-oriented sections of statistics, and one study evaluated overall performance across chosen majors in marketing-oriented sections. The remaining sections of this paper will describe the methodology used in the aforementioned studies, present preliminary findings, and outline the major analyses and their implications.

STUDY METHODOLOGY

One faculty member taught two sections of the introductory business statistics course with a focus on finance and accounting (F&A) topics and applications, while another faculty member did the same with a focus on marketing (MKT) topics and applications. The four sections, out of a total of 13 offered, were given in 75-minute sessions on Tuesdays and Thursdays.

All students were informed of the course foci in writing both prior to registration and during the first two weeks of the semester when students maintain the opportunity to enter or switch classes. It was strongly suggested that students with specific interest in the F&A and MKT disciplines enroll in one of the dedicated sections; however, it was made clear that if their schedules precluded such enrollment they could take any of the other nine sections that covered a broader set of applications across the business disciplines. Likewise, students who were undeclared or had specific interest in other disciplines were encouraged to enroll in a general section, but permitted to join one of the dedicated sections. In the four study sections combined, 31% of the students had discipline-specific course majors, 16% were undeclared, and 53% selected the section for their own convenience, having already chosen a major not aligned with their section's focus.

A waiver from the university Institutional Review Board was obtained for this joint study because there were no course interventions that would require subject consent. Historically, as long as overall course goals are met in core-required courses with multiple sections, instructors have liberty to design and conduct their specific courses as they deem pedagogically fit; moreover, it was made clear in advance to all students that the intent was to focus on discipline-specific topics and applications in the four study sections. Additionally, the key topic coverages of fundamental numeracy, descriptive statistical methods, inferential statistical methods, and an introduction to regression analysis that are common to all one-semester undergraduate business statistics courses were to be maintained in the discipline-specific sections.

As shown in the Appendix, the distinctions between the discipline-specific course sections and the more general course sections were primarily in the topics selected, the depth and breadth given to each, and the applications taught using methods best suited for those applications. The

MKT courses were concept- and definition-oriented with limited algebraic formulas and mathematical symbols. The F&A courses, taught at a higher expectation of numeracy, placed more emphasis on formulas and symbols. Both types of courses were heavily dependent on analysis and interpretation of results through computer printout, and both had projects requiring written and oral presentation.

Development

What are the factors that determine success in a statistics course? Johnson and Kuennen's (2006) research indicates that very basic mathematics skills are among the most important indicators of student success, even in a statistics course where many of the skills directly assessed (such as analyzing data with descriptive statistics, hypothesis testing, or linear regression) are not necessarily of a basic skills nature. On the other hand, they found that neither taking calculus nor the ACT Math score (measuring higher mathematics skills such as algebra, geometry, and trigonometry) had a significant effect on course performance. This was true across different teaching methodologies and course structures, regardless of the level of mathematics presented or the relative emphasis on computation versus interpretation. Their findings are consistent with Ben-Zvi and Garfield's (2004) research which revealed that difficulties with underlying math concepts interfered with a student's ability to grasp statistical concepts.

Given the importance of basic math skills in learning statistics, and the fact that these skills vary across students, a 25-question mathematics assessment quiz (MAQ) reviewing topics first learned in fourth through ninth grades was administered in the four class sections at the beginning of the semester to evaluate students' current understanding of prerequisite material for the courses. If appropriate, the plan was to use these scores as a covariate when assessing differences in student performance by selected major at the end of the semester. Students were unaware that the MAQ was going to be administered, precluding the possibility of any intentional refreshment of mathematical skills prior to the assessment.

The MAQ sheets were graded on a scale from 0 to 25 that corresponded to number of correct answers and then returned to the students with an aligned list of Khan Academy videos that would help them refresh on questions they missed.

The Data

The obtained dataset was based on information collected from 52 students enrolled in two finance and accounting-oriented course sections (28 in Section 02, 24 in Section 06) and 62 students enrolled in two marketing-oriented course sections (33 in Section 04 and 29 in Section 16).

Aside from collecting the MAQ results as well as information on what major the students had selected (i.e., course discipline-specific, other major, or undeclared), the only other data that were recorded for the purpose of this research were the midterm and final exam scores, which were given equal weight in the overall course average.

The Outcome Measure for the Study

Assessment of learning is based on course performance, and the outcome measure TAvg is selected as the most appropriate proxy for course grade. TAvg is the standardized average of

two equally weighted course assessments, a midterm and final exam, given in each section of the two study groups – the finance and accounting-oriented courses and the marketing-oriented courses. Since the two types of courses had very different topic emphasis there was no reason to directly compare overall course performance between the two study groups and the use of the overall standardized (*Z*) scores over the combined sections within each study group provides a monotonic transformation, preserving the rank ordering of students' performance.

The Intended Analyses

Aside from an analysis of covariance (ANCOVA), a set of orthogonal contrasts was initially planned so that the primary overall comparison could be made between the performances of those students who had selected the major corresponding to the course orientation versus the other majors combined. The secondary comparison would be between the performance of students majoring in the "opposite" course orientation against those who have chosen other majors along with students who were undeclared. The final, but nevertheless important comparison in this orthogonal set, would be to assess whether there were significant differences in student performance between those who had declared "other" majors versus those who were undeclared. This latter comparison was of particular importance to the university administration who have opined that students who are able to select a major demonstrate more incentive toward their studies and outperform their peers who remain undeclared.

If the research hypothesis holds, the respective end-of-semester ANCOVA along with the aforementioned set of planned orthogonal contrasts and some additional non-orthogonal comparisons (Dunnett, 1955) should indicate that those students with selected majors aligned to the course orientation will outperform those who are undeclared or those who have selected other disciplines as their major. Such separate findings could then be synthesized and strengthened through a meta-analysis (e.g., Stoufer et al., 1949; Rosenthal, 1991; Shadish & Haddock, 2009).

In addition to this, one of the planned orthogonal contrasts should also be able to confirm or refute the administration's claim that undeclared students are significantly weakest with respect to overall course performance.

EXPLORATION AND DISCOVERY: PRELIMINARY RESULTS

Descriptive Summary Statistics for Outcome Variable TAvg

Table 1 displays key summary statistics for the outcome variable TAvg for each chosen major category based on course orientation.

Table 1: Summary of TAvg Descriptive Statistics by Chosen Major and Course Orientation

Marketing-Oriented Courses:

Major	*n*	Mean	StDev	Minimum	Q1	Median	Q3	Maximum	Skewness
F&A	12	0.173	1.117	-2.043	-0.520	0.424	0.904	1.657	-0.73
MKT	13	0.530	0.696	-0.701	-0.102	0.532	1.095	1.585	-0.06
OTH	29	-0.057	0.931	-2.152	-0.755	-0.048	0.750	1.548	-0.28
UND	8	-0.914	0.959	-2.551	-1.771	-0.755	-0.075	0.170	-0.72

Finance and Accounting-Oriented Courses:

Major	*n*	Mean	StDev	Minimum	Q1	Median	Q3	Maximum	Skewness
F&A	22	0.473	0.852	-1.905	-0.135	0.683	0.984	1.810	-1.11
MKT	7	0.349	0.993	-0.667	-0.540	0.000	1.143	1.842	0.47
OTH	13	-0.357	0.962	-2.032	-0.826	-0.286	0.460	1.207	-0.39
UND	10	-0.822	0.710	-1.746	-1.326	-0.984	-0.365	0.635	0.77

Student Persistence

Student persistence is defined as the percentage of enrollees who complete the midterm and final exam. The two marketing-oriented course sections respectively began and ended with 33 and 29 students, a 100% persistence rate. On the other hand, the two finance and accounting-oriented course sections began with 34 and 31 students, respectively, and ended with 28 and 24 students, a persistence rate of 80%.

The observed significant difference in the persistence rates may be attributable to a number of factors. With respect to the finance and accounting-oriented sections, one student could not complete the course because of a family emergency. Among the remaining 12 students who did not finish the course, four (33.3%) withdrew in the first four weeks and eight (66.7%) did so immediately after learning their midterm test results. Possible reasons for these withdrawals include a realization of limited mathematical preparation for a more rigorously-conducted course, a realization that finance or accounting was not going to be a career objective, or a desire to change into a more generally-oriented course section.

Table 2 provides key MAQ summary statistics for this group and it should be noted that the mean MAQ score of 11.77 is only 73 percent as high as the MAQ score of 16.12 obtained by the 52 F&A students who completed the courses.

Table 2: Key MAQ Descriptive Statistics for Students Not Finishing the F&A Courses

n	Mean	StDev	Minimum	Q1	Median	Q3	Maximum	Skewness
13	11.77	4.83	4.00	7.00	13.00	14.00	20.00	0.03

Other factors that may have affected the persistence rates could be teacher likeability and course interest. Perception is key here. If a student feels more comfortable relating to a particular instructor there should be less likelihood for course withdrawal. Additionally, if a student feels a particular course format is more interesting and relevant there should be less likelihood for course withdrawal. With respect to the latter, students taking a marketing-oriented business statistics course may more readily relate to topics pertaining to advertising, retailing, and consumer behavior, regardless of whether they have chosen marketing as their major. On the other hand, non-major students taking a finance and accounting-oriented course may not feel the same kind of connection with the course. Even those who have declared finance or accounting as their chosen major usually have limited-to-no background in these business disciplines when they enroll in the statistics course, typically in their freshman or lower sophomore semesters.

The Class Section Breakdowns

The four classifications of major used here are F&A (finance and accounting), MKT (marketing), OTH ("other" major), and UND (undeclared). Using the chi-square test for independence, there was no indication of a significant enrollment pattern by chosen major across the four class sections ($\chi^2 = 12.890;$ *p*-value = 0.168.). Moreover, within each course orientation there was no evidence of a difference in student major based on the section they enrolled in (for F&A: $\chi^2 = 2.083;$ *p*-value = 0.555; for MKT: $\chi^2 = 0.632;$ *p*-value = 0.889.). However, when collapsing class sections based on course orientation, there is evidence of a significant difference in student major by course orientation and this is what was intended and expected ($\chi^2 = 10.260;$ *p*-value = 0.016).

Justification for Combining the Sections

The following summaries in Table 3 provide justification for combining the two marketing-oriented sections and the two finance and accounting-oriented sections.

Table 3: Summary of Key Descriptive and Inferential Comparisons Between Class Sections

Marketing-Oriented Sections:

Variable	Section	*n*	Mean	StDev	Minimum	Q1	Median	Q3	Maximum	Skewness
MAQ	S04	33	16.545	4.273	9.000	12.500	17.000	20.000	24.000	-0.15
	S16	29	15.340	5.540	6.000	10.000	16.000	20.000	24.000	0.09
TAvg	S04	33	-0.206	1.045	-2.551	-0.683	-0.048	0.514	1.585	-0.49
	S16	29	0.235	0.907	-1.463	-0.356	0.351	0.913	1.657	-0.31

Comparisons in MKT Sections	**Separate-Variance *t* Test**	***p*-Value**
MAQ Means in S04 vs S16	*t* = 0.95	0.349
TAvg Means in S04 vs S16	*t* = -1.78	0.080

Finance and Accounting-Oriented Sections:

Variable	Section	*n*	Mean	StDev	Minimum	Q1	Median	Q3	Maximum	Skewness
MAQ	S02	28	16.214	3.823	8.000	14.250	17.000	19.000	25.000	-0.31
	S06	24	16.000	3.683	7.000	14.250	16.000	18.000	22.000	-0.61
TAvg	S02	28	-0.218	1.062	-2.032	-0.905	-0.222	0.841	1.842	0.01
	S06	24	0.254	0.877	-1.746	-0.405	0.540	0.889	1.810	-0.38

Comparisons in F&A Sections	**Separate-*Variance* *t* Test**	***p*-Value**
MAQ Means in S02 vs S06	*t* = 0.21	0.838
TAvg Means in S02 vs S06	*t* = -1.75	0.088

With respect to both the marketing-oriented courses and the finance and accounting-oriented courses, there is no evidence of a difference in mean MAQ performance in between sections with the same focus. Although there is some tendency toward better TAvg performance in the sections meeting later in the day (S06 and S16) compared to those meeting earlier in the day (S02 and S04), the difference in results is not significant and there is no reason to expect a

systematic difference since both sections within each discipline-focus were taught the same way. Therefore, it is reasonable to combine the two MKT sections together and the two F&A sections together for the main analysis.

Evaluating the Mathematics Assessment Quiz (MAQ) Score as a Potential Covariate

The MAQ, given in each class section by surprise early in the semester, provided a baseline measurement of student fundamental mathematical ability and was deemed a possible covariate. Table 4 summarizes the evaluation of the MAQ scores as a potential covariate. In the marketing-oriented course sections the MAQ scores were clearly significantly correlated with TAvg, the performance measure used in all analyses, while in the finance and accounting-oriented course sections a weaker positive association was indicated. Not shown here, both stem-and-leaf displays indicated a central clustering of MAQ scores with little-to-no skewness and the respective study groups (i.e., 52 and 62 students) are of sufficient size to discount the importance of the normality assumption in statistical inference. Moreover, when comparing the MAQ scores across the four chosen majors in each of the two study groups (i.e., F&A and MKT), there was no indication of a significant lack of homogeneity of variance and a one-way ANOVA *F* test showed no evidence of a significant difference in MAQ scores. Therefore, we concluded that the MAQ was a good covariate so that ANCOVA was the appropriate tool for ascertaining whether differences in overall performance across the chosen majors could be uncovered in each study group.

Table 4: Evaluation of MAQ as a Potential Covariate

	Finance & Accounting Sections	Marketing Sections
Assessing Correlation with TAvg		
Pearson	r = +0.228; p-value = 0.104	r = +0.387; p-value = 0.002
Spearman	ρ = +0.256; p-value = 0.067	ρ = +0.426; p-value = 0.001
Assessing Normality		
Anderson-Darling Test	AD = 0.978; p-value = 0.013	AD = 0.700; p-value = 0.064
Assessing Homoscedasticity		
Bartlett's Test	B = 5.66; p-value = 0.130	B = 4.52; p-value = 0.211
Levene's Test	L = 1.34; p-value = 0.272	L = 2.63; p-value = 0.058
Assessing Differences in Means		
ANOVA *F* Test	F = 0.10; p-value = 0.959	F = 0.34; p-value = 0.793

Since there was no evidence of a difference in entering student mathematical ability across the four categories of chosen major in these study groups, we may surmise that any difference in mean TAvg course performance among the four major categories using one-way ANCOVA in the separate group studies would likely be due to the influence of interest in the selected course orientation as a driver of increased motivation to succeed.

THE MAJOR ANALYSES AND IMPLICATIONS

The research hypothesis of interest is that there should be more learning by students who enter a class with specific subject interest because the course should be of more relevance and importance to them.

To test this hypothesis, two ANCOVA models will be developed along with their respective sets of adjusted means. Next, a description of the developed set of orthogonal contrasts, key to the analysis of the research hypothesis, will be provided along with a description of the developed

set of non-orthogonal *a priori* pairwise comparisons. Lastly, a description of the meta-analysis methods used for combining the results of the two separate studies will be presented.
If the findings from the two correlational studies support the hypothesis that introductory business statistics taught with a conceptualized and discipline-specific approach demonstrates more learning when compared to the more traditional, generalized approach, then the results would have several implications for improving business statistics instruction. First, discipline-specific course offerings would need to be developed to replace the current, more general course offerings. Second, textbook authors would need to develop shorter, discipline-specific texts that focus on the relevant topics, applications, and problems for each functional area of business.

Moreover, if the research hypothesis holds and teaching within specific course disciplines is good for teaching introductory business statistics, it would seem to follow that it will also be the appropriate way to teach introductory business analytics. Students should find it more relevant and interesting to explore, search, drill down, and use interactive databases when the subject matter is in their field of selected interest. Fortunately, the recent AACSB Standard 9 mandate (2017) to integrate analytics in the undergraduate curriculum provides much flexibility, enabling accredited business school programs to design courses and make curriculum changes while maintaining their particular education missions.

Scope and Limitations

As in much educational and social science research, randomized experiments for undertakings such as the one described here for F&A and MKT major groups cannot be developed because students self-select their majors and there is no randomizing process for the researcher to control. Therefore, correlational studies must be employed (Sheskin, 2011). In lieu of an experimental treatment variable, the chosen major is a classification variable (Keppel, 1982) and it is possible that the students within specific majors may differ systematically with respect to characteristics other than the classification variable major. Such potential confounding precludes cause-and-effect inferences permitted in true experimental studies. Nevertheless, and although the results of such correlational studies pertain specifically to the groups involved, the implications of the findings can be strongly suggested for similar educational contexts.

APPENDIX: TOPIC OUTLINES FOR DEDICATED COURSES FOR FINANCE & ACCOUNTING MAJORS AND FOR MARKETING MAJORS

Introductory Statistics for Finance & Accounting Majors

Topics

- Review of fundamental mathematics for finance and accounting majors.
- Data visualization through tables and charts with finance applications.
- Numerical descriptive measures in finance (including Sharpe and Treynor ratios).
- Introduction to index numbers with emphasis on the CPI-U and S&P500 Index.
- Probability and mathematical expectation with finance applications.
- Introduction to decision-making with applications in investing.
- Introduction to confidence interval estimation and hypothesis testing with finance applications.
- Simple linear regression (including CAPM with beta and alpha coefficients).
- Time series decomposition and forecasting.

Introductory Statistics for Marketing Majors

Topics

- Review of fundamental mathematics for marketing majors.
- Questionnaire design and sampling techniques.
- Data visualization through tables and charts with marketing applications in Pivot Table drilldowns.
- Introduction to probability with marketing applications in cross-classification tables.
- Numerical descriptive measures in marketing.
- Normal distribution and sampling distributions of $\bar{X}$ and P.
- Confidence interval estimation with marketing applications.
- Hypothesis testing (one-sample, two-samples, and multiple-samples) with marketing applications.
- Simple linear regression (descriptive and inferential) with marketing applications.

DECISION SCIENCES INSTITUTE

A taxonomy of digitalization: an in depth understanding of the phenomenon

ABSTRACT

Digitalization is gaining importance in the business world yet the literature on digitalization lacks two major aspects. First, in providing a comprehensive vision on digital transformation of firms and second, in having empirical studies which could aid the advancement of the field. This study attempts to create a taxonomy of digitalization as an operations strategy based on three classification variables i.e. drivers, providers and capabilities of digitalization. The classification variables are populated through literature review and cluster analysis will be conducted to form strategic clusters of firms based on which set of drivers, providers and capabilities form a digital strategy.

Keywords: Digitalization, Taxonomy, Digital Transformation

INTRODUCTION

Configuration studies are an important tool for understanding the different phenomenon of management. These taxonomies are especially useful for exploration purposes where the aim is to gather a holistic understanding of the phenomenon. The purpose of this paper is to come up with a taxonomy of digitalization which is an emerging phenomenon and requires considerable attention in terms of research. For the purpose of theory development in this area it is necessary to have an in depth understanding of the different factors at play which are effecting the firms performance. Taxonomies serve as an appropriate mechanism which aid in exploration of the phenomenon, theory building and in identifying the different dimensions and their constituent factors which explain digitalization.

We treat digitalization as an operations strategy where firms make efforts to shift their operations to a digital state. Operations strategy is defined as “the building or positioning of resources in a way which enhance the competitiveness of a firm in the marketplace”(Southard and Swenseth, 2003). Digitalization as an operations strategy will guide firms as to what set of environmental drivers and practices will lead to certain capabilities of digitalization. The operations strategy has two important components namely “content” and “process”. Most of the manufacturing strategy studies focus on the content part which constitutes the choices and actions a company takes to achieve its goals. The literature on digitalization has not paid much attention to the topic of its realization in firms and neither has identified the different tasks which enable digitalization.

Digitalization itself is not a new phenomenon and the word “digitalization” has been extensively used in previous studies. However, the emergence of the fourth industrial revolution also called industry 4.0 has given it a new connotation yet the extant literature is not clear with respect to the definitions of these terms. This study creates a taxonomy for digitalization which is the broader phenomenon and is defined as “the integration of digital technologies to transform activities, processes, actors, and goods from analogue to digital to facilitate new forms of value creation” (Hagberg et al., 2016).

Classification Variables

The literature on digitalization is widespread and has been used in various ways. This study makes use of digitalization as an operations strategy and aims to identify the set of practices which enable the implantation of digitalization in firms and also what are the value additions due to this digitalization. We choose three classification variables based on previous studies which were populated with different constituent factors through a literature review of the relevant domain. These classification variables are the drivers, providers and capabilities of digitalization (Ketchen Jr and Shook, 1996). Drivers are the set of external and internal factors which force a firm to transit from their current traditional state to a digitalized one. These drivers include the volatility of demand, the uncertainty of the market place, the intensity of competition in the industry, technological dynamism, intense rivalry and many more (Gunasekaran et al., 2018, Buer et al., 2018, Ooi et al., 2018). The providers are the internal practices and resources which need to be developed and modified so as to support the goal of digitalization. These include organization factors, individual factors, technological factors, knowledge related factors, integration, collaboration, supply chain dynamics, data analytics and IT proficiency (Bokrantz et al., 2017, Battaïa et al., 2018). The capabilities are the outcomes of digitalization which enable the firm to sustain a competitive advantage such as mass customization, responsiveness, intelligent decision making, agility, flexibility, efficiency and servitization (Cenamor et al., 2017, Hermann et al., 2016, Arnold et al., 2016, Rüßmann et al., 2015).

Methodology

Digitalization is a new phenomenon and hence as a first step a literature review was conducted to explore the factors which would fall under the drivers, providers and capabilities. The classification variables were populated using inductive approach due to the exploratory nature of the study. A total of 33 journals with 4*, 4 and 3 ratings in the ABS list 2015 were selected for literature review. These journals belonged to the two categories of Operations & Technology Management and Information Management. Scholarly Peer reviewed articles published in the time frame 2010 – 2018 in English language were selected as a first steps. Articles were searched with the keywords Digitalization, industry 4.0, cyber physical systems and Industrial Internet. The selection of these keywords was based on their frequent usage in articles published in the nascent domain of digitalization. A total of 2409 articles appeared in these searches from which only those were selected which talked about digitalization in the connotation of the fourth industrial revolution. Articles which appeared due to the mere existence of the words “digital” and “digitalization” but not relevant to the specific domain and those which were duplicates were excluded in the first iteration. This resulted in remaining 121 articles which were skimmed for the identification of drivers, providers and capabilities. After the third iteration of a total of 32 usable articles were skimmed to extract content for the classification variables. The content was then clubbed into dimension based on their similarity. The content of the clusters will be operationalized using exiting literature.

Data will be collected from manufacturing and non-manufacturing firms, telecom, software houses and service sector. Cluster analysis will be conducted and strategic clusters of the firms will be made.

Innovate or merge?
The role of corporate social responsibility in the relationship between R&D and mergers and acquisitions

ABSTRACT

In this research, we study how recent developments in corporate social responsibility (CSR) impacts the relationship between R&D investment and mergers and acquisitions (M&A). We find that CSR scores positively moderate the relationship. For firms with high CSR scores, higher R&D investment intensity is associated with a higher likelihood of M&A, but for firms with sufficiently low CSR scores, higher R&D intensity is associated with a lower likelihood of M&A. This finding suggests that CSR may create an insurance-like buffer that mitigates risks, and may improve knowledge sharing and absorption capabilities that ease the integration process during M&A.

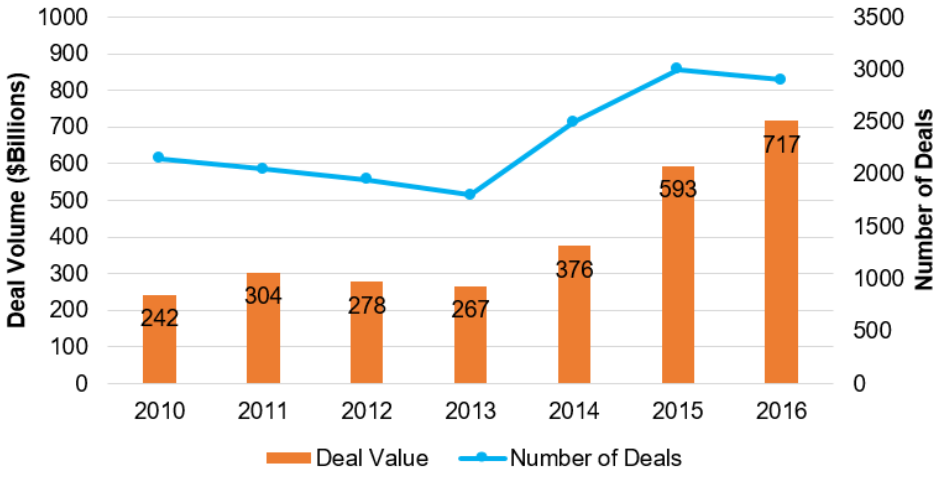
KEYWORDS: innovation, R&D investment, merger and acquisition, corporate social responsibility, emerging markets

1. INTRODUCTION

Innovation is critical to the firms' survival and long-term success in the markets. The mantra, "Innovate or Die", has been echoed across industries from traditional consumer packaged goods (CPG) to high-tech products (Caldbeck, 2016). Innovation can be obtained internally by investing in research and development (R&D), externally by merger and acquisition (M&A), or both. The past years have seen a significant increase in M&As driven by technological innovations (See Figure 1), and about 20% of M&A deals from 2015 to 2016 involved high-tech targets, whereas, in 2012, it was 14% (BCG M&A Report, 2017). A firm can replace its R&D investment by acquiring an innovative firm, or alternatively, leverage its R&D to enhance its market position by acquiring a firm for market access. A fundamental question, however, is whether M&A can be employed as a substitute to replace R&D or used as a complement to enhance its market access (Cassiman & Veugelers, 2006). The answer hinges on firms'

capabilities to manage risks in post M&A knowledge sharing and integration. Recent developments in corporate social responsibility (CSR) have shown CSR provides an insurance-like mechanism for firms to mitigate internal and external risks (Godfrey et al., 2009; Jacobs et al., 2016), and therefore may have significant implications to the relationship between R&D investment and M&A. This research contributes to the literature by focusing on the role of CSR in the relationship between R&D investment and M&A.

Figure 1. Tech M&A Value and Volume



The literature and evidence of “innovate or merge” is mixed. Some argue for a substitutable effect, where firms that underinvest in R&D are more likely to choose to “replace” internal R&D with M&A, indicating a negative relationship between R&D investment and M&A (Phillips & Zhdanov, 2012; Seru, 2014). For example, General Motors (GM) acquired Cruise Automation, a developer of autonomous vehicle technology, in 2016, which allowed GM to quickly access self-driving technology without its own R&D investment. Others, however, argue for a complementary effect, where R&D-intensive firms are more likely to engage in M&A because they can leverage their strong knowledge base to expand to new markets post M&A, indicating a positive relationship between R&D investment and M&A (Bena & Li, 2014; Entezarkheir & Moshiri, 2017, Cassiman & Veugelers, 2006). Tesla acquired SolarCity, a solar energy and panel provider, to leverage Tesla’s technology assets and create a vertically integrated energy company. Regardless of the types, innovation-driven M&As are risky. Fail to manage the risks associated with lack of integration of knowledge and capabilities, loss of autonomy, incompatibility of brand images, or cultural clash between the acquirer and the target company, may cause disruptions on existing organizational routines and structures after M&A (Ahuja & Katila, 2001; Puranam & Srikanth, 2007). “Nortel went on frequent buying sprees, often using its own stock to take over tiny companies with promising technologies. In 2000 alone, it bought 11 companies for a total of $19.7 billion” (CBC News, September 16, 2009). These aggressive innovation-driven M&A activities eventually wiped out shareholders’ wealth and led to the downfall of Nortel (FinancialPost 2014). Moreover, the risk exposure during M&A for firms with extensive investment in R&D may be higher than the risks for those that underinvest in R&D. This is because the potential negative impact of failures of M&A is likely higher for firms with established technological assets and reputation (Cassiman & Veugelers, 2006). Leveraging such high value assets and technical knowhow is challenging, and potential damages to reputation in the case of failure can be substantial and long lasting. While this

seems to suggest that the replacement effect of M&As applies to firms of low R&D intensity, it has been argued that high R&D intensity firms may also leverage better-developed technological infrastructure to ease risks involved in integrating new technologies and new organizations under M&A (Bauer & Matzler, 2014). Therefore, the literature is not settled with whether M&A is a replacement of R&D, and the answer seems to hinge largely on the firm's risk exposure and impact, and the absorptive capabilities to manage and mitigate the risks, in M&A integration (MacCormack & Mishra, 2015; Cohen & Levinthal, 1990; Hitt et al., 2009).

Effectively managing risks depends on a firm's ability to absorb internal and external knowledge, to promote learning, and to facilitate integration during the process (Hitt et al., 2009), which is what CSR programs are set out to accomplish. CSR programs are designed to achieve sustainable growth and value creation for both their stakeholders and society (Sodhi, 2015), by enhancing corporate governance that facilitates sharing of information and knowledge, and integration of organizations, and by mitigating internal and external risks. This design purpose positions CSR perfectly as a potential facilitator for M&A integration and a buffer for its risk exposures. The extant literature has focused on the role of firms' investments in R&D in their M&A decisions, but mostly overlooked the potential effect of CSR, which is the focus of this research.

The connection between CSR, R&D, and M&A can often be observed in real business cases. In 2012, Microsoft acquired Yammer, StorSimple, and MarketingPilot, to advance its market position in social networks and cloud-based storage and marketing (Price 2012). More recently, Qualcomm acquired NXP Semiconductors in a record $47 billion deal. The objective is to quickly develop and improve chips and sensors for drones, self-driving cars, mobile payment and other devices. Interestingly, both Microsoft and Qualcomm have been active leaders in CSR. Qualcomm's ten-year-old program Qualcomm Wireless Reach "brings advanced wireless technologies to underserved communities globally, improving lives with programs that strengthen economic and social development" (www.qualcomm.com/company/wireless-reach). In fact, many firms with high investments in R&D have embraced CSR at an early stage, and they are often involved in M&A rumors and deals (Hopkins, 2009).

Evidence and literature both indicate that these two roles of CSR as a facilitator and a buffer have their roots in various aspects of CSR programs. First, firms with effective CSR programs tend to be better at sharing and absorbing information and knowledge with stakeholders, which helps develop strong and long-term relationships with stakeholders (Luo & Du, 2012). The improved relationships with stakeholders promote mutual trust and lend an insurance-like benefit to firms under high uncertainty. In recent surveys conducted by PwC, for example, CEOs indicate their plans to increase their firms' engagement in CSR activities to restore stakeholder trust during a crisis (PwC 2013; 2014). Furthermore, by better aligning corporate governance and promoting social value and diversity, CSR fosters creativity, broadens absorptive capacity, and facilitates knowledge spillover across organizations, which can help R&D intensive firms hedge high risks in M&A (Hoisl, Gruber and Conti 2017; Porter & Kramer, 2006). CSR also creates goodwill among stakeholders, partners, and customers, which may reduce external risks in case of failure (Deng et al., 2013). Second, CSR can enhance internal adaptability and social inclusiveness, which facilitates the integration process post M&A. For instance, CSR contributes to "improved risk management, reputation, employee engagement or customer loyalty", as a part of a firm's M&A due diligence process (p.7, PwC Principle for Responsible Investment Report, 2012). In the M&A case of Tech Data Corp and Avnet, Tech Data set up internal improvement and communication tools for employee knowledge sharing with Avnet, which eased the integration process. This case was made possible by the firms' "common cultures, shared values, and commitment", which are core components of CSR (Thomson Reuters Corporate Responsibility Ratings). Hence, by promoting

social value and strengthening stakeholder relationships, easing the integration process and reducing barriers between organizations, CSR programs create much-needed support to mitigate the risks during and post M&A (Kramer, 2011; Porter & Kramer, 2006; Lins et al., 2017).

The existing literature on R&D and M&A offers mixed views on the relationship between R&D investment and M&A, without involving the important role of CSR. To further examine this complex relationship and the much-overlooked effect of CSR, this research addresses the following research questions: *Is M&A a substitute for a firm's internal R&D or is it a complement? And more importantly, how does CSR moderate the relationship between R&D investment and M&A?*

To answer these questions, we collect firm-level data from multiple data sources and construct econometric models to connect a firm's R&D intensity to its acquisition decision. To examine the role of CSR, we include CSR scores of acquiring firms and focus on CSR's moderating role in the relationship between R&D and M&A. We apply conditional logit models to analyze firms' R&D investment intensity, CSR scores, and M&A likelihood. Our main results show that R&D intensity can be positively or negatively associated with M&A, suggesting that M&A can be both complementary and substitutable to R&D investment. One key factor in separating the two effects is CSR. We find that CSR scores positively moderate the relationship between R&D and M&A. This is because CSR creates an insurance-like buffer that mitigates risks by improving knowledge sharing and absorbing capabilities that ease the integration process during M&A. For firms with low CSR scores, less R&D intensive firms employ M&A to "replace", or to substitute, R&D. For firms with sufficiently high CSR scores, R&D intensity is positively associated with M&A, which implies a complementary relationship between R&D and M&A. We further extend our research to M&A cases involving target firms in emerging markets, which are challenging for U.S. firms because of the economic, technological and social gaps between the two markets. While CSR programs encourage open communications and embrace different corporate structures and cultures, the lack of regulations and laws for intellectual property protection in emerging markets hinders the possibilities of leveraging innovative capabilities by U.S. firms. Our results support this argument and suggest that the moderating role of CSR is still positive but is weaker when target firms are in emerging markets. In addition to studying R&D intensity as a R&D input, we also examine a R&D output and the corresponding effect of CSR. We find that regardless of CSR, a more efficient firm in R&D is more likely to engage in M&A. This finding is different from our main results based on R&D intensity, an input for R&D, where M&A can be a "replacement" for R&D for low CSR firms but is consistent with our results for sufficiently high CSR.

We contribute to the emerging stream of research in the operations management literature that studies the effect of CSR on firm strategy. Previous research has focused on the impact of CSR on organizational risk (Servaes & Tamayo, 2013; Jacobs et al., 2016), supply chain risk (Jira & Toffel, 2013; Porteous et al., 2015; Giannakis & Papadopoulos, 2016; Jacobs & Subramanian, 2011; Letizia & Hendrikse, 2016), and operational and cost efficiency (Gui et al., 2015; Alev et al., 2015; Alev et al., 2016; Jacobs et al., 2016). Our contributions extend the existing literature by investigating the role of CSR in the relationship between R&D and M&A, and by focusing on CSR's facilitating effect of knowledge sharing and its mitigating effect of risks in M&A decisions. Lee & Tang (2017) call for research on socially responsible value chain innovations. As R&D investments facilitate value chain innovations and M&As create value chain wide changes, this research, with a focus on CSR, answers the call at a strategic level of firm decisions.

The rest of paper is organized as follows. We first review the literature drawn from operations management, finance, and strategic management that is related to M&A, innovation,

and CSR. We then discuss our data and variables. In the subsequent section, we present our main econometric models, followed by discussions of the main results. We also discuss some robustness tests and extensions, and we conclude with managerial implications and final remarks.

2. LITERATURE REVIEW

Existing literature on M&A has mostly focused on operating synergies and performance implications in post M&A, particularly the mechanisms through which firms can succeed in post-integration period, and its impact on pricing, inventory pooling, and cost efficiency (Ahuja & Katila, 2001; Cho & Wang, 2016; Hitt et al., 1991; King et al., 2008; Zhao, 2009). Less understood are the complex factors driving a firm's adoption of M&A. Among the typical drivers of M&A, such as increasing market share, diversifying businesses, and acquiring complementary resources, capability, and knowledge, innovation is one that is critical to a firm's long-term success. Previous studies have examined the association between a firm's innovation and M&A, with mixed findings as either replacement (Zhao, 2009; Phillips & Zhdanov, 2012) or complementarity (Bena & Li, 2014; Entezarkheir & Moshiri, 2017). It is hence unclear whether a firm's innovation will encourage or discourage a firm's decision-making with regard to M&A. The highly-limited M&A research in the operations literature has focused on the impacts on inventory pooling as a result from economies of scale, and subsequent cost savings and pricing effects (Cho & Wang, 2016; Cho, 2014), without involving innovation in M&A decisions.

Corporate social responsibility can play an important role in M&A, but a firm may have mixed feelings towards it. CSR reflects the extent to which a firm actively engages in environmental, social, and economic initiatives in response to a diverse set of stakeholder interests (McWilliams & Siegel, 2001). Many firms engage in CSR activities in the hope to build a reservoir of goodwill to attenuate negative reactions from stakeholders in different situations, one of which is M&A (Deng et al., 2013). However, firms that focus on CSR also try to attend to all stakeholders in strategic decisions and thus may be unwilling to merge or acquire other firms. This is because mergers and acquisitions are likely to unsettle key stakeholders in a firm, damaging a firm's CSR commitment and thus stakeholder support (Morgan, 2009). In spite of the growing importance of CSR, the question that how a firm's CSR performance influences its R&D and M&A strategies is still subject to debate.

In this study, we focus our attention on a firm's innovation and CSR as two important factors in the firm's M&A decision. Specifically, we examine how a firm's investment and efficiency in R&D, and the firm's CSR score, will impact the firm's adoption of M&A as a strategic option. We review the related literature in the following on M&A, R&D, and CSR.

2.1. The Role of R&D in M&A

Extensive research has been conducted to study the relationship between R&D investment, often used as a measure for innovation, and M&A decisions, with mixed findings.

First, research in finance and management literature shows that a firm's R&D investment is often negatively related to the firm's involvement in M&A. Firms consider M&A for several reasons: efficiency related gains, market power, disciplining, agency costs, and diversification (Zhao, 2009), among which "buying innovation" is an important one (Higgins & Rodriguez, 2006). With limited resources and tight financial budgets, M&A can be an efficient way of increasing innovation when firms lag behind in their internal R&D investment. This may happen either because of risks during the internal innovation process, a lack of resources and expertise, or a focus on core competence that does not include innovation (Phillips & Zhdanov, 2012).

Hence, less R&D intensive firms may find it optimal to acquire innovative firms, avoiding the risky and time-consuming process of internal innovation (Puranam & Srikanth, 2007). R&D-intensive firms, on the contrary, less likely depend on M&A to source innovation for two reasons. On one hand, the larger R&D investment creates the greater resource and capability, particularly related to innovation. Hence, M&A becomes less attractive to R&D intensive firms as the likelihood of resource redundancy will increase and the target firm's resource is less beneficial and potentially counterproductive when acquired. On the other hand, for a R&D intensive firm, M&A often involves high-valued, intangible assets and critical human capital, which may be more challenging to integrate after M&A. Risks of integration failure in M&A are high because of inherent complexity and uncertainty during M&A. Difficulties in the integration of knowledge and capabilities, loss of autonomy, incompatibility of brand images, or cultural clashes between the acquirer and the target company all contribute to the high risks (Ahuja & Katila, 2001; Puranam & Srikanth, 2007). In addition, the potential failure of integration may disrupt the acquiring firm's established R&D process by affecting its culture for innovation (Burgelman et al., 1996), lowering the acquiring firm's incentives for developing new products and process ideas (Ornaghi, 2009). Furthermore, the integration tasks in a merger, especially a mega merger, distract management from long term planning and execution of R&D, as their attention and efforts are redirected to more immediate challenges such as aligning people, systems, and cultures (Bansal & Mark, 2015). Thus, acquisitions may reduce the acquiring firm's commitment to internal innovation, which is key to such firm's continued success (Hitt et al., 1991).

The literature also shows the possibility that a firm's R&D intensity is positive related to the M&A choice. First, firms that focus on internal innovation tend to be more risk-taking, as their past successes may increase their tolerance of risks of failure (Miller & Friesen, 1982). They may constantly seek to acquire niche resources, technical capacity, and new market access, which also lead to a high likelihood of M&A activities (King et al., 2008). Through M&A, firms that focus on internal innovation can better leverage their R&D resources, learn from others, and dampen market competition (Entezarkheir & Moshiri, 2017). For instance, the development of a new drug in the pharmaceutical industry may take several years and large investments. The requirement for large investments may lead to mergers between large companies in this industry, such as GlaxoWellcome and SmithKlinee Beecham in 2001 and Hoechsr and Rhone Poulenc in 1998 among many others (Jost & van der Velden, 2008). Second, R&D intensive firms may be better equipped and more efficient in recognizing, exploiting, and adapting external innovation developed in other firms, making it easier to effectively integrate with the targets (Cohen & Levinthal, 1990). Thirdly, R&D-intensive firms may also accumulate assets and capabilities through extensive innovation activities, allowing them to more easily create synergies with other firms during M&A (Bena & Li, 2014).

2.2. The Role of CSR in the Relationship between R&D and M&A

Firms that consider CSR in M&A decisions tend to assess opportunities with a holistic approach, and thus may be conservative towards MA when different types of risks are involved. Firms with a CSR focus often evaluate the scope and cost of potential impacts of M&A, including cultural and social impacts, as well as environmental impacts such as remediating soil and water contamination (Deloitte 2009). A comprehensive review of M&A also likely brings attention to incompatibility in CSR between the two firms, discouraging M&A for those with seriously committed CSR programs and ethical standards. A KPMG survey found that a third of companies interviewed had been impacted by environmental, safety, and social issues post M&A from target firms, and 42 percent resulted in higher operating costs and 21 percent in

direct financial liabilities (KPMG 2004). In addition, the more important CSR is to a firm, the more likely the stakeholders of the firm can wield power and influence over the firm's strategic decisions, such as in the case of M&A (Gedajlovic & Shapiro, 2002). Firms with high CSR scores may be concerned that the disruptive nature of M&A activity would destroy the interests of various stakeholder groups, lowering their CSR standards and damaging the firms' CSR culture (Morgan, 2009). The integration process post M&A is difficult and distracts management from attending to stakeholder interests (Bansal & Mark, 2015). On the other hand, however, firms with active and engaging CSR initiatives are often more open-minded and more adaptive toward M&A. For example, firms with more experience in social programs can be less concerned with cultural barriers in the post M&A integration (Meckl & Theuerkorn, 2015).

More importantly, the role of CSR in M&A may extend to the relationship between R&D and M&A because of the interactions between CSR programs and R&D activities. First, a R&D-intensive firm with extensive knowledge sharing and absorbing resources and capabilities may more readily gain from synergies during M&A integration, to which CSR further contributes (Hitt et al., 2009). A R&D intensive firm with a highly committed CSR initiative may invest in, for instance, green product innovation or social service offerings, allowing firms to possess more differentiated assets and capabilities. CSR, therefore, strengthens the complementarities in the resources and capacities behind R&D and hence encourage M&A (Hull & Rothenberg, 2008). Second, a R&D-intensive firm may be less likely to engage in M&A, because of the complexity and risks involved during the integration process, which can lead to disruptions on organizational routines, corporate culture, and innovation outcomes. A firm's CSR programs protect the acquiring firm from such risks in post M&A integration by offering an insurance-like effect (Jacobs et al., 2016; Godfrey et al., 2009). The insurance-like effect indicates that by actively involved in CSR, the firm sends positive signals to stakeholders and accumulates moral capital that can be leveraged by the firm in difficult times (Godfrey et al., 2009). In other words, a firm's good reputation, as enhanced by CSR, can serve as an intangible asset and attenuate negative stakeholder responses (Kang et al., 2016). Many R&D intensive firms build their success upon their well-trained and highly desirable employees and high-value customers (Wu et al., 2016). Effective CSR programs enhance corporate governance and stakeholder relations, mitigating the risks and concerns of key stakeholders that are significantly affected by M&A (Bekier et al., 2001). CSR programs promote corporate and social value for openness, diversity, and collaboration, all compatible with R&D intensive firms, accelerating the integration process to take advantage of synergy.

While the roles of innovation and CSR in M&A decisions have been extensively discussed in finance and management, the effect of CSR in moderating the relationship between R&D and M&A has not been studied, particularly in the operations management literature. In addition, while R&D investment creates pro-innovation corporate environment and culture, the ability and efficiency to convert the investment to innovation and financial performance is more important and relevant to operations management. We study these largely untapped issues to contribute to the operations literature.

3. DATA AND RESEARCH SETUP

In this research, our goal is to study the relationship between R&D and MA, and the moderating effect of CSR in this relationship. In this section, we introduce our data samples, definition of variables, and research setting.

3.1. Dataset Overview

From Thomson Financial's SDC Database (SDC), we develop our sample based on all completed U.S. and Cross-Border M&A cases with announcement dates between January 1, 2005 and December 31, 2015. The SDC database has been commonly used to study M&A. We focus our analyses on the domestic M&A cases and extend to the cases in emerging markets as extensions. Following the prior literature (Bena & Li, 2014), we include acquisition cases in our sample based on the criteria below: *(a)* The acquirer has to be a U.S. firm with financial information available from Standard & Poor's COMPUSTAT dataset (Compustat). *(b)* The acquirer owned less than 50% of the target firm before the bid was announced and should have owned more than 90% of the target firm post-acquisition. The transaction size of a deal has to be greater than a million (in U.S. dollar), and the payment method has to be a cash offering. We exclude the payment method using security offering as such an M&A activity may have little impact on the acquirer's R&D expense. *(c)* Neither the acquirer nor the target firm is from the financial sector (SIC 6000–6999). Acquirers and targets in the financial sector are typically high leveraged firms, and this industry is highly regulated.

In our extended studies, we consider M&A cases that involved target firms from the emerging markets. We define a country as an emerging market country if the country is covered by one of the analysts at International Monetary Fund (IMF), BRICS+Next Eleven, FTSE Group (FTSE), Morgan Stanley Capital International (MSCI), Standard & Poor's (S&P), Emerging Markets Bond Index (EMBI), Dow Jones, Russell Investments Emerging Markets Fund (Russel), and Columbia University Emerging Market Global Players (EMGP) (See Appendix Table A.1). An M&A case is included in the sample for emerging markets if the target firm is from a country identified based on the above standards.

We collect the CSR data from the Thomson Reuters ASSET4 database (ASSET4), which has provided comprehensive CSR evaluations for firms in the Russell 1000 beginning in 2005. Information in ASSET4 has been collected since 2002 for evaluating firms' CSR performance on environmental, governance, and social dimensions. To assess a firm, ASSET4 considers more than 900 evaluation points, which are equally weighted to calculate 250 key performance indicators (KPIs). Each including firm receives an annual z-score based on KPIs for environmental performance, corporate governance, and social performance respectively. All the primary data used in the assessment are objective and publicly available.

In addition, we collect financial information for R&D expenditure and other firm-level control variables from Compustat. We extract quarterly data from Compustat, 91,475 domestic M&A cases and 82,917 emerging market M&A cases from SDC, and 13,851 year-level observations from ASSET4. We split domestic M&A and emerging market M&A and consolidate the three data sources using 9-digit CUSIP, 6-digit CUSIP, and ISIN as identifiers. The final merged domestic M&A sample (called the original domestic M&A sample) includes 9,449 observations, and the final merged emerging market M&A sample (called the original emerging market M&A sample) includes 5656 observations.

3.2. Definition of Variables

We define our key variables as follows. For M&A case *m* announced at time *t* (in fiscal year *y* and fiscal quarter *q*), we denote *ACQ* as a binary variable with 1(0) to indicate whether firm *i* is the actual acquirer in M&A case *m* or not. *RDI* represents a firm's R&D intensity, while *CSR* as corporate social responsibility performance, *M/B* as Market-to-book ratio, *ROA* as return on assets, *CFO* as cash flow, and *LEV* as the financial leverage.

First, the dependent variable *ACQ* = 1 for the unique actual acquirer with a unique target firm in a domestic M&A deal. Bidders or potential competitors (potential acquirers) are coded as zero. We exclude acquiring firms with cross-border M&A experience in this sample for the main

analysis and examine such cases with emerging market targets in our extended studies. Observations are grouped based on the M&A cases with the actual and potential acquirers. While the actual acquirer of each M&A case in the SDC database is observable, the same cannot be said about potential acquirers. We generate a "potential acquirer" pool comparable to the actual acquirers following a procedure developed in Bena & Li (2014). The details of the procedure will be discussed later with the estimation techniques.

The main independent variable for R&D investment is R&D intensity (*RDI)*. *RDI* is defined to measure a firm's input for innovation (Han, Dong and Dresner 2013). Consistent with previous research (Chen & Miller, 2007), we calculate *RDI* as the ratio of R&D expenditures to firm total assets (Compustat item RD/AT). We exclude observations with missing R&D information in Compustat.

We measure a firm's CSR performance using a score set from the ASSET4 ESG database that reflects the extent of the firm's involvement in CSR-enhancing practices (Cheng, Ioannou and Serafeim 2014). Operations literature also measures CSR combining a variety of areas including community, corporate governance, human rights, environment, etc. (Chatterji et al., 2009; Chen and Delmas 2011; Jacobs et al., 2016). We focus on corporate governance and social performance as our main CSR components. Firms experienced in social programs are more willing to engage in M&A, as they do not see cultural barriers and knowledge transfer as challenges in integrating with other firms (Morgan, 2009), and corporate governance influences significantly the reorganization after a merger (Wang & Xie, 2008). Specifically, in the social and corporate governance domains of ASSET4, firms are asked whether they have the appropriate "internal communication tools" to improve employee relations, the appropriate mechanism to protect intellectual properties, the internal information tools to develop balanced board structure, and the appropriate limitations to the shareholders right to approve significant company transitions such as M&As. To calculate the comprehensive CSR score for each firm, we take the average between social and corporate governance scores, which are normalized and curved to derive ratings between 0 and 100 for each company. The higher the value, the better the firm performs in CSR.

Following the existing literature (Blonigen & Taylor, 2000; Marquardt & Zur, 2014), we identify and develop our main control variables relevant to M&A decisions. First, we control for Market-to-Book ratio (*M/B)*, a measure of overvaluation, growth opportunities, and asset complementarity, as the ratio of market value of equity to the book value of equity (Compustat item PRCC* CSHO/ CEQ) (Andrade et al., 2001; Shleifer & Vishny, 2003). In addition, we control for Return on Assets (*ROA*) as net income scaled by total assets (Compustat item NI/AT). Furthermore, we control for Cash Flow (*CFO),* as cash and short-term investment scaled by total assets (Compustat item CHE/AT), and Leverage (*LEV),* as total debt scaled by total assets (Compustat item DLTT/AT), because they reflect a firm's resource and risk. Table 1 shows the data summary and definitions.

Table 1. Variable Definition and Summary Statistics	
Variable	Definition
Dependent Variable	
ACQ=0	Potential acquirers
ACQ=1	Actual acquirers
Independent Variables	
CSR	Average score of social and corporate governance performance
RDI	R&D expenditure scaled by total assets
Control Variables	
M/B	The ratio of market value of equity to the book value of equity
ROA	Net income scaled by total assets
CFO	Cash and short-term investment scaled by total assets
LEV	Total debt scaled by total assets
Matching Covariate	
SIZE	The log-transformed total assets

	Domestic M&A Sample				Emerging Market M&A Sample

4. METHODOLOGY

We develop two econometric models to test our research questions. We estimate these models to achieve two goals: *1)* to test for the direct relationship between R&D input and the likelihood of M&A, and *2)* to test for the potential moderator, CSR, of the association.

4.1. Conditional Logistic Regression

To estimate the likelihood of a firm to be involved in M&A as an acquirer, we need to understand the difference between the actual acquirer and its competitors, i.e. those who are potential acquirers, in an M&A case. Given the lack of information from competing bidders, we apply two standards to define the potential acquirer(s). We first identify industries based on prior literature, which suggests that an acquirer and its competitors are likely to operate in the same industry (Andrade et al., 2001). We use actual M&A deals as the unit of grouping. For M&A deal *m* announced at time *t*, we group each actual acquirer and its competitors by industry, defined by the 2-digit SIC code. This grouping process creates a pool of potential acquirers clustered by time-industry dyad (Maksimovic et al., 2013). There are no M&A activities for potential acquirers in the same period, or the year before, when they are grouped to an actual acquirer. In addition, potential acquirers with similar sizes to that of the actual acquirer are more likely to be actual

competitors in an M&A case (Gorton et al., 2009). To select the potential firms with similar sizes, we apply a propensity score matching approach. Propensity scores provide sampling weights (Hirano et al., 2003; Levine & Toffel, 2010) for assigning different weights to treatment and control observations based on observable covariates. We split all firms into two groups. We define firms with at least one M&A activity as the treatment group and firms without any M&A activity as the control group. Then, we use a Logit regression to calculate propensity scores (*pscore*), where the dependent variable is whether a firm has been an acquirer ever, and the covariate is the firm's log-transformed total assets. In each group, we control for the inverse probability weights (IPW) by assigning the weight for the actual acquirer as *1/pscore*, while the weights for the potential acquirers as 1/(1-*pscore*). Therefore, potential acquirers are given more weights if they are similar to actual acquirers in our analysis (Desyllas & Hughes, 2010; Hirano & Imbens, 2001). Figure 2 shows the kernel density estimation (DeFond et al,. 2016) in examining distributions of firm's total assets across the treated firms and the control firms and Table 2 shows the tests for the mean difference between the treatment group and the control group before and after matching. Both suggest that the propensity score distributions are reasonably similar after reselecting.

Figure 2. Kernel Density Estimation

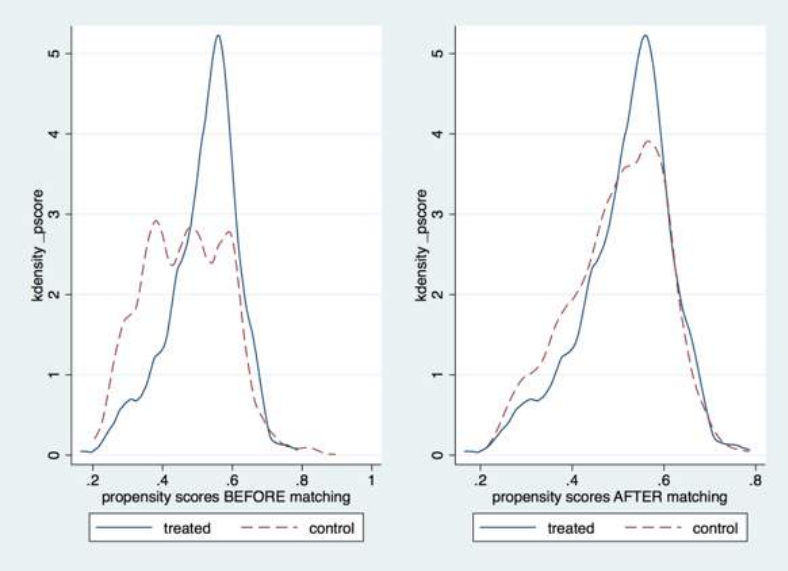

Table 2. Test for Matching Quality						
		Mean			t-test	
Variable		Treated	Control	%bias	t	p-value
SIZE	Unmatched	8.65	9.39	-52.50	-25.14	0.00
	Matched	8.64	8.64	0.00	-0.01	0.99

In stratification and grouping, we utilize the weighted conditional (or fixed-effects) logistic regression. A conditional logistic regression model is more appropriate than a classic logistic regression model in our analysis because the latter would result in biased predictions when grouped data is analyzed (Selvin, 2004). In each M&A case, the actual acquirer may compete with other potential acquirers, thus, the possibility of the acquirer-target combining is conditional on the differences between the actual acquirer and the potential acquirers. Because each M&A

case may involve a limited number of bidders, we randomly draw up to 5 firms from the pool of potential acquirers and group them with the actual acquirer. Each stratum has one observation for the actual acquirer and up to five observations for the potential acquirers matched with the actual target. We drop the acquirer with more than one M&A case in a quarter so that the same firm will not be observed multiple times in the same quarter. The conditional likelihood approach deals with the possibility to be the acquirer in an M&A case *m* in Equation (1):

$$P(Y_{m1}=1, Y_{m2}=0, \dots, Y_{mk}=0 | \mathbf{T_{m1}}, \mathbf{T_{m2}}, \dots, \mathbf{T_{mk}}, \textstyle\sum_{i=1}^{k} Y_{mi}=1) = \frac{\exp(\mathbf{T_{m1}B})}{\exp(\mathbf{T_{m2}B})+\exp(\mathbf{T_{m3}B})+\cdots+\exp(\mathbf{T_{mk}B})} \quad (1)$$

where *Y* is the outcome of whether firm *i* is an actual acquirer or a potential acquirer in M&A case *m* ($k \leq 6$, one actual acquirer with up to five potential acquirers), and **T** is a matrix of firm-specific information, such as CSR performance, R&D intensity, and other financial statuses. Because our observations are grouped by the unique M&A case, deal time, and acquirer industry, the conditional logit model also controls for industry fixed effects and deal fixed effects, such as the target firm's financial information, deal size, and the macro-economic environment around the deal time.

4.2. Endogeneity

We discuss the potential endogeneity in R&D intensity and CSR in the following section. On one hand, the M&A preparation may reversely affect R&D investment and CSR performance. These related decisions can be jointly determined by some unobserved factors that lead to an omitted variables problem. Resource commitment toward M&A preparation and planning diverts resources that would be allocated to R&D or CSR. On the other hand, M&A activities may reversely affect R&D and CSR. The acquirer may reduce the R&D investment immediately after acquiring an innovative firm (Cassiman & Veugelers, 2006). Choi et al. (2015) shows that, while acquiring a socially responsible target may create synergy that improves focal firm's CSR, it may also lower the focal firm's CSR performance due to the target's social irresponsibility.

4.1.1. Lagged Independent Variables

To address the simultaneity problem, we use lagged independent variables and control variables to predict the possibility of a firm to become an acquirer. Firms may make M&A decisions based on their current and previous financial and operational performance. However, whether they are able to complete M&A deals later is unpredictable due to different unobserved risks. Therefore, M&A completion may be exogenous to the financial and operational status of the firms in the preparation phase of M&A. Assuming that a firm starts to prepare an M&A case before making the announcement rather than during or after the announcement, we lag independent variables to a year before the deal and lag controls by a quarter before the deal to avoid the potential simultaneity. We control for the interaction between CSR and R&D intensity (*RDI*CSR*) to test for the moderating effect. We present the main regression Equation (2) below:

$$\mathrm{Prob}(ACQ_{i,m,t}) = \alpha + \beta_1 RDI_{i,m,t-1} + \beta_2 CSR_{i,m,t-1} + \beta_3 RDI_{i,m,t-1} * CSR_{i,m,t-1} + \mathbf{X}_{i,m,t-1} * \mathbf{B} + \delta_m + e_{i,m,t} \quad (2)$$

where the subscript *i* represents the firm, *m* the deal number, and *t* the deal announcement time. **X** is the matrix of control variables including *M/B*, *ROA*, *CFO*, and *LEV*. $\boldsymbol{\delta}$ first absorbs the deal fixed effects such as the target's financial performance and the time fixed effects. Because

the actual acquirer and the potential acquirers are in the same industry and have similar total assets, δ also captures the industry and firm size fixed effects. R&D intensity and *CSR* are lagged one year before the deal announcement date, and **X** are lagged one quarter before the deal announcement date.

4.1.2. Instrumental Variables

We address the potential endogeneity issues of CSR and R&D intensity by using instrumental variables (IVs) to show the robustness. The IV approach requires instruments that are highly correlated with the endogenous variable and uncorrelated with the error term. To predict the CSR performance, we adopt the political voting pattern in the state where the firm headquarters is located (*BLUE*). A Firm's CSR performance may be highly correlated to the external political environment because of its CEO's political engagement (Deng et al., 2013; Di Giuli & Kostovetsky, 2014; Chatterji & Toffel, 2016). For example, Di Giuli & Kostovetsky (2014) find that firms in Democratic-leaning states are more socially responsible than those in Republican-leaning states. To address the endogenous CSR performance, Deng et al. (2013) apply a dummy instrument, which is coded as 1 if firms are headquartered in a Democratic state (blue) and 0 if in a Republican state (red). Such a dummy IV defined at the quadrennial level may not have the variations for the yearly firm-specific CSR strategy. Instead, we collect each state's annual party affiliation from Pew Research Center (PRC). PRC randomly selects participants and asks their party identifications. We define our IV, *BLUE*, as the democratic advantage by using the share difference between democratic and republican. Therefore, we consider that *BLUE* should be largely exogenous with firm characteristics. To address the endogenous *RDI* in our research, we use the lagged 3-year moving average R&D intensity (*M_RDI*). Lagged values of the data are less likely to be influenced by current shocks. Thus, *M_RDI* is formatted exogenously.

5. ANALYSIS AND RESULTS

5.1. Analysis—Bootstrapping

The pool of potential acquirers includes the potential competitors that are in the same industry and have a similar size as the actual acquirer but did not have any M&A activity in the same period. Due to the data limitation of ASSET4, many firms that do not report their CSR performance are missing in the pool of potential acquirers. Therefore, the pool of potential acquirers represents a subsample of the potential acquirer population. Given the observed data, we estimate bootstrap-based conditional logit regressions. Bootstrapping is a type of resampling where large numbers of smaller samples are repeatedly drawn, with replacement, from a single original sample so that the sample data can be the inference about a population (Cameron et al., 2008; Simar & Wilson, 1998). In our case, we treat the pool of actual acquirers with the pool of potential acquirers as the original sample. Each bootstrap sample consists of the actual acquirers and up to five potential acquirers randomly drawn with replacement from the pool. A bootstrap sample is a smaller sample that is "bootstrapped" from the original sample. The actual acquirer group and control acquirer group do not remain constant across bootstrap because each observation in the original sample can be drawn multiple times to a bootstrapped sample. We also drop strata with a control group size smaller than or equal to five since the variation across the bootstrap can be relatively small. A different regression is fitted for each bootstrap sample as a result. We bootstrap 1000 times to get 1000 subsamples. After an independent regression for each bootstrapped subsample, we collect a matrix composed of 1000 coefficient

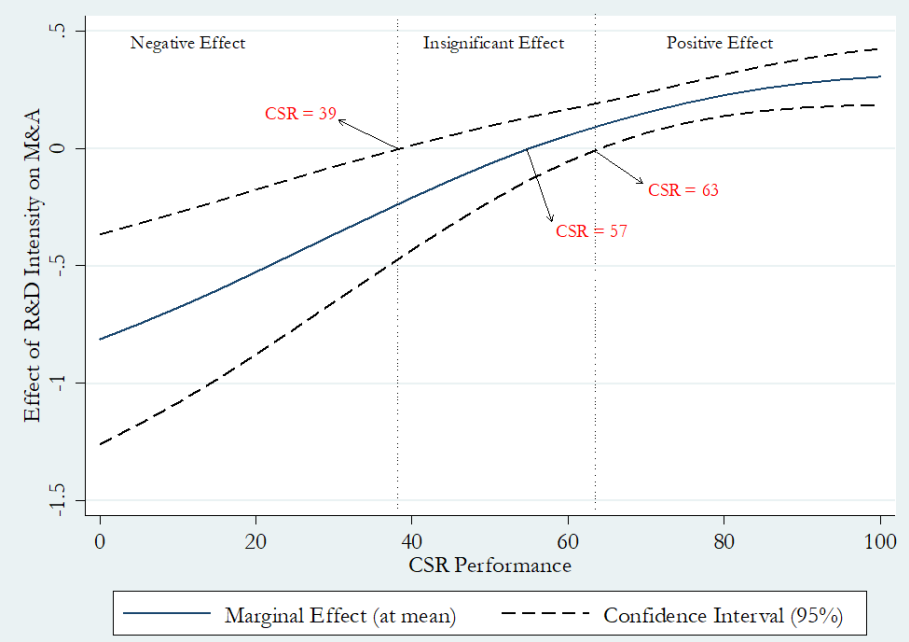
vectors to obtain an empirical distribution that is close to the true population distribution. Ideally, if we have an accurate subsample of the actual competitors, we only need to run a simple model to collect the coefficient of each variable. Unfortunately, we cannot match the exact competitors to the actual acquirer because of missing peer information in the SDC database. Instead, after bootstrapping, we calculate the median and standard deviation of each coefficient in Equation (4) from the coefficient matrix. The estimated standard deviations are the bootstrapped standard errors, while each *z* value is calculated by using the median divided by the bootstrapped standard error (Bena & Li, 2014; Efron & Tibshirani, 1994).

5.2. Main Result—R&D Intensity

We present the model estimates in Table 4 based on the domestic M&A sample as our main results. We later extend these results to target firms in emerging markets.

In Model (1) of Table 4, we first show the direct effect of R&D intensity on the possibility to acquire. As we discussed early, literature is mixed—some argue for a substitutable effect, that a less R&D intensive firm may obtain innovation through acquisition (Seru 2014; Phillips & Zhdanov, 2012), others find it to be the opposite, a complementary effect, that a R&D intensive firm can leverage its strengths in innovation in M&A (Bena & Li, 2014, Cassiman & Veugelers, 2006). We find that *RDI* has a positive and significant (0.40, $p < 0.05$) association with *ACQ*. In Model (2), however, after we control for the interaction between CSR and R&D intensity to explore the moderating effect, we find that the linear term of *RDI* becomes negative and significant (-2.06, $p<0.01$). More importantly, our primary interest, the interaction term *CSR* RDI,* is positive and significant, 0.04 ($p<0.01$). The combination of the negative linear term and the positive interaction term connects the two conflicting streams of literature with CSR, indicating that M&A can be both a substitute and a complement to R&D, depending on CSR. Specifically, when CSR performance is low, firms with low R&D intensity tend to replace R&D with M&A, whereas firms with high R&D are less likely to be an acquirer. A better CSR performance positively moderates the relationship between R&D and M&A, such that with sufficiently high CSR performance, firms with high R&D intensity become more likely engaged in M&A. Figure 3 shows the interaction between R&D intensity and CSR in a Johnson-Neyman plot (Shang et al,. 2017), which indicates that the marginal effect of CSR on R&D-M&A relationship is significantly negative if the CSR score is below around 39. As the score moves from 39 to around 62, the marginal effect is insignificant. When it goes beyond 62, the marginal effect becomes positive and significant.

Figure 3. Johnson-Neyman Plot: The Marginal Effect of CSR on R&D and M&A Relationship



The linear term of CSR performance has a positive and significant effect on the likelihood of M&A in two models. In addition to moderating the innovation-related risks, the positive coefficients of CSR indicate that a better CSR performance encourages and facilitates firms to acquire new resources because the barriers of post-merger integration are lowered. Other findings not directly related to R&D and CSR are consistent with prior work on M&As (Maksimovic & Phillips, 2001; Moeller et al., 2004). We show that firms with lower M/B ratios, less cash flow, better ROA, and higher leverage are more likely to engage in M&As as acquirers.

In Model (3) and Model (4), we show the two-stage IV estimations. We include three IVs presented in Section 4.2.2 to predict the endogenous *CSR* and *RDI* in the first stages. Then, we plug the predicted CSR performance (*CSRhat*) as well as R&D intensity (*RDIhat*) into the second stages. Given that all F-statistic values in the first stage are greater than 10, indicating our IVs are valid in predicting the endogenous variables, the two-stage model results are qualitatively consistent with our main results based on the weighted conditional logit model. The Wald tests of exogeneity also indicate the correlation between the error terms in the structural equation and those in the reduced-form equation for the endogenous variable (Wooldridge, 2010). We observe that the *p*-values of the Wald tests of exogeneity are significant in the two models and the null hypothesis of no endogeneity is rejected.

5.3. Robustness Checks

In this section, we present and discuss a number of robustness checks. The detailed results are included in Appendix Table A.2.

Innovation-related M&A

We argue, and our main findings suggest that a firm's CSR performance may mitigate the innovation-related risks in M&A. Our sample contains M&As of a variety of different purposes. To provide a more focused view of this role of CSR, we zoom in on the innovation-related M&A cases by creating a subsample with such cases only. We define, following SDC categorization, innovation-related acquisitions as deals if one of the deal purposes is to develop new products or to acquire patents, new technologies, or intellectual properties. When reconstructing the dependent variable, *ACQ*, we code the actual acquirers of innovation-related M&As as 1. The grouped potential acquirers are coded as 0. This subsample includes 524 innovation-related cases. We show that the positive moderating effect of CSR remains significant for innovation-related acquisitions.

Sample Construction and Weighting Standard

First, we adjust the number of potential acquirers to check whether the main results are sensitive to potential acquirers. When grouping the actual acquirers with the control acquirers, we randomly draw up to five control acquirers by industry and firm size. As robustness checks, we control for the closest one potential acquirer and, then, control for ten closest control acquirers of the actual acquirer. The results remain the same. In addition, we control for the total asset and market-to-book ratio as the covariates in propensity score estimation to test for weighting approach, and the results are highly consistent with the main results.

Alternative Model Configuration

We also test if our findings are robust when using a different sampling approach. Instead of using M&A deals to group each stratum, we use the SIC-quarter dyad as the grouping standard. We add firms engaged in more than one M&A deal within a quarter and reform the dependent variable as the aggregate number of deals completed in a quarter. Therefore, our new dependent variable (*MA_COUNT*) follows a Poisson distribution. We estimate a Poisson regression with industry and time fixed effects to test the relationships between R&D intensity, CSR, and M&A activities. These results explain how R&D intensity affects M&A frequency, and how CSR moderate this relation. The results are consistent with those from our main model.

6. EMERGING MARKET M&A AND RESEARCH QUOTIENT

6.1. Cross-border acquisitions of emerging-market multinationals

As emerging markets have seen significant improvements in technology in the recent decades, targeting firms in the emerging markets for M&A is no longer motivated solely by cheap resources and labor. The growing scale of economic activities in emerging markets provides opportunities for firms to leverage technological advantages and develop new markets (Parker, Ramdas & Savva, 2016; Han et al., 2013). The existing literature shows a different role of R&D in emerging market M&A decisions. On one hand, firms in the emerging markets are often

behind in technology and less innovative than firms in the U.S. (Lall, 2003), and therefore, acquiring innovative firms to compensate or replace internal R&D is less likely. US firms that target emerging markets are more likely to extend new markets and sell their new products that are technologically advanced and innovative (Hitt et al., 2000). On the other hand, Meyer et al. (2009) indicate that firms target emerging markets for M&A opportunities based on demand of local resources rather than innovative technologies. Because firms in the emerging markets are significantly behind in technologies and innovation, it is difficult for R&D-intensive firms in the U.S. to take advantage of the resources from emerging markets for technological benefits. The cultural and economic differences may also make it ineffective for R&D-intensive firms to develop synergy after acquiring firms in the emerging markets.

In terms of the role of CSR performance in emerging market M&A decisions, there are two different opinions in the existing literature. On one hand, poor corporate governance practices in emerging markets have been well documented in the literature (Aybar & Ficici, 2009). If the difference between the acquirer and the target is too much, it is difficult to develop synergy after merger. On the other hand, when the focal firm has strong corporate governance (relative to the target), the governance of the target firm can be improved so that part of the post-merger synergy value can be obtained (Martynova & Renneboog, 2008). We consider that CSR may perform a different moderating role when the target firm is in the emerging markets.

In this section, we examine the role of R&D intensity and CSR in emerging market M&As. We group the actual acquirers and potential acquirers based on the emerging market M&A cases. All actual acquirers and potential acquirers are domestic firms. All targets are firms in the emerging markets. We replicate the weighted conditional logistic model with the bootstrapping procedure in the previous section. The actual acquirers only have the emerging market activities in the studied period and have no other M&A activities in the previous year. We present the model estimates in Table 5. In Model (5), we find that the combined effect of R&D intensity becomes negative (-0.56, $p<0.10$), indicating that R&D intensive firms are less likely to target the emerging markets. The coefficients of CSR remain positive (0.018, $p<0.01$) and consistent with the domestic M&A model. This finding shows a positive effect of CSR on both domestic M&A and cross-border M&A. We also test the moderating effect of CSR in Model (6). The positive moderating effect (0.10, $p<0.01$) shows that firms with higher R&D intensity and better CSR performance are more likely to acquire targets in emerging markets than those with high R&D intensity but lower CSR performance. While this positive moderating effect of CSR is consistent with that for domestic targets, it is weaker because the combined direct and moderating effect of R&D intensity is negative, as in Model (5). Compared with the positive combined effect for domestic targets, this negative effect shows that substantial technological gaps and cultural and economic differences between U.S. acquirers and emerging market targets may intensify the challenges in knowledge sharing and post M&A integration, which weakens the positive effect of CSR.

6.2. Research Quotient

R&D intensity measures the portion of internal R&D investment in total asset, which can be seen as a measure of R&D input. However, heavy investment in R&D does not necessarily produce the desired outcome, that is, innovation and firm financial performance (Chandrasekaran et al., 2015). Rather, a highly R&D intensive firm with a low level of innovation outcome tends to lack necessary knowledge sharing and absorptive capacities to fully convert the investment to the outcome. In this case, merging with a different company will further burden the acquiring firm's inefficient or inadequate learning capacities, leading to higher risks and lower innovation and financial performances. On the other hand, a firm with a higher efficiency

in converting R&D investment to innovation and financial outcomes should have a more adaptive and capable internal mechanism to facilitate knowledge sharing and absorbing post M&A (Cohen & Levinthal, 1990). Moreover, efficient R&D improves operations and aligns with the output of CSR (Jacobs et al., 2016). In this regard, R&D input of a firm, i.e. R&D investment, may function differently from the firm's ability to create R&D output, i.e. R&D efficiency, in the firm's decision with respect to M&A. The existing literature, therefore, is mixed on the association between R&D and M&A, and the potentially different mechanisms, between R&D investment and R&D efficiency. In this section, we adopt a measure of R&D output, i.e., research quotient (*RQ*), to test if *RQ* is related to R&D differently from R&D intensity (Knott, 2008; Cooper et al., 2015).

RQ is available in the *WRDS RQ™ database* from 2005 to 2010. To match this variable with our timeframe, we re-estimate *RQ* following Cooper et al. (2015), but without considering advertising expenditure because of the missing value issue. Based on the assumption that R&D is one of the factors to maximize the output (Knott 2008), we estimate, *RQ*, as the output elasticity of R&D, by applying the Cobb-Douglas production function with natural logarithm transformation(Cooper et al., 2015).Then, in Equation (3), we derive *RQ* by using a multilevel model that allows for the heterogeneity among firms in the output elasticity for R&D expenditure:

$$lnY_{it} = (\beta_0 + \beta_{0i}) + (\beta_1 + \beta_{1i})lnK_{it} + (\beta_2 + \beta_{2i})lnL_{it} + (\beta_3 + \beta_{3i})lnR_{i,t-1} + (\beta_4 + \beta_{4i})lnS_{i,t-1} + \varepsilon_{it} \quad (3)$$

where *i* represents the focal firm and *t* represents the fiscal year. β and β_i capture the general effect and the firm-specific error of each exponent. *Y* is annual revenue, and *A* represents a firm fixed effect; *K* is capital, *L* is labor, and *R* is lagged R&D expenditure. *S* is lagged R&D spillovers (Eeckhout & Jovanovic, 2002), which is computed as the sum of the differences in R&D expenditure between focal firm *i* and rival firm *j* with more knowledge (R&D) than the focal firm in the same 4-digit SIC industry. We construct *RQ* for each firm-year using rolling 7-year windows from 1997 to 2015, following the *WRDS RQ™* process. For example, *RQ* for each firm in 2015 is estimated based on data from the 2009 to 2015 window. We obtain the best linear unbiased predictions (BLUPs) after multilevel analysis to estimate the industry-level random effects. Then, *RQ* for each firm-year, capturing by $\beta_3 + \beta_{3i}$, represents the revenue increase when investing 1% more on R&D. In addition, *RQ* is controlled at the end of the fiscal year prior to the merger announcement because literature shows that the successful R&D input at a previous stage will increase the commitment to the allocation of future R&D resources (Nelson & Winter, 1982). The correlation between our estimated *RQ* and the *RQ* from *WRDS RQ™ database* is 0.85.

In Table 6, we show the effect of the R&D output, *RQ*, and the moderating effect of *CSR*. *RQ* captures firm's ability to convert R&D to profit. We find the direct effect of *RQ* is positive and significant (2.75, $p<0.01$) in Model (7). In Model (8), the positive moderating effect of CSR (0.023, $p<0.05$) shows the robustness and consistency. However, the linear term of *RQ* remains positively and marginally significant (1.27, $p<0.1$), which means firms with higher *RQ* still seek the opportunity to acquire new resource even CSR performance is at a low level.

7. DISCUSSION AND CONCLUSION

Using a combination of datasets over the period 2005-2015, we examine the R&D and M&A relationship with a focus on the moderating role of CSR. We find M&A can be employed as both a substitute and a complement to R&D investment, depending on CSR performance. In particular, when a firm's CSR score is low, the relationship between R&D intensity and M&A likelihood is negative, indicating the substitutable effect, which is supported by the existing literature shown as a "replacement" role of M&A. When the CSR score is sufficiently high, however, the R&D and M&A relationship becomes positive, suggesting a complementary effect of M&A. Our findings contribute to the literature by highlighting the moderating role of CSR that

reconciles the opposite effects of R&D on M&A.

Replacing internal investment in R&D with M&A is risky, mainly because of the uncertainties involved in the integration process and in absorbing the new knowledge and technology. Resorting to M&A to grow market for innovative firms can be riskier, not only because of uncertainties and challenges in integrating new organizations and leveraging technological knowledge, but because of the high costs of failure for the established acquirers. This is where CSR engagements play a key role—CSR functions as an insurance-like mechanism that reduces internal risks in integration by enhancing absorptive capabilities to sharing knowledge and information, and accommodating different corporate cultures and structures, and reduces external risks by protecting corporate and brand reputation in case of failure. As such, this buffering effect of CSR is more critical and value-added for innovative firms that have invested substantially in R&D and established reputation. Literature has well documented the R&D and M&A relationship, with conflicting findings, but has not investigated these effects from the perspective of CSR and its moderating role in the relationship. This research is a first empirical attempt in this regard and firmly establishes the significant role of CSR.

Furthermore, by including data from M&A target firms in emerging markets and using an alternative measure for R&D efficiency, this research strengthens our major finding with regard to CSR in the R&D and M&A relationship. It also expands and enriches the literature of R&D and M&A by incorporating different cultures and economic conditions in emerging market, and by allowing a more in-depth understanding of the R&D effect, i.e., investment vs. efficiency. Acquiring a target firm from emerging markets involves higher risks, because of differences in corporate culture, economic and regulatory environment, and governance. While the firm's higher social values, and open and absorptive corporate environment still strengthen the R&D and M&A relationship with emerging market targets, the barriers in communication and knowledge sharing further challenge the integration process. Further, R&D is a process—while R&D investment creates infrastructure and provides resources that enable and facilitate the process, the outcomes of the process also depend on many other factors (Cooper et al., 2015). Therefore, a firm with low R&D investment may find acquiring another firm with established technologies an efficient replacement strategy, but a firm with low efficiencies of converting R&D efforts into meaningful outcomes will less likely be able to take advantage of the acquired technologies via M&A. This research is a first attempt to connect R&D efficiency, as a comparison to R&D investment, to M&A, with the moderating effect of CSR.

These findings have important managerial implications. First, establishing effective internal process and programs, as well as external reputation, CSR is critical for managers in making M&A decisions. An effective role of CSR encourages knowledge sharing and coordinates integration risks post M&A, and as a result, enhances R&D under M&A. Managers challenged by investing in R&D or replacing it by M&A should strengthen CSR programs and improve corporate governance and social image. Further, the moderating role of CSR remains positive even for emerging market targets, but it is weaker compared with U.S. targets. Acquiring an emerging market firm is still risky for R&D intensive firms, even after taking into account of the positive CSR effect. Moreover, when a firm's R&D is highly efficient, it can leverage the high efficiency to expand its market, and CSR can help increase the likelihood of the firm choosing M&A as a strategy. Therefore, managers considering M&A as a R&D option should focus on increasing R&D efficiency as an output, rather than investment as an input, and better coordinate R&D and CSR activities.

This research is limited by data availability from target firms, in particular for the CSR related information. Future research can increase data sources and improve CSR data availability. Particularly, the current analysis can be extended to study CSR synergy between

acquiring firms and target firms, if more and higher quality CSR data for the target firms is available. Further, because CSR can better facilitate post M&A integration, a post M&A analysis could explore whether or not a firm with established CSR programs could recover faster from M&A shock.

This table reports coefficient estimates from conditional logit models in Equation (2) with the adjustment of the dependent variable. Model (A1) and Model (A2) test if our model is sensitive to the purposes of M&A. The dependent variable is equal to one for the actual acquirers who merge for acquiring new technologies or patents and zero for the potential acquirers. We control for total assets as the covariate of propensity score matching. Then, we randomly draw up to 5 potential acquirers from the pool of potential acquirers to match with the actual acquirers. We present the median and standard deviation (as the bootstrapped standard error) of the empirical distribution of coefficient estimates from conditional logit regressions of 1000 bootstrapped samples.

ABSTRACT

A review of literature suggests that further empirical research, supported by an applicable and appropriate theoretical base, is critical to further understanding the relationship between types of innovation implementation of sustainable supply chain management (SSCM) practices in different industries. In this study, we adopt a multi-level innovation perspective to explore the relationships between innovation creation and the development of SSCM practices through theoretical lenses of organizational learning, ambidexterity, and absorptive capacity. Our multiple case design contributes to supply chain management and innovation literature and practice by identifying the different innovation types that emerge when SSCM practices are being implemented.

KEYWORDS: Sustainability, Innovation, Supply Chain Management, Case Research

INTRODUCTION

Sustainability as a business phenomenon has occupied the attention of academicians, practitioners, and consumers for more than three decades (Linton, Klassen, & Jarayaman, 2007; Adams, Jeanrenaud, Bessant, Denyer, & Overy, 2016). The World Commission on Environment and Development (WCED) defines sustainability as “satisfying today’s needs without compromising the needs of future generations” (WCED, 1987, p. 43). Sustainability in organizations refers to the optimization of its three dimensions: environmental, economic and social (Elkington, 1997; Kaynak & Montiel, 2009; Svensson et al., 2016). Since the early 1990s, interest in sustainability has been expanding and now, as a result, includes supply chain management (SCM). Both practitioners and academicians have attempted to explain the importance of sustainable supply chain management (SSCM) in organizations (Handfield, Sroufe, & Walton, 2005; Linton et al., 2007; Srivastava, 2007; Carter & Rogers, 2008; Min & Galle, 1997). Surveys show that more than half of the executives queried believe that sustainability is extremely important for new product development, firms’ reputation, new practices, and as an overall strategy in their organization (Bonini & Gorner, 2011). However, a

significant number of organizations still do not know how to implement sustainability (The pain of sustainability, 2012). Some of the main challenges that companies face implementing sustainable practices are the costs associated with sustainability implementation, accurate risk assessment issues, fear of tradeoffs, and changes in corporate priorities (Epstein, 2008).
A review of the literature makes clear that sustainability can be effectively implemented by adopting new approaches to product development, adopting new processes, modifying an organization's structure (Hausten, Luther, & Schuster., 2014), and engaging in stakeholder management (Kaynak et al., working paper), but effective implementation also requires consideration of the internal and external factors that can affect firms' supply chains. Competition in the market and the need to improve sustainability forces companies to focus on innovation as well as on their research and development efforts. As the Rio Declaration of 1992 states in Principle 9, a focus on developing and adapting new technologies is a must for seeking the new practices and new implementations that will enable sustainable development in organizations (Rennings, 2000). Implementing new sustainable practices requires that organizations create new eco-innovations in their supply chains, and several studies address supply chain practices that can assist firms in achieving their sustainability goals (e.g., Adams et al., 2015; Wu, 2013). A frequently cited article in the Harvard Business Review (Nidumolu, Prahalad, & Rangaswami, 2009) as well as other studies (Seebode, Jenrennaud, & Bassent, 2012; Tohidi & Jabbari, 2012), for example, state that the ability to create innovative products, processes, and ways of operating is crucial if an organization implements sustainable practices.

Although there have been studies that investigate innovation in the context of sustainability, their scope is limited. Most address innovation from a single perspective (a micro or macro level). A study by Dangelico and Pujari (2010), for example, focuses on product innovation, whereas Schaltegger, Lüdeke-Freund, and Hansen (2012) emphasize business model innovation, and Elzen, Geels, and Green (2004) investigate system innovation. A single-level perspective limits the research to a narrow scope; thus, it often obscures the big picture of innovation, its creation, and its effects on firm performance.

Despite a vast amount of literature on the creation of innovation and its types, research on levels of innovation that show the magnitude of innovation coverage is lacking. Until now, only a few studies have attempted to examine various levels of innovation in a single study (Boons, Montalvo, Quist, & Wagner, 2013). Meyer and Goes (1988) investigated innovation from a multi-level contextual perspective. In this study, we will adopt a multi-level innovation perspective to explore implementation of SSCM practices because they are important to the creation of innovation and its types (Roy, Sivakuvar, & Williamson, 2004; Adams, Jeanrenaud, Bessant, Denyer, & Overy, 2015). Implementing sustainability in supply chain management transforms the business arena into a competitive landscape and compels firms to alter the way they think about products, technologies, processes, and business models (Nidumolu et al., 2009), and these alterations require a series of innovations on multiple levels.

A review of literature suggests that further empirical research, supported by an applicable and appropriate theoretical base, is critical to further understanding the relationship between types of innovation implementation of sustainable SCM practices in different industries Organizational learning, ambidexterity, and absorptive capacity theories are appropriate theoretical lenses through which the research for this study can be viewed. Organization learning theory explains the processes by which organizations develop, innovate, and implement (Hedberg, 1981; Dibella, Nevis, & Gould, 1996).. In this study, absorptive capacity will help explain the relationship among SSCM practices and innovation patterns in firms' adapted sustainability practices in their supply chains. Ambidexterity directly affects how organizations approach the creation of new knowledge and innovation. In this research context, ambidextrous organizations use different strategies and approaches in the innovation process that seek new SSCM practices. Taking into consideration the theories cited above, this study proposes to find answers to the following question: What specific innovations do companies generate to implement SSCM practices effectively in specific industries?

We have utilized a multiple case design to achieve the purpose of this study. In addition to interviews, company reports and other available secondary data sources have been examined to triangulate the findings. This research contributes to supply chain management and innovation literature and practice by identifying the different innovation types that emerge when SSCM practices are being implemented in various industries.

LITERATURE REVIEW

Sustainable Supply Chain Management

Resource scarcity and operational inefficiencies in SCM have made sustainable supply chain management (SSCM) essential for organizations. Sustainability has been defined and become the focus of several research projects in various disciplines for three decades; however, in-depth research on SSCM has not yet been developed. SSCM is defined as an approach to supply chain management that creates, protects, and grows long-term environmental, economic, and social values for all levels in the chain (The Sustainable Supply Chain, 2010). Several studies have investigated the three-dimensional approach — environmental, social and economic — to sustainability in SCM (e.g., Seuring & Müller, 2008; Ahi & Searcy, 2013; Beske, Land, & Seuring, 2014).

Scholars have conducted numerous studies of SCM practices; however, only a few of these studies have focused on SSCM practices. SSCM practices encompass the internal and external practices of a firm that are implemented to make its supply chain more sustainable in terms of all three dimensions of sustainability (Kaynak & Montiel, 2009; Morali & Searcy, 2013; Paulraj, Chen, & Blome, 2015).

Sustainable supply chain practices (SSCP) are defined as activities or actions taken to improve supply chain-related functions or processes by increasing sustainability efforts in its social, environmental, and economic aspects (Golicic & Smith, 2013). Each aspect of sustainability impacts different processes and functions. The environmental aspect of SSC practices has been the major focus of SSCM research. Increasingly scarce resources, pollution, and waste have drawn attention to the environmental aspects of SSCM research and application (Zhu & Sarkis, 2004). The term green supply chain practices (GSCP) is commonly used in the research literature to refer to a number of activities performed by an organization to minimize its impact on the natural environment (Vachon & Klassen, 2006; Sarkis, Gonzalez-Torre, & Adenso-Diaz, 2010). Zhu, Sarkis and Lai (2008) also assert that green supply chain practices are an adoption of environmentally friendly supply chain management practices that include such things as cooperation with customers, eco-design, waste reduction, recycling, and the reuse and substitution of materials (Carter & Narasimhan, 1998), reverse logistics (Eltayeb & Zailani, 2009), supplier management inventory (Liu et al., 2012), supply selection and evaluation (Ben-Brik, Mellahi, & Rettab, 2013), and investment recovery (Perotti, Zorzini, Cagno, & Micheli, 2012). The current environmental and green practices that have been examined in the literature are listed in Table 1.

Recognition of the importance of sustainability's social aspects is growing significantly. Organizations that focus on social aspects of SSCP provide guidelines on corporate social responsibility initiatives, thereby creating a sustainable organization culture among employees and applying fair labor practices at all levels of their supply chains (e.g., Lopez, Garcia, & Rodriquez, 2007; Kaynak & Montiel, 2009). Increasing labor and workers' rights issues, community involvement efforts, and fair trade and sourcing have become focal points for firms whose operations are implementing sustainability (Erkul et al., 2015). As Table 2 shows, researchers have identified some of the social sustainability practices organizations can follow to comply with sustainability standards throughout the supply chain such as those relating to supplier ISO 26000, external codes of conduct, and employee health and safety (Castka & Balzarova, 2008; Spence & Bourlakis, 2009; Erkul et al., 2015).

The research on the economic aspect of SSCP emphasizes the reduction or elimination of environmental impact and increasing the economic value of an organization by reducing the cost of inputs such as eco-sourcing and waste management practices (e.g., Melnyk et al., 2003; Kaynak & Montiel, 2009, Golicic & Smith, 2013; Erkul et al., 2015). Improved sustainability efforts will enable firms to improve their brand reputation which will lead to higher market value (Shrivastava, 1995). Table 3 lists studies that examined the economic aspects of sustainability at the time firms were implementing sustainable practices.

Innovation and Multi-Level Perspective

Innovation has been a prominent phenomenon in the history of organizational research. For decades and for various reasons, practitioners and scholars have been studying the importance

of innovation in organizations (Biemans, 1992; Storey & Salaman, 2005; Trott, 2008; Simon, 2009). These investigations have produced an immense body of literature on innovation and definitions of the term, but so far no consensus has been reached on a definition of innovation (Rowe & Boise, 1974; Dewar & Dutton, 1986; Utterback, 1994; Utterback & Afuah, 1998; Garcia & Calantone, 2002). For this study, we will adopt the definition from the frequently cited study by Damanpour and Evan (1984) that defines innovation as "the implementation of an internally generated or a borrowed idea — whether pertaining to a product, device, system, process, policy, program, or service — that was new to the organization at the time of adoption" (Kaynak, 1997, p. 25). The holistic viewpoint considers innovation as changes in process, product, or organization aimed at adapting to an organization's external environment or to change its own external environment (Damanpour, 1996). For these reasons, innovation and its derivatives are used to explain the phenomena that include new products and services, processes, technology, structure, systems, and new programs in an organization.

Organizations' innovativeness is a key aspect of innovation development (Hult et al., 2004; Wang & Ahmed, 2004; Lee & Tsai, 2005), and several studies have already investigated organizations' innovativeness and types of innovation in various fields and settings. Wolfe (2007) asserts that across diverse disciplines, there are three major research streams regarding

innovation typology: product vs. process (Gopalakrishnan & Damanpour, 1997), radical vs. incremental (Ettlie, Bridges, & O' Keefe, 1984; Normann, 1971), and technical vs. administrative (Evan, 1966).

Innovation has also been examined at many levels: micro, meso, and macro (Goffin & Pfeiffer, 1999). For this study, we propose a multi-level perspective of innovation characterized by structural and dynamic dimensions. The structural dimension pertains to the hierarchy of levels nested within one another where the most internal level is that of innovation representation at the micro-level of innovation. In other words, the micro level innovation is a single product, process, or technology level that is nested within the meso and macro levels of innovation, both of which are a broader phenomenon. Organizational learning theory has significant implications for the development of new knowledge and absorptive capacity over time, which may lead to much broader innovations and innovative performance of organizations (Cohen & Levinthal, 1989). Innovativeness as a shared system of meaning can be formed at each of these levels. The dynamic dimension pertains to the interrelationships among the different levels of innovation and the way they impact each other. The micro level innovations are much more specific and their effects on the environment are significantly limited as compared to meso and macro level innovations. As companies move to meso and macro level innovations, the effects of innovations on the environment become greater, respectively. The multi-level perspective claims the ability to analyze the innovation process from a broader perspective, the transition of simple incremental innovations to a new system of production or process, perhaps even a new socio-technical system that changes how a society operates (Smith et al., 2010). This broader perspective requires different innovation types at each level to cope with internal and external environmental factors.

The essential characteristic of the multi-level innovation perspective is that firms' organizational learning capacity and innovation creation process will vary in response to their environment, competition, and strategy. Thus, there will be a strong mutual relationship between a firm's choice of an innovation strategy and, particularly, the industry in which the firm operates.

Micro level innovation refers to an innovation that introduces a new or significantly improved service, process, or product at a level where it is effective only in its specific function. The scope of micro innovation is limited to a single product or process level, and most of the time it is a modification of existing technology, product, or service. Therefore, micro innovations are only marginal departures from existing practices and largely reinforce the existing potential of firms (Henderson & Clark, 1990; Ettlie, Bridges, & O'Keefe, 1984; Meyer et al., 1990). The difference between micro level innovation and the other two levels, meso and macro, is clear and distinct.

Over the past two decades, literature on innovation has emphasized organizational-level innovations, and this emphasis includes supply chains. *Meso level innovations* are defined as sets of activities linked by some product or process groups that create significant improvements or changes in organizations such as using or sharing new technologies or production systems

with suppliers (Malerba, 2004). Knowledge and technology varies across organizations or industries in terms of their specificity, tacitness, complexity, and interdependence (Breschi et al., 2000). The main characteristic of meso level innovation is that innovation patterns tend to display commonalities across elements of an organization such as different departments within the company that use the same innovative technology or buyers-suppliers who use the same innovative process in their supply chains. At the meso level of innovation, micro innovations are amplified by elements of an organization and its supply chain. In the last three decades, we have seen some dramatic examples of innovation creation at the meso level in big corporations and their supply chains like Proctor & Gamble's (P&G)'s Continuous Replenishment System which operates in conjunction with its suppliers. This system changed the company's whole supply chain strategy and its supply chain operations.

Macro level innovations can be defined as breakthrough changes that lead to newer and/or improved systems and structures. A list of examples of macro level innovations that have changed the structure of industry and even society might include such innovations as printing, the computer, and micro loans. Macro level innovations have a broader context than product and or process innovations; they require fundamental structural changes (Frantzeskaki & De Haan, 2009). The invention of the steam engine seems to be a product innovation; however, it also created a fundamental transition from carriage to automobiles and eventually to planes (Geels, 2002). Moreover, this far-reaching transition changed society and how it operates. Macro level innovations affect broader organizational and societal contexts; in other words, these innovations not only include product and process innovations but also changes in the external environment such as industry, government and policies, culture, consumer behaviors and habits, and management styles of firms (Kemp & Rotmans, 2005; Geels, 2006).

Innovation and Sustainable Supply Chain Management Practices

Our literature review indicates that firms implementing sustainability in their supply chains may map their innovation creation process at three levels: (1) whether it focuses on single and limited innovations, (2) the firm's view of innovation has broadened to include its supply chain and other business functions, and (3) the extent to which innovation extends beyond the supply chain to become closer to society and industry.

Based on organizational learning (OL) theory, sustainability, and OL support each other (Senge, 1999), and OL is essential for sustainability innovation (Sinkula, Baker, & Noordewier, 1997). Moreover, OL encourages a holistic approach to innovation and sustainability at every level. The literature shows that the higher the level of learning orientation, the greater the degree of firm innovativeness (Calantone et al., 2002; Weerawardena et al., 2006). The OL theory helps firms transform existing knowledge into new insights about products, processes, and services (Nonnaka, 1994), and it can explain the transformations that occur between different levels of innovation (Jimenez & Valle, 2011). Knowledge sharing within organization and with a supply

chain through interaction creates an appropriate environment for firm innovativeness (Jerez-Gomez Céspedes-Lorente & Valle-Cabrera., 2005).

In the multi-level innovation approach, organizations at the micro level of innovation add new sustainable products or processes to their existing product line and processes. In this stage, organizations aim to improve their sustainability efforts and reduce their sustainability impact by reducing waste and focusing on lean practices. Firms focusing on improving their environmental sustainability, for example, concentrate on pollution prevention, environmental certification, life cycle assessment, eco-design product and process design, reserve logistics activities, waste management, green purchasing, and upstream practices (e.g., Zhu & Sarkis, 2004; Klassen & Johnson, 2004; Zhu & Sarkis, 2011; Nikbakshsh, 2009; Srivastava, 2007; Walton & Handfield, 1998). At this level, innovations are typically incremental, address one issue at a time and tend to be focused inward with regards to both development and outcome. Companies typically rely on internal resources to innovate, and the resulting innovations are most likely company-centric: their intent is primarily to reduce costs or maximize profits.

Organizations at the meso level observe significant improvements in innovations, and they introduce new products or processes that may also improve other supply chain units such as downstream and upstream elements. This level can be exemplified as a new business model innovation in sustainability. Organizations at the macro level are already introducing significant innovations that change other agents in the industry and society that are parts of a broader interconnected ecosystem. As they move from the micro to the macro level, firms have a significant impact on sustainability in the system. Tesla cars, for example, will never be completely sustainable as long as its electrical vehicles are charged by fossil-powered energy sources. However, focusing on innovation and continuous learning, Tesla is expanding its product line to include solar energy panels and high capacity batteries, both of which perfectly represent the transition from micro to meso level innovation.

Every organization has different learning capabilities and absorptive capacities and, for this reason, organizations can, based on their resources and capabilities, move through different innovation levels. The leaps from the micro to the meso level and the meso to the macro level require radical shifts in an organization's mindset, shifts that vary with each company. Not all organizations start at a single level. Some launch innovations directly at the meso level by using business model innovation to implement sustainability in their supply chains. Lifestraw, a personal water filter company, is an excellent example of an organization that starts from meso level innovation. Its business model focuses not only on product and process innovation but also on meso level innovations that include unique distribution, societal, and financial innovation. Lifestraw targets markets that do not have access to clean water; thus, carbon-offset systems become a financial option. So, while this framework shows innovation and SSCM practices implementation as a sequential process, some ambidextrous organization can straddle more than one level. The ambidextrous organization is one that has a specific business unit or department experimenting with a more advanced stage of innovation while the rest of the

organization maintains a conventional approach. The ambidextrous approach to sustainability provides organizations flexibility and better chances for survival in the market (Van Looy, Martens, & Debackere 2005).

At the macro level of innovation, organizations perceive their sustainability initiatives as being part of industry and society, not distinct from them. At this level, innovations are designed and created to be collective and part of the system, and they are more break-through than incremental. System innovation is a great macro level innovation that includes not only a firm's supply chain partners but also includes competitor and other environmental actors. Because the concept is so broad, only very few new sustainable practices qualify for this level.

Rather than focusing only on innovations of limited scope, organizations can benefit from a broader new technology or process in their supply chains. Organizations may see opportunities to have all entities in their supply chains comply with sustainability standards, or serve new markets with sustainable products, or become new entrants with business models based on creating sustainability in their holistic operations.

Regarding the discussion above, the role of innovation in SSCP varies with the level of innovation, and firms need to introduce many different innovations and practices in quick succession. This could mean developing more than one version at once to comply with and achieve sustainability goals in the marketplace and learn where to focus their energies next. In short, companies need to be highly adaptable, so their SSCM practices need to be highly adaptable too. Firms tend to have diverse patterns while implementing SSCP.

RESEARCH METHODOLOGY

To achieve the objective of this the study, an exploratory qualitative research approach was adopted. The advantage to this approach is that researchers are able to obtain participants' stories and their insights into the phenomenon under study. It is because we want these stories and insights about firms' sustainability efforts that we employed the case study approach. One other advantage to this approach is that the case study methodology helps researchers explore a confined system of a case or multiple case by utilizing in-depth data collection from information sources rich in context (Creswell, 1998). Moreover, this methodology enables researchers to not only question the concepts and phenomenon itself but also provide a rich, in-depth context (Yin, 2003; Stake, 2013). The multi-case study method utilizes analysis within cases and between cases, and it produces a literature referred to as "creative reframing" (Eisenhardt, 1989). Researchers are interested in case studies because of both their commonality and uniqueness. To date, only limited empirical work has been done that draws on qualitative data to explore the relationship between innovation and SSCM. The multi-case study approach was utilized for this research because it provides robust methodological support that can generate new theories and detailed information (Eisenhardt, 1989; Ellram, 1996) that can help researchers explain the symbiotic relationship between sustainability and innovation. This

comparative, multi-case study is designed to explore how organizations in different industries develop and implement sustainable practices in their supply chains through the innovation creation process.

Case Selection

We used established criteria from the literature to select the companies for this study. The companies were chosen from multiple industries to identify innovation and SSCM patterns, and only companies that have implemented sustainability in their supply chains were recruited to participate. Multiple industry perspectives may reveal different patterns due to both the nature of the specific industry and the similarities among industries. External sustainability indices and rankings will be used to ensure that the selected companies have developed some form of sustainability practices. We consulted the following sources to select participant companies: (1) The Dow Jones Sustainability Index (DJSI). This index monitors the sustainability initiatives and performance of more than 500 top sustainability companies around the world; (2) The MSCI/KLD Index/Ranking. The MSCI/KLD is a global index that rates 6000 companies (11,000 with subsidiaries) based on their sustainability efforts and performance; (3) Global Reporting Initiative (GRI). The (GRI) is a comprehensive, global database that includes sustainability reports by companies and organizations about the economic, environmental, and social impact caused by their everyday activities.

In this study, 30 companies from eight different industries were contacted and 13 of them from seven industries agreed to participate. Two companies from each industry were selected to analyze the industry effect on the phenomena. At the end of case selection one participating company was eliminated from analysis due to a non-existing pair in the same industry. All companies are publicly traded global companies. U.S. and global companies that are based in the U.S. will be selected on the basis of research interest and ease of accessibility. Interview respondents were selected based on their involvement in innovation, sustainability implementation and adoption in their supply chain management.

Data Collection

The unit of analysis for this study is the individual organization, and data for each participant company is gathered from multiple sources: (1) semi-structured interviews, (2) internal company documents, and (3) publicly available online data (e.g., annual financial and sustainability reports). Semi-structured interviews enable the researchers to gather detailed information about the relationship between innovation and SSCM, the subject of our research, and provide answers to our research questions (Patton, 2005). Rigorous guidelines and steps will be followed in case selection, data collection and the data analysis process (See Figure 1). Combining multiple data sources enabled an in-depth investigation of sustainability (Yin, 2008) that includes current practices of SSCM and relevant innovation in the organizations being

studied. (Due to space limitation we could not include a copy of the interview protocol in the paper.)

After the selection of case participants, each interviewee was contacted by email and/or telephone (see Table 4 for the overview of the companies that participated in our study). From each company, two titles were identified to be part of the research. All the participants were knowledgeable about the research topic and have experience on the topic in their company. Titles of respondents vary in most cases. Regional and global supply chain directors/managers, lead sustainability officers, sustainability directors, lead R&D researchers/engineers and purchasing managers are the titles of the participants. In this stage, researchers obtained information about interviewees' willingness to participate in the study and scheduled an interview with interviewees. In this first communication, participants were informed about the study and interview process.

DATA ANALYSIS

Reliability and Validity

Scholars have criticized the validity of qualitative studies and their methodology, but researchers can utilize numerous validation methods to increase a study's reliability and rigor (Creswell & Miller, 2000). In this study, a triangulation method was used to establish credibility and validation. Data were triangulated by using several forms of data collected such as literature review, media interviews, and other documents. In addition, transcripts were rated by two researchers and patterns were identified based on their agreements. One of the most severe limitations of case research is that findings cannot be generalized due to the small number of cases. On the other hand, case methodology provides deep insights of unexplored phenomena that cannot be achieved by other methodologies.

Within Case Analysis

Pharmaceutical Industry

In this study, we selected two pharmaceutical companies to analyze the phenomena (see Table 4 for the overview of the companies that participated in our study). Industry has a unique nature, R&D development budgets are very high, and regulations imposed by both government and industry are strict. The cases studied in this research are major players in the industry. Both companies are market leaders in sustainability and members of the Pharmaceutical Supply Chain Initiative (PSCI) organization, which aims to support pharmaceutical suppliers in their efforts to operate with consistent quality while remaining compliant with industry standards of sustainability and consistent with industry expectations regarding labor, health and safety, environment, ethics, and management systems.

Firm A leads the Over the Counter (OTC) market in US and captures the majority of medicines. The division operates as headquarters and a research center for their products. North America office controls majority of the functions such as product development, manufacturing and supply chain activities. The office also controls the operations and manufacturing facilities in Mexico.

Economical sustainability is the main driver for Company B's implementation of sustainability practices in its supply chain. Lean practices, internal supply chain practices, and waste management practices are the main economical practices that have been implemented in its supply chain. The firm eventually realized that lean practices, resource, and waste management practices improved its environmental sustainability. Interviewees added that most of the innovation and practices are relevant to single product and process levels, though some, such as lean practices, have a broader scope. The firm established lean practices and worked with its supply chain players so that it affects a broader range and magnitude of sustainability practices. The social aspects of sustainability and social practices were not well developed until recent years, but Company B now has new social initiatives that capture the social aspects of sustainability.

Medical Device Industry
As in the pharmaceutical industry, innovation and improvement are crucial in the medical device industry if it is to survive and be successful. Innovation creation and R&D activities help the firm increase its efficiency and improve product and process performances. On the other hand, the medical field has very strict regulations which may slow down innovation creation.

The companies C and D emphasize the process innovation that will enable it to reach their sustainability goal. Water consumption, efficient material management, and waste management are some of the major improvements that enable companies to create operational advantage. Additional improvements in production processes and sustainable sourcing with green manufacturing facilities have improved production's sustainability performance.

The quality of life of both employees and the community is important in this industry. Firm C, for example, has continuous improvement programs that promote employee health and safety as well as community wellness. These programs are the major social sustainability efforts undertaken with the aim of increasing Company C's sustainability initiatives.

Confectionary
In this industry, companies E and F implement several sustainability practices to reduce their environmental impact such as reducing carbon emission waste, water consumption, and packaging material. Supplier development is another practice they implement to promote both environmental and social sustainability. Innovation in processes and their supply chain, the company believes, is the key to reaching sustainability goals. The companies in the industry mainly focus on process and social innovation to increase sustainability initiative.

Advanced Energy Storage and Solutions
The companies in the advanced energy storage and solutions industry suffer from a poor sustainability image due to the materials they use in their products. But the industry also has the highest recycling rate compared to other industries. Advertisements, recycling educations, and buyer-integrated recycling programs make the industry one of the top performers in recycling.

The companies implement continuous improvements, and they pursue new technological advancements in battery technology. These innovations range from enhancements of existing products with higher reliability and efficiency rates, to innovative service solutions, and to transformative technologies that will change the power solutions of the future. For example, Company H's innovation strategy is based on delivering better products that reduce costs, extend product life cycles, and reduce environmental impact. By recycling batteries, the firm decreases its costs significantly and it tries to impose the same sustainable practices on its suppliers, so that they too can achieve a lower environmental footprint while still making money. Waste management and lean manufacturing are the other practices that the company actively implements to promote sustainability.

Heating and Energy Solutions
Heating and energy solutions industry is an industry that has a direct effect on sustainability issues. The industry is evolving around new energy sources, so efficiency is becoming a key factor in the heating and energy solutions industry.

Company I, for example, engages in all three aspects of sustainability. The major activities that the company implements for environmental and economic sustainability are material management, recycling, eco-product, waste management, process design, and lean practices. The company also focuses on elevating the quality of life of its employees and society by implementing health and safety practices and educational programs.

Small Electronics
The small electronics and personal electronics industry is growing drastically due to new technological developments. Increasing efficiency due to automation and lower labor costing developing countries support the rising trend of small electronics. The industry is known for fast-paced product introduction and technological developments. The downside of new product introduction is growing in sustainability concerns. Increased energy consumption due to high use of electronics, electronic waste, limited recycling programs, and some health and well-being effects of small electronics challenges the sustainability of the industry. Both companies 'emphases are on their environmental and manufacturing processes. To achieve these environmental goals, firms K and L implement new practices and technologies that enable them to reuse and recycle materials and reduce waste from their operations. The scope of recycling and waste management is generally limited (micro level) and is usually implemented in both companies in this study.

Between Case Analysis

Each case described above has gone through a unique process of innovation and sustainability in its operations. This evolutionary process and the relationship between innovation and SSCM practices and the levels of innovation are captured in this study. We now discuss how each of these areas of comparison plays out in these cases.

The results of the cross-case analysis showed that the innovation creation process varies based on companies' resources and product types; however, some innovation patterns are similar. The companies emphasize innovation because of market conditions and economic factors, and they pursue innovation and sustainable practices with the aim of cutting their long-term operational costs. Environmental and economic practices such as waste management and quality management are the most common practices across industries and the cases studied. Only a few of the cases actually innovated to implement social sustainability practices to impact society and improve the quality of life in their communities.

Some industries are highly regulated, so product development in such industries as pharmaceuticals and medical devices can take years. Those industries tend to focus on

product/process innovation at the micro level, quality and lean management practices at the meso level, and social practices at the macro level, such as social initiatives in developing countries.

DISCUSSION

This research investigated innovation creation and the implementation of sustainable supply chain management practices to answer the research question: “What specific innovations do companies generate to implement SSCM practices effectively in specific industries.” While companies create innovations to implement sustainability in their supply chains, there are some specific innovations that outshine the others in SSCM practices implementation in different industry condition. All the cases studied have participated in various activities that developed new, innovative sustainable processes as well as products. The interviews allowed us to understand the innovative activities in different industries and firm settings. Implementing sustainability practices has also led companies to the development of diverse innovation mixtures from a multi-level perspective. Companies have focused on micro innovations to improve their current processes and products, and they have focused on meso innovations mainly to increase supply chain sustainability and efficiency. Results showed that macro level of innovations are rare, almost non-existent in current market conditions, and they are currently limited to social aspects of sustainability such as society welfare practices in the markets of developing countries.

As noted earlier, a multi-case research approach was utilized to investigate our research question with a relevant theoretical framework. The results indicate that organizational learning, absorptive capacity, and an ambidextrous orientation of the firms have significant effects on innovation and SSCM practice implementation and management. Firms vary to some degree in management approaches and exploration-exploitation ratio; however, all sustainability-oriented firms follow an ambidextrous strategy. Firms with high revenues and R&D budgets tend to manage implementation simultaneously and effectively, and they aim to pursue the original innovations that guarantee technological advances in the future. Given finite resources, firms need to balance exploration and exploitation during the process of innovation and implementing SSCM practices. Otherwise, they fail to develop both new sustainable products and processes for market launching and original technologies for sustainability implementation and its outcomes while continuing their current operations. However, some industries such as pharmaceuticals and medical device/ technologies, have been significantly affected on implementation processes due to higher regulations and industry requirements.

Cross-case analysis helps researchers identify uncommon innovation patterns, practices, and development processes. The advanced power storage and energy solutions industry is unique in its nature. Products and sourcing are standard, mature, and unsustainable. The main product can be one of the most toxic products that every consumer uses every day such as batteries. Furthermore, interviewees unconventionally expressed their concerns about their products’ future because current technology has reached 95 percent capacity. But market demand is

growing due to increasing use of electronics, hybrid cars, and new energy solution options. All these factors encourage battery producers to be more innovative in their internal and external processes and adopt such practices as product life cycle analysis, recycling/waste management, and lean practices within the company and throughout the supply chain; innovations yield higher efficiency and lower costs.

> *Proposition 1: In industries with mature products, where market demand for new products is high, companies are more likely to create internal and external process innovations that lead to economic sustainability.*

In some industries, products must align with sustainability demands of the market. In this study, two companies in the heating/energy solution industry are distinctive from others. These two companies must be sustainable due to characteristics of the products they manufacture. Customers of this industry seek the energy efficiency that will reduce costs and be greener. Because they produce sustainable products, the companies are aware that social sustainability practices are needed to achieve complete sustainability and increase customer satisfaction, and these factors are the ones that ultimately motivate firms to emphasize sustainability in all three aspects.

> *Proposition 2: In industries with sustainability-oriented products, companies tend to emphasize all three dimensions of sustainability along their supply chains.*

Cross-case analysis reveals that companies in innovative industries have different innovation creation patterns and prioritize their innovation choices based on the characteristics of the products and industry. In this study, for example, small electronic companies chose to implement innovations that emphasize eco-product design, product life cycle analysis, and process efficiency by employing lean and quality management practices. In other words, the industry is dynamic, so firms must come up with new products frequently. Therefore, these firms channel their sustainability efforts into the product and process level.

> *Proposition 3: In industries with innovative products emphasize micro and meso level innovations rather than macro innovations. These companies are more likely implement product and internal/external process practices than social practices.*

Overall, this research revealed that the pattern of innovation creation and the implementation of SSCM practices in the studied organizations differed based on the industry in which they are operating. Future studies can be conducted to see if these results hold for other organizations in different industries.

Little research has been performed using a survey methodology to study sustainability in supply chain management. After developing appropriate measurements, the use of survey methodology could provide greater insight and generalizability into how innovations are created

and sustainable practices are implemented in companies and their supply chains which by expanding this research could be used to verify results of this study.

In addition, further research is needed to assess recent changes in sustainability as well as industry and market conditions. Involvement in sustainability has increased substantially since early 2000, and more stakeholders are demanding that organizations be sustainable in their operations, especially in their supply chains. As a result, companies are driven to sustainability by business needs versus just “being good.” Since most firms have been implementing sustainability for over a decade, applications of sustainability may be less challenging in some cases. Future research is needed to study sustainability within supply chains to determine if they keep innovating and continuously improving, as they stated in the interviews.

LIMITATIONS AND CONCLUSION

As with all empirical studies, this one has several limitations that must be considered when interpreting the above findings. To begin with, we address several issues with the research methodology used. In the studies that use a multi-case qualitative approach, the results of the study are based on researchers’ interpretation of the data. As a result, researcher bias can inevitably be present. To mitigate this bias, two researchers transcribed and analyzed the data.

The study was also limited by the number of companies selected for analysis. These companies are large, global organizations considered leaders in sustainability. They are involved in industries that are innovative and amenable to sustainability, and they have a history of being sustainable and addressing environmental, economic, and social issues. Different results may have been found if the following types of companies had been used: smaller-sized companies, companies in sustainability-averse industries such as oil or mining industries, companies with weaker sustainability standings, and companies in less regulated and developing countries.

The research data were also limited based on the relatively limited number of interviewees for each case. The participants were all related to sustainability and supply chains in upper-level management. The results may have been different if a larger number of participants was included in the study or if participants from different functions of operations had been included. Finally, the study only utilized a case methodology to explore phenomena, and this limitation may create some shortcomings in generalizing the results in different company settings.

Implementation of sustainability in supply chains is a complex process. It is affected by several factors such as industry, customer demand, suppliers, government and industry regulation, and financial markets. It also requires full collaboration within organizations and initial investment. This research provided insights into the relationships between innovation and SSCM practices and their complex implementation patterns in various industries. The findings of this research contribute to ongoing sustainability research that examines the influence of innovation creation that ultimately may affect firms’ sustainability outcomes.

ABSTRACT

This paper considers the impact of institutional uncertainty on supply chain quality management (SCQM). The influence of institutional environments on SCQM practices is important to understand as lengthening supply chains cross international borders and are subject to increasingly complex institutional jurisdictions. Generally, SCQM facilitates stability of resource flows in institutional contexts. As uncertainty increases, SCQM practices are proposed to shift from abiding postures to those that evade and alter unstable institutional settings. An implication is that effective inter-organizational quality management requires capability for coping with political and legal instabilities that influence quality-related aspects of resource exchange between supply chain members.

KEYWORDS: Quality management and systems, Relationship management, Innovation Process, Contracts, Outsourcing, Supply chain management, Conceptual modeling

INTRODUCTION

Supply chain quality management (SCQM) is a systematic approach to performance management involving the coordination and integration of business processes among upstream sellers and downstream buyers to create value and achieve customer satisfaction (Foster, 2008; Robinson & Malhotra, 2005). SCQM is essential to integrating supply chains as it spans organizational boundaries to govern quality-related attributes of transactions between supply chain members (Flynn & Flynn, 2005; Ford, 2015; Terziovski & Hermel, 2011).

Although modern supply chains operate in a variety of environments, research concerning external contexts that shape SCQM practices has only recently captured scholarly attention (Foster, 2011). For example, Ford (2015) proposed that the intensity and nature of SCQM was contingent on the degree of uncertainty present in supply chain environments. Generally, the more uncertain the environment, the greater the SCQM intensity required to stabilize the quality of resource exchange between supply chain partners. Empirical investigations into antecedents of supply chain integration (e.g., Wong & Boon-itt, 2010) offer confirming evidence in this regard.

Research that investigates SCQM as a function of the external environment can be enriched by extending the uncertainty construct into the institutional realm. Institutional uncertainty should play a significant role in shaping inter-organizational quality management

activities. In the context of supply chain management, institutional uncertainty fosters unpredictability and doubt about the political and legal systems in which supply chain managers operate. Political and legal systems are essential components of supply chain environments because institutions therein set "the rules of the game" for everyday market exchange and its governance (Baumol, 1990; Williamson, 2000).

Although they generally change slower than everyday market contexts, institutional environments provide evolving backdrops for SCQM practices that are important to understand, particularrly as lengthening supply chains cross international borders and are subject to increasingly complex institutional jurisdictions (Foster, 2011). Uncertainties about institutional environments such as those brought about by regime change and regulatory revision should prompt managers to adjust their SCQM practices to better stabilize resource flows (Ford, 2015). The nature of those adjustments constitutes the primary focus of this paper.

This study extends research into the external context of SCQM by considering the impact of institutional uncertainty on SCQM practices. The paper proceeds as follows. First, Williamson's (2000) hierarchical model of economic institutions is employed to link previous work that conceptualizes SCQM as a means for stabilizing resources flows in uncertain environments to the institutional context. Then, drawing from concepts developed by Henrekson and Sanandaji (2011) in the domain of institutional entrepreneurship, propositions are developed that frame SCQM as a progression of postures meant to abide by, evade, or alter governing institutions as uncertainty increases. Finally, these propositions are summarized and discussed along with their theoretical and practical implications. A primary contribution of this work is the idea, largely novel to the quality literature, that effective inter-organizational quality management requires capability for responding to, and in some cases altering, political and legal systems that influence quality-related aspects of resource exchange between supply chain members.

GENERAL RELATIONSHIP

Because they are rarely self-sufficient, organizations must interact with their environments to acquire resources for survival and growth (Lawrence & Lorsch, 1967; Pfeffer & Salancik, 1978). Conditions of interdependence arise as organizations rely on each other for production and trade of important resources in supply chains (Handfield, 1995). Maintaining orderly resource flows from supply chain partners thus becomes a primary organizational objective (Katz & Kahn, 1978). Unfortunately, operating environments are prone to uncertainty that challenges the stability motive (Emery & Trist, 1963; Pfeffer & Salancik, 1978; Weber & Meyer, 2014). As uncertainty increases, interdependent organizations are likely to establish negotiated environments where exchanges are governed by various mechanisms aimed at stabilizing resource flows (Cyert & March, 1963; Williamson, 1991; Oliver, 1991; Paulraj & Chen, 2007; Wong et al., 2011).

Central to the governance of exchange among supply chain members is managing the *quality* of resource flows (Flynn et al, 2010). Poor quality upsets resource exchange (Ford, 2015). For example, low quality shipments might be rejected outright or create subsequent problems in the supply chain that hinder trade. To stabilize the quality of resource flows, managers develop sets of practices—supply chain quality management (SCQM) practices—that govern quality-related dimensions of supply chain exchange.

Like their intra-organizational counterparts (Flynn et al., 1995), SCQM practices can be categorized as core or infrastructure based (Ford, 2015). Core SCQM practices are formal activities that enhance uniformity and reduce quality-related upsets in resource flows between supply chain partners. Examples of core SCQM practices include quality incentive contracting

and audits of supplier facilities. Infrastructure SCQM practices are informal activities that strengthen relationships between supply chain partners. Interorganizational problem-solving teams and joint customer/supplier planning groups exemplify infrastructure SCQM practices. Table 1 displays representative SCQM practices associated with the various categories of the Baldrige Criteria for Performance Excellence (CPE).

Table 1: Traditional Supply Chain Quality Management Practices
Adapted from Ford (2015)

Baldrige CPE Category	Representative Practice	Quality Practice Orientation
Leadership	• Senior leader participation in inter-organization quality initiatives • Development of cross organization visions and values • Senior leader information sharing between organizations	Infrastructure
Strategic Planning	• Joint customer:supplier long range planning • Strategic initiatives that involve collaboration with supply chain partners	Infrastructure
Customer Focus	• Engagement with customers in market listening and learning processes • Customer relationship and complaint management • Co-development of product and service specifications	Core/Infrastructure
Information & Analysis	• Extensive customer and supplier databases • Cross organization data sharing • Supplier process capability assessment	Core
Workforce Focus	• Inter-organizational problem-solving teams • Customer-supplier training programs • Incentive systems that reward inter-organization collaboration	Infrastructure
Process Management	• Supplier quality assurance system registration • Supplier selection and evaluation processes • Joint product and process design	Core

- Co-managed work systems and processes

Because risk of quality problems increases as environments become less stable (Sitkin et al.,1994), SCQM efforts are likely to intensify in uncertain contexts so that quality of resource flows can be stabilized (Ford, 2015). Moreover, SCQM practices should assume different orientations depending on whether volume or technological uncertainty is present in the environment (Ford, 2015). Volume uncertainty impairs ability to accurately forecast quantity requirements in supply chain relationships (Geyskens et al., 2006). When volume uncertainty is present, managers are likely to orient SCQM toward core practices, such as quality contracting and audits (e.g., Gray & Handley, 2011; Sroufe & Curkovic, 2008), in order to reduce the likelihood of interorganizational quality problems (Zhu et al., 2007). Technological uncertainty stems from unpredictable standards or specifications, or from general conditions of rapid innovation or technological ferment that reduce ability to forecast technical requirements in supply chain relationships (Benner & Tushman, 2003; Geyskens et al., 2006). When technological uncertainty is present, SCQM orientations shift toward practices that build relational infrastructure and interorganizational capacity for cooperation (e.g., Dyer & Singh, 1998; Geyskens et al., 2006; Handley & Gray, 2013; Heide, 1994; Kanter, 1994) to increase the likelihood that quality of resource flows will be maintained in turbulent supply chain settings.

While volume and technological uncertainty have been long been seen as important dimensions of external environments (e.g., Walker & Weber, 1984), uncertainty stemming from institutional forces is likely to shape supply chain contexts as well (Williamson, 2008). Williamson's (2000) hierarchical model of economic institutions (Figure 1) is useful for conceptualizing institutional dimensions in supply chain environments. The bottom level of the hierarchy, L4, represents markets, or "the game." This is the level of everyday resource allocation in supply chains. Economic actors play the game by making decisions about prices, quantities, incentives, quality, and other factors that drive market exchange. The dynamic nature of markets keeps this level in a constant state of flux.

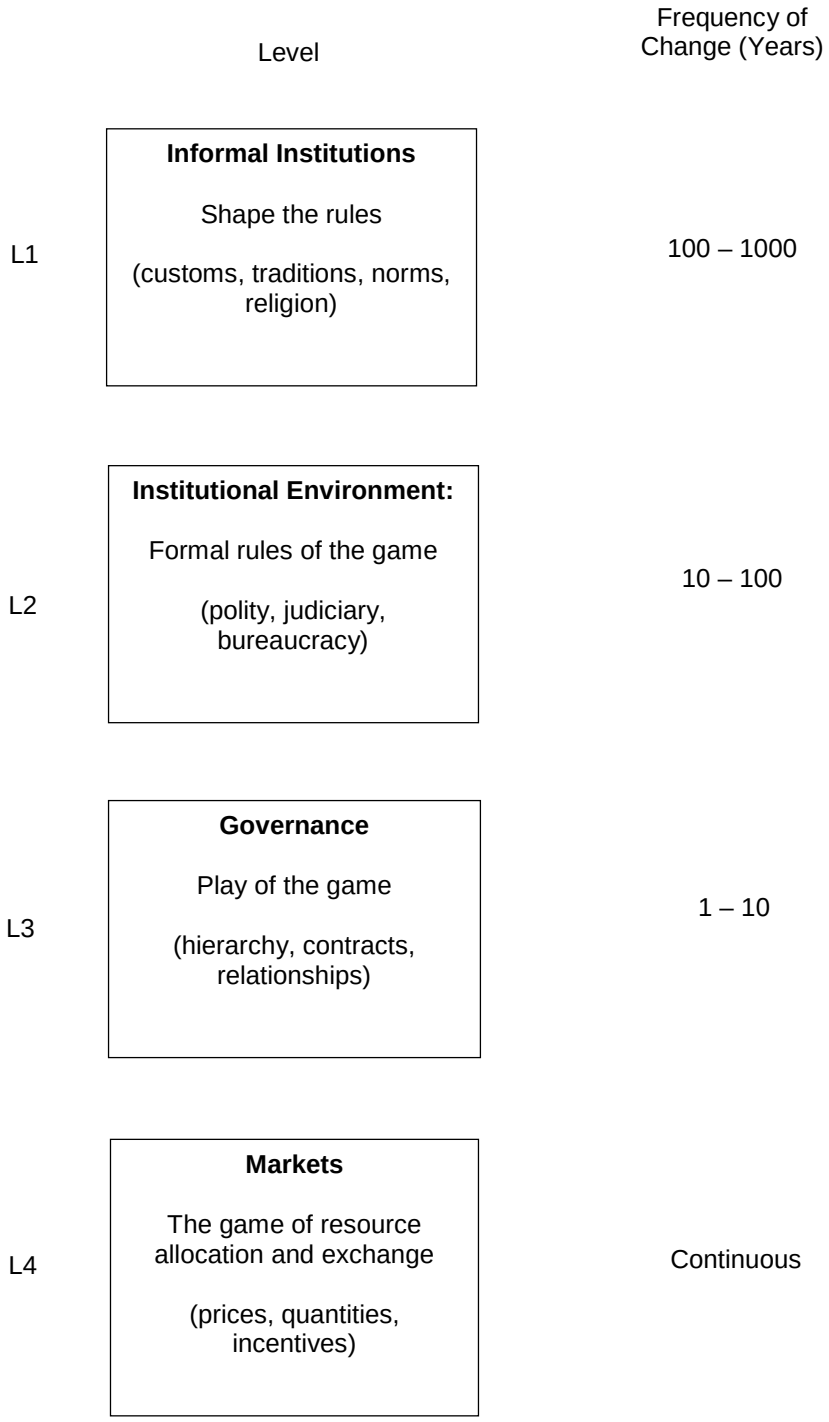
One level higher in the hierarchy, L3, involves mechanisms that buyers and sellers employ to govern resource exchange. These mechanisms direct "the play of the game" and include contracts and organizational hierarchy that assist in stabilizing resource exchange. Because they serve to maintain stable resource flows between supply chain partners, SCQM practices such as those noted in Table 1 can be seen as methods of exchange governance associated with L3. The L3 environment is less dynamic than L4, with important changes occurring perhaps over one- to ten-year time spans (Williamson, 2000).

Presiding overhead is the institutional environment, L2. The institutional environment establishes the formal "rules of the game" for the lower levels of the hierarchy and, when necessary, enforces those rules as well (Baumol, 1990). Because the rules important to market exchange generally concern property rights and contract law, L2 traditionally involves political and legal systems as well as acts of administrative bureaucracy. The institutional environment changes slower than lower levels (Dimaggio & Powell, 1983; Williamson, 2008). The institutional environment is influenced from above by an L1 level involving informal customs, norms, and traditions that evolve very slowly and are generally not subject to economizing behavior by market actors.

Uncertainty increases at the institutional level when doubts surface about the rules of the game or their enforcement. This uncertainty may stem from various sources. For example, voluminous laws and regulations may be difficult for supply chain managers to understand. Newly elected regimes may foster reservations among practitioners about how rules will be interpreted and enforced. Varied legal opinions rendered by courts may create confusion about

how laws will be applied toward particular exchange relationships between supply chain members. Slow moving bureaucracies could reduce confidence in the content and timing of new regulations as well as the disposition of contests over existing regulations.

Figure 1: Hierarchy of Economic Institutions
Adapted from Williamson (2000)



It is uncertainty associated with the institutional level (L2) that is the primary focus of this paper. How uncertainty at the L2 level shapes SCQM is discussed below.

SCQM RESPONSES TO INSTITUTIONAL UNCERTAINTY

Because institutional uncertainty can be conceptualized as originating at a level that presides over everyday environments facing supply chain managers (Williamson, 2008), it is reasonable to question whether it constitutes a unique problem for inter-organizational quality management. Perhaps institutional uncertainty is merely an antecedent of the volume and technological uncertainties that supply chain managers routinely cope with. For instance, doubts about a newly elected regime's regulatory stance at the institutional (L2 in Figure 1) level might create volume uncertainty in a supply chain to be dealt with actions at the governance (L3) or market (L4) levels. If institutional uncertainty merely trickles down to shape everyday uncertainties experienced by supply chain managers, then there may be little that is interesting about the situation from a theoretical standpoint.

However, institutional uncertainty *does* present unique challenges to supply chain managers. One issue involves coping with time lags between institutionally caused disturbances in the environment and everyday supply chain effects. For instance, it may take several years before the regulatory preferences of an incoming political regime manifest in routine volume or technological uncertainties. Uncomfortable with waiting out the process and its potentially undesirable consequences, supply chain managers might consider preempting the lagged effects with near term actions that respond to institutional forces directly and provide clarity sooner rather than later.

A larger issue involves the effect of institutional uncertainty on SCQM practices themselves. Rather than indirectly influencing everyday supply chain uncertainties, instability at the institutional level could motivate managerial responses that differ from the stable of practices in Table 1 designed to cope with volume or technological uncertainty.

Insight into the shape of such practices can be drawn from research in institutional entrepreneurship. When facing institutional uncertainty, managers can respond entrepreneurially in three general ways (Henrekson & Sanandaji, 2011): they can *abide* by the existing institutional order, they can *evade* its influence, or they can *alter* the institutional environment in some way. SCQM practices that address institutional uncertainty can be viewed in a categorically similar fashion as a function of the general level of perceived institutional uncertainty present.

Low Institutional Uncertainty

When institutional uncertainty is low, managers possess little doubt about the compatibility of their SCQM practices with existing institutions. Institutional rules that influence SCQM practices, such as government-enforced product quality and safety standards, are generally understood and uncontested. Because the institutional environment (L2 in Figure 1) is viewed as relatively benign, managers are likely to abide by the existing institutional order. Maintaining the status quo under such circumstances supports the stability motive and preserves resource flows (Oliver, 1991).

With the higher level (L2) institutional environment perceived as stable and non-threatening, supply chain managers are likely to focus attention on instabilities emanating from lower levels of the hierarchy (L3 and L4). Volume and technological uncertainties prone to impact everyday resource exchange are easier to recognize, and managers can draw from their stable of traditional activities appearing to Table 1 to orient SCQM toward addressing them. High levels of volume uncertainty will prompt core SCQM orientations that emphasize formality while high levels of technological uncertainty will engender infrastructure SCQM orientations that favor informal relationship building (Ford, 2015).

When institutional uncertainty is perceived as low, the cost of bearing that uncertainty by assuming an abiding posture in SCQM is presumed to be low as well. Managers will favor the status quo and draw from their familiar set of SCQM practices to maintain resource stability in the event of volume and technological uncertainty.

Proposition 1: At low levels of institutional uncertainty, organizations will prefer abiding postures composed of traditional core and infrastructure SCQM practices.

Rising Institutional Uncertainty

As institutional uncertainty rises, doubts increase about the legal and regulatory backdrop that establishes the rules for everyday supply chain exchange. Abiding SCQM postures that worked well in stable institutional environments become problematic for supply chain quality managers because maintaining status quo measures when institutional environments are in flux can be risky. Rules thought to govern routine supply chain exchange may no longer apply, rendering the stock of traditional SCQM activities appearing in Table 1 ineffective. Moreover, because abiding postures reinforce the prevailing institutional order (Henrekson & Sanandaji, 2011), supply chain managers might fear that they will fortify undesirable institutions in-the-making if they maintain status quo SCQM measures.

Because institutional uncertainty increases the cost of keeping what has worked in the past (Bylund & McCaffrey, 2017), supply chain managers will search for alternative arrangements that will stabilize resource flows and their quality despite institutional turbulence. Due to the cost of change, however, managers will generally be reluctant to change practices too radically. Therefore, when they begin to sense that institutional uncertainty is rising, managers are likely start with incremental changes that still constitute an abiding posture. Early attention will be paid to the existing stable of SCQM practices (Table 1) and how its application can be modified to better facilitate quality of resource exchange. In particular, managers are likely to reduce their reliance on core SCQM orientations. By definition, rising institutional uncertainty decreases confidence in rules and regulations that shape governance of technical quality practices. For example, doubts about how contracts might be enforced by a new legal regime could reduce the perceived utility of quality contracting and quality auditing. It follows, then, that core SCQM orientations aimed at governing formal aspects of quality transactions will appear less attractive.

Instead, managers will increasingly favor infrastructure SCQM orientations as institutional uncertainty grows. Infrastructure SCQM practices such as interorganizational steering committees and problem-solving teams, and customer/supplier quality training programs, involve informal exchanges that are generally not legally enforceable. As such, infrastructure SCQM practices generally fall outside the purview of institutional control. Moreover, infrastructure SCQM practices focus on relationship-building between supply chain members. These relationships build governance mechanisms grounded in trust, joint action,

and procedural fairness that establish strong alliances over time (Chen & Paulraj, 2004; Dyer, 1997; Poppo & Zenger, 2002). Because they do not depend on particular rules or regulations, infrastructure SCQM practices can endure large institutional shifts while encouraging mutually beneficial collaboration between supply chain members on quality matters. By shifting toward infrastructure SCQM orientations, managers can develop relational governance mechanisms that stabilize resource flows in turbulent institutional settings.

Proposition 2: As institutional uncertainty increases, abiding will occur in the form of greater orientation toward infrastructure SCQM practices.

While helpful, greater use of infrastructure SCQM orientations is unlikely to be completely satisfactory as institutional uncertainty continues to rise. Inter-organizational relationship building can improve agility in unstable settings, but it underutilizes specialized assets that have been developed for formal governance of the quality of resource exchange (Handley & Gray, 2013). Quality contracting and auditing capabilities, for example, may depreciate from lack of use as managers reduce core SCQM orientations. As such, supply chain managers will seek ways to more fully employ SCQM assets by evading the influence of institutions perceived to be in a state of flux.

Evading postures are attractive because they manifest in activities that occur at the familiar, everyday levels of supply chain exchange, L3 and L4. Change at these levels is viewed by managers as relatively inexpensive as it usually requires extending existing practices to new domains that evade the reach of undesirable institutional forces. Examples of evasion at the L4 level in the context of SCQM include developing relationships with customers and suppliers deemed to be less affected by institutional turmoil in particular markets (e.g., “offshoring”), and intensifying market listening posts to extract more quality-related information in noisy institutional settings.

Evading at the L3 level involves modifying governance structures that stabilize quality of resource exchange despite institutional uncertainties that cast doubt about overarching rules of the game. For instance, supply chain managers might be uncertain about the level or direction of government-imposed quality standards perceived to be in a state of flux, or, under the auspices of a new political regime, managers might distrust the legal system’s ongoing capacity to justly enforce contracts.

Successful evasion often requires more collaboration among trading partners. A trade group, for example, might sponsor a committee of industry representatives to develop quality-related standards for industry use. Self-sanctioning contracts and voluntary quality audits based on trust and social control might replace legally enforceable contracts. It should be noted that greater reliance on collaboration during evasion suggests that the increased emphasis on infrastructure SCQM orientations proposed by Proposition 2 above may be a necessary antecedent of achieving evading postures

Proposition 3: As institutional uncertainty increases, SCQM practices will shift away from abiding postures and toward evading postures.

Abiding and evading SCQM postures are preferable because they permit managers to operate on familiar levels (L3 and L4), thereby keeping cost of change low. As institutional uncertainty grows, abiding and evading postures may not sufficiently stabilize the quality of resource exchange. For example, revision of an influential quality assurance standard with mandatory requirements linked to supply chain resource exchange might be perceived as too risky to leave in the hands of government bureaucrats alone. Under such circumstances,

managers might seek to alter their institutions in order to directly shape the formal rules of the game.

Altering is generally the most expensive posture for coping with institutional uncertainty because it requires managers to operate on L2—a level more familiar to politicians and bureaucrats than to most supply chain managers. As such, it could be viewed as a "last resort" approach generally pursued when other measures are deemed ineffective in suitably stabilizing the quality of resource flows in unstable institutional settings.

To keep altering costs low, managers will first prefer indirectly influencing the direction of institutional policy. For example, supply chain members might work through a trade group to convey their preferences with respect to quality regulation to government officials. The trade group channel is particularly attractive because it keeps managers in their familiar operating environment while agents lobby on their behalf. Moreover, the cost of retaining lobbying agents can be split among several supply chain partners. Campaign contributions, when done within legal limits, constitute an additional way for supply chain members to legitimately influence policy.

In some cases, however, the indirect approach may be insufficient. Agents may be incapable of accurately conveying the preferences of their supply chain principals, particularly if those preferences are highly technical in nature. Uncertainty in the institutional environment may also be such that managers doubt that their preferences, even if perfectly conveyed, would be adequately reflected in formative policies. Under such circumstances, altering postures will demand direct involvement of supply chain managers in institutional processes. Direct involvement is likely to begin in part-time or temporary capacities to keep costs low. For example, joint committees composed of industry participants and government bureaucrats might convene to draft the new quality assurance standard discussed above. Supply chain participants might also volunteer particular managers to serve in unelected positions of authority to oversee the development of governing rules and their subsequent enforcement.

Proposition 4: As institutional uncertainty increases, SCQM practices will shift away from abiding postures and toward altering postures.

Extreme Institutional Uncertainty

If institutional uncertainty rises to extreme levels where most rules of the game and their subsequent enforcement are in doubt, then trade between supply chain partners may decrease as the instability of resource exchange drives many operators to take transactions off the market through vertical integration (Williamson, 1991). Bringing transactions in-house permits better control over quality and reduces the need for both formal and relational governance mechanisms because disputes are subject to resolution by internal forbearance rather than by external court order (Williamson, 2008). Vertical integration can be seen as a form of evading where taking transactions off the market reduces the need for inter-organizational quality management and is replaced with intra-organizational quality management.

Proposition 5: If institutional uncertainty reaches extreme levels, then some evading in the form of vertical integration will occur that effectively reduces intensity of SCQM.

However, vertical integration may not completely insulate even diversified organizations from intrusion by institutional forces. Because few organizations become completely self-sufficient, it is likely that even vertically integrated firms must still manage quality-related exchanges with external partners. While shortening the supply chain might reduce the effects to

some degree, it does not fully shield organizations from institutional vagaries. Supply chain partners might also find the potential gains from specialization and trade too compelling to vacate. Higher transaction costs associated with unstable institutional environments may not offset the potential benefits perceived from keeping the supply chain long with high division of labor.

Consequently, when institutional uncertainty is extreme, evading and altering postures are likely to persist. The nature of those postures should become extreme as well. Supply chains will stretch around the globe to evade uncomfortable institutional regimes. If global expansion does not offer adequate relief from hostile institutional environments, then those environments could be evaded by taking markets underground. Black markets will form with voluntary quality standards and self-sanctioning enforcement. Altering postures will also become extreme. Supply chain members might also seek to install representatives in direct positions of political power in order to shape quality-related rules of the game in their best interests. Joint government-industry verticals might form, complete with quality-related rules and enforcement set by industry officials that have acquired legal authority to do so.

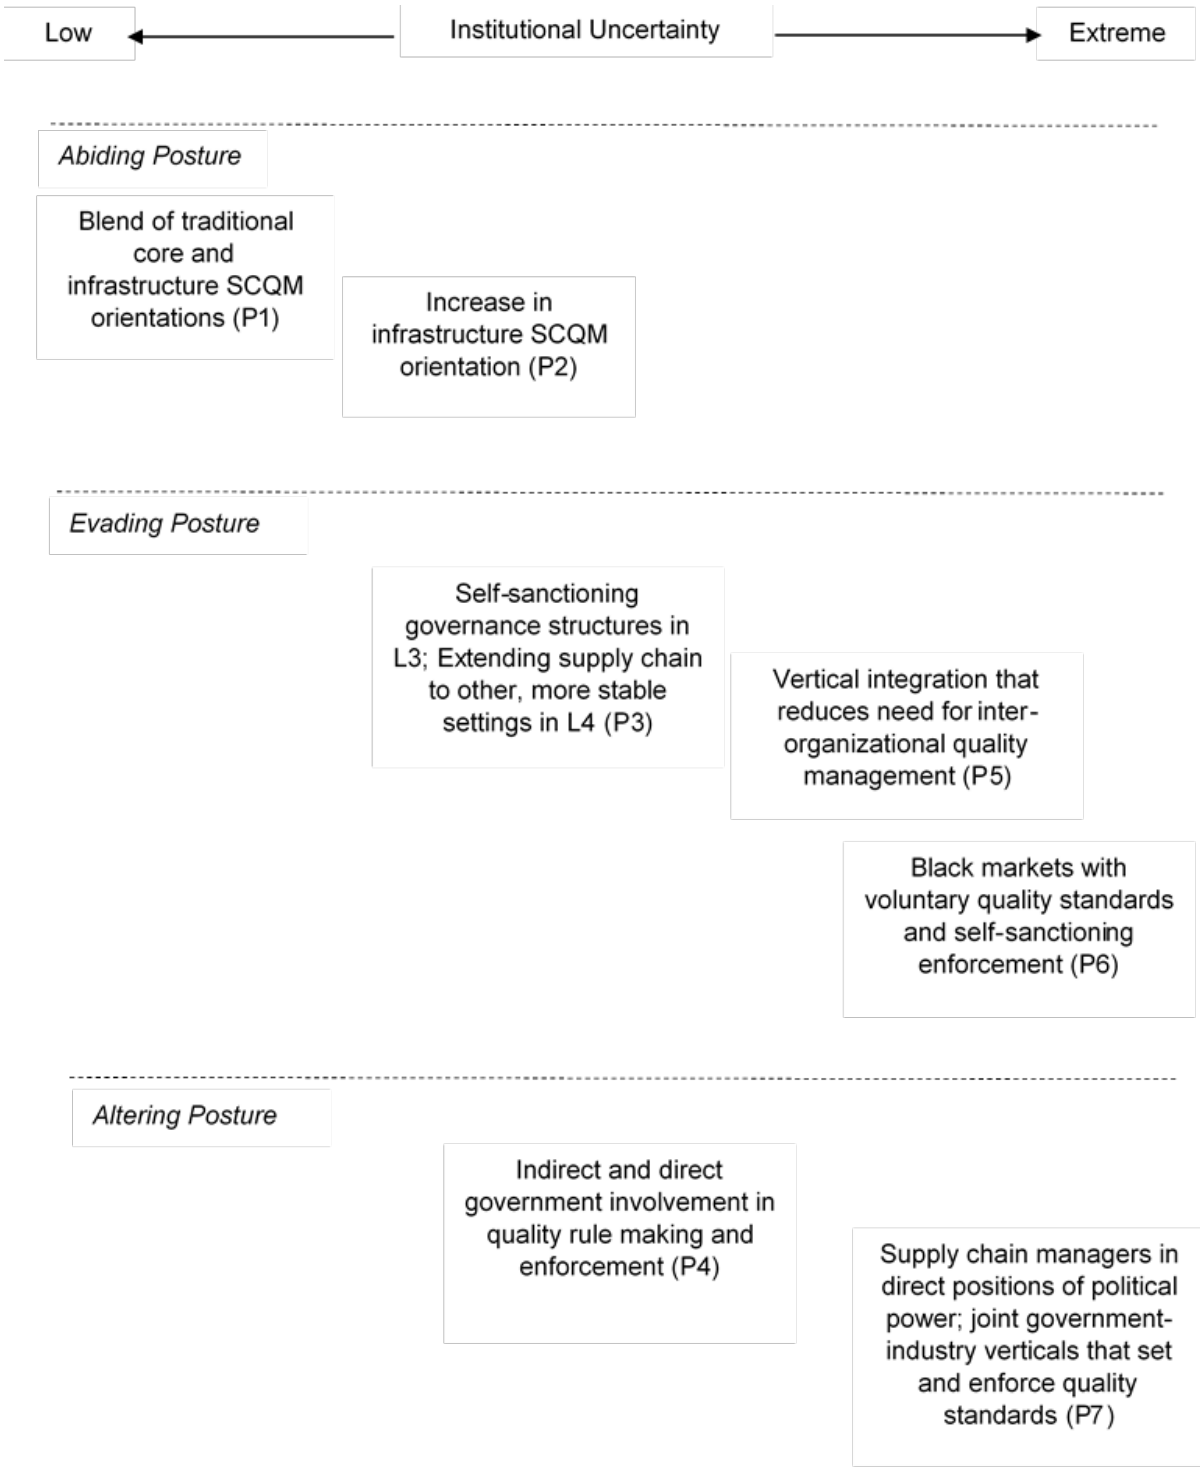
Proposition 6: If institutional uncertainty reaches extreme levels, then extreme evading SCQM postures will form to cope with the uncertainty.

Proposition 7: If institutional uncertainty reaches extreme levels, then extreme altering SCQM postures will form to cope with the uncertainty.

DISCUSSION

The framework proposed by this study appears in Figure 2. A general purpose of SCQM can be seen as stabilizing the quality of resource flows between supply chain partners in uncertain institutional environments). When institutional uncertainty is low, then managers are content to abide by the existing "rules of the game" by drawing from their traditional stable of core and infrastructure SCQM practices to manage resource stability (Proposition 1). As institutional uncertainty begins to increase, managers will initially re-orient SCQM toward more relationship-building with supply chain partners to facilitate inter-organizational adaptability in unstable settings (Proposition 2). In order to better utilize specific assets related to SCQM, organizations will be prone to evade mounting institutional uncertainty by, for instance, seeking trading partners in operating environments less subject to the institutional instabilities present in particular markets (Proposition 3). If an evading posture does not sufficiently stabilize resource flows, then organizations will pursue the costlier approach of altering its institutional environment by indirect or direct political involvement that permits supply chain members to influence the rules of the game (Proposition 4). When institutional uncertainty is extremely high, then some vertical integration is likely to occur to evade institutional processes that could jeopardize resource stability (Proposition 5). However, residual exposure to institutional vagaries as well as gains perceived from specialization and trade might prompt extreme forms of evading and altering, such as the formation of black markets with voluntary quality control, and joint government-industry verticals that permit industries to directly regulate quality standards, to cope with extreme institutional uncertainty (Propositions 6 and 7).

Figure 2: Supply Chain Quality Management as a Function of Institutional Uncertainty



This study extends inquiry about the influence of external environments on inter-organizational quality management into the institutional domain. Institutional environments are increasingly important to understand as supply chains lengthen across the globe and must operate under complex political and legal jurisdictions. A primary implication of this study is that SCQM practices must include capability for evading and altering unstable institutional settings—perhaps in extreme manners.

In the quality management literature, this implication is a novel one. Institutional environments are often portrayed as being beyond the interests and control of supply chain managers. While working with core and infrastructure SCQM practices such as those noted in Table 1 are commonly seen as within the scope of quality managers, evading and altering political processes are not. Hopefully, this paper will encourage dialogue and work in this direction.

Although the framework developed here offers a conceptual foundation, it must be tested and validated. Empirical work might pick up where others have left off in studies of how quality management practices differ across various supply chains and industries (e.g., Choi & Rungtusanatham, 1999). Variables might be introduced that capture country-related differences in perceived institutional uncertainty and in the abiding, evading, and altering postures of SCQM articulated here. In the context of entrepreneurship, Bylund & McCaffrey (2017) suggested that institutional uncertainty involves the extent to which managers trust the willingness of political institutions to provide ideological and political support for entrepreneurial action. Higgs (1997) added that the security of property rights rests not so much on the letter of the law but on perceptions about the character of governments that create and enforce those laws. Future investigations could incorporate similar ideas into construct development for empirical testing should prove useful.

From a practical standpoint, previous work (e.g., Ford, 2015) has alerted managers to the prospect of external contingencies in interorganizational quality management. Stabilizing the quality of resource flows may require different SCQM orientations in turbulent environments compared to stable environments. This study extends this implication to the institutional context. As institutional uncertainty grows, managers may need to stretch beyond their traditional stable of technical and relational SCQM practices for skills that allow them to evade and, in some cases, alter political and legal systems that influence their ability to manage the quality of resource exchange between supply chain members.

ABSTRACT

In this paper, we consider a 3-tier supply chain network. There is one manufacturer, several warehouses and several retailers. Retailers' demand is constant and they do not allow shortage of inventory. We find the location of the manufacturer, number of warehouses and their locations, warehouse allocations to the retailers, and the inventory policies for the retailers and the warehouses. The purpose is to minimize average total cost in the long run. The cost function comprises of location, transportation and inventory holding costs. A math formulation and heuristics is developed.

KEYWORDS: Joint location and inventory problem, 3-tier supply chain, Cost minimization, Heuristic solution, Supply Chain Network

INTRODUCTION

Supply chain is evolving into a critical functional domain for organizations. One of the critical aspects of a good supply chain is its design. Supply chain design or supply chain network design determines that the number of facilities that a company is operating, the size of these facilities and their locations are optimal. A well designed supply chain network provides the companies significant opportunity for cost saving.

Our problem falls under the broad category of supply chain network design. The motivation comes from a manufacturer in the dairy sector that has two categories of customer centers, one with high demand and the other with low demand. Since UHT milk has shelf life of less than three months care is needed in its handling and efficient operation of milk supply chain is critical for success of companies in this sector. This manufacturer has a plant in a city with highest demand which is obvious. Furthermore the company has distribution centers in this city as well as other cities with different demands. For cities with low demand, the manufacturer has predetermined distributors. The distributors place order once or twice every week depending on the demand. They are supposed to inform the manufacturer of their requirements one day in advance. The company ensures a complete and timely order to the distributors. The distributors are only allowed to order in full-truckloads. As the demand for its product grows, the manufacturer is interested in reevaluating its supply chain network design to make it efficient and responsive.

A large set of companies are getting interested in reengineering their supply chain networks owing to the fluctuations in the oil price and rising transportation costs (Dong et al., 2009). This need has resulted in researchers studying the network design problem and coming up with models and solutions that both add to the literature and provide real life solutions for the companies. This paper is a continuation of this effort where we examine a 3-tier supply chain network with one manufacturer located in a high demand market, intermediate distribution centers or warehouses and multiple demand centers. These demand centers are cities in our case. We cluster the cities based on transportation and reordering costs. The distribution centers may be located at all the cities.

Alternatively, the firm can have a centralized distribution center for all the demand centers. We are interested in determining the number and location of distribution centers to serve a given set of existing cities. The objective is to reduce overall setup, transportation and inventory related costs over an infinite planning period.

We are furthermore interested in determining the inventory replenishment decisions from these warehouses to their respective markets. The problem hence falls into the domain of integrated facility location and inventory decisions.

We develop a mixed integer program for solving the deterministic demand problem. The goal is to determine the number and location of warehouses and optimal inventory policy for the given distribution network such that total cost of ordering, warehouse operations, transportation and inventory holding is minimized. The problem is both interesting and unique as it addresses an important practical problem in a multi-echelon distribution network with variable transportation cost and multiple warehouses that has not yet been addressed in literature.

LITERATURE REVIEW

The Network Design Problem

Given a set of existing customers, the network design problem is concerned with finding the number of facilities, their locations and allocation of facilities to the customers that would minimize the total cost of running the supply chain network. Initial work focused on determining models and efficient solution methods for finding answer to the network design problem under different settings of the two-echelon system. For example Baumol (1958) describes a heuristic for a non-linear warehouse location model. Later these studies were expanded to include the three-echelon case. An example is a recent study by Amiri (2004) in which they examine a three-echelon network to determine the number, location and capacities of plants and warehouses to open in order to meet all customer demand at minimum cost.

The extensive research conducted in the network design arena can be broadly into two categories i.e. uncapacitated facility location problem (UFLP) and capacitated facility location problem (CFLP). The above mentioned models have several common characteristics namely, a single-period planning horizon, deterministic parameters (i.e., demands and costs), a single product, one type of facility, and location–allocation decisions.

Extensions to this work include the multi-period and multi-product facility location problems. Furthermore, problems have started incorporating the stochastic nature of such problems. Although location decisions are made at the strategic level, a number of issues are strongly related to them. One such issue concerns inventory control policies.

The standard approach to the network design problem seeks to find locations of facilities and their allocation to customer sites without considering the inventory policy decision. Once the task of determining the number, location and allocation of facilities is complete the decision regarding inventory policy is made i.e. inventory policy decisions consider the location of facilities as given. However, consideration of inventory decisions while determining the location of facilities can have an impact on the solution to the network design problem. Croxton and Zinn (2005) consider inventory costs in the network design problem and show that including inventory in network design problems often significantly affects optimal design of the network.

Thus we have a new stream of research that focuses on the network design problem while simultaneously considering inventory policy decision. The problem is known as integrated location-inventory problem. The research in this area falls into two categories. One stream of research addresses the problem by including inventory costs without explicitly incorporating inventory related variables, for example Croxton and Zinn (2005). Another stream proposes a solution to the integrated location-inventory problem by explicitly considering both location and inventory related variables (Teo and Shu, 2004; Romeijn et al, 2007). Since our problem falls into the domain of latter research stream we go on to discuss this further.

Erlebacher and Meller (2000) developed an analytical model to decide on the number of distribution centers, their location and customer allocations that minimize fixed costs of operating the distribution centers, inventory holding costs at the distribution centers and transportation costs between plant and distribution centers and distribution centers and customers. They develop heuristic procedures to solve the problem since it is NP-hard.

More recently Uster et al. (2008) develop the integrated warehouse-inventory model in a three-echelon setting. They show that the model can be decomposed into two sub-models that resemble the single warehouse multi retailer (SWMR) problem and Weber problem respectively. They develop heuristic solutions to their problem.

We extend the work of Uster et al. (2008) by considering multi-warehouse problem in a three-echelon distribution network. We propose to study a supply chain network consisting of a single manufacturer at a given location, intermediate warehouses whose number and locations have to be determined and two markets one with high and the other with low demand. We intend to develop a MIP model for this network that would provide heuristics to solve for the number and location of warehouses as well as the inventory lot size.

THEORETICAL DEVELOPMENT/MODEL

Our problem includes fixed locations of manufacturing facility and demand centers. We have given transportation cost, inventory holding cost, warehouse operating cost and ordering cost. These costs are dependant on both number and location of warehouses and inventory lot sizes. These are the decision variables in our problem. These variables are consistent with those presented in Uster et al. (2007) except that we additionally need to determine the number of warehouses and their locations. The number of warehouses has been used as a decision variable in previous studies, for instance, Teo and Shu (2004).

The problem is to determine the location of a single manufacturing plant, number and location of distribution centers that are going to serve a known set of cities where there is constant deterministic demand for the product being made by the plant, allocation of cities to distribution centers and inventory ordering policy for the distribution centers and the cities. We consider a set of n≥2 cities. The known locations of the cities are denoted by $f_j = (aj,bj)$, $j \in N = \{1,2,\ldots\ldots..,$

n}, respectively. Each city has one bin. The unknown location of distribution center i is denoted by $X_i = (x_i, y_i)$, $i \in M = \{1,2,....., m\}$.

In determining the number, location and allocation of distribution centers as well as inventory policy for the distribution centers and cities we consider the following costs:

1. fixed operating costs of the distribution centers
2. order setup costs at distribution centers and bins
3. transportation costs from plant to distribution center and from distribution centers to the cities
4. inventory holding costs at the distribution center and at the bins in different cities

Following assumptions are used while developing the model:

1. The plant and distribution centers have unlimited capacity
2. A city cannot be served by multiple distribution centers
3. The vehicle transporting goods from plant to distribution center has unlimited capacity
4. Trucks used to transport goods from distribution center to cities have limited capacity
5. Cost of truck is proportional to the amount of truck space utilized
6. All trucks have same capacity
7. Demand at the cities is deterministic and constant
8. Transportation costs, fixed ordering costs and inventory holding costs are linear

We now develop the notations for the problem and then proceed with problem formulation.

Notations related to the network

N = set of cities with one bin in each city, N = {1,…., n}
M = set of distribution centers, M = {1,…., m}
X_0 = location of plant
f_j = location of cities, f_j = (aj,bj), $j \in N = \{1,2,....., n\}$
w_{ij} = constant deterministic demand rate at city j served by distribution center i

Input Parameters

f_i = fixed cost of operating the distribution center i
c_d = fixed truck capacity at distribution centers
c_p = fixed rail capacity at plant
s_{ij} = fixed setup and ordering cost from distribution center i to facility j
t_{ij} = per-mile transportation cost between the distribution center i and facility j
h_j' = unit inventory holding cost rate at city i
h_i' = unit inventory holding cost rate at distribution center i
h_{ij} = echelon holding cost rate at city j if it is supplied by distribution center at i

Tb = fixed base period (set a priori)
X0 = vector of unknown plant location, X0 = (x0, y0)
Xi = vector of unknown location of distribution center i, Xi = (xi, yi)
zij = {1 if DC i is open and serves city at j
0 otherwise

Using the above assumptions and notations we develop the objective function representing the system wide total annual cost. The function is expressed as follows:

$$\text{Min } Z = \sum_{i=1}^{m} f_i z_{ij} + \Big[\sum_{i=1}^{m} \sum_{j=1}^{n} (t_{ij} w_{ij} d(X_i, f_j)/c_d) + \sum_{i=1}^{m} \sum_{j=1}^{n} (t_{oi} d(X_0, X_i)/T_i)$$

$$+ \sum_{i=1}^{m} \sum_{j=1}^{n} s_{oi}/T_i + \sum_{i=1}^{m} \sum_{j=1}^{n} s_{ij}/T_j + \sum_{i=1}^{m} \sum_{j=1}^{n} 1/2\, h_i w_{ij} \max\{T_i, T_j\} + \sum_{i=1}^{m} \sum_{j=1}^{n} \tfrac{1}{2} h_{ij} w_{ij} T_j \Big] z_{ij}$$

subject to

$$\sum_{i=1}^{m} z_{ij} = 1$$

$$\sum_{j=1}^{n} w_{ij} * T_j <= (\sum_{j=1}^{n} w_{ij}) * T_i'$$

The first term represents the fixed operating cost that would incur if a distribution center at i is opened to serve customer set j. The second term is the annual transportation cost from distribution center to cities at j. The third term is the annual transportation cost from plant to the open distribution centers. The fourth and fifth terms are the fixed setup and ordering costs at the opened distribution centers and the cities respectively. The sixth and seventh terms represent the holding costs at the distribution centers and the cities.

The first constraint guarantees that only one distribution center serves a given city. The second constraint ensures that the quantity leaving the distribution centers is less than equal to the quantity leaving the plant.

Clustering

Clustering is a method of grouping together similar data. In clustering, data points that have close resemblance to each other are placed in one cluster. Points in one cluster are similar to each other while differ from data in other clusters. A more formal definition of clustering is presented in Witten and Frank (2001). “These [obtained] clusters should reflect some mechanism at work in the domain from which instances or data points are drawn, a mechanism that causes some instances to bear a stronger resemblance to one another than they do to the remaining instances."

Clustering problems are such that finding their solution is equivalent to seeking a global solution to the non-linear optimization problem which is NP-hard (Fung, 2001). Hence heuristic procedures are developed for the formation of clusters. The large range of cluster heuristics available may be broadly classified into two groups, namely parametric and non-parametric clustering methods. For the sake of brevity we will explain a few heuristic that have some resemblance to the clustering algorithm presented in this paper. For a detailed overview of clustering algorithms we refer the reader to Fung (2001).

Gillet and Miller (1974) made a sweep algorithm for cluster development. The algorithm consists of a forward sweep and a backward sweep. In the forward sweep locations are partitioned beginning with the location that has the smallest angle from a given location. The backward sweep is similar except that it forms clusters considering a reverse set of locations.

Jung and Mathur (2007) refined the algorithm by Gillet and Miller (1974) to form clusters for their vehicle routing problem. They index the retailers in increasing order of angular position from the warehouse and continue to put the retailers according to this order, in a cluster as long as the sum of demands of the retailers in the cluster do not exceed a specified parameter $D_{max.}$

We develop our cluster heuristic for the multiple warehouse multiple retailer problem in a similar fashion except that we consider weighted distances of locations from plant and distribution centers in deciding clusters.

Single Warehouse Multiple Retailer Problem

The one warehouse multiple retailer problem has been studied extensively since the breakthrough work of Roundy (1985). The problem considers deterministic and constant demand at the retailers over an infinite horizon. Shortages are not allowed. Retailers place orders at the warehouses which in turn place orders with the manufacturer. The inventory holding cost rates are facility dependant and are greater at the retailers as compared to those at the warehouse.

Roundy (1985) showed that the solution to the one warehouse multiple retailer problem can be approximated to within 98% accuracy. We use the algorithm developed in Roundy (1985) to find the reorder intervals in our network.

Lower Bound to the Multiple Warehouse Problem

One of the components of the objective function of our problem is the transportation cost. It is a major cost driving the decision concerning number of warehouses. The transportation cost as formulated in our problem has two components as depicted below.

$$\sum_{i=1}^{m}\sum_{j=1}^{n}(t_{oi}d(X_{0,}\,X_i)/T_i) + \sum_{i=1}^{m}\sum_{j=1}^{n}(t_{ij}w_{ij}d(X_{i,}\,f_j)/c_d) \qquad (1)$$

For ease of use, we call the first component T(1) and the second component T(2).

The first component is the inbound transportation cost i.e. cost of transporting goods from the plant to the distribution centers. The second component is the outbound transportation cost which is the cost of transporting goods from the distribution centers to different cities. The vehicle transporting goods from the plant to the distribution centers has unlimited capacity while the vehicles delivering products from distribution center to various cities have limited capacity c_d.

It is obvious to see that if we increase the number of warehouses the transportation cost from the plant to the distribution center increases. Since inbound transportation cost is a product of per unit transportation cost t_{oi} and $d(X_{0,}\,X_i)$ the distance between plant at X_0 and distribution center at X_i and the distance traveled from plant to distribution center increases as the number of distribution center increases, hence the inbound transportation cost rises as we increase the number of distribution centers irrespective of the reorder interval $T_{i.}$ On the other hand increasing the number of warehouses decreases the outbound transportation cost. It is clear from the second component of our transportation cost that as we increase the number of distribution centers (DCs) the distance traveled from DCs to the cities decreases. As an extreme case consider we have a DC in each city. If this happens then $f_j = X_i$ and the distance $d(X_{i,}\,f_j)$

between DC and the city to which the DC supplies is zero. Hence in this scenario the second component of our transportation cost becomes zero.

Thus we see that as the number of distribution centers m → ∞ , T(1) → ∞ and T(2) → zero. The total transportation cost is hence a convex function with a minimum value.

Now we go on to show that the minimum value to the transportation cost function in our problem occurs when the number of warehouses satisfy the following criteria.

$$d(X_i, f_j) < d(X_0, X_i)/T_i \quad (2)$$

The total transportation cost of establishing a distribution center in a city i = (1…m) is given by:

$$\sum_{j=1}^{n} (t_{oi} d(X_0, X_i)/T_i) + \sum_{j=1}^{n} (t_{ij} w_{ij} d(X_i, f_j)/c_d) \quad (3)$$

Given a fixed time interval T_i the above expression reduces to:

$$\sum_{j=1}^{n} t_{oi} d(X_0, X_i) + \sum_{j=1}^{n} (t_{ij} w_{ij} d(X_i, f_j)/c_d) \quad (4)$$

where w_{ij}/c_d give the number of vehicles traveling from the distribution centers to their respective cities in the interval T_i.

Though $t_{ij} < t_{oi}$, $t_{ij} * w_{ij}/ c_d$ is an increasing function of number of trips. For an average level of demand for any medium sized organization it is easy to see that the parameter $t_{ij} * w_{ij}/ c_d$ would have a value much greater than t_{oi}. We thus have

Since $t_{ij} * w_{ij}/ c_d >> t_{oi}$, the total transportation cost will be minimized only when distribution centers are established such that

$$d(X_i, f_j) < d(X_0, X_i) \quad (5)$$

Cluster Heuristic for the MWMR Problem

We develop a cluster heuristic to solve the multiple warehouse multiple retailer problem. The clusters are developed using an approach similar to that used in Jung and Mathur (2007). We first locate the plant using the famous center of gravity approach. The center of gravity method finds a weighted average location for the new facility that needs to transport and receive shipments from a set of pre-existing facilities.

Once we have determined location of the plant, we find the number and location of distribution centers. In order to establish the distribution centers we calculate Euclidean distances from plant to the existing locations. Next we sort the locations and index them based on increasing sequence of distances from the plant. These locations belong to a set of cities L = (1…..n). The distribution center is established at a location with the lowest index value to minimize transportation cost from the plant to the distribution center.

After establishing the first distribution center we form cluster in the following fashion. For a given set of locations as long as the distance of the locations from the distribution center DC1 is less than its distance from the plant they are placed in a cluster C1 = (1….n_1). L is updated by L <- L\ C1 such that L1 = (n_1+1….n_2). For the remaining locations a distribution center DC2 is established as before. Second cluster C2 is formed such that distance of the new set of locations L1 = (n_1+1….n_2) from DC2 is less than their distance from the plant and L is updated by L <- L\ C2.

Clusters are formed until L != {Ø}.

Given the established distribution centers, reorder intervals are calculated using the approach in Roundy (1985). This forms input to the cluster heuristic. Transportation costs are reevaluated on the reorder interval. We get new values for $d(X_0, X_i)/T_i$ and the number and location of the distribution centers is calculated again. If this results in incremental improvement in solution to the cost function we accept the solution. The procedure is repeated until the improvement is less than a pre-specified percentage value.

The step-wise procedure is for Cluster Algorithm is as follows:

Step 1: Locate the plant using center of gravity.

Step 2: Calculate distances from plant to cities and sort cities in ascending order of distance from plant. Assign cities to L = {1….n} where n is the number of cities in the set.

Step 3: Locate DC1 at a city (location) such that $d(X_0, X_i^*) < d(X_0, X_i)$ (for all cities in L). Update DC by DC U {DC1}.

Step 4: Form cluster C1 such that $d(X_i, f_j) < d(X_0, X_i)$ (for all j). Update set of clusters C by C U {C1}. Update L by L <- L\ C.

Step 5: Repeat steps 3 and 4 until L != {Ø}.

Step 6: Update distance from plant $d(X_0, X_i)$ by $d(X_0, X_i)/T_i$ where T_i is calculated using the approach in Roundy (1985). Go to step 2.

Step 7: Repeat steps 2 to 7 until incremental improvement in cost is below a specified percentage p%.

RESULTS

The program was implemented in C++ and run on a personal computer. Several runs of the program showed reduction in cost when multiple warehouse multiple retailer problem is considered as compared to single warehouse multiple problem. A detailed analysis of the results will be presented in a newer version of the paper.

CONCLUSION & FUTURE RESEARCH

Later on a system dynamics model for the three-tier distribution network considered in this paper may be developed. The integrated location and inventory analysis may then be performed from a system dynamics perspective and the results compared to those determined using this study.

mmeybodi@iuk.edu

ABSTRACT

The focus of this article is to demonstrate the relationships between lean manufacturing (LM) principles and integrated product design and development (IPDD). Comparison and analysis of several critical factors show high degree of resemblances between the two methods. A number of hypotheses regarding similarities between factors of the two methods were developed and tested. Survey data strongly supports the hypotheses regarding similarities between the LM and IPDD methods. Statistical results also indicate compared with conventional companies, by utilizing IPDD, lean manufacturing organizations are able to design and develop products with better quality, less development time, higher frequency, and lower development and manufacturing costs.

KEY WORDS: Integrated Product Desing and Development, Lean Manufacturing

INTRODUCTION

Innovation and speedy new product development is crucial for companies to gain competitive advantage in a global market. Creating new product ideas that are consistent with organizational strategy and moving these ideas through the stages of design, development, and introduction quickly has been the hallmark of successful world class organizations (Jacobs and Chase, 2011; Ferioli et al. 2010; Roulet et al. 2010; Towner, 1994). Introducing new products to the market early has several strategic and operational advantages. It often means premium prices, building name recognition, controlling a large market share, and enjoying the bottom line profits. Better competitive position in the market makes it also difficult for competition to enter the market (Cooper and Kleinschmidt, 1994; Lofstrand, 2010; Zahra and Ellor, 1993).

Despite its well-known strategic role, for large number of manufacturing organizations innovation, design, and successful management of new product development (NPD) has often been a major challenge. Long development time, prohibitive development and manufacturing costs, and questionable quality have been the common result for many of these organizations. The primary factor contributing to such unsuccessful result is perhaps the use conventional sequential method of NPD by these organizations (Blackburn, 1991; Morgan and Liker, 2006). However, manufacturing literature for the past two decades clearly shows that through their lean manufacturing practices, some world class organizations such as Toyota have dominated competition not only in the area of manufacturing but also in the area of innovation, design, development, and quick commercialization of new technologies ((Marisa et al. 2008; Heinzen and Hoflinger 2017; Clark and Fujimoto, 1991; Ulrich and Eppinger, 2004; Michael, 2008; Unger and Eppinger 2009). Instead of traditional sequential approach to NPD, a successful strategy employed by these world class organizations is IPDD. The focus of this article is to understand such contrast

between the two type of organizations. The question of interest in this article is: Are there relationships between success in LM practices and success in IPDD?

LITERATURE REVIEW

Lean manufacturing has been a great force in the world of manufacturing since mid 1980's. Some of the main benefits of a LM such as lower inventory, quicker delivery, and lower cost have been well documented (Cook and Rogowski, 1996; Hobbs, 1994; Payne, 1993; Temponi and Pandya, 1995; Deshpande and Golhar, 1995; Billesbach, 1991; Handfield, 1993; Lawrence and Hottenstein, 1995; Golhar, Stamm, and Smith, 1990; Moras and Dieck, 1992). In the simplest form, LM requires maximizing value added production activities by removing unnecessary wastes. Identification and elimination of waste and respectful treatment of employee are the two fundamental principles of a LM system (Hobbs, 1994; Payne, 1993; Wantuck, 1983; Womack and Jones, 2003). Elimination of waste is achieved by adopting practices such as continuous quality improvement, setup time reduction, utilizing flexible resources, group technology layout, and pull production system (Gargeya, and Thompson, 1994; Sohal, Ramsay, and Samson, 1993; Suzaki, 1987)). Respectful treatment of people often means employee empowerment; it includes elements such as team work, fair compensation, employee training and new positive attitude toward suppliers (Sohal, Ramsay, and Samson, 1993; Wantuck, 1983). Unfortunately, since its beginning in mid 1980's, often a narrow view of LM has been accepted and utilized by western manufacturers. Application of LM to reduce inventory and increase deliveries is only a small fraction of the full potential benefits of a LM system (Blackburn, 1991; Kristav, 2016; Gilbert, 1994; Towner, 1994). To take advantage of the full benefits of LM, one needs to have a much broader view of LM principles (Blackburn, 1991). Looking at LM as a process of eliminating waste and respectful treatment of employee, its principles can be applied to other areas including service areas such as healthcare, education, government, and NPD (Womack and Jones (2003). Application of lean principles to NPD has great opportunity to shorten product development time, improve design quality, and reduce product development and manufacturing costs (Anand and Kodali, 2008). The company that originated famous LM system, TPS, also developed Toyota Product Development System (TPDS). TPDS employs LM principles and tools such as value stream mapping, Kanban, 5S system, and continuous improvement to eliminate waste from product development activities and bring quality products to market faster than their leading competition (Morgan and Liker, 2006; Ward, 2007). The focus of this article is on special case of TPDS called integrated method of new product development (IPDD).

The remainder of the article is organized in the following manner: First, an overview of the differences between conventional sequential and recent IPDD is presented. Second, the article compares and analyzes similarities between LM and IPDD for a number of critical factors followed by a set of test of hypotheses on similarities between the factors. Third, the article tests NPD performances for conventional sequential method and IPDD method. Research methodology, results, and conclusion are the final sections of the article.

TRADITIONAL VS. INTEGRATED PRODUCT DESIGN AND DEVELOPMENT

NPD process is a sequence of inter-connected activities in which information regarding customer needs is translated into final product design. In a traditional NPD nethod, also known as sequential or "over-the-wall" approach, the NPD process typically involves phases such as idea generation and validation, preliminary design, final design and prototyping, and pilot production and ramp-up (Wheelwright and Clark, 1992; Russell, and Taylor, 1998). Traditionally, this design process is managed sequentially by personnel from various functions of the organization. A major drawback of this approach to NPD is that the output from one design stage is passed to the next stage with little or no communication. Lack of communication and feedback among sequential stage causes

the process to require too many design changes which causes the process to require longer development time which indeed causes the process to be too slow, too costly, and often of poor quality. The two elements of long delay and design changes during the delay creates a never-ending cycle where time delay causes design change and to accommodate design change it needs more time. The final result is that the designs are often rejected because the design is either outdated due to long development time or it is infeasible in term of manufacturing capability (Blackburn, 1991; Ulrich and Eppinger, 2000).
Unlike traditional "over-the-wall" approach to NPD where functional units work sequentially and downstream functions are not involved until late in the process, IPDD requires early involvement of cross functional teams. It requires that designers, manufacturers, marketers, suppliers, and customers work jointly to design product and manufacturing process in parallel. The design team must truly understand the concept of simultaneous engineering in which activities of product and process design are performed in parallel and in a coordinated manner The objective is to integrate product design and process planning into a common activity (Albers and Braun, 2011; Liang, 2009; Anderson, 2008; Clark and Fujimoto, 1991; Donnellon, 1993; Millson, Ranj, and Wilemon, 1992; Shunk, 1992). Application of IPDD under various manufacturing environments in order to shorten development time, improve quality, reduce risks, and reduce development cost is reported by these researchers (Anderson, 2008; Skalak, 2002; Kowang and Rasli, 2011; Lofstrand, 2010; Moges, 2009). Due to early cross-functional communication, IPDD approach enables an organization to be more innovative in terms of improving design quality, shortening development time, reducing design risks, and reducing development and manufacturing costs (Lynch et.al, 2016; Blackburn, 1991; Ulrich, and Eppinger, 2000; Arora and Mital, 2012; Katzy et.al, 2012; Zirger and Hartley, 1996).

COMPARISON OF LEAN MANUFACTURING AND IPDD FACTORS

For the past few decades, there has been an extensive volume of research in the area of LM. As a result, there is a set of generally accepted guidelines that organizations can follow to achieve manufacturing success. However, there has been limited research on the application of LM principles to NPD and there is no comparable set of guidelines for successful management of NPD process. Recently, a number of world class NPD companies have attempted to apply the principles of lean manufacturing to NPD activities. The company that started the most famous LM system, Toyota Production System (TPS) is also started Toyota Product Development System (TPDS). TPDS employs lean principles and enable the company to bring the highest quality products to market faster than their leading competition. Also, a number research on the application of lean principles to NPD process has shown that achieving certain manufacturing process improvement such as reducing variation, reducing rework and yield loss, solving process bottlenecks, and managing capacity, can significantly reduce NPD times.

Similarities between LM and IPDD for a number of critical factors are shown in Table 1, (Blackburn, 1991; Spencer and Guide, 1995). Following is a brief comparison and analysis of selected factors in Table 1:

Layout

Layout in LM environment is often in the form of product focus and manufacturing cells. This type of layout is necessary because small lot size production requires that the layout to be compact and efficient to ensure smooth flow of materials and close communication between work stations. Unlike conventional manufacturing, where material is pushed forward, the flow in a LM environment is in two directions; material is pulled forward, but information flows backward to provide feedback on performance and material requirements.

In IPDD, overlapping of a large number of activities requires a complete change in layout that facilitates communication and encourages team work. Instead of organizing by sequential functions, IPDD emphasizes on cross-functional integration and the formation of a design team. The design team sits together in one location, creating a type of project layout. A project layout creates an environment for frequent, two-way communication between team members, which encourages concurrent development of a product and its associated processes.

Table 1. Comparison of LM and IPDD Factors

Factor	LM	IPDD
Layout	GT/Cellular manufacturing	Project/Design teams
Process and information flow	Two way flow: material downward, information backward	Parallel activities: Two way flow of information among team members
Set-up/Transition time	Short	Short
Lot size	Small	Small (batches of information)
Quality	Quality at the source, continuous quality improvement, low rework activities	Early detection of design quality problems, continuous design improvement, low redesign activities
Inventory	Low	Low
Manufact./Develop. Cost	Reduced	Reduced
Lead time	Fast delivery	Short development time
Customer focus/Market responsiveness	More responsive to changes in customer demand	More responsive to product design changes
Workeforce empowerment and teamwork	High	High
Workforce flexibility	High	High
Scheduling	Localized team control, team responsibility	Localized team control, team responsibility
Decision making	Manufacturing team	Design team
Supplier involvement	High level of sharing information, quality partners	High level of involvement in product development
Technology	Integrated systems, new technology after process simplification	Integrated CAD, CAE, CAM
Workplace organization	Utilizes 5S practices to organize, clean, and sustain the workplaces	Utilizes 5S practices to organize design team and data for easy access to information to conduct NPD activities
Standardization	Standardization of parts and components is a critical component of LM	Creates a standard method of doing activities (i.e. data collection, flow charting, blue prints, etc.)
Value added	High	High

Lot Size

In contrast to conventional manufacturing, lean manufacturing requires production of small lot-sizes. Production of small lot-sizes is possible by drastically reducing set-up times. It is well documented that production of small lot-sizes in LM is closely associated with improved quality, reduced inventory, faster delivery, and more responsive to market demands.
Similar to LM, IPDD also utilizes small lot-sizes; the only difference is that in LM small lot sizes of goods are processed but IPDD requires small lot-sizes of information. That is, continuous two way communication in IPDD is similar to early release of small batches of information (Blackburn, 1991; White, 1993). With the early release of small batches of information, downstream constituents can begin working on different phases of the design while final design is evolving. The early release of information reduces uncertainty and encourages early detection of problems, which enables organizations to avoid costly, time-consuming changes.

Employee and Supplier Involvement

In LM environment, management encourages employee involvement and team work. The responsibility for job scheduling and quality are often passed to the teams at the shop floor. Due to small lot size production, delegation of authority to the teams at the shop floor is essential for smooth production flow. Also, in LM suppliers work closely with manufacturing organization to improve quality and shorten delivery time.
Similar to LM, in IPDD the responsibility for scheduling of the activities pushed down to product development team at the lowest level. Passing responsibility down to the team is essential to achieve a high level of activity coordination and information sharing among team members. Also, in IPDD suppliers work closely with the design team to reduce development costs, shorten development time, and offer ideas toward improving the quality of the design.

Quality

In LM and IPDD environments, organizations are often proactive and quality means getting it right the first time. In LM, since batch sizes are small quality at the source and continuous quality improvement are the main foundations. Shop floor workers are empowered to become their own inspectors responsible for the quality of their output. In IPDD, because of the teamwork and two-way flow of information between team members, and utilization of quality improvement tool such as six sigma process quality problems are detected earlier and solved before they have a cumulative impact on the rest of the project (Chakravorty and Franza, 2009).

Technology

In a LM system, technology is not viewed as a substitute, or shortcut to process improvement. Rather, technology has been utilized after process analysis and simplification has been performed. The role of technology in IPDD is also enormous; it requires that the design team with diverse expertise makes a large number of interrelated decisions regarding the form, fit, function, cost, quality, and other aspects of the design (Karagozoglu and Brown, 1993). This requires supply and processing of relevant information from multiple sources in a coordinated manner. Successful organizations use technology in their NPD process similarly to the way they use technology in their LM system. In IPDD, the design team utilizes appropriate technologies and tools at various stages of NPD process. Effective use of technologies and tools can dramatically shorten NPD time, reduce number of prototypes, cut costs, and improve quality of the design (McKay et al. 2011; Yamamoto and Abu Qudiri 2011; Roulet et.al (2010). The key to

the success of technology in IPDD is building an effective design team with open cross-functional communication lines.

FACTOR HYPOTHESES

Comparison and analysis of factors in Table 1 show a high degree of similarities between LM and IPDD. To study further, a set of twenty hypotheses (H1-H20) that statistically test similarities between LM and IPDD will be presented. The hypotheses are shown in Table 2. Each hypothesis in Table 2 consists of two parts- a and b. In part a, the test is conducted for LM factors and the corresponding test for IPDD factors is conducted in part b. The last hypothesis examines the overall impact of LM principles on IPDD.

Hypotheses (H1-H20):
There is a high degree of similarities between LM and IPDD factors.

PRODUCT DESIGN AND DEVELOPMENT PERFORMANCES

The following dimensions of quality, time, competency, development cost, and manufacturing cost are used to measure the performance of NPD (Ulrich and Eppinger, 2000; Wheelwright and Clark, 1992):

- **Quality**: Quality is ultimately reflected in the price customers are willing to pay, the market share, and the bottom line profit. In NPD, quality problems are often the results of incomplete information and miscommunication among various functions. Quality often means a minimal number of redesign or rework. In this article, number of design changes during the development process and early manufacturing phase is used as a measure of design quality.
- **Development time**: Development time is the length of time between initial idea generation until new product is ready for introduction to the market. Shorter development time raises the competitive value of new product in terms of premium price, larger market share, and higher profit margin.
- **Development competency**: Development competency is the ability of the organization to develop future products better, faster, and cheaper. Competent workforce and effective use of technologies are important elements of organizational NPD competency. Frequency of new product introduction to the market is used as a measure of development competency.
- **Development cost**: This is the total cost from the early idea generation until the product is ready for manufacturing. For most organizations, development cost is usually a significant portion of the budget and must be considered in light of budget realities and the timing of budget allocations.
- **Manufacturing cost**: Manufacturing cost includes initial investment on equipments and tools as well as the incremental cost of manufacturing the product. There is a close relationship between manufacturing cost and the type of decisions made during the early design stage. Although early design decisions determine about 70 percent of future manufacturing cost, organizations often spend far too little time and resources during this stage (Huthwaite, B. 1991). To save future manufacturing cost, it is prudent for the companies to spend more time and resources during the early design phases of NPD process where critical design decisions are made.

Table 2. Survey Items for Comparison of LM and IPDD Factors
(1=strongly disagree, 5=strongly agree)

1a. In LM, layout is often in form of group technology (GT) or cellular manufacturing (CM).	1b. In IPDD, the layout emphasizes is on cross-functional integration and formation of project or design team.
2a. In LM, GT or cellular manufacturing layout allows smooth flow of materials downward and information flow backward.	2b. In IPDD, project layout formed by the design team allows frequent and two way flow of information among team members.
3a. LM system requires short set-up time.	3b. IPDD requires fast transition (i.e. short set-up time) from one part of the design to another.
4a. LM system requires production of small lot-sizes.	4b. In IPDD, continuous and two-way flow of information among team members is equivalent to releasing small batches of information.
5a. In LM, due to production of small lot-size, quality at the source and continuous quality improvement are essential to the success of the system.	5b. In IPDD, due to simultaneous development of product and process, early detection of design quality problems and continuous improvement of the design are essential to the success of NPD process.
6a. In LM, production of small lot-size is associated with improving quality.	6b. In IPDD, continuous and two-way communication among team members encourages early detection of the design problems, which is associated with improving design quality.
7a. In LM, production of small lot-size is associated with reducing inventory.	7b. In IPDD, continuous and two-way communication among team members associated with reducing unnecessary amount of information among team members.
8a. In LM, production of small lot-size is associated with reducing manufacturing cost.	8b. In IPDD, continuous and two-way communication among team members encourages early detection of the design problems, avoids costly design changes, which is associated with reducing development cost.
9a. In LM, production of small lot-size and smooth flow of materials downward and information flow backward is associated with reducing delivery time.	9b. In IPDD, continuous and two-way communication among team members encourages early detection of the design problems, avoids time consuming design changes, which is associated with reducing NPD time.
10a. In LM, organizations are more responsive to the changes in customer demand.	10b. In IPDD, the design teams are more responsive to the changes in product design.
11a. In LM, management encourages workforce empowerment and teamwork.	11b. In IPDD, management encourages employee empowerment and teamwork.
12a. LM requires high level of workforce flexibility.	12b. IPDD requires high level of design team flexibility.

Table 2. Survey Items for Comparison of LM and IPDD Factors
(1=strongly disagree, 5=strongly agree) (Continue)

13a. In LM, detailed shop floor responsibilities such as job and employee scheduling are passed to the local teams.	13b. In IPDD, detailed design responsibilities such as development activities and employee scheduling are passed to the design teams.
14a. In LM, suppliers work closely with manufacturing teams.	14b. In IPDD, suppliers work closely with the design and development teams.
15a. In LM, close relationship between suppliers and manufacturing teams is essential in improving quality, reducing manufacturing cost, and shortening delivery time.	15b. In IPDD, close relationship between suppliers and design and development teams is essential in improving design quality, reducing design and development cost, and shortening design and development time.
16a. In LM, new technologies such as robots are integrated into manufacturing system after process analysis and simplification has been performed.	16b. In IPDD, new technologies such as IT and CAD are integrated into the design and development process after process analysis and simplification has been performed.
17a. LM utilizes 5S practices to organize, clean, and sustain the workplaces.	17b. IPDD utilizes 5S practices to organize data and design team members for easy access to timely information to conduct NPD activities.
18a. In LM, standardization of parts and components is a critical component of the system.	18b. In IPDD, standard method of doing activities such as data collection and organization is a critical component of the process.
19a. In LM, due to the principles of elimination of wastes, process activities contain high value added content	19b. In IPDD, simultaneous communication among team members, NPD process contain high value added content.
20a. In LM, elimination of wastes and respectful treatment of people are the two main principles.	20b. Similar to LM, the main principles of elimination of wastes and respectful treatment of people are applicable to IPDD.

PERFORMANCE HYPOTHESES

In the second set of hypotheses (H21-H25), the differences between NPD performances for lean manufacturing companies and conventional companies are tested.

Hypotheses (H21-H25):

H21: By utilizing IPDD approach, LM companies are able to design new products with fewer design changes than conventional companies(better quality).

H22: By utilizing IPDD approach, LM companies are able to design new products faster than conventional companies.

H23: By utilizing IPDD approach, LM companies are able to design new products more often than conventional companies.

H24: By utilizing IPDD approach, LM companies are able to design new products with less development cost than conventional companies.

H25: By utilizing IPDD approach, LM companies are able to design new products with less manufacturing cost than conventional companies.

RESEARCH METHODOLOGY

The target population for this study consisted of manufacturing firms in the states of Illinois, Indiana, Ohio, Michigan, and Wisconsin. A sample of 500 manufacturing firms with more than 50 employees was chosen from manufacturers' directories of those states. The sample covers organizations in variety of industries ranging from fabricated metal, communication, electronics, automotive, toots, chemicals, rubber, and paper products. A comprehensive survey instrument based on examination of the literature and critical factors listed in Table I was developed. A panel of practitioners and researchers with experience in LM and NPD was used to validate the survey. In addition to general organization and managerial profile items, the survey contained 40 items (20 paired) regarding similarities between LM and IPDD factors. The twenty paired questionnaire items are shown in Table 2.

[Take in Table 2]

Also, the survey instrument contained a number of questionnaire items on NPD performances for LM companies using IPDD and conventional companies. Out of 91 completed surveys received, 84 surveys were usable resulting in a response rate of 17%. Based on a number of questionnaire items on the principles of LM practices, 33 organizations were grouped as LM companies and 51 organizations were categorized as conventional companies.

The survey data indicates that majority of respondents had various high level managerial positions from organization with less than 500 employees. Presidents and vice presidents accounted for 29% and plant managers accounted for 30% of the sample. About 35% of the sample had other managerial positions such as operations/production managers, quality managers, and the remaining 6% were production line supervisors. In terms of manufacturing and NPD experience, about 28% of the respondents had between 10 to 20 years and 60% had more than 20 years of manufacturing experience. About 72% of the sample had more than 10 years of LM experience and close to 65% of the sample had more than 10 years of NPD experience.

RESEARCH RESULTS

As stated earlier, in the first set of hypotheses the objective was to examine similarities between LM and IPDD for a set of paired factors shown in Table 2. For each item, the null hypothesis was that the mean response for LM is equal to the mean response for IPDD. The differences between the mean responses for LM and IPDD were compared using the statistical t-test. The respondents were asked to rate each element of Table II based on the degree of their agreement (1=strongly disagree, 5=strongly agree) to the question. Table 3 shows the result of similarities between LM and IPDD.

[Take in Table 3]

As shown in this table, overall the respondents strongly agreed with the statements regarding similarities between LM and IPDD factors. The mean ratings for about 70% of the factors for both LM and IPDD are above 3.80. Specifically, out of twenty hypotheses, the respondents agreed that there is a high degree of similarities between LM and IPDD for all except three hypotheses H3, H6, and H8.

For H3, the mean ratings for LM and IPDD are respectively 4.34 and 3.81. This means although the respondents understood that short set-up and fast transition time are the main requirements of successful LM and IPDD, the relationship between short set-up and LM was much stronger.

Table 3. Comparison of LM and IPDD Factors (1=strongly disagree, 5=strongly agree)

* SD = Standard deviation

This is a reasonable result because an average manufacturing manager has longer experience with LM than IPDD. They clearly understood that successful LM requires small lot-size and small lot-size requires short set-up time. However, due to their shorter experience with IPDD and because IPDD is primarily an information processing process, the links between small batches of information and fast transition time is not clear. H6 hypothesizes the relationships between small lot-sizes and quality improvement for both LM and IPDD. For this test, the mean ratings for LM and IPDD are respectively 3.43 and 3.89. This indicates for an average manager it is easier to recognize the relationship between CEID and quality improvement than the relationship between LM and quality improvement. The higher rating for IPDD is perhaps due to continuous and two way communication among design team members, which encourages early detection of the design problem. The LM result is also consistent with the literature because although total quality management and quality improvement are fundamental requirements of successful LM, an average manufacturing manager has difficulty to understand this relationship. The relationships between small lot-size and reduced manufacturing cost in LM and the relationship between small batches of information and reduced development cost in IPDD are examined in H8. The mean ratings for LM and IPDD are respectively 3.58 and 3.94. For the same reasons as H6, this means for an average manager it is easier to understand this relationship in IPDD than LM. The LM result is interesting and also consistent with the literature because reduced manufacturing cost in LM is primarily due to elimination of wastes, a fundamental principle of LM, and an average manufacturing manager has difficulty to see this relationship. The overall impact of lean principles on LM and IPDD is examined in H22. It is

obvious that the data supports the hypothesis as the mean ratings for LM and IPDD are respectively 4.56 and 4.29 indicating strong agreement with the statements that the main principles of waste elimination and respectful treatment of people in LM can also be applied in IPDD.
The last column of Table 3 shows correlation coefficients between LM and corresponding IPDD factors. The correlation coefficients in Table 3 strongly support the above analysis. With the exception of three hypotheses H3, H6, and H8 other coefficients are greater than 0.60 indicating a high degree of linear association between LM and IPDD factors.

The performance hypotheses (H21-H25) state that by utilizing IPDD approach, LM companies are able to design new products with fewer design changes, faster, more often, with less development cost, and less manufacturing cost than conventional companies.

Table 4. NPD Performances for Conventional and LM Companies using IPDD

Factor	Mean Conventional	Mean LM	p-value
Number of design changes	5.36	3.28	0.004
Development time (Months)	37.22	24.73	0.003
Development competency (Months)	49.46	32.72	0.005
Development cost	144.60*	100*	0.005
Manufacturing cost	135.75*	100*	0.005

* data reported in terms of percent improvement

Table 4 provides useful statistical information regarding NPD performances for LM and conventional companies. The average number of design changes for conventional and LM companies are respectively 5.36 and 3.28, a quality improvement of 63%. The average development time for conventional and LM companies are respectively 37.52 and 24.73 months, an improvement of 52%. For development competency, the average time between introduction of new products for conventional companies is 49.46 months and 32.72 months for LM companies, an improvement of 51%. Table IV also indicates that LM organizations enjoy a 45% reduction in NPD cost and 36% reduction in manufacturing cost. From the last column of Table 4, it is clear that the hypotheses are strongly supported by the data as the p-value for all five hypotheses is less than 0.005.

CONCLUSION

The focus of this article was to demonstrate possible links between LM practices and IPDD. First, comparison and analysis of a number of factors showed remarkable similarities between LM practices and IPDD. Second, a set of paired hypotheses was used to test similarities between LM practices and IPDD factors. Statistical results clearly support the hypotheses regarding similarities between LM and IPDD for majority of factors. Specifically, out of twenty two hypotheses, the respondents agreed that there is a high degree of similarities between LM and IPDD for all but three hypotheses. The last pair of hypotheses that examines the overall impact of LM principles is especially important. Statistical results strongly agreed that the main principles of waste elimination and respectful treatment of people in LM is also applicable to IPDD. The correlation coefficients between LM and IPDD factors also supported the same result. Third, statistical results also indicate that compared with conventional companies, LM companies are able to develop new products with 63% better quality, 52% less development time, 45% less development cost, and 36% less manufacturing cost. Also frequency of new product introduction is 51% faster than conventional companies.

In summary, statistical results of the article show strong links between LM practices and IPDD. Managerial implication of the research is that successful implementation of LM principles goes much beyond inventory reduction and frequent deliveries. For LM organizations success in IPDD is the result of knowledge and technology transfer from their LM system into their product design and development process.

ABSTRACT

The integration of drones and internet of things technology has created numerous opportunities for supply chain industry globally. The Big Data collected by Drones working with IoT sensor networks can help logistics companies monitor supply chain visibility, changing weather conditions to study the changing consumer behavior.
KEYWORDS: IoT, Drones, Supply chain, Logistics, Big Data

INTRODUCTION

The supply chain industry globally is being influenced by the digital disruption, thanks to the turbulent ecommerce retail industry. The present day consumer expects a seamless, faster purchasing experience

Today's supply chain industry is undergoing change in a big way, wherein the players are looking at capturing their share of market by delivering the goods to the customer in the shortest possible time at a lower cost. This effort calls for collecting information about the changing requirements of the customers at the speed of light, without which they have a risk of being thrown to the back seat in the ever changing supply chain industry. Hence, the logistics players have started looking for better alternatives to be ahead of their competitors.

OBJECTIVES OF THE PAPER

The basic objectives that would be achieved are:

1. Understanding the importance of big data analytics in the context of supply chain.
2. Understanding the various viewpoints on the need of drones in supporting the last mile delivery.
3. Understand the need and importance of integrating big data and drones into supply chain.

BIG DATA ANALYTICS IN SUPPLY CHAIN

The growth in adoption of supply chain technologies coupled with huge collection of data shifted the management focus from heuristics to data-driven decision making, giving rise to the big data era. Big Data Analytics (BDA) plays an important role in transforming and improving the functions of supply chain and decision making. The present day managers prefer taking decisions based on the data driven insights rather than relying on their intuitions (Davenport, 2006).

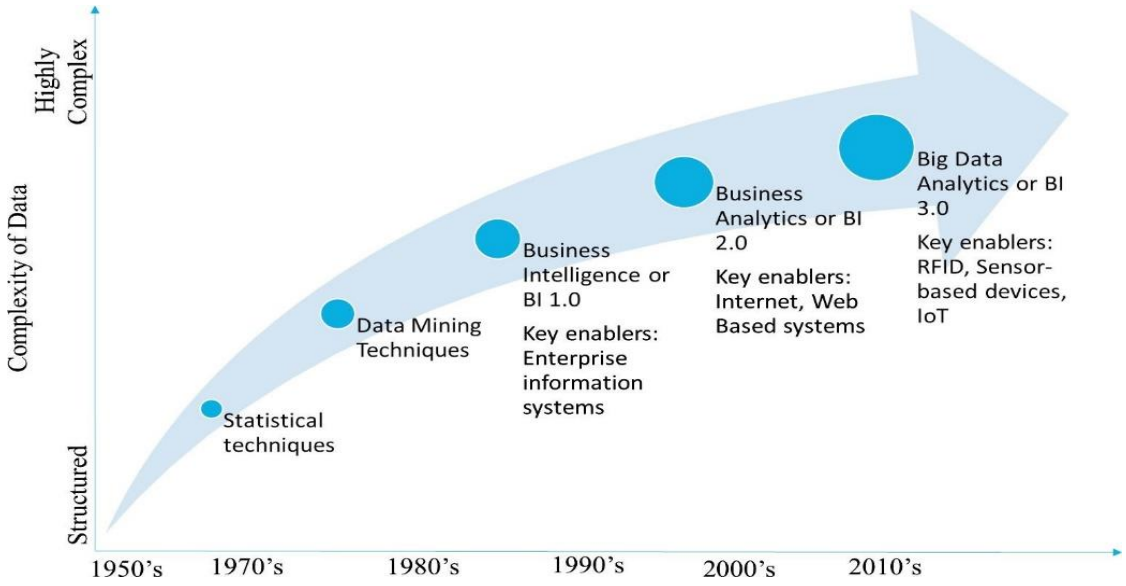
The perceived benefits of BDA have motivated organisations to develop their technical and organisational capabilities to extract value from data. But practitioners face extreme difficulties in understanding the required capabilities to transform data into value. The idea of generating value depends on an organisation's ability to capture, store and analyse a large volume of complex data with the support of advanced analytics (Yesudas et al., 2014). Though the phenomenon of Big Data is used worldwide, it has not emerged to the extent it was expected to be. During the past decade we have seen a tremendous increase in adoption of a variety of Information and Communication Technologies (ICT) for Supply Chain Management (SCM), such as RFID, Enterprise Resource Planning (ERP) to Internet of Things (IoT), etc., which has triggered huge data generation in the supply chain. The continuous efforts of firms to create more sophisticated technology for collecting data at different stages of supply chain have resulted in the new era of big data.

Supply chain signifies flow of information along with material and financial flow (Souza, 2014). With the adoption of ICT technologies, supply chains are enabled to monitor the information flow and inclined towards collecting and analysing a variety of data for efficient management (Chae and Olson, 2013).

A firm's supply chain has to manage the inflow of more than 100 gigabytes of data every day (The Economist, 2010) and about 90% of data available today are generated in the recent past years (Fawcett and Waller, 2014). Estimates shows that the usage of RFID tags would increase rapidly to 209 billion units by 2021 (Marr, 2014; Tachizawa et al., 2015). The number of networked sensors used in automotive, retail and transportation have increased at the rate of 30% per year (Manyika et al., 2011), as it is perceived that the sensor-based technology could substantially reduce the operational cost by 10–25% (Hahn and Packowski, 2015). The volume of digital data is growing exponentially and is expected to reach 35 Zeta bytes by 2020 (Tien, 2015). As a result, companies are increasingly recognising the value of data and advanced analytics tools. Adoption of BDA technologies has the potential to improve organisation's capabilities in the turbulent market environment (Meredith et al., 2012). Hence, to effectively deal with the diffusion of BDA technologies into the supply chain, various issues related to its adoption and practice has to be addressed.

Supply Chain Analytics (SCA) is the term used to indicate Big Data and analytics activities in supply chain management (Wang et al., 2016a, 2016b; Sahay and Ranjan, 2008; Souza, 2014). Chae et al. (2014a, 2014b) argued that there are three sets of resources (Data management resources, IT-based supply chain planning resources, and Performance management resources) collectively constitute SCA. Put together, supply chain analytics is the use of information and analytics tools to support efficient flow of material along the supply chain.

Big Data differs from traditional Business Intelligence (BI) solutions in terms of its scalability and the ability to store a variety of data types (structured and unstructured) in real-time as majority of traditional BI systems are inadequate and only able to store and analyse structured data aggregated at specific time intervals. From 1950 to 2010, the complexity of data has increased gradually, and hence, BDA has emerged as the technology to tackle BD challenges.



Evolution of Big Data Analytics

Big Data is related to technological advancement associated with new kinds of database architectures such as Hadoop, NoSQL, and distributed parallel processing of data. BD technologies can handle volumes of data and also can effectively manage a variety of data types such as textual information from online blogs, customer reviews, etc. (Mortenson et al., 2015). Vera-Baquero et al. (2015) argued that traditional BI systems are insufficient to integrate data from heterogeneous data sources. A widely acceptable definition of BD from Gartner is given as ‘‘high-volume, -velocity and -variety information assets that demand cost-effective, innovative forms of information processing for enhanced insight and decision making” [Beyer and Laney, 2012, p. 2].

According to Manyika et al. (2011), ‘‘Big data refers to datasets whose size is beyond the ability of typical database software tools to capture, store, manage, and analyse.” Based on the nature of data, the BD was characterised mainly by three dimensions such as ‘Volume,’ ‘Velocity,’ and ‘Variety’ (Manyika et al., 2011; Sonka, 2014). However, apart from the 3V’s, BD can also be characterised by another two dimensions as ‘Veracity’ and ‘Value’ (Manyika et al., 2011; Neaga et al., 2015; Ge and Jackson, 2014). ‘Volume’ refers to magnitude of data generated; ‘Variety’ refers to ‘‘structural heterogeneity in a dataset” (Gandomi and Haider, 2015, p. 138), ‘Velocity’ refers to the speed at which data is generated, analysed and acted upon(Gandomi and Haider, 2015), ‘Veracity’ or Verification refers to ensuring data quality, verifying unreliable and uncertain data; and ‘Value’ relates to economic benefits of Big Data (Mishra et al., 2016). From the capabilities perspective, BDA is defined as ‘‘the capability to manage and analyse petabytes of data and enable companies to deal with clusters of information that can impact the business” (Hurwitz et al., 2013, p. 22). Hofmann (2015) defined the three V’s of Big Data from capabilities perspective as ‘‘the ability of the organisations to process the volume of data integrated from a variety of data sources at a high velocity”. Richey et al. (2016) empirically explored the perception of SC managers about big data. While practitioners have recognised the Volume, Variety, Velocity and Veracity characteristics of Big Data, but there is no consensus attained regarding its definition.

LITERATURE REVIEW

I. Role of Big Data Analytics in Supply Chain

The literature on Big Data Analytics is reviewed in terms of the following capabilities:

1. Data generation capability

Data Generation (DG) capability is the ability of organisations to seek, identify, create, and access data from heterogeneous data sources across organisational boundaries. Better insights can be drawn from a good quality data through Enterprise information systems (EIS), which are mostly structured and transactional in nature. Adoption of electronic supply chain management (e-SCM) such as Internet-based inter-organisational systems, Internet based electronic data interchange (EDI) has enhanced communication, coordination, and collaboration across organizational boundaries (Lin, 2014). The adoption of these systems would generate volumes of data through data exchange from the members of supply chain network. Supply chain practices such as collaborative planning, forecasting, and replenishment (CPFR) also generate additional data that needs to be stored and monitored (Chae and Olson, 2013). Apart from these, the ability to collect data from the internet and its significance in improving supply chain performance is also addressed recently (Bhattacharjya et al., 2016; Mishra and Singh, 2016).

2. Data Integration and Management (DIM) capability

DIM capability is the ability of organisations to utilise tools and techniques to collect, integrate, transform and store data from heterogeneous data sources. The level of data integration, and ability to integrate different types of data gathered across organisational boundaries in real-time constitutes DIM capabilities.

Integrating vast amount of supply chain data distributed in heterogeneous sources is a big challenge for the firms (Stefanovic, 2014). DIM can be sub-divided into data acquisition, data pre-processing, and data storage. The dynamic supply chains makes it imperative to possess the capabilities of real-time access and scalability of data storage. The complex nature of BD makes the traditional database systems incompatible (Ge and Jackson, 2014). Hence, Chae and Olson (2013) considered that Inter organizational systems (IOS) such as Web-based or cloud-based EDI (Electronic Data Interchange) could be useful for enhancing data integration capability. Data integration capability can improve visibility, responsiveness, and performance of material management, and provide a 360-degree view of manufacturing operations (Xiong et al., 2015). Data storage component includes a set of hardware and software infrastructure that are suitable for scalability, storing data of different types and the systems to support fast querying and retrieval of data (Hu et al., 2014).

In supply chain context, there could be several reasons for reluctance in sharing data among its members. Some of the major barriers to data sharing are sensitivity, fear of losing competitive advantage and problems with access and control of information sharing (Radke and Tseng, 2015). Supply chains are dynamic in nature and prone to environmental uncertainty.

To streamline data sharing process, it is imperative to have data access control with firms in a short relationship and limit the access when the relationship perishes. If data is scattered and not integrated to provide a single point of truth, organisations would lack a valuable resource for decision making i.e. quality data; therefore, SCM demands DIM capabilities.

3. Advanced analytics capability

Advanced Analytics capability is defined as the ability of an organisation to utilise tools and techniques to analyse supply chain data in batch wise, realtime, near-time, or as it flows to extract meaningful insights for decision making. Data analytics techniques are classified into descriptive, predictive and prescriptive analytics (Souza, 2014). With the increase in analytics capabilities from descriptive to prescriptive analytics, organisation's decision-making capabilities at operational (short-term), tactical (mid-term) and strategic (long-term) level would certainly improve. Descriptive analytics is based on the principle of classical statistics methods, whereas

predictive analytics is the combination of statistics, data mining, and machine learning techniques (Blackburn et al., 2015). While descriptive analytics rely on historical data, predictive analytics utilises historical data including external data from other sources. Manyika et al. (2011) discussed various analytical techniques available to analyse Big Data, such as association rule mining, classification, clustering, crowdsourcing (data collected through web 2.0), data fusion and integration, ensemble learning, machine learning, genetic algorithm, network analysis, neural network, predictive modelling, sentiment analysis, spatial analysis, and time series analysis.

The dynamic nature of SCM demands real-time data analytics capabilities, which enables processing of real-time data (such as RFID data) to monitor processes and events (Manyika et al., 2011). Hahn and Packowski (2015) reviewed in-memory analytics application for real-time data processing in supply chain context, and categorised its application into (i) Plan and optimise (ii) Predict and act, (iii) Sense and respond, (iv) Monitor and navigate. Descriptive analytics on RFID and GPS data enables continuous monitoring of material flow in supply chain, increasing the visibility of assets. Predictive analytics helps in sensing and reacting to supply risk, demand risk, and operations risk, and also can be used to predict delivery, asset utilisation, maintenance, productivity, and sales forecast. Data mining techniques are applied in the area of supply chain fraud detection to reduce supply chain risks (Kraus and Valverde, 2014). Similarly, leveraging prescriptive analytics can be beneficial to plan and optimise supply chains either at operational or strategic level using aggregate data from transactions and granular data from day to day business operations.

4. Data visualisation capability

Data Visualisation capability is the ability of organisations to utilise tools and techniques to render information visuals and deliver the data-driven insights in a timely manner to the decision makers. Data visualisation is ‘‘the representation and presentation of data that exploits our visual perception abilities in order to amplify cognition” (Kirk, 2012, p. 17). The two main purposes of data visualization are sense-making (data analysis) and communication of abstract information through the graphical display (Few, 2009). In supply chain context, data visualisation capabilities are important and can be beneficial for SCM in various ways such as monitoring future demand, optimise distribution networks, visualise delivery routes and material tracking. The primary goal of data visualisation is to intuitively represent knowledge and information using various techniques such as tag cloud, graphs, Clustergram, and heat maps (Chen and Zhang, 2014; Manyika et al., 2011). In particular, heat maps which could display geographical information such as consumption location, transaction density, etc. is valuable to develop new distribution strategies (Tachizawa et al., 2015). Tools such as desktop applications, interactive web and mobile applications offer capabilities to executives, decision makers and customers to interact with the analytics ecosystem (Barlow, 2013). The presence of data visualisation capabilities can effectively support the three analytics capabilities (descriptive, predictive, and prescriptive) (Assunção et al., 2015). Highly interactive visualisation would help users to interpret, find patterns and make decisions quickly and effectively from raw data as well as content from analytics system.

5. Data-driven culture

Data-driven culture is an intangible resource representing the beliefs, attitudes, and opinion of people towards data driven decision-making. According to Aho (2015, p. 284) ‘‘The transformative potential of Big Data lies in treating data as an asset.” Aho (2015) argued that Big Data involves extensive change management and development of new organizational culture to transform the organisation. According to Kiron and Shockley (2011), three main characteristics constitutes data driven culture such as (i) Analytics should be treated as a valuable or strategic asset by an organisation, (ii) Top Management should support and

leverage analytics across the organisation, and (iii) Accessibility of Data-Driven insights to decision makers. Real-world case examples have highlighted the significance of the support from the implementation team and top management for developing BDA capabilities (Wamba et al., 2015). Lavalle et al. (2010) conducted a survey to identify the significant barriers to adoption of analytics in organisations, and found that apart from the challenges of technology and data quality, culture and managerial issues are the significant barriers to analytics adoption. Sangari and Razmi (2015) have empirically verified that organisations find it difficult to establish cultural competence in supply chains. Hence, to build transformational BDA capabilities, business and IT leaders in organisations have to work together and develop new strategies to address the needs of technology and business. Finally, Cao et al. (2015) argued that presence of the data-driven culture would facilitate organisations to make decisions based on facts to develop new products and services.

6. Cloud computing capability

Integrating cloud computing capability to leverage BDA for SCM can be of significance to attain maximum value from the investment. Cloud computing infrastructure can support the integration of data from both intra- and inter-organisational sources and provide scalable storage. From Resource Based View perspective, cloud computing is viewed as a complementary resource while BDA being the primary resource for improving performance. Different types of cloud-based service models are available such as infrastructure as a service (IaaS), platform as a service (PaaS) and Software as a service (SaaS), which are further deployed in four different ways such as private cloud, community cloud, public cloud, and hybrid cloud (Bruque Cámara et al., 2015). In the context of a supply chain, cloud-computing services such as IaaS can be deployed on a community level to facilitate data sharing between supply chain partners within the network. Neaga et al. (2015) argued that several business models based on cloud computing such as Analytics as a service (AaaS), Big Data as a service (BDaaS) and Knowledge and information as a service (KaaS/IaaS) can be adopted to leverage BDA. Further, cloud computing can be used to integrate and store structured and unstructured data from different sources, along with cloud-based data warehousing and Cloud-based data sharing (Tien, 2012). Alfaro et al. (2015) argued that to facilitate access of the analysed data and visualise it into cloud, an integrated architecture of personal cloud, supply cloud, manufacturing cloud, warehouse cloud and logistics cloud can be utilised to transfer information in near real time. Hence, integrating BDA on cloud will improve virtual integration causing supply chain boundaries to disappear (Fawcett and Waller, 2014).

7. Absorptive capacity

Absorptive Capacity (ACAP) plays a significant role in both assimilation and extraction of value from BDA. Cohen and Levinthal (1990, p. 128) defined Absorptive capacity (ACAP) as ‘‘the ability of a firm to recognize the value of new, external information, assimilate it, and apply it to commercial ends, which are critical to its innovative capabilities.” Malhotra et al. (2005, p. 145) perceive it as ‘‘the set of organisational routines and processes by which organisations acquire, assimilate, transform, and exploit knowledge to produce dynamic organisational capabilities.” Moreover, Zahra and George (2002), reconceptualised ACAP into potential ACAP (PACAP) and Realised ACAP (RACAP). According to Roberts et al. (2012), in the context of technology assimilation, ACAP is treated as an asset in the form of prior knowledge possessed by an organisation which foster innovation. BDA as a knowledge infrastructure could enhance knowledge transfer from supply chain partners and increase recipient firm’s ACAP. In the context of extracting value from technology like BDA, ACAP can be conceptualised as a dynamic capability, which could complement BDA capability in generating business value.

8. BDA maturity in supply chain context

Organisations who are better informed of their current state of BDA capabilities are in better position to tackle challenges while adopting it (Lavalle et al., 2010). Maturity models (MM) can help organisations to measure their current state of technological competence benchmarked against industry standards. The term 'maturity' was defined as ''state of being complete, perfect, or ready" (Simpson and Weiner, 1989). Starting from Nolan (1973), several BI and Big Data MM were developed both in academia and industry to help organisations realise their current potential and prepare for future endeavours.
According to Min, Shiwen, and Yunhao (2014), big data typically comprises masses of unstructured data that needs more real-time analysis. Manyika et al. (2011) defined big data as the next frontier for innovation, competition, and productivity (Intel IT Centre – Peer Research, 2012). Richard et al. (2011) in their IDC whitepaper stated that big data technology could be described as a new generation of technologies and architectures, designed so that enterprise organizations could economically extract value from very large volumes of a wide variety of data by enabling high-velocity capture, discovery, storage and analysis. This definition is largely agreed to by many researchers and enterprise industrial R&D managers (Seref and Duygu, 2013; Min et al., 2014; Manyika et al., 2011; Janusz, 2013), although it is also obvious others have different views. The IDC, one of the most influential leaders in big data and its research fields, defines big data in two of its reports (Gantz & Reinsel, 2011; Richard et al., 2011), and outlines some attributes of big data as the four Vs, that is, big data development sources (Variety – V1), big data acquisition (Velocity – V2), big data storage (Volume – V3), big data analysis (Veracity – V4), and finally modulating towards big data value adding or implementation benefits to industry (Value-adding – V5).

II. Drones in Supply Chain
Recently the applications of drones have been proposed for more efficient last-mile delivery (Murray and Chu 2015) (Ponza 2016) (Agatz, Bouman, and Schmidt 2015) (Ha et al. 2015) (Olivares et al. 2015) (Savuran and Karakaya 2015) (Ferrandez et al. 2016) (Wang, Du, and Ma 2014). In this approach, trucks carry some drones in addition to packages. At some points in their routes, drones are launched to deliver supplies to customers. Thus, not only trucks, but also drones are used to deliver supplies to recipients.

APPLICATIONS OF DRONES IN SUPPLY CHAIN
A drone is an unmanned aircraft, more formally known as unmanned aerial vehicles (UAVs) or unmanned aircraft systems (UAS). Essentially, a drone is a flying robot, remotely controlled or can fly autonomously through software-controlled flight plans in their embedded systems working in conjunction with onboard sensors and GPS.
UAVs take different forms, with different control levels, with the capacity to carry a very wide range of payloads. They perform various functions with inbuilt intelligent stabilization systems to keep them flying and can carry sensors, the most common device is a camera mounted on gimbals to obtain high-quality video and still photography. Depending on their lift capacity and payload specifications, UAVs can also carry multiple sensors to extract a wide range of information, increasing the number of possible applications and the business value of their outcomes.
Uses of drones are widespread and include parcel delivery, rural deliveries, surveillance, surveying, and reading barcodes and RFID (radio frequency identification). Drones can have a variety of components added to them; this adaptability allows drone technology to benefit any industry. Business applications aside, drones are being produced as a consumer toy with sizeable markets and growing demand.
Based on a report from market analysis firm Tractica, worldwide sales of consumer drones reached $1.9 billion in 2015, and the market will continue to grow for the next few years.

Tractica forecasts that worldwide consumer drone shipments will increase from 6.4 million units in 2015 to 67.7 million units annually by 2021.
One of the main reasons to use drones is their faster speed and no need for roads. There are many developments taking place globally that can impact the supply chain industry.
The developments fall into two broad categories:
1. Informational/Analytical Innovation:
Cloud computing, big data, and cognitive analytics to capture, store, analyze, and derive insights from data, disseminating and capturing data generated by the Internet of Things (IoT).
2. Physical innovation:
Technologies that take a more physical form, such as drones, driverless vehicles, robotics, smart glasses/augmented reality, and 3-D printing.

The segmentation of the supply chain industry into the two categories is only arbitrary, whereas it is very much evident that the two categories are linked with each other in a big way. The physical innovation along with analytical innovation, enabled through advanced software technologies would optimize the resources. This type of innovation adds visibility to the supply chain coupled with physical devices resulting in improvements in customer service, inventory, cost, and supply chain excellence.
Many companies are using the drone applications for various uses internally within their supply chain operations, which are as given below:
1. Inventory visibility: A drone navigates the entire warehouse and checks the physical inventory by scanning the barcodes and reading the RFID tags. A large amount of inventory data is captured in less time, increasing accuracy and operational efficiency.
2. Facilities inspection: The drones are used to inspect various physical facilities in the entire supply chain, such as truck movement, road and rail routes, traffic congestions, which are used to plan the delivery of goods in advance.
3. Yard management: Transportation vehicles pass through the trailer yards, which is an intersection between transportation and warehousing. Hence, the yard management system is very critical to track and manage the transportation and inventory assets optimally.
4. Service and repair: The drones are used to deliver spare parts to large equipment manufacturers located in remote areas, without incurring huge costs of transportation. This makes the process of servicing large machinery easy and faster.
5. Customer Service: As the e-commerce is growing day by day, the need for a more viable solution to the problem of delivery in heavily congested and confined urban areas is vital for the logistics companies. Last mile delivery becomes difficult in urban areas across many global locations, and hence drones can be used to reach to various locations without being stuck in heavily congested traffic situations.
6. Save Money: According to Bloomberg, human crews make up almost 50% of the cost of operating a cargo ship. If automation can save that amount of money, we expect a major trend toward cargo drones to arrive soon.
7. Eliminate Human Error: The possible errors that can be made by human beings, such as negligence, willful act, etc., can be eliminated by using the cargo drones.
8. Deliver Goods to Places We Wouldn't Normally Go: Remote areas of the world, such as oceanic islands, Arctic regions, or troubled or remote areas are often inaccessible due to poor communications and transportation networks to those locations, where it's either too dangerous or too costly to ship goods there regularly. Unmanned aircraft can perform these tasks efficiently in extreme conditions.

DATA GATHERED BY DRONES
Drones have become digital eyes in the sky, harvesting visual data that computers transform into valuable insights and efficiencies for the users. In the present world, commercial drones are

creating 3D maps of bridges and construction sites, surveying previously unexplored areas, spotting safe places to mine and helping speed disaster relief efforts. They have become the tools for digitizing the real world, and the supply chain companies can use computer technologies and artificial intelligence (AI) to track and manage things.
The drones are programmed with a pre-planned flight plan, and rely on specific locations to trigger the camera, which captures digital images of land and Earth-bound objects, which are assembled into a 3D digital map. They collect thousands of gigabytes of data, which needs to be analyzed properly.
Drones have the potential to enhance many different types of activities previously done by humans. Small-package delivery, land surveys, CAD analysis, videography, herd counting, forest growth measurement, stocking shelves, inspecting well sites, and inspecting rail tracks are just some examples where drone technology can enable employees to work faster and more efficiently.

INTEGRATION OF BIG DATA AND DRONES IN SUPPLY CHAIN

The companies not only have access to data from every link in their supply chain from sensors on the factory equipment to GPS on delivery trucks and bar code scanners in the store, but they can collect the data generated by delivery drones. This large amount of data creates an enormous dataset, the analysis of which can be useful to optimize supply chain, increase end-to-end visibility and drive efficiency for their customer.
The logistics industry stands on the front line with other industries in the Big Data revolution. In a supply chain context, Big Data means companies can analyze not only their own supply chain data in ways never before possible, they can also aggregate their data with other competitors to drastically increase their ability to detect trends in supply chain industry.
The amount of data collected by the shippers has grown significantly. Connectivity gained through Internet of Things (IoT) is producing countless data points, which needs to be analyzed and used in a way that creates value. Shippers can supplement the traditional data with external indicators, such as weather, to predict consumer behavior and identify potential supply chain disruptions. Drawing on data can help to predict when to ship or stage products ahead of a weather event or when to ship items based on demand.

CONCLUSION

Due to capacity constraints and flight range limits, drones are not able to be used as the sole vehicle for distributing supplies. The combination of trucks and drones seem to be an effective approach for last-mile delivery. In this combined system, trucks are used for two purposes: deliver larger packages, carry drones to a location close to the customers' locations and launch them for faster delivery.
As the global supply chain industry is growing and the emphasis is on faster customer service at lower cost, the dependency on third party logistic providers is decreasing and the companies are focusing on making the delivery directly to the consumers on their own. This calls for adopting the usage of drones to achieve the dual objectives of faster delivery and low cost. Hence, the companies should leverage on adopting the usage of big data for competitive advantage by converting huge amounts of data collected by drones into valuable propositions. However, as drone use increases, employees will need to be trained and licensed in drone operation and will need to understand how to operate, manage, and understand the data collected by drones.

Integrating Supply Chain Simulation Game with Linear Programming Optimization in a Supply Chain Management Course

Dmitriy Shaltayev, Associate Professor of Management

Luter School of Business, Christopher Newport University,

1 Avenue of the Arts, Newport News, VA 23606

(757) 594-8914

dmitriy.shaltayev@cnu.edu

Abstract

This paper discusses the use of linear programming optimization in an undergraduate supply chain management class at Christopher Newport University in conjunction with online simulation game. The supply chain management class is a required major class offered to students enrolled in a BSBA program with concentration in management. The class is a broad overview of the supply chain management discipline. In order to provide students with a hands-on experience designing and managing the supply chain, the supply chain simulation game by LittleField Technology is used. The paper provides the game overview, as well as formulation of LP problem in order to design an optimal supply chain to meet customer's demand while maximizing the company profit.

Use of simulation games to illustrate academic concepts is not new. Active learning and simulation-based pedagogy are becoming more prevalent in supply chain management classes. At the same time management science tools and techniques, such as applications of linear programming are oftentimes covered in a separate introductory course. Models, discussed in management science often cover various topics in a piece-meal fashion. Typical material covered includes direct transportation model, transshipment model, assignment problem, and a few others. In order to avoid "silo learning" affect and illustrate the application of management science to solving supply chain problems, this paper describes an attempt to integrate linear programming optimization with the simulation game in an undergraduate supply chain management course. The supply chain simulation game used in the class is offered by Responsive Learning Technologies (www.responsive.net). In the simulation game students are required to manage a two-tiered supply chain company in order to maximize profit. In the course of the game teams of 2-3 students must identify in which locations they want to build production factories, how much manufacturing daily capacity to procure for each factory, and where to construct distribution warehouses. Together with facility locations, students must address which modes of transportation to use between factories and warehouses, as well as between warehouses to customer markets. The assignment implies that supply chain, designed by students, must be balanced, with total production capacity sufficient to meet total demand. Therefore, the starting point of the supply chain configuration is creating a demand forecast for each region where the virtual company operates in the supply chain game. In this paper we propose an exercise where the configuration of the supply chain described above is determined by formulating and solving an integrated facility location and trans-shipment LP problem. Such analysis will provide an application of the management science modeling approach to a simulated scenario which models real business issue. It is important that an introductory class in management science is either a pre- or a co-requisite for such exercise.

ABSTRACT

United States healthcare ranked last compared to 10 other industrialized nations based on variables such as quality, access, efficiency, equity, and healthy lives. This paper examines the existing literature in e-health environment, examines five current case examples, then introduces seven key information technology (IT) that should be integrated into healthcare and healthcare system (HAHS) that could improve healthcare and enhances the United States position in the world healthcare system. The seven key IT include (1) the Internet, (2) big data analytics, (3) wearable computing (4) mobile computing, (5) virtual and augmented reality, (6) robotics, and (7) artificial intelligence (Bidgoli, 2018).

KEYWORDS

INTRODUCTION AND BACKGROUD

According to a study conducted in 2014, United States healthcare ranked last compared to 10 other industrialized nations as follows: (1) United Kingdom, (2) Switzerland, (3) Sweden, (4) Australia, (5) Germany & Netherlands (tied), (6) New Zealand & Norway (tied), (7) France, (8) Canada, (9) United States. The Key variables used in the study were quality, access, efficiency, equity, healthy lives. They are briefly explained below (Unknown, 2014):

Quality- This includes effective care, safe care, coordinated care, and patient-centered care.

Access- Due to high cost and lack of universal healthcare for the nation, healthcare system is not available to everybody compared to their counterpart nations in the study.

Efficiency- Due to high administrative costs, avoidable emergency room use, and duplicative medical testing, efficiency is relatively low.

Equity- Due to high cost the healthcare system is mostly available to wealthier people and those that have full-time employment.

Healthy lives- Measured based on mortality amenable to medical care, infant mortality, and healthy life expectancy.

The United States spends the most on healthcare compared to these other nations. Another study published in 2017 covering 184 countries indicated that U.S. per capita spends far more than other countries with similar life expectancy (Brink, 2017). We believe a proper integration of IT tools and techniques into healthcare and healthcare system can play a major role and offer a positive impact on all of the five key variables mentioned above. We define electronic health (e-health) as: The integration of IT tools and techniques into healthcare and healthcare system in order to reduce overall cost and improve quality, access, efficiency, equity, and healthy lives.

The integration of IT tools and techniques into healthcare and healthcare system in addition to improving healthcare in general, it could also improve reporting, claims processing, data management, and process automation that collectively should reduce the growing cost of HAHS.

THE LANDSCAPE OF ELECTRONIC HEALTH

A recent survey on the status, applications, deployment, challenges, and opportunities presented by e-health reveals interesting facts as follows:

Medical mistakes in the U.S. hospitals and healthcare institutions are the third leading cause of death and nearly 98,000 people annually lose their lives in this way. E-health could significantly reduce this number (Ehteshami, et al. 2013).
The experience of Angelina Jolie, the well kwon actress highlights how cloud computing can help address cancer by cutting the cost of genomic sequencing and enabling data sharing (Puranik, 2017).
The 'doctor's bag of the future could be a 3D printer by allowing doctors to create or make wherever they are, in the space or a remote rural area (Strickland, 2017).
Apple is working with a start-up called Health Gorilla to turn the iPhone into a personal hub for all of its customers medical information, this could add diagnostic data to the iPhone, including blood work, by integrating with hospitals, lab-testing companies such as Quest and LabCorp and imaging centers (Farr, 2017).
Senate bill would pay doctors to use Facetime with patients enabling physicians and other healthcare providers to evaluate patients via video chats such as Facetime (Mearian, 2017).
IBM Watson in conjunction with FDA are exploring blockchain for secure patient data exchange, the initial focus for blockchain will be oncology-related data exchange (a-Mearian, 2017).
IBM Watson artificial intelligence platform has joined forces with researchers at MIT and Harvard to use genomic data to defeat drug-resistant cancers (Mearian, 2016).
Aetna gave away 50,000 Apple Watches to its employees and subsidize others for customers. It is working with Apple on iOS-exclusive integrated health apps for iPhone, iPad, and Apple Watch devices (a-Mearian, 2016).
Artificial intelligence could help diagnose mental disorders using machine learning in order to train software to spot verbal tics associated with schizophrenia, depression, and bipolar disorder (Frankel, 2016).
A toy-like cardboard contraption that sells for less than $20 online from Google, as a virtual reality tool, has helped save the life of a baby who was so sick that doctors told her parents to take her home to die (Cohen, 2016).
Because of the availability and readily access to healthcare data, government and industry leaders caution that medical data must come with context in order to provide meaningful insights for patients and researchers (Corbin, 2014).
As the resistance reduces, IT leaders are helping more and more health care providers move to the cloud from the on-premise IT computing (Linthicum, 2014).
IBM and Pathway Genomics working on a mobile app that uses personal history and genetics to assess risks and plan exercise in order to keep people healthier (Gaudin, 2014).
A recent Pew Internet study suggests that rising smartphone adoption in the United States seems to be motivating people to use mobile health (Eastwood, 2013).
Health care workers in the developing world are using mobile phones to address critical health needs ranging from maternal mortality to HIV testing to clean water (Kim, 2012).
By filtering through 2 billion public tweets, John Hopkins University scientists discovered health patterns, including misuse of medications (Samson, 2011).
IoT medical devices will play a major role in healthcare system, according to recent surveys, healthcare providers, manufacturers, and regulators believe cybersecurity risks of IoT medical devices and connected legacy systems are a top security concern (Kawamoto, 2017).
Many hospitals transmit health records unencrypted due to lack of budget and personnel to address security concerns (b-Mearian, 2016).
Hackers want your healthcare data which is much more valuable than credit card information (Rashid, 2015).
California DOJ report on data breaches shows most losses in healthcare revolve around stolen devices, due to weak use of encryption that, poses greatest risk to healthcare data (Yegulalp,2014).

RESEARCH QUESTIONS

What are critical success factors in design and implementation of an electronic health system?
What are the key IT components of an electronic health system?
Is the adoption of an electronic health system ROI justified?

CONCLUSION

This paper examined the existing literature in e-health environment, reviewed five current case examples, and then introduced seven key information technology (IT) that should be integrated into healthcare and healthcare system (HAHS). This integration should improve healthcare and enhances the U.S. position in the world healthcare system. The seven key IT include (1) the Internet, (2) big data analytics, (3) wearable computing (4) mobile computing, (5) virtual and augmented reality, (6) robotics, and (7) artificial intelligence. The paper also assessed major risks associated with e-health systems including security and privacy of medical records, and risks associated with medical IoT devices and then recommended an e-health plan for implementation. These seven IT tools could improve key variables (quality, access, efficiency, equity, and healthy lives) in the healthcare and healthcare system.

ABSTRACT

This paper examines the interaction of delivery and inventory models and the effect of delivery performance on the supplier's and buyer's costs in a two-stage supply chain. From a supplier's prospective, the effect of the timeliness of delivery can be described by supply chain delivery performance models. From a buyer's point of view, supply chain delivery can be represented by inventory models. This comparison and supporting analysis bridges existing gaps found in the literature and contributes to linking and coordinating the delivery and inventory sub processes within supply chains. Theoretical and managerial implications of the findings are discussed.

KEYWORDS: Delivery performance, Supply chain management, Inventory models, delivery time, two levels of storage

INTRODUCTION

Supply chain management serves as the foundation of an organization's overall competitive strategy for attaining and maintaining competitive advantage. The Supply Chain Operations Reference-model (SCOR) defines the delivery process as one of five supply chain processes (plan, source, make, deliver, and return). The timeliness of delivery is a key concern to customers and numerous empirical studies have documented the importance that on-time delivery plays in the operation of the supply chain (da Silveira & Arkader, 2007; Iyer et al., 2004; Salvador et al., 2001). This paper herein evaluates an effect of the timeliness of delivery within a two-stage supply chain on both a supplier and a buyer.

From a supplier's prospective, the effect of the timeliness of delivery can be described by supply chain delivery performance models (Bushuev and Guiffrida, 2012). Models for evaluating delivery performance within supply chains can be categorized into two groups: i) index based models (see for example, Wang and Du, 2007; Garg et al. 2006), and ii) penalty cost based models (see for example, Shin et al., 2009; Guiffrida and Nagi, 2006). Both categories of models are similar in that delivery timeliness to the final customer is analyzed with regard to a delivery window whereby a supplier is penalized for untimely (early or late) delivery. As identified in Gunasekaran and Kobu (2007) delivery performance should be measured in financial terms. Therefore, this paper focuses on penalty cost based delivery performance models. Although a supplier cannot guarantee delivery timeliness, it can decide when the product will be shipped and thus increase or decrease probabilities of early and late deliveries. The concept of the optimal position of the delivery window (OPDW) proposed by Bushuev and Guiffrida (2012) extended the research in this area. The concept shows that the optimally positioned on-time portion of the delivery window can minimize the expected penalty costs of untimely (early and late) delivery for any delivery time distribution with a continuously

differentiable probability density function. By applying this concept a supplier can determine when to initiate the shipment of the product so as to minimize the expected penalty cost for untimely delivery. Delivery performance models investigate penalty costs for untimely delivery for a supplier; hence the models can be used as a supplier's point of view on supply chain delivery performance.

On the buyer's side, early and late deliveries introduce waste in the form of excess cost into the supply chain; early deliveries contribute to excess inventory holding costs while late deliveries may contribute to production stoppage costs, lost sales and loss of goodwill. Thus, delivery will affect the buyer's inventory level and inventory models represent the buyer's point of view on supply chain delivery. It is in the buyer's best interest to minimize inventory costs and probability of stockouts. Under the concept of the delivery window used in delivery performance models, the customer sets benchmarks in time which are used to classify deliveries as being early, on-time, or late. In general, when the delivery window is imposed on the underlying delivery time pdf (probability density function), the delivery performance model becomes a stochastic model with three possible outcomes: early, on-time, and late delivery. In classical inventory models, there are two possible outcomes (stockouts and no stockouts) in each inventory cycle that can occur as a result of the demand during lead time. Late delivery contributes to stockouts; on-time delivery contributes to no stockouts. In practice, usually the storage capacity for inventory is limited and industry has a long history of working to address the effects of limited storage space (Kempf et al., 2011). When a limited storage space is considered three outcomes are now possible: stockouts, overloading, and no stockouts and no overloading; where overloading means the level of inventory exceeds the storage capacity. Delivery time is a common element that affects the delivery outcomes (early, on-time, and late) and inventory outcomes (stockouts, overloading, and no stockouts and no overloading). Hence it is an attractive factor for further study.

Two formulation approaches have been reported in the literature for inventory models with limited storage space. The first approach takes the form of a resource constrained optimization problem with storage capacity as the constraining resource (see for example Hausman et al., 1998; Zhao, 2007). A second modeling approach due to Hartley (1976) recognizes that outside storage space can be rented hence the optimization of the inventory decision variables is addressed from a modeling perspective that accommodates two levels of storage: owned warehouse (OW) and rented warehouse (RW). Hence, the models with capacity constraints are just a special case of the models with two levels of inventory with the costs for rented warehouse equal to infinity. Previous researchers mostly focused on deterministic models with two storage facilities (for example, Sarma, 1983; Lee and Hsu, 2009).

Inventory models assume that a reorder point (a time when a buyer places an order) defines when the product will be shipped and, as a result, when it will arrive to the buyer. In reality a supplier ships the product and the time when the product will be shipped is the supplier's decision. How the supplier's delivery decision will affect buyer costs? Could the buyer influence the supplier's delivery decision? The answer can be found comparing delivery and inventory models as supplier's and buyer's points of view. However, the existing literature has a gap between two research streams (supply chain delivery performance and inventory management) and fails to provide a research which considers the problems together. This paper bridges existing gaps found in the literature and contributes to linking and coordinating the delivery and inventory sub processes within supply chains. This paper explains how supply chain delivery performance and inventory models define a supplier's and buyer's points of view respectively and how different points of view affect managerial decisions.

To facilitate the comparison of the models under study we present them sequentially. Initially the delivery performance model, which captures the supplier's point of view, is presented. The inventory model, which captures the buyer's point of view, then follows. This

paper is further organized as follows. Section 2 provides a supplier's point of view based on delivery performance models and defines the optimal delivery decision derived from the models. In Section 3, a new inventory model is developed proposing a buyer's point of view on the delivery. The comparison of delivery performance and inventory models as supplier's and buyer's points of view is presented in Section 4. A buyer's strategy for delivery performance optimization is discussed in Section 5. Section 6 presents a summary and discusses future research directions.

DELIVERY PERFORMANCE MODELS AS A SUPPLIER'S POINT OF VIEW

An integral component found in many supply chain delivery performance models is the concept of the delivery window. Under the concept of a delivery window, contractually agreed upon benchmarks in time are used to classify deliveries as being early, on-time, and late (see Figure 1). When delivery occurs outside the on-time portion of the delivery (early or late), the supplier incurs a contractually specified penalty cost. When delivery is within the on-time portion of the delivery window, no penalty cost is incurred (see for example, Schneiderman, 1996; Freehand, 1991).

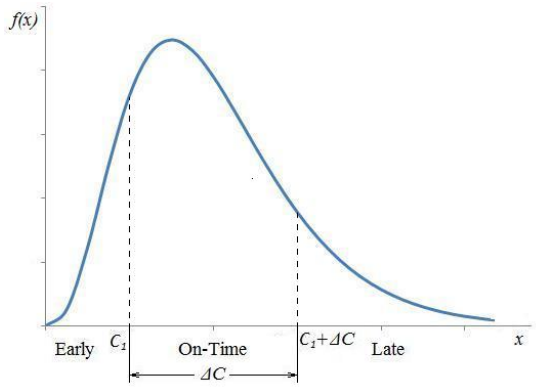

Figure 1. Illustration of a Delivery Window

Legend: *f(x)* is the probability density function (pdf) of delivery time, c_1 is beginning of on-time delivery, Δc is the width of the on-time portion of the delivery window.

Guiffrida & Nagi (2006) defined the expected penalty cost per period for untimely delivery for a two-stage serial supply chain as:

$$Y = QH\int_{a}^{c_1}(c_1 - x)f(x)dx + K\int_{c_1+\Delta c}^{b}(x-(c_1+\Delta c))f(x)dx, \quad (1)$$

where Y = expected penalty cost of untimely delivery,

$QH\int_{a}^{c_1}(c_1 - x)f(x)dx$ = expected penalty cost of early delivery,

$K\int_{c_1+\Delta c}^{b}(x-(c_1+\Delta c))f(x)dx$ = expected penalty cost of late delivery,

$f(x)$ = probability density function (pdf) of delivery time x,
QH = penalty cost per time unit early (levied by the buyer),
K = penalty cost per time unit late (levied by the buyer),
a = earliest acceptable delivery time,
b = latest acceptable delivery time,

c_1 = beginning of on-time delivery,
Δc = the width of the on-time portion of the delivery window.

The model makes the following assumptions: (i) there is a single product with a fixed delivery lot size Q, (ii) the delivery time consists of the internal manufacturing lead time(s) of the supplier plus the external lead time associated with transporting the delivery lot size from supplier to buyer, and (iii) a make-to-order replenishment policy is in effect.

The parameter c_1, the beginning of on-time delivery, defines the position of the on-time portion of the delivery window and together with the width of the on-time portion of the delivery window (Δc) and delivery time distribution parameters establishes the probabilities of early, on-time, and late delivery. These probabilities directly affect the value of the expected penalty cost (Y). As demonstrated in Bushuev and Guiffrida (2012), Y is a convex function of c_1 and the optimal value of c_1 (which is defined as c_1^*) that minimizes Y can be determined by evaluating

$$K \cdot P_{late} = QH \cdot P_{early}, \text{ or } P_{late} / P_{early} = QH / K \quad (2)$$

where $P_{late} = \int_{c_1+\Delta c}^{b} f(x)dx$ is the probability of late delivery,

$P_{early} = \int_{a}^{c_1} f(x)dx$ is the probability of early delivery.

In the supply chain delivery performance model, c_1 defines beginning of on-time delivery with respect to a time when a product is shipped (which is shown on Figure 1 as zero point). Since the on-time portion of the delivery window is fixed by a contract, changing c_1 means altering the time when a product is shipped. In the paper herein we assume that the supplier uses the concept of the optimal position of the delivery window (OPDW) to define the optimal value of c_1 and, accordingly, a time when the product should be shipped to the buyer.

INVENTORY MODELS AS A BUYER'S POINT OF VIEW

In this section, we define the mathematical form for a stochastic continuous review (Q, R) inventory model with two levels of storage. The goal is to find the optimal reorder point (R^*) which will minimize the expected total cost. We assume that the lot size (Q) is not a decision variable in the model to maintain consistency with the delivery performance model which also assumes constant lot size. To construct the model, we employ the following notations and assumptions.

Notations

C_O = Cost of overload (cost of holding extra inventory when inventory level is higher than size of warehouse, \$/unit time);
C_S = Cost of stockout (\$/unit time);
D = Demand (units/unit time);
H = Holding cost per unit per year (\$/unit/unit time);
L = Lead time (unit time), random variable with probability density function (pdf) $f(L)$;
Q = Order quantity (Lot size, units);
Q_{max} = Size of warehouse (units);
R = Reorder point (units);
S = Ordering cost (\$/order).

Assumptions

The following assumptions about the model are made:
(1) Average lead time and its pdf are known.
(2) A single product, instantaneously replenishment, and no quantity discounts.
(3) Stockouts are backordered.
(4) Storage is limited by the capacity of the OW, however additional storage can be purchased at an RW.
(5) Demand is first met from RW until it is empted. Items in OW are used only after RW is depleted.
(6) The transportation cost between warehouses is negligible.
(7) Holding costs are applied to any unit of inventory on hand (at OW and RW).
(8) Reorder point $R > 0$.
(9) No interaction between orders ($0 \le L \le Q/D$).
The last assumption is supported by other researchers, the "interval between placing orders is usually large enough so that there is essentially no interaction between orders" (Hadley and Whitin, p. 203) or the probability of crossover is small enough to be ignored.

The model

As shown on Figure 2, there are three possible (probabilistic) outcomes for the inventory model. These outcomes are:

1. $L > R/D$. Inventory level reaches zero level and in addition to inventory holding cost we are paying for stockouts, because of late delivery.
2. $A/D \le L \le R/D$, where $A = R - (Q_{\max} - Q)$ (*B* area, $B = Q_{\max} - Q$). No stockouts, no overload. Thus, we have inventory holding cost only.
3. $L < A/D$. When delivery occurred, the inventory level will exceed $Q_{\max}$, so we are paying for overloading and inventory holding cost.

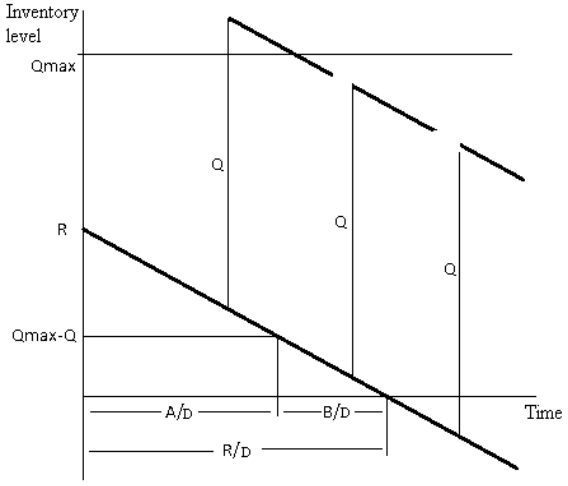

Figure 2. Typical outcomes

The probability of each outcome can be found by integrating the probability density function of lead time over the appropriate outcome specific limits. The probability of late delivery, when stockout occur (outcome 1) is

$$P_{late} = P(L > R/D) = \int_{R/D}^{\infty} f(L)dL \,. \quad (3)$$

The probability of on-time delivery without stockouts and overloading (outcome 2) is

$$P_{ontime} = P(A/D \le L \le R/D) = \int_{A/D}^{R/D} f(L)dL \,. \quad (4)$$

The probability of early delivery, when overload occur (outcome 3) is

$$P_{early} = P(L < A/D) = \int_{0}^{A/D} f(L)dL \,. \quad (5)$$

The total cost per unit time is (see Appendix A for proof):

$$\mathrm{E}(TC) = S\frac{D}{Q} + \frac{H}{2}\left(Q + 2(R - \mathrm{E}(L)D)\right) + \frac{H}{2Q}(Y_{late})^2 + \frac{C_0}{Q}Y_{early} + \frac{C_S}{Q}Y_{late} \quad (6)$$

Where the first element is ordering cost, the second two elements are inventory holding cost, and the last two elements are costs of overload and stockout, respectively.
The reorder point is optimal when (see Appendix B for proof):

$$H\left(Q - Y_{late}P_{late}\right) + C_0P_{early} = C_SP_{late} \,. \quad (7)$$

COMPARISON OF DELIVERY PERFORMANCE AND INVENTORY MODELS

In the previous sections, the costs associated with the delivery process were defined for a supplier and a buyer. Both a supplier and a buyer are interested in minimizing their costs, but that might involve conflicting goals. They have a certain influence on the delivery process attempting to minimize their costs, but neither can change all parameters which affect the cost functions alone. A supplier has control of the time of delivery only and would apply the concept of the optimal position of the delivery window to find an optimal time of delivery. A buyer can affect the supplier's optimal time of delivery by defining the penalties for untimely delivery in the contract which is a common purchasing agreement practice. A supplier would prefer a time of delivery that will minimize its costs and penalties equal to costs of overload and stockout. How can a buyer achieve this goal? Supplier's and buyer's points of view on delivery performance are compared to answer this question.

The supply chain delivery performance model shown in Section 2 describes a supplier's point of view on delivery performance. In Section 3 an inventory model was introduced as a buyer's point of view. Both of these models demonstrate costs related to a product delivery for a supplier and a buyer (equations (1) and (6) respectively). Table 1 summarizes the key parameters in the cost functions of each model and identifies the model commonalities which support a comparison of the points of view of the supplier and buyer.

Table 1. Connection between parameters of supplier's and buyer's cost functions

Supplier	Buyer	Description
QH	C_o	Cost of early delivery / overload ($/unit time)
K	C_s	Cost of late delivery / stockout ($/unit time)
x	L	Random variable: Delivery lead time (unit time)
Δc	$Q_{max} - Q$	Width of on-time portion of delivery window (unit time) / (units)
c_1	R	Decision variable: Beginning of on-time delivery (unit time) / Reorder point (units)

Both models (supplier's and buyer's) have three possible outcomes: early delivery (overload), on-time delivery (no overload and no stockouts), and late delivery (stockouts). These outcomes are related to the same random variable in both models: delivery lead time. This random variable is compared with a decision variable to define the outcomes.

The decision variable in the delivery performance model (beginning of on-time delivery, c_1) is connected with the reorder point (R) decision variable in the inventory model. They have different dimensions, however the ratio $\frac{R-(Q_{\max}-Q)}{D}$ used in the inventory model has the same meaning as c_1 in the delivery performance model. The width of the on-time portion of the delivery window (Δc) is measured in time units in the delivery performance model and in units of product in the inventory model ($Q_{max} - Q$). Through the conversion $\frac{Q_{\max}-Q}{D}$ the common unit of time can be introduced into the inventory model thus enabling a direct comparison between the delivery and inventory models. For further discussion we define R_b^* as the optimal reorder point for a buyer and $R_s^* = c_1^* D + Q_{\max} - Q$ as the optimal reorder point for a supplier. A buyer would prefer to have $R_b^* = R_s^*$, because in this case a supplier choosing an optimal delivery will minimize buyer costs too. Differences between R_b^* and R_s^* are determined by differences in the delivery performance and inventory models.

There are several differences in the models. First, the delivery performance model determines the total cost per delivery while the inventory model finds the cost per unit time. For the inventory model the cost per delivery (cycle) is shown in equation (A.10). The optimal reorder points for both equations (A.10) and (6) are the same, thus the dimension of the inventory cost function does not affect the optimal solution. Hence, the difference does not forbid comparing the optimal solutions of the delivery performance and inventory models. Second, the delivery performance model has one decision variable c_1, while classical inventory models assume two decision variables: R and Q. The lot size Q does not affect the supplier's decision about the time of delivery; therefore Q is not used as a decision variable in the inventory model herein. Thus, the difference was eliminated to keep a connection with the delivery performance model. Third, the inventory model has two extra parameters which are not included in the delivery performance model: S and H which define ordering and inventory holding costs. S does not affect the optimal value of R which is clear from (7).

The value of H defines the difference between the difference between the optimal values for the delivery performance and inventory models and, as a result, the difference between the supplier's and buyer's optimal decisions (R_s^* and R_b^*). If $H = 0$, there are no differences between R_s^* and R_b^* and there is accordance between optimal R and c_1. The higher H the bigger impact of inventory holding cost on the optimal value of R for a buyer and the bigger difference between supplier's and buyer's optimal decisions.

BUYER'S STRATEGY FOR DELIVERY PERFORMANCE OPTIMIZATION

From a supplier's prospective, a delivery strategy is pretty simple. Assuming that the width of on-time portion of the delivery window and penalty costs per time unit early and late are defined by the contract, a buyer should choose a shipping time based on OPDW to minimize its costs. From a buyer's prospective, a delivery strategy is more complicated. In the inventory model that defines a buyer's point of view on supply chain delivery performance, the decision variable is a reorder point which defines a shipping time. Unfortunately for a buyer, they cannot directly force a supplier to ship at the time optimal for the buyer.

Assume the supplier chooses a time when the product will be shipped based on the concept of the optimal position of the delivery window. How will it affect the buyer's costs? What should the buyer do to optimize its own costs? The only way a buyer can influence a supplier's delivery decision is during the contract negotiation process. Assume the buyer has enough power to choose any reasonable penalties for untimely delivery (QH and K). If a supplier has more power than a buyer, then the supplier will ask for no penalties for untimely delivery and will ship the product when it is appropriate from supplier's production prospective. Thus, the buyer should choose the values of QH and K so that the shipping time which is optimal for the supplier is optimal for the buyer too. How to choose these values? There are two questions that should be answered.

The first question is how to choose the ratio QH/K which is optimal for the buyer? From equation 2, it can be concluded that the ratio QH/K defines the optimal value of c_1. Thus, knowing the ratio is enough to find the optimal shipping time for a supplier. The buyer's strategy should be the following:

1. Find an optimal reorder point for the buyer.
2. Based on the optimal reorder point, calculate the ratio of probability of late to probability of early deliveries.
3. Use this ratio to define penalties (QH/K should be equal to the ratio).

The second question is how high the values of QH and K should be? If the values are too low, the possible penalties are too low and will not force the supplier to delivery on-time. If the values are too high, it will affect the willingness of the supplier to sign the contract. The penalties should be reasonable and a buyer should explain why such high penalties should be applied to the buyer. Therefore, a buyer can penalize a supplier based on the buyer's costs of overload and stockout. When an early delivery occurs the supplier is penalized for early delivery and the buyer incurs an additional cost to rent a warehouse. It is reasonable to assume that a buyer will ask a supplier to pay for the rented warehouse and per the model $QH = C_o$. Late delivery will lead to stockouts for a buyer on one side and to penalties for late delivery for a supplier on another. In this case, a buyer can charge its supplier by the amount equal to its stockout costs, then the penalty per unit time is $K = C_s$. On-time delivery does not assume any penalties for a supplier and no additional costs (except inventory holding cost) for a buyer.

Assume a buyer wants its supplier to pay for overloads and stockouts choosing $QH = C_o$ and $K = C_s$. The problem is that if a buyer chooses $QH = C_o$ and $K = C_s$, the supplier's and buyer's optimal decisions will not be the same ($R_s^* \neq R_b^*$) for any $H \neq 0$ and the buyer's costs will not be minimized. Thus, the effect of holding cost on the buyer's optimal reorder point should be counterbalanced by changing the penalty costs for early and/or late delivery. How should the values of QH and K be changed? To answer this question, the effect of holding cost and costs of stockout and overload on the optimal reorder point is investigated in the following propositions.

Proposition 1. A buyer can decrease the supplier's optimal reorder point (R_s^*) by increasing the cost of overload (C_O) (see Appendix C for proof).

Proposition 2. A buyer can increase the supplier's optimal reorder point (R_s^*) by increasing cost of stockout (C_S) (see Appendix C for proof).

Proposition 3. For $QH = C_o$, $K = C_s$, and $H > 0$, the optimal reorder point for a buyer is less than the supplier's optimal reorder point ($R_b^* \leq R_s^* = R_b^*(H = 0)$) (see Appendix C for proof).

From proposition 3, it can be concluded that the supplier's optimal reorder point (R_s^*) should be decreased to be equal to the buyer's reorder point (R_b^*). It can be done in two ways:

- Setting the penalty for early delivery higher than the cost of overload ($QH > C_O$);
- Setting the penalty for late delivery lower than the cost of stockout ($K < C_S$).

If a buyer chooses to increase the penalty for early delivery compared to the cost of overload ($QH > C_O$), it means that the supplier will have to pay for overload more than it requires to cover

rented warehouse costs. Thus, the penalties paid by the supplier will cover some inventory holding costs too. If a buyer chooses to set the penalty for late delivery lower than the cost of stockout ($K < C_S$), the buyer will have to pay the difference in a case of stockout. It could be a combination when a buyer increases the penalty for early delivery and decreases the penalty for late delivery at the same time.

CONCLUSION

The model presented herein coordinates the logistics and inventory management sub systems within a supply chain and represents a generalized modeling approach to the evaluation of supply chain delivery performance. An effect of the timeliness of delivery within a two-stage supply chain on both a supplier and a buyer is evaluated. From a supplier's prospective, the effect of the timeliness of delivery can be described by supply chain delivery performance models. The buyer's point of view on supply chain delivery is represented by inventory models with two levels of storage. In addition to the main contribution, the paper extends research in the area of stochastic models with two levels of inventory. The new model proposed herein differs from existing models by cost dimensions. The optimal solution for the model is found.

The paper explains how supply chain delivery performance and inventory models define a supplier's and buyer's points of view respectively and how different points of view affect managerial decisions. A supplier's optimal decision is based on the optimal position of the delivery window developed by Bushuev and Guiffrida (2012). The OPDW concept minimizes a supplier's costs for untimely delivery choosing an optimal shipping time. The shipping time chosen by a supplier might be nonoptimal for the buyer and the buyer should penalize the supplier such that the supplier's optimal decision is optimal for the buyer too.

Managerial implications of the findings which include a buyer's strategy for delivery performance optimization are discussed in Section 5. It is based on the assumption that the supplier utilizes an optimally positioned delivery window to determine a time when the product will be shipped. The paper suggests a buyer penalize a supplier for untimely delivery based on the costs of stockout and overload ($QH = C_o$ and $K = C_s$). In this case, the penalties will be high enough to cover the buyer's expenses associated with untimely delivery. If the penalties are matched with the costs, the supplier's optimal shipping time is optimal for the buyer only if there is no inventory holding cost. The buyer can force the supplier to choose a shipping time that will be optimal for the buyer by setting the penalty for early delivery higher than the cost of overload ($QH > C_O$) and/or setting the penalty for late delivery lower than the cost of stockout ($K < C_S$).

There are several directions for future research. Since a buyer can have other dimensions of stockout and overload costs, research linking the delivery performance model and inventory models with different cost dimensions should be done. Moreover, the research can be extended to 3-stage and n-stage supply chains and supply chains with several suppliers and/or buyers.

APPENDIX A

We are calculating costs for each of three outcomes (excluding ordering cost).
In the case of on-time delivery we have inventory holding cost only. The cost per cycle is equal to the squares of two trapezoids (see Figure 3 areas A and B) multiplied by holding cost (H)

$$C_{ontime} = H\frac{Q}{2D}\left[\left(R+Q-LD\right)+\left(R-LD\right)\right] = H\frac{Q}{2D}\left(Q+2(R-LD)\right). \quad \text{(A.1)}$$

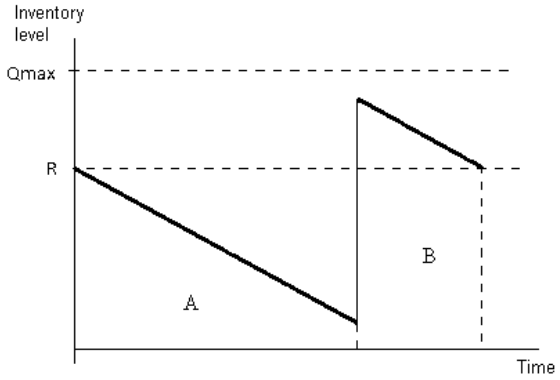

Figure 3. Outcome 2: On-time delivery

The expected cost for on-time delivery is

$$\mathrm{E}(C_{ontime}) = \frac{H}{2D}\int_{A/D}^{R/D} Q\big(Q + 2(R - LD)\big) f(L)dL\,. \tag{A.2}$$

The cost of early delivery includes holding and backordering costs. The holding cost is described the sum of the areas A and B on Figure 4. And the backordering cost is defined by the length C

$$C_{early} = H\frac{Q}{2D}\big(Q + 2(R - LD)\big) + C_O\frac{A - LD}{D}\,. \tag{A.3}$$

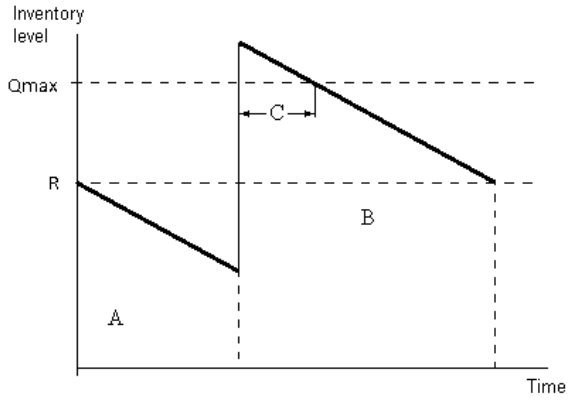

Figure 4. Outcome 3: Early delivery

The expected cost for early delivery is

$$\begin{aligned}\mathrm{E}(C_{early}) &= \frac{H}{2D}\int_{0}^{A/D} Q\big(Q + 2(R - LD)\big) f(L)dL + \frac{C_O}{D}\int_{0}^{A/D}\big(A - LD\big) f(L)dL = \\ &= \frac{H}{2D}\int_{0}^{A/D} Q\big(Q + 2(R - LD)\big) f(L)dL + \frac{C_O}{D}Y_{early},\end{aligned} \tag{A.4}$$

where $Y_{early} = \int_{0}^{A/D}\big(A - LD\big) f(L)dL$.

For late delivery inventory cost is described by A and B areas (Figure 5)

$$C_{Inv\,late} = \frac{H}{2}\left(\frac{Q}{D} - (L - R/D)\right)(Q + R - LD), \text{ or}$$

$$C_{Inv\,late} = H\frac{Q}{2D}\big(Q + 2(R - LD)\big) + \frac{H}{2D}\big(R - LD\big)^2. \quad \text{(A.5)}$$

Knowing that the stockout length of time is equal to C, the cost for late delivery is

$$C_{late} = H\frac{Q}{2D}\big(Q + 2(R - LD)\big) + H\frac{(R - LD)^2}{2D} + C_S\frac{LD - R}{D}. \quad \text{(A.6)}$$

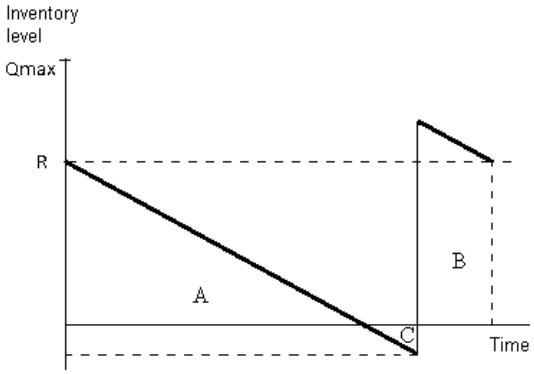

Figure 5. Outcome 1: Late delivery

The expected cost for late delivery is

$$\mathrm{E}(C_{late}) = \frac{H}{2D}\int_{R/D}^{\infty} Q\big(Q + 2(R - LD)\big)f(L)dL +$$

$$+ \frac{H}{2D}\left(\int_{R/D}^{\infty}\big(R - LD\big)f(L)dL\right)^2 + \frac{C_S}{D}\int_{R/D}^{\infty}\big(LD - R\big)f(L)dL = \quad \text{(A.7)}$$

$$= \frac{H}{2D}\int_{R/D}^{\infty} Q\big(Q + 2(R - LD)\big)f(L)dL + \frac{H}{2D}\big(Y_{late}\big)^2 + \frac{C_S}{D}Y_{late},$$

where $Y_{late} = \int_{R/D}^{\infty}\big(LD - R\big)f(L)dL$.

The total expected cost per cycle including ordering cost is

$$\mathrm{E}(C) = \mathrm{E}(C_{ontime}) + \mathrm{E}(C_{early}) + \mathrm{E}(C_{late}) = S + \frac{H}{2D}\int_{A/D}^{R/D} Q\big(Q + 2(R - LD)\big)f(L)dL +$$

$$+ \frac{H}{2D}\int_{0}^{A/D} Q\big(Q + 2(R - LD)\big)f(L)dL + \frac{C_O}{D}Y_{early} + \quad \text{(A.8)}$$

$$+ \frac{H}{2D}\int_{R/D}^{\infty} Q\big(Q + 2(R - LD)\big)f(L)dL + \frac{H}{2D}\big(Y_{late}\big)^2 + \frac{C_S}{D}Y_{late}.$$

$$\mathrm{E}(C) = S + \frac{H}{2D}\int_{0}^{\infty} Q\big(Q + 2(R - LD)\big)f(L)dL + \frac{H}{2D}(Y_{late})^2 + \frac{C_0}{D}Y_{early} + \frac{C_S}{D}Y_{late}. \quad \text{(A.9)}$$

$$\mathrm{E}(C) = S + \frac{H}{2D}Q\big(Q + 2(R - \mathrm{E}(L)D)\big) + \frac{H}{2D}(Y_{late})^2 + \frac{C_0}{D}Y_{early} + \frac{C_S}{D}Y_{late}, \quad \text{(A.10)}$$

where $\mathrm{E}(L)$ is expected value of *L*.

Using that the number of cycles per unit time is *D/Q*, the total cost per unit time is

$$\mathrm{E}(TC) = S\frac{D}{Q} + \frac{H}{2}\big(Q + 2(R - \mathrm{E}(L)D)\big) + \frac{H}{2Q}(Y_{late})^2 + \frac{C_0}{Q}Y_{early} + \frac{C_S}{Q}Y_{late}. \quad \text{(A.11)}$$

APPENDIX B

To find the optimal reorder point we take the derivative of the total cost by *R*. Using that

$$\frac{dY_{early}}{dR} = \frac{1}{D}(A - \frac{A}{D}D)\,f(\frac{A}{D}) - 0 + \int_0^{A/D} f(L)dL = P_{early}, \quad \text{(B.1)}$$

where $\frac{dA}{dR} = 1$, and

$$\frac{dY_{late}}{dR} = 0 - \frac{1}{D}(\frac{R}{D}D - R)\,f(\frac{R}{D}) + \int_{R/D}^{\infty}(-1)f(L)dL = -P_{late}, \quad \text{(B.2)}$$

we have

$$\begin{aligned}\frac{d\mathrm{E}(TC)}{dR} &= 0 + \frac{H}{2}2 + \frac{H}{2Q}\big(2Y_{late}P_{late}\big) + \frac{C_O}{Q}P_{early} - \frac{C_S}{Q}P_{late} = \\ &= H + \frac{H}{Q}\big(Y_{late}P_{late}\big) + \frac{C_O}{Q}P_{early} - \frac{C_S}{Q}P_{late}.\end{aligned} \quad \text{(B.3)}$$

The optimal reorder point is when

$$H\big(Q - Y_{late}P_{late}\big) + C_0P_{early} = C_SP_{late}. \quad \text{(B.4)}$$

To prove convexity of the total cost by *R* we take the second derivative. Using

$$\frac{dP_{early}}{dR} = \frac{1}{D}f(\frac{A}{D}) - 0 + \int_0^{A/D} 0dL = \frac{1}{D}f(\frac{A}{D}), \quad \text{(B.5)}$$

$$\frac{dP_{late}}{dR} = 0 - \frac{1}{D}f(\frac{R}{D}) + \int_{R/D}^{\infty} 0dL = -\frac{1}{D}f(\frac{R}{D}), \quad \text{(B.6)}$$

we have

$$\frac{d^2\mathrm{E}(TC)}{dR^2} = 0 - \frac{H}{Q}\Big(-Y_{late}\frac{1}{D}f(\frac{R}{D}) - (P_{late})^2\Big) + \frac{C_O}{QD}f(\frac{A}{D}) + \frac{C_S}{QD}f(\frac{R}{D}), \quad \text{(B.7)}$$

$$\frac{d^2\mathrm{E}(TC)}{dR^2} = \frac{H}{Q}\Big(\frac{1}{D}f(\frac{R}{D})Y_{late} + (P_{late})^2\Big) + \frac{C_O}{QD}f(\frac{A}{D}) + \frac{C_S}{QD}f(\frac{R}{D}). \quad \text{(B.8)}$$

Because all elements of (B.8) are positive, $\frac{d^2\mathrm{E}(TC)}{dR^2} > 0$ and E(*TC*) is convex by *R*.

APPENDIX C

Proof of Proposition 1.

The follow derivatives are used

$$\frac{dP_{early}}{dC_O} = \frac{1}{D}(dR^*/dC_O)\,f(A^*/D) - 0 + \int_0^{A^*/D} 0\,dL = \frac{1}{D} f(A^*/D)(dR^*/dC_O); \tag{C.1}$$

$$\frac{dP_{late}}{dC_O} = 0 - \frac{1}{D}(dR^*/dC_O)\,f(R^*/D) + \int_{R^*/D}^{\infty} 0\,dL = -\frac{1}{D} f(R^*/D)(dR^*/dC_O); \tag{C.2}$$

$$\frac{dY_{late}}{dC_O} = 0 - \frac{1}{D}\left(\frac{R^*}{D}D - R^*\right) f(R^*/D)(dR^*/dC_O) + \\ + \int_{R^*/D}^{\infty} \left(-dR^*/dC_O\right) f(L)\,dL = -P_{late}(dR^*/dC_O). \tag{C.3}$$

Hence, we have

$$H\left(Y_{late}\frac{1}{D} f(R^*/D)(dR^*/dC_O) + P_{late}(dR^*/dC_O)P_{late}\right) + \\ + P_{early} + C_0\frac{1}{D} f(A^*/D)(dR^*/dC_O) = -C_S\frac{1}{D} f(R^*/D)(dR^*/dC_O), \tag{C.4}$$

$$dR^*/dC_O\left(Y_{late}\frac{H}{D} f(R^*/D) + H(P_{late})^2 + \frac{C_0}{D} f(A^*/D) + \frac{C_S}{D} f(R^*/D)\right) = \\ = -P_{early}, \tag{C.5}$$

$$\frac{dR^*}{dC_O} = -\frac{D \cdot P_{early}}{H \cdot Y_{late} f(R^*/D) + H \cdot D(P_{late})^2 + C_0 f(A^*/D) + C_S f(R^*/D)}, \tag{C.6}$$

All parameters in the derivative (C.6) are always positive. Thus, the derivative is negative, that means that increasing C_O will decrease R^*. ■

Proof of Proposition 2.

The follow derivatives are used

$$\frac{dP_{early}}{dC_S} = \frac{1}{D}(dR^*/dC_S)\,f(A^*/D) - 0 + \int_0^{A^*/D} 0\,dL = \frac{1}{D} f(A^*/D)(dR^*/dC_S); \tag{C.7}$$

$$\frac{dP_{late}}{dC_S} = 0 - \frac{1}{D}(dR^*/dC_S)\,f(R^*/D) + \int_{R^*/D}^{\infty} 0\,dL = -\frac{1}{D} f(R^*/D)(dR^*/dC_S); \tag{C.8}$$

$$\frac{dY_{late}}{dC_S} = 0 - \frac{1}{D}\left(\frac{R^*}{D}D - R^*\right) f(R^*/D)(dR^*/dC_S) + \\ + \int_{R^*/D}^{\infty} \left(-dR^*/dC_S\right) f(L)\,dL = -P_{late}(dR^*/dC_S). \tag{C.9}$$

Hence, we have

$$H\left(Y_{late}\frac{1}{D} f(R^*/D)(dR^*/dC_S) + P_{late}(dR^*/dC_S)P_{late}\right) + \\ + C_0\frac{1}{D} f(A^*/D)(dR^*/dC_S) = P_{late} - C_S\frac{1}{D} f(R^*/D)(dR^*/dC_O), \tag{C.10}$$

$$\frac{dR^*}{dC_S} = \frac{D \cdot P_{late}}{H \cdot Y_{late} f(R^*/D) + H \cdot D(P_{late})^2 + C_0 f(A^*/D) + C_S f(R^*/D)}, \tag{C.11}$$

All parameters in the derivative (C.11) are always positive. Thus, the derivative is negative, that means that increasing C_S will decrease R^*. ■

Proof of Proposition 3.

To prove the proposition, it should be shown that for fixed parameters of delivery time distribution and fixed costs of overload and stockout, order quantity, and size of warehouse, increasing holding cost (H) will decrease the optimal reorder point (R^*).

The follow derivatives are used

$$\frac{dP_{early}}{dH} = \frac{1}{D}(dR^*/dH)\,f(A^*/D) - 0 + \int_0^{A^*/D} 0\,dL = \frac{1}{D} f(A^*/D)(dR^*/dH); \tag{C.12}$$

$$\frac{dP_{late}}{dH} = 0 - \frac{1}{D}(dR^*/dH)\,f(R^*/D) + \int_{R^*/D}^{\infty} 0\,dL = -\frac{1}{D} f(R^*/D)(dR^*/dH); \tag{C.13}$$

$$\frac{dY_{late}}{dH} = 0 - \frac{1}{D}\left(\frac{R^*}{D}D - R^*\right) f(R^*/D)(dR^*/dH) + \\ + \int_{R^*/D}^{\infty} \left(-dR^*/dH\right) f(L)\,dL = -P_{late}(dR^*/dH). \tag{C.14}$$

Hence, we have

$$Q - Y_{late}P_{late} + H\left(Y_{late}\frac{1}{D} f(R^*/D)(dR^*/dC_S) + P_{late}(dR^*/dC_S)P_{late}\right) + \\ + C_0\frac{1}{D} f(A^*/D)(dR^*/dC_S) = -C_S\frac{1}{D} f(R^*/D)(dR^*/dC_O), \tag{C.15}$$

$$\frac{dR^*}{dH} = \frac{D\cdot(Y_{late}P_{late} - Q)}{H\cdot Y_{late} f(R^*/D) + H\cdot D(P_{late})^2 + C_0 f(A^*/D) + C_S f(R^*/D)}. \tag{C.16}$$

Because the denominator is always positive, the sign of the derivative (C.16) depends on numerator.

$$Y_{late}P_{late} - Q = (Y_{late} - Q)P_{late} - Q(1 - P_{late}) = \\ = \left(\int_{R^*/D}^{\infty}\left(LD - R^* - Q\right) f(L)\,dL - Q\int_0^{R^*/D} f(L)\,dL\right)P_{late} - Q(1 - P_{late}) = \tag{C.17}$$

$$\left(\int_{R^*/D}^{\infty}\left(LD - R^* - Q\right) f(L)\,dL - Q(1 - P_{late})\right)P_{late} - Q(1 - P_{late})$$

Because $0 \le P_{late} \le 1$, the only element that can be positive in equation (C.17) is the first integral. Using the assumption (9) No interaction between orders ($0 \le L \le Q/D$), we can write

$$\int_{R^*/D}^{\infty}\left(LD - R^* - Q\right) f(L)\,dL = \int_{R^*/D}^{Q/D}\left(LD - R^* - Q\right) f(L)\,dL. \tag{C.18}$$

The value of $(LD - R^* - Q)$ is always negative for any $R^*/D \le L \le Q/D$, hence the integral (C.18) is negative. Thus, it can be concluded that the derivative (C.16) is negative, that means that increasing H will decrease R^*. ■

INVESTIGATING THE EFFECTS OF SOCIAL MEDIA USE ON WORK EXHAUSTION

ABSTRACT

As the amount of time people socializing online increases, the influence of social media use in workplace rises up as well. Our observation shows that individuals feel they are experiencing less work exhaustion when socializing with their family members and close friends. Drawing on the theory of involvement and social media interaction, we identify the theoretical connections between vertical interactivity and involvement constructs, which eventually exert an impact on work exhaustion. We then evaluate the interactivity-involvement-work exhaustion model empirically using a survey of 300 social media users. The results indicate that user's perception of support, enjoyment, and personal identification are negatively related to work exhaustion. The resulting theoretical implications for social media research and practical implications for organizations are discussed.

KEYWORDS: Social Media, Work Exhaustion, Social Involvement, Social Network Site (SNS), social media interaction.

INTRODUCTION

Social media are internet-based applications including social gaming, media sharing, discussion forums, reviews, blogs, and micro blogs (Zhang and Mao 2016). Facebook, LinkedIn, Pinterest, and Instagram are the most popular social media sites. The number of social media users in the whole world is nearly 2 billion, about 30% of the global population nowadays. Users devoted 2.53 hours to social media sites (e.g., Facebook, Twitter) on a daily basis. They compulsively check their social media several times a day to satisfy "social update" during their non-work time (e.g., eating, attending, meeting, crossing the street, or driving) (Kwon et al., 2016).

Social media supports personal purposes such as maintaining their relationships with friends, meeting new peers (e.g., Facebook, Google+), participating in groups sharing similar hobbies and interests (e.g., FanIQ and Super Green Me) (Kwon and Wen, 2010). At the same time, social media can also support career-related tasks (e.g., Linkedin and Konnects), informational and educational goals (e.g., the Student Room, Academic.edu). Some users accept social media purely for the personal connection or entertainment purposes, while others may use them for professional purpose. They directly connect professional partners, sharing professional knowledge, and consolidating professional contacts by social media (Salehan et al., 2017). As the usage of social media covers both within and outside of the career-related tasks, the boundaries between work and non-work domains become blurring (Derks and Bakker, 2014). Social media even makes it difficult for employees to disconnect with work even when they are outside of normal work hours (Butts et al., 2015). Thus, although the social media have enhanced the flexibility to employee's work and lives, they may influence the employee's workload and work exhaustion (Armstrong et al., 2015). However, there are few studies concerned the influence of social media usage during non-work time in employee's work exhaustion.

Consequently, we need an investigation to better understand the effects of social media use on users' perceptions of work-related pressure or difficulties that are hard to resolve. Therefore, we address the following research question in the social media context:

Research Question: How does social media use influence work exhaustion?

In this study, we draw on previous work in interaction in social media, the theory of involvement, and work exhaustion to guide the research model. First, as social media are digital platform for interaction (Gunawardena et al. 2009), we identify an important social media interaction – the interaction with family and close friends. Further, as "an object or stimulus associated with the physical characteristic of communication media (TV, radio, and print)" is the crucial antecedents of involvement (Zaichkowsky 1986), social media interaction can influence users' involvement. We classify involvement into two types: cognitive involvement and affective involvement. Then, we examine how involvement leads to work exhaustion. We expect our findings to extend the understanding the effects of social media usage during non-work time on work exhaustion.

LITERATURE REVIEW

Social Media Interaction

Online interaction is defined as "the extent to which users can participate in modifying the form or content of a website in real time"(Steuer 1992). The website interactivity includes mechanical interactivity and social interactivity(Hoffman and Novak 1996). Mechanical interactivity is used to measure the website's usability based on control-related theory (e.g., the flow theory, and information control theory et al.), which reflects the extent to which users' interaction with website technology (Venkatesh and Agarwal 2006). Social interactivity means the website is the electronic media for users, which enables users to engage in social communication (e.g. email or reciprocal communication et al.)(Zhenhui, Chan et al. 2010).

Social media is mainly used for social interaction, especially vertical interaction, which refers to "the need for forward and backward linkages with existing close connections such as family and close friends" (Salehan, Kim et al. 2017). Interactivity in Facebook-style social media is considered to be a form of vertical interaction (Stefanone, et al. 2011). Social media users watch and share entertaining content or maintain close relationships with family and existing friends during the non-work time. At the same time, the user may also establish new social linkage to receive social support and bridge social capital, as is good for their profession. Despite some research has been done attempting to reveal the insights of personal social media use (e.g., hedonic use), these types of behavior remain under-explored. Therefore, this study will concentrate on the dimensions of these types of use behavior.

The Involvement-Related Theories

Involvement is defined as "a person's perceived relevance of an object based on inherent needs, values, and interests" (Zaichkowsky 1985). The application of involvement construct has been extended to websites. Website involvement is defined as the perceived relevance of the website based on the consumers' inherent needs, values, and interests (Mcmillan et al. 2003). Website involvement covers cognitive involvement and affective involvement (Jiang et al. 2010). Social media is internet-based application, which is extended from the websites. Thus we can research social media based on the theory about website involvement. This study will provide valuable insights about the social media involvement by studying the disparate internal processes of social media users.

Cognitive involvement means "rational, thinking" and is motivated by utilitarian or cognitive factors(Park and Young, 1986). Affective involvement means "emotional, hedonistic" and is motivated by value-expressive or affective factors (Putrevu and Lord 2013). Present studies

show that users' interaction with website will induce cognitive involvement and affective involvement. Specifically, merchandise description, the price, delivery and return policy in the website will heighten the cognitive involvement. The colors, animation, sound, and peripheral site information will heighten the affective involvement (Eroglu et al. 2003). However, there are few studies about involvement in social media.

As reviewed above, this paper will explain the effect of interactivity on perceived support from the perspective of cognitive involvement, explain the effect of interactivity on perceived enjoyment and identification from the perspective of affective involvement.

Work Exhaustion

Work exhaustion can influence significantly turn-away intention (Blau 2007). Work exhaustion will happen, as an individual believe that remaining the current profession will not alleviate the career experience. One of the cures of work exhaustion is to change professions (Armstrong et al. 2015). Prior research has verified that perceived workload, autonomy, fairness of rewards influence significantly work exhaustion (Moore 2000).

What's more, social interactivity has a significant influence on work exhaustion (Ahuja et al. 2007). However, few researches have explored the mechanism why social interactivity can reduce or strengthen the work exhaustion. This paper will explain the mechanism from the involvement perspective.

HYPOTHESES DEVELOPMENT

Our research model consists of three pillars: (1) the vertical interactivity; (2) components of involvement; (3) the work exhaustion. There are five constructs in the model explaining the relationships between social interactivity by social media and work exhaustion from the involvement perspective.

The Influence of Vertical Interactivity on User's Involvement

The vertical interactivity means that users watch and share entertaining content or maintain close relationships with family and existing friends by social media during the non-work time. While users vertically interacting by social media, they may achieve a needed support (Lee et al. 2017). For example, users interacting with their peer may achieve social support, as will reduce users' negative emotions(Lu et al. 2012). Users interacting with their family and existing friends will achieve credible personalized recommendations, as will simplify the process of making decisions (Xiao and Benbasat 2007).Thus, The vertical interactivity is a key opportunity to achieve needed support for users.

At the same time, the vertical interactivity is spontaneous, passionate, low cost, and live (Borah and Tellis, 2016). They consume the social media to satisfy psychological needs (Elihu, 1974). For example, users could obtain leisure from vertical interactivity (Ahram et al. 2011). What's more, seeking recreation and friendship by social media is the most important motivation for users to interact online (Ridings and Gefen, 2004). Hence, we hypothesized that:

H1: The vertical interactivity is positively related to perceived support.
H2: The vertical interactivity is positively related to perceived enjoyment.

Social identification is defined as “the degree to which an individual perceives herself or himself as a member of a group or social category, and subsequently conforming to the attitudinal and behavioral stereotypes of that group” (Tajfel, 1981). People are influenced by their friends and family and conform to the expectations of others (Deutsch and Gerard 1955). Social media provides new venues for users to express themselves and perceive the normative and social values from their family and friends (Kwon and Wen 2010). The more users vertically interact with friends and family, the greater they understand the expectations of others. By the direct effect of social media, users may act according to social influence and be identified by their family and friends (Chen 2014). According to the social identities, users will overlay positive attributions (e.g. credibility and attractiveness) onto those in-group members (Clark and Maass 1988; Carr et al. 2013). Furthermore, they will even provide arbitrary cues such as language on social media to guide social identification process (Bigler et al. 1997, Seargeant and Tagg 2014).Hence, we hypothesized:

H3: The vertical interactivity is positively related to social identification.

The Influence of Users’ Involvement on Work Exhaustion

Work exhaustion indicates “a state of physical, emotional, and mental exhaustion caused by long-term involvement in demanding situations” (Malakh-Pines et al. 1981). Work exhaustion is an important indicator of dissatisfaction level about their work, which may lead to turnover intention (Moore 2000). Work exhaustion is caused by having too many pressures, conflicts, and demands combines with too few rewards, acknowledgments, and successes (Kanner et al. 1978). Most people will perceived exhaustion when their life is imposed on more stress than support (Pines 1993).

As far as social media usage during non-work time is concerned, users will received social support from their online friend. Perceived support from social media may balance uses’ stress and support in life. At the same time, perceived enjoyment from social media during non-work will reduce the stress in life (Van der Heijden 2004). Hence, we hypothesized:

H4: Perceived support is negatively related to work exhaustion.
H5: Perceived enjoyment is negatively related to work exhaustion.

Social identification indicates the degree to which an individual perceives herself or himself as a member of a group or social category, and subsequently conforming to the attitudinal and behavioral stereotypes of that group (Tajfel 1981). Social identification consists of cognitive identification and affective identification (Talaga and Beehr 1995). Users who have cognitively identified themselves as “employees should connect with work even when they are outside of normal work hours” may be like to work seriously. According to the definition of affectively identification, Users who have affectively identified themselves as “employees should connect with work even when they are outside of normal work hours” may feel emotional attachment of the class. Employees who connect with work even when they are outside of normal work hours are sometimes being perceived as hard-working (Watanabe and Yamauchi 2016). Hence, we hypothesized:

H6: Identification is negatively related to work exhaustion.

RESEARCH METHOD

Online Survey Method

The data used to test our theoretical model were collected from WeChat, a leading social media application in China that provides a platform for communicating online, creating profile pages and more. To mirror the demographics of a typical online user, the sampling frame we used included users with full-time jobs who interacted on WeChat. We developed an online survey questionnaire that by following these practices: at first, all the items of various constructs were adapted according to our existing research; secondly, we modified the preliminary questionnaire based on the results of a pretest; and finally, we administered the survey online.

The items that related to vertical interactivity were adapted from Jiang and Salehan (Jiang et al., 2010; Salehan, Kim et al., 2017). The items that related to perceived social support were adapted from Liang et al., 2011. The items related to perceived enjoyment were adapted from Chen, 2014. The items related to identification were adapted from Mael and Ashforth, 1992. The items related to work exhaustion were adapted from Armstrong, Brooks et al., 2015. The constructs were measured on a seven-point Likert scale. Due to page limit, we are not attaching the instrument, which is available upon request.

Demographic Profiles of the Sample Data

The questionnaire was distributed to actual WeChat users online. We eliminated disqualified data points by following these criteria: respondents with no full-time job; respondents who provided the same answer to more than 80 percent of all questions; and respondents who completed the questionnaires in under five minutes. This gives us 300 clean data entries. Among these respondents, 44 percent were male and 56 percent were female. The majority (>70 percent) of respondents were between 20 and 30 years of age, while 86.3 percent had a degree in higher education of at least two years. Descriptive characteristics for the respondents are listed in Table 1.

Table 1: Sample Demographics (N=300)

Measure	Item	Count	%
Gender	Male	132	44.0
	Female	168	56.0
Age	≤19 years	33	11.0
	>20 and ≤30 years	201	73.6
	>30 years	46	15.0
Education	High school or below	24	8.0
	2 years of college	105	35.0
	4 years of college	154	51.3
	Graduate school or above	17	5.7
WeChat usage time	Less than 6 months	26	8.6
	6 to 12 months	32	10.6
	1-3 years	196	65.3
	Over 3 years	46	15.3

Occupation	Private Sector	109	36.3
	Government	76	25.5
	Education	82	27.3
	Students	28	9.3
	Other	5	1.6

DATA ANALYSIS

We analyzed the sample data for the study using the partial least squares (PLS) method, since PLS is less restricted in sample data distribution, measurement scales and residual distributions (Chin, 1998). PLS is also better able to maximize the explained variances in defendant variables, as is shown in prior IS studies (Gefen and Straub, 2005). Based on these methods, we first analyzed the measurement model and then tested the structural model to verify our hypotheses.

Testing Measurement Model

Principal components factors (PCF) were used to examine the convergent validity of the study's scales. Bartlett's test of sphericity generated a Kaiser-Meyer-Olkin (KMO) statistic of 0.877, which was significant at 0.01, indicating that the data were suitable for applying principal components analysis. We extracted six factors with six values above 1, which explained 82.466 percent of the total variance. Table 2 presents the factor loadings of the items after applying Varimax rotation. The results show no cross-loadings and good discriminant and convergent validity.

Table 2: Principle Component Factor Analysis with Varimax Rotation

Factors	**1**	**2**	**3**	**4**	**5**
Ver1	**0.914**	0.241	-0.102	0.079	0.071
Ver2	**0.827**	0.279	-0.078	0.157	0.038
Ver3	**0.856**	0.220	-0.032	0.086	0.084
Sup1	0.326	**0.745**	-0.126	0.149	0.183
Sup2	0.324	**0.835**	-0.134	0.227	0.203
Sup3	0.294	**0.793**	-0.174	0.203	0.131
Ide1	0.068	0.192	-0.182	0.292	**0.736**
Ide2	0.099	0.167	-0.208	0.290	**0.747**
Pen1	0.055	0.130	-0.228	**0.592**	0.397
Pen2	0.105	0.219	-0.195	**0.828**	0.246
Pen3	0.189	0.165	-0.213	**0.794**	0.175
Wex1	-0.159	-0.158	**0.815**	-0.226	-0.150
Wex2	-0.134	-0.101	**0.921**	-0.099	-0.097
Wex3	0.066	-0.066	**0.756**	-0.174	-0.151
Eigenvalues	2.191	2.979	2.424	1.989	1.796
Percentage of variance	19.593	15.179	17.587	14.107	13.016
Cumulative	19.593	34.772	52.359	66.466	79.482

Table 3 summarizes the additional validity measures of the scales. The standard loadings of the items were mostly above 0.7. The average variance extracted (AVE) for each construct was

above 0.5, which meant that the scales had a good convergent validity (Bagozzi and Yi, 1988). Composite reliabilities (CRs) were used to evaluate the internal consistency of the measurement model. As shown in this table, the CRs were all above 0.9, indicating that the scales had good reliability. In addition, Cronbach's alpha was above 0.8, indicating that the scales were reliable (Nunnally, 1978).

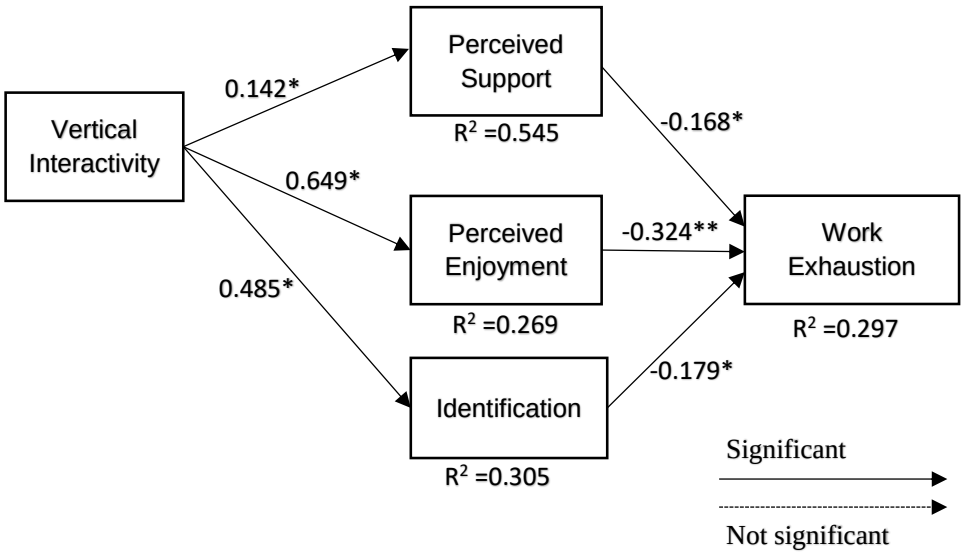
Table 3: Results of Confirmatory Factor Analysis

Factor	Item	Standard loading	AVE	CR	Cronbach's alpha
Vertical interactivity	Ver1 Ver2 Ver3	0.9120 0.9037 0.9111	0.820	0.920	0.957
Perceived support	Sup1 Sup2 Sup3	0.9534 0.9101 0.9097	0.879	0.903	0.955
Identification	Ide1 Ide2	0.9234 0.9486	0.902	0.917	0.848
Perceived enjoyment	Pen1 Pen2 Pen3	0.8995 0.9230 0.9525	0.865	0.929	0.882
Work exhaustion	Wex1 Wex2 Wex3	0.9018 0.9131 0.8597	0.854	0.940	0.899

Testing the Structural Model

We then tested our research model. The findings of the test are summarized in Figure 1. The results were as follows: H1(r=0.142, T-value=2.547), H2(r=0.063, T-value=0.783), H3(r=0.052, T-value=0.869), H4(r=0.649, T-value=12.127), H5(r=0.485, T-value=6.632), H6(r=0.469, T-value=7.100), H7(r=-0.130, T-value=2.195), H8(r=-0.315, T-value=5.253), H9(r=-0.152, T-value=2.510). All the hypotheses were supported. The proportions of variance were 53.7 percent for perceived support; 27.1 percent for perceived enjoyment; 24.9 percent for identification; and 26.1 percent for work exhaustion. All control variables were insignificant.

Figure 1: The Research Model (p*<0.05, p**<0.01)



DISCUSSION AND LIMITATIONS

The ubiquitous use of social media in workplaces has become an issue that concerns practitioners in numerous ways. First, job performance has been studied in prior literature arguing there are connections between online social media behavior and how employees perform in workplace; Second, using social media in personal live may influence professional activities; third, the future development of social media has the tendency to increase the use of social media in professional IT applications. Therefore, our study is timely and important as it is one of the early studies to investigate the above-mentioned issues. This study also positions itself as an extension of prior social media research that focuses on adoption and diffusion (e.g., Qiu *et al*. 2015).

This study makes three new contributions to existing theory. First, by investigating vertical interactivity and horizontal interactivity in the context of social media, this study complements existing research on other types of online interactivity. The study shows that both vertical and horizontal interactivity can affect users' perceived support, while horizontal interactivity can affect users' perceived enjoyment and identification. Next, our study found that perceived support, perceived enjoyment and identification are important factors in alleviating users' work exhaustion, with perceived enjoyment being the most important of those three factors. Although previous studies have shown how social media contributes to users' personal and professional performance (Salehan, Kim et al., 2017), the reasons why have not been studied. Thus, this study complements existing research by discussing the reasons why social media contributes to employees' performance. On the other side, practitioners can borrow our findings to create, modify, and implement managerial improvements that aim to reduce the negative effects of personal social media activities in professional settings, and to enhance the positive impacts that social media usage introduces to the workforce (e.g., reducing work pressure and strengthen coworker relationships).

This study has two main limitations. First, the sample may be biased due to the fact that all respondents were Chinese and most were male. Second, our research focuses exclusively on the effects of involvement. Other relational constructs could also affect work exhaustion. Future studies may examine the influence that constructs such as trust or social inclusion have on work exhaustion (Andrade and Doolin, 2016). In addition, use of social media may have both positive and negative outcomes and the potential negative effects should be a future subject of study. We stressed on the statistical significance in the structural model testing rather than the practical one, which can be addressed in the later studies.

ABSTRACT

With the continuous development of Internet of Things (IoT), Information and communication technology (ICT) and Automation Control System (ACS) in agriculture field, greenhouse and aquafarm management has earth-shaking changes. The introduction of intelligent monitoring and tracking of the whole process from the production of crops, processing, transportation to sales and other procedures can effectively overcome the impact of complex and volatile climate, the geographical limitation, natural disasters, pests and diseases, and other factors to improve crop yields, growing process and production quality. Utilizing social media helps farmers to promote their products to consumers for direct sales and precision marketing.

KEYWORDS: Internet of Things, Intelligent Agriculture, ACS, Greenhouse, Social Media

INTRODUCTION

A country is comprised of its people, and people depend on food." The availability of food is not only essential for maintain life, but also affects the social stability, harmony, and economic development of a country. In recent years, the price of food has risen continuously, and issues such as population growth and land degradation have resulted in losses of arable land. Additionally, crop failures caused by climate anomalies have become increasingly widespread. Relevant experts have also expressed concerns that global food supplies may undergo an unexpected crisis in the near future.

The recent report by the Consultative Group on indicates that the global food crisis is expected to intensify in the next 40 years (Blaikie et al, 2000). Fierce international competition for food has prompted various governments to explore overseas markets and increase domestic self-sufficiency to avoid the problems related to food supply shortages (Friedmann, 1992).

Take the world's biggest agricultural country – China for example, despite a long history of agriculture, China is not immune to this global development. Millions of farmers are limited to farming and producing crops on only 9% of the world's arable land (Ghose, 2014). In addition, the frequent droughts and natural disasters experienced recently have severely impacted local crop growth and harvest yields. Accordingly, since China's reform and opening up, at the beginning of each year, relevant authorities have published a policy document dubbed the "No. 1 Central Document" on agriculture, farming villages, and farmers (Jialing & Jian, 2018). This document demonstrates the central government's emphasis on the complexities of developing farming

villages and sets the tone for China's agricultural growth. For many years, the policy advice has incorporated the latest technology concepts to provide the technological tools for agriculture and promote the integration of agriculture and technology, the mechanization of labor processes, and the inclusion of information technology in agricultural production and management objectives. China's central authority also expects to utilize technological innovations to establish high-yield, high-quality, efficient, safe, and modern agricultural systems. Therefore, it's valuable contribution if we can use new technologies to increase the productivity of agriculture.

In this paper, intelligent agriculture is constructed by using IoT applications which is crucial for prosperous farming villages and sustainable operations. By implementing environmental monitoring and automatic control through the use of sensors, networks, cloud computing, and other advanced technologies, governments can increase agricultural efficiency and develop traditional agriculture into modern technology-based agriculture. Intelligent agriculture concepts can be applied to not only whole grain, fruit, vegetables, and flower crops, but also livestock and aquaculture. Such concepts offer various advance protection measures through the inclusion of real-time energy management systems (EMSs), thereby reducing the risk of infection among livestock.

Although most intelligent applications in the agriculture, fishery, and livestock industries are still in the promotion and advocacy stages, lots of successful implementations have been achieved in recent years by using IoT, ICT, ACS technologies. Furthermore, in many cities and towns in China and Taiwan, transition assistance has been provided to experimental breeding and cultivation units, farmers and fishermen specializing in high value agricultural products, and major electronics manufacturers intending to invest in agricultural production.

LITERATURE REVIEW

The Internet of Things (IoT) and big data are two hot topics with respect to commercial, industrial, and other applications including agriculture. The term "IoT" was coined in 1999 and refers to the world of devices connected to the Internet, which is the method by which much of big data is collected, concentrated and curated (Gubbi et al., 2013). Big data additionally refers to the analysis of this information to produce useful results (John, 2014).

A primary driving force behind the IoT and big data has been the collection and analysis of data concerning consumer behaviors in order to find out what people buy and why. An example of this is the loyalty cards that shoppers use at grocery stores and other retail outlets. Using these cards, retailers and their suppliers can ascertain what customers buy which products, and can then use this information to increase sales and profits. The commercial and governmental sectors are showing how the IoT and big data can be used to improve operations, but how can these concepts be profitability extended into agriculture and other related industrial sectors?

Big data is the new norm for enterprise analytics and it is pervasive across many industries. The data becomes big when the volume, velocity, and/or variety of the data exceed the abilities of your current IT systems to ingest, store, analyze, or otherwise process it. Big data typically conveys an individual perspective of perceived magnitudes of information greater than expected, and may express a conundrum of comprehension and utilization (Provost & Fawcet, 2013).

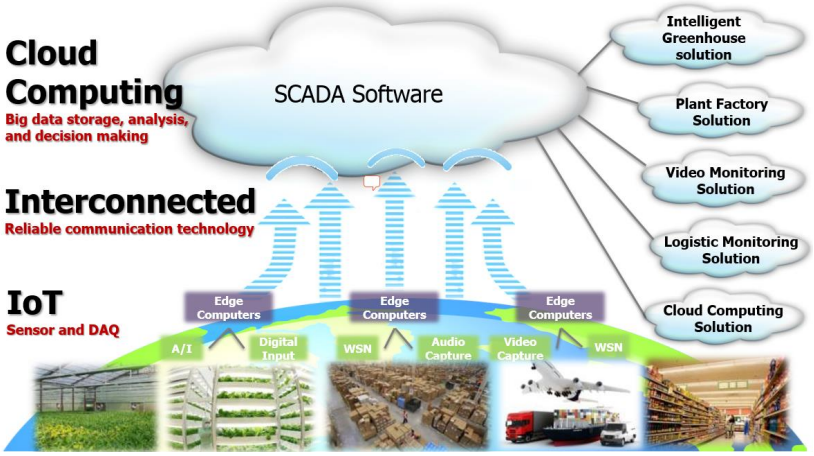
Data input originally came from limited human-based measurements, observations and manual data entry—but most data today is automatically generated by sensors, with the trend of field sensors becoming more numerous and smarter with more reporting capabilities continuing to

grow. Once this rapidly expanding stream of data is collected, it then needs to be concentrated and curated, terms that will be explained in detail later in this article. This curated data must then be visualized and analyzed in order to improve operations, a process that will also be expanded upon.

PROPOSED MODEL AND METHOD

IOT, ICT and ACS technologies that accelerate the burgeoning of intelligent agriculture. Three key elements that growing fast in the past years play the key role of building intelligent agriculture infrastructure – IoT, interconnection and cloud computing as shown in Figure 1.

Figure 1: The infrastructure of intelligent agriculture



In IoT layer, sensors and Data Acquisition Device (DAQ) collect information from field. It's obvious how designers are incorporating sensors into countless devices used throughout our everyday lives. Smartphones react to user inputs by tracking the smallest of gestures, automobiles constantly monitor vehicle motions to achieve stability control, and buildings vary environmental controls to provide both comfort and energy savings. In some ways, the vast availability of sensors and their produced data has provided kindling for the IoT and big data fire, while the automated method of querying these sensors, largely over the Internet, has sparked the fire to life. When looking from a system-wide perspective, the sensing function can be considered to exist at the lowest level, or out on the "edge". Table I offers a list of common sensor types, and shows how the IoT sees the world.

Table I: Types of Sensors

1. Temperature	7. Position, angle, displacement, distance, speed, acceleration
2. Pressure	8. Vision
3. Level	9. Vibration
4. Flow	10. Current, voltage and other power parameters
5. Density	11. pH and other analytical values
6. Proximity	12. Moisture, humidity and other weather conditions

The classic four measurements for production processes are flow, level, temperature, and pressure. Additionally, chemical, pharmaceutical, water treatment, and food industry processes will rely on analytical measurements of pH, dissolved oxygen and many other specific variables.

Environmental and facility control systems will look for temperature, moisture, humidity and other weather conditions. Extending into the mechanics of many types of equipment and machinery, there are various sensors for measuring position, angle, displacement, distance and proximity. Speed and acceleration sensors monitor the change of those same sensed values over time, while vibration sensors monitor the frequency and/or amplitude of motion. For electrically driven equipment, sensing devices report the instantaneous current and voltage values and other related power parameters. Even more esoteric is the use of vision sensing systems to track produced parts, verify quality, or simply read tags. Vision systems in particular can generate huge amounts of image data. Sensors generate numerous types of signals, but these various signals must all be transduced from the raw measurement into a useful signal format for transmission. A classic method of transmitting a single analog value is to use a transducer that scales the value into a 4 to 20 mA signal wired to a control system analog input module.

More advanced “smart” transducers can convert the sensed signal into a standard digital communications protocol, Ethernet-based in many cases. Signal converters are also available that can effectively upgrade legacy type signals and equipment by transforming proprietary or obsolete serial signals to modern open network protocols. “Smart” transducers or sensors are preferred for several reasons. Not only can the primary sensor signal be monitored, but very often there are additional process values available that prove useful. For example, most smart pressure, flow and level instruments include temperature measurement, very useful for signal compensation and general health monitoring. Smart sensors and instruments usually also collect and transmit diagnostic information including device status, alarms and events. Finally, sensors and transducers networked via serial or Ethernet links can provide simplified installation, particularly for wireless variants. There are many paths to collect data, and this data must then be concentrated.

In Interconnection layer, collected information has been concentrated and transferred to data storage. Data typically journeys from networked sensors to some form of data storage or concentration device. This device or devices can exist in a number of locations. Classically, the data would be deposited in large PC server or mainframe systems in a control room or mission control center. Table II identifies some other data concentration options.

Table II: Types of Data Concentrators

1. Data loggers
2. Embedded controllers
3. Embedded PCs
4. PLCs
5. Multi-variable instruments and transducers
6. Smart sensors

Older data loggers, many still in use today, consist of round or scrolling paper charts with ink pens tracing information, similar to an analog earthquake seismograph. Today’s data loggers are fully digital and offer numerous improvements. Solid state data loggers can accept large quantities of input channels, capturing values at defined sampling intervals with the capacity to store tens of thousands of data values in volatile or non-volatile memory. This type of device makes it practical and economical to extend data logging to remote locations. These data loggers may be network-connectable, or may have removable memory cards or USB connectivity for archiving the stored data to a higher-level system. Embedded controllers are often used as a dedicated means to automate equipment. Although primarily tasked with cost-effective machine control, these

controllers often have sufficient memory and processing capabilities to also perform data logging. Similarly, embedded PCs have more than enough power to perform automaton and data logging tasks, and often are configured with rotating or solid state hard drives that can provide significant data storage capacity. PLCs are used in many of the same applications as embedded controllers. Historically, a PLC's strong suit has been reliable, flexible, and high-speed control of machinery. They have also been a common gateway for providing raw data to higher level data concentrators.

Recent years have found PLC processing power and memory capabilities increasing, and in fact the most capable PLCs are now often called process automation controllers. Whatever the moniker, the latest PLCs offer impressive non-volatile storage capabilities, and some even offer historian modules that plug into the PLC chassis. For many cases, this makes the PLC itself a viable option for concentrating data. And looking back for a moment at sensing devices, the most capable of these often have on-board data logging. Often these devices can log to memory cards or USB memory, or they can be networked into a higher level data concentrator. Just as there are myriad options for collecting data, there are more options than ever for concentrating the abundance of this information. Data concentration can be scaled to meet the need, ranging from many smaller field devices all the way up to large centralized or distributed PC-based systems. It's becoming more straightforward to reduce the amount of manual human intervention required to obtain useful data, which in turn drives up the quantity and quality of data available for curation, and eventually interpretation.

In cloud computing layer, information storage, analysis and management – we call it "curation". Once data has been harvested from sensors, and concentrated onto some type of storage system, it becomes important to organize the information in a manner that helps users make sense of it. The activity of "curating" this data typically involves the use of database software. Curating is usually accomplished at the PC server level, since database management is an advanced software function that requires equally capable hardware. Some of the most well-known commercially available business databases include Oracle Database, Microsoft SQL Server, Microsoft Access, SAP Sybase, and IBM DB2. These software packages are used throughout industry for maintaining all sorts of data, and they offer a platform for querying and analyzing information. However, not all data is exactly the same. In the business and commercial world, data often consists of customer information, financial transactions, product stock level, stocking quantities, and shipping information. This transactional data requires very secure data storage, with relatively slow rates of data collection. Interruptions to data access and other functions aren't critical.

When we look at the manufacturing world, we find that a large amount of the information obtained from sensors consists of time-series information where each sample is the value of a sensor with a timestamp. This real-time data is sampled repeatedly. Process data may also include alarm values and discrete process events. Manufacturing data must be stored and accessed in real-time, and uptime is critical. In agriculture field, although the raw data is not as much as manufacturing factory, but there still have large amount of real-time data came from soil water content sensor, temperature sensor, fishpond dissolved oxygen sensor, wind speed sensor and etc. Some of them are critical and some have long term influence on the yield. Curated data is commonly available within an organization over the facility or company network, which is often referred to as an "intranet" or a "private cloud". The Ethernet is considered a "public cloud", but there are secure methods to link multiple facilities or data sources using it.

To a great extent the data collection, concentration, and curation activities occur silently and unseen after initial configuration. These activities must be in place to act as a foundation for visualizing and analyzing information. However, simply presenting users with large tables of values from a historical database will not help most people to understand the data, since most people are more visually oriented towards graphical representations of data such as charts, graphs and other symbols. Data scientist Nate Silver, interviewed by Jon Gertner in Fast Company, relates that “The flood of data means more noise (i.e., useless information) but not necessarily more signal (i.e., truth).” He goes on to state that “People blame the data, when they should be asking better questions” (Nate, 2013). The right data visualization tools can help users understand data and ask the right questions, and to quickly interpret and act upon the answers.

Fortunately, more options than ever are available to display quantities of information and help users make sense of it (Table III). At the field level, many analyzers and data loggers offer local displays or come with associated operator interfaces. These devices often allow users to view trends of data, alarms and events.

Table III: Types of Visualization and Analysis Tools

1. Smart phones
2. Tablets
3. Operator Interface Terminals
4. PC-based HMIs
5. Data loggers
6. Transducer and analyzer displays

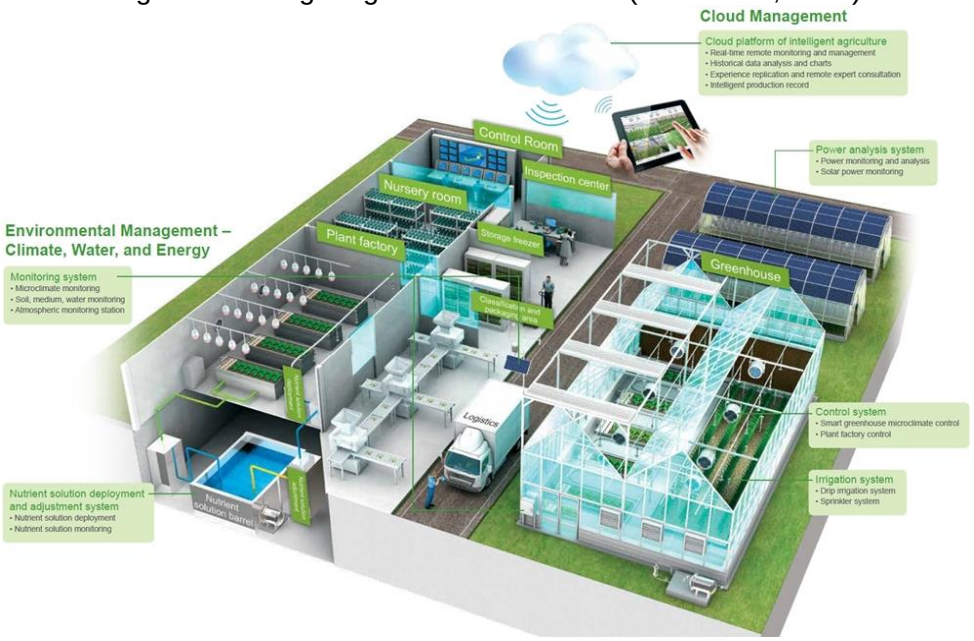
If the controller/OIT is provided by an equipment manufacturer or system integrator, there is a good chance that useful local indications, data logging/trending, and alarming capabilities will be built-in and thus readily available without any extra effort required by the end user. For many applications, the point where visualization and analytical performance really gains traction is when software on a PC platform taps into historical data. The software historians mentioned in the “Curation” section offer their own visualization and reporting tools. Operators can trend various data points over chosen time ranges, and effectively perform their own investigation of the available data (Figure 2). The dashboard distills the key elements to show the most important facts about what is happening, allowing users to quickly interpret conditions and make smart decisions.

Figure 2: Operator interface terminals typically include data

RESULT

To build an intelligent agriculture ecosystem, a series of comprehensive intelligent farm, greenhouse, plant factory, and aquaculture and livestock solutions can be developed by IoT technologies. Here we illustrated the typical smart greenhouse solution as shown in Figure 3.

Figure 3: Intelligent greenhouse solution (Advantech, 2018)



This solution includes sub-systems as following:

i. Monitoring Systems

- Soil, medium, and water monitoring
- Monitor soil/media for pH, conductivity, temperature, humidity etc. for the best growing conditions
- Monitor water quality including pH, conductivity, temperature, dissolved oxygen etc.
- Provide optimal settings and send warnings via SMS/e-mail when incidences occur so that optimum conditions can be maintained
- View historically stored data and produce graphs to view trends
- Microclimate monitoring
- Use sensors to monitor environmental aspects such as temperature, relative humidity, sunlight, carbon dioxide, wind speed and produces images of crop growth
- Provide optimal settings and send warnings via SMS/e-mail when incidences occur so that optimum conditions can be maintained
- View historically stored data and produce graphs to view trends
- Atmospheric monitoring station
- Use sensors to monitor atmospheric conditions such as: temperature, relative humidity, wind speed, wind direction, rain, snow and sunlight
- Improve the efficiency of greenhouses by analyzing the difference between internal and external temperatures
- Use historical analysis to predict short-term changes in the atmosphere to enhance the stability of the indoor climate

ii. Control Systems

- Intelligent greenhouse microclimate control
- Use sensors to monitor indoor and outdoor atmospheric data and automatically adjust the temperature, humidity, shade nets, insulation curtains, fans, skylights etc.

• Configure devices separately for multiple crops
• Adaptive greenhouse management for a wide range of controls
• Reduce labor costs and errors and diseases for greater quality and stability

Plant factory control

• Use sensors to monitor temperatures, relative humidity, carbon dioxide concentration using air conditioning systems, circulating fans, artificial light sources etc.
• Use indoor air conditioning to save 70% of water consumption
• Adjust artificial light to shorten production time and increase capacity

iii. Power Analysis Systems

• Power monitoring and analysis
• Use sensors to see and record the greenhouses' electrical status
• Use recorded power data to calculate and analyze the cost of each device
• Automatically use shade nets to reduce the intensity of the sunlight and reduce power usage
• Analyze independent power sources and adjust their use depending on the requirements
• Calculate the total cost of electricity generation and its use

iv. Irrigation Systems

• Drip irrigation system
• Use drip irrigation sensors to monitor soil moisture conductivity, pH levels etc.
• Use soil moisture sensors to control conditions and quality
• Permeability ensures that water from the pipeline is used
• Drip devices, plugged into a PE pipe, automatically regulate the flow
• With no water between crops, weeds can't grow
• Drip irrigation systems are: labor, water, energy & yield improving
• Irrigating water and fertilizer directly on the soil, crop roots maintain the optimal conditions to increase production
• Sprinkler system
• Soil moisture sensors control the sprinkler system
• The analog sensors' signals are converted from analog to digital for saving
• Convert signals to the same value as the soil moisture tension meter to become linear
• Monitor soil moisture conductivity, pH and other sprinkler data for the best conditions
• Provide strategies for control conditions, schedule and quantity
• Automatic correction of salinity during freezing temperatures
• Low construction cost, and rapid foliar absorption, increases greenhouse humidity and reduces temperature
• A low-cost and labor-saving irrigation management system

v. Nutrient solution deployment and adjustment Systems

• Nutrient solution deployment
• Effectively monitor and control the deployment of the nutrient solution, and manage routine work, including water quality used to modulate the conditions
• Adjust the proportion and concentration of the nutrient solution, and then send the information to the irrigation
• Crops grow at different rates, automatically adjust the nutrient solution for better growth nutrient solution adjustment
• Real-time monitoring of various conditions, means that changes can be made as soon as an issue is seen

- Get the benefits of circulating nutrients and use a clean room to increase fertilization & yield, and prevent diseases
- Automatically adjust the nutrient solution schedule according to the crops' requirements

vi. Cloud platform of smart agriculture

- Real-time remote monitoring and management
- Remotely check real-time information and control next line through computers, tablets, mobile phones, and other devices
- Manage distributed systems, nutrients, temperatures etc. across multiple greenhouses
- Provide different workers with different levels of authority
- Get real-time information via SMS and e-mail alerts
- Analysis of historical data and charts
- Integrated charts for analysis & problem identification for enhanced crop cultivation
- Sensor data's automatically uploaded to the cloud for future analysis and queries
- Provides private cloud and public cloud
- Remote expert consultation
- Share greenhouse experiences and data with other greenhouses to get advice
- Improve farmer education by providing the latest green innovations
- Experts can provide objective & accurate diagnosis
- Intelligent production record
- Record details of the production system eg. location, farmer, soil quality, growth, harvesting time, fertilizer use etc.
- Automated production of records for an exact record of quality control, pesticide residue etc.

CASE STUDY AND SUMMARY

In 2016, the output value of agricultural products in Taiwan was $17.18 billion, an increase of $0.42 billion (+2.6%) over the previous year, of which the output value of agricultural products was approximately $8.88 billion, accounting for 51.7% of the total output value of agricultural products; the output value of livestock and poultry products was approximately $5.54 billion, accounting for 32.2%; fishery product output value of approximately $2.77 billion yuan, accounting for 16.1%; forest production value of approximately $6.7 million; agricultural product output value ratio in the past 10 years is roughly maintained at about 40~50% of agricultural products, 30% of livestock products, and 20% of fishery products.

Edible corn is one of the major vegetables in many countries and one of Taiwan's representative grain crops. According to the Taiwan Agricultural Commission's comprehensive statistics, in the Republic of China 104 years, the domestic corn planting area was 27,000 hectares (ha), accounting for 83% of the total grain planting area. The consumption of corn was divided into sweet corn, waxy corn and white corn. The 104-year output value of the Republic of China was 1,918,738 thousand yuan, with a growth rate of 15%. Sweet corn was used for fresh food, processing and canning, threshing and freezing, while waxy corn and white corn were fresh or baked. Among them, sweet corn is the favorite of consumers due to its high sugar content in the milk ripening period, crisp texture, good flavor, and rich nutrition. The sweet corn flavor is most influenced by the content of grain sugar and the thickness of the peel, but at present, the quality of sweet corn in Taiwan is mostly classified by appearance.
In Taiwan, government encourages and supports the implementation of intelligent agriculture solution. The biggest project of intelligent agriculture in past 5 years is provided by Advantech and its Eco-Partners in Figure 4 and this project is scheduled to close in the end of 2018. It's planned to integrate of expert systems and intelligent computing as shown in Figure 5.

Figure 4: The structure of intelligent agriculture solution

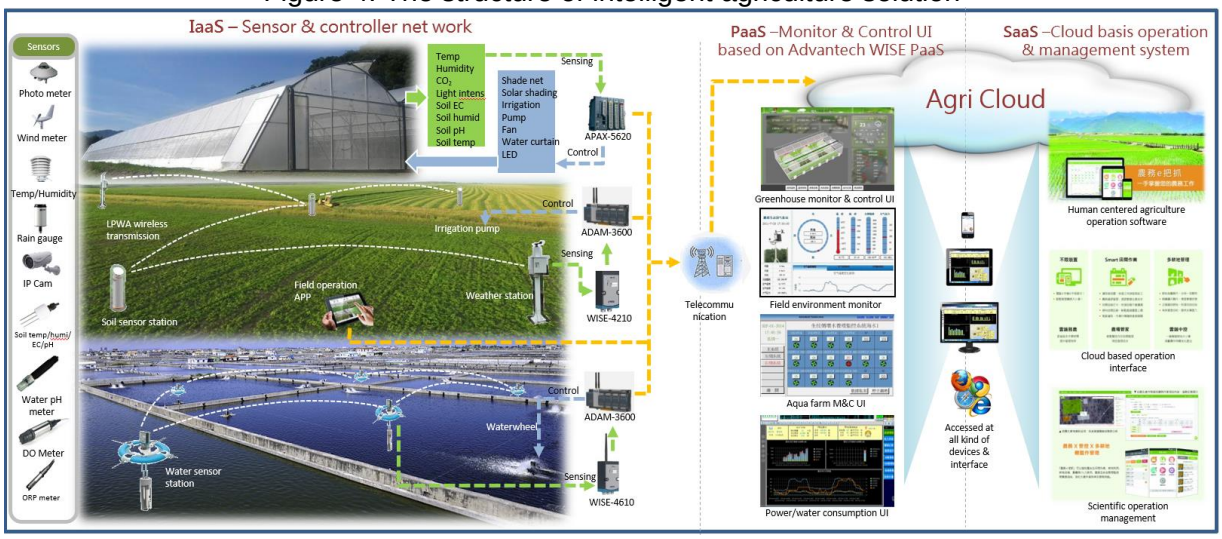


Figure 5: Integration of expert systems and intelligent computing

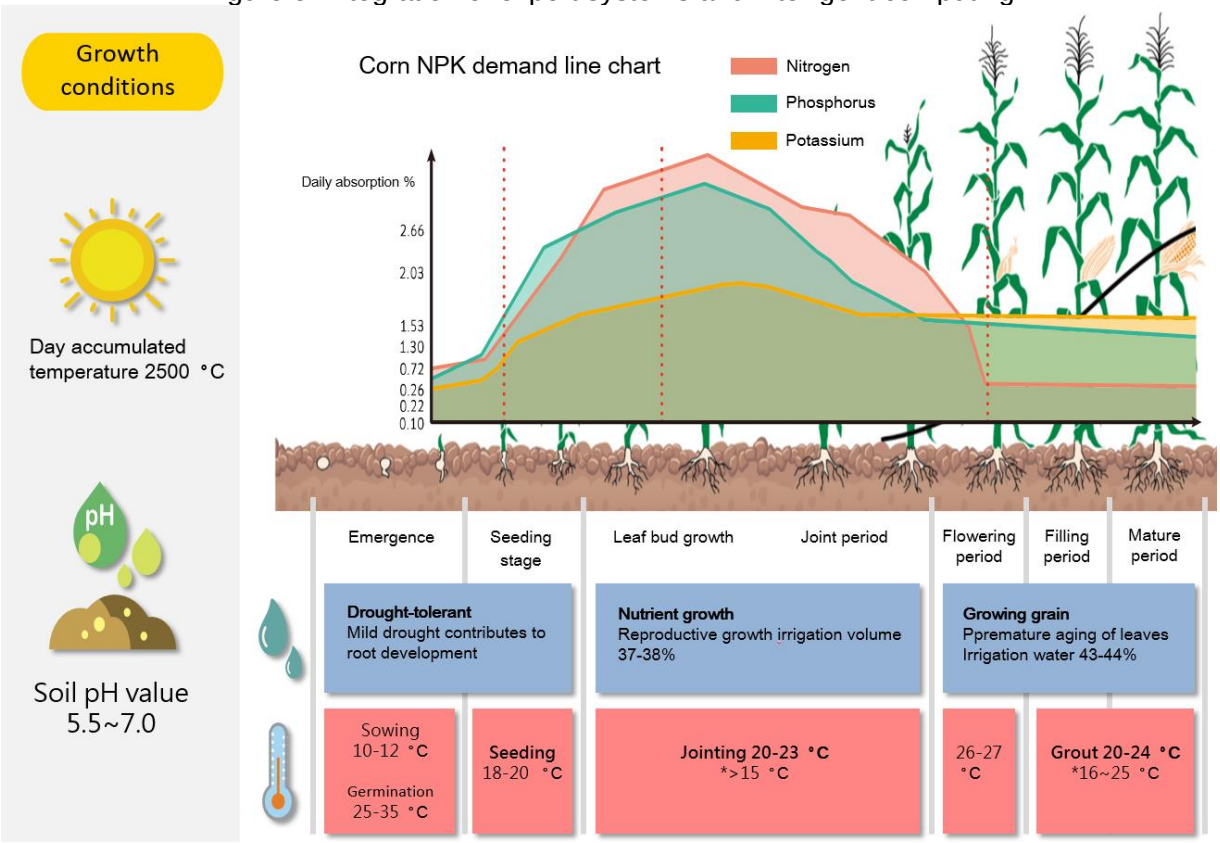
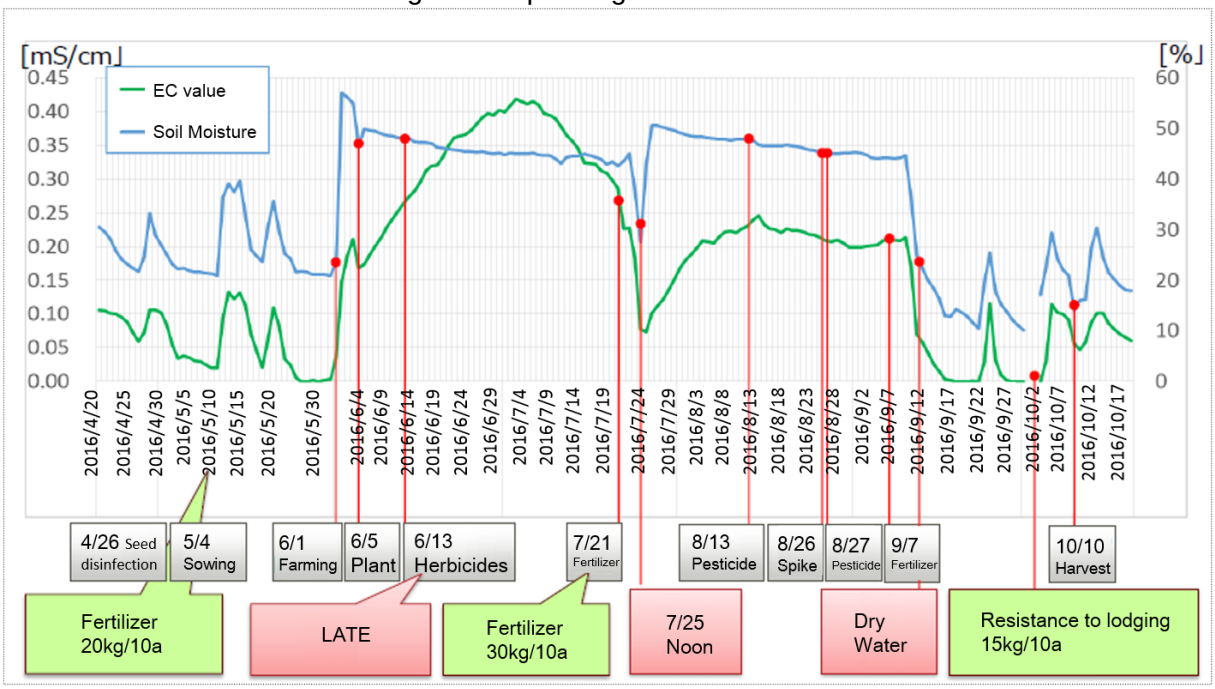


Nowadays, Software as a Service (SaaS) company plays an important role for domain-focus analysis. In Figure 6, there is another case of rice growth predictive analysis by combination of real-time data and past historical average data of growth curve to provide data-driven insight to farmer to adjust the environment to conform optimal growth condition.

Figure 6: Optimal growth conditions



CONCLUSION

An increasing number of 2nd generation farmers are expressing willingness to adopt technological products, and numerous technology giants have made investments in the agriculture industry. Supported and promoted by the governments of several countries, relevant IT hardware and software technologies are ready for deployment, and the development of intelligent agriculture is expected to attract substantial attention in the future.

Intelligent agriculture can also create unexpected economic synergy. The software and hardware required for industrial upgrades, as well as warehousing, logistics, transportation, and online shopping applications will undoubtedly prompt the development of various industries. While social media becomes popular as an advertisement tool in the past years, it facilitates agriculture business transformation from traditional way to e-commerce (Topsümer & Yarkin, 2018). Through online marketing, it expand business opportunity to domestic and international. Farmers promote their crop products by story-telling to end customers or consumers for direct sales and precision marketing. In Figure 7, it shows the target of intelligent agriculture.

Herewith, we truly believe that “Intelligent agriculture” is extremely meaningful for governments, farmers, relevant industries, and even the public.” The revolution of agriculture accelerated by IoT and cloud computing technology will be booming in the coming years.

subedi@marshall.edu

ABSTRACT

This study investigates the impact of both generations and culture in relation to the trust in transformational leadership. Using a polynomial regression analysis, we demonstrate that congruence between leadership style and cultural setting fits better for Generation X than for Generation Y. We also tested the county difference on relationship between transformational leadership and trust for each generation.

KEYWORDS: Generation, Transformational Leadership, Trust, Culture

INTRODUCTION

A review on transformational leadership and trust literature indicates trust plays different roles in the leadership process: as an outcome of leadership (Bass & Avolio, 1995; Podsakoff et al., 1996), a mediator (Yukl, 1989; Jung & Avolio, 2000; Podsakoff, MacKenzie, Moorman & fetter, 1990), and a moderator (Bass & Avolio, 1994; Nichols, 2008). This study build on previous research investigate 1) how different generations understand leadership differently; 2) how people from different cultural settings perceive their leaders differently and trust their leaders at a different level.

GENERATION, TRANSFORMATIONAL LEADERSHIP, TRUST, AND CULTURE

Generation refers to a cluster of people born in the same certain period of time who share similar values and attitudes thereby representing the characteristics of that specific era (Rogler, 2002). The common experiences tie a generation's members can be reflected in the way they view work and workplace (Schewe & Evans, 2000). Generations should be considered by leaders and their organizations as one of the important parts of the diversity mix (Arsenault, 2003). Social scientists differ somewhat on how to name and segment the generations.

The theory of transformational leadership originated with the work of Burns (1978) and later was developed by Bass (1985, 1998). The major premise of the theory is the leader's ability to

motivate followers to accomplish more than they planned to accomplish (Krishnan, 2005). Effective transformational leadership may not be realized if trust is absent.

Culture is crucial to understand leadership (Hofstede, 1991).In this study, we test a model and suggest that each dimension of culture is significantly related to leadership. Different generations perceive these situations differently. Trust in their leaders depends on the match between the situation and generation. Specifically, we propose that individualistic and low uncertainty avoidance culture provide a favorable situation for a strong transformational leadership.

Individualism/Collectivism

Individualism/Collectivism dimension describes whether the culture values individuals' goals or group goals (Hofstede, 1980).in individualistic culture, a weak transformational leader combines with collectivistic culture, creates a favorable situation where Generation X works better than Generation Y. In collectivistic culture, Generation Y is full of confidence in interacting with his/her leaders. Generation Y is expected to perceive more trust in leadership than does Generation X in collectivistic culture. Thus, we propose that:

H1a: When transformational leadership is weak, Generation X perceives more trust in leadership than does Generation Y in collectivistic culture, while Generation Y perceives more trust in leadership than does Generation X in Individualistic culture.

H1b: When transformational leadership is strong, Generation Y perceives more trust in leadership than Generation X does in collectivistic culture, while Generation X perceives more trust in leadership than Generation Y in Individualistic culture.

METHOD

Sample

Data were collected from full-time employees in USA and in China who worked in a range of occupations. The response rate was 86%. We obtained valid data from 153 American and 150 Chinese full-time employees. On average, they were 53.8% female, 49.3% Generation X, with 5.62 years of full-time work experiences. Of the employees, 33.82% has a high school diploma, 26.96% has an associate's degree or technical certificate, and 32.84% has a Bachelor's degree.

Measures

We adopted transformational leadership scale developed by Podsakoff et al. (1990).The measures of trust was borrowed from existing literature (Podsakoff et al.,1990; Casimir et al.,2006). Culture was measured by using scales developed by Hofstede's (1991, 2001). Generation is a categorical variable having two categories: Generation X and Generation Y.

RESULTS

We used polynomial regression analysis to test the moderation effects proposed in this study. The results indicate that the relationship between transformational leadership and trust varies across two generations and individualistic/collectivistic culture. In addition, the R^2 change

associated with the interaction term (i.e., ΔR^2) is 0.0138. We applied MatLab to plot two 3-D surfaces for Generation X. The results provide support for Hypothesis 1a and 1b.

DISCUSSION

This study contributes to the growing literature on transformational leadership by investigating a previously unexamined factor, generation. The study also offers new insights regarding whether culture factors impact trust in transformational leadership. In addition, we examined the congruence effect between generation and culture. The study helps to better understand the use of contingency leadership in East cultural.

LIMITATIONS AND CONCLUSIONS

The current research has several limitations. First, relatively small samples and second, some other factors such as job design and other demographic variables may influence the leadership-effectiveness relationship. In conclusion, the study shed some lights on implications for managers who work in different cultural settings and facing different generation employees.

Justification of Lean manufacturing for sustainable competitive advantage: Analytic hierarchy process approach

Rajesh Kr Singh

ABSTRACT

Market requirements are changing very fast. To compete under such business environment, organizations are trying to adopt emerging advanced manufacturing practices to reduce different kind of wastage in their operations. Lean manufacturing system has emerged as an important approach to enhance value addition in production systems. However, it has been observed that many small and medium enterprises (SMEs) particularly in developing countries are still reluctant in implementing lean manufacturing practices. By using the analytic hierarchy process (AHP) approach, study has tried to justify the implementation of a lean manufacturing system for Indian small manufacturing organizations.

KEYWORDS: Lean Manufacturing, SMEs, AHP, Competitiveness

INTRODUCTION

Due to globalized market, competition is in terms of low manufacturing cost, lesser delivery lead time, and new product features. Organizations are trying to adopt new advances in manufacturing systems. Hall (1983) and Schonberger (1982), have discussed about an approach developed by Japanese known as Lean Manufacturing to increase the production rate and decrease overall cost in the manufacturing units. It was previously known as the Toyota Production System (TPS) or the Just-in-Time (JIT) system (Toyota, 1988; Womack et al., 1990). In the United States, Lean manufacturing has become very popular in academia and also in industry. In recent time, many automobiles and other manufacturers are actively adopting the lean manufacturing concepts. According to Maccoby's (1997), one-fourth of United States manufacturing firms have tried to adopt the lean manufacturing system in their processes. Lean manufacturing tries to reduce wastage in production, inventory, human resource, etc. Some researchers (Cusumano and Takeishi, 1991; Womack and Jones, 1996b) have observed that when we shift from traditional manufacturing system to lean manufacturing, it had a significant positive impact on the performance of manufacturing units. It has been observed from the

literature that SMEs are still lagging behind in application of these lean manufacturing principles to become competitive. Therefore, objective of this study to identify major benefits of lean manufacturing and to justify its application in Indian SMEs.
Remaining part of the paper is organized as follows. Section 2 deals with literature review, Section 3 deals with research methodology i.e. AHP and finally section 4 is results and discussion with concluding remarks.

LITERATURE REVIEW

The term "lean manufacturing" was first coined by Womack et al. (1990) in their book "The Machine That Changed the World". The lean manufacturing describes the profound revolution that was initiated by the Toyota Production System against mass production system. Womack and Jones continued their research in lean manufacturing and studied those companies which use lean manufacturing in their second book, "Lean Thinking" (Womack and Jones, 1996). They explained that lean manufacturing is a way of thinking, and the whole system approach that creates a culture in which everyone in the organization continuously improve operations. In his most recent book about the Toyota system, Liker (2004) describes the management principles of Toyota.
According to Sohal and Eggleston (1994), lean manufacturing increases the net profit because it reduces the wastages in the production system. Lean manufacturing increases productivity of the plant so that production rate increases (Philips, 2002). Shingo (1989) states that lean manufacturing decrease waste in the plant. Lean manufacturing eliminates the non value adding process so that wastage get decreased. Gilson et al. (2005) have observed that Lean manufacturing improves the quality of product because it uses the standard process to make a product. According to Lian and Van (2007), lean manufacturing improves the flexibility in production systems. According to Azharul and Kazi (2013), the amount of inventory gets reduced in industry by using lean manufacturing. With the help of Lean manufacturing, lead time gets reduced because it decreases the set up time of machine.
List of benefits after the adoption of modern lean manufacturing in place of traditional manufacturing are summarized in table 1.

Table 1: Benefits of Lean Manufacturing

SN	Abbreviation	Benefits of LM	References

RESEARCH METHODOLOGY

To justify the lean manufacturing vs. traditional manufacturing for SMEs, AHP approach has been used. Saaty (1980) had suggested analytic hierarchy process (AHP) to solve complex

problems. Kodali and Chandra (2001) used AHP for justification of total productive maintenance. Study has four phases, as follows:

1. Structuring the problem and building the AHP model
2. Collecting data from expert interviews
3. Determining the normalized priority weights of individual factors and sub factors
4. Synthesis-finding solution to problem.

Phase 1: Structuring a hierarchy model of benefits

In this phase, we formulate the appropriate hierarchy of AHP model. AHP model consist of goal, main factors and result. The goal of our problem is to justify the lean manufacturing over traditional manufacturing. This goal is placed on the first level of the hierarchy as shown in Figure 1. Second level consists of seven major benefits. The third and last level consists of two alternatives, i.e., lean manufacturing and traditional manufacturing. AHP model is shown in Figure 1.

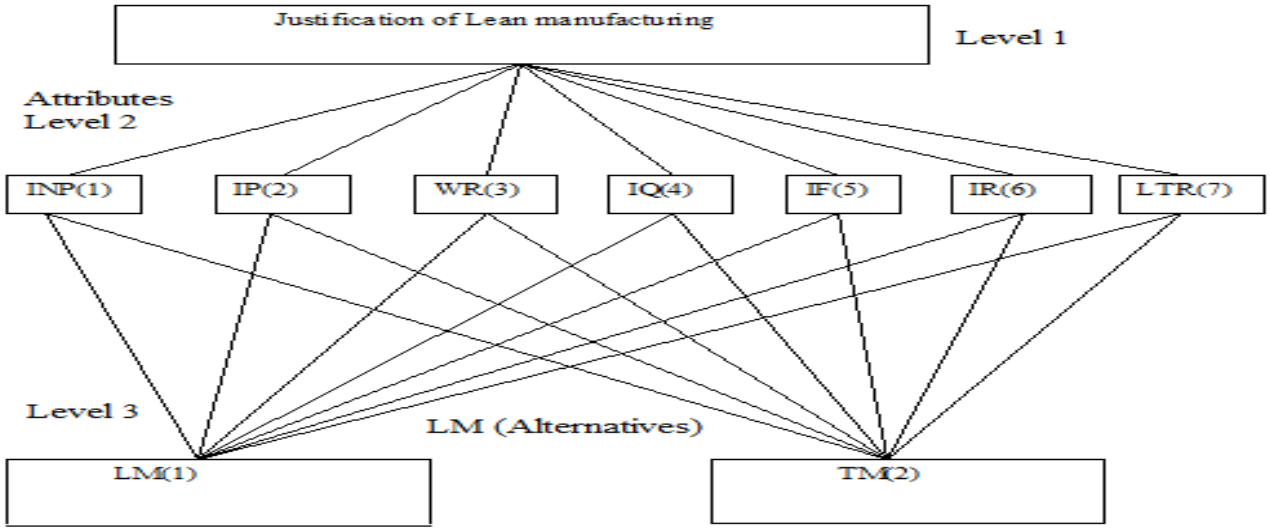

Figure 1: AHP model (Source- Adopted from Singh, 2012)

Phase 2: Measuring and collecting data

After building the AHP hierarchy, next step is measurement and data collection. It was done by a team of experts. This team assigns pair-wise comparison to the main factors used in the AHP hierarchy. We use nine-point Saaty's scale (Table 2) to assign relative scores to pair wise comparisons amongst the main factors. Team consisted of twelve experts of varying relevant field experience. Bayazit (2005) used AHP approach in decision making for flexible manufacturing system by having a team of six experts from various departments. Zaim et al. (2012) also used a team of five decision experts while selecting maintenance strategy. Singh (2013) used AHP for prioritsation of factors in coordinated supply chain.

Table 2: Thomas Saaty's nine-point scale

Intensity	Importance of one factor over other
1	Equal Importance
3	Weak Importance
5	Strong Importance

7	Demonstrated Importance
9	Absolute Importance
2,4,6,8	Intermediate values between the two adjacent judgment
Reciprocals of above non-zero	If activity *i* has one of the above non-zero numbers assigned to it when ompared with activity *j* then *j* has the reciprocal value when compared with *i*

Source: Saaty (1994)

Phase 3: Determine normalized weights

In order to find out the relative importance of seven major benefits of lean manufacturing, pair wise comparison judgment matrices are made with the help of experts' opinion. Table 4 shows the pair-wise comparison matrix for level 2 criteria.In pair wise comparison, we use the Consistency ratio (CR) to measure the consistency level. Saaty (1994) has suggested the acceptable level of Consistency ratio (CR) for different matrices. For 3×3 matrix acceptable Consistency ratio (CR) is 0.05 and for 8×8 matrix is 0.08 and for large matrix is 0.1. If consistency level with in the acceptable range, then weight result is valid. We check the consistency of judgments by following steps:

• Let the pair-wise comparison matrix is denoted by P1 and principal matrix is denoted by P2

• Then define P3 = P1 * P2; and P4 = P3 / P2

• $\lambda_{max.}$ = average of the elements of P4

• Consistency index (CI) = $\frac{(\lambda_{max} - n)}{n-1}$

• Consistency ratio (CR) = CI / RCI corresponding to n. ……. (1)

Where RCI = Random Consistency Index and n = Numbers of elements (Table 3)

Table 3: Average random index values

N	1	2	3	4	5	6
RCI	0	0	0.58	0.90	1.12	1.24

Source: Saaty (1980)

If CR is less than 10%, judgments are considered consistent,

If CR is greater than 10%, the quality of judgments should be improved.

So, CR should be ≤ 10% for consistent results

RESULTS AND DISCUSSION

A set of global priority weight can be determined for each of the lean manufacturing and traditional manufacturing by multiplying local weight of lower factors with weight of all the parent nodes above it and then adding all the products for corresponding alternative.

Table 1 shows seven main factors/benefits of lean manufacturing. AHP model developed as shown in Figure 1 is used for justification of Lean manufacturing in SMEs. Then we make pair-wise comparison judgment matrices to find out the normalized weight. Pair wise criteria comparison matrix shown in table 4. This table shows all the seven major benefits of lean manufacturing. After that we calculate the CR value to check the degree of consistency of the pair wise comparison matrix. CR for level 1 is shown in table 5. Then we follow same procedure to find the PV and CR for other levels. Table 6 shows the results. It is observed from table 6 that all seven benefits of lean manufacturing have more PV in comparison to traditional manufacturing. CR value is also less than 0.1 for all decision factors. Local weight of attributes

for alternatives shows in table 7. Global weight of major benefits for lean manufacturing are shown in table 8.

Out of seven major benefits of lean manufacturing, lead time reduction has highest global weight (0.33832). Less lead time is required to obtain maximum profit because lead time decrease production increase. Second highest global weight is to increase productivity (0.22258). If productivity increases then net profit would also increase. So we increase the productivity in such a manner that overall cost of operation decrease. Improved flexibility has third highest global weight (0.15218). If flexibility increases in production system then profit increased. Fourth highest global weight is improves quality (0.07793). With the help of lean manufacturing, quality of product also increases. Waste reduction is the fifth benefit of lean manufacturing with global weight is 0.04861. With the help of lean manufacturing we can eliminate non value added process so that our wastage is reduced. Sixth benefit of lean manufacturing is inventory reduction and its global weight is 0.03804. With the help of lean manufacturing, raw material and work in process inventory get decreased because of standard process and JIT. Next benefit of lean manufacturing is increase in net profit. Therefore lean manufacturing help in production increase, inventory decrease, waste decrease, lead time decrease, increase flexibility and improved quality. Global desirability index of lean manufacturing and traditional manufacturing are shown in table 3.9. Global desirability index of lean manufacturing is 0.89568 and traditional manufacturing is 0.10431. So this analysis shows that application of lean manufacturing is better for Indian SMEs for being competitive in global market.

Table 4: Criteria pair wise comparison matrix (level 2)

	INP	IP	WR	IQ	IF	IR	LTR	P.V
INP	1	1/9	1/5	1/5	1/8	¼	1/9	0.02025
IP	9	1	6	5	3	6	¼	0.24732
WR	5	1/6	1	1/3	1/5	2	1/7	0.05556
IQ	5	1/5	3	1	¼	3	¼	0.08907
IF	8	1/3	5	4	1	4	1/3	0.16908
IR	4	1/6	1/2	1/3	¼	1	1/8	0.04279
LTR	9	4	7	4	3	8	1	0.37591

Following steps are used to normalize the table of seven main benefits and to calculate the CR value.

Let P_1 is pair wise comparison matrix and P_2 is principal vector matrix

$$P_2 = \begin{Bmatrix} 0.02025 \\ 0.24732 \\ 0.05556 \\ 0.08907 \\ 0.16909 \\ 0.0428 \\ 0.37591 \end{Bmatrix}$$

Then $P_3 = P_2 \times P_1$

$$P_3 = \begin{Bmatrix} 0.1502595 \\ 2.0663064 \\ 0.4008324 \\ 0.671103 \\ 1.3440995 \\ 0.3117478 \\ 3.142288 \end{Bmatrix}$$

$P_4 = P_3/P_2$

$$P_4 = \begin{Bmatrix} 7.420271 \\ 8.35473 \\ 7.214518 \\ 7.534481 \\ 7.949064 \\ 7.284357 \\ 8.359096 \end{Bmatrix}$$

Average of elements of P_4 ($\lambda_{max.}$) = 7.7309308

Now consistency index (CI) = $\frac{(\lambda_{max} - n)}{n-1}$ = 0.121822

And consistency ratio (CR) = CI / RCI = 0.092289

Table 5: Consistency ratio of comparison matrix

CR	0.092289

So CR is less than 0.1, result is consistent.

7	LTR	0.37591	0.9	0.1

Desirability index of alternatives global weight of lean manufacturing and traditional manufacturing is calculated by using the equation 3. Table 8 shows desirability index of alternatives global weight.

Table 8: Desirability index table of alternatives global weight

S.NO.	ATTRIBUTES	LM GLOBAL WT.	TM GLOBAL WT.
1	INP	0.01799	0.00225
2	IP	0.22258	0.02473
3	WR	0.04861	0.00694
4	IQ	0.07793	0.01113

5	IF	0.15218	0.01690
6	IR	0.03804	0.03759
7	LTR	0.33832	0.104316

Global desirability index of modern maintenance management and traditional maintenance management is calculated by using the equation 4. Table 9 shows the global desirability index of alternatives.

Table 9: Global desirability index of alternatives

GLOBAL DESIRABILITY INDEX OF LM	0.89568
GLOBAL DESIRABILITY INDEX OF TM	0.10431

Global desirability index of lean manufacturing is 0.89568 and global index of traditional manufacturing is 0.10431. So lean manufacturing is justified for SMEs to become globally competitive.

CONCLUDING REMARKS

Lean manufacturing had been very popular tool in eliminating waste across all functions. Bigger organizations are using different tools of lean manufacturing to become competitive. However, in small and medium organizations are still in nascent stage in implementing lean tools across different functions. SMEs are not well organized and are reluctant for any up gradation due to resource constraints. The present study has tried to identify seven benefits of lean manufacturing. These are improved productivity, waste reduction, improved quality, improved flexibility, inventory reduction and lead time reduction. Based on priority weights of these benefits, study has tried to find the global desirability index for lean manufacturing system and traditional manufacturing system for SMEs. It has been found that desirability index for a lean manufacturing system is quite high as compared to traditional manufacturing system. Therefore, it may be recommended based on the findings that lean manufacturing is very useful for making SMEs competitive in the global market.

ABSTRACT

This work attempts to find the fundamental elements for developing countries to detonate desired economic takeoff, a challenge the mainstream economics is unable to answer. Other than using anecdotes and methods of data mining, this paper employs the thinking logic of systems science and the rigor of game theory. After successfully establishing two theorems, a list of key elements is provided for a developing economy to possess in order to develop its momentum for a self-sustained economic development. Other than its theoretical value, this work is expected to produce practical economic benefits for developing nations that desire to prosper economically.

KEYWORDS: consumer good, industrial good, market fermentation, holistic thinking, first law on state of motion

INTRODUCTION

In the last century, countries from around the globe attempted to modernize and to industrialize themselves. Although their GDP grew tremendously, they failed to develop a self-sustaining momentum of economic growth (Acemoglu & Robinson, 2012; Breslin, 2009; Chang, 2003; Rostow, 1960). By studying the industrial revolutions in England, the United States of America, Japan, and modern China, Wen (2016) discovers that most factors, considered crucial for kick-starting an industrial revolution (Lipton, 1977; Studwell, 2013) are actually not relevant much; instead to be successful, one nation has to start humbly in its rural areas within a politically stable environment.

Poverty tends to be self-perpetuating; growth tends to generate its own momentum, once an initial growth is started (Hartwell, 2017). To build a self-sustaining momentum, the initial growth needs to occur in the rural area (Mendels, 1972), which simultaneously helps nurture the coordination and specialization of labor, improve the wages and purchasing power of grassroots population, and ferment the formation of markets (Gilboy, 1932). Considering the present state of world affairs, this might be the only way for a developing nation to succeed in its attempt of developing a self-sustaining momentum of economic growth.

Only when markets of sufficient purchasing power and sophisticated distribution network exist, mass production appears (Fleischman & Parker, 2017; Smith, 1776). Here, the market and distribution network are developed with the manufacturing sector and commerce function as

employers and producers of wealth, and transfers resources from agriculture to industry and services (Deane, 1957).

This paper contributes to the literature of development economics in several different ways. First, by answering Hartwell's call in (1965), this work develops a scientific methodology that can be employed to derive sound, reliable, and practically duplicable conclusions in economic history. Second, two results on the dynamics of market competition are established rigorously. One result says that with a profit opportunity, there will appear competition(s) even although the incumbent firms also pursue after the opportunity. The second result explicitly shows how intensifying market competition stimulates innovation or market expansion or both have to occur. Third, on top of these results the systemic yoyo model is employed to uncover a list of key elements necessary for a developing nation to develop a self-sustaining momentum of economic growth.

The rest of this paper is organized as follows: Next section introduces the basics of systems science and the yoyo model to be used in the rest of the paper. Two theorems based on systemic intuition and game theory are shown in the following section. The main section details the key elements necessary for developing a self-sustaining momentum of economic growth. The last section concludes this presentation.

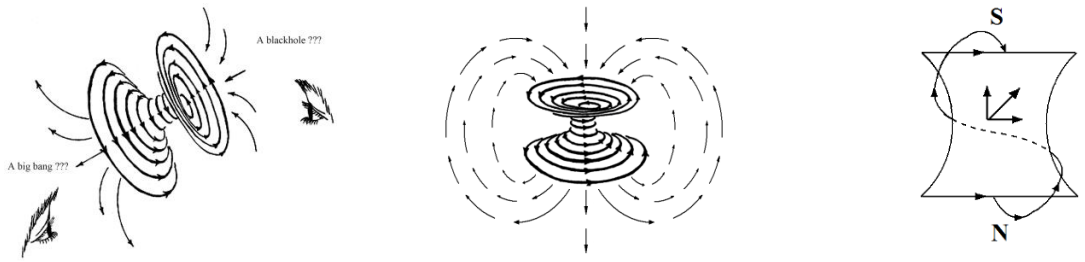
BASICS OF SYSTEMS SCIENCE AND YOYO MODEL

To make this paper self-contained, this section looks at the basics of systems thinking and the systemic yoyo model.

Because the fundamental character of economic entities is their organization, to explain and to understand organization behaviors one has to look at the entities holistically instead of focusing on individual parts and processes (von Bertalanffy, 1924; Rostow, 1960). In the past 90 plus years, studies in the language of systems science and systems thinking have brought forward brand new understandings and discoveries to some of the major unsettled problems facing the very survival of the mankind (Klir, 1985; Lin, Y., 1999).

Similar to how numbers and algebraic variables are originated from collections of things, the concept of systems exists within every object, event, and process. For instance, behind collections of objects, say, employees working for a particular company, one has the abstract numbers, such as 0 (employees), 1 (employee), 2 (employees), etc. And behind each business organization, a market, or a regional economy, a system vividly emerges; it relates the whole, component parts, and the environment with their interconnectedness being emphasized. In fact, it is the interconnected whole, parts, and the environment, the totality is known as a firm, market, industry, economy, etc.

The importance of systems science is manifested in its capability of solving problems that have been either difficult or impossible for the traditional science to deal with. The particular speaking language and thinking logic of systems science is the systemic yoyo model (Lin, Y., 2007), Figure 1, similar to how the Cartesian coordinate system plays its role in the development of modern science (Kline, 1972).



(a) (b) (c)

Figure 1. (a) Eddy motion model of the general system; (b) The meridian field of the yoyo model; (c) The typical trajectory of how matters return

Specifically, on the works of Wu and Lin (2002), Lin Y (1988) and Lin et al (1990), the concepts of inputs, outputs and converging and diverging eddy motions are coined together in the model (Figure 1) for every system of concern. That is, each system is a multi-dimensional entity that spins about its axis with Figure 1(a) being the specific case in our 3-dimensional space, where some of the outputs return to the system as inputs (Figure 1(b)).

This systemic model implies that each organizational entity, be it tangible or intangible, can all be seen theoretically as a realization of a multi-dimensional spinning yoyo with an eddy field, which spins perpendicular to the axis, and a meridian field, which revolve parallel to the axis. The fields stay in constant motion (Figure 1(a)). When the motion stops, the entity will no longer exist as an identifiable system. Figure 1(c) shows that the interaction between the eddy and meridian fields makes all the returning outputs travel along a spiral trajectory.

COMPETITIVE INVITATION OF THE MARKET

To describe the dynamics of market competition, assume that an oligopoly market is occupied by *m* firms, *m* = 1, 2, … They provide consumers with mutually substitutable products, and enjoy their respective shares of loyal consumers who purchase only from their firms as long as the price is not more than their reservation price 1. To potentially increase their consumer bases, these incumbent firms compete over the switchers with adjustable prices charged to their customers. Assume that these firms produce their products at constant marginal costs, which are set to zero without loss of generality, and that the managements of these *m* firms are well aware of each other's pricing strategies and have established their best responses by playing the Nash equilibrium through pure self-analyses.

Appearance of New Competition

For this oligopoly market, we have the following result regarding when the market actually invites new competition.

Theorem 1. In the Nash equilibrium, an if-and-only-if condition for one firm to enter the market profitably, as a competitor of the incumbents, is that the magnitude of market segment of switchers is greater than zero.

Because the entrant does not have any royal consumer in the particular product market, it is natural for it to uniformly randomizes its price P over the interval [0,1] as long as the firm could make profits on the average. Here, the constant marginal costs of this entrant are set to zero without loss of generality. And intuitively, the market is a systemic yoyo field. If seen from

above either the input side or the output side, the yoyo body in our 3-dimensional space is a pool of spinning media of all kinds, such as goods, information, money, credit, etc., that appear and exist in business activities (Figure 2).

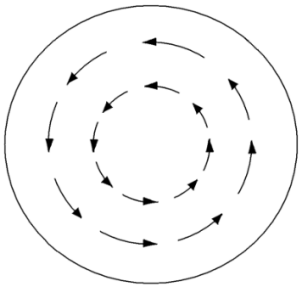


Figure 2. A systemic view of the marketplace

Now the dishpan experiment (Hide, 1953; Fultz, et al., 1959) indicates that when the movement of the media within the systemic pool in Figure 2 is under enough pressure created by either a sufficient speed of rotation or sufficient difference in the temperature between the center and the periphery of the dish, the uniform movement in Figure 2 will become chaotic, in Figure 3. So, it means that the media within this spinning dish has to be disturbed either orderly or chaotically. That is, local patterns of flow appear inevitably.

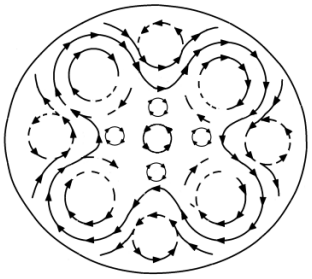

Figure 3. Asymmetric flow observed in Fultz's dishpan experiment

Practically Theorem 1 implies that with demand supplier(s) will appear to fill the market need. The following result shows how the base of loyal customers can deteriorate with intensifying competition and explains why in the current globalizing economy the market landscape changes faster and customers become less patient than before.

Theorem 2. In the Nash equilibrium, when the market grows with an increasing number of incumbent firms, the base of loyal customers for each of these firms will diminish.

All the detailed proofs of Theorems 1 and 2 are omitted to limit the length of this paper.

How is a Market Formed over Time?

Based on the systemic yoyo model, initially family-based workshops (the small eddies in Figure 4(a)) gradually evolve into a sizable market (the overall dish in Figure 4(b)). At the beginning, no regional commerce existed or the scale was ignorably small, so the overall circular dish in Figure 4(a) does not spin. With development of transportation and communication, the region becomes connected through transfers of goods and information, the originally unrelated small shops become connected, Figure 4(b), where the spin of the dish models the fact that goods

and knowledge are now travelling across the region and the original shops, the local eddies, are also serving the entire market. The greatly increased market demands motivate the originally small shops to evolve into large factories employing advanced technologies. In the meantime, the greatly increased supplies of goods and services spoil customers, making them pickier than before.

SELF-SUSTAINING MOMENTUM OF ECONOMIC GROWTH IN DEVELOPING NATIONS

This section looks at how to cultivate a desired self-sustaining momentum of economic growth in an impoverished developing nation. For the convenience of communication, let us first characterize the developing nation: It is assumed to be autarkic and unorganized without any of the symbols of a modern society, such as factories, cars, highways, shopping malls, etc. After having bought food, people have almost nothing left for their wants. See (Cipolla, 1994, p. 25-26) for a vivid description of the preindustrial Europe.

Peasants are tied to the land and have to spend long hours daily on the land to maintain their subsistent livings. Natural disasters generally cause great losses to the land and people. Because land size and population size under control signify power and wealth, rulers use all means to gain the monopoly power to expropriate others (Ebrey, 1999). In such a nation, family is the basic unit of the society and has to produce everything for daily lives. It is risky for any family to specialize in producing just one type of household good and to depend on different sources for other necessities (Smith, 1776, Chapter III).

Merchants, as a class, are treated negatively; the nation, as a whole, suffers from political instability and social trust. So, the transaction cost of contracting is prohibitive high because of the lack of a legal system, making it hard or even impossible to put together large tracts of land, to ensure reliable supply of materials and related supports, and to get created products into the market. Without a unified domestic market and a well-organized commercial network in the international market, the few existing small proto-industries cannot grow to the critical level and density of the so-called proto-industrialization (Kriedte, et al., 1977). The government is absent in the formation of large regional and national markets, which makes the costs of social coordination impossible to overcome. That is, this nation does not have unified domestic markets for the exchange of goods, labor, and finance.

The socio-economic situation of this nation can be well modeled as a static dish with many local, isolated eddy pools representing the unrelated small workshops, Figure 4(a), that provide for their respective families without much exchange with the outside world. When the nation is trapped in the Malthusian poverty equilibrium, its yoyo structure stays forever in the same pattern as in Figure 4(a).

To the developing nation, acquiring a self-sustaining momentum of economic growth represents a process that not only changes the mode of production at all different levels, but is also an endeavor of nation development and strengthening. The process represents a huge systemic project that requires large-scale coordination among all social classes and interest groups, mobilizes all citizens, and utilizes resources in ways never seen before. If successful, it creates economic prosperity, organizational consolidation, and projecting capacity of influences.

Since the Industrial Revolution of England in the late 18th century, scholars have tried to uncover the exact causes underneath the dramatic social-economic changes in order to help developing nations to kick-start their own self-sustaining momentum of economic growth (Hartwell, 2017; Gerschenkron, 1962). However, all of these studies suffer from major weaknesses, such as the lack of relevant data (Fleischman & Parker, 2017), suggestions that are not practically operational (Lipson, 1949), the constraint of linear thinking (Soros, 2003), and the missing of holistic thinking (Hartwell, 2017). So, contrary to what is done in the literature, this paper utilizes the results established in the previous section and in (Lin & Forrest, 2011) to clarify what the key elements are in successfully producing self-sustaining momentum of economic growth in the impoverished developing nation. Based on the literature and what has be established earlier, we provide the following list of key elements for the developing nation to have in order for it to produce the desired self-sustaining momentum.

Element 1: Establish an unwavering national goal to become wealthy and powerful;
Element 2: Constantly aim at raising the basic standards of living;
Element 3: Purposefully support the fermentation of markets;
Element 4: Stimulate the development of primary target industries; and
Element 5: Always look at the next stage of momentum building.

An Unwavering National Goal

Similar to the management of large corporations (McGrath, 2013), an unwavering long-term development goal and related strategies are absolutely needed for the developing nation to produce its self-sustaining momentum of economic growth. In fact, powerful nations throughout history have always purposefully reshaped the world. By studying the history, Kyrkilis and Simeon (2015) and Wen (2016) recognize that not having any long-term national goal of economic development is a recipe for failure; and the lack of such a national goal generally means that the nation is unable to muster the support of its capable citizens to organize the population through creating jobs, maintaining social order, and political stability. Consequently, the government officers of different levels would most likely become problem solvers busy with urgent crises one after another without any vision on the long-term development. In short, only a focused, strong government could possibly ensure political stability and social order of the nation and defend its interests (Stein & Arnold, 2010).

When the developing nation is modelled as the dishpan in Figure 4(a) or Figure 4(b), the population is naturally distributed over the entire dishpan with some individuals located within a local pool while some others along the periphery. That implies that in making a long-term development goal, equality and prosperity for the population cannot be achieved simultaneously. So, to entice the entire population to participate, wealth creation (or the local eddies in Figure 4) has to be the priority. And because the local pools in Figure 4 is created by distribution unevenness of the ‘fluid’ within the dishpan, this model implies that for the developing nation to produce its self-sustained momentum of economic growth it has to naturally develop market exchanges with the support of central planning. The central planning is reflected as the spinning speed of the dishpan. The systemic mechanism that is in the play is that the formation of market exchange and central planning interact with each other as a feedback system, Figure 5.

Strategy 1 in the systemic model is market exchange and Strategy 2 the central planning, or vice versa. The feedback mechanism helps the economy to produce the desirable output.

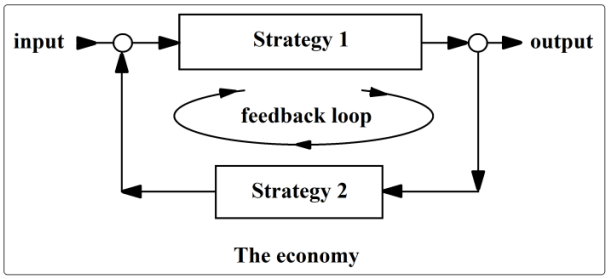

Figure 5. How a feedback system works to produce desired outcomes

Constantly Aim at Raising the Basic Standards of Living

In Figure 4 with the formation of the market 'fluid particles' have to be relocated in the strengthening spin of the local pools. This fact implies that the important first step in producing the desired self-sustaining momentum is to free up labors from the land by increasing the supply of crops. To maintain political stability and fight against foreign aggressions, the increased supply of crops should be materialized through domestic production, which can generally be accomplished through policies and technologies. The former is a consequence of central planning. For example, Crespi et al (2016) show how tax policies impact firm level investments. And the latter reflect how market exchanges play their roles. As for technologies, they have to be introduced at levels appropriate to the quality of the labors in order to produce tangible benefits. In summary, the agricultural output has to be increased so that a large proportion of the available labor can participate in industrial and commercial activities without jeopardizing the secure supply of food.

With central planning, the infrastructure necessary for producing the desired self-sustaining momentum, such as irrigation systems, road networks, and power grids, will be constructed and maintained. It is because all of these projects need to be organized, coordinated, and financially supported by various levels of the government.

The reason why the flow pattern in Figure 4(a) evolves into that of Figure 4(b) is because of the increasing difference in the forces acting on the 'fluid's' particles located along the periphery and at the center of the dish. That means that when a financial system appears across the land, the national economy emerges and local firms beyond the boundary of family are formed, where money is appropriately seen as the 'fluid' in the 'dish' of the economy. To maintain the difference between the periphery and the center of the dish increasing in order to eventually reach the state in Figure 4(b), the government needs to encourage commerce and merchant activities and when necessary to directly participate in them. Such determined efforts of the government based on unified beliefs and promoted values will mobilize the population so that primitive firms will evolve into a large-scale rural industrialization, leading to the formation of unified domestic markets of light consumer/industrial goods and labors. Now, Theorem 1 implies that with the purchasing power of the population increasing and responding to the growing market demand, firms will automatically emerge due to the spirits of entrepreneurs; and with accelerating exchange speed of money and goods, local, then regional markets will appear, followed by the formation of national markets

What the attempt of constantly aiming at raising the basic standards of living accomplishes is to establish a tight association between the government and its people, as shown in Figure 6 where the government is modeled by the axis of spin and the population the

layers of the spinning field. The government (the axis of spin) exists because of and for the people (the spinning field). By connecting the people through creating domestic markets (the meridian field that holds the eddy fields together), the yoyo structure of the nation becomes more solidified than before.

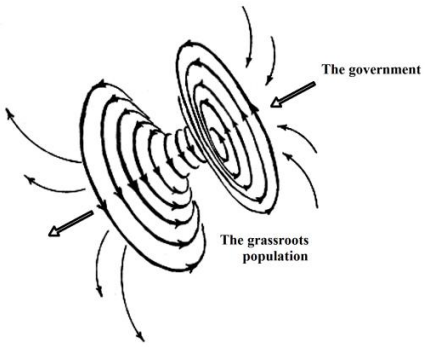

Figure 6. By connecting the people, the nation becomes more solidified

Purposefully Support the Fermentation of Markets

When the dish in Figure 4(a) spins faster, the earlier unrelated local pools will become connected and start to interact, Figure 4(b). That is, with beliefs unified, labors of individual families are organized into teams so that coordinated production becomes possible, the local pools in Figure 4(b). That is, the initially isolated eddies in Figure 4(a) are growing through the leadership of local governments so that the prohibitive transaction costs of contracting in the developing society can be practically overcome. Although the developing nation does not have a powerful class of merchants to play the role of market creators, the fact that the spin of the dishpan in Figure 4 affects the entire dish implies that local government officials, serving as public “merchants”, can fill into this missing link. These officials help create local, regional, national, and international markets for local businesses through supporting village firms in whatever means necessary. In short, all levels of the government, under the national mission, facilitate the creation and expansion of firms and the creation of markets.

With the spin in Figure 4 accelerating, the earlier stagnant and isolated local eddies (Figure 4(a)) grow larger and become connected. That is, with the combined effect of the population’s desire to improve quality of life and the government officials’ mandate to develop their local economies, rural industries flourish and the nation will soon experience rapid proto-industrialization and economic takeoff.

In summary, our systemic modeling and Theorems 1 and 2 imply that to successfully develop the market, the key includes: a national push for a mercantilism ideology; government’s participation in the effort of proto-industrialization; encouragement and protection of commercial activities; transformation of autarkic peasants into cooperation-based manufacturing and industrial organizations; and creation of high purchasing power for the grassroots population. And market fermentation is important because it simultaneously evolves with mass production, which in turn helps the developing economy to transit into a more advanced stage.

In theory, what purposefully supporting the fermentation of markets does is to strengthen the meridian flows – sufficient purchasing power – of the yoyo field - the nation (Figures 1(b) and 6) – that help speed up the spin intensity of the yoyo body. When a market of goods appears, firm(s) will surface to meet the demand, making the competition of the market more intensified, as implied by Theorem 1.

Stimulate the Development of Primary Target Industries

The evolution of the local eddies from what is shown in Figure 4(a) to those in Figure 4(b) models the deepening rural industrialization and an expanding market of manufactured goods and services. With the increase of households' incomes and that of the purchasing power of market, profit-driven activities are invited and encouraged. That transforms part-time peasant workers into full-time workers, and scattered local firms into factories. That is when large-scale mass production, mass distribution, and mass exchange emerge with the competition for market shares. As the market depth of manufactured goods, the purchasing power of the market players, and the mastery of skills of the converted peasant-workers improve over time, triggered will be a dramatic transition from an economy of family-based, autarkic, agrarian production to one that is factory-based industrial mass production. To make the transition successful, there is a need for parties to focus on several primary target industries and a class of light industrial goods, which are income elastic and do not initially require much capital input and know-hows.

Among all imaginable products, food, cloth, and shelter are the most basic for survival. Comparing the productions of these three necessities of life, spinning and weaving are the one that is not constrained by weather, season, and daylight. And the textile market is the largest and most income-elastic when compared to other light consumer goods, such as jewelry, pottery, furniture, etc., as Deane (1979, p.66) puts: "(Cotton textile) was cheap enough to come within the budget of the lowest income groups and fine enough to be desired by rich as well as poor; it was salable in tropical as well as in temperate climates; …" Therefore, this market can grow rapidly, support easily mass production and stimulate innovation under competition. In other words, the textile and clothing industry should be one of the nation's primary target-industries for promotion.

Similar to what is analyzed above, other target industries should also possess the following characteristic: The production can be separated into intermediate stages, each of which can be entertained by workers without much training. When those production stages that require mechanical motion are identified, they will then be replaced by machines operated by natural power. As a domino effect, one particularly mechanized production stage naturally creates demand for mechanization of other stages in order to keep the demand/supply of intermediate-stage goods stay in synch. That is actually how the entire production becomes mechanized.

To summarize, what the development of primary target industries accomplishes includes: 1) The government coordinates the expansion of small firms and the development of market of manufactured goods; 2) the mechanization of production and functionality of markets stimulate each other; 3) new varieties of the existing goods, new consumer goods, intermediate goods, and even raw materials are discovered and invented (Theorem 2); and 4) if the domestic market does not have enough magnitude, the developing nation will have to rely more heavily on the international market.

Always Look at the Next Stage of Momentum Building

When its capacity to mass-produce goods reaches a threshold level, the developing nation's markets, both domestic and foreign, should have been developed immensely. Now the following law on the state of motion will come into play.

First Law on State of Motion (Lin, 2009): Each imaginable and existing entity in the universe is a spinning yoyo of a certain dimension. Located on the outskirt of the yoyo is a spin field. Without being affected by another yoyo structure, each particle in the said entity's yoyo structure continues its movement in its orbital state of motion.

This law implies that the growth momentum of the manufacturing sector and the market of the developing nation will continue. That in turn will make the mass production of modern goods immensely profitable. In other words, a wide-ranging economic boom, driven by the growth momentum, will spill over to many different sectors of development, which is the so-called moment of economic *takeoff* (Rostow, 1960).

CONCLUSION

If we model the developing nation's government as the axis of spin and the grassroots population as the yoyo field in Figure 6, then we can see that both of them coexist such that the former is a reflection of the latter. That is, the government is determined by the grassroots population; if the government sees the need for the population to evolve in a particular way, then the government has to first mobilize the population so that they can evolve simultaneously.

Specifically, this paper shows theoretically that after forming a primitive market, competition will naturally intensify; and the intensifying competition will encourages innovation in production and expansion of the market. That will help develop the desired momentum of self-sustained economic development. Implicitly, this paper shows that the eventually successful development of the desired momentum of economic growth needs to be started in the rural area with the grassroots population, where humble, labor-intensive, and low-value-added products are produced to meet the needs of the grassroots populace (Mendels, 1972), while a large market that can absorb the massively produced goods emerges.

Because the successful develop of the desired momentum of economic development comes as a consequence of coordinated efforts of many participants and of synchronized allocation of resources, the government has to be in the play actively. The government needs to support a mercantilist ideology, employ its administrative power, upkeep the creation and maintenance of markets, and build infrastructure (Ashton, 1970).

Other than its theoretical results, this paper also contributes to the literature with its new methodology, based on a particular way for researchers to utilize their intuition, followed by rigorous reasoning. Because of this, this new methodology is expected to be widely useful in the study of historical economic events, where Hartwell (1965) had realized the deficit in language-based expositions.

Abdullahi I. Musa PhD
Kaduna State University
Musob2@yahoo.com

ABSTRACT

Hypertension is a serious health problem globally. Hypertension information program for individual decision is critical to sustainable health. Unfortunately, few studies exist on hypertension information among vulnerable urban poor in developing countries. This study adopted interpretative paradigm and grounded theory methodology to answer two questions: what are the knowledge of hypertension among urban poor? And, how urban poor access hypertension information?. Inductive analytical processes of open coding, axial coding and selective coding was employed to analyze data. Findings suggest that knowledge of hypertension among urban poor conflicted with orthodox medical knowledge and they access hypertension information informally via strong ties

KEYWORDS: Health Information, Access to Health Information, Hypertension, Health Epistemology, Health Ontology

INTRODUCTION

Globally, cardiovascular diseases accounts for approximately 17 million deaths annually, out of which 9.4 million cases resulted from complications of hypertension. Hypertension is responsible for at least 45% of deaths due to heart diseases and 51% of deaths resulting from stroke (WHO, 2013). Hypertension is one of the major causes of premature deaths worldwide and the figure appears not slowing down. For instance, it is estimated that by 2025 there will be1.56 billion adults living with high blood pressure (WHO, 2013), and Africans are more genetically predisposed to developing high blood pressure (Adebayo, 2013).

Hypertension is a global health concern as 1.13 billion suffer from hypertension (Cable News Network, 2016). Hypertension information and communication programs has been developed and implemented in several countries with the objectives of educating communal members about the dangers of hypertension (Pan American Health Organization and World Health Organization, 2017). While there are abundance of studies on hypertension in developing regions (Feng, Pang and Beard, 2014), most of these studies are not focused on knowledge of hypertension and how individuals access information on hypertension in context and situations. Specifically, very little is known about what urban poor know about hypertension and how they access information on hypertension. To save life and reduce the adverse consequences of hypertension there is the critical need to uncover the knowledge of hypertension among urban poor and how urban poor in resource constrain setting of

Africa access information to answer their concerns, worries, and questions about hypertension. This study is significant to public health officials for designing evidence based hypertension information, education, and awareness program.

The Problem Focus and Significance of the Study

Africa has the highest prevalence of hypertension estimated at 46% of adults aged 25 and above, there were approximately 80 million adults with hypertension in sub-Saharan Africa in 2000 and projections based on current epidemiological data suggest that this figure will rise to 150 million by 2025 (WHL, 2014).
In Africa, low-socioeconomic persons are more susceptible to illnesses, including hypertension and cardiovascular diseases (Wilson, Kliewer, Plybon, and Sica, 2016, Kurtzleben, 2012, Adebisi and Somali, 2013, Cable News Network, 2016). In particular, hypertension is very prevalent in Africa compared to Europe and USA (AU, 2013). The high prevalence of hypertension in Africa is a source of worry. To reduce hypertension and the risk associated with it among the urban poor, early diagnosis is very important.

Early diagnosis of hypertension is associated with improved long-term survival (Lau, Hubert and David 2015). In the same vein studies indicate that though there is no cure for hypertension, but it can be effectively managed for life when the patient is diagnosed earlier. Unfortunately, despite the importance of early diagnosis in preventing and controlling the prevalence of hypertension the number of urban poor living with high blood pressure is scary. For instance, in Nigeria about 57 million suffer from hypertension (Gachomo, 2013). Of the 57 million diagnosed with hypertension only one percent knew that they had high blood pressure. There is therefore the compelling need to investigate the knowledge of hypertension among urban poor in Nigeria. To help reduce the adverse consequences of hypertension this study investigates the knowledge of hypertension among urban poor and how urban poor access information on hypertension.
This study is significant because a grounded theory methodology and method (Glaser and Strauss, 1967) was adopted to answer questions related to knowledge of hypertension among urban poor and how urban poor in resource constrain setting access information on hypertension, In line with grounded theory approach (Glaser and Strauss, 1967) findings of the study were translated into 2 conceptual models—one depicting the knowledge of hypertension among the urban poor and the other depicting a conceptual model of how urban poor access information on hypertension. The two conceptual models offer scholarly insights of hypertension in the context of urban poor case study of a developing country. The models is potentially useful for public health policy makers and public health information and communication practitioners in designing evidence-based hypertension information and communication programs that are suitable to urban poor in resource constrain settings. More so, findings of the study can spur interest among global and public health policy makers to conduct further empirical inquiries about knowledge of hypertension among urban poor in developing regions of Africa, Asia, and Latin America

LITERATURE REVIEW

This study is about knowledge and access to information on hypertension. Conceptually knowledge is rooted within the scholarly content area of epistemology and ontology. Ontology refers to the study of the existence, nature, or being of a certain entity. It also refers to philosophy of reality (Khushf, 2016). Epistemology on the other hand refers to the body of philosophy that involves the study of knowledge (Maraqah, 2014). It addresses how people know and how people know what they know (Kruss, 2005). Accordingly, health

ontology and health epistemology refers to people's knowledge, attitudes and associated behaviors which pertain to diseases, illnesses, and their prevention, and treatment (Encyclopedia of Medical Concept, 2012). Health ontology and health epistemology are related to epistemological beliefs (Bientzle, Cress and Kimmerle 2014).

Epistemological beliefs are the cognitions (i.e., understandings) individuals have on knowledge and knowing and how (new) knowledge is perceived and processed *(*Bientzle, et al. 2014). Studies indicate that people's epistemological beliefs influence how they deal with health knowledge *(*Bientzle, et al. 2014).

Epistemological beliefs represent important concept for investigating health information behaviours, specifically, the concepts can be used by scholars to uncover individual knowledge about diseases and how individuals in specific contexts access information on disease and illnesses. This is critical because (Spancer, Phillips and Ogedegbe, 2005) states that people whose ontological and epistemological beliefs are discordant with traditional biomedical concepts of hypertension have poor blood pressure control than those whose beliefs are concordant with the biomedical paradigm. Closely related to health epistemology and health ontology is the notion of information, health information, and access to health information.

Information

Information was discussed and characterized by Buckland, (1991) he characterized information as process, as knowledge and as thin, as a process when it perform the function of informing, which involve transmitting information from a source to a recipient, information as a knowledge when it perform the function of imparting knowledge to an individual, and information as a thin when it is tangible. Likewise, Feynman (2006) noted that "Information is not simply a physical property of a message: it is a property of the message and your knowledge about it." In essence, Rubin (as cited in Aina 2004) states that information is process data from which meaning arises and it is communicated.

Health Information

Health information denotes quality information about physical, metal and social wellbeing (WHO, 2017). They further explained that health information is a national asset that can be used by policy-makers, planners, health care providers, development partners and the general public to track health-system performance, to support better health policies and make effective health- related decisions. In other words, the goal of health information is to contribute to attaining universal coverage of quality services for improved health outcomes through improved access and utilization of health information.

Access to Health Information

Access to health information is the ability of a person to access published and unpublished knowledge on all aspects of health and healthcare (Edewor, 2010). In essence, access to health information is a crucial factor to healthy life and critical to many facets of health care design and delivery Okwilagwe (as cited in Edewor, 2010). Also, Klinedinst, (2012) stated that access to reliable health information is potentially the single most cost-effective and achievable strategy for sustainable improvement in health care. Furthermore, (Health Information Exchange, 2013) itemized the benefit of access to health information as improve health care quality and patient outcomes by reducing medication and medical errors, reduce unnecessary tests and services and improve the efficiency of care by ensuring everyone involved in a patient's care has access to the same information, access

to health information reduce administrative costs by making many administrative tasks simpler and more efficient, it increase patient involvement in their own health care and reduce the amount of time patients spend filling out paperwork and briefing providers on their medical histories, and access to health information coordinate with and support public health officials to improve the health of your community.

Previous Studies: Health Information, Knowledge, and Access to Health Information

Several empirical inquiries were undertaken to determine health information, knowledge, and access to health information. For instance, Chang (2013) conducts a study to explore patient's perception and knowledge regarding hypertension and hypertensive guidelines on sodium intake and lifestyle modification in a work environment in the republic of Panama. Health Beliefs Model was use as a theoretical frame work for the study. The study research questions sought to uncover patient's perception of being hypertensive, knowledge about the hypertensive guidelines, patient perceived barriers to follow lifestyle modification, patient's perceptions and knowledge regarding sodium intake, and perceived barriers to follow sodium intake recommendation. This qualitative study used an exploratory approach and semi structured in depth interviews to answer the research question. Emerging themes illustrated that participant's perspectives of hypertension had become their drives towards the management of their disease and through their daily lives constant different factors played the role of motivation or discouraging their non pharmacological treatment. Participants had also given a list of barriers and coping strategies in order for them to keep their disease management.

In another similar study, Guatam (2012), studied the health knowledge and health beliefs about cardiovascular disease among students. The study sought to determine the risk of developing cardio vascular disease (CVD) in the population and to assess correlation between knowledge, health beliefs, and personal risks. Five questions were asked in the research which sought to uncover the overall levels of knowledge and health beliefs about CVD, the relationships between knowledge, knowledge subtypes, and health belief about CVD, the personal risks of developing CVD, personal variables that predicts CVD, and personal variable that predicts CVD individual health beliefs. The Health Belief Model provided the theoretical framework for this study. Findings revealed that knowledge about cardiovascular disease was low among the study participants, and that perceived susceptibility, severity, and barriers regarding CVD were low.

A study by Robinson (2012) examines the relationships between hypertension (HTN) management behaviors and beliefs about HTN among a sample of African American Adults who self report having a diagnosis of HTN, by applying the constructs of the Health Belief Model. Two questions were asked in the research which sought to uncover significant differences in HTN management behavior among African American and combination of the independent variables that will account for the most variability in self reported HTN management behaviors among African Americans. One hundred and sixty nine African American adult residents from four public housing apartment building in inner-city Cleveland, Ohio, completed a 46- item questionnaire. Multiple regression and one-way ANOVA with Turkey's HSD criterion analysis were used. Findings revealed that hypertension management behavior among participants between age fifty one to seventy were significantly higher than that of participant less than fifty years, and HTN management behavior of those who were diagnosed more than five years ago where significantly higher than those who were diagnosed less than one year ago. Finding also revealed that the best combination variables accounting for the most variability in self reported HTN management behaviors as perceived barriers, age and self efficacy.

Wheeler (2011), undertakes a study to examining the knowledge and perceptions of

zoonotic disease risk and information-seeking behavior amongst small and mixed animal owners in the inter Mountain West. Health Beliefs Model (HBM) Serve as a theoretical frame work for the study. The study contains the following research questions 1. Which of the HBM constructs effectively predict the adoption of prophylactic behavior? 2. Do the HBM constructs found to predict the adoption of prophylactic behaviors in this study follow the pattern found in previous preventive health behavior studies using this model? 3. Is knowledge of MRSA and Salmonella associated with greater compliance with prophylactic behaviors? 4. Are veterinary health care professionals the preferred source for clients seeking information about health risks related to zoonotic disease? 5. Does a difference in risk perception and protective behavior exist between mixed animal owner and small animal owners? 6. Does a difference in information seeking behavior exist between mixed animal owners and small animal owners? 7. Do demographic trends in this study population reflect trend in the general population? 8. Are the information seeking behaviors found to be most prominent among the study population reflective of trends in the general population?. One thousand names were randomly selected from the client lists of the James L. Voss Veterinary Teaching Hospital at Colorado State University. Four hundred participants responded to a mailed. Descriptive analysis was used for this study. Findings revealed that, adopting protective behavior is best achieved by perceiving greater benefits to adopting the recommended behavior, perceiving fewer barriers, and receiving more cures to action. Results also found differences between small and mixed animal owners in several area of enquiry, including knowledge of disease, perception of risk, perception of cues to action and information seeking behaviors.

Summary of the Review

The literature review discusses health ontology and health epistemology, access to hypertension information, and previous studies on knowledge were reviewed. The objectives of their studies, the methodology they used and their findings in respect to the theory were highlighted

In spite of the many researches already carried out in a variety of fields especially on knowledge, awareness, and perceptions, to the best of my knowledge there is lack of data specific on knowledge of hypertension among urban poor in Zaria when this current study is being conceptualize. Factors affecting diagnosis behavior are unique to individuals and are context specific, and therefore, studies done in other countries may not apply to circumstance surrounding Zaria metropolis.

METHODS

Research paradigms are based on varying philosophical foundations and conceptions of reality, each paradigm, in turn is implemented by associated methodological approaches and strategies Lincoln and Guba (as cited in Villiers, 2005). This study adopts interpretive paradigm, interpretivist beliefs human thoughts and behavior are shaped by the meanings attributed to it within a particular culture, at a given moment in time (Dilthey, 2010). Therefore, this study uses qualitative approach to answer the following research questions:

RQ1. What are the knowledge of hypertension among urban poor in Zaria? To answer this question, the researchers asked the following sub questions

a. Please share with me your knowledge on causes of hypertension?
b. Share with me your knowledge on prevention of hypertension?
c. What types of symptoms can make a person believe he/she has high blood pressure at the moment?
d. Kindly share with me your knowledge about people who are likely to have

hypertension?
RQ2. How does the urban poor access information on hypertension? To answer this question the researchers asked this sub question
a. How do you come across the information you share with me on hypertension?
The questions above were asked in order obtain a naturalistic depiction of urban poor knowledge and access to information on hypertension using Grounded Theory methodology.

GROUNDED THEORY APPROACH

The Grounded Theory approach was first developed by Barney Glaser and Anselm Strauss in their 1967 book title The Discovery of Grounded theory, one of the goals of the book was to provide legitimate approach for undertaking qualitative research (Johnson, 2008). Grounded theory is an approach for developing theory that is "grounded in data systematically gathered and analyzed' (Strauss & Corbin, 1994)
In essence, Grounded theory is a research method that will enable you to develop a theory which offers and explanation about the main concern of the population of your substantive area and how that concern is resolve or processed (Scott, 2009). Furthermore, Glaser (1978) states Grounded theory is use to 'get though and beyond conjecture and preconception to exactly the underlying processes of what is going on, so that professionals can intervene with confidence to help resolve the participant's main concerns'. Crooks (2001) explained further that Grounded theory is Ideal for exploring integral social relationships and the behaviour of groups where there has been little exploration of the contextual factors that affect individual's lives. Hence, this study explored knowledge and access to information on hypertension among the urban poor in Zaria in order to come up with construct that can be use by hypertension information professional to design hypertension information program for the urban poor in Zaria.

Scope of the Study

This research focused on knowledge and access to information on hypertension among the urban poor in Zaria. The participants are mainly the urban poor living on or below average poverty line for developing countries ($2) two dollars a day (World Bank, 2015) and reside in Zaria metropolis.

Selection Criteria and Study Area

Eligible study participants met the following criteria: The urban poor living on or below average poverty line for developing countries, ($2) two dollars per day (World Bank, 2015). And must reside in Zaria, **Exclusion criteria include the following**; Resident of Zaria living above average poverty line for developing countries, ($2) two dollars per day (World Bank, 2015). Zaria is a major city in Kaduna State, north west Nigeria, as well as a Local Government Area formerly known as Zazzau, Zaria is located about 75km north of Kaduna, the state capital. Zaria was one of the seven Hausa city states. The 2006 Census population was 408,198 (Bugaje, Yakubu and Ogala, 2008)

Sample

Study participants were recruited using an exponential non-discriminative snowball sampling technique. A snowball sample is a non-probability sampling technique that is appropriate to use in research when the members of a population are difficult to locate.

(Crossman, 2015). Snow ball sample technique is use for this study because most Nigerians usually do not disclose their earning.

Data Collection

A semi-structured, open-ended interview questions to elicit narrative responses from participants was used. This choice is based on the following considerations: 1. The semi-structured design gives the participants ample time and scope to express their diverse views and allows the researcher to react to and follow up on emerging ideas and unfolding events (Nohl, 2009). 2. Semi-structured interviews allow not only for assessing the participants opinions, statement and convictions, they also allow to elicit narratives about their personal experience (Creswell, 2009)

Procedure for Data Collection

The researcher identified one Zaria urban poor with income less than two dollars per day that was willing to participate in the study, the first subject recruited to the sample group provides multiple referrals. Each new referral was explored until primary data from sufficient amount of samples are collected. Research assistant were only use as an interpreter from Hausa language to English language for two respondents. In addition to the purpose of the study and the study procedure, the following information was discussed with the participant: potential risks and benefit, cost, compensation, voluntary participation /withdrawal and confidentiality. Data are collected from participant in the following geographical location in Zaria; 2 participants from Emanto, 5 participants from Gaskiya, 7 participants from Tukurtukur, 3 participants from Congo, and 3 participants from Sabo.

Data Analysis

The researcher and professional transcriptionist was use to transcribed the interview, the transcription was done individually and collectively. The goal is to achieve naturalistic transcriptions, thematic analysis was use as the data analysis strategy to guide verbatim participant transcript. This method is recommended for a comprehensive and organized summary of qualitative descriptive research, it identifies, analyzes and reports patterns within data (Braun and Clarke, 2006)
This qualitative thematic analysis began with a thorough reading of transcripts followed by organization of their content according to each interview guide question number. In specific, the researcher followed analytic inductive process described by Creswell (2013) each of the 20 interviews was transcribed and examined back and forth between themes and the database until the researcher has established a comprehensive set of themes. The researcher use quantitative analysis to determine the frequency of occurrence and percentage of categories and sub categories.

RESULTS

The researcher conducted a thematic analysis of 20 qualitative interviews with Zaria urban poor in order to investigate and explore their knowledge about hypertension. The responses provided multiple views and insights into complex socio cultural factors relevant in understanding knowledge and access to information on hypertension among the urban poor in Zaria.
One hundred and seventy nine (179) narratives explaining knowledge of hypertension were highlighted and recorded in Microsoft word. Highlighted narratives were coded using

iterative analysis method which involves series of steps as informed by Krathwoli (cited in Musa, 2013), following these steps, the researcher read through the data looking for variance and similarities in the narratives. The descriptions of the 5 categories were presented in (See table 1), while (table 2) display 5 categories arranged by sub-categories, frequencies, and percentages of frequencies. (Table 3 & 4) presented the coding template

Table 1: Descriptions of Five Categories		
S/N	CATEGORIES	DISCRIPTIONS
RQ1	What are the knowledge of hypertension among urban poor in Zaria?

The Knowledge of Hypertension among the Urban Poor in Zaria

In order to understand knowledge of hypertension among urban poor in Zaria, a series of question were asked so they could elicit their actual thoughts about hypertension. The

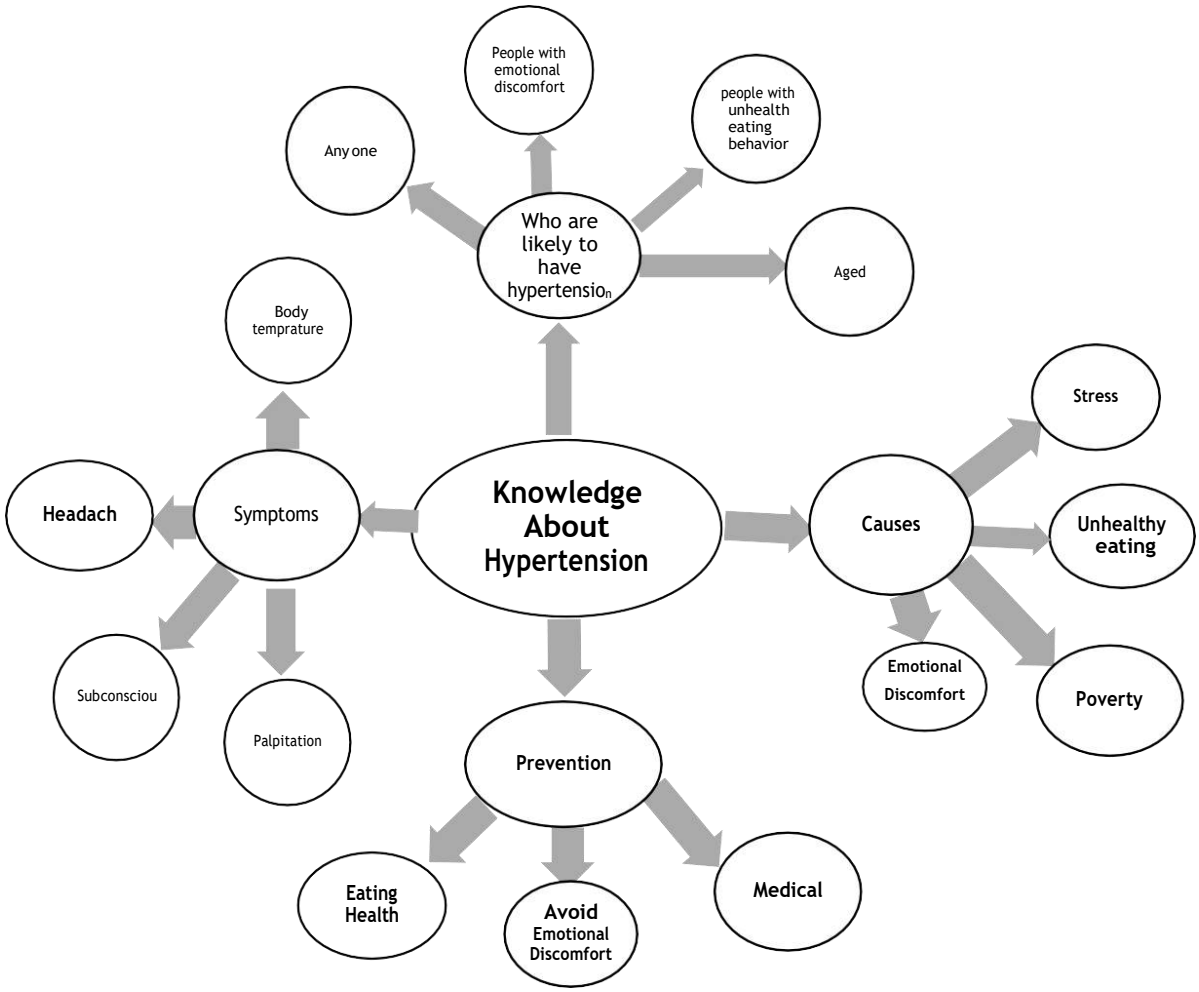
knowledge of hypertension among the urban poor in Zaria appears in four categories as follows:(1) knowledge about causes of hypertension (2) knowledge about how to prevent hypertension(3) knowledge about symptoms of hypertension and (4) knowledge about who are likely to have hypertension. (See table 3 and Illustration 1)

Table 3: Knowledge about Hypertension

RESEARCH QUESTION 1	SUB – QUESTION	SUB CATEGORY	CATEGORY
What are the knowledge of hypertension among urban poor in Zaria	Can you please share with me your knowledge on causes of hypertension	-Emotional Discomfort - Stress -Poverty -Unhealthy Eating Behavior **Others:** Infected food by cockroaches If somebody is entering sun too much	Knowledge about cases of hypertension **Others**
	Share with me your knowledge on prevention of hypertension	-Avoid Emotional Discomfort Eating Healthy Taking Medicine **Others:** -Preventing cockroaches from entering food Government intervention Avoid entering Sun too much Wash mouth every morning Sleep in a well ventilated room	Knowledge about hypertension prevention **Others**
	What types of symptoms can make a person believe he/she has high blood pressure at the moment	Headache Body temperature Palpitation Unconscious Abnormal Sleep Loss of Appetite Swollen of some part of the body **Other's** loss of energy -soliloquizing Fatness Always sweating Shivering Blood reduction	Knowledge about symptoms of hypertension **Other's**

	Kindly share with me your knowledge on who are likely to have hypertension	Aged people Poor People Hypertension can affect any body Fat people Pregnant women Rich people Children People Experiencing Emotional Discomfort People with unhealthy eating behavior **Others**: Destiny Inheritance	Knowledge about who are likely to have hypertension **Others**
		those that use to smoke People with criminal mind People that stay under sun for too long	

Illustration 1: Knowledge about Hypertension



The categories are discussed below.

Category One- Knowledge about C**auses of Hypertension** (32/148; 21.6)

This category describes narratives related to knowledge about causes of hypertension. There are four sub-categories explaining causes of hypertension as knowledge of the urban poor in Zaria, the categories are (1) emotional discomfort (17/148, 11.4%), (2) Stress (4/148 2.70%), (3) poverty (3/148 2.02%) and (4) unhealthy eating (8/148; 5.40%). These four subcategories are explained below

Emotional Discomfort

This sub-category depicted narratives related to knowledge on causes of hypertension. The researcher finds that most of the respondents have knowledge that hypertension is associated with thinking too much, worries, anger and bothering. A participant noted that "like when somebody use to think he did not use to associate with people, he sit in a different place and he will always be thinking." In another similar narrative a part states "to my own experience and opinion actually hypertension has a lot of causes, the major cause is deep thinking, sometime isolating yourself, then the second one is being angry or being in agony or being in bad relationship."

Stress

This sub-category reveals stress as knowledge of the urban poor in Zaria about the causes of hypertension, respondent notes that "What I can say, you see, for now, the kind of environment, the community we are in there are so many stress, the people living in this society face stress which means the difficulties which people are in is one of the major factor causing this hypertension." Another one observe that "too much thinking and stress in working place also cause hypertension"

Poverty

The sub-category showcases narratives related to poverty as knowledge of the urban poor regarding cause of hypertension. It reflects poor economic situation in which one finds himself, A participant noted that "family that are not well to do, poverty is one of the great factor that assist smooth running of the disease" he further explained that "a person can have wives, 11 to 20 children and he need to take care of them, their schooling, education, feeding, you see all these "ehn" all for him to cater for them, this kind of thing can probably lead to hypertension"

Unhealthy Eating

Apart from emotional discomfort, stress and poverty, the urban poor in Zaria also have knowledge that unhealthy eating is a cause of hypertension. The narratives included knowledge on what people eat and how we eat food like salt, oil, sugar, kola nut etc were mentioned by respondents. A participant stated that "I don't know if salt use to cause hypertension because if people have hypertension they use to ask them to stop eating salt." Another respondent also explain that "Our mother use to eat kola nut, the doctor advice us that we should try our best to stop her from eating too much kola nut, because it is one of the causes."

Others (2/148; 1.35%)

This explains other knowledge about causes of hypertension which are only mention by a single participant. This consists of (1) Infected food by cockroaches (1/148 0.6%). (2) staying under sun for too long (1/148 0.67%). The following narratives were noted from some of the participant "If you finish cooking you need to cover your pot if you don't cover it and cockroaches enter hypertension can catch you" "If somebody is entering sun too much can cause hypertension"

Category Two- Knowledge about Hypertension Prevention (28/148; 18.9%)

The category reflects knowledge on ways to prevent hypertension. The category consists of three sub-categories; Avoid emotional distress (16/148; 10.8%), eating healthy (8/148; 5.40%), medical (4/148; 2.70%), the three subcategories are explained below.

Avoid Emotional Distress

The urban poor in Zaria narrated that avoiding emotional distress is a major way of preventing hypertension, avoiding emotional distress include narratives on recreational activities, avoid thinking too much, exercising, avoiding loneliness and taking rest. A respondent notes that "How to prevent this hypertension is to avoid engaging in some commitment and avoid engaging with somebody that will make you angry and also make yourself to rest in one place, you just have to go far away from somebody who will make you angry." Another participant notes that
Always try to feel free, free your mind don't even try to start thinking about things that happen to you in the past. Do not have someone at heart it will not help you, always be free. Do not isolate yourself live together with people, try to bring topic for discussion and always contribute to discussion, at the same time laugh with people. Apart from this you can watch football, play football, exercise regularly, and make sure you join people to watch football. If you are alone try to read novel, books, newspaper keeping yourself busy. Are you getting me? Books, particularly if you are a Muslim you have to be reading Quran.

Eating healthy

This sub-category portrays narratives related to eating healthy as knowledge of the urban poor in Zaria about hypertension prevention, it includes narratives related what people eat. A participant mentioned that "If doctor say you should stop eating something you should stop eating it, like salt, me am not eating salt, when am going to cook food am going to put star magi I will not put salt at all, my husband is not complaining because even him is having the same problem" another respondent said "you use native oil or substitute it with oil that does not contain cholesterol like turkey oil"

Medical

This subcategory depicts narratives related to taking medicine and taking advice from medical practitioners as knowledge of the urban poor in Zaria regarding hypertension prevention. A respondent explained that "like this Moringa am holding now is a herb, we use to boil it, is a medicine of hypertension, scientist research about it, this Moringa you boil it until the water change, if you keep on boiling inside pot you observe for one to two hours of boiling, then you remove the leave one after the other you sieve the water inside cup allow the water to cool and then drink at once, later you can now eat the leave, this will help to prevent hypertension*"* another respondent also noted that "the ways I think we can reduce hypertension is to seek advice from those that are in the field, go to hospital for advice and check my blood pressure"

Others **(5/148; 3.37%)**

This explains other knowledge on prevention of hypertension which could not be discussed above because they are mention by one participant. They are (1) preventing cockroaches infection (1/148 0.6%) (2) Government intervention (1/423 0.6%), (3) avoid staying under the sun for too long (1/148; 0.67%), (4) wash your mouth every morning (1/148; 0.67%) and (5) sleeping in a well ventilated room (1/148; 0.67%). The following narratives were noted from the subcategories "cover your pot of food so that cockroaches will not enter" "You should avoid entering sun too much is not

good" "if you wake up in the morning you need to wash your mouth"
If government will create job the difficulties that most of our people who are not employed by the government will be reduced if not eradicated, income should also be increased. Government should try to provide medication for ill people, they should provide therapy that will counsel people, and you know some are illiterate. Now we are in a modern technology, we have TV, Handset, and website so you see they can use radio, TV, and the rest so that there can be a program which people can take necessary precaution.
for instance if you want to sleep find good place, a place that have ceiling fan, once you have hypertension you cannot sleep in a warm room, you understand room that does not have fan, air condition or any other thing. Once you have hypertension, you should find a good place to sleep. Let say a place that have fan, the important thing here is fan, if you don't have money to buy air condition you should buy fan.

Category three- Knowledge about Symptoms of Hypertension (31/148; 20.9%)

The category includes narratives related to knowledge on symptoms of hypertension. The category consists of seven sub-categories which include headache (9/423; 6.08%), borody temperature (5/148; 3.37%) palpitation (4/148; 2.70%), subconscious 4/143; 2.70%), abnmal sleep (3/148; 2.02%), loss of appetite (3/148; 2.02%), swollen of some part of the body (2/148; 1.35%), the subcategories are explained below

Headache

This sub-category describes narratives related to headache, most urban poor in Zaria identify headache as a symptom of hypertension. Respondent noted that "Symptoms are as follows like I told you my mother is facing the problem although is not all the time that if the problem arise I will be present, but some time she will start telling us that she is feeling headache are you getting the point, so headache is one of the symptoms of it."

Body Temperature

This subcategory portrays narrative related to body temperature as knowledge of the urban poor about symptom of hypertension. A respondent noted that "Any body that has it will be feeling heat in the morning and in the afternoon he will be catching cold" another said "most of them have high fever, your body will always be abnormal"

Palpitation

This sub-category portrays narratives related to heart beating as knowledge of the urban about symptoms of hypertension. One respondent narrated that "that time if I go hospital to complain that my heat is beating they will give me drug and it will normal, then later if am going on the road may be a car just pass I will be scare" another respondent observe that "when it become chronic some time you will be having difficulty in breathing, you will always be breathing abnormal and when it keep on like that you can easily fall down."

Subconscious

The sub-category considers narratives related to symptoms like fainting and dizziness as knowledge of the urban poor regarding blood pressure check. A respondent stated that "symptoms of the illness emm, there are many symptoms one is dizzy, that is when you are feeling like falling down because my mother is suffering from it, when we realize that she is having that we quickly take her to hospital

and the moment we got there the doctor diagnosed she is having this hypertension, we then realized is one of the symptoms of hypertension". In another narrative a respondent said "My father use to tell me that sometime when you are walking you felt dizzy."

Abnormal Sleep

This sub-category refers to narratives related to not sleeping well as knowledge of the urban poor in Zaria pertaining to symptom of hypertension. A respondent stated that "the symptom is lack of sleep even when he sleep, middle of the night he will wake up and he will no longer feel sleep" another respondent also asserted that "there are so many symptoms identified with hypertension most especially laziness, too much sleeping"

Loss of Appetite

The sub-category explains loss of appetite as knowledge of the urban poor about symptom of hypertension. It includes narratives related to having less desire for food or drink. A respondent is of the opinion that "some time you can lost appetite, and not feeling the actual taste of what your are eating"

Swelling of some Part of the Body:

Depicts narratives related to abnormal swollen part of the body as knowledge of the urban poor in Zaria pertaining to cases of hypertension. A respondent noted that "once you observe somebody, you can observe may be his leg or her leg, you find the leg swollen that is the symptom or sign of hypertension." another respondent also stated that "Swollen in neck, sometime chest, all are symptom which we can use to identify people with hypertension"

Others **(6/148; 4.05%):**

This explains other knowledge on symptoms of hypertension which could not be discussed above because they are narrated by one participant. These includes lose of energy (1/148; 0.67%), soliloquizing 1/148; 0.67%), fatness (1/148; 0.67%), always sweating (1/148; 0.67%), Shivering (1/148; 0.67%) and blood reduction (1/423; 0.67%). The following responses were noted from the subcategories "Lost of energy because you can find yourself in a situation whereby you cannot do something" "actually the first symptoms is you see a person behaving inhuman, you see a person going usually you see him talking to himself" "fat women that think too much, they can collapse suddenly" "So this symptoms, when you see a person some time is always sweating" "at time you find the person shivering also I think fever headachy and the rest" "You will feel headache, fever, no appetite, your blood will reduce small"

Category four- Knowledge about People who are likely to have hypertension (37/148; 25)

This entry reflect knowledge on who are likely to suffer from hypertension, the category explains the kind of people that are likely to be infected with hypertension. The category is divided in to eight sub-categories: (1) aged people 8/148 5.40% (2) poor people 4/148 2.70% (3) hypertension can affect any one 5/148 3.37% (4) fat people 3/148 2.02% (5) pregnant women 3/148 2.02% (6) children (2/148; 1.35%) (7) people experiencing emotional discomfort (7/148; 4.72%) (8) people with unhealthy eating behaviour (5/148; 3.37.40%). These subcategories are explained below.

Aged

According to the data many urban poor in Zaria have knowledge that elderly people are liable to hypertension, narratives in this sub-category reflects old people as a group that might likely suffer from hypertension. Respondent explained that "Most cases, in my opinion, they are not young people they are old people, the reason is that due to age, the age is already high and their commitment is much." Another respondent stated that "all those people that I have seen that are having hypertension are old people."

Poor People

Knowledge of the urban poor in Zaria portrays another group of people that might likely have hypertension as the poor people. This subcategory reveal narratives related to poor socio economic status. participant noted that "let say poor man he does not have money to feed his family he can have hypertension" In a similar response another participant explained that "poverty contribute a lot in hypertension because when somebody has family wife and children and he has to provide for them, As a result of small thinking it will continue before you know is already worst, thinking about how to pay children school fees, lack of social amenities. One of the participants also narrated that like guys now for instance, let me tell you one thing now because as I told you is thinking that cause hypertension like guy now, a person who want to buy car and has no money to buy and he put his mind that he must buy the that car, for instance I give you little example. A person doesn't have money to buy trouser shirt to make himself guy, you understand? And he does not want to steal, or beg, he doesn't have work to do and his friend living fine, put on good cloth everything nice and he does not have those things, from there he will start thinking about how to get money, that thinking can cause hypertension

Hypertension can Affect any one

Narratives from this subcategory depict that anybody can fall victim of hypertension as knowledge of the urban poor regarding who are likely to fall victim of hypertension. One participant observed that "anybody can have hypertension due to some conditions you engage yourself either you are poor or rich." Another participant also stated that "Anybody can catch the disease either you are old or young, male or female".

Fat People

The subcategory reflects knowledge about those that are likely to have hypertension as fat people. A participant narrated that "most of the times are those that are fat and those that have too much fat in the body, even slim person can have it but most are fat."

Pregnant Women

This sub-category depicts narratives related to pregnant woman as knowledge about cases of hypertension. The sub-category reveals narratives related to women most especially pregnant women as a group that might likely suffer from hypertension. A participant notes that "there is one of my sisters throughout her pregnancy she will be hypertensive till she deliver". Another participant observed that "majority of those who have hypertension are women, If you observe and research, you will find or if you go to the hospital you will find out that majority are women, for instance some pregnant women."

Children

The sub-category explains that children are also group that can suffer from hypertension as

knowledge of the urban poor. A participant said "yes, yes am sure you may know that people that are very old are common with hypertension, am sure that has to do with old age "ko" but for now most of our people now you can see small children when they get to hospital they might be diagnosed with hypertension." Another participant notes that "imagine a baby have hypertension, is a blood, anybody can have hypertension."

People Experiencing Emotional Discomfort

The sub-category shows that people experiencing emotional discomfort are liable to hypertension, it's depicts narratives related to people that think too much, people that undergo frustration and people that worry a lot. Participant narrated that "deep thinking especially when you are in agony when you keep on worrying, when you keep on thinking about things that border you"

People with Unhealthy Eating Behaviour

The sub-category presents group of people that might likely fall victim of hypertension, the sub-category include narratives related to people with unhealthy eating behaviour as knowledge of the urban poor in Zaria. It depicts narratives related to what people eat or drink like alcohol, taking kola nut, expired food taking too much salt and magi. One of the participant narrated that "there is one of our neighbor is a doctor, is a medical doctor we take our mother there he tell us that when somebody is taking hot drink, alcohols, like whiskey, he also mention kola nut because he ask our mother is she taking kola nut, and she answer yes she is taking, he also ask our mother to stop taking kola nut that it may cause hypertension to her" Another participant noted that "some time is the type of food we are eating most especially expired food, you know some have no knowledge of it, many people don't know the actual deadline of the product because they are not educated even the people selling it they don't know the expiry date of the product and they are selling it to people. This kind of product can even cause hypertension that is what the doctor said".

Others (6/148; 4.05%):

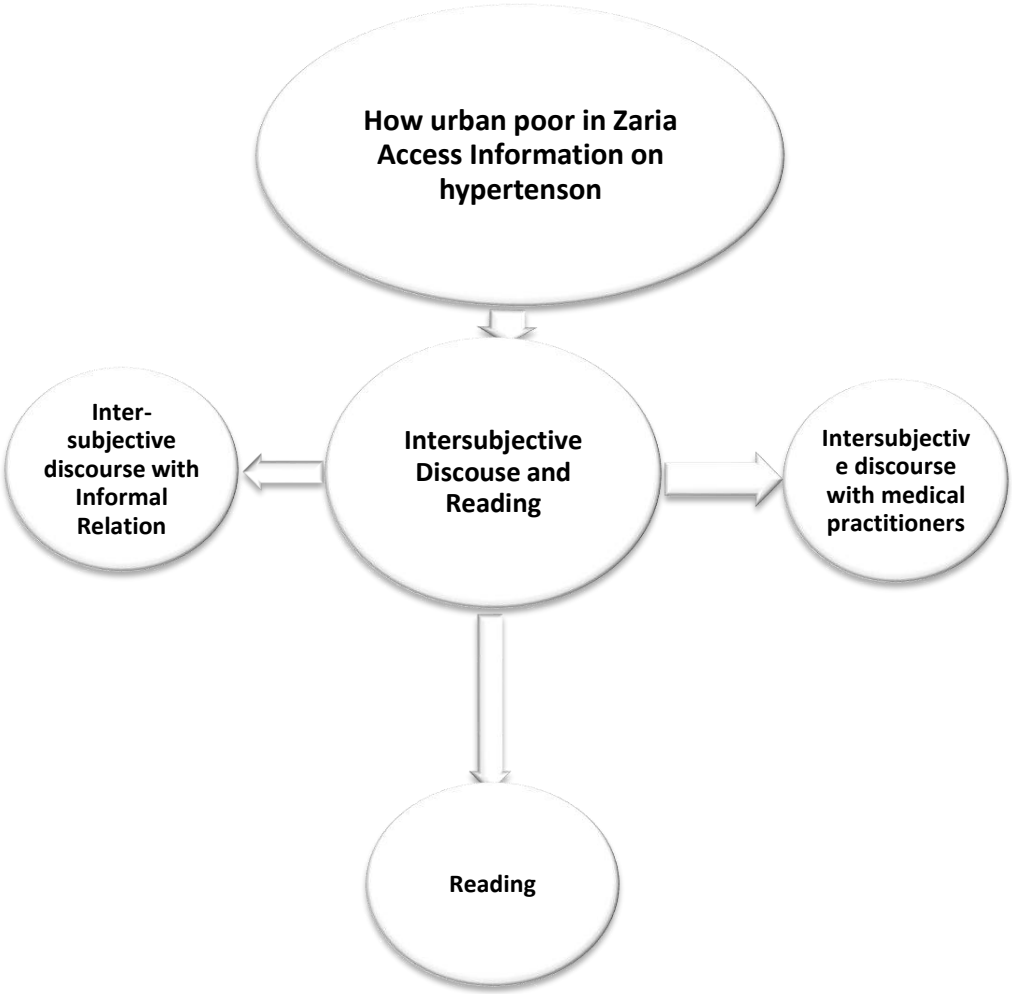
This explains knowledge of the urban poor in Zaria about other group of people who might likely suffer from hypertension which could not be discussed above because they are view of one participant. They are: (1) rich people 1/148 0.67% (2) smokers 1/148 0.67% (3) people with criminal mind (1/148 0.67%) (4) destiny (1/148 0.67%) (5) Genetics (1/148 0.67%) (6) people that are staying under the sun for too long (1/148; 0.67%). The following narratives were noted from some of the respondents "If it is rich man let say let say in term of family, let say in his commitment, let say too much of money, in term of sharing his own money he can have hypertension" "those that use to smoke can have it" "another set of people that can have hypertension are people with criminal activities because they always commit crime, Are you getting me? Because a person suppose to live freely but a criminal person usually after committing crime later he realize the negative effect of it" "Frankly speaking there is no such stage of human development that could be said that they normally have hypertension because some time I see it as a destiny if Allah wishes you. You will never run away from the cycle of destiny" "It could be probably inherit" "people that are trekking in the sun and inhaling dust can have hypertension"

Access to Information on Hypertension among the Urban Poor in Zaria

In order to identify hypertension information access among urban poor in Zaria, a series of question were asked so they could describe their ways of accessing information about hypertension. Hypertension information access among urban poor in Zaria appears in one category: inter-subjective discourse and reading. (See table 4 and illustration 2 below).

Table 4: Hypertension Information Access			
Research Question 2	Sub Question	Sub Category	Category
How do urban poor in Zaria access information on Hypertension	How do you come across the information you share with me on Hypertension	- Inter subjective discourse with informal relations - Inter subjective discourse with Medical Practitioner - Reading	Inter subjective and Discourse reading

Illustration 2: Hypertension Information Access



The category is discussed below.

Category One- Inter Subjective Discourse and Reading (26/26; 100%)

This category include narratives related to how urban poor in Zaria obtain information on hypertension, it explains the source related to friends, family, medical personnel and reading. The category is divided into three sub-categories; (1) inter-subjective discourse with informal relation (15/26; 6.25%) (2) inter-subjective discourse with medical practitioner (8/26; 30.7%) (3) reading (3/26; 11.5%) . The subcategories are explained below

Inter subjective Discourse with Informal Relations

This sub-category depicts narratives related to source of information from relatives and friends, it accounts the source as father, mother, aunty, cousin, grand parent, and family friends. A participant said “I am telling you all this because am having grandmother that is suffering from the same problem, she is having hypertension up till now, it is from her I got all what am telling you now.” Another one stated that “there is one of my cousins that is having hypertension, she mostly explains to me.” In addition to these, one of the respondents narrated that

“let say my mother, let me give you example of my mother, so, my mother is having hypertension as result of that she has already died and she was pregnant then. From the test they discover that she was having hypertension, what we thought about that is that some time we children we use to make her angry all the time, we use to disobey her this make her fall in this condition. In hospital they try to do operation to save the baby but due to hypertension is too high they cannot do the operation and also she has lose some blood and she need additional blood before going for that operation.”

Inter-Subjective Discourse with Medical Practitioners

The sub-category explained medical personnel as a source of accessing hypertension information. A participant stated that “as I said earlier, when I took my mum to the hospital, they will be telling us here are some of the causes, they will highlight the problem and possible solution to her.” Another narrated that

“as I told you earlier my father die due to hypertension and when we go to physiotherapist for exercise, some time the doctor consult their students in front of us, so I listen to them because I know It will be very useful to me because if my family or my neighbor might have this problem I can tell them how to prevent it”.

Also one participant explained that

“as I told you my mother is having the disease am the one that normally take her to hospital, even next week we shall be going there, today is Wednesday ba, next Wednesday I will take her there because we normally take her there every two weeks, the doctor normally tells me the symptoms and the sign of it, whenever I realize these symptoms in my mum I quickly take her to the hospital.”

Reading

The sub-category depicts narratives related to hypertension information access through reading. Respondent said “I was one time a science student I do read biology course, my future ambition is to become a doctor, a medical practitioner by God grace and by God will”

DISCUSSION, IMPLICATIONS AND CONCLUSIONS

The objective of the study is to explore knowledge and access to information on hypertension among the urban poor in Zaria using Barner Glaser and Anselm Strauss Grounded theory approach to derive a model of hypertension information for the urban poor in Zaria. The study adopted a qualitative research method, using case study research design as a specificexponential non-discriminative snowball sampling technique was used for this study, which made sample of 20 participants.

RQ1. What are the Knowledge of Hypertension among Urban Poor in Zaria?

Four (4) constructs explained this research question. These constructs are explained below:

The Participants have Knowledge on the Causes of Hypertension.

The participant showcases knowledge about causes of hypertension as emotional discomfort, stress, poverty, and unhealthy eating behavior. The participants portrayed emotional discomfort as a cause of hypertension. They believed that emotional discomfort results from thinking too much, worries, anger and bothering. They believe that if you are too perturbed by pressing issues that can result to hypertension. Other than the emotional discomfort the findings from the study reveals that the participant consider stress as a cause of hypertension, they explained that stress encountered at work, difficulties and too much of commitment can lead to hypertension. Moreover, participant perceived poverty as a cause of hypertension, they belief that hypertension can occur due to overwhelmed economic responsibilities of a family man. They belief poverty can make a man to think too much, faces agony and emotional pressure in life, which will result to hypertension. In addition, this study reports that unhealthy eating behavior reveals knowledge on causes of hypertension among the participant, they belief unhealthy eating like too much intake of salt, kola nut, sugar, and vegetable oil can cause hypertension.

Emotional discomfort, stress, poverty and unhealthy eating behavior are considered as indirect causes or factors that may increase risk of hypertension (Woolstone, 2016; Mayor 2016; Kurtzleben, 2012; Eitel, 2015). Findings identified that the participants positive knowledge on indirect causes of hypertension. This is because (Woolstone 2016) stated that emotional discomfort can temporarily boost blood pressure, fortunately, these spikes in pressure are usually too fleeting to threaten your health. But when emotional turmoil becomes a way of life, your blood pressure can take a dangerous, long term climb. The urban poor are also in line with the explanation of Mayor (2016) that the body produces a surge of hormones when you're in a stressful situation. These hormones temporarily increase your blood pressure by causing your heart to beat faster and your blood vessels to narrow. He further explained that there is no proof that stress by itself causes long term high blood pressure. However, short term stress related spikes in your blood pressure added up over time may put you at risk of developing long-term high blood pressure

The participants are also in line with the statement of Wilson, Kliewer, Plybon, and Sica, (2016) that people in low-socioeconomic-status environments are more susceptible to illnesses, such as hypertension and cardiovascular diseases. Similarly A.U (2013) reported that the prevalence of hypertension is increasing among poor section of the Africa society. Also a study conducted by Kurtzleben (2012) Showed that diabetes, high blood pressure, and heart attacks were slightly more likely to afflict those in poverty than those who are not. Unhealthy eating also reflects knowledge on causes of hypertension among urban poor in Zaria this is in line with explanation of Cleveland (2014) that when you eat too much salt, which contains sodium, your body holds extra water to "wash" the salt from your body. In

some people, this may cause blood pressure to rise. The added water puts stress on your heart and blood vessels. Also, Michaud (2015) stated that the caffeine in kola nut increases systolic and diastolic blood pressure by increasing the resistance in the peripheral veins. Furthermore, Pullen (2014) asserted that eating too much sugar can lead to weight gain over time, which puts you at risk of high blood pressure. In addition, Eitel (2015) stated that the American Heart Association recommends that people with heart disease eat a well-balanced diet low in sodium and saturated fats. Solid fats, such as butter and margarine, contribute a high level of saturated fat to your diet, so the AHA suggested switching to healthier alternatives. Liquid cooking oils can be used in place of solid fats for cooking and flavoring foods.

Although the exact cause of hypertension is unknown, there are several factors and conditions that may increase risk (WHO, 2013). The participants portrayed knowledge on factors and condition that may increase the risk of hypertension. But some of the participant held that staying under sun for too long and cockroaches are causes hypertension. However, (Parry, 2014; Macrae, 2014; Bakalar, 2014; broyd, 2013; fischer, 2014; Entin 2014) stated that a little time spent outdoors in the sunlight can lower blood pressure. While base on my knowledge there is no study that show link between hypertension and cockroaches. This has an implication because lack of knowledge on cause of hypertension will negatively affect its prevention.

The Participants have Knowledge about the Prevention of Hypertension.

The participants portray knowledge of prevention of hypertension as avoiding emotional distress, eating healthy, medical and avoid staying under sun ray for too long. The participants regard avoiding emotional distress as a way preventing hypertension. They believe emotional distress can be avoided by engaging in recreational activities, avoid thinking too much, exercising, avoiding loneliness and resting. The participants also portray eating healthy as a way of preventing hypertension, they believe that by reducing salt, sugar and kola nut intake one can prevent hypertension. Furthermore, taking medical step depict knowledge of urban poor in preventing hypertension, they belief that taking local herbs and visiting medical practitioner are the right steps in preventing hypertension. However, data reveals only one respondent has knowledge of visiting medical practitioner and having blood pressure check as a means of preventing hypertension.

The findings identified avoid emotional distress as knowledge of hypertension prevention among the participants. This is positive because Woolstone (2016) states that emotional control may decrease a person's risks for developing hypertension. The urban poor in Zaria also show positive knowledge about prevention of hypertension, compared to WHO (2013) recommendation of physical activities for at least 30 minutes a day, five time a week and following medical advices. Furthermore, participants are in line with the statement of Frisoli, Schmieder, Grodzicki and Messerli (2012) that in numerous epidemiologic, clinical, and experimental studies, dietary sodium intake has been linked to blood pressure, and a reduction in dietary salt intake has been documented to lower blood pressure.

The findings from this study reveal that the participants held that avoid staying under sun for too long can prevent hypertension. However, (Parry, 2014; Macrae, 2014; Bakalar, 2014; broyd, 2013; fischer, 2014; Entin 2014) asserted that while too much sun exposure may bring on skin cancer, researchers have found evidence getting some rays could protect against high blood pressure, however, sun bathing is not recommended as a way to treat high blood pressure. In addition, despite WHO (2013) recommendation that all adults should know their blood pressure level, however only one respondent poses knowledge of blood pressure check as a way of preventing hypertension, this has implication because hypertension symptoms are silent. The findings also reveal that urban poor take local herbs

to preventing hypertension, this also have implication, because the side effect of local herbs might not be known

The Participants are Knowledgeable about Symptoms of Hypertension.

Participant reveal knowledge on symptoms of hypertension as headache, body temperature, palpitation, unconscious, abnormal sleep, loss of appetite, and swollen of some part of the body. It is discovered in this study that the participants believe that hypertensive patient often experience symptoms. It is also found that the participant believe hypertensive patients are characterized with heart beating. They also have the belief that hypertension victim are characterized with fainting and dizziness.
However, WHO (2013) reports that there is a common misconception that people with hypertension always experience symptom, but the reality is that most hypertensive people have no symptoms at all. Meanwhile, WHL (2014) elucidated further that when the effects of hypertension start to damage one or more of the usual target organs such as brain, kidneys, heart, eyes or blood vessels. Then symptoms of the damaged organ manifest themselves. This is a late stage of *primary* hypertension, the large majority of cases (90%). Also when there occurs a disease that causes high blood pressure the symptoms of high blood pressure are those of the underlying disease. This is called *secondary* hypertension.
Despite the fact that “High blood pressure is called the “silent killer” because it often has no warning signs or symptoms” (Anderson, 2016). The participants do not know that hypertension symptoms rarely occur and this has negative implication on early diagnosis of hypertension.

The Participants Portray Knowledge About People Who are Likely to Have Hypertension**.**

Participants indicates knowledge about people that are likely to have hypertension as aged people, poor people, fat people, people with criminal mind, hypertension can affect any one, pregnant women, children, people experiencing emotional discomfort, and people with unhealthy eating behavior. They believe old age is a risk factor to hypertension. They are also of the opinion that fat people are likely to suffer from hypertension and its complications. Aside from aged people and fat people the participants believe hypertension can affect anybody, they belief that anybody can fall victim of hypertension and its complications. Moreover, the participants identify pregnant women as a group that is likely to fall victim of hypertension. In addition the participants indicate children, as a group that might likely suffer from hypertension. These beliefs exist largely among participants because they have come across different group of people suffering from hypertension.
The finding discovered that participant revealed positive knowledge on who is likely to have hypertension. This is because WHO (2013) stated that blood pressure typically increases with age, especially once one has passed middle age. The increase in blood pressure with age is mostly associated with structural changes in the arteries and especially with large artery stiffness. The participants are in line with the America Heart Association (2016) explanation that being overweight increases your chances of developing high blood pressure. A body mass index between 25 and 30 is considered overweight. A body mass index over 30 is considered obese. AHA (2016) explained further that the more you weigh the more blood flow you need to supply oxygen and nutrients to your tissues. As the volume of blood circulated through your blood vessels increases, so does the pressure inside your arteries. Also (National Institute of Heath, 2015; Keplan, 2016) asserted that anyone can develop high blood pressure; however, age, race or ethnicity, being overweight, gender, smoking, lifestyle habits, and a family history of high blood pressure can increase your risk for developing high blood pressure.

The participants are also in line with Zamorski and Green (2014) elucidated that pregnancy induced hypertension (PIH) is more common during a woman's first pregnancy and in women whose mothers or sisters had PIH. The risk of PIH is higher in women carrying multiple babies, in teenage mothers and in women older than 40 years of age. Other women at risk include those who had high blood pressure or kidney disease before they became pregnant. The cause of PIH isn't known. Also Falkner (2010) stated that hypertension is detectable in children and adolescents and, as in adults, is associated with a positive family history of hypertension, obesity, and life-style factors

How do urban poor in Zaria access information on hypertension?

One (1) constructs explained hypertension information access. This construct is explained below:

The Participants Access Hypertension Information Through Inter Subjective Discourse and Reading**.**

Participants access hypertension information through inter subjective discourse with informal relations, and medical practitioners and reading. The participants access hypertension information through inter subjective discourse with informal relations such as father, mother, aunty, cousin, grand parent, and family friends. Most respondents have one or two friends and family member whom are suffering from hypertension and they come to know about hypertension through them. The findings also reveal inter subjective discourse with medical practitioners as a mean through which Zaria urban poor access hypertension information. The urban poor in Zaria come to know about hypertension by taking hypertension victim to the hospital for treatment, going to the hospital to know about hypertension not willingly but conditional. Inter subjective discourse with medical practitioner arise from taking sick patient to the hospital.

Inter-subjectivity emphasizes that shared cognition and consensus is essential in shaping our ideas and relations Gillespie and Cornish (2010). In the same manner the responses show that the participants access hypertension information through inter subjective discourse with informal relations and inter subjective discourse with medical practitioners.

Discovering from the study that the participants access hypertension information through inter subjective discourse with informal relations has an implication. This is because informal relations are close associate and they are not formal source of hypertension information, therefore both appropriate and inappropriate information are accessed.

Furthermore, the study reveals that the participant who possess basic education access hypertension information through reading. The participants reveal that they have read about hypertension in their text books. And they stick to it because they find it easy to understand.

Reading is a means of language acquisition, communication, and of sharing information and ideas (Douglass, 2014). In the same manner the responses show that the participant access hypertension information through reading

Limitation of the Study

The exact population of the urban poor in Zaria is not known. The researcher visited Federal Bureau of Statistics for the statistic of total population of Zaria urban poor living below the average poverty line for developing countries, but all effort by the researcher to ascertain the total population of the study proves abortive. However the sample population for this study did not include Zaria urban poor who live above the average poverty line for developing countries ($2), two dollars a day (World Bank, 2015).

Conclusion

Scholars have made various attempts to address a person's knowledge of threat of a health problem; the uniqueness of this study is based on employing Grounded theory approach to derive a model of hypertension information for the urban poor in Zaria. Understanding the categories derived from this study has the potential of design an hypertension information program suitable for the urban poor in Zaria, Kaduna state.

The findings from this study has reveal emotional pressure, poverty, unhealthy lifestyle, sunlight and cockroaches as the causes of hypertension, however, sunlight and cockroaches reflects confliction between their knowledge and orthodox medical knowledge about the causes of hypertension, also the urban poor in Zaria do not know that hypertension symptoms rarely occurs, this shows that their knowledge about hypertension is deficient and this also contributes to late diagnosis of hypertension. Therefore, health policy makers such as ministry of health, world health organization (WHO), world hypertension league (WHL), Nigeria hypertension society (NHS), etc should consider above constructs when designing enlightenment and awareness programs on causes of hypertension in order to improve knowledge of hypertension among the urban poor in Zaria.

In respect to access to hypertension information, this study indicates that the urban poor in Zaria Kaduna state access hypertension information through inter-subjective discourse and reading, therefore, local decision makers and hypertension information provider should make hypertension information available in social spaces where inter-subjective discourse take place. Social spaces include mosque, churches, tea joint, cinema, motor pack, fitness centre, and online social media etc. This can be done by placing poster, stickers, and distribution of handbill, pamphlet in these social spaces.

ABSTRACT

Lean manufacturing has faced resistance in the Brazilian shipbuilding industry. This paper analyzes lean manufacturing implementation at "*Atlântico Sul" Shipyard (EAS)*, the largest Brazilian shipyard. Although the literature emphasizes waste reduction, human related issues were crucial for shipyard productivity improvement. Finally, lean manufacturing must be adjusted to specific industrial contexts.

KEYWORDS: Shipbuilding, Lean Manufacturing, Productivity. Case Study

INTRODUCTION

In 2004, PETROBRAS stimulated by oil discoveries in the Pre-Salt, decided to renew its ship fleet to transport oil and derivatives. Under the guidance of the Brazilian Federal Government, PETROBRAS has decided to place orders at local shipyards, aiming to reactivate the Brazilian Shipbuilding Industry (ICN). The Fleet Modernization Program (PROMEF) was created to renew the fleet of oil transportation and exploration vessels, since the that one was already quite old (average age above 25 years).

In the first phase of the program (PROMEF I), PETROBRAS has sought national shipbuilding decentralization away from the state of Rio de Janeiro, which had most of the national active shipyards. Thus, consortiums could take part on PETROBRAS-TRANSPETRO's bids with "virtual shipyards" (they had a project and financial commitments to build a new shipyard, but not the physical assets yet). The rationale behind this agreement would be to allow modern shipyards to be built in a time shorter than the delivery time of international shipyards (a few years delivery time due to a heated global demand for cargo ships and oil tankers).

The main winner of the PROMEF bids was the consortium led by "Camargo Correa" and "Queiroz Galvão", two of largest Brazilian EPC). This consortium also had a technology

partnership with SAMSUNG HEAVY INDUSTRIES from Korea, to transfer technology of ship production. To attend PROMEF demand, the consortium built in the industrial complex of SUAPE, Pernambuco, “Atlântico Sul” Shipyard (EAS), the largest shipbuilding in the southern hemisphere. EAS portfolio was composed of twenty-two Suezmax-type ships; a P-55 platform helmet; five Aframax-type ships, all placed by PETROBRAS-TRANSPETRO.
The physical structure of EAS was built from 2006 to 2010. In parallel with the construction of the physical facilities, the yard had to carry out an extensive program of labor qualification, beginning the processing of steel sheets to produce the first Ship in 2008. At the EAS installation, there was also an effort in the acquisition of state-of-the-art equipment, using advanced technologies such as welding robots as recommended by the literature (Liker & Lamb, 2000a).

Despite all the investment, theresults of the first ships at EAS were disastrous in terms of costs and delivery time. After several changes in the company's board, which consisted of re-runs of the representatives of the consortium companies, the shareholders decided for a radical change. An executive with great experience out of the shipbuilding industry (several industrial plants implanted in the automotive sector) was appointed. The new board quickly understood that the yard would not be competitive only by adding new technologies and equipment, and by providing traditional employee training. A radical change in the productive processes was needed to drastically reduce the waste in the yard. The new board decided, despite all the skepticism of the people associated with traditional shipbuilding, by adopting the lean manufacturing system.

LITERATURE REVIEW

Lean Manufacturing is a methodology coming from Japan that has made great contributions in several industrial sectors (Bhamu & Sangwam, 2013). This methodology is based on two pillars: reduction of waste and respect for people (Liker & Lamb, 2000b). There are seven main types of waste: (i) production above what is required, (ii) waiting, (iii) unnecessary transportation (iv) wrong or over-processing, (v) excess inventory, (vi) unnecessary movement, (vii) defects.
In addition to the traditional wastes focused on lean manufacturing, Liker & Lamb (2000b) add to the non-use of employee creativity. The focus on the human issue has its importance, given that the perspective of implementing lean manufacturing in the West has been predominantly technical focusing on waste reduction. The pillar of respect for people has been neglected, being considered something inherent of an Eastern culture and perhaps not completely applicable to Western countries.

The expected results of lean implementation in shipbuilding would be: improving the quality of the final product; reduction of manufacturing time; improvement of image vis-à-vis customers and suppliers; and improvements in the materials management system (Liker & Lamb, 2000a). In lean manufacturing, short feedback loops prevent propagation of errors and minimize waste. Restricting the use of large batches of stock prevents quality problems from being hidden and only manifested later when someone is going to use a non-working part (Liker & Lamb, 2000). This allows for a better quality of products and processes, as well as an improved production flow (Storch & Lim, 1999).

Despite the important quality gains, productivity is the focus of the lean methodology (Sanders et al., 2016). The reduction of the production lead time allows the improvement in customer service and increase of yard utilization, generating greater productivity. The reduction of this lead time results from the reduction of the time spent in activities that do not add value, and real

time problem identification and resolution. The elimination of activities that do not add value to the business, positively affects the morale and employees' sense of accomplishment. At the same time, lean production imposes discipline on employees to act on a set time, before the part moves forward in the system.

Despite the success in sectors such as the automotive industry, the application of the lean philosophy at the shipbuilding industry has been low, with a greater focus on employee safety improvement and damage protection (Phogat, 2013). Despite that, some lean methodology implementations have achieved significant results. A yard in Mississippi, U.S.A., implemented Lean Manufacturing in 2000 with a 54% reduction in manufacturing time, a reduction of rework by 80%, and a 29% increase in productivity. The Puget Sound shipyard in the U.S. also implemented a serial flow in its operations and obtained a 73% reduction in production lead time. Statistics also show that in the period from 1965 to 1995, the Japanese shipbuilding industry improved its productivity by 150%, mainly due to the development of lean principles and adoption of the Toyota production system (Phogat, 2013).

For lean implementation in the shipbuilding industry, it is suggested starting the program at the technical area as a long-term philosophy. Thus, moments of crisis where short-term solutions are sought, would not be good time for its deployment (Liker & Lamb, 2000b). Kaizen is seen in the literature as a key approach this implementation. It is a continuous improvement process involving employees at different levels in the plant hierarchy (Beifert et al., 2017). They propose suggestions for improvement on a regular basis, where the most efficient proposals are implemented. Kaizen workshops would then, be used for training and change implementation (Shah & Ward 2007). In this process, learning would be more by action than training, with mandatory participation during working hours. Also, the use of value stream pilots, metric establishment, and lean leader identification would demonstrate opportunities for major financial impacts.

The literature discusses barriers to lean manufacturing implementation. High costs and long lead times for deployment and restructuring, and reliance on a top-down approach are generally viewed as the main problems. Parveen and Rao (2009) indicate that high acquisition costs, high market volatility, and demand for customized products can outweigh the gains obtained in quality and productivity in the shipbuilding industry, which could discourage the lean implementation. Given the previous discussion, this work has the objective of presenting the case study of the implementation of lean production in the EAS yard, presenting its implications and unfolding.

METHODOLOGICAL PROCEDURES

This study is an applied and exploratory research. It is applied due to the practical use of available knowledge of lean manufacturing in an industrial organization; and exploratory because it provides some insights to a topic that has not been explored in the Brazilian shipbuilding industry. Due to the complexity of the shipbuilding sector, a greater flexibility was required at the field research, not allowing an exact and a priori definition of the paths to be followed. This paper converged to a predominantly qualitative approach, based on data collection, reduction, organization, analysis, interpretation, verification and validation (Miles & Hubermann, 1994).

In this study, we have used archival documents such as institutional shipyard documents, on site observations (which allowed the process mapping), and interviews as data sources. Based

on the interviewees' reports, observed data and secondary documents, we describe in detail facts and data, aggregating information to academic knowledge, highlighting the descriptive characteristic of qualitative research. Data analysis, in turn, was performed through comparisons and contrasts of theoretical and collected data, generating inferences resulting from the cases (Yin, 2009). In the empirical field, our interest was characterized by the understanding of meanings in the research process itself. Our focus was the understanding of the lean manufacturing implementation at EAS, thus confirming the qualitative characteristic of this work (Merriam, 1998).

To determine which members of the shipyards would be our respondents, we used the strategic importance criterion for change implementation of the yard production system. Thus, the shipyard CEO, the EAS directors (contracts, finance, supply, operations and planning), and the Corporate Production Manager were interviewed, totaling six in-depth interviews. Some stakeholders were also interviewed for participating directly in internal shipyard change processes (such as a contract manager for TRANSPETRO, an infrastructure analyst for the Merchant Marine Department - DMM and a representative of the classification society ABS – American Bureau of Shipbuilding) totaling three additional interviews. The interviews were transcribed and analyzed by more than one researcher. Excerpts related to the topics of waste reduction and respect for people were identified and categorized. Using a temporal point of view, we analyze the shipyard initial situation, the change actions and results, and the prospects of the lean system implementation.

RESULTS

This section will describe the shipyard status found by the new board and actions taken to implement the lean manufacturing system.

Shipyard Status before the Lean Implementation

The new board found a chaotic shipyard status. The delivery time and production costs for the first ships (especially due to the low productivity), surpass the PETROBRAS-TRANSPETRO contractual values. Although the quality of the final product was guaranteed, production costs were extremely high, especially due to losses on the production process and reworking. The first two ships cost twice as much as planned. From the third ship, production costs were gradually reduced, but accumulated losses were totaling more than one billion Reais (more than four hundred million dollars) at the time the new board of directors took over the shipyard. As a result, the enterprise lacked credibility (especially financial credibility), since few people believed that the yard could become a profitable business.

The new board represented a complete change of a traditional Brazilian Shipyard board. All people coming from the old shipbuilding industry were replaced (the CFO was the only member kept from the previous board, but he was coming from the shipbuilding industry). So the new management board was a disruption at the paradigms and resistances of the former Brazilian shipbuilding industry.

> The yard will not be able to live with it here. I need to eliminate the losses. Why do I paint three times? Why do you have 200% rework here? The problem is the cost of quality. If you lose a ship, you lose R $ 370 million. (EAS CEO).

The yard diagnosis by the new board was bad. There were no detailed production processes, or even process designs, but rather EAS actions were sought to comply with client regulations (PETROBRAS-TRANSPETRO), the financial agent requirements (Merchant Marine Fund - FMM), and the Classification Society evaluations (American Bureau of Shipbuilding). There was no clear shipyard culture. There were representatives of the partner companies (four presidents from the majority shareholders had took turns in the yard command of the yard assuming different agendas and keeping their own organizational culture). In addition to the natural difficulty related to the shipbuilding production learning curve, there was no clear production strategy. For instance, the first ships manufactured at EAS (Suezmax-type ships) had delivery times much larger than the established at the contract terms. To speed up those delivery times EAS had imported part of the hulls (called half-ships), instead of assembling them internally. However, this strategy, was discontinued after EAS manufacturing only two ships.

> Then look at the (learning) curve of the Suez; makes no sense ... and they never had a constructive strategy. They started making a whole ship, then came the half-ships from outside ... then we never made a ship like the other (EAS CEO).

The New Board Actions to organize the EAS

In this subsection we will discuss strategic actions taken by the new board, as well as the effective changes in the shipyard production system, to improve EAS results.

Strategic Decisions

The new board has brought to EAS a new focus on cost reduction and competitiveness. In this new perspective, production costs would have to be adjusted to the product sales value (Production Costs = Sales Price - Profit Margin), and not as occurred in the Brazilian shipbuilding mentality, where production costs were added to the profit margins and pushed into the negotiation of vessel sale prices.

> The naval industry is kind of prostituted, right? it is cost plus the profit margin, not this is the price and I must get into the cost. So, this equation is inverted in the industry and that must change ... otherwise we will not fulfill this business (EAS CEO).

EAS's previous experience with rig shells contracting (contracts were canceled after yard high preparation investment) showed that there was no strategically defined product line at the shipyard. The new board, based on the skills already developed at the shipyard, has decided to focus manufacturing of less technologically complex ships (oil tankers), which was the focus of PETROBRAS-TRANSPETRO contracts. After a while, that yard production line could be expanded to manufacture container ships (an already existent market that could be attended by EAS competences).

Another strategic decision by the new board, was the vertical integration of manufacturing and assembly activities, previously carried out by third parties. Productivity improvement has weighed on this decision. The yard had competence and resources (equipment, space, skilled labor, etc.) to do these activities. The use of many outsourced companies operating within the EAS facilities and, consequently, a low utilization of internal resources, only had damaged the yard productivity.

> So, when I look at the manufacturing part my only input here is steel, so I do not have a need for a chain. I do everything inside the house, the only thing I must buy (*besides equipment*) is accessory, integrated accessory (small parts, stairs, handrail, etc.) ...Conclusion is what I told you, I will not need any of them. Do everything internally. We used to have one thousand and five hundred providers here (EAS CEO).

Another factor for vertical integration in manufacturing and assembly was he local and national supply chain inadequacies. This action was supported by a supplier cost analysis, which corroborated to the elimination of most existing local and national suppliers. The idea of integrating a local or even national supply chain was also hampered by supplier corporate culture, who used to develop inadequate business practices, to the detriment of supply quality.

The use of local suppliers has been problematic since the beginning of yard operation. It was known that domestic suppliers of the naval industry were not cost or quality competitive against international suppliers (MDIC, 2003). Even so, to reduce the risks of supplies and to meet the national content index (CN), several contracts had been celebrated with those suppliers. However, before the new board arrived, 60% of contracts placed to Brazilian suppliers had been canceled due to quality/delivery problems.

Despite difficulties with the local supply basis, there was the understanding that, in the long term, vertical integration would not be the definitive yard answer. High internal integration would represent high capital intensive (equipment and facilities) business, which was not desirable from the shareholder standpoint. In this sense, some longer-term contracts with local suppliers have been carried out in the EAS. Some of these suppliers started working at the yard site to provide better customer service, either in client support, or operator training.

Lean Manufacturing Capabilities at EAS

In this section we will discuss the development of the four capabilities in EAS (Process Design, Kaizen, Improvement Sharing, and Training) related to lean manufacturing. Our emphasis will be placed on the first two capabilities. At the end of the section, we discuss the role of people in the yard changes.

Process Design

Given the EAS situation, the new board initially decided to map all processes, including the administrative ones, getting help from external consultants. The value mapping in EAS production was detailed. According to the interviewees, that step has taken at least six months. The yard was organized into eight mini factories: steel processing (blasting / preparation); sheet cutting; welding of profiles; block assembly; painting; assembly of accessories; (Figure 1).

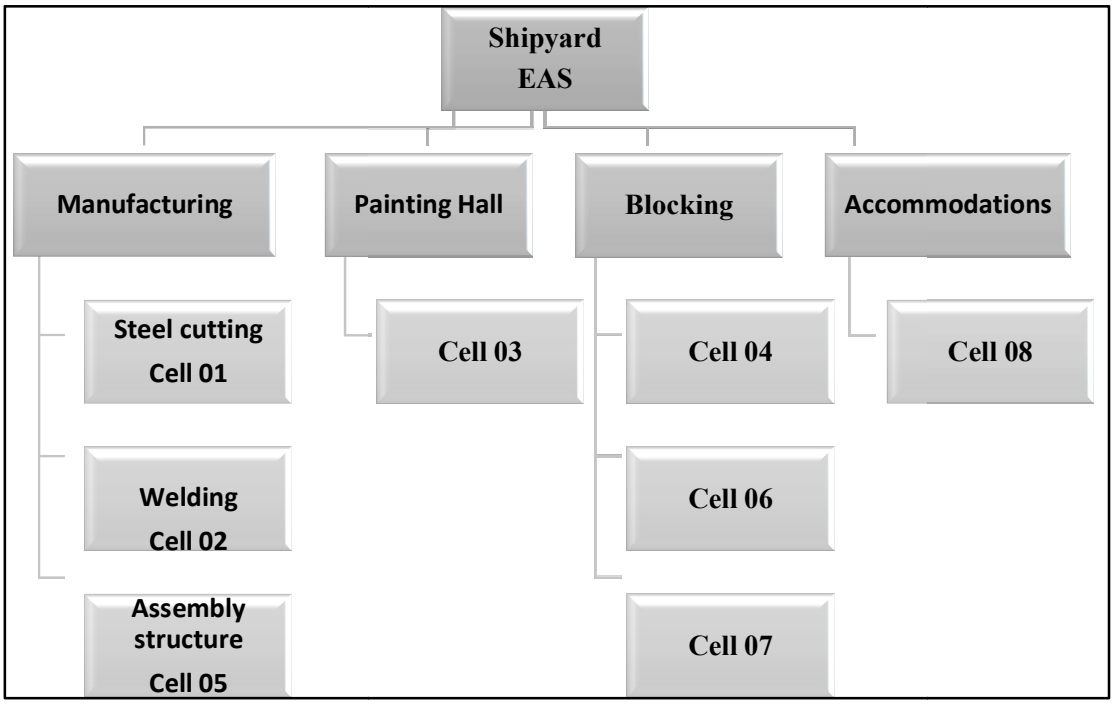

FIGURE 1 – MINI-FACTORIES AT EAS SHIPYARD

This new layout would allow each mini factory to focus on a specific part of the shipbuilding process. The mini-factory value streams were mapped, and an adequate number of people were allocated to each one, as well as, an adequate cycle time was defined. The mini-factory manager defines the schedule manager weekly. The supervisor takes this schedule, divides it by days, and delivers it to the leader. The leader divides those tasks into hours.

Each of these mini-factories has a cost center, reported directly to the EAS CEO. Any extrapolation of the mini factory's budget requires a negotiation process to analyze the possibility of resource transferring from another mini-factory that is on the loose. The mini factory cost control has helped the new board to control its key accounts and the yard cash flow control.

> Between 12 and 16 accounts represent 90% of my expenses. I have direct control over them, before I did not have. How did this work out here; economic accounting is POC. So, it's a margin projection, you know that when the margin does not happen you have to make the loss. (EAS CEO).

A block assembly management was created to record the block production history. That control would help not only to solve block related problems, but also future block related problems. The same control system was reproduced for each sheet and part produced at the shipyard. This would help to implement a PDCA for production continuous improvement, especially critical for reducing the yard total amount of men hours. In addition to changes in production control systems, there were changes in layout, significant reduction of physical space and equipment, showing that many of the original investments during the yard construction stage were oversized.

> If we were to do the yard today, I would pick up these bridges and throw it all away. It was going to be the opposite, the lines would be like this, I would not need this building (painting station) ... it's hard for them (shareholders) to hear it, all this money spent here I would not need it, I would need ¼ of what was built here to make a shipyard, to make eight ships a year (...) this yard is still going to be reduced to half of what it is today. This yard has an interesting feature; we make the block here, but the ship leaves on the other side; it is weird ... It still has lots to be worked on (EAS CEO).

Some traditional shipbuilding processes, such as painting has been redesigned to reduce costs (dry painting is much faster than the original water painting), to improve process quality, to expand partnership with key suppliers (subsidiaries of multinational ink suppliers), and to increase delivery flexibility. EAS managers have paid close attention to operations bottlenecks by planning for better use of expensive equipment (such as the fifteen hundred tons moving cranes). These simple ideas that increased the yard equipment utilization, like some others, were possible by a fresh look from people outside the shipbuilding industry.

> The staff had a table, put the plate there and cut it. After he cut, he had to take that material out to get another plate. That's a rule; then we raise the ruler and I have two tables. So, I cut into one table and I'm catering to the other one. While this one is being unloaded the other (table) is already cutting (the plate). So, I am utilizing the equipment capacity much more, (before) I have utilized at most 50% of the equipment. The “Golias” (crane) worked one each time; the other stood still. Nope, they will work simultaneously: one on this side and another on the other side (Corporate Production Manager).

In the new production system, the smallest unit of control was the team (composed of around 10 people) and managed by the team leader. Each team leader has a control framework that is the hour-hour. Then, at each hour closed, he needs to go to the board to see if he/she has met the team goal. If he/she did not meet the hourly goal, but still can meet the production within the working day, a countermeasure is triggered to recoup the production shortfall. For example, the leader may decide to release only a portion of the team at the scheduled lunch time to not stop production. If a question is out of the team leader's hand, such as overtime utilization he/she calls out the supervisor, who oversees eight teams, asking for authorization. If it is an issue where the supervisor has no autonomy to decide, the problem goes up to the mini factory manager. The mini factory manager has a once-a-day meeting called KPI (Key Performance Indicator), where performance figures are tracked in a frame.

All the decision staggering is supported by visual controls, indicating a production deficit (red color) or a production attainment (green color) in relation to the target (black color). There is no computerized production control system as in traditional project management. The logic of visual management is to simplify and facilitate control and even allow problems to surface as advocated by the lean manufacturing literature.

> The yard is big. So, I must be able to walk in the yard, any of us, and realize if the yard is good or if it is bad. Then, whenever I walk in the yard I only have one question to ask - is it good or bad? -... when I define what is good and what is bad, then I can add value to this

> business ... So, when I walk around the yard I already know which mini factory is up to date, which mini factory is late, where is the most critical point (Corporate Manager of Production).

Production lead times are tighter than the respective lead times for the customer. These goals are doggedly pursued, but in case you cannot solve a problem on time, there is still some slack to use. If necessary, the manager can request support from the “help chain”, via radio, telephone, etc. The “help chain” is formed by multifunctional members of sectors such as Quality, Manufacturing, Supplies, etc. The help chain is triggered when a mini factory finds that it will not be able to finish its job on time (usually triggered at 15% of the task completion time) due to several factors such as inability to meet a deadline, failure to approve an item, drawing issues, etc.

> At that moment there are seventy people from the mini factory II who are assisting the mini factory V that is delayed one day on its goal. I must to build (ship) with a million four hundred thousand HH. it's of no use (if only) factory II be good, I need the yard to be good, I need to deliver the ship there at the other end (EAS CEO).

Workshops KAIZEN

The Kaizen workshops were instrumental for deploying the EAS strategic goal of building the AFRAMAX vessels with one million four hundred thousand HH (number of hours lower than the one from the SUEZMAX series), in tactical and operational actions. In the workshops, teams start with a productivity number and analyze the bottlenecks and constraints preventing that achievement.

> Look, I have a machine here and my machine is 30% efficient and with 30% I'm not going to meet the demand I need. The efficiency of it needs to be at least 60%; that's a knot. So, that comes here on Wednesday and from there develops a Kaizen for improving from 30 to 60 (Corporate Production Manager).

The Kaizen workshop starts on Mondays with a theoretical presentation of what must be done, and which tools will be used. On Tuesdays, Wednesdays and Thursdays it is usually the work of data collection and implementation, and on Fridays the balance is made, celebrating the correct ones and correcting the errors. It could have more than one workshop per week at a mini-factory, implying that it may have up to eight simultaneous workshops. According to the Corporate Production Manager celebration is an important component of the kaizen workshop success: "Everything that went right we celebrate and everything that went wrong action plan of at most thirty days. This is the systematic ... It's wrong to give a lot. "

Kaizen has created a discipline to raise all kinds of process related problems that could affect the yard production. For each type of problem, a solution or countermeasure is designed. The solution consisted in acting on primary causes so, that the problem did not return. If there was no definitive problem, a countermeasure would be activated to momentarily resolve it. An example of a countermeasure is the use of kanban for inputs within the factory. As in certain situations, the exact consumption of certain inputs may not be known. Then, a kanban solves the lack of input problem, until the precise demand size could be determined.

At data collection time of this study, there have been over 120 Kaizen workshops deployed, with hundreds of thousands of ideas implemented, generating visible waste reduction and improvements at all levels in the yard. In those workshops all those directly involved with the change are present: from the operator of a machine to the leaders, supervisors and managers. Measurements are taken before and after the improvements, to see how effective the changes would be.

Improvement Sharing and Training

The improvement sharing competency was supported by information sharing at horizontal level. Employees were encouraged to develop the habit of searching information about a specific problem. According to the Production Corporate Manager, once a week there is an operational meeting of improvement group managers, who use to walk into the factory, and look for production information. Weekly improvement meetings show a cultural change in the yard, since people no longer accept error passively. In those meetings, there are people from all the areas: finance, personnel, manufacturing, planning, etc. There is also a regular board meeting to address business strategies, supported by daily follow-up meetings, to monitor the implementation of defined actions.

> Did you ever come to our meetings here on Wednesdays? It's a good altercation. So, we fight and must be separated. I'm reaching the level I want because when it starts like this it is cool. The production guy does not accept what engineering did wrong; the logistics guy does not accept what the guy from the warehouse made. It is a nourishing fight, in which everyone wants to improve (EAS CEO).

The training competency at EAS was developed using mainly through the on-the-job training provided by the immediate supervisor. There is a cascading training, where the board trains their managers, managers train their supervisors, and supervisors train their leaders, who ultimately train their team. The training was carried out in a continuous mode, focusing on employee autonomy to solve problems.

> Each moment of ours is a moment of training, this is a posture that we must have. So, I'm going to get to a painting that is red ... I call the people involved and - Why is it red? What was the action you took? - So, I try not to just charge at any cost, that's training, - Okay, but what can we do? The idea is that we do not give the fish; they must learn how to fish. So, we go there, it's Socratic Method; I will instigate them to arrive at this solution, this process takes a little longer than simply giving the answer, but it is forever (EAS CEO).

We can observe the goal is not only problem solving, but construction of operational autonomy. Employees are encouraged to think, and they end up developing their own problem-solving skills. The focus is to stimulate reflection and participation. Managers are not always able to solve problems, but they build commitment and empowerment at the operational levels. The human factor was crucial to the changes at EAS. Considering that actions such as leadership development and organizational culture change have had little prominence in the production literature, we will be highlighting those issues in the next section.

The Importance of Human Factors to the changes at EAS

The new board of directors sought to be as transparent as possible, at the change times, showing the yard situation, and discussing the importance of increasing productivity to avoid the enterprise closure. In this context, there was an emphasis on operational leadership. The production leader had two major missions at EAS: to keep a productive flow; and make improvements. There was a task assignment hierarchy, as well as, a resource request hierarchy composed of various levels (leader, supervisor, mini factory manager, director board). This hierarchy keeps control and allow the open discussion about resource needs to solve problems, fulminated the old culture of "slipping deadlines."

> People used to do like this: "It happened; now you cannot change!" Okay, what do we have to do to accomplish it? We need to put in more people? We need to put more resources? Put a crane? Bring another forklift? Do I have to make a different plate? We cannot say simply we cannot do it; this does not exist, there is no such option. It will happen and on the established date. This is the control, and then it triggers our whole process, which is the leader's hour-hour, which is the supervisor's daily control, the manufacturing manager's planning, the weekly board meeting that deals with our operations. Then, it unleashes the tools that we use to make this happen (Corporate Production Manager).

Good ideas are rewarded in ceremonies with everyone from the yard present. The best ideas from the mini factories, the seven best ideas and the best of all from the yard are awarded monthly. The significant number of ideas showed the success of the program. However, differently from lean manufacturing models such as the Toyota system, the spirit of competition between employees was encouraged.

> (Before) There was no sense of competition. So, this year I told the guys that we were going to organize some Olympics; I must start waking up those guys. So, what I saw here is convenient (behavior). At the beginning this was very difficult, because nobody understood what was happening, now everyone wants to break records: A winning culture (EAS CEO).

Focusing on intermediate leadership for implementing change and a serving attitude can be perceived throughout the organization. Leadership was identified, and the manager's role change from an activity prosecutor to an operational work facilitator (called positive leadership). The EAS CEO stated incisively: "Who has to serve is the boss. I that I must get there and see if it's okay and what I can help; that's the boss's role. So, until we reversed the pyramid here, it was a big fight. "

Control mechanisms and action plans were created not to punish those who made a mistake but to focus on the reaction plan for the problem solving. The commitment to excellence was instilled in Kaizen meetings. Errors have been part of the process, but never disseminated, and people must not accommodate to them.

> Nobody accepts a block, a plate, a piece that passed with defects, (he) does not accept. This is the role of each one here, and it took a year and so much to change this business. So, the staff arrives to say: "No, you have to; you are wrong”. In fact, that wrong/right is our way. (EAS CEO)

An interesting point at EAS changes was the valorization of the female participation in the labor force, which is predominately masculine in the Brazilian shipbuilding industry. There were a significant number of women in the technical areas of the shipyard such as Engineering, and Production Control Planning (PCP). Almost all employees that schedules and controls the factory floor are women. It was found at Kaizen meetings that the PCP and Engineering employees had little integration and, consequently there was a lot of rework. Multifunctional work cells coordinated by female employees were then created to redesign the process and define responsibilities.

Despite the lean pillar of respect for people, there was a strong reduction of jobs during the lean implementation at EAS. The number of employees has been reduced from 10,800 to 3,000 employees. As processes have improved, the overstaffing became apparent. Then, good and committed employees were gradually getting better and more productive. However, during that downsizing, there were openings for employees to have access to the entire board, to speak up, and to talk about what bothered them.

> Before ... their work was just to keep appearances; this does not last long with me. You can see that a lot of people who left were those people who tried to hide the truth from us and we do not accept it. This cultural change has leveraged the current spirit here. (EAS CEO).

Productivity improvements and results at EAS

The needed productivity for processing a ton of steel was 176 HH. With lean implementation it was necessary at most 127HH for the same work, with some reductions up to 90 HH. Due to the productivity improvement, it was estimated that it would reach between 80 and 90 HH in a few months, which would meet the expectations of the client PETROBRAS-TRANSPETRO. However, the planning of the new board was much more ambitious: it would reach in a short time the mark of 44 HH by processing a ton of steel and zero error, in building the new series of Suezmax-type vessels. This would be a competitive number even compared to the more productive international shipyards. Noticeable dramatic process improvements have which helped lessen the resistance to new changes.

> I used to make a flat block in eight days; today I make a flat block in four hours ... I used to make a sub-block that's one of our sub-assemblies around three days, and we're doing it in 35 minutes. So, those numbers are already measured with engineering control…when we designed and said we were going to make a block in four hours the staff said "will not do it". In fact, we did not it in four hours; we did in two (Corporate Production Manager) .

The increased productivity and process improvement have created a new paradox for the yard. With the amount of resources available at EAS, two ships could be built simultaneously on two production lines. However, the faster the ships are manufactured, the faster the portfolio orders would end. That is, if the shipyard would move fast in ship manufacturing, in two years it would no longer have orders to fulfill, which would be a problem if no new orders would have been placed.

Costs were reduced in the ship-to-ship production. The ninth ship (from the series of twelve SUEZMAX ships) was the first one without financial loss, and the tenth ship was the first

profitable one at EAS. No less important, in the view of the interviewees, there was a cultural change, especially work behaviors at tactical and operational levels.

> Today you can see that people are proud, beat in the chest to say that area is mine, in this area I am the boss. That was something that would not happen. Before, problems always used to escalate up and up; when there was an answer to the problem, the situation had already changed (Planning Director).

There is a general perception at EAS that top-down and bottom-up adaptations were made. The idea of autonomy with accountability has been bought by employees. People at the operational level are embracing their areas and solving most problems without having to turn to the boss. The cultural change has been described in an interesting way in the following dialogue:

> There was the stage when there was foolishness in the yard, and no one was punished or identified. Then, there was the phase where people with bad behaviors were identified, but not punished. And now, they have reached the stage when those who do nonsense are identified and punished for their mistakes. That matches the yard's CEOs turn for the last years (DMM Analyst).

EAS FUTURE PERSPECTIVES

The future perspective for EAS would become a fully “ship assembler" yard. In this sense, there is the understanding that ideally the production bottleneck would move to the dry dock. However, the remaining low order backlog does not encourage a significant increase in EAS production. In a fully “ship assembler" configuration, there would be a significant participation of systemists, who could occupy empty space at EAS site, delivering supplies directly to the EAS assembly line. The yard intends in the future not to buy only equipment or supplies but buying full services from suppliers. Thus, purchases would be based on utilization and not by acquiring inventory (that would be owned by suppliers).

> In the future I do not want to buy any welding machine, I want Supplier 1 and Supplier 2 to give me the best technology, the best wire, the best machine ... I do not want to buy EPI. I want to get on a machine and take EPI just like I buy Coca-Cola down there (at the vend-machine) ...I do not want to have inventory, I do not want to have suspended money. I want to pay just for what I use. (Corporate Production Manager)

There new board even foresees a future collaboration with the neighboring yard (PROMAR). A clear advantage of collaboration between these yards would be supply cost reduction for common parts, and even the deployment of common warehouses and sharing of service areas. This collaboration could also be supported by the complementarity of each shipyard's expertise. In that sense the demand of a yard for services that it does not do so well, would migrate to the neighboring shipyard and vice versa. Thus, PROMAR could be a potential future supplier of full blocks to EAS. The partnership between neighboring shipyards would be breaking the history of competition and non-collaboration between Brazilian shipyards. This new collaborative approach is assumed by the new board:

> Formally we have nothing (partnership with the neighbor yard) which is a shame for both of us. I have a very different position on this, the fact that they come here and see what we're doing does not mean they're going to do it, because if it was the case, everybody would make a car like Toyota. (Planning director)

CONCLUSIONS

P1Using the theoretical lens of lean manufacturing, we have analyzed significant improvements, especially productivity gains, at EAS, the largest Brazilian shipyard. We could verify in those changes not only the waste reduction pillar, but mainly the respect for people pillar, sometimes so neglected at the production and operations literature. All seven major wastes described in the literature were addresses by the EAS lean implementation. Leadership and commitment were the basis for a new organizational culture. Several strategic decisions, such as the elimination of most of outsourced functions, although going in the opposite direction to the one suggested by the literature (Liker & Lamb, 2000a), have helped waste reduction and productivity increase. Thus, like al best practices, lean manufacturing implementation must be adjusted to specific industrial contexts.

Contrary to the literature (Liker & Lamb, 200b), the lean system has been implemented at a time of crisis, leading to elimination of many jobs. On the other hand, the rapid results have strengthened a culture of excellence and commitment to productivity. Employee participation was so intense that it allowed the creation of a yard cultural identity, anchored at the lean production pillars. The four capabilities of the Toyota Production System have been gradually developed, processes and value chain ideas were designed, and waste reduction mechanisms were implemented. An improvement chain has been fed by information sharing, communication and continuous training.
We conclude that the major reason for lean implementation success at EAS was the human related pillar. This is in line with (Emblemsvag, 2014), which concludes that the human side, especially related to training and people empowerment, is important for lean deployment in the shipbuilding industry. The new board leadership has leveraged a massive employee participation and promoting a paradigm shift from and old-fashioned vision that some manufacturing best-practices may not be applicable to the shipbuilding industry. Thus, the production and operations literature should not overlook the importance of leadership at best-practices implementation. Finally, employee willingness to participate in something big was captured on the EAS CEO citation:

> What we are doing here is very basic but this was a motivation to make history, because of what we are going to do at this yard, we are going to make a different base for the whole (shipbuilding) industry to come and copy us (EAS CEO).

ABSTRACT

This study examined the use of symmetrical logo designs for products that promote beauty as a brand promise. We proposed that brands reflecting a 'beauty' component would have a greater proportion of logos that were symmetrical, compared to a sample of non-beauty brands. The results support this proposition.

KEYWORDS: Symmetry, logos, content analysis, brand promise, brands

INTRODUCTION

Logos are one of the graphic design elements of a brand and serve numerous important functions. Shimp (2007), for example, notes that logos serve as a 'shorthand way of identifying a brand." (p. 195). Watkins & Gonzenbach, (2013) state that logos help communicate the *personality* of the brand (or organization) to the target audience. Hynes (2009) reminds us that logos can act as a mark of quality and a way to increase a company's reputation. Finally, logos help differentiate the brand from competing alternatives (Janiszewski and Meyvis, 2001; MacInnis, Shapiro, and Manu, 1999; Park, Eisingerich, Pol, G. and Park, 2013).

As such, logos should be designed to ensure that they effectively communicate the appropriate message to the intended target audience. In this study, we restrict our analysis to the concept of symmetry, which Merriam-Webster defines as "the quality of something that has two sides or halves that are the same or very close in size, shape, and position" (http://www.merriam-webster.com/dictionary/symmetry). Research has shown that symmetry is associated with a perceptions of attractiveness and beauty (Enquist and Arak , 1994; Rhodes, Proffitt, Grady, & Sumich, 1998; Rhodes, Sumich, & Byatt, 1999; Berri, Simmons, Van Gilder, & O'Neill, 2011). Based on this evidence, we propose that logo symmetry would be particularly relevant in

industry sectors that promote beauty and attractiveness as a core brand promise. In particular, it is argued that logo symmetry would be particularly meaningful for brands that reflect elements of beauty as part of their selling proposition. In this study, we examine brand logos from the cosmetic and fashion industries.
\
The rationale for selecting these industries is supported by their market characteristics. With regard to hari care, the FDA defines cosmetics as "intended to be applied to the human body for cleansing, *beautifying*, promoting *attractiveness*, or altering the appearance without affecting the body's structure or functions." Similarly, Phillips and McQuarrie (2009) note that advertising in the fashion industry “is conceived as a means for presenting an idealized image to which women are taught to aspire” which implies that beauty and attractiveness are central to the intended message (58). Flower and Carlson (2015) build on this by reminding that many of the fashion images in fashion advertising rely on the “ideals of fashion, beauty, and even sexuality (Ger and Belk 1996; Hung et al. 2007; Fowler 2012).” (136-37) As such, the cosmetic and fashion industries are appropriate for the current study.

We begin the study with a brief review of the concept of symmetry and its relationship to perceptions of attractiveness. As an exploratory analysis, we then propose that logo designs for beauty brands are more likely than non-beauty brands to utilize symmetrical logos. The method of analysis is then presented, followed by the results. We conclude with a discussion of the managerial implications and directions for further research in this area.

LITERATURE REVIEW

At the fundamental level, Henderson and Cote (1998) remind us that good logos are: (1) easily recognized, (2) convey the same meaning to members of the intended target audience, and (3) evoke positive feelings. These general guidelines are intended to assist brand managers with a useful template for developing an appropriate logo. This review focuses on the third guideline with an emphasis on the relationship between design symmetry and positive affect.

In this regard, the graphic design literature has long argued that symmetry elicits a positive affect relative to asymmetry (Dondis, 1973; Bevlin, 1989). More recently, it has been shown that the positive effect of symmetry may depend on what is being measured. Bajaj and Bond (2014) found that symmetrical logo designs were rated higher by respondents than asymmetrical designs in terms of ‘artistic quality’. Conversely, asymmetric designs were rated higher in terms of ‘energy’. The important implication to be taken from this research is that the decision to use either a symmetrical or asymmetrical design should be based on the objective at hand. In other words, symmetry is but one factor to be considered in the design of a logo.

Nonetheless, the overall evidence linking symmetrical designs to positive affects is relatively strong. Henderson and Cote (1998), for example, cite research demonstrating that symmetry “is the primary determinant of pattern ‘goodness,’ which produces positive affect”. (16) (Clement, 1964; Garner and Clement, 1963). A review of synonyms for ‘goodness’ include such terms as *decency*, *morality*, *integrity*, *virtuousness* while antonyms include such terms as *badness*, *evil*, and *immorality*. suggests that the notion of ‘goodness’ implies elements of ethical and socially desirable behavior. (http://www.merriam-webster.com/dictionary/goodness). It would appear, therefore, that logo designs that reflect symmetry are more likely to be viewed from the perspective of ‘goodness’, a positive affect.

In a related study, Enquist and Arak (1994) examined the influence of symmetry and found that it was positively related to perceptions of *attractiveness*. The notion of attractiveness can be considered a positive affect given its definition: 'the qualities in a person or thing that as a whole give pleasure to the senses' (http://www.merriam-webster.com/thesaurus/attractiveness).

Using attractiveness as the outcome variable, Enquist and Arak found that respondents perceived symmetrical patterns to be more attractive than asymmetrical ones. Furthermore, they posited that the preference for symmetrical designs may result from a universal need to recognize objects; as indidivuals learn to recognize objects, 'preferences can develop for particular forms that have no objective existance in nature'. (p. 21, Watson & Thornhill, 1994) This explanation is consistent with a suggestion by Henderson and Cote (1998) that good logos should be easily recognized.

Symmetrical designs have also been shown to be processed more efficiently as well (Reber, 2002; Reber, Schwarz, & Winkielman, 2004). The central argument is that symmetrical designs generate better processing fluency because symmetrical designs can be elaborated on more efficiently. Similarly, Garner (1974) argued that symmetrical designs are more easily processed because they have less information than asymmetrical ones.

Given the evidence on symmetry, it would seem particularly relevant for industries that emphasize attractiveness and beauty as part of their "brand promise" to use symmetrical logos. In this regard, a brand promise can be defined as the marketer's vision of what the brand must be and do for consumers (Kotler and Keller, 2009) and this is most commonly communicated to the intended audience through promotional activities. Given: (1) the cosmetic and fashion industries use of attractiveness and beauty as a brand promise and (2) the relationship between symmetry and perceived beauty, then (3) an analysis of the degree to which logo symmetry is evident in these industries appears warranted.

If the results reveal that beauty brands utilize symmetrical logo designs, it would imply that beauty brands are relying on scientific evidence to guide decision making. Conversely, should the logo designs show that beauty brands do not utilize symmetrical design to any greater or lesser extent than non-beauty brands, it would imply that companies in these industries are not responding to the scientific evidence. In either case, the results will reveal the efficiency of the market in adopting established evidence regarding the relationship between beauty and symmetry.

Based on this review, we present the following hypothesis:

H1: Logo designs for beauty brands will reflect greater symmetry than logo designs for non-beauty brands.

METHOD

The samples were obtained by reviewing online listings of fashion and hair care brands. A sample of leading U.S. charitable organizations was also utilized to serve as the comparison group. We selected charitable organizations because their core brand promise does not focus on elements of beauty. As such, charities represent a meaningful contrast to beauty brands. Based on guidelines by Henderson and Cote (1998) on logo design, two coders were trained to distinguish between symmetrical and asymmetrical designs. Any discrepancies were resolved through consultation with a third coder. Brands that did not utilize a logo were excluded from the analysis.

The test for differences between the groups, a cross-tabulation was developed and evaluated through the use of the Pearson chi-square statistic. Cross tabulation analysis (also known as contingency table analysis) is a common method for analyzing categorical data (nominal measurements). Qualtrics (2011) estimates that more than 90% of all industry analyses involve cross tabulations.

RESULTS

The data for the cross-tabulation is presented in Table 1. Each data cell contains information on the observed value (Obs Val), the expected value (Exp Val) and the individual X^2 values for each cell. Hair-care and fashion were combined into the category 'beauty brands'. Charitable organizations were categorized as 'non-beauty brands". For this data, the X^2 is 4.41, with 1 degree of freedom (p-value = .036), supporting the hypothesis that the sample of beauty brands will have a higher proportion of symmetrical logos relative to the sample of non-beauty brands.

Table 1: Data and Analysis of Cross Tabulations

	Symmetrical Design	**Asymmetrical Design**	**Total**
Beauty brands	Obs Val = 39 Exp Val = 33.86 X^2 =	Obs Val =18 Exp Value = 23.14 X^2 =	N=57
Non-Beauty brands	Obs Val = 21 Exp Value = 26.14 X^2 =	Obs Val = 23 Expected Value =17.86 X^2 =	N=44
Total	N=60	N=41	N=101
Decision	X^2 Statistic = 4.41 P<.05 (.036)	Decision: .036<.05 The groups differ in the proportions of symmetrical versus asymmetrical logos.	

DISCUSSION AND CONCLUSIONS

This exploratory study examined logo designs from a sample of brands characterized as reflecting 'beauty' as a brand promise and compared them with logo designs from a sample of brands that do no promote beauty as a brand promise. Based on the evidence presented in the literature, it was hypothesized that beauty brands would have a higher proportion of symmetrical logos relative to non-beauty brands. The results support the hypothesis, although it was also shown that not every beauty brand utilized a symmetrical logo.

While the results support the notion of relatively efficient transfer of research to practice, one might reasonably ask: if the evidence is strong, why haven't even more beauty brands used symmetrical logos? Studies have commented on this issue and provide some useful insights on what is commonly referred to as the 'research-practice gap' (Gill, 2018). Kauppinen-Räisänen and Grönroos (2015), for example, presented ideas on how to 'bridge the gap' between scholarly knowledge and business practice in services. Cascio (2007) notes that academics

use management science 'to create new knowledge' but practitioners 'are not always receptive to academic theory". Bogomolova, Szabo, & Kennedy (2017) studied the factors that influence price-promotion decisions and found that they were most often based on "intuition and untested assumptions" rather than evidence from the literature. These representative examples suggest that the evidence presented through scholarly research is sometimes, and perhaps often, not utilized by practitioners; i.e., there is an apparent gap between research and practice.

What factors hinder the adoption of research knowledge? Barends and colleagues (2017) addressed this issue and found that while most managers in their survey reported having positive attitudes towards scientific research, they also indicated that they lacked the time needed to review it and, even when they have the time, they have a limited understanding of it.

In this context, the apparent gap between scientific evidence and practice is somewhat understandable; scientific journals and other related forums typically use writing styles and norms that might not be readily understood by those not in the scholarly academy. As such, scientific articles it is sometime claimed that scientific articles are often read only by a small group of like-minded scholars. Here is how Donald Hambrick explained it during his presidential address at the Academy of Management Annual Meeting (1993):

> 'Each August, we come to talk with each other; during the rest of the year we read each other's papers in our journals and write our own papers so that we may, in turn, have an audience the following August—an incestuous, closed loop' (p. 492, as reported in Hamet and Maurer, 2017).

To help mitigate the gap between research and practice, scientific research is sometimes re-written to appeal to a wider audience. For example, Thompson, Hamilton, and Rust (2005) published an article in the *Journal of Marketing Research* that investigated the concept of 'feature fatigue'. Subsequently, the Harvard Business Review published a more practitioner-oriented version of the same research and by the same authors. In this way, it would appear that the market has developed a means for disseminating knowledge to a wider audience.

In other contexts, decision makers may understand the knowledge, but fail to act upon it. Pfeffer and Sutton (1999) refer to this phenomenon as the 'knowing-doing' gap. They attribute it to a basic human propensity: 'the willingness to let talk substitute for action'. (136) That is, when confronted with a problem, 'people act as if discussing it, formulating decisions, and hashing out plans for action are the same as actually fixing it.' (136). In their cross-sectional study of companies, Pfeffer and Sutton found that companies often do substitute talk for action. But, there is a remedy: the authors found that when Xerox was required to document quality improvements (and the managerial practices that led to the improvement), meaningful action occurred.

With respect to the current study, it appears that the knowing-doing gap is not very evident; that is, logos for beauty brands do tend to reflect the evidence in the literature. This was, of course, expected given the strength of the evidence and the fact that our understanding of the relationship between symmetry and positive perceptions has been known for over 50 years. (e.g., Clement, 1964). However, it would be interesting to know whether the logos were developed using the research evidence or if they were developed based on some other criteria. Additionally, it would be interesting to determine which came first? It may be that some brands developed symmetrical logos irrespective of the scientific evidence.

Finally, it is important to clarify the intent of this study. Overall, the investigation was only intended to document the use of symmetrical logo design by beauty brands and compare the proportions with a sample of logos from non-beauty brands. It did not examine the effectiveness of the logo design nor did it investigate the reasons that managers decided to use symmetry. As noted above, additional research is needed to better understand the rationale used by management to incorporate certain design characteristics into their logo. The results of this exploratory study, however, provide support for further investigations.

Machine Learning Pairs Trading using Google Tensorflow

Andrew Brim
Utah State University
4205 Old Main Hill, Logan, UT 84322
andrew.brim@usu.edu
435-797-0643

ABSTRACT

Many financial trading strategies are statistically based. Wouldn't a machine learning system be a perfect fit, to run optimal mathematical trading strategies? The idea of machine learning financial trading is nothing new. This paper takes an approach using some of the latest machine learning techniques including Google's Neural Network, Tensorflow.

KEYWORDS: Machine Learning, Neural Networks, Pairs Trading

INTRODUCTION

Pairs trading looks at the relationship of financial instruments or commodities that are cointegrated, in our example cheese and milk futures, in which we traded one instrument based on the movements of the other. In the case of cheese and milk futures, when the prices of the two converged closer together, we sold the higher priced milk and bought the lower priced cheese. When the prices converged back to the mean, one or both positions would be profitable. If one understands the cointegration relationship, one can better predict price movements(Engle and Granger, 1987). In other words, we could watch the prices of milk and cheese futures, and predict, in some instances, price movements based on their cointegrated relationship.

Google Tensorflow was used to create a layer of perceptrons in a Neural Network to test for cointegration. We showed that Tensorflow can be used to pick out possible pairs of commodities which are good candidates for pairs trading. Essentially each perceptron tested whether or not it detected cointegration, and at what level. The next layer performed a trading test to see whether, a simple pairs trading strategy was profitable for that pair. The following is an example of milk and cheese future prices, which we detected as highly cointegrated by Tensorflow, then tested with a pairs trading strategy, and found to be profitable.

```
total buys:  4.0
total sells:  3.0
milk profit:  4.26
cheese profit:  -0.284
total profit:  3.976
Beginning cash:  1000.0
Final cash:  1313.03758907
```

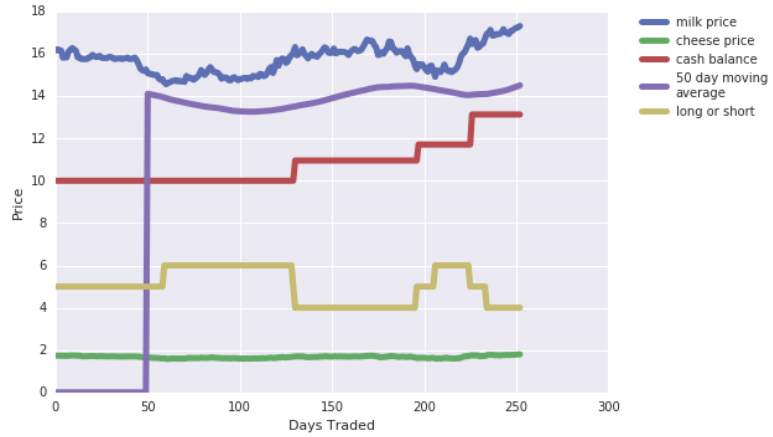

Fig. 1 Milk and Cheese Pairs Trading Simulation Results

Figure 1 shows the results of a trading simulation for milk and cheese future prices, run by Tensorflow. The returns for trading milk and cheese for one year was 31.3% percent. This is an extremely successful trading strategy, especially for commodities such as milk and cheese. The figure shows the price of milk and cheese over the last 12 months, and the results of our pairs trading algorithm. The blue and green lines represent the prices of milk and cheese. The purple line shows the moving average of the price difference between milk and cheese, which is used to generate buy and sell signals. The red line is our cash balance beginning at $1000.00, scaled down 1/10 and then overlaid on the graph. The yellow line is a buy or sell signal, also overlaid on the graph to show buys (line up) and sells (line down). When we saw the moving average line coming down, we bought milk and sold cheese expecting the price to move back up to the average. Conversely, when the line went up, we sold milk and bought cheese.

The period of 12 months was found to be optimal by Tensorflow based on its cointegration test of 12 months worth of milk and cheese prices. The first layer of perceptrons in Tensorflow used the Augmented Dickey-Fuller test (ADF) for cointegration (at a 95% confidence interval). Results of the statistical test allowed us to determine whether or not the pair was cointegrated.

PAIRS TRADING

Pairs trading is a strategy that simultaneously buys and sells a pair of financial instruments, or commodities, that are cointegrated. If the two instruments are highly cointegrated and their prices diverge from each other, then in time the prices will correct (Engle and Granger, 1987). In pairs trading, one observes deviations from the mean of the difference of the two prices in the pair, and places simultaneous buy and sell positions when they occur.

A common analogy for a cointegrated pair is a drunk man walking a dog(Murray, 1993). The drunk man performs a random walk and the dog follows. While the two may appear as two random walks, they always move together because of the leash. Similarly, if cheese and milk prices are cointegrated, one may expect prices that are far apart to converge back to a mean. If the prices are too close, they will diverge away to the mean. The mean gives us a baseline to determine trading opportunities.

In the example of milk and cheese, let's say the average price of a milk future is around $16.00 and the average price of a cheese future is $1.75. This makes an average difference of $14.25, a good baseline to make trading decisions. In this instance, we used a ceiling of 107% (or $15.25) and a floor of 93% (or $13.25). An array of possible floors and ceilings were tested, ie. 107%/93%, 105%/95%, and 103%/98%. A ceiling of 107% (or $15.25) and a floor of 93% were found to be optimal. If the average difference of milk and cheese went above $15.25, then we said that these cointegrated prices were too far apart, and we expected them to converge back to $14.25. If the average difference went below $13.25 we expected the prices to diverge back to $14.25. When we detected the prices to be too far apart, we took a short (selling) position in milk, and a long (buying) position in cheese, expecting that when the difference in price converged back to the mean, the price of milk would have gone down and cheese up. This strategy is market risk neutral, inasmuch as we don't care what the rest of the market is doing. We simply care about the current price difference between milk and cheese, the average price difference between milk and cheese, and the cointegrated value.

Even if both positions are not profitable it is likely that at least one position will be. This is where machine learning can help us. Testing for cointegration is statistical, and Tensorflow allows us to do the testing more efficiently and dynamically while performing trading simulations at the same time.

PROPOSED METHOD

To pairs trade, cointegrated pairs are needed, preferably, as highly cointegrated as possible. Using the previous analogy, we wanted to find a drunk/dog pair with a strongly elastic leash that we could dependably predict will continue to come back to the mean. This is where a Neural Net, such as Tensorflow can help. A tensor is simply an array of numbers. We created a neural network where the inputs and outputs to the perceptrons were all tensors. The perceptrons can be programmed to perform any task. In our case the perceptrons tested for cointegration. Additionally they can take any tensor as input, and they can easily scale as the input datasets become very large.

In our case, we created the first layer in our Tensorflow NN to calculate cointegration. Each perceptron will receive a pair of milk and cheese prices. Because all of the prices were cheese and milk futures, for testing purposes, we used a variety of time frames ranging from 1 month and 4 years. After each perceptron received its data (a tensor), and ran an ADF test. The ADF at a 95% confidence level told us, whether or not we can with a 95% confidence reject the null hypothesis that cointegration did not exist. For our purposes we considered this sufficient to move forward under the assumption that cointegration existed enough to test with a trading simulation.

The results from the perceptrons indicated that the longest time frame tested, in this case 48 months, did exhibit the highest cointegration. However, once we got to 12 months the cointegration yielded a very small change as we moved out to 48 months. In other words, 1 year's worth of

milk and cheese prices had a higher cointegration that any time frame shorter and very similar to any time frame longer. Therefore, for running trade simulation purposes, 1 year's worth of cheese and milk prices will yield returns, sufficient to prove out a pairs trading strategy.

The first layer of our NN perceptrons included cheese and milk prices as inputs. The output was then passed to the second layer which ran a pairs trading simulation test. Because most of the inputs were subsets of 1 year, running the trade simulation test for 1 year yielded the same performance results for any time frame shorter than 1 year. We intended to demonstrate that machine learning can give us the tools to find good pairs for pair trading, and to test to see how well they perform in trading strategies. We also showed that Tensorflow works well for this purpose.

The technologies used included: Google Tensorflow, Google Datalab to run Tensorflow and host jupyter notebooks used for testing. python 2.7.9 on Linux Ubuntu. The milk and cheese prices were supplied by websole.barchart.com via json api.

EXPERIMENT

We used Google Tensorflow, running on Google Datalab, to build a Neural Network. First, we retrieved cheese and milk futures prices from websole.barchart.com via their json api. The data was then cleaned and stored in nd arrays. The data pulled from websole.barchart.com was requested in increments to be tested for cointegration in our perceptrons in the NN. Initially we test for cointegration in cheese and milk for the time frames: 1, 2, 3, 4, 5, 6, 9, 12, 24, 36 and 48 months. As shown in the results section, the ADF critical score was -2.86 (between -5 to 5 is desired) as we approach 12 months. Beyond 12 months, the critical score remained close to -2.86 as the time period increases. 12 months was adequate to establish maximum cointegration for cheese and milk futures.

In a Tensorflow perceptron, the functionality is customized. In our environment we created perceptrons to check for cointegration at different time intervals, and then ran trading simulations to test for profitability using a classical pairs trading strategy. First, we created a session for the perceptron to run. The inputs were nd arrays of milk and cheese prices supplied for the given time frame. The output was an nd array with the ADF values for the critical values 1, 5 and 10%. An example perceptron output would be: [-3.44363, -2.8673966, -2.5698893]. This was interpreted as a 1% critical value of -3.44, a 5% critical value of -2.86, and a 10% critical value of -2.56. The example perceptron output suggested that the pair in question could be treated as cointegrated.

After the pairs were tested for cointegration, we proceeded with the trading simulation test. A future work would create a multi-layer NN with multiple types of pairs, with trading tests comprising the layers of the NN. For testing purposes, we simply performed a trading simulation test for 12 months' worth of cheese and milk prices.

TRADING SIMULATION

The trading simulation used real prices, and allowed us to test if a simple pairs trading strategy would be profitable over time. The strategy kept track of the moving average of the change between milk and cheese futures prices. As shown in Figure 1, the average price difference between cheese and milk is an estimated $14.25. The moving average of the difference, changes as the price changes and we keep track of this. Any time the price difference increases past 7% over the moving average,

or decreased 7% below the average we simultaneously bought and sold milk and cheese futures, expecting the price to correct, thereby making our positions profitable.

In Figure 1, the yellow line is not a price, but rather a signal that shows whether we are long or short milk. When the price of milk moved down initially, we entered a long position for milk, expecting the price to rise. The price did rise back to the moving average and we sold, creating a profit as shown in our cash balance. The price of milk continued to rise, until it is above 7% over the moving average. At that point we shorted milk, as shown by the yellow line. Once the price corrects, or return back to the moving average, we closed the short contract. We see our profit in the cash balance.

This cycle repeated again twice more, one long and one short position. In our 12 month simulation, this trading strategy produced a cash balance increase from $1000.00 to $1313, or a portfolio increase of 31.3%. Figure 2 shows simulation output for a single trade (not the entire simulation).

```
buying tight 0.93587128612
Long milk at:  14.65
Short cheeses at:  1.61
untighten 1.00409263636
cash before:  1000.0
Milk buy,sell prices,delta:  14.65 15.23 0.58
Cheese buy,sell prices,delta:  1.643 1.61 -0.033
new cash:  1039.59044369
```

Fig. 2 Example simulation trade performed by a perceptron

RESULTS

The trading simulation output shows the buy and sell positional movements as the simulation detects trading opportunities. In the trade output above you can see the simulation detects a "tight" scenario, or the price difference converging away from the moving average. We bought milk at $14.65, and sold cheese at $1.61. You can see, once the spread moved back to the average the positions are closed, resulting in a new cash balance of $1039.59, and a profit of $39.59 or 3.959% for the trade.

Figure 3 is a sample output from a perceptron performing a cointegration test on 12 months of cheese and milk futures prices. As part of the ADF test, it performed a regression on the pair, then tested the residuals for a unit root. At the end of the output, the ADF critical value of 5% is shown, indicating that we can with a 95% confidence interval, reject the null hypothesis that cointegration does not exist.

CONCLUSION

The intent of this study was to test whether Tensorflow NN can be used to detect highly cointegrated pairs. The research tested that relationship with a classical pairs trading strategy to verify it's profitability. The pairs trading strategy tested yielded 31.1% returns. We showed that an NN layer of perceptrons performing ADF tests for cointegration can be effective and scalable. As the demand for testing more and more pairs grows, Tensorflow can easily create more perceptrons and more layers in the NN to handle more data. In this experiment, we limited ourselves to a classical pairs trading strategy to verify the usability of the cointegrated pair in a trading environment. However, using Tensorflow, one may easily use customized types of trading simulation tests. We conclude that machine learning techniques and mathematically based trading strategies work very well together.

FUTURE WORK

Pairs of financial instruments used for pairs trading can come from the stock and bond markets, commodities, FX currency pairs, and derivatives markets including: rates derivatives, credit derivatives, and other futures and options. It is conceivable that the data from an infinite array fo pairs

can be tested in a Tensorflow NN.

Additionally, there is room for expanding the types of tests possible on those pairs. One could add more customized pairs trading strategies, or other tests entirely. For example, for stocks market prices, one could add layers in the NN to derive information regarding the company's financial health information or media feeds.

ABSTRACT

We investigate the optimal quality strategy and the service fee and capacity decisions of a service system with quality-conscious consumers. We find offering a high quality service by charging a higher price with a feasibly larger capacity is more profitable when informed consumers become more quality-conscious. With both informed and uninformed consumers, by using a threshold-based quality perception strategy, we find either the high or low quality strategy may be adopted and maintained the capacity serving the market at the threshold level. The results advance our understanding of the commonly observed queuing phenomenon in service industries with theoretical insights.

KEYWORDS: Quality strategy, Service design, Pricing, Capacity, M/M/1 Queue

INTRODUCTION

In all the branches of Din Tai Fung in Taiwan [Din Tai Fung has close to 150 branches around the world as of June 2018], a chain restaurant known for its xiaolongbao, long queues are always observed. Diners regularly queue for an hour or longer during peak hours for its signature steamed dumplings (Hwarng and Yuan, 2016). There are many possible reasons that consumers are willing to wait eagerly and patiently for certain popular products or services. One of the main reasons is quality. Indeed, consumers are becoming increasingly quality-conscious. However, long waiting time may inadvertently drive potential consumers away even though quality is the reason for forming long queues.

In the increasingly competitive and socially-networked market, consumers are becoming more conscious or demanding in product and service quality. Services of higher quality are usually

perceived to be of higher value. Thus, delivering high quality services arguably is the best sustainable strategy for success in today's competitive business environment. Although service providers have recognised the importance of service quality, providing high quality services can be costly. While Philip Crosby, known as a quality guru, asserted that "quality is free", an organisation has to invest heavily and "makes certain its products and services are delivered to the customer by a management system that does not condone rework, repair, waste or non-conformance of any sort." At Din Tai Fung Taiwan, in order to maintain the high quality standard, more than 50% of the revenue was invested in staff training, benefits and salaries, that are among the highest in the industry (Hwarng and Yuan, 2016). Therefore, to service providers, how to execute a sustainable strategy through its decisions in quality, price, and capacity is critically important.

In this paper, we investigate the appropriate quality strategy and its associated decisions in capacity and price for a service provider when facing quality-conscious consumers. We consider two categories of cases. First, the case with all informed consumers, e.g., the service quality is publicly known, is considered the benchmark case. Second, the case with both informed and uninformed consumers, we focus on a *threshold-based quality perception* used by uninformed consumers to form their opinions about quality of the service. The findings provide both theoretical as well as practical insights for service operations.

LITERATURE REVIEW

This paper builds on and advances two streams of literature, namely consumers' quality perception and purchase decision-making in service consumption, and the price and capacity decisions in service operations with delay sensitive and quality-conscious consumers.

A more extensive review of relevant literature is available upon request.

MODEL SETUP

Our model is motivated by Din Tai Fung's operations in the dinning and hospitality industry. A service provider offers a service of quality q to consumers in the market with a potential size Λ. Consumers are *quality-conscious*, where high quality services are always preferred. Generally, given all the other conditions fixed, the higher quality of the service is, the larger service value to consumers. The service provider first decides her quality strategy, and after that makes decisions on the service fee, denoted by p, and the service capacity which is measured by the service rate, μ. As quality is often a long-term operational strategy, the service fee and capacity decisions are dependent on the service quality strategy. Consumers can observe the service fee and capacity before making purchase decisions. However, service quality may be unknown to all or some consumers.

We assume the service is delivered through an M/M/1 queue system, where consumers have to join the queue to procure the service. We assume the queue is unobservable so that consumers have to take into account the expected waiting time when making purchase decisions. Consumers are *forward-looking* when making queue-joining decisions, in the sense that purchase decisions are made based on the comparison between the expected values from procuring the service and the reservation values before joining the queue.

We model consumers' value perception by the framework proposed by Zeithaml (1988). We use the superscript E to denote consumers' perception/expectation before joining the queue.

Given the service fee and capacity, based on the *percieved service quality*, q^E, an arriving consumer calculates the expected value based on his perception from purchasing the service, defined as below:

$$V^E = V(q^E) - p - CW(\lambda, \mu), \tag{1}$$

where $V(q)$ is the *service value* when the quality level is q, and $CW(\lambda, \mu)$ is the expected waiting cost when the arrival rate is λ, defined as

$$CW(\lambda, \mu) = \begin{cases} \frac{w}{\mu - \lambda}, & 0 \le \lambda < \mu, \\ +\infty, & \mu \le \lambda \le \Lambda, \end{cases}$$

where w is the waiting cost per unit time.

The service value depends on the *intrinsic value* of the service, denoted by v, and its quality. For analytical tractability, we assume the service value is the sum of the intrinsic value of the service and the quality of the service such that

$$V(q) = v + \alpha q, \tag{2}$$

where $\alpha \in [0, \bar{\alpha}]$ measures consumers' *quality-consciousness*, i.e., consumers always perceive a larger service value when the quality becomes higher. [Note that from consumers' perspective, the intrinsic value of the service and its quality may be interdependent, i.e., v depends on q. We refrain from such formulation for analytical tractability.] A consumer's reservation value is denoted by $V^r \ge 0$. The reservation value captures the consumption choices from other substitutable service options. Therefore, if $V^E \ge V^r$, an arriving consumer will join the queue to procure the service.

Denote the *effective arrival rate* as λ, which depends on the service capacity and service fee as well as consumers' perceived service quality, i.e., $\lambda = \lambda(\mu, p; q^E)$ such that

$$v + \alpha q^E - p - \frac{w}{\mu - \lambda} \ge V^r,\ \lambda \in [0, \Lambda],\ \lambda < \mu. \tag{3}$$

Note that the effective arrival rate depends on the perceived service quality. Therefore, how consumers perceive the service quality becomes critical, especially when they have different levels of information regarding the true service quality.

The service provider can always expand the service capacity to provide a faster service, or charge a lower service fee to attract more demand. To maintain the intrinsic service value and quality, expanding service capacity is at the cost of $C(\mu; q)$, which measures the *marginal capacity cost per unit time* and increases in μ when the service quality is q. We assume there are two service quality levels, q_H and q_L, with $q_H > q_L \ge 0$. If the service with quality q_H is offered, then we say that the service provider adopts the high quality strategy; otherwise, she adopts the low quality strategy. The capacity cost is linear in terms of the service rate μ for expositional simplicity such that $C(\mu; q_H) = \beta_H \mu$ with a high service quality, and $C(\mu; q_L) = \beta_L \mu$ when the service quality is low, where $\beta_H > \beta_L > 0$. The parameters β_H and β_L measure the *marginal capacity cost per unit capacity and time* when the service quality is high and low, respectively.

In the following analysis, we assume the following condition holds:

$$v \ge 2\sqrt{\beta_H w} + V^r. \tag{4}$$

The service provider knows consumers' quality-consciousness, and first decides the service quality strategy $i \in \{H, L\}$, and then chooses μ and p to maximize her expected profit rate taking

consumers' quality perception into account, as below

$$\max_{q_i\in\{q_H,q_L\},\mu>0,p\geq 0}\{\pi(\mu,p;q_i)\}=\max_{q_i\in\{q_H,q_L\}}\left\{\max_{\mu>0,p\geq 0}\left\{(p-\beta_i\mu)\lambda(\mu,p;q^E)\right\}\right\}. \tag{5}$$

As the effective arrival rate depends on consumers' quality perception, the above profit maximization problem suggests that service provider's quality strategy and operational decisions depend on consumers' perception about the service quality.

THE CASE WITH INFORMED CONSUMERS

When the service quality is common knowledge, all consumers know the exact quality of the service. Thus, consumers' peceived quality confirms with the actual service quality, i.e., $q^E=q$.

We use the superscript m to denote the optimal decisions and the effective arrival rate as well as the profit. The following result in terms of the optimal service fee and capacity decisions under the case with informed consumers holds. All the proofs are available from the authors upon request.

Proposition 1 *Given the quality strategy $i\in\{H,L\}$, the optimal service capacity and service fee are given as $\mu_i^m=\lambda_i^m+\sqrt{\frac{w}{\beta_i}}$ and $p_i^m=v+\alpha q_i-\sqrt{\beta_i w}-V^r$, respectively, and the optimal profit is $\pi_i^m=\left(v+\alpha q_i-2\sqrt{\beta_i w}-\beta_i\lambda_i^m-V^r\right)\lambda_i^m$, where $\lambda_i^m=\min(\lambda_i,\Lambda)$ is the effective arrival rate, and λ_i is given by*

$$\lambda_i=\frac{v+\alpha q_i-2\sqrt{\beta_i w}-V^r}{2\beta_i}. \tag{6}$$

The impact of consumers' quality-consciousness

In order to ensure the attractiveness of the high quality strategy for the service provider to adopt, we make the following assumption in terms of the *quality-cost ratio*,

$$\frac{q_L}{\beta_L}<\frac{q_H}{\beta_H}, \tag{7}$$

i.e., compared between the two quality strategies, the quality-cost ratio under the low quality strategy is smaller than that under the high quality strategy.

For ease of analysis, we assume the potential market size Λ is large enough such that $\Lambda>\max(\lambda_H,\lambda_L)$. The quality-cost efficiency assumption (7) for the two quality strategies implies the following result:

Corollary 1 *Suppose the potential market size Λ is large enough. There exist quality-consciousness levels $0<\alpha_1<\alpha_2<\alpha_3<\alpha_4$ such that*

- *if $\alpha\geq\alpha_1$, then $p_H^m\geq p_L^m$, i.e., the optimal price under the high quality strategy is higher than that under the low quality strategy;*
- *if $\alpha\geq\alpha_2$, then $\pi_H^m\geq\pi_L^m$, i.e., the optimal profit under the high quality strategy is higher than that under the low quality strategy;*
- *if $\alpha\geq\alpha_3$, then $\lambda_H^m\geq\lambda_L^m$, i.e., the optimal arrival rate under the high quality strategy is higher than that under the low quality strategy;*

- *if $\alpha \geq \alpha_4$, then $\mu_H^m \geq \mu_L^m$, i.e., the optimal capacity under the high quality strategy is higher than that under the low quality strategy.*

Corollary 1 indicates that consumers' quality-consciousness affects the operational performance of the service provider under the two quality strategies.

THE CASE WITH INFORMED AND UNINFORMED CONSUMERS

In this section, we consider the case with heterogeneous consumers where they have different information about the service quality. However, all consumers have the same level of quality-consciousness, which is known to the service provider. We assume the proportions of informed and uninformed consumers in the market are $\phi \in [0, 1]$ and $1 - \phi$, respectively, which are known to the service provider. Uninformed consumers know that some consumers are informed about the service quality; however, they do not know the exact composition of consumers in the market.

As widely observed in reality or laboratory experiments, consumers often infer the quality of a product or service by the sale quantity. Therefore, in this section, we consider uninformed consumers use the following *threshold-based perception strategy* to infer the service quality, where the threshold is charaterized by a demand rate λ_b:

- The *high-demand-high-quality* perception strategy, where

  > *If the effective arrival rate is larger than λ_b, then uninformed consumers will perceive a high service quality; otherwise, uninformed consumers will perceive a low service quality.*

We also investigate the case with the *high-demand-low-quality* perception strategy adopted by the low quality-conscious consumers in the long version of this paper, which is available upon request. By Proposition 1, we first consider two special scenarios where uninformed consumers' quality perception is opposite to the actual service quality. The first scenario is when the actual service quality is low, but uninformed consumers perceive it high. Denote the effective arrival rate as

$$\lambda_L^H = \frac{v + \alpha q_H - 2\sqrt{\beta_L w} - V^r}{2\beta_L} > \max(\lambda_H, \lambda_L). \tag{8}$$

The second scenario is when the actual service quality is high, but uninformed consumers perceive it low. Denote the effective arrival rate as

$$\lambda_H^L = \frac{v + \alpha q_L - 2\sqrt{\beta_H w} - V^r}{2\beta_H} < \min(\lambda_H, \lambda_L). \tag{9}$$

The case with high quality-conscious consumers

Depending on the magnitude of λ_b relative to λ_H, we consider two cases separately: (1) $\lambda_b \leq \lambda_H$, and (2) $\lambda_b > \lambda_H$. Given the quality choice $q_i \in \{q_H, q_L\}$, denote the optimal arrival rate in equilibrium as λ_i^e. The corresponding price, service rate, and the expected profit are denoted as p_i^e, μ_i^e, and π_i^e, respectively. Under the optimal quality choice, the optimal price, service rate, and the expected profit are denoted as p^*, μ^*, and π^*, respectively.

The case with a low demand threshold

In this section, we first focus on the case with $\alpha_b \geq \alpha_3$. Given the high-demand-high-quality perception strategy, for the case with a low demand rate threshold such that $\lambda_b \leq \lambda_H$, by Proposition 1, the following result holds:

Proposition 2 *For the case with $\alpha_b \geq \alpha_3$ and $\lambda_b \leq \lambda_H$, given $\alpha \geq \alpha_b$, the optimal quality strategy, the price and service rate decisions are given as follows:*

- *If $(1-\phi)\Lambda < \lambda_b$, then providing a high quality service is more profitable; the optimal price is $p^* = p_H$; the optimal service rate is $\mu^* = \mu_H$; the effective arrival rate in equilibrium is $\lambda^* = \lambda_H$; the optimal profit is $\pi^* = \pi_H$.*
- *If $(1-\phi)\Lambda \geq \lambda_b$, denote $\lambda_L^e = \min(\lambda_L^H, (1-\phi)\Lambda)$, $\mu_L^e = \lambda_L^e + \sqrt{\frac{w}{\beta_L}}$, $p_L^e = v + \alpha q_H - \sqrt{\beta_L w} - V^r$, $\pi_L^H = (v + \alpha q_H - \beta_L \lambda_L^e - 2\sqrt{\beta_L w} - V^r)\lambda_L^e$. Then, there exists a unique $\lambda_c < \lambda_H$ such that $(v + \alpha q_H - \beta_L \lambda_c - 2\sqrt{\beta_L w} - V^r)\lambda_c = \pi_H$ and*
  - *if $(1-\phi)\Lambda \geq \max(\lambda_c, \lambda_b)$, then providing a low quality service is more profitable; the optimal arrival rate in equilibrium is $\lambda^* = \lambda_L^e$; the optimal service rate is $\mu^* = \mu_L^e$; the optimal price is $p^* = p_L^e$; the optimal expected profit is $\pi^* = \pi_L^H$;*
  - *otherwise, providing a high quality service is more profitable; the optimal price is $p^* = p_H$; the optimal service rate is $\mu^* = \mu_H$; the optimal arrival rate in equilibrium is $\lambda^* = \lambda_H$; the optimal profit is $\pi^* = \pi_H$.*

We next consider the case with $\alpha_b < \alpha_3$ and $\lambda_b \leq \lambda_H$. If $\alpha \geq \alpha_3$, then the optimal quality strategy, the price and service rate decisions are given by Proposition 2. Therefore, we focus on the case with $\alpha \in [\alpha_b, \alpha_3]$, where the following result holds:

Corollary 2 *For the case with $\alpha_b < \alpha_3$ and $\lambda_b \leq \lambda_H$, if $\alpha \in [\alpha_b, \alpha_3]$, then the optimal quality strategy, the price and service rate decisions are given as follows:*

- *Under the high quality strategy, the optimal price is $p_H^e = p_H$; the optimal service rate is $\mu_H^e = \mu_H$; the effective arrival rate in equilibrium is $\lambda_H^e = \lambda_H$; and the optimal profit is $\pi_H^e = \pi_H$.*
- *Under the low quality strategy, there exists a unique $\lambda_{c2} < \lambda_L$ such that $(v + \alpha q_H - \beta_L \lambda_{c2} - 2\sqrt{\beta_L w} - V^r)\lambda_{c2} = \pi_L$. If $(1-\phi)\Lambda < \max(\lambda_b, \lambda_{c2})$, then the optimal price is $p_L^e = p_L$; the optimal service rate is $\mu_L^e = \mu_L$; the effective arrival rate in equilibrium is $\lambda_L^e = \lambda_L$; and the optimal profit is $\pi_L^e = \pi_L$. If $(1-\phi)\Lambda \geq \max(\lambda_b, \lambda_{c2})$, the arrival rate in equilibrium is $\lambda_L^e = \min(\lambda_L^H, (1-\phi)\Lambda)$; the optimal service rate is $\mu_L^e = \lambda_L^e + \sqrt{\frac{w}{\beta_L}}$; the optimal price is $p_L^e = v + \alpha q_H - \sqrt{\beta_L w} - V^r$; and the optimal profit is $\pi_L^e = (v + \alpha q_H - \beta \lambda_L^e - 2\sqrt{\beta_L w} - V^r)\lambda_L^e$.*
- *The optimal quality strategy can be determined by comparing π_H^e and π_L^e.*

By Corollary 2, if $\alpha < \alpha_3$ and uninformed consumers adopt the high-demand-high-quality perception strategy, it could be the case that the service provider always provides a high quality service especially when $(1-\phi)\Lambda < \max(\lambda_b, \lambda_{c2})$ and $\alpha \geq \alpha_2$ (see Corollary 1). A low quality service is always provided if $\alpha < \alpha_2$.

The case with a high demand threshold

Next, we consider the case with $\lambda_b > \lambda_H$. For expositional simplicity, we first denote the following price and service rate decisions as well as the corresponding effective arrival rates and expected

profits under either high quality or low quality strategies when the service provider determines the market coverage.

- Suppose the service is high, there are three cases in terms of market coverage:
  1. Only informed consumers are served and uninformed consumers perceive a low quality:
  $$\mu_H^e(1) = \lambda_H^e(1) + \sqrt{\frac{w}{\beta_H}},\ p_H^e(1) = v + \alpha q_H - \sqrt{\beta_H w} - V^r, \tag{10}$$
  where $\lambda_H^e(1) = \min(\lambda_H, \phi\Lambda)$ and $\pi_H^e(1) = (v + \alpha q_H - 2\sqrt{\beta_H w} - \beta_H \lambda_H^e(1) - V^r)\lambda_H^e(1)$.
  2. Both types of consumers are served and uninformed consumers perceive a low quality:
  $$\mu_H^e(2) = \lambda_H^e(2) + \sqrt{\frac{w}{\beta_H}},\ p_H^e(2) = v + \alpha q_L - \sqrt{\beta_H w} - V^r, \tag{11}$$
  where $\lambda_H^e(2) = \lambda_H^L$ and $\pi_H^e(2) = (v + \alpha q_L - 2\sqrt{\beta_H w} - \beta_H \lambda_H^e(2) - V^r)\lambda_H^e(2)$.
  3. The service provider maintains the arrival rate at λ_b to serve both types of consumers where uninformed consumers perceive a high quality:
  $$\mu_H^e(3) = \lambda_H^e(3) + \sqrt{\frac{w}{\beta_H}},\ p_H^e(3) = v + \alpha q_H - \sqrt{\beta_H w} - V^r, \tag{12}$$
  where $\lambda_H^e(3) = \lambda_b$ and $\pi_H^e(3) = (v + \alpha q_H - 2\sqrt{\beta_H w} - \beta_H \lambda_H^e(3) - V^r)\lambda_H^e(3)$.
- Suppose the service quality is low, there are two cases in terms of market coverage:
  1. Both types of consumers are served and uninformed consumers perceive a low quality:
  $$\mu_L^e(1) = \lambda_L^e(1) + \sqrt{\frac{w}{\beta_L}},\ p_L^e(1) = v + \alpha q_L - \sqrt{\beta_L w} - V^r, \tag{13}$$
  where $\lambda_L^e(1) = \lambda_L$ and $\pi_L^e(1) = (v + \alpha q_L - 2\sqrt{\beta_L w} - \beta_L \lambda_L^e(1) - V^r)\lambda_L^e(1)$.
  2. Only uninformed consumers are served and a high quality is perceived:
  $$\mu_L^e(2) = \lambda_L^e(2) + \sqrt{\frac{w}{\beta_L}},\ p_L^e(2) = v + \alpha q_H - \sqrt{\beta_L w} - V^r, \tag{14}$$
  where $\lambda_L^e(2) = \max(\lambda_b, \min((1-\phi)\Lambda, \lambda_L^H))$ and $\pi_L^e(2) = (v + \alpha q_H - 2\sqrt{\beta_L w} - \beta_L \lambda_L^e(2) - V^r)\lambda_L^e(2)$.

We consider the cases with $\alpha_b \geq \alpha_3$ and $\alpha_b < \alpha_3$ separately. Based on the above five cases of market coverage, the following result holds:

Proposition 3 *For the case with $\alpha_b \geq \alpha_3$ and $\lambda_b \geq \lambda_H$, given $\alpha \geq \alpha_b$, the optimal quality strategy, the price and service rate decisions are given as follows:*

- *There exists a unique threshold arrival rate $\lambda_c < \lambda_L$ such that $(v + \alpha q_H - 2\sqrt{\beta_H w} - \beta_H \lambda_c - V^r)\lambda_c = \pi_L$. If $\phi\Lambda > \lambda_c$ and $(1-\phi)\Lambda < \lambda_b$, then the optimal strategy is to provide a high quality service. While if $\phi\Lambda < \lambda_c$ and $(1-\phi)\Lambda \geq \lambda_b$, then the optimal strategy is to provide a low quality service.*

- *For other cases, the optimal quality strategy and the corresponding price and service rate decisions can be determined by comparing among* $\{\pi_H^e(1), \pi_H^e(2), \pi_H^e(3), \pi_L^e(1), \pi_L^e(2)\}$.

Next, we consider $\alpha_b < \alpha_3$. Given α, if $\alpha \geq \alpha_3$, then the optimal quality strategy, the optimal price and service rate decisions can be characterized by Proposition 3. Thus, we focus on the case with $\alpha \in [\alpha_b, \alpha_3)$. The following result holds:

Corollary 3 *For the case with* $\alpha_b < \alpha_3$ *and* $\lambda_b > \lambda_H$*, given* $\alpha \in [\alpha_b, \alpha_3]$*, the optimal quality strategy, the optimal price and service rate decisions are given as below:*

- *Under the high quality strategy, there exists a unique* $\lambda_{c1} < \lambda_H$ *such that* $(v + \alpha q_H - \beta_H \lambda_{c1} - 2\sqrt{\beta_H w} - V^r)\lambda_{c1} = (v + \alpha q_H - \beta_H \lambda_b - 2\sqrt{\beta_H w} - V^r)\lambda_b$*. If* $\phi\Lambda < \lambda_{c1}$*, the optimal price is* $p_H^e = p_H^e(3)$*; the optimal service rate is* $\mu_H^e = \mu_H^e(3)$*; the effective arrival rate in equilibrium is* $\lambda_H^e = \lambda_b$*; and the optimal profit is* $\pi_H^e = \pi_H^e(3)$*. If* $\phi\Lambda \geq \lambda_{c1}$*, the optimal price is* $p_H^e = p_H^e(1)$*; the optimal service rate is* $\mu_H^e = \mu_H^e(1)$*; the effective arrival rate in equilibrium is* $\lambda_H^e = \lambda_H^e(1)$*; and the optimal profit is* $\pi_H^e = \pi_H^e(1)$.

- *Under the low quality strategy, there exists a unique* $\lambda_{c2} < \lambda_L$ *such that* $(v + \alpha q_H - \beta_L \lambda_{c2} - 2\sqrt{\beta_L w} - V^r)\lambda_{c2} = \pi_L$*. If* $(1-\phi)\Lambda < \max(\lambda_b, \lambda_{c2})$*, then the optimal price is* $p_L^e = p_L$*; the optimal service rate is* $\mu^* = \mu_L$*; the effective arrival rate in equilibrium is* $\lambda_L^e = \lambda_L$*; and the optimal profit is* $\pi_L^e = \pi_L$*. If* $(1-\phi)\Lambda \geq \max(\lambda_b, \lambda_{c2})$*, the arrival rate in equilibrium is* $\lambda_L^e = \min(\lambda_L^H, (1-\phi)\Lambda)$*; the optimal service rate is* $\mu_L^e = \lambda_L^e + \sqrt{\frac{w}{\beta_L}}$*; the optimal price is* $p_L^e = v + \alpha q_H - \sqrt{\beta_L w} - V^r$*; and the optimal profit is* $\pi_L^e = (v + \alpha q_H - \beta_L \lambda_L^e - 2\sqrt{\beta_L w} - V^r)\lambda_L^e$.

- *The optimal quality strategy can be determined by comparing* π_H^e *and* π_L^e.

CONCLUDING REMARKS

In this study, we made some encouraging steps towards the better understanding of (1) the effect of consumers' level of quality-consciousness on the price and capacity decisions; and (2) how best to offer a service, namely, at what quality level, high or low, if consumers are informed or uninformed about the service quality?

Based on the benchmark case where consumers are quality-conscious and informed about the quality, the study shows that the more quality-conscious the consumers become, the higher quality of service should be provided to be more profitable. In reality, however, consumers are heterogeneous in their knowledge about the quality of service, i.e., some are informed about the service quality while the rest are uninformed, the results suggest that the service provider's quality strategy and its associated price and capacity decisions should depend heavily on the uninformed consumers' perception about the quality of service. We were able to shed some light in this regard by using a demand-based quality-perception strategy, and demonstrate the crucial role of the threshold demand rate. If the proportion of informed consumers is relatively low, it is advisable to offer services at a lower level of quality. If the proportion of informed consumers is relatively high, providing a higher level of service quality is desirable. At the threshold demand level, maintaining a relatively low level of service quality is sufficient.

For further studies, it would be interesting to consider competition among service providers in this context.

ABSTRACT

The objective of this paper is to define the conceptual domain of the brand charisma construct and identify its foundational dimensions. All luxury brands have image, symbolism and prestige to some degree, but those with charisma build on these to generate extraordinary levels of buyer attachment and motivation. But how do luxury brands make claims of having a charismatic personality, and what are the charismatic characteristics they claim to have? Drawing upon charismatic leadership theory and qualitative data from luxury brand consumers, we shed light on the behavioral attributes of charismatic brands. Given the importance of building sustained brand-consumer relationships, a systematic understanding of brand charisma has the potential to create high impact for scholarship and practice. For luxury brand managers across the delivery channel, insights into the foundations of a charismatic brand personality can help in brand strategy and brand program decisions.

KEYWORDS: brand charisma, luxury consumers, exploratory, conceptual domain

INTRODUCTION

There is increasing evidence that a large and stable segment of customers seek to build relationships with brands (Fournier, 2008; Schau, Muñiz & Arnould, 2009). Research has established that consumers not only seek out brands for the instrumental and functional roles they serve, they also seek meaningful connections with brands and their corporate entities (Aaker, 2012). As a result, companies build brand equity through brand personalities that encourage consumer interactions and build relationships (Lloyd & Woodside, 2013). A brand personality refers to the overall persona created by a cluster of human-like characteristics attributed to a brand name (Azoulay & Kapferer, 2003). Brand personalities studied in the mainstream marketing literature include those based upon trust (Chaudhuri & Holbrook, 2001) and warmth (Aaker et al., 2010), with particular impact in specific market situations. Trusted brands, for example, are found to be impactful in service contexts given consumers' perceived risk, while warm brands are seen as relevant in non-profit contexts. In the context of relationships between luxury brands and their consumers, traditional views of brand personality are less relevant since luxury brand-consumer relationships transcend functional relationships (Keller, Parameswaran & Jacob, 2011). Given the role of emotional and transformative brand values in luxury branding, we propose brand charisma as a brand personality most likely to resonate with luxury brand consumers.

Although the importance of corporate brand personality to organizational success is acknowledged in the organizational behavior and communications literature (Czarniawska, 1997; Waeraas, 2010), where organizations are personified and attributed with human personality traits, we contend that brands are 'born' with neither charisma nor personality, and that there can be no such thing as brand charisma that is inherited "by virtue of natural endowment" (Hatch & Schultz, 2013). External perceptions thus determine whether brands have a similar status as charismatic individuals. Therefore, in order to acquire charismatic status, brands must display evidence of having charisma. But how do luxury brands make claims of having a charismatic personality, and what are the charismatic characteristics they claim to have?

Webster's dictionary offers one definition of charisma as "*a special magnetic charm or appeal*". Most of the research on charisma to date has focused on the area of leadership where charismatic leaders are viewed to create a sense of excitement among followers, build strong bonds, and ultimately possess the ability to exercise strong influence on the values and behaviors of followers (Fanelli & Misangyi, 2006; House, Spangler & Woycke, 1991). Although attempts have been made to generalize charisma to all human beings (Verčič & Verčič, 2011), little is known about the conceptual domain of brand charisma and how to measure it.

Grounded in existing literature on general charisma, charismatic leadership and consumer-brand relationships, we view strong brands in a similar way to strong leaders in society. Drawing upon this literature, and coupled with findings from an exploratory study of luxury brand consumers, the objective of this paper is to define the conceptual domain of the brand charisma construct and identify its foundational dimensions. All luxury brands have image, symbolism and prestige to some degree, but those with charisma build on these to generate extraordinary levels of buyer attachment and motivation. Charismatic brands are expected to lead to consumer admiration and advocacy, brand resonance, and ultimately result in increased willingness to engage with and consume the brand. Over time, they likely evolve to an iconic status. Our research has the potential to break new ground in academic brand research and specifically in the emerging area of luxury brand management. Given the importance of building sustained brand-consumer relationships, a systematic understanding of brand charisma has the potential to create high impact for scholarship and practice. For luxury brand managers across the delivery channel, insights into the foundations of a charismatic brand personality can help in brand strategy and brand program decisions.

The paper is organized as follows. Acknowledging that brands act as intentional agents (Kervyn, Fiske & Malone, 2012), we first review existing literature on charisma in general and charismatic leadership theory in particular to shed light on the charisma construct. In doing so, we acknowledge recent thinking that people relate to brands similarly to the way they relate to people around them (Hatch & Schultz, 2013; Verčič & Verčič, 2011), and we highlight the importance of understanding brand charisma for building sustained brand-consumer relationships. We then outline our research objectives specific to the conceptual domain and operationalization of brand charisma, and follow this with data collection procedures, sample selection and analytical methods. Finally, we discuss the results of our study, highlighting their exploratory nature. Areas for future research are also discussed, together with the study's limitations.

LITERATURE REVIEW

Brands as Intentional Agents

The idea that consumers' relationships with brands can be characterized in ways that resemble their relationships with people has gained considerable ground in the areas of branding and consumer behavior (Dion & Arnould, 2011; Fournier, 2008). Research on brand perception has shown that consumers not only care about a brand's features and benefits but also about a relationship aspect of brand perception (Fournier, 2008) and an emotional aspect (Shekhar, Dash & Purwar, 2013). Just as individuals have a host of different relationships with the people they interact with, they also have different types of relationships with the brands that have relevance to their lives. As individuals acquire more information through their interactions with others, their perceptions are based more on the relationship (Fiske, 1991). This suggests that over time, consumers will likely base their perception of charisma on their relationship with the brand.

Recent published work suggests that brands act as intentional agents (Kervyn, Fiske & Malone, 2012; MacInnis, 2012). The model of social perception called the Stereotype Content Model (SCM) maps out how people perceive social groups on two dimensions of social perception: warmth and competence, to guide their decisions about and interactions with other people and social groups. Just as people can be characterized in terms of warmth and competence (Fiske, Cuddy & Glick, 2007), so too can brands. Aaker et al. (2010) for example, found that brands that are both competent and warm positively impact purchase intentions. Perceptions of warmth and competence represent cognitive appraisals and result in emotions (feelings of admiration) which subsequently impact purchase behavior.

Brand building for certain extraordinarily successful brands may therefore include aspects of a social process best described as charismatic building. But what is charisma? We now shed light on this concept by first examining literature on the concept of charisma in general. This is followed by a review of charismatic leadership theory and existing instruments for measuring charisma.

The Concept of Charisma

Charisma comes from two Greek roots: (a) *charizesthai*, which means "to favour or to gratify: and (b) *charis*, meaning "gift". A natural starting point for understanding the concept of charisma is the work of Max Weber. Weber (1947) referred to charisma as a widely perceived appeal which transcends ordinary conceptions of reality, while Shils (1965) referred to the quality which is imputed to persons, actions, roles, institutions, symbols, and material objects because of their presumed connection with ultimate, fundamental, vital, or order-determining powers. These definitions imply that charismatics have a kind of aura. Smothers (1993) was the first to propose that brands, as well as people, can have charisma. He defined charisma as "the quality which is imputed to persons, actions, roles, institutions, symbols and material objects because of their presumed connection with ultimate, fundamental, vital, or order-determining powers" (Smothers, 1993, p.100). Following Weber (1947), Smothers (1993) argued that brand charisma is a social construction of the customers who give a brand its legitimacy. If we accept the notion that brands are like people, then it seems logical to identify the kinds of people that generate the highest levels of motivation. According to Smothers (1993), establishing that a brand has charisma amounts to demonstrating it is endowed with exceptional qualities by those it touches. In other words, determining if a brand has charisma means demonstrating it has exceptional qualities as believed by those who consume it (Hatch & Schultz, 2013).

Although Smothers (1993) follows Weber (1947) in assigning responsibility for the social construction of brand charisma to customers, his conceptual definition lacks specificity. We argue that greater clarity of the conceptual domain of brand charisma can be found in

charismatic leadership theory (CLT). In the psychology and management literature, individuals who foster the highest levels of loyalty and motivation among large groups are called charismatic leaders (Avolio, Walumbwa, & Weber, 2009). Charismatic Leadership Theory (CLT) generally takes a leader-driven approach where leader behaviors form the basis of followers' attributions (Conger & Kanungo, 1987; House & Howell, 1992). Drawing upon psychological theory to explain charisma, House (1977) was the first to propose that the basis of charisma is the emotional interaction that occurs between followers and their leaderAccording to House (1977), charismatic leaders display confidence in their own abilities and in their followers, set high expectations for themselves and their followers, and show confidence that these expectations can be achieved. Charismatic leaders are also role models for others, courageous (they challenge the status quo), self-confident, pro-social assertive (dominant and powerful), have moral conviction and are competent. Bass (1985) also describes charisma as the emotional component of leadership which is "used to describe leaders who by the power of their person have profound and extraordinary effects on their followers" (Bass, 1985 p. 35). Bass (1985) argues that charismatic leaders communicate symbolically, use imagery and are persuasive in communicating a vision that promises a better future. Later definitions of charisma suggest that charisma can have both behavioral and attributional components. Avolio, Bass and Jung (1999, p. 444) for example, define charisma as that which "provides followers with a clear sense of purpose that is energizing, is a role model for ethical conduct and builds identification with the leader and his or her articulated vision". Attributional characterizes the attributions of the leader made by followers as a result of how they perceive the leader. Behavioral components focus on the specific behaviors of the leader that followers can observe directly (Avolio, Bass and Jung, 1999).

Leaders with charisma also foster inspiration motivation, express their values by creating a value-laden vision of the future, and express confidence that followers can accomplish their collective objectives (Wilderom, van den Berg & Wiersma, 2012). Other studies suggest that charismatic leaders are guided by altruistic principles and higher cognitive moral development levels (Turner el al., 2002). The charismatic leadership framework of Shamir, House and Arthur (1993) posits that charismatic leaders use messages related to moral values on route to influencing a follower's self-concept, which denotes the totality of an individual's thoughts and feelings with reference to himself or herself as an object (Hong & Zinkhan, 1995). In a similar way, brands can use their vision and mission as a platform to implicate the self-concept of consumers. In this way, it is argued that leading brands can have exceptional effects on consumers, who are motivated by increased levels of self-esteem, self-worth, self-efficacy, identification with the brand and social identification. Just as charismatic leaders affect followers because of motivational mechanisms that are induced by leader behaviors (Shamir, House and Arthur, 1993), brands affect consumers that are induced by the behaviors of the brand.

It is clearly evident that 'charisma' does not represent a singular attribute. Grounded in an extensive study of charismatic leaders, Conger & Kanungo (1998) propose six characteristics to result in such attributions (see Table 1): being visionary, articulate, sensitive to the environments, sensitive to member needs, unconventional, and taking personal risks. The key behaviors in the House (1977) and Shamir, House & Arthur (1993) theories include articulating an appealing vision, emphasizing ideological aspects of the work, communicating high performance expectations, expressing confidence that subordinates can achieve them, showing self-confidence, modeling exemplary behavior, and emphasizing collective identity. Other researchers have further differentiated between the content of the vision and the use of an expressive style to communicate it (Kirkpatrick and Locke, 1996).

The emerging consensus today stresses the dyadic nature of the charismatic relationship (Weierter, 1997; Howell & Shamir, 2005) i.e. charismatic leadership is located in the relationship between the leader and the follower meaning that leaders and followers come together to form a dynamic relationship. This approach puts charismatic leadership in the relationships connecting individuals rather than the attributes of the leader or follower (Balkundi & Kilduff, 2006) i.e. followers will base their perceptions of charismatic leadership on their relationship with the leader (Campbell et al., 2008).

Our systematic review of CLT suggests that charisma is a sociological construct associated with a leader who generates extreme levels of loyalty and motivation among followers. A brand that is charismatic should therefore create a response in its audience or followers that is characterized by extremes of motivation and attachment beyond expectation. CLT tells us that charismatic leaders use communication and image-building strategies to appear powerful and confident (House, 1977). They engage in followers' self-concepts (Shamir, House & Arthur, 1993), they are risk-takers and are unconventional (Conger and Kanungo, 1998; House 1977). They know how to emotionally connect with followers and are good storytellers (Towler, 2003). A charismatic leader is also one who can influence, inspire and motivate their followers (Shamir, House & Arthur 1993; Waldman and Yammarino, 1999). They exude confidence, dominance, energy, a sense of purpose and vision, and the ability to articulate the goals and ideas for which followers are already prepared psychologically (Bass, 1985; Conger & Kanungo,1998; House, 1977). Charismatic leaders are also thought to possess outstanding rhetorical ability (Harvey, 2001).

Table 1: Observable characteristics of charismatic leaders. Adapted from Conger and Kanungo (1998)

Characteristic	**Meaning**
Vision	Inspirational, able to motivate, has vision, often brings up ideas about possibilities for the future, provides inspiring strategic and organizational goals, consistently generates new ideas for the future of the organization
Articulation	Exciting public speaker, skillful performer when presenting to a group
Environmental sensitivity	Readily recognizes constraints in the social, cultural, physical environments and within the organization, recognizes the skills and limitations of other members in the organization, recognizes new opportunities and seizes them to achieve goals
Behavior	Engages in unconventional behavior to achieve organizational goals, uses non-traditional means to achieve organizational goals, often exhibits very unique behavior that surprises other members of the organization
Personal risk	Engages in activities involving personal risk and self-sacrifice, takes high personal risk for the sake of the organization, often incurs high personal costs
Sensitivity to member needs	Shows sensitivity and expresses personal concern for the needs and feelings of members in the organization, influences others by developing mutual liking and respect

Existing instruments for measuring charisma

Despite the concept of charisma being popularized by Weber (1947), the number of scales constructed to measure the concept is sparse and most of these are specific to the context of

leadership. The most widely cited measure for charismatic leadership behavior uses the 20-item Conger-Kanungo charismatic leadership scale. In a series of empirical studies, the Conger-Kanungo measurement scale has undergone testing and validation (Conger & Kanungo, 1992, 1994; Conger et al., 1997). More recently, Verčič & Verčič (2011) have validated a 24-item scale measuring six human charismatic dimensions. Despite these instruments, there is no clarity on the conceptual domain of brand charisma and no instrument for its measurement. Moreover, both instruments are of limited use when measuring brand charisma. Some authors have examined if a human charisma scale can be adapted to measure brand charisma. For example, Lee, Workman & Jung (2015) used 17 of the 24 items from the human charisma scale cited by Verčič & Verčič (2011) to measure brand charisma. Factor analysis identified four dimensions: communicative, powerful and dominant, attractive and honest and reliable. However, the scale lacked content validity assessment, which is a fundamental first step in construct validation of a new measure.

Summary

Despite the obvious breadth of research examining charismatic leadership in the psychology and management literature, research on the concept of charisma and its relationship to brands has remained limited due in part to the lack of consensus regarding what brand charisma really is. The most useful definition of charisma seems to be in terms of attributions of charisma to a leader by followers (consumers) who identify strongly with the leader (the brand). The follower's attribution of charisma thus depends on the observed behavior of the leader. Brand charisma is therefore socially constructed and an observable behavioral process. Charisma is an attribution, and specific characteristics are causally responsible for this attribution. But in brand-consumer relationships, what are the behavioral components responsible for such attributions? Does brand charisma have a set of attributes similar to or different from the attributes identified in theories of charismatic leadership? Given the complexity of the phenomenon, measuring brand charisma is also fraught with problems of construct ambiguity and validity issues. This necessitates research on two major fronts: identifying the behavioral attributes of charismatic brands, and developing valid and reliable measures of such behavioral dimensions for use in future research. The focus of this research is on the former. In the remainder of this article, we present an exploratory study to shed light on the behavioral attributes of charismatic brands (the first objective) and posit a model of the elements or attributes of charisma in brand-consumer relationships for future empirical investigation.

RESEARCH APPROACH

Since the charisma construct has not been well delineated in literature examining consumer-brand relationships, but has been studied extensively in the field of leadership, the study did not follow a purely inductive (grounded theory) approach to data collection (Strauss & Corbin 1994). Rather, its design was largely exploratory to shed light on the domain of the construct within a brand- consumer context (Creswell, 2013). As noted earlier, brand charisma as a brand personality is most likely to resonate with luxury brand consumers because luxury brand-consumer relationships transcend functional relationships (Keller, Parameswaran & Jacob, 2011). To this end, focus-group sessions with 55 luxury brand consumers, were used as the data collection method (Miles & Huberman 1994). Qualitative research in the form of focus groups is a highly suitable research method for exploratory investigation, especially when little is known about a phenomenon. The concept of brand charisma fell into this category. Focus groups also act as a convenient method for interviewing a number of people in situations involving the exploration of complex issues requiring group interaction (Calder, 1977).

Five focus group sessions were conducted, each lasting 50 minutes. All participants were recruited from several postgraduate courses at a leading University in the United Arab Emirates (UAE) and were all identified as consumers of luxury products. The United Arab Emirates is one of the largest and most dynamic economies in the Gulf region with UAE residents' spending on luxury goods reaching more than $8 billion in 2017 (Maceda, 2018). Participants were predominantly female (65%) and ranged in age from 22 to 45.

At the beginning of each focus group session, participants were provided with an operational definition of charisma: “Charisma is the quality which is imputed to persons, actions, roles, institutions, symbols and material objects because of their presumed connection with ultimate, fundamental, vital, or order-determining powers”. Participants were then asked what makes a brand charismatic. In addition participants were asked to identify three charismatic brands (and the reasons why they are charismatic) and three brands that were not charismatic (and the reasons). These questions were designed to guide subsequent group discussion. Following the recommendations of Kidd & Parshall (2000), one of the researchers took on the role of moderator during these discussions. Data were collected via whiteboard summaries as well as written summaries from individuals within each focus group. The whiteboard summaries were digitally photographed. Each group varied between 9-12 individuals following the recommendations of Churchill and Iacobucci (2002) and Fern & Fern (2001). After the fourth focus group, participants were repeating information that had been gleaned from previous groups. The fifth group was thus treated as a final confirmation as no new information surfaced from this group.

The analysis followed the sequence of steps described in Miles & Huberman (1994, p. 10), who "define analysis as consisting of three concurrent flows of activity: data reduction, data display, and conclusion drawing/verification". In the first phase (data reduction), we broke the data down for each focus group into "thought units" (e.g., Gioia & Sims 1986), these thought units ranged from a phrase to several sentences. In the second phase (data display), all of the thought units were organized into emergent categories. Data reduction was undertaken for each of the 5 focus groups, using a list of basic codes devised prior to fieldwork. Subcodes were added to categorize information further within each of the main codes. However, not all codes were pre-specified. Additional insights frequently surfaced during data collection, and analysis, with additional codes emerging as a result. The codes were arranged in the form of 5 within-case displays which took the form of a matrix or a network according to which was most appropriate to the interview being analyzed (Miles & Huberman 1994). The within-case analysis generated insights into what makes a brand charismatic. The within-case displays were then reduced in order to create a conceptually ordered meta-matrix which assembled the descriptive data from each of the within-case displays in a standard format (Miles & Huberman 1994). This was the most inductive phase of the analysis. As much as possible, we allowed the categories to emerge from the data. We then assigned labels to each category in an attempt to capture the shared message of the thought units within it. Disagreements among the researchers regarding the categories (and their labels) were resolved by using a "blind" research assistant not familiar with the charismatic leadership and brand-consumer relationship literatures. This additional researcher was utilized to complete an independent content analysis. Independently derived findings were then compared and contrasted.

FINDINGS

The patterns we observed across all five focus groups and 55 respondents allowed us to draw inferences regarding behaviors that characterize brand charisma from the perspective of luxury brand consumers. These behaviors do not reside naturally in a brand, but in the way the brand is perceived. As noted earlier, we suggest that charisma is an attribution, thus charisma can be

attributed to any ‘persona’ that displays the relevant behavior. Our analysis of the whiteboard and individual summaries, suggests that brand charisma is not a single attribute but manifests itself in 9 different behaviors. Table 2 includes the names of each charismatic behavior, corresponding codes and illustrating examples provided by respondents. In the discussion that follows, we present findings that shed light on the conceptual domain of brand charisma and the behaviors that make luxury brands charismatic as perceived by luxury brand consumers. The number by each code represents the respondent that mentioned the corresponding codes.

Table 2. Meta-Matrix: Brand Charisma Behaviors as perceived by Luxury Brand Consumers

Charismatic Characteristic	Code and Description	Illustration (Examples)
1. Communication	- The brand is expressive with its communication (3, 7, 10, 14, 18, 25, 31, 38, 44, 48, 50, 51) - The brand is enthusiastic with its communications (3, 10, 25, 31, 38, 44, 53) - The brand continuously connects with its customers at an emotional level (2, 4, 8, 9, 14, 15, 25, 31) - The brand is optimistic with its communication (25, 31, 38, 44, 52, 53) - The brand is engaging with its communication (2, 3, 10, 25, 31, 38, 46, 48, 53)	"Cartier is so innovative in its communication" "Apple always has a story to tell. Behind each product, there is a history of what brought it to market. I feel inspired by those stories. It adds inherent value to the brand" "Chanel advertising always uses charismatic celebrities to communicate its message, those who are in the limelight like Natalie Portman after the Thor 2 success" "Fossil does not significantly differentiate itself in the way it expresses itself to consumers" "Fossil's communication doesn't inspire and excite. It is such a boring brand" "Michael Kors advertising involves relatable pictures which viewers can connect with" "I love the Louis Vuitton core values ads. They really connect with me at an emotional level" "Brand like Chanel, Hermés, Louis Vuitton and Gucci express themselves so beautifully and elegantly. They are so engaging"
2 Admiration and inspiration	- The brand is magical (7, 8, 14, 17, 22, 27, 35, 41) - The brand attracts great admiration (1, 2, 3, 6, 8, 9, 12, 13, 15, 16, 22, 25, 28, 29, 31, 36, 40, 42, 48, 52, 55) - The brand easily grabs/attracts my attention (12, 14, 15, 16, 19, 48) - The brand has significant positive influence on other people (1, 4, 7, 10, 12, 15, 18, 24) - The brand is inspirational (1, 2, 8, 9, 12, 13, 15, 16, 22, 25, 28, 29, 31, 36, 40, 42, 43, 52, 55) - The brand has my respect (2, 8, 9, 12, 13, 15, 16, 22, 28, 29, 31, 36, 40, 42, 43, 52, 55) - The brand is passionate (5, 29, 44, 53) - The brand has something special (10,12, 13, 23, 2, 30,46) - The brand is highly talked about by others (1, 2, 4, 6, 8, 9, 12, 13, 15, 16, 22, 25, 28, 29, 31, 36, 40, 42, 43, 52, 55) - The brand is a role model (8, 9, 12, 13, 15, 16, 22, 25, 28, 29, 31, 36, 40, 42, 49)	"Chanel is a charismatic brand because it is highly attractive and influences people in a positive way" "Audi is my favourite car brand, it promises for the future and inspires youth to become future successful businessmen" "Ferrari is such an inspirational brand. It is so magical and has a rare character which demands so much respect" "Emirates has a personality that you admire in a way; you don't feel the same way when you fly the other companies. It certainly has my respect!" "Aston Martin has a sense of heritage, and a certain sense of mystique and unattainability. It has something so special that no other luxury car has" "People gain so much respect and admiration from others when they own a Rolex" "Chanel influences people in such a positive way" "Mont Blanc has an image of being influential" "I am so envious of those people who can buy Chanel" "Louis Vuitton is such a passionate brand. Their stores stands out so much. It is a role model for all other luxury fashion brands" "The same brands I referred to earlier [Chanel, Hermés, Louis Vuitton and Gucci] are talked about by so many different people, many of whom will never be able to afford to buy them"
3. Honesty and reliability	- The brand is reliable (9, 15, 16, 22, 25, 31, 39) - The brand is a highly trusted one (4, 13, 19, 25, 31, 52) - The brand is honest (15, 16, 19, 25, 31, 51, 52, 55)	"Apple is popular, reliable and trustworthy and these traits are reflected in its personality" "Emirates is a trusted and reliable brand and renowned for its quality service" "Many luxury brands today recognize the importance of being honest and transparent when it comes to reporting. The Kering Group is a good

	- The brand is sincere (9, 11, 15, 19, 22, 26, 34, 36, 41)	example of this. The Chalhoub Group in the Middle East are also transparent in what they report about sustainability" "I feel that Chanel has so much sincerity in what it does. There is nothing pretentious about the brand. It really believes in what it is doing"
4. Attraction	- The brand is magnetically attractive (1, 3, 7, 10, 11, 13, 14, 21, 23, 46, 50, 51) - The brand is charming (1, 7, 8, 14, 15, 26, 33, 34, 36, 44, 45, 47, 50, 52, 53) - The brand is very appealing (2, 6, 8, 12, 28, 49, 50) - The brand is beautiful (2, 6, 7, 8, 11, 16, 22, 34) - The brand is elegant (2, 6, 7, 8, 11, 16, 34, 44, 47, 50, 52) - The brand is trendy (6, 7, 21, 27) - The brand is sophisticated (2, 8, 12, 26) - The brand has style (6, 7, 21, 27) - The brand stands out (1, 3, 7, 10, 11, 13, 14, 21, 23, 46, 49, 50, 51, 54) - The brand attracts but is not ostentatious (3, 7, 10, 11, 13, 14, 21, 23, 46, 47, 50) - The brand is classy (2, 8, 12, 26, 47)	"Charisa is like having a charm or an attractive character that people can relate to. Louis Vuitton is a good example" "Chanel is synonymous with beauty" "Omega is so attractive" "Patek Philippe is so sophisticated and stylish. The brand charms potential buyers" "The name of the Hermés brand speaks for itself and attracts people to it" "Hugo Boss is depicted as a brand for men who are extremely stylish, confident, appealing and have strong personalities: "Chanel is an incredibly seductive and attractive brand" "D&G is so appealing" "Chanel has so much charm and appeal" "Michael Kors doesn't charm me and the designs are boring" "The complete feeling of wearing Chanel is charismatic in itself" "The look, the feel of being in it and how people envy you when you drive a Jaguar; it's all about class, confidence and beauty" "Ralph Lauren offers specific quality products that showcase style and prestige" "Roberto Cavali has a different character to other brands. It is so classical and gives out so much aura" "Rolls Royce is such a classy brand" "You will always think about a Porsche driver in a specific way that they are unique and elegant in choice" "Chopard shows sophistication in status and speaks for itself. The fact that it attracts buyers of a certain type of social status makes it charismatic" "I see Tiffany & Co as a simple, elegant and classy brand and these things make the brand charismatic"
5. Visionary	- The brand has a vision for the future (1, 2, 8, 9, 12, 13, 15, 16, 22, 25, 28, 29, 31, 36, 40, 42, 43, 52, 55) - The brand has lots of positive energy (2, 8, 9, 10, 12, 13, 15, 16, 22, 25, 28, 29, 31, 36, 40, 42, 43, 47) - The brand consistently generates new ideas for the future (1, 2, 8, 9, 12, 13, 15, 16, 22, 25, 28, 29, 31, 36, 40, 42, 43, 52, 53, 55) - The brand is dynamic (2, 8, 9, 10, 12, 13, 15, 16, 22, 25, 28, 29, 31, 36, 40, 42, 43, 47) - The brand is outgoing (2, 8, 9, 10, 12, 13, 15, 16, 18, 22, 25, 28, 29, 31, 36, 40, 42, 43, 47, 49) - The brand is innovative (1, 2, 8, 9, 13, 15, 16, 22, 25, 28, 29, 31, 36, 40, 43, 52, 53, 55) - The brand is exciting (2, 8, 9, 10, 12, 13, 15, 16, 22, 25, 28, 29, 31, 36, 40, 42, 43, 45, 47) - The brand is ambitious (2, 8, 9, 10, 12, 13, 15, 16, 18, 22, 25,	"Apple has a vision for the future and is innovative, which by default makes it unique and ambitious and risky" "L'Oréal is spontaneous and has so much energy. They keep launching new products every so frequently, getting celebrities to endorse their products, and improving their products. All of this keeps me on my toes, interested, and makes me want to purchase new products as they come out" "Apple's personality is so open. They always brings something new to the moment" "Apple is a great example of radical and incremental innovation" "Mango is not visionary because if follows change and does not innovate" "Tesla is such an exciting and dynamic brand. It is disrupting the car market and is so ambitious" "Take Chanel for example. It creates trends and shapes the future"

	28, 29, 31, 36, 40, 42, 43, 47, 49) - The brand is a creator of trends (17, 23, 46, 48)	
6. Powerful and dominant	- The brand is bold (2, 8, 12) - The brand is strong (2, 8, 12, 21, 27, 28, 35) - The brand is controlling (8, 12, 19, 21, 27, 28, 35) - The brand exuberates power (7, 12, 14, 21, 28, 28, 35) - The brand displays confidence (2, 6, 11, 17, 18) - The brand is a market leader (4, 19, 25, 35) - The brand is assertive (1, 2, 8, 12, 18) - The brand is a benchmark for all (4, 6, 7, 12, 22, 25, 38, 39) - The brand is influential (1, 2, 4, 8, 19, 25, 35) - The brand is not a follower (46) - The brand is fearless and daring (2, 8, 12, 27, 35, 36)	"Apple changes the lifestyles of consumers. Also, it is a role model or a benchmark which forces other companies to follow" "Aston Martin has charisma because it is bold and powerful" "Mont Blanc is strong and unique" "Humer significantly differentiates itself from all other competitors and does not follow market trends' "Fossil is a follower of market trends and does not create new ideas" "Fendi copies all other brands. For example the shape of the bags and colours" "Rolls Royce is so powerful; it the benchmark for the luxury car industry" "Brands such as Chanel Rolls Royce fear nobody. They are so daring"
7. Sensitive to the environment	- The brand models ethical standards (4, 6, 7, 12, 18, 22, 25, 28, 38, 39) - The brand considers what is moral/ethical (4, 6, 7, 9, 12, 18, 22, 25, 28, 38, 39, 41) - The brand goes beyond company self-interest (28, 35) - The brand raises awareness of important environmental issues and takes corresponding action (2, 3, 6, 7, 9, 10, 12, 18, 21, 22, 25, 28, 38, 39, 41, 46, 48, 52)	"de Grisogono follows a notable cause, breast cancer, it appeals to me because I can relate to its main purpose" "I know that brands such as Prada, Chanel, Hermés, L'Oréal and Louis Vuitton stand out in terms of their ethical and environmental performance" "If you take expensive fashion clothes, do they always come with a guarantee of ethical standards when it comes to producing them? I mean luxury fashion brands you always more for the clothing you but, but those people on the production lines and in the cotton fields, are they automatically paid more? I don't believe so, this behavior is not right. I often think that it is about higher profits for these brands" "I read a study a few months ago that says that climate change will have a big negative effect on raw materials used in luxury and this is going to have a pretty big impact on those communities that are farming these materials" "Luxury jewelry brands such as Chopard and Tiffany & Co now used stones that are ethically mined and they also recycle gold and silver and work with ecologically conscious mines. They are acknowledging the importance of sustainability through these actions"
8. Displays unconventional behaviour	- The brand engages in unconventional behavior to achieve its goals (9, 15, 16, 26, 27, 30, 34, 42) - The brand is outspoken (15, 16, 26, 27, 30, 34, 42) - The brand achieves its goals by non-traditional means (9, 15, 16, 26, 27, 30, 34, 42) - The brand is known for its provocative/controversial behavior (6, 9, 11, 13, 15, 16, 26, 27, 30, 34, 42, 45, 46) - The brand surprises customers (7, 15, 16, 26, 27, 30, 35, 48)	"A Charismatic brand is one that surprises you with things that you don't expect" "Apple's vision for innovation makes it risky and unconventional" "Desigual, the Spanish brand has charisma because its controversial ads capture a lot of attention. I like this behavior because it breaks from the norm" "Last year I bought a Tudor luxury watch. I know that these guys always push the envelope and use celebrities that are totally unconventional such as Lady Gaga, I love this approach" "I love Tom Ford because it is so provocative. It has a stunning, sexy sleek style" "Last year I came across an Yves Saint Laurent ad which was so controversial and provocative. The ad showed a model in fishnet stockings and a fur coat I think spreading her legs and wearing roller skate high-heels"

9. Associated with a strong leader (existing or former)	- The CEO/creative director insists on his/her own values and does not give them up easily (4, 6, 11, 13, 15, 19, 28) - The CEO/creative director has extraordinary leadership and communication skills (4, 6, 11, 13, 15, 23, 29, 30, 37) - The CEO/creative director is inspiring and energizing (4, 5, 6, 11, 13, 15, 19, 28)	"A charismatic brand is synonymous with great leadership. Steve Jobs is the perfect example. He always stood by his principles and own set of values" "Karl Lagerfeld is such an iconic person. He is such an inspirational designer for Chanel" "I was saddened to see Christopher bailey step down as the inspirational CEO of Burberry last year. He transformed Burberry into an iconic brand and was the first person to push the use of social media in the marketing and selling of luxury".

Behavior 1: Communication

Respondents in all five focus groups described the nature of the brand's communication as a vehicle to legitimize brand charisma. This behavior describes communications messages reflecting articulation, expressiveness, and formulated in an eloquent way. For example, respondent 7 in focus group 1 stated: "Brand like Chanel, Hermes, Louis Vuitton and Gucci express themselves so beautifully and elegantly. They are so engaging". Respondents made similar statements from focus groups 2, 3, 4 and 5. For example, respondent 15 from focus group 2 stated: "I love the Louis Vuitton core values ads. They really connect with me at an emotional level". These illustrations clearly show that charismatic brands demonstrate highly expressive communication, which is articulate in nature as well as elegant. The importance of being viewed as a highly expressive and articulate brand was further reinforced by the widespread use of storytelling as a communications tool. As stated by respondent 44 in focus group 4: "Apple always has a story to tell. Behind each product, there is a history of what brought it to market. I feel inspired by those stories. It adds inherent value to the brand".

Behavior 2: Admiration and inspiration

Brands that elicit great admiration, draw attention easily, and inspire were also described by respondents across the 5 focus groups. We labeled this behavior 'admiration and inspiration' to encompass a set of behaviors that include both inspiration to others and drawing attention and admiration. For example, respondent 8 in focus group 1 stated "Chanel is a charismatic brand because it is highly attractive and influences people in a positive way". Similarly, respondent 22 in focus group 3 stated: "Ferrari is such an inspirational brand. It is so magical and has a rare character which demands so much respect". These findings are consistent with existing research (Dion & Arnould, 2011) which contends that luxury retail draws on the principles of art and magic to assemble the charismatic persona of the creative director and to diffuse his/her aesthetic ideology to the brand. Moreover, luxury retail strategy enlists magical and aesthetic principles within and without the store to achieve these ends.

Behavior 3: Honesty and reliability

Brands that are honest and reliable were also identified by respondents. Respondents across all 5 focus groups made reference to qualities such as reliability, trustworthy, honesty, and sincerity. For example, respondent 19 in focus group 2 stated: "I feel that Chanel has so much sincerity in what it does. There is nothing pretentious about the brand. It really believes in what it is doing", while respondent 36 in focus group 4 stated: "Many luxury brands today recognize the importance of being honest and transparent when it comes to reporting. The Kerring Group

is a good example of this. The Chalhoub Group, as a major distributor and retailer of luxury in the Middle East are also transparent in what they report about sustainability".

Behavior 4: Attraction

The fourth charismatic behavior identified by respondents revolved around expressions of attractiveness. An attractive brand is one that is magnetically attractive, charming, appealing, beautiful, elegant, sophisticated and classy. For example, respondent 7 in focus group 1 stated "Charisma is like having a charm or an attractive character that people can relate to. Louis Vuitton is a good example", while respondent 34 from focus group 3 stated: "Chanel is synonymous with beauty". Respondents made similar comments from the other focus groups. For example, respondent 12 from focus group 2 stated: "Patek Philippe is so sophisticated and stylish. The brand charms potential buyers", while respondent 47 from focus group 5 stated: "I see Tiffany & Co as a simple, elegant and classy brand and these things make the brand charismatic".

Behavior 5: Visionary

Respondents in all five focus groups also described the importance of being visionary as a vehicle to legitimize brand charisma. This behavior reflects whether the brand has a vision for the future, has positive energy, focuses on unexploited and futuristic opportunities, and is dynamic, outgoing and ambitious in nature. For example, respondent 22 in focus group 3 stated: "Tesla is such an exciting and dynamic brand. It is disrupting the car market and is so ambitious", while respondent 48 in focus group 5 stated: "Take Chanel for example. It creates trends and shapes the future". These findings suggest that charismatic brands are perceived to be "visionary' in their outlook and behavior and stand out as model examples for other organizations. Being visionary clearly says something about the brands strength of character and the will to achieve this vision.

Behavior 6: Powerful and dominant

Respondents across all 5 focus groups made reference to qualities such as strong, controlling, confidence, assertive, influential, market leadership, a benchmark for all and audaciousness. We labelled this behavior 'powerful and dominant'. For example, respondent 4 in focus group 1 stated: "Apple changes the lifestyles of consumers. Also, it is a role model or a benchmark which forces other companies to follow", while respondent 28 in focus group 3 stated: "Aston Martin has charisma because it is bold and powerful". Similarly, respondent 36 in focus group 4 stated: "Brands such as Chanel Rolls Royce fear nobody. They are so daring".

Behavior 7: Sensitive to the environment

Respondents across several focus groups also described brand charisma in terms of sensitivity to the environment. This behavior characterizes the ability of the brand to adapt to environmental changes and revolves around whether the brand models ethical standards, goes beyond company self-interest and raises awareness and takes action on important environmental issues. For example, respondent 12 in focus group 2 stated: "If you take expensive fashion clothes, do they always come with a guarantee of ethical standards when it comes to producing them? I mean luxury fashion brands you always more for the clothing you but, but those people on the production lines and in the cotton fields, are they automatically paid more? I don't believe so, this behavior is not right. I often think that it is about higher profits for these brands", while respondent 21 in focus group 3 stated: "Luxury jewelry brands such as Chopard and Tiffany & Co now used stones that are ethically mined and they also

recycle gold and silver and work with ecologically conscious mines. They are acknowledging the importance of sustainability through these actions".

Behavior 8: Displays unconventional behavior

The eighth behavior to emerge from our data analyses was unconventional behavior. This behavior encompasses being outspoken, achieving goals by non-traditional means, and exhibiting provocative/controversial behavior. For example, respondent 26 in focus group 3 stated: "Desigual, the Spanish brand has charisma because its controversial ads capture a lot of attention. I like this behavior because it breaks from the norm", while respondent 15 in focus group 2 stated: "Last year I bought a Tudor luxury watch. I know that these guys always push the envelope and use celebrities that are totally unconventional such as Lady Gaga, I love this approach". Similarly, respondent 6 in focus group 1 stated: "Last year I came across an Yves Saint Laurent ad which was so controversial and provocative. The ad showed a model in fishnet stockings and a fur coat I think spreading her legs and wearing roller skate high-heels". These findings highlight the importance of doing things that other brands do not, and doing them in a way that is perceived as unique and different, and not following conventional methods of operation.

Behavior 9: Association with a strong leader/creative director

The final behavior to emerge from our data analyses described behaviors associated with strong leadership. For example, respondent 4 in focus group 1 stated: "A charismatic brand is synonymous with great leadership. Steve Jobs is the perfect example. He always stood by his principles and own set of values". Similarly, respondent 15 in focus group 2 stated: "I was saddened to see Christopher bailey step down as CEO of Burberry last year. He transformed Burberry into an iconic brand and was the first person to push the use of social media in the marketing and selling of luxury". Our findings are consistent with luxury research (Dion & Arnould, 2011) which contends that luxury draws on the principles of art and magic to assemble the charismatic persona of the CEO/creative director and to diffuse his/her aesthetic ideology to the brand.

DISCUSSION AND IMPLICATIONS

Acknowledging that little is known about the conceptual domain of brand charisma and the behaviors associated with its legitimization, the objective of the current study was to identify the behavioral attributes of charismatic luxury brands. Determining if a brand has charisma means demonstrating it has exceptional qualities as believed by those who consume and interact with the brand (Smothers, 1993). Although existing research on brand charisma assigns responsibility for the social construction of brand charisma to customers (Lee, Workman and Jung, 2015; Smothers, 1993), the charismatic behaviors that give a brand its legitimacy lack specificity. The results of the current study demonstrate the importance of nine core behaviors as perceived by luxury brand consumers and support a multidimensional conceptualization of the brand charisma construct. Drawing upon Conger and Kanungo's (1998) attribution theory, our findings show that brand charisma represents consumer perceptions of the brand in terms of whether it is expressive in its communication, admired and inspires, honest and reliable, attractive, visionary, powerful, sensitive to the environment, unconventional in its behavior, and lead by a strong inspirational leader. Although Lee, Workman and Jung (2015) claim to provide a valid and generalizable scale to measure brand charisma using items adapted from the human charisma scale of Verčič and Verčič (2011), concerns regarding the content validity of the scale exist. Our findings demonstrate a broader set of charismatic behaviors than the four

behaviors identified by Lee, Workman and Jung (2015). Moreover, these behaviors stretch well beyond the power and influence of charismatic corporate leaders/creative directors.

These nine behaviors form a constellation of components or dimensions of brand charisma. It is possible that different luxury brands can be seen as equally charismatic, yet their underlying charismatic structure has different behavioral configurations. We argue that the different behavioral attributes lend themselves to formative measurement using a first-order formative second-order reflective measurement model. First-order reflective measurement assumes that such core behaviors are reflective in nature i.e., the behavioral attributes are viewed as affected by the same underlying concept. However, we suggest that measuring brand charisma in this way is inappropriate. Brand charisma is formed from combining different behaviors, suggesting that the multi-dimensional and multifaceted nature of the construct can be specified as a summative index. Measuring brand charisma formatively means that the observation of one type of behavior does not imply the existence of other types of behaviors.

The insights generated in this study will be useful to practitioners in developing a better understanding of the behaviors that legitimize brand charisma. As noted earlier, charisma is an attribution, and specific characteristics are causally responsible for this attribution. Acknowledging that brand charisma is a key driver of healthy brand-customer relationships, our findings provide the managers with a bird's eye view of the behaviors responsible for such attributions.

LIMITATIONS AND DIRECTIONS FOR FUTURE RESEARCH

Given that the focus of this study was explicitly on obtaining insights rather than testing theory, depth of understanding rather than generalization was the prime concern (Miles and Huberman 1994). We acknowledge that are findings are exploratory in nature. However, without strong qualitative insights to understand the behaviors associated with brand charisma as perceived by consumers, marketers lack the foundation to better understand how consumers develop relationships with brands. Our research has several limitations. First, the study was conducted only in one context (luxury branding) and one country (United Arab Emirates). The findings of this study should be replicated in other contexts and countries. Second, although the current study advances theoretical understanding of the conceptual domain of brand charisma, it does not present and empirically validate an instrument to measure the construct. Given the increasing importance of emotional and transformative brand values in luxury branding, there is a need to develop a measurement instrument for managers to better gauge customer perceptions of brand charisma. Future research should therefore focus on the development of a valid and reliable measurement scale. The results of this exploratory study have identified an initial pool of potential items to measure brand charisma, which can be used in a future quantitative investigation of the brand charisma concept. Content and face validity checks are obvious next steps followed by rigorous psychometric analysis undertake using survey data from a sample of brand consumers. Future research should also examine how behavioral configurations differ across brands and how these configurations affect relationships between brands and their customers. Finally, we acknowledge that brand charisma is not a characteristic uniquely attributed for luxury brands. Future research should establish of the behavioral configurations identified in the current study have relevance to brands that have more mass appeal.

ABSTRACT

We propose a bi-objective model to analyze the satisfaction for relief supplies at the minimal cost for a humanitarian operation. We use different modes of transportation for distribution and satisfaction scoring in terms of met and unmet demand. We also consider constraints on transportation supply due to the disaster. The model is applied to the data on relief distribution missions after May 2015 earthquake in Nepal.

KEYWORDS: Humanitarian logistics, relief distribution, decision making, transport capacity

INTRODUCTION

Relief supply after the disaster is extremely challenging due to the dynamically changing disaster situation and the demand for relief supplies. This situation has been witnessed mostly in large-scale disasters. Demand can change due to the identification of new disaster places or the changes obtained through the reassessment of the disaster area. Similarly, the relief supplies may arrive but the distribution of those supplies may be constrained due to the limited capacity or inaccessibility of the disaster locations. That means there are concurrent changes in supply capacity and demand situations. Alternate transportation might also have to be considered for urgent supplies in order to meet the relief demand in some inaccessible areas. Even if there may be no direct and immediate costs accounted for relief supplies through these modes, there would still be some costs due to the allocation of these resources.

The research considers two objectives: one, to meet the expected demand, and; two, to reduce the direct cost of immediate operation by considering the information on available transport options (mode and route) and the demand in different locations. The main contribution of the paper is the consideration of the two objectives by considering alternative distribution methods and maximizing satisfaction through the reduction of unmet demand. The model provides the opportunity to provide a better distribution option for relief supplies.

LITERATURE REVIEW

Comprehensive reviews of optimization models in humanitarian logistics are given in Canhuye

et al (2012) and Özdamar et al (2015). Some essential features that should be considered for the satisfaction of victims through deprivation costs are given in Holguin-Veras et al (2012, 2013). The notion of deprivation cost is analyzed in more detail by Gutjahr and Fischer (2018), who show that the deprivation cost increases exponentially to a higher level when the response materials are not sent to the victims on time. The authors mention that the smaller the time range of distribution frequency, the smaller would be the deprivation time. However, this also depends on the type of relief supplies. For food supplies, the deprivation would be much higher compared to that for the non-food items for the same distribution frequency.

Most previous literature (Özdamar et al., 2004 and Yi and Özdamar, 2007, Özdamar, 2011, Rottkemper et al., 2012) in relief planning propose single-objective dynamic models considering serviceability. Serviceability in these studies is considered mainly in terms of minimizing the time and maximizing the supply reach.

Özdamar et al. (2004) and Yi and Özdamar et al. (2007) maximize the serviceability minimizing unmet demand. Both of these studies focus on vehicle routing and scheduling. Özdamar (2011) focuses on the air transportation of the resources and propose a model for dynamic scheduling of the helicopters. The aim is to minimize the total mission time which is the sum of the flight time and loading and unloading time.

Facilities location models have also been developed by different authors. Vahdani et al. (2018) Boonmee et al (2017), Baskaya et al. (2017) and Khayal et al. (2015) have proposed different location and allocation models by considering different aspects of relief distribution. Balcik et al (2010), on the other hand also mention the need for a coordinated distribution of emergency logistics.

Rottkemper et al., (2012) considers a part of uncertain demands that may appear in the resource planning. The model considers the land-based distribution of the resources and minimizes the sum of the transportation, holding and the penalty cost of unsatisfied demands.

Several multi-objective models have also been proposed. Tzeng et al. (2007) discuss the multi-objective model with three objectives of cost, response time and distribution fairness. The cost objective includes setup and operational costs of transfer depots and distribution of relief resources. The response time objective includes the travel time between the resources collection points, transfer depots and demand centers. The distribution fairness objective includes the maximization of satisfaction in distribution fairness by considering a weighted score for the satisfaction value for each relief supply item in different planning periods. The multi-objective model proposed by Gralla, Goentzel, and Fine (2014) has similar objectives.

Nikoo et al. (2018) propose a transportation network design model with three objectives as well: minimizing the length of the network for distribution, minimization of the total time required for distribution, and the minimization of the number of routes. Their objective function is focused mainly on network design. The authors also consider some kind of prioritization of the objectives by giving more weightage to the goal of reaching to the victims. The objectives are analyzed as single objectives and with weights assigned to different functions.

Cao et al. (2018) also consider a multiobjective model for relief distribution. The authors consider the maximization of the perception of satisfaction on relief supplies, minimization of the satisfaction deviation at any two distribution centers, and the minimization of the perceptual satisfaction by considering the relief response period. In essence, the model considers satisfaction in different aspects in order to develop a relief supply model.

The review shows that the current research in response planning overlooks the capacity limitations in response phase and availability of the limited numbers of helicopters availability. We present a response planning model which considers resource distribution with mixed transportation modes (land and air) to maximize utilization of the available number of helicopters. We also consider satisfaction level of the victims so that it can be maximized for the distribution of resources in far-flung areas as well by considering satisfied and unsatisfied

demand. Therefore, the proposed model is different compared to what has been presented so far in the literature. We consider the actual disaster situation in Nepal's earthquake and propose a network structure which could maximize supply reach to the disaster regions with available transportation capacity. The model is solved through simultaneous (joint optimization) of both objectives.

MODEL AND SOLUTION METHODOLOGY

In order to develop the model, we consider the distribution of, $\boldsymbol{K}$ set of commodities, $\boldsymbol{K_1} = \{\boldsymbol{1}, \ldots, \boldsymbol{k_1}\}$ referring to food commodities and $\boldsymbol{K_2} = \{\boldsymbol{k_1} + \boldsymbol{1}, \ldots, \boldsymbol{k_1} + \boldsymbol{k_2}\}$, referring to non-food commodities. We consider the planning horizon with $\boldsymbol{\mathcal{T}}$ number of short distribution periods *t.* We consider $\boldsymbol{\mathcal{C}}$ as collection points and $\boldsymbol{\mathcal{D}}$ as demand area (or a region) and $\boldsymbol{A_d}$ as demand points in $\boldsymbol{\mathcal{D}}$. Then supplies collected at a location in a period can be considered as S^{kt}_c. We consider vehicle types $\boldsymbol{\mathcal{V}}$ that may consider a set of helicopter $\boldsymbol{L_d}$trucks types, and vehicles $\boldsymbol{\mathcal{V}_{ad}}$ that are able to access a particular demand location in the disaster area $\boldsymbol{\mathcal{D}}$. Food demand is represented per period as D^{kt}_{ad} and non-food demand is represented only for the beginning of response time, as D^{0k}_{ad}. We assume the maximum number of trucks rented varies over the time, N^{0t}_{cv} and N^{t}_{dv}. Helicopters of different types available are H^{t}_{v}.

Table 1: Notations used in modeling

Symbol	Description
Parameters:	
$\boldsymbol{D_{ad}^{kt}}$	Periodic demand for food commodity *k* at ADP *a* of DB *d* in period *t*
$\boldsymbol{D_{ad}^{0k}}$	One time demand for non-food commodity *k* at ADP *a* of DB *d*
$\boldsymbol{S_c^{kt}}$	Commodity *k* collected at CP *c* in period *t*
$\boldsymbol{V_c^0}$	Inventory holding capacity at CP *c*
$\boldsymbol{V_d^1}$	Inventory holding capacity at DP
$\boldsymbol{V_{ad}^2}$	Inventory holding capacity at ADP *a* of DB *d*
$\boldsymbol{Q_v}$	The capacity of the vehicle of type *v*
$\boldsymbol{N_{cv}^{0t}}$	Maximum number of trucks of type *v* that can be rented at CP *c* in period *t*
$\boldsymbol{N_{dv}^{t}}$	Maximum number of trucks of type *v* that can be rented at DB *d* in period *t*
$\boldsymbol{H_v^t}$	Number of available helicopters of type *v* in period *t*
$\boldsymbol{HT_v}$	Maximum number of trips possible from a helicopter of type *v* within the length of a time period
$\boldsymbol{T_{cdv}^{0t}}$	Cost of transportation from CP *c* to DP *d* in period *t* using a truck of type *v*
$\boldsymbol{T_{dav}^{t}}$	Cost of transportation from DB *d* to its ADP *a* in period *t* using vehicle of type *v*
$\boldsymbol{F}$	The fixed cost of allocating a helicopter to a DB
$\boldsymbol{H^0}$	Unit inventory holding cost at CPs
$\boldsymbol{H^1}$	Unit inventory holding cost at DBs
$\boldsymbol{H^2}$	Unit inventory holding cost at ADPs
Variables:	
$\boldsymbol{g_{dav}^{kt}}$	Amount of commodity *k* distributed from DB *d* to its ADP *a* using vehicles of type *v* in period *t*
$\boldsymbol{\delta_{ad}^{kt}}$	Net demand for commodity *k* at ADP *a* of DB *d* in period *t*

	$= D_{ad}^{kt}$ for $k \in \mathcal{K}_1$
	$D_{ad}^{0k} - \sum_{n\in\mathcal{T}, n<t} \sum_{v\in\mathcal{V}} g_{dav}^{kn}$ for $k \in \mathcal{K}_2$
h_c^{0kt}	Inventory of commodity *k* at CP *c* in period *t*
h_d^{1kt}	Inventory of commodity *k* at DB *d* in period *t*
h_{ad}^{2kt}	Inventory of food commodity *k* at ADP *a* of DB *d* in period *t*
u_{ad}^{kt}	Unsatisfied demand for food commodity *k* at ADP *a* of DB *d* in period *t*
u_{ad}^{0k}	Unsatisfied demand for non-food commodity *k* at ADP *a* of DB *d* by the end of the time periods $= D_{ad}^{0k} - \sum_{t\in\mathcal{T}} \sum_{v\in\mathcal{V}} g_{dav}^{kt}$
s_{ad}^{kt}	Satisfaction score for food commodity *k* at ADP *a* of DB *d* in period *t* $= (D_{ad}^{kt} - u_{ad}^{kt})/D_{ad}^{kt}$
s_{ad}^{0k}	Satisfaction score for non-food commodity *k* at ADP *a* of DB *d* by the end of the time periods $= (D_{ad}^{0k} - u_{ad}^{0k})/D_{ad}^{0k}$

x^t_{cdv} is the number of trucks of type-*v* (having capacity Q_v) traveling from C to D in period *t*. A set of truck types that can access a D, *is* $\mathcal{L}_d$. r^{kt}_{cdv} represents the amount of commodity-*k* carried by x^t_{cdv} with the number of trips as y^t_{dav}. Similar to DBs, ADPs are also required to be serviced by specific types of vehicle. Therefore, we identify a set of vehicle types, which includes both the truck types and the helicopter types that can reach to ADP-*a* of DB-*d* represented by $\mathcal{V}_{ad}$. The number of trips of vehicles of type-*v* from DB-*d* to ADP-*a* in period *t* represented by y^t_{dav}; and its value is equal to 0 for all those vehicle types that are not in $\mathcal{V}_{ad}$. The number of helicopters trips z^t_{dv} is restricted by H^t_v trips that it can make. Each helicopter of type-*v* can make a maximum of HT_v trips. Therefore, y^t_{dav} for helicopters depends on the maximum number of trips possible by z^t_{dv}.

We assume that satisfaction is measured with a score based on the proportion of demand satisfied. The satisfaction score $s_{ad}^{kt} = (D_{ad}^{kt} - u_{ad}^{kt})/D_{ad}^{kt}$ for food commodity as no delays are allowed. For non-food commodity, s_{ad}^{0k} depends on the unsatisfied demand of the commodity at the ADP by the end of the distribution periods represented by u_{ad}^{0k}.

The relief distribution model is formulated as follows:

$$f_1 = \min \sum_{t\in\mathcal{T}} \sum_{c\in\mathcal{C}} \sum_{d\in\mathcal{D}} \sum_{v\in\mathcal{L}} T_{cdv}^{0t} x_{cdv}^t + \sum_{t\in\mathcal{T}} \sum_{d\in\mathcal{D}} \sum_{a\in\mathcal{A}_d} \sum_{v\in\mathcal{V}} T_{dav}^t y_{dav}^t + \sum_{t\in\mathcal{T}} \sum_{d\in\mathcal{D}} \sum_{v\in\mathcal{H}} F z_{dv}^t + \sum_{t\in\mathcal{T}} \sum_{k\in\mathcal{K}} \sum_{c\in\mathcal{C}} H^0 h_c^{0kt} + \sum_{t\in\mathcal{T}} \sum_{k\in\mathcal{K}} \sum_{d\in\mathcal{D}} H^1 h_d^{1kt} + \sum_{t\in\mathcal{T}} \sum_{k\in\mathcal{K}_1} \sum_{d\in\mathcal{D}} \sum_{\epsilon\mathcal{A}_d} H^2 h_{ad}^{2kt} \quad (1)$$

$$f_2 = \max \sum_{t\in\mathcal{T}} \sum_{d\in\mathcal{D}} \sum_{a\in\mathcal{A}_d} \sum_{k\in\mathcal{K}_1} s_{ad}^{kt} + \sum_{d\in\mathcal{D}} \sum_{a\in\mathcal{A}_d} \sum_{k\in\mathcal{K}_2} s_{ad}^{0k} \quad (2)$$

subject to

$$\sum_{d\in\mathcal{D}} x_{cdv}^{t} \le N_{cv}^{0t} \qquad \forall c\in\mathcal{C}, v\in\mathcal{L}, t\in\mathcal{T} \qquad (3)$$

$$\sum_{a\in\mathcal{A}_d} y_{dav}^{t} \le N_{dv}^{t} \qquad \forall d\in\mathcal{D}, v\in\mathcal{L}, t\in\mathcal{T} \qquad (4)$$

$$\sum_{d\in\mathcal{D}} z_{dv}^{t} \le H_{v}^{t} \qquad \forall v\in\mathcal{H}, t\in\mathcal{T} \qquad (5)$$

$$\sum_{a\in\mathcal{A}_d} y_{dav}^{t} \le HT_{v} z_{dv}^{t} \qquad \forall d\in\mathcal{D}, v\in\mathcal{H}, t\in\mathcal{T} \qquad (6)$$

$$\sum_{k\in\mathcal{K}} r_{cdv}^{kt} \le Q_{v} x_{cdv}^{t} \qquad \forall c\in\mathcal{C}, d\in\mathcal{D}, v\in\mathcal{L}, t\in\mathcal{T} \qquad (7)$$

$$\sum_{k\in\mathcal{K}} g_{dav}^{kt} \le Q_{v} y_{dav}^{t} \qquad \forall d\in\mathcal{D}, a\in\mathcal{A}_d, v\in\mathcal{V}, t\in\mathcal{T} \qquad (8)$$

$$h_{c}^{0kt} = h_{c}^{0kt-1} + S_{c}^{kt} - \sum_{d\in\mathcal{D}}\sum_{v\in\mathcal{L}} r_{cdv}^{kt} \qquad \forall c\in\mathcal{C}, k\in\mathcal{K}, t\in\mathcal{T} \qquad (9)$$

$$h_{d}^{1kt} = h_{d}^{1kt-1} + \sum_{c\in\mathcal{C}}\sum_{v\in\mathcal{L}} r_{cdv}^{kt} - \sum_{a\in\mathcal{A}_d}\sum_{v\in\mathcal{V}} g_{dav}^{kt} \qquad \forall d\in\mathcal{D}, k\in\mathcal{K}, t\in\mathcal{T} \qquad (10)$$

$$h_{ad}^{2kt-1} + \sum_{v\in\mathcal{V}} g_{dav}^{kt} - h_{ad}^{2kt} + u_{ad}^{kt} = \delta_{ad}^{kt} \qquad \forall d\in\mathcal{D}, a\in\mathcal{A}_d, k\in\mathcal{K}_1, t\in\mathcal{T} \qquad (11)$$

$$h_{ad}^{2kt} \le \left| h_{ad}^{2kt-1} + \sum_{v\in\mathcal{V}} g_{dav}^{kt} - \delta_{ad}^{kt} \right| \qquad \forall d\in\mathcal{D}, a\in\mathcal{A}_d, k\in\mathcal{K}_1, t\in\mathcal{T} \qquad (12)$$

$$u_{ad}^{kt} \le \left| \delta_{ad}^{kt} - h_{ad}^{2kt-1} + \sum_{v\in\mathcal{V}} g_{dav}^{kt} \right| \qquad \forall d\in\mathcal{D}, a\in\mathcal{A}_d, k\in\mathcal{K}_1, t\in\mathcal{T} \qquad (13)$$

$$\sum_{v\in\mathcal{V}} g_{dav}^{kt} \le \delta_{ad}^{kt} \qquad \forall d\in\mathcal{D}, a\in\mathcal{A}_d, k\in\mathcal{K}_2, t\in\mathcal{T} \qquad (14)$$

$$\sum_{k\in\mathcal{K}} h_{c}^{0kt} \le V_{c}^{0} \qquad \forall c\in\mathcal{C}, t\in\mathcal{T} \qquad (15)$$

$$\sum_{k\in\mathcal{K}} h_{d}^{1kt} \le V_{d}^{1} \qquad \forall d\in\mathcal{D}, t\in\mathcal{T} \qquad (16)$$

$$\sum_{k \in \mathcal{K}_1} h_{ad}^{2kt} \leq V_{ad}^2 \qquad \forall d \in \mathcal{D}, a \in \mathcal{A}_d, t \in \mathcal{T} \qquad (17)$$

$$x_{cdv}^t = 0 \qquad \forall c \in \mathcal{C}, d \in \mathcal{D}, v \in \mathcal{L} \backslash \mathcal{L}_d \; t \in \mathcal{T} \qquad (18)$$

$$y_{dav}^t = 0 \qquad \forall d \in \mathcal{D}, a \in \mathcal{A}_m, v \in \mathcal{V} \backslash \mathcal{V}_{ad}, t \in \mathcal{T} \qquad (19)$$

Objective (1) minimizes the total cost of transportation. Objective (2) maximizes the satisfaction scores. Constraints (3) and (4) are the restrictions on the maximum number of available trucks for rent. Constraint (5) allocates the available helicopters. Constraint (6) ensures that the possible number of helicopter trips is maintained. Constraints (7) and (8) are the capacity limitations of the vehicles. Constraints (9) and (10) are the balance equations at the CP and DB, respectively in period *t*. Constraint (11) is the balance equation at ADP for food commodity. Constraint (11) together with constraints (12) and (13) determines the unsatisfied and excess amount of food supplies at each of the ADP in each period. Constraint (14) confirms that the distribution of non-food supplies to ADPs do not exceed their net demand. Constraints (15) to (17) are inventory storage capacity limitations at CPs, DBs, and ADPs, respectively. Constraints (18) and (19) ensure that the distribution of supplies takes place using vehicle types reachable to the destinations.

In order to solve the model, compromise programming method has been used. In this method, distance metrics are used to find the best possible options. Let f_1^* **and** f_2^* represent the optimal value of objectives and l_∞represent the distance metric. Then in this case, we have

$$\textbf{min} \quad l_\infty \qquad (20)$$

subject to

$$\frac{f_1 - f_1^*}{f_1^- - f_1^*} \leq l_\infty \qquad (21)$$

$$\frac{f_2^* - f_2}{f_2^* - f_2^-} \leq l_\infty \qquad (22)$$

Eqs. (3) to (19)

APPLICATION CASE

We use the actual network distribution for the case of Nepal Earthquake 2015. The network consists of a CP located at the capital city Kathmandu and 14 Demand areas and 744 demand points. Some of the demand points are only accessible through helicopters. Table 1 shows the total number of ADPs in each DB and the number of ADPs that are reachable only by air after the disaster.

Table 2: Total and number of ADPs that must be reached by air

DBs	1	2	3	4	5	6	7	8	9	10	11	12	13	14
Number of demand points	18	55	62	44	42	89	59	67	18	49	79	52	54	56
Number of demand points only accessible by air	9	10	0	0	0	9	0	14	0	5	10	6	2	3

We consider one package of food- commodity and one package of the non-food commodity with a four day period for a planning horizon for distribution planning. Although food items are needed to be supplied after the first supply period, the demand for non-food items is satisfied

when they are supplied once. We assume that all demand is satisfied at the end of the planning horizon. Table 3 shows the periodic supply capacity at the supply point. It is assumed that 0.5kg per person per day for the food item and 4.5 kg per household for non-food items.

Table 3: Supply capacity at the CP for the planning period

Time period	1	2	3	4
Food item supply capacity (kg)	10950	10950	10950	14123
Non-food item supply capacity (kg)	4972	4972	4972	5611

In the model, four types of trucks and three types of helicopters are considered. Table 4 shows the capacities of each type of these transportation modes. Each helicopter is assumed to make two trips a day (due to distance coverage, loading, unloading, and distribution).

Table 4: Vehicle types and capacities

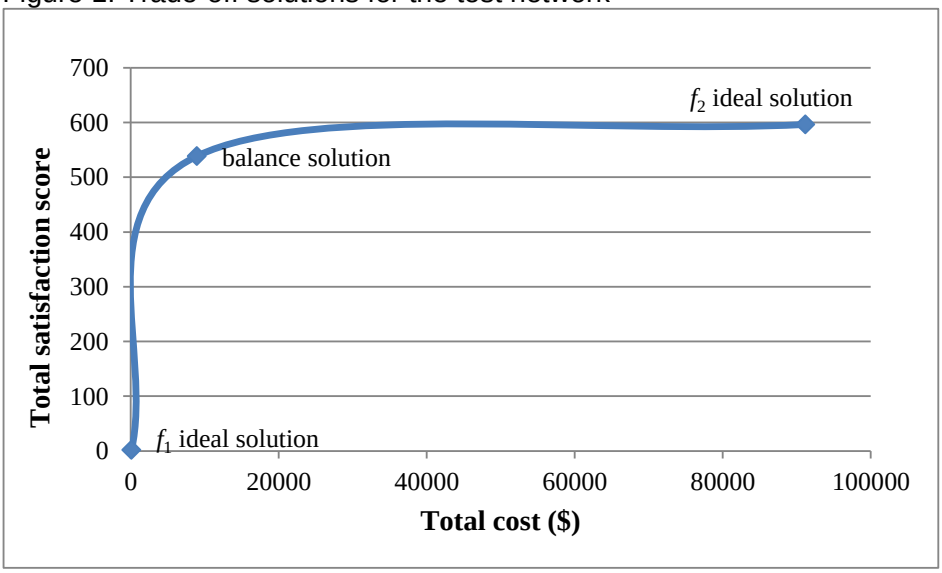
Vehicle types	V1	V2	V3	V4	V5	V6	V7
Capacity (kg)	500	1070	1500	3000	1000	1700	3000

Costs for trucks are based on fuel cost per km, but the cost of the helicopter is based on the cost of allocation only. It is assumed that the helicopters are provided with no immediate cost. Other parametric cost values are generated based on the authors work in Nepal.

RESULTS AND DISCUSSIONS

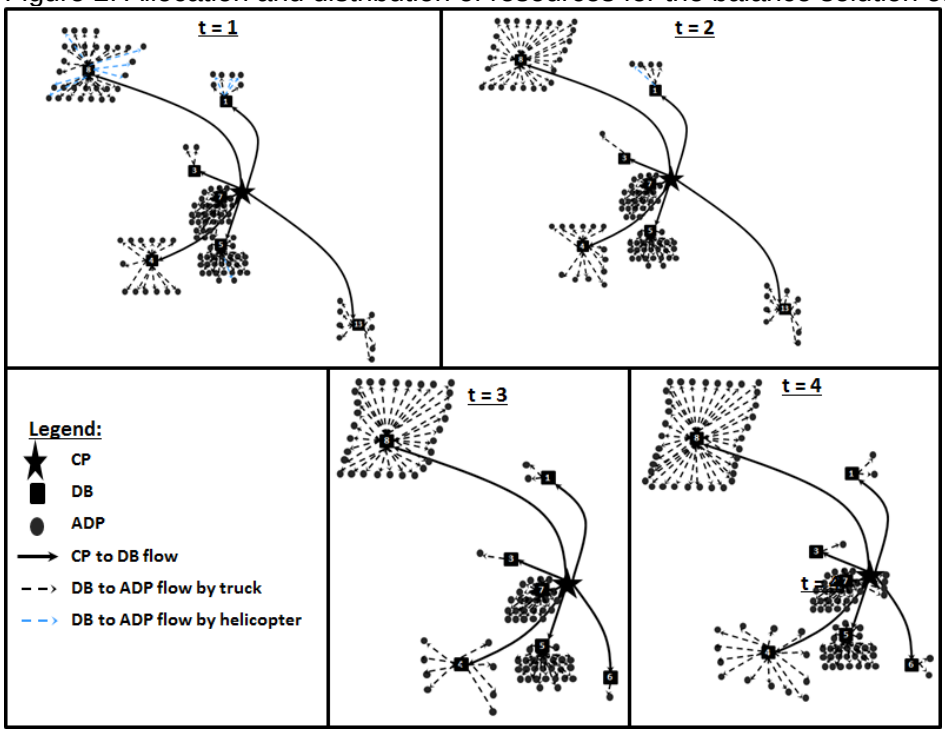
Figure 1 shows that for cost optimality, the solution is very small, about 100 because it tends to use maximum helicopter due to lower cost for the relief agencies and supplies to the nearby locations. The balanced solution associates a cost of about $9000 and maintains a satisfaction score of about 540. The satisfaction score here is close to the optimal value based on the solution methodology. Deliveries for a balanced solution are mainly done through the trucks.

Figure 1: Trade-off solutions for the test network



In terms of commodity distribution, Figure 2 shows the allocation and distribution of resources in the network for the four periods. It shows helicopters are used more for the initial periods and then it gets reduced as the truck supply starts arriving at the location. It also means that the demand of distant locations is met through the helicopters in the beginning periods.

Figure 2: Allocation and distribution of resources for the balance solution of the test network



CONCLUSION AND FURTHER RESEARCH

We present a bi-objective model for assessing relief supplies in an earthquake disaster setting. The model considers several demand points, fewer distribution centers, and one central supply point. We find that when there is a change in demand and supply, it has impacts on demand satisfaction. Increase in demand or decrease in supply creates more dissatisfaction but the reverse situation is not necessarily true due to supply capacity constraints. However, given the constant demand and unlimited transport capacity, the cost and satisfaction levels increase with an increase in supply capacity. The results show that if cost is the only consideration, then supplies are dispatched to the nearest location first irrespective of more acute demand problems in other areas. This can be avoided by considering multiple supply points in the future research. The focus should also be to consider temporary distribution points between the supply points and the demand points so that inter-allocations among such temporary locations can be promoted to mitigate the problem of demand and supply dynamism. Such temporary locations can also reduce the cost of transportation and increase satisfaction levels.

ABSTRACT

We examine the antecedents of innovation speed in the context of loosely coupled systems as encompassed in modular interconnected processes and fluid partnering in enhancing innovation speed. Specifically, we evaluate the importance of coordinating mechanisms – standard process and content interface, and structured data connectivity in developing modular interconnected process. We also examine whether or not a fluid partnership and information quality enhance innovation speed. The results indicate that standardized process and content interfaces are positively associated with modular interconnected processes. Modular interconnected processes positively influence ability to reconfigure supply chain partners. Fluid partnership enhanced information quality, which, influences innovation speed.

KEYWORDS: Modular interconnected process, innovation speed, information quality

INTRODUCTION

Rapid changes in dynamic business environment (Teece, 2012) and shortening of a product lifecycle (Chien, Chen & Peng, 2010; van Iwaarden & van der Wiele, 2012; Bakker et al., 2014) require organizations to introduce innovative products and services at a periodic interval to keep up with the evolving demands of customers. At the heart of innovation speed literature lies the question as to how can a firm offer series of innovative products or services relatively quickly so that it can continuously reinvigorate the sources of revenue.

Our contention is organizational design can be a source for innovation if the organization is designed to act like a loosely coupled system. In this study, we address following research questions: how can we design organizations to act like a loosely coupled system? How the various elements of a loosely coupled system interact with each other? How does a loosely coupled organizational design affect innovation speed?

THEORETICAL BACKGROUND AND HYPOTHESES

Loosely Coupled System

Loosely coupled system is where coupled subsystems are responsive to one another, but each subsystem also "preserves its own identify and some evidence of its physical and logical separateness" (Weick, 1976; p. 3). Loose coupling could occur among individuals, among organizations, among subunits, between organization and its environment, between activities, etc. (Orton & Weick, 1990).

The extent of an integration of a system determines the degree of its coupling. In the case of manufacturing a vehicle, if all the components of a vehicle were manufactured in-house, as in the case of Ford - Model T, then the system would be characterized as a tightly coupled system. On a contrary, a disintegration of systems into modules, outsourcing of components, and components compliance with design standards will result in a loosely coupled system. Orton and
Weick (1990) argued that a system needs to have dialectical characteristics of *distinctiveness* and *responsiveness* to be a loosely coupled system. The *distinctiveness* of components is achieved when various suppliers conducts their tasks independently, making a system loosely connected. The *responsiveness* of a system is achieved when suppliers conform to design and output standards while conducting their tasks. Responsiveness refers to the coupling of a system as there is some degree of linkage among various components at interfaces so that output of processes conducted by each partner is compatible at the interfaces.

Modular Interconnected Process and Standardized Process and Content Interfaces

Modular interconnected process refers to "the breaking up of complex processes into subprocesses (activities) that are performed by different organizations independently and simultaneously with clearly specified interlinked outputs" (Gosain et al., 2004; p. 16). Modular interconnected process assumes the two important aspects of a loosely coupled system- responsiveness and distinctiveness.

We argue that standardized process and content interface and structured data connectivity are coordinating mechanisms that could take over the role of manager to coordinate various business units (Sanchez & Mahoney, 1996). In the power plant industry, for example, one of the components required for the construction of the power plant is pipe hangers. Primarily, two parties are involved in making pipe hangers – an engineering firm that draws designs of pipes and a supplier firm responsible for fabricating the design. In a research study, Arbulu and Tommelein (2002) found that the absence of an industry-wide standard of a

pipe design resulted in operational inefficiencies and the lack of coordination among partners. Lack of standardized industry-wide design meant that the standardized design was built only after a supplier was chosen and consulted, increasing the time-to-market (Arbulu & Tommelein, 2002). The presence of standardized process and content interface was important for two parties to perform their respective tasks immediately. Based on the discussion, we present our first hypothesis:

H1: Standard process and content interface is positively associated with modular interconnected process.

Structured Data Connectivity and Modular Interconnected Process

Structured data connectivity refers to the exchange of electronic data and content with another enterprise in a specific format (Gosain et al., 2004). Similar to standardized process and content interface, the prime importance of data connectivity lies in its ability to act as a coordinating mechanism for autonomous modules (Zuiderwijk & Janssen, 2013). While standardized process and content interfaces relate to the distinctiveness aspect of a loosely coupled system; structured data connectivity relates to the responsiveness aspect. Structured data connectivity allows value chain partners to communicate easily and effectively in real time using electronic format. The purpose of structured data connectivity is to provide guidelines to codify and exchange data in an electronic format so that it could be shared with suppliers in a real time. Partners, then, could decipher the coded data seamlessly, without ambiguity, improving their responsiveness (Gosain et al., 2004).

H2: Structured data connectivity is positively associated with modular interconnected process

Modular Interconnected Process and Fluid Partnering

Fluid partnering refers to the ability to effectively and efficiently reconfigure supply chain network (Duysters & De Man, 2003). We argue that fluid partnering reflects modularity in relationship between organizations where managers have flexibility to replace ineffective/inefficient partners with the one who possesses the capability to meet the changing demand in the business environment (Gosain et al., 2004). The competitive pressure (Aghion et al., 2005; Gilbert, 2006) and changing customers tastes (Jaworski & Kholi, 1993; Erdil et al., 2004) could force a business to innovate a component(s) of a product. If an existing partner does not have the capability to supply a new component, then the replacement of that partner becomes inevitable. The ability to seamlessly switch partners is critical for business organizations to preserve its competitive edge (Stevenson & Spring, 2007).

Modularity in a process implies an ability of the process to disconnect easily form old processes as well as connect easily with new processes. Thus, we hypothesize:

H3: Modular interconnected process is positively associated with fluid partnering

Modular Interconnected Process and Information Quality

Information quality refers to relevancy, value-addition, timeliness, and completeness of information (Li and Lin, 2006). The presence of better quality of information in the collaborative relationships involving information sharing, problem solving, and joint decision making has a positive influence on supply chain performance (Wiengarten et al., 2010). Modularity enhances information quality through two mechanisms-environmental sensing and local adaptation.

One of the advantages of a loosely coupled system that reinforces the distinctiveness aspect of such system is its ability for a local adaptation. A supplier adapting to its local environmental contingency avoids the entire system from having to go through a change, which

also increases the chance of adaptability and survivability (Sanchez & Mahoney, 1996). Customarily, it is a learning inertia that prevents innovation from occurring (Liao, Fei, & Liu, 2007). One of the causes of learning inertia is organizational size. Larger organizations could be bureaucratic in nature, which could also be more rigid in the face of a dynamic business environment (Ruef, 1997). On a contrary, smaller organizations are nimble in terms of decisions making ability and are likely to adapt to environmental changes more easily. One of the benefits of modularity and local adaptation is similar to what small organizations have that result in their nimbleness – lesser bureaucratization. In a modular interconnected process, each module adapts to its local constraints, resulting from its local environment. Local adaptation also enables each module to have a lesser number of decision-makers, hence lesser bureaucratization. This could result in a lesser conflict of interests (Carlile, 2004), increased creativity (Hirst et al. 2011; Thompson, 1965), and a free flow of information. Based on the discussion, we hypothesize that

H4: Modular interconnected process is positively associated with information quality

Fluid Partnering and Information Quality

Fluid partnering helps to enhance information quality in two ways – selection and attrition process of suppliers will, over time, enhances the information quality; heuristics – trial and error learning, will enhance the quality of information in the long-run.

Given the changing demands of customers in a dynamic business environment, the alteration of a component of a products or services could be inevitable. This could result in a search for a new partner with a skill to fulfill the new demand. Of course, replacement of partners could have a negative implication on the efficiency of a project completion. But, Schwab and Miner (2011) argue that if partners replacements occur frequently, then the costs involved in the replacement of a partner declines and the organization becomes more effective and efficient at replacing partners. The idea resembles the learning curve in partner selection (Li & Rowley, 2002).

Fluid partnering also helps to create weak ties among partners. The partners with weak ties have varying ability to bring novel ideas and creativity (Granovetter, 1973), which will help to foster innovation speed. Based on the discussion, we hypothesize:

H5: Fluid partnering is positively associated with information quality H6: Fluid partnering is positively associated with innovation speed

Information Quality and Innovation

Quality information has four aspects – it should be relevant, valuable, timely, and complete. Relevant information is useful information. Irrelevant information is a burden to a firm. Cognitive limitation of individuals or even organizations hinders them from grasping excessive information. When inundated with information, organizational actors could find it difficult to interpret, comprehend, and benefit from the excessive information (Cohen & Levinthal, 1990; Bawden, Holtham & Courtney, 1999). Irrelevant information could be a noise and increase the rate of error (Edmunds & Morris, 2000). It is only when a firm has a complementary knowledge base, they can absorb new information and learn from it (Lane & Lubatkin, 1998). The exchange of relevant and concise information could reduce the information overload (Butcher, 1995), distraction (Klapp, 1986), and protect organizational actors from processing unnecessary information (March & Simon, 1958).

Another element of information quality is the exchange of information in a timely manner. Because product/service lifecycles are shortening (Chien, Chen & Peng, 2010; van Iwaarden & van der Wiele, 2012; Bakker et al., 2014), firms need to rely on the real-time information to address pressing issues in business environments.

H7: Information quality is positively associated with innovation speed

METHODS

The sample was drawn from the target population of the U.S. service organizations. Zoomerang was used for the data collection. Zoomerang consists of two million registered users and provides a platform to conduct online surveys. It provides an option to filter prospective respondents based on 500 attributes. In the previous studies, researchers have used Zoomerang for the data collection (Ojha et al., 2014; Cudney & Elrod, 2011). The characteristics of the sample are presented in table 1. The sample is evenly distributed across different organizational size based on the number of employees and sales revenue.

Table 1: Sample characteristics

Sales		**Respondents**	
<$1 million (m)	83	Vice President/Asst. Vice President	19
$1 million - $ 10 million	79	CFO/Treasurer/Controller	13
$10 million - $100 million	55	Director/Asst. Director/ Department Head	41
$100 million - $ 1 billion	17	Manager/Asst. Manager	144
> 1 billion	30	Small business owner	21
Total sample	**264**	Doctor/Physician	26

Measures

The measures used in the study are established in the prior studies. To adopt the measures in the context of our study, we modified the measures. The scales that were used to measure variables are presented in Appendix A.

We used Gosain et al., (2004) source to measure Standardized Process and Content Interface (SPCI). A 3-items on a 7-point Likert scale was used to measure SPCI. Three items on a 7-point Likert scale were used to measure Structured Data Connectivity (SDC). Modular Interconnected Process (MIP) was measured using three items on a 7- point Likert scale. Fluid Partnering (FP) was measured using three items on a 5-point Likert scale. We used four items

on a 7-point Likert scale to measure Information Quality (IQ). Three items were used to measure innovation speed. We included three control variables in the study, which are number of employees, sales revenue and industry types. Number of employees was a proxy for a company size, sales was a proxy for resource available, and industry type controlled the effect of differences in industry structure.

RESULTS

Structural equation modeling (SEM) was used to test the hypothesized nomological structure and the direct relationship between variables. The psychometric properties of scale were identified by evaluating reliability and validity of constructs. Confirmatory factor analysis was conducted to examine the discriminant and convergent validity of constructs. Two-step technique was used to examine measurement model and structural model (Anderson & Gerbing, 1988). The two-step technique ensures that the hypotheses testing is conducted after researchers assess the model fit of a measurement model, internal consistency, and convergent and discriminant validity.

Convergent, Discriminant Validity, and Composite Reliability

Table 2 presents validity and reliability of the constructs used in the study. The value of average variance extracted (AVE) for all constructs are above 0.50 threshold, providing support for convergent validity (Fornell & Larcker, 1981). Moreover, the square root of AVE of each construct is greater than its correlation with other variables in the model (Fornell & Larcker, 1981), providing support for discriminant validity.

Table 2. Validity and reliability of the constructs

	CR	AVE	MSVASV	IS	SDCI	MIP	SDC	FP	IQ
IS	0.938	0.835	0.1530.064	0.914					
SPCI	0.876	0.706	0.0270.012	-0.072	0.840				
MIP	0.886	0.723	0.4080.123	0.236	0.136	0.850			
SDC	0.783	0.546	0.0340.020	-0.029	0.164	-0.185	0.739		
FP	0.930	0.815	0.3280.118	0.391	0.051	0.314	-0.074	0.903	
IQ	0.890	0.673	0.4080.177	0.328	0.079	0.639	-0.181	0.573	0.820

Note. CR = Composite reliability; AVE = Average variance extracted; MSV = Maximum shared variance; ASV = Average shared squared variance; IS = Innovation speed; SDCI = standardization of process and content interfaces; MIP = Modular interconnected process; SDC = Structured data connectivity; FP = Fluid partnering; IQ = Information quality

We conducted the confirmatory factor analysis (CFA) using the measurement model where latent variables used in the study were freely correlated. All items measuring its latent variable were statistically significant.

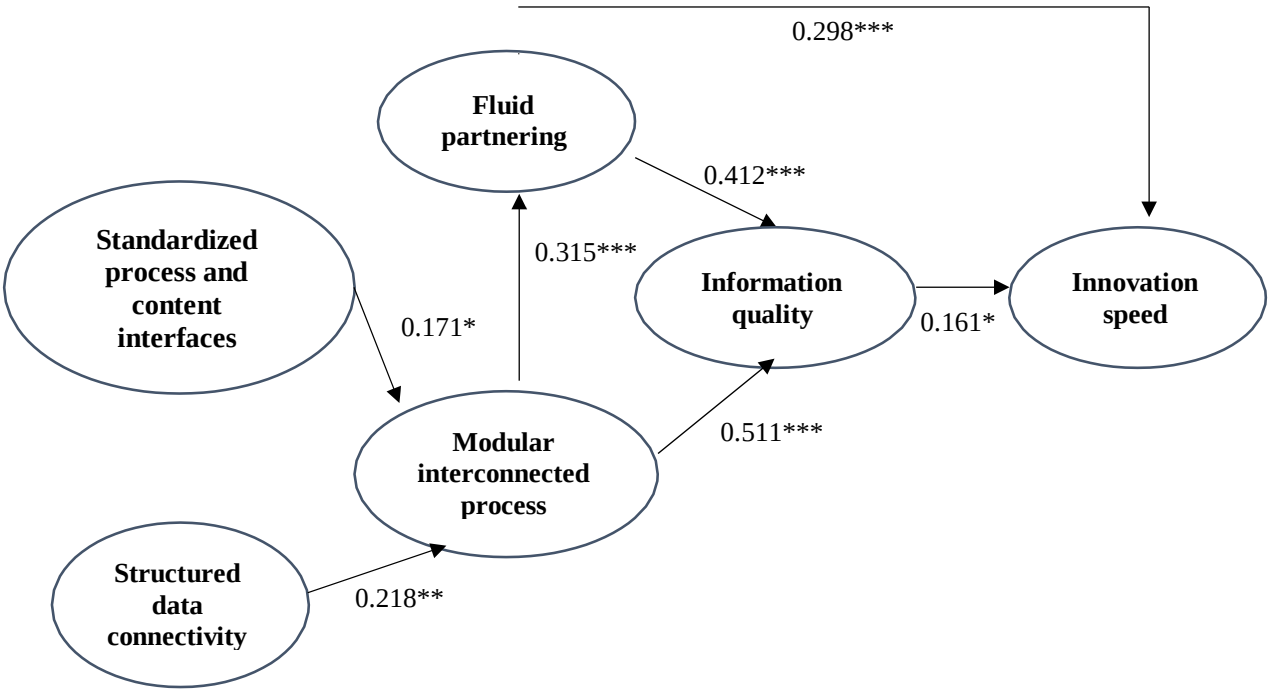
Evaluation of Nomological Structure

We evaluated the fit indices of both the measurement model ($\chi 2$ [df] = 317.771[137], p = 0.000; CFI = 0.949; RMSEA = 0.071) and the causal model ($\chi 2$ [df] = 323.103[144], p = 0.000; CFI = 0.949; RMSEA = 0.069), which were quite satisfactory. The fit indices provided support for the nomological structure of the research model (Kline, 1998). With regards to control variables, results indicated that none of the control variables were statistically significant.

Test of Hypotheses

Figure 1 provides the research model along with path loadings. Hypothesis 1, which stated that standardized process and content interface was positively associated with modular interconnected process was supported (β = 0.171, p = 0.012). Hypothesis 2 stated that structured data connectivity was positively associated with modular interconnected process. This hypothesis was supported (β = 0.218, p = 0.003). The positive association between modular interconnected process and fluid partnering, as stated in hypothesis 3, was supported as well (β = 0.315, p = 0.000). Hypothesis 4, which tested the positive association between modular interconnected process and information quality was supported (β = 0.511, p = 0.000). Hypothesis 5, which stated fluid partnering was positively associated with information quality was supported (β = 0.412, p = 0.000). Hypothesis 6 stated that there was a positive association between fluid partnering and innovation speed, which was supported (β = 0.298, p = 0.000). Lastly, hypothesis 7, which stated that fluid partnering was positively associated with innovation speed was also supported (β = 0.161, p = 0.036).

Figure 1. Research model with path loadings ***$p \leq 0.001$; **$p \leq 0.01$.



DISCUSSIONS AND CONCLUSION

Primarily, the results of the study reinforce the concepts presented in a loosely coupled system (Weick, 1976). Drawing the equivalence between a loosely coupled system and a modular interconnected system, we implemented the various benefits of the loosely coupled system to develop arguments for our hypotheses. We include both distinctiveness and responsiveness aspects of a loosely coupled system in the research model as modularity and coordination mechanisms respectively. This permits us to perform the dialectical interpretation of the modular interconnected process, which Orton and Weick (1990) believe to be inseparable characteristics

of loosely coupled system.

There are various dependencies both within and between organizations: task-task dependencies, task-resource dependencies, and resource-resource dependencies. Crowston (1997) proposes various coordinating mechanisms to overcome problem encountered in each of these dependencies. Pertinent to our study is the

The findings of this study also contribute to dynamic capability (Eisenhardt & Martin, 2000; Teece, Pisano & Shuen, 1997). O'Reilly & Tushman (2008) present that change in the business environment is inevitable and one of the ways to address environmental change is through developing the dynamic capability. Our research thus reinforces the three underlying dimensions of dynamic capability – adaptation, integration, and reconfiguration – for competitive advantage. The adaptation of skills among modular partners is achieved through generation of constant standards and rules at the interfaces. The ability to easily reconfigure the partnering (fluid partnering) allows the integration of only the most competent suppliers in the modularity. Competent suppliers could introduce relevant and valuable ideas essential for innovation. The outcome of which is observed in the organization's ability to ramp up their innovative activities.

One of the limitations of this study is its failure to explicate the types of innovation a firm is conducting. As evidenced by research findings, different types of innovations require distinct types of organizational structures. While an organic organizational structure is apt for radical idea generation, a mechanistic organizational structure favors incremental innovation (Nord & Tucker, 1987; Sheremeta, 2000). It is intuitive to assume that MIP itself is an organic, as the decision-making authorities are separated and interaction between subunits is restrained. But from a module's standpoint, the identification of organizational design that is apt for the structure of a module – interactions of functional departments and decision- making authorities within a module – is something we propose for future researchers to examine.

Appendix A. Operationalization of constructs

Standardization of Process and Content Interfaces (SPCI; Gosain et al., 2004): 7 points Likert- scale

- Extent to which your business process interfaces with your supply chain partners are similar across all partners, in terms of rules and procedures.
- *Very similar for all partners, moderately similar across partners, extremely specific for each partner*
- Extent to which the business process interfaces with your supply chain partners are similar across all partners, in terms of data formats.
- *Very similar for all partners, moderately similar across partners, extremely specific for each partner*
- Extent to which information exchanged (e.g., sales reporting, service information, service availability, inventory information, etc.) with your supply chain partners needs to be converted/translated to be interpreted by your business unit.
- *Does not need to be converted/translated, needs to be converted/translated moderately, needs to be converted/translated extensively*

Structured Data Connectivity (SDC; Gosain et al., 2004): 7-point Likert scale

- What is the extent to which you can exchange data in electronic formats with your supply chain partners and other potential supply chain partners?
- *Mostly electronic, Equally electronic and non-electronic, Mostly non-electronic*
- What is the extent to which you can exchange data in real time with your supply chain partners and other potential supply chain partners?

- *Extensive real-time exchange, Equally Real time and batched exchanges, Mostly batched delayed exchanges*
- What is the extent to which data exchange with your supply chain partners is structured (rather than free format exchange such as e-mail text)?
- *Data can be highly structured, Moderate support for structured data, No support for structured data*

Modular Interconnected Processes (MIP; Gosain et al., 2004): 7-point Likert scale (*Strongly disagree, Neutral, Strongly agree*)
- The processes conducted in conjunction with your supply chain partners are divided into clearly understood activities to be performed by you and each of your supply chain partners.
- The output/job requirements of your supply chain partners from your business unit and your requirements from your supply chain partners are precisely specified and understood.
- The activities performed by your company and your supply chain partners are performed simultaneously to a large extent.

Fluid Partnering (FP; Rosenzwieg & Roth, 2007): (5-point Likert scale; strongly disagree, neutral, strongly agree)
- You are adept at reconfiguring network of supply chain partners in very short time.
- You have the ability to quickly coordinate activities across a dynamic pool of supply chain partners.
- You have the ability to effectively maintain a shifting network of supply chain partners.

Information quality (IQ; Gosain et al., 2004): 7-point Likert scale
- How would you rate the information exchanged with your supply chain partners in terms of its relevancy to your business needs?
- *Not relevant, Moderately relevant, Very relevant*
- How would you rate the information exchanged with your supply chain partners in terms of its value-added to your business needs?
- *Of no value, Moderately valuable, Very valuable*
- How would you rate the information exchanged with your supply chain partners in terms of its timeliness?
- *Always late, Sometimes on time, Very timely*
- How would you rate the information exchanged with your supply chain partners in terms of its completeness?
- *Incomplete, Moderately incomplete, Very complete*

Innovation speed (IS):
- How does your business unit's ability to develop new services at a high rate compare with your competitors?
- How does your business unit's ability to develop new features in your existing services at a high rate, compare with your competitors?
- How does your business unit's ability to develop new service delivery technology, at a high rate, compare with your competitors?

ABSTRACT

The purpose of the study is to explore a new estimator for estimating precise population mean. We suggest a sublime population mean ratio type estimator and analyze its properties for several samples. We calculate the efficiency of the proposed estimator for both analytical as well as empirical perspectives. The study attempts to prove that the suggested estimator is improved over other competing estimators.

KEYWORDS: Ratio estimator, Median, Study variable, Auxiliary variable, Percentage relative efficiency (PRE).

INTRODUCTION

Population mean estimation is a very common problem in sampling surveys. Aim of the researcher is to search the most efficient population mean estimator. Auxiliary information enhances the efficiencies of the estimators and there is a sufficient amount of information available in the literature of theory of sampling. One of the brummagem of the auxiliary variable is that it is collected on additional cost of the survey. The recent references include Yadav and Kadilar (2013), Yadav and Mishra (2015), Yadav et al. (2016) and Abid et al. (2016). The alternative of the secondary variable is to use the known parameters of study variable for exalted estimation of the population mean. We have used population median as a variable for improved estimation of population mean for selected data set. The information on population median is easily available as it does not require information on every unit of the population but it requires information in some intervals. The very good examples have been presented by Subramani (2016) information on population median of study variable is readily available.

LITERATURE REVIEW

In the literature, many authors and researchers have suggested various improved estimators for population mean utilizing known auxiliary information. Following is a summary of the competing estimators of population is presented in Table 1.

Table 1: Summary of Literature Review of Existing Estimators

PROPOSED ESTIMATOR

As discussed in section 1, known information on population median of study variable which is many times readily available can be utilized for enhancing the population mean estimation. We propose the following estimator by getting motivated by Nangsue (2009) and Subramani (2016) as,

$$t_p = \bar{y}\left(\frac{M}{m}\right)^b \tag{1}$$

Where b is the regression coefficient of the line Y on M, given by $b = \frac{s_{ym}}{s_m^2}$.

The bias of t_p up to the approximation of order one can be obtained as,

$$Bias(t_p) = \bar{Y}\left[(B+B^2)\frac{1-f}{n}\frac{C_m^2}{2} - B\frac{\bar{M}-M}{M} - B\frac{1-f}{n}(C_{ym} + \frac{\mu_{12}}{S_m^2 M} - \frac{\mu_{21}}{S_{ym}M})\right] \tag{2}$$

The MSE of t_p up to the approximation of order one is expressed as,

$$MSE(t_p) = \frac{1-f}{n}\bar{Y}^2[C_y^2 + B^2C_m^2 - 2BC_{ym}] \tag{3}$$

EFFICIENCY COMPARISON

Under this segment, Table 2 shows the theoretical improvement of the proposed estimator over other competing estimators along with the assumptions for which it performs better than the other competitive estimators.

Table 2: Theoretical efficiency of suggested estimator over competing estimators of population mean

S.No.	Estimator	Condition under which suggested estimator have more efficiency compare to the competing one
1.	Sample Mean estimator	$[\upsilon_1 + r] > 2$
2.	Watson (1937) estimator	$\lambda C_y^2(1-\rho_{yx}^2) + r > 1$
3.	Cochran (1940) estimator	$\lambda[C_y^2 + C_x^2 - 2C_{yx}] + r > 1$
4.	Bahl and Tuteja (1991) estimator	$\lambda[C_y^2 + 4C_x^2 - 4C_{yx}] + r > 1$
5.	Kadilar and Cingi (2003) estimator	$\lambda[C_y^2 + 4C_x^2 - 4C_{yx}] + r > 1$
6.	Srivastava (1967) estimator	$\lambda C_y^2(1-\rho_{yx}^2) + r > 1$
7.	Reddy (1974) estimator	$\lambda C_y^2(1-\rho_{yx}^2) + r > 1$
8.	Gupta and Shabbir (2008) estimator	$r - \nu_1 > 0$
9.	Singh and Solanki (2012) estimator	$r - \nu_2 > 0$
10.	Solanki et al. (2012) estimator	$\lambda C_y^2(1-\rho_{yx}^2) + r > 1$
11.	Ekpenyong and Enang (2015) estimator	$r - q > 0$
12.	Kadilar (2016) estimator	$\lambda C_y^2(1-\rho_{yx}^2) + r > 1$
13.	Nangsue (2009)	$\lambda C_y^2(1-\rho_{yx}^2) + r > 1$
14.	Subramani (2016) estimator	$\lambda[C_y^2 + R_{13}^2 C_m^2 - 2R_{13} C_{ym}] + r > 1$
15.	Soponviwatkul and Lawson (2017)	$\lambda C_y^2(1-\rho_{yx}^2) + r > 1$

NUMERICAL STUDY

For the verification of the theoretical educts, we have taken into consideration the population given by Subramani (2016). Table 3 represents the different parameters of the population under consideration, and for this population, MSEs of various competing estimators and suggested estimator have been calculated. The PREs of the suggested estimator have also been calculated over the competing estimators.

Table 3: Parameters of the population under consideration

Parameter	Value
N	20
n	5
${}^{N}C_{n}$	15504
$\overline{Y}$	41.5
$\overline{M}$	40.0552
M	40.5
$\overline{X}$	441.95
R_{13}	1.0247
C_y^2	0.008338
C_x^2	0.007845
C_m^2	0.006606
C_{ym}	0.005394
C_{yx}	0.005275
ρ_{yx}	0.6522
ρ_{ym}	0.81543

RESULTS AND DISCUSSION

Table 4 shows several estimators for estimating population mean with their MSE that ranges from 2.15 to 1.09. However, the MSE of suggested estimator is 1.0073, which is lower than all competing estimators of population mean. Thus, our research for an efficient estimator of population mean demonstrates that precise estimation is possible without a large survey and eventually costs of surveys and analysis of large data can be minimized.

CONCLUSION

The study presented an enhanced estimator of the population mean and explained the biases and MSEs. The conditions under which the suggested estimator is a better predictor of mean than the competing estimators are discussed and justified through the numerical examples. The results show that the suggested estimator has lower MSE than every competing estimator of population mean. The worth notable thing is that the aim of searching the most efficient estimator have been achieved without increasing the cost of the extensive survey. We expect that academicians and professional will use the proposed estimator to estimate the mean of the population. We also expect that the researchers will further explore similar estimators to simply the predictions. The study will useful for future researchers for producing application research work using the proposed mean estimator in various areas of businesses. Furthermore, professional can use the estimator in developing software for predictive modeling.

DECISION SCIENCES INSTITUTE
On Sharing Preferences in Social Networks

ABSTRACT

In this paper, we study sharing in online social networks through the lens of resource-allocation. Specifically, we study whether people with large networks share as much as people with small networks. Our work shows three influencing factors in content-sharing inequality: individual sharing tendencies, sharing tendencies of one's friends, and content relevance. We then show that, content shared by an individual is determined by the number of his/her friends who are frequent sharers; thus, network composition plays a role in content-sharing.

KEYWORDS: Content-sharing inequality, Theil inequality, Online social networks, and Pareto distribution.

INTRODUCTION

Sharing is an intrinsic part of human nature, manifested in everyday experiences of tangible entities (e.g. food, wealth) and intangible entities (emotions, ideas, advice). While the sharing of tangible entities such as wealth and possessions conforms to the social norms of reciprocity and status consistency (McPherson, Smith-Lovin &Cook, 2001), the concept of sharing emotions or ideas is far less studied. Social Networking Sites (SNSs) have emerged as a significant platform in modern social discourse by facilitating sharing between users in myriad ways (e.g. likes, shares, posts, tags, followers, pins and tweets, to name a few). However, individual sharing patterns differ; some share frequently, while others merely lurk (Nonnecke & Preece, 2000). Individuals also tend to exhibit homophily (Meeker, 1971) and networks have been shown to follow the rich-get-richer pattern (Albert & Barabasi, 2002), where individuals who are new to the network are more likely to form friendships with individuals who have larger networks, than with individuals who have smaller networks. In this paper, we study the volume of content-sharing and its relationship with network size, i.e. we seek to answer the question: do people with large networks share more, less or as much as people with small networks?

To answer this question, we looked at self-reported findings of sharing tendencies of Facebook users. We borrow on the framework in (Murimi, 2016) and grouped users into one of four categories of sharers: frequent (posting at least once a day), moderate (posting at least once a week), sparse (posting at least once a month) and non-sharers (users who do not post). Users were additionally asked to provide network sizes (small or large), and the perceived sharing tendencies of friends on their network. Our results showed that users with large networks shared less than users with small networks. While the inverse relationship between network size and sharing tendencies may appear as contrary to intuition, we posit that this provides further evidence of the theory of weak ties (Granovetter, 1973). Since large networks are comprised primarily of weak ties, users are not inclined to share as much information as they would with a smaller network of friends. We call this phenomenon of inverse correlation between network size and content-sharing as the inequality of content-sharing, and analyze the various parameters affecting this inequality with the help of the Theil inequality index.

The Theil index of inequality was first proposed by the econometrician Henri Theil as a tool to measure the inequality of income distribution (Conceicao & Ferrera, 2000). Since then, numerous studies to quantify the inequality of income distribution have used the Theil index to capture effects such as public-school finances (Evans, Murry & Schwab, 1977), health outcomes (Navarro et al, 2006) and racial segregation (Reardon & Firebaugh, 2000). This paper presents the first application of the Theil index to a content-sharing inequality in SNSs, and while content-

sharing and income distribution appear to be disjoint aspects of the human experience, they both exhibit a fundamental inequality in distribution –a larger portion of the wealth is generated by fewer individuals. Our findings show a similar inequality exists in content-sharing as well. Users with small networks share more content than those with large networks. We extend the heretofore limited scope of the Theil index into the realm of content-sharing in SNSs, and do so with another frequently used aspect of the unequal income-distribution literature: the Pareto distribution. The Pareto distribution, which is frequently used to model the 80/20 rule of income distribution, belongs to the family of heavy-tail distributions such as the power-law distribution and the Zipfian distribution. These heavy-tail distributions have been used to measure inequality in areas such as income, graph structure of the World Wide Web, stock returns and sizes of files, human settlements and particles (Reed & Jorgensen, 2004; Stutzmann, 2006; Zukernam, Neam& Addie, 2003; Addie, Neame & Zukerman, 2002).

LITERATURE REVIEW

The centrality of content-sharing to the social network experience has enabled a variety of studies on the nature of the content and the content-sharers themselves. In (Burke, Marlow & Lento, 2009), the authors show that newcomer sharing is directly proportional to the activity level of the newcomer's contacts. Sharing is also focused – people offer varying amounts of attention to various contacts in their networks (Backstrom et al, 2011). The authors studied this balance of attention as a function of network sizes and tie strength. Sharing content on a SNS also has the effect of reaching a wider than anticipated audience (Bernstein et al, 2013) and is not limited to the more familiar scenarios of viral online content (Berger & Milkman, 2012). In (Sleeper et al, 2013), the authors found that users frequently self-censored their posts to manage their online reputation. The content of the post and the intended audience also influenced sharing (Zhao, Lampe & Ellison, 2016). Sharing as a function of social learning and network effects was studied in (Qiu, Tang & Whinston, 2015). The need to present different information to different online audiences was studied through the mechanism of faceted identities in (Farnham & Churchill, 2011). The relationship between personality traits and online behavior was explored in (Gosling et al, 2011), where the authors found that an individual's personality online is an extension of their offline personality. The underlying elements behind sharing of goals and motivations, manifested as cooperative behavior and social cognition, was studied in (Dominey & Warneken, 2011). The role of content-sharing in enabling information discovery was studied in (Stutzmann, 2006). Sharing was identified as functional building block of social media alongside presence, identity, relationships, conversations, groups and reputation (Kietzmann et al, 2011). Voluntary, informal knowledge-sharing (VIKS) was studied in (Lee et al, 2004). The authors defined VIKS as serendipitous, spontaneous and extemporaneous sharing of information. VIKS interactions were noted as opportunities for learning and teaching, and social engagement. Knowledge sharing was also studied in (Leonardi et al, 2014), where the author analyzed the nature of communication between employees of a financial services organization over a new enterprise social networking site. This work studied the concept of communication visibility, where users can make inferences about their co-workers' knowledge based on the content of messages. This inference was enabled through network translucence (who knows whom) and message translucence (who knows what). A similar framework is observed on most social networking sites, where user's friends are visible to others and their activities on the network (posts, shares and likes) are visible to subsets of their contacts on the network. Settings enable users to narrow the scope of the message translucence and even network translucence – users possess the abilities to limit the number of friends who can see their network activities (Granovetter, 1973; Stutzmann 2006; Mitzenmacher 2004).

From a theoretical perspective, the inequality of content-sharing is related to the theory of weak ties (Granovetter 1973), homophily (Meeker 1971) and network structure (Albert & Barabasi, 2002). Our model of inequality in content-sharing is derived from local and global factors influencing the sharing: sharing tendencies of an individual's contacts, relevance of a post and the sharing tendency of the individual. Furthermore, our approach also applies to the model of interpersonal exchange developed in (Meeker 1971), where interpersonal exchanges is described according a framework of six elements: reciprocity, rationality, altruism, group gain, status consistency, and competition. Recent research has shown that an individual's standing in a SNS is impacted by the composition of the contacts in her network, volume of content shared (Murimi 2016) and the nature of shared content (Hajargasht & Griffiths, 2015). Finally, our measure of inequality in content-sharing in social networks is related to other metrics of inequality studied in offline social networks such as social capital (Cattell 2001) and information diffusion (Kempe, Kleinberg & Tardos, 2005). The focus of our work is to quantify the inequality of content-sharing in terms of the Theil index and to analyze the sensitivity of this index to factors such as network size and sharing tendencies of both the individual and his/her contacts.

CONTRIBUTIONS

Our main contribution is to show that sharing of content in social networks is inequitable, i.e., while one would expect that individuals with large networks would share more than individuals with smaller networks, our research shows that content-sharing follows an inverse relationship with network size. We study this inequality of content-sharing using the Theil index. We model the inequality of content-sharing using a Pareto distribution. Specifically, we study the following model: The number of posts on an individual's feed arises from the sharing tendencies of friends in his/her network. We model the number of posts that an individual makes as a function of three parameters: (a) the individuals' own sharing tendency, which can lie in any of the four categories mentioned above, (b) the number of posts that appear in his/her Newsfeed, which in turn is a function of the sharing tendencies of his/her friends on the network, and finally, (c) the relevance of the posts in one's News feed.

We consider the simple model, where the sharing tendency of an individual is fixed, i.e. if an individual is a frequent sharer, she/he remains so for the duration of network use. We also exclude other News feed items such as content recommendations and advertisements from non-individuals (such as business and other organizations) in our analysis of content-sharing. This enables us to focus on the reciprocity of content sharing between individuals. Consider a network where n_r percent of individuals have small networks and n_l percent of individuals have large networks, and $n_r \gg n_l$. The number of posts made by these individuals is Pareto distributed, i.e. n_r percent of individuals share s_r percent of posts and n_l percent of individuals share s_l percent of the posts, and $s_r \ll s_l$.

The shape parameter of the Pareto distribution has important implication is the calculation of the Theil index. We show that when the composition of the network is split evenly among small and large networks, the slope of the Theil index increases with the shape parameter. In other words, the inequality of content-sharing persists, since the individuals with small networks are expected to post less than the individuals with large networks. In this setting, we show that if the number of individuals with small networks is same as that of individuals with large networks, then the shape parameters of the Pareto distributions modeling the sharing tendencies of individuals on small networks (α) and on large networks (β) dominate the sharing patterns. Specifically, we show that as the difference between the values of the shape parameters tends to zero, i.e., $\alpha \rightarrow \beta$, with an increase in the number of posts from individuals with large networks, there is a corresponding decrease in the number of posts from individuals with small networks. Our hypothesis for this behavior is the underlying Pareto distribution, which assumes an inverse

Table 1: Findings of Inequality in Content-Sharing			
Network Size		Sharing Tendency	
$\boldsymbol{n_{regular}}$	78%	$\boldsymbol{s_{regular}}$	81%
$\boldsymbol{n_{large}}$	21%	$\boldsymbol{s_{large}}$	18%

relationship between network size and sharing. An increase in the shared content from individuals with large networks signals the availability of less content on the news feed from individuals with smaller networks. However, as $\alpha \gg \beta$, an increase in the number of individuals with small networks or an increase in the value of α increases the number of posts on an individual's feed. This is in line with the Pareto distribution, since individuals with small networks share more than individuals with large networks. Additionally, we investigate extreme inequality of sharing in scenarios where a few individuals are responsible for all the content shared on the networks. Even in this situation of extreme inequality of content-sharing, we show that as the number of individuals with small networks increases, the inequality of content-sharing can be reduced (since individuals with small networks post more than individuals with large networks). Another method to reduce the extreme inequality is to increase the value of the sharing parameter α. As α increases, the sharing tendency of users increases, thus reducing the inequality. Finally, we show that in a network where both individuals with small networks and large networks have similar sharing tendencies($\alpha \to \beta$), the network takes on a more homogenous form. This contributes to the inequality of content-sharing since individuals with small networks would post as much as individuals with large networks and thus increase the value of the Theil index.

METHOD

A sample size of 118 students was used to obtain the data in this study. In addition to the definition of the four categories of sharers (frequent, moderate, sparse, and non-sharers) introduced above, the following terms will be introduced and defined in the context of SNSs for our study. We define content as any kind of activity performed by a user. Thus, status updates, shares, likes (and related emotion-conveyors), comments, page creation and following activities are considered as shareable content, since it has the potential of showing up on the News feed of friends in the individual's network. The average network size of our survey participants was found to be 651 friends. Thus, we categorized networks as belonging to one of two categories: small networks (1-650 friends) and large networks (greater than 650 friends). Based on the definition of the various kinds of sharers and network size categories, students were asked to answer the following questions: (a) perception of their own sharing tendency (b) preferred sharing tendency (c) percentage of friends on their network whom they would associate with a sharing tendency – for example: 40% of friends are frequent sharers, 10% of friends are non-sharers, etc. and (d) user's own network size.

Table 1 shows the inequality of content-sharing as a function of network size. Individuals with small networks (n_r) comprise 78% of the network and report sharing 81% of the content (s_r), while individuals with large networks (n_l) comprise 21% of the network and share only 18% of the content. Thus, we see that individuals with small networks share more than individuals with large networks. This inequality of content-sharing is the basis of the work in this paper, where we study the various factors influencing the inequality of content-sharing in networks. In the next section, we study the impact of three factors (a) network composition (b) sharing tendency of the self and (c) relevance of content on the content-sharing inequality.

MODEL

We use the Pareto distribution to model the sharing tendency f of an individual. The Pareto distribution is defined by a shape parameter and a scale parameter. The shape of the Pareto curve representing the inequality is influenced by the value of the shape parameter. We use the shape parameter to determine the minimum number of posts made by an individual. We denote the Pareto distribution of sharing inequality in small networks with the scale and shape parameters as x_m and α respectively. For the case of large networks, we denote the Pareto distribution with the scale and shape parameters as x_n and β respectively. We model the mean number of posts by an individual with the Pareto distribution (x_m, α), where α is proportional to the sharing tendency of the individual (s), the relevance of the posts on the feed, and the composition of the network (n).

$$\boldsymbol{\alpha \propto rns} \quad (1)$$

The composition of the network, n, is described in terms of the frequency of the posts made by users in distinct categories. The number of posts on a user's feed in terms of n_m (number of moderate sharers), n_f (number of frequent sharers) and n_s (number of sparse sharers) is given as,

$$n = (n_m)/7 + (n_f) + (n_s)/30 \quad (2)$$

We exclude the contributions of non-sharers in our calculations of the number of posts in (2), since their activity in invisible on one's News feed. Thus, the CDF of the Pareto-distributed sharing tendency is given as:

$$F(x) = \begin{cases} (x_m/x)^{\alpha}, & x \geq x_m \\ 1 & , \ x < x_m \end{cases} \quad (3)$$

Our analysis can be readily extended to the case of the Poisson Pareto Burst Process (PPBP) which has been shown in (Zukerman, Neams & Addie, 2003; Addie, Neame & Zukerman, 2002) to closely model the bursts of Internet traffic.

Theil Index

The Theil index has been used extensively (Conceicao & Ferreira, 2000) in income inequality literature to characterize the complex dynamics of inequality among rich and poor countries. Here, we use the Theil index, T_I, to characterize the inequality of content-sharing between content-rich and content-poor groups of SNS users. The value of the Theil index, as a function of the network sizes (n_r, n_l) and sharing tendencies (s_r, s_l) is derived as (Granovetter, 2006):

$$T_I = s_r \log(s_r/n_r) + s_l \log(s_l/n_l) \quad (4)$$

We model s_r and s_l as Pareto-distributed sharing tendencies as a function of the network sizes n_r and n_l respectively. Thus,

$$\boldsymbol{s_r = \alpha x_m^{\alpha}/n_r^{\alpha+1}} \quad (5)$$

$$\boldsymbol{s_l = \beta x_n^{\beta}/n_l^{\beta+1}} \quad (6)$$

Case 1: Zero Inequality

Here, we study the conditions under which the Theil index of inequality in content-sharing is zero when there is an equality in network composition, i.e. $n_r = n_l$. Within this constraint, we study two

Figure 1: Relationship between minimum number of posts in small $\mathbf{x_m}$ and large networks $\mathbf{x_n}$ for zero inequality in content-sharing.

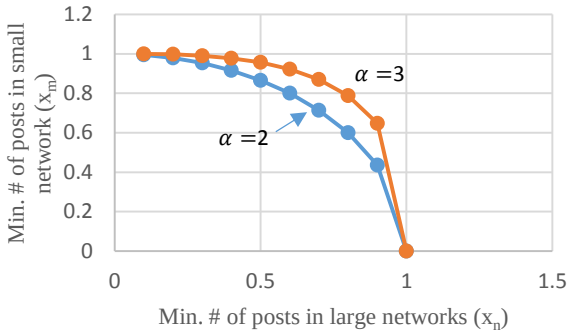

Figure 2. Relationship between network composition $\mathbf{n_r}$ and minimum number of posts $\mathbf{x_m}$

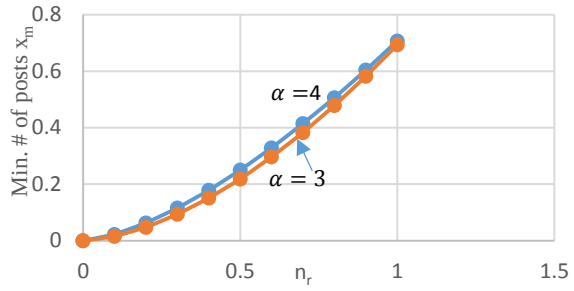

cases (a) the sharing tendencies of both small and large networks is similar, i.e. $\alpha \rightarrow \beta$, and (b) the sharing tendency of the small networks is much less than the large networks, i.e. $\alpha \ll \beta$. Substituting (6) in (5), we find that when $\alpha \rightarrow \beta$, for T_I to be equal to zero,

$$x_m = (1 - x_n^{\alpha})^{1/\alpha} \tag{7}$$

This relationship between minimum number of posts in small and large networks is depicted in Figure 1. In Figure 1, we see that, for the inequality of content-sharing to be zero, as the number of posts from friends with large networks increases, there is a decrease in the number of posts from friends with small networks. We suggest that this behavior is due to the underlying Pareto distribution, which assumes an inverse relationship between network size and sharing. An increase in the shared content from individuals with large networks signals the availability of less content on the news feed from individuals with smaller networks.

Next, we investigate the condition when $\alpha \ll \beta$ for $T_I = 0$.

$$x_m = 10\text{^}[(\log \beta + \beta \log x_n)/(\beta + 2)] \tag{8}$$

Figure 2 shows the impact of network composition on the minimum number of posts. As the percentage of people with small-sized networks (n_r) increases, the minimum number of posts seen on one's news feed increases. This is intuitive since people with small networks share more than people with large networks. The shape parameter of the Pareto distribution, α, also impacts

Figure 3. Impact of Sharing Tendency on the Minimum Number of Posts

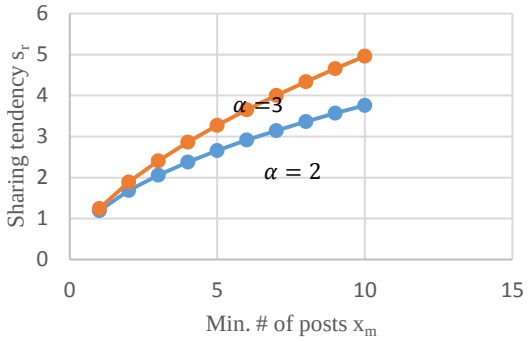

Figure 4. Extreme Sharing Tendencies

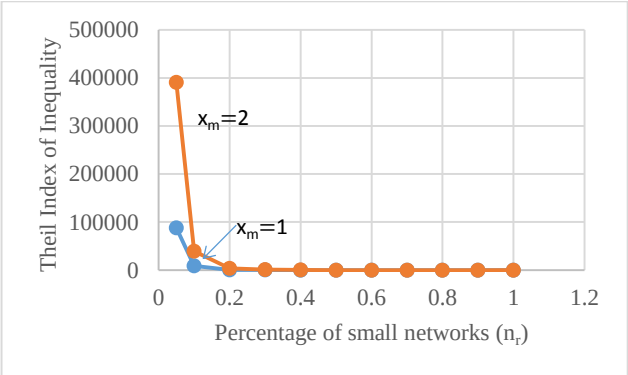
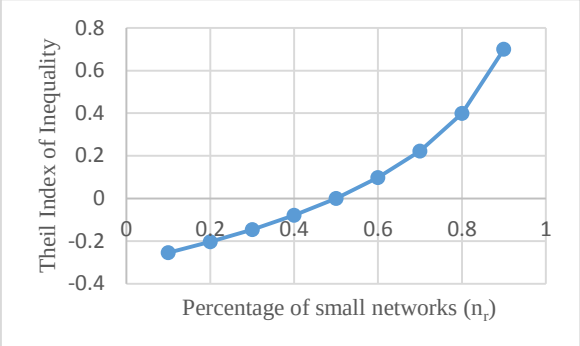


the minimum number of posts. As the value of α increases, the minimum number of posts increases. Figure 3 shows the sharing tendency of an individual as a function of the minimum number of posts by friends in the network. As the minimum number of posts increases, there is a greater probability that at least some of them will be deemed 'shareable', and this causes an increase in the sharing tendency of the individual. Similarly, a decrease in the number of people with large networks points to a corresponding increase in the number of people with small networks.

Case 2: Extreme Sharing Tendencies

In this case, we analyze extreme sharing tendencies, i.e., what happens if $\boldsymbol{n_{regular}} \ll \boldsymbol{n_{large}}$ and $\boldsymbol{n_{regular}} \gg \boldsymbol{n_{large}}$? (i.e.1 person does 99% of the sharing and the other 99% do 1% of sharing? Figure 4 shows the conditions under which extreme inequality exists, i.e. a few individuals share majority of the content. Here, we investigate the scenario where friends with small networks comprise less than 2% of the individual's network. The value of the Theil index of inequality in this case is extremely high, and points to the fact that in such networks, content-sharing by individuals with smaller networks should be much less than content-sharing from friends with large networks. Also, as the minimum number of posts from small networks (x_m) increases, the inequality increases since the large networks are sharing less, and their reticence is helping to drive up the inequality of content-sharing.

Figure 5. Impact of Equal Sharing Tendencies



Case 3: Homogeneous Sharing Tendencies

What happens when irrespective of network size, people share the same, i.e., $s_{regular} = s_{large}$?

$$T_I = -0.3 - 0.5\left(\log n_{regular} + \log n_{large}\right) \quad (9)$$

In Figure 5, we see that when the sharing tendencies of large networks and small networks are the same, the Theil index of inequality in content-sharing increases. This trend is as expected, since content-sharing is expected to be directly proportional to network size. Yet, the inversely proportional relationship between the two is the driving factor between the inequality of content-sharing. This is amplified when the sharing tendencies are equal – as the percentage of friends with small networks increases, it implies a corresponding decrease in the percentage of friends with large networks and creates a scenario where people with small networks share more than people with larger networks.

CONCLUSIONS

The main contribution of this paper is to model sharing in social networks, and to show that the inequality of content-sharing can be realistically modeled using the Pareto distribution. The Theil index of inequality in content-sharing was used to demonstrate various scenarios of inequality by performing a sensitivity analysis to the parameters that affect content-sharing. The patterns of content-sharing in social networks initiates an intriguing new area of study that raises many questions. Among these are:

1. In this paper, we have assumed that sharing tendencies are fixed. Thus, a frequent sharer or sparse sharer does not change sharing patterns. However, in practice, sharing patterns are a function of various global (news events), regional (local events such as city-wide events) and individual circumstances (life events). We considered an extremely simple news feed; ads, trending news and sponsored content had no influence on the posts. The study of these diverse scenarios will require the development of new models.
2. Our work is based on categorizing users into two broad categories: small networks and large networks. However, even with large networks, individuals do not engage with all or most of the friends on the network. In a SNS, network size management can be accomplished in several ways: unfriending, hiding/unfollowing, creating separate sets of friends for communication or just communicating with only a specific subset of friends regularly on the network. Our work has not considered the implications of users who have large networks, but communicate only with a subset of the friends on the large network. How can the network be modeled to reflect such a structure? Does the network then resemble a homogeneous composition of individuals with small networks?

3. We focus on the inequality of content-sharing. However, there might be SNSs where content-sharing might be equitable. A study of the sharing patterns and network structures within these SNSs would be insightful in learning more about computer-mediated communication in SNSs.
4. Our model also discounts the role of non-sharers (individuals who do not share) on a social network. There are many reasons why individuals do not share: they would like the benefit of observing the News feed from their friends, but do not want to engage with any of the content due to the nature of the online exchange, or perhaps individuals are more interested in snooping on the network and are content with being mere observers of their friends' lives on the network. Alternately, we may not be able to view an individual's posts (and thereby deem them as a non-sharer) because of the non-sharer's privacy settings. The non-sharer may have blocked an individual from viewing their posts using privacy settings. Thus, while the non-sharer is sharing, none of the shared content is visible to the blocked friend. How does a non-sharer contribute to the content-sharing inequality on the network? These and other related questions are central to the formation of social identity in SNSs and merit further research to uncover how people decide whether to share or not to share.

ABSTRACT

This study presents students perceptions about the online and traditional components of ten Decision Science courses offered in a hybrid fashion in a small mid-western Jesuit Business School. Our goal is to have a better understanding about the learning value and effectiveness of online teaching compared to traditional teaching.

KEYWORDS: Online, education

INTRODUCTION

With the growing demand for education from non-traditional students many universities are turning to hybrid and online courses. As more and more top universities continue to embrace online education such a delivery mechanism is gaining credibility and popularity while reducing cost and increasing accessibility and flexibility. Hybrid courses are blended courses which are offered partially in class and partially online using course delivery platforms such as Blackboard. Online and hybrid model can increase the access of education which can otherwise be bound by time and geographical constraints. Online classes are also appealing to students who want to do things independently in their own time and pace (Lorenzetti, 2005). However the flexibility that online classes provide may take away the face to face disciplined interaction that certain students require to do well. Hybrid courses may be able to provide the best of both worlds. That is the fundamental reason to conduct more and more studies comparing learning outcomes from online and traditional classes and report such outcomes along with lessons learnt. Such research work may help other instructors across disciplines that are looking for more knowledge to succeed in their online teaching endeavors which is growing more and more in the current times particularly for higher education in Business.

The majority of studies comparing student performance in online versus traditional classes show no significant difference (Russell, 1999; Fredda, 2000; Dutton et al., 2001, Lorenzetti, 2005) which is also a motivation for higher education institutions to promote more and more online classes. Larson and Sung (2009) suggested that there are no differences in learning perceptions between the online and face to face delivery models and hybrid classes do well when it comes to learning effectiveness and student and faculty satisfaction. Most research on online education suggests that online education is as effective and in some cases more

effective than traditional classroom education. Comparing student perceptions about their learning in face to face and online classes is needed to determine whether and how students can develop and grow as Business professionals with the desirable skills that help them succeed in the real world work environment.

RESEARCH QUESTION

Despite extensive research comparing student perceptions and learning outcomes from online and traditional education there is continued need for more research in discipline context. With growing interest and demand in online education we are interested in finding out whether the perceived value and effectiveness of online teaching is equivalent to that of traditional teaching. We are investigating this specifically for Decision Science courses but believe that the findings could be applicable to Business education as well as higher education in general. The main purpose of our study is to describe students' perspectives in hybrid Decision Science courses.

RESEARCH METHODOLOGY

Data for this study was collected over a period of three years through a survey of college students enrolled in ten hybrid Decision Science courses. These ten different courses were taught by three Decision Science faculty members. Four out of the ten courses were senior level undergraduate courses while the remaining six courses were graduate courses. All of these courses were previously taught in traditional manner in a class room setting. The faculty members modified these courses to be taught and delivered in hybrid fashion. One third to two third of the classes were taught online and the remaining classes were taught face to face. The ten Decision Science courses from which we collected our data are as follows:

1. BUS 3150 Quantitative Methods for Decision-Making
2. BUS 3160 Control of Operations Management and Quality
3. BUS 3170 Management of Information Systems
4. BUS 4940 International Studies in Business
5. MBA 5200 Decision Analysis
6. MBA 5260 Information Systems and Technology
7. MBA 5320 e-Business Strategies
8. MBA 5370 Project Management
9. MBA 5940 International Studies in Business
10. EMBA 6200 Global Supply Chain Management

All the students participated in the survey which was a required assignment for each of these classes. The survey questionnaire included a set of questions that reputable universities use to collect data related to online teaching. There were a total of 24 questions in the survey. Out of the 24 questions, 19 were based on a 4 point Likert scale ranging from strongly disagree to strongly agree and 5 questions were open ended that helped us to collect suggestions and comments from the students which could help us to improve the courses. The 19 questions included questions from three categories – student, course readings and feedback, and course design and delivery. All the course materials for the online portions of the hybrid classes were provided to the students using Blackboard course management platform. The course material posted in Blackboard course site included: lesson content, assignment, quizzes, and discussion boards (specifically for the online classes). The students reflected on their experiences in the online and the face to face classes through their survey responses. The students' responses were analyzed and presented in the next section.

RESULTS

The students perceptions in the courses were somewhat varied with the delivery format which might be of interest to administrators as well as educators as they attempt to address the challenges of increasing demand for flexible online courses.

The student related aspects for the online and the face to face classes were overall almost similar with the average for the face to face classes being 0.925 whereas the online classes average being 0.918. As we can see from table 1, within the student category the students claimed that the amount of time / effort that they put for the face to face classes were higher than the online classes (0.970 vs 0.924). Students also claimed that the lectures, activities, and assignments reflected course objectives almost equally for online and face to face classes (0.985 vs 0.971). The students rated both types of classes as equally challenging (0.931 vs 0.930). The perceived understanding of concepts and principles in face to face classes were higher than the online classes (0.925 vs 0.892). Students confidence levels in applying the course principles in new situations was slightly more in face to face classes (0.888 vs 0.869). Technology used was helpful for learning in online classes more than face to face classes (0.916 vs 0.889). Students comfort level with their learning was equivalent for the two types of classes (0.910 vs 0.905). Students were almost equally likely to recommend the online classes as well as the face to face classes (0.925 vs 0.916). Overall based on these results from student specific questions related to the courses it seems like the online and face to face classes are close to being equivalent with some differences within the underlying measures. This finding is encouraging and provides some insight about how students compare between the two delivery mechanisms and how educators can improve their courses taking these student perceptions into account.

Table 1: Student

Category	Criteria	On-Ground	On-Line
Student	The amount of time/effort I put into this course was as expected (hours per week)	**0.970**	**0.924**
	Course lectures, activities, and assignments reflected course objectives	**0.971**	**0.985**
	The course was intellectually challenging	**0.931**	**0.930**
	I gained good understanding of concepts and principles	**0.925**	**0.892**
	I feel confident I can apply the principles in new situations	**0.888**	**0.869**
	Technology used was helpful for learning	**0.889**	**0.916**
	I was comfortable with my learning	**0.910**	**0.905**
	I will recommend this course to others	**0.916**	**0.925**

The course readings and feedback aspects of the face to face classes were also comparable to those of the online classes with the average for the face to face classes being 0.909 and the average for online classes being 0.908. As we can see from table 2, within this category the students claimed that assignments were returned slightly faster for online classes than in comparison to face to face classes (0.997 vs 0.970). Students felt that the topics were explained, presented, and demonstrated slightly better in online classes than in comparison to face to face

classes (0.886 vs 0.874). They clearly felt more stimulated to think critically about the subject matter in face to face classes than in comparison to online classes (0.922 vs 0.897). According to the students the variety of teaching methods used in face to face classes were almost similar to those used for online classes (0.788 vs 0.785). The students also claimed that the course materials were presented in more clear and logical way in face to face classes than in comparison to online classes (0.943 vs 0.911). Finally, the students felt that the tone of announcements in the online classes were more welcoming than that of the face to face classes. These findings suggest that although the overall course readings and feedback aspects for face to face and online classes were almost equivalent there are some specifics which are clearly more valued in one delivery versus the other showing that each delivery mechanisms have certain strengths and weaknesses. Having prior knowledge of these differences can be helpful to educators to mitigate the weaknesses inherent in a delivery mechanism.

Table 2: Course readings and feedback

Category	Criteria	On-Ground	On-Line
Course Readings and Feedback	Returned assignments within a reasonable time	**0.970**	**0.997**
	Explained and presented/demonstrated topics clearly	**0.874**	**0.886**
	Stimulated me to think critically about subject matter	**0.922**	**0.897**
	Used a variety of teaching methods which helped my learning	**0.788**	**0.785**
	The course materials were presented in a clear and logical manner	**0.943**	**0.911**
	Overall tone of announcements was welcoming and friendly	**0.956**	**0.971**

The course design and delivery aspects were slightly more favorable for face to face classes as compared to the online classes (0.937 vs 0.923). As we can see from table 3, within this category the students approved of the organization of the face to face classes slightly better than that of the online classes (0.929 vs 0.913). The students claimed that the delivery of the face to face classes were more in line with their expectation than in comparison to the online classes (0.928 vs 0.889). However the students clearly felt that the overall quality of the online classes met their expectations better than the face to face classes (0.957 vs 0.917). The course activities met student expectations more for face to face classes than in comparison to online classes (0.970 vs 0.923). Finally the students claimed that the course activities scheduling was more convenient to the university schedule for face to face classes than the online classes. These findings provide some rich insights about student perceptions and could be valuable to educators to design better courses that provide better satisfaction and learning to students.

Table 3: Course design and delivery

Category	Criteria	On-Ground	On-Line
Course Design and Delivery	The organization of the course met my expectation (if you evaluate this as a C or D, please tell us what to do to improve)	0.929	0.913
	The delivery of the course was as I expected (if you evaluate this as a C or D, please tell us what to do to improve)	0.928	0.889
	The overall quality of this course met my expectation (if you evaluate this as a C or D, please tell us what to do to improve)	0.917	0.957
	My expectation of the course activities was met best in (if you evaluate this as a C or D, please tell us what to do to improve)	0.970	0.923
	Course activities scheduling was more convenient to my university schedule with (if you evaluate this as a C or D, please tell us what to do to improve)	0.941	0.934

CONCLUSIONS AND FUTURE RESEARCH

Student performance is a very important measure of the success of an online course. However student perception and satisfaction is equally important for better design of online courses and programs leading to continued success of such courses and programs. In this study we accomplished this by gauging students' perceptions and feelings about the online and face to face components of ten hybrid courses.

Overall it was encouraging to find that students' perceptions about online and the face to face classes related to student aspects were equivalent. However we noticed a few differences in how students felt about some of the underlying measures. For example students felt that they put more time and effort in face to face classes than in comparison to online classes. Requirement to be in class in a specific time could be a possible reason for this feeling which could come in the way for non-traditional students' schedule. Students also suggested that they gained better understanding of concepts and principles and felt more confident in applying the principles in new situations in a face to face class than in comparison to online classes. This suggests that the engagement with the instructor and peers in class is a valuable aspect of face to face classes that somewhat gets lost in an online class. However instructors can use discussion boards and more real time collaboration with the students to have this aspect in an online course. The idea is that the students should not feel lost and alone in cyber space. Finally, the students'' felt that technology used was more helpful in their learning in online classes. This is an important contribution of online courses because students can be better prepared to utilize technology in the real world due to their online class experiences.

Students' perceptions about course readings and feedback for face to face and online courses were also equivalent. However there were some differences in underlying measures. For example students felt that assignments were returned faster in an online class. Also topics were more clearly demonstrated in online classes. This is a very positive finding demonstrating the strength of a structured online class. Online classes are potentially more organized than face to face classes. However students also claimed that face to face classes were more stimulating to them thus highlighting the importance of student engagement with faculty and peers in their learning satisfaction. Students also felt that course materials were presented more clearly in face to face classes also suggesting the need that online classes must be more organized so that students do not feel lost. Students also felt more positive tone in announcements in online classes. The reason could be that instructors put more time and thought in making these announcements which give more positive feeling than when they announce in class.

Students' perceptions about course design and delivery were more favorable for face to face classes. The course delivery met students' expectations better in face to face classes. This again shows that online classes must be more organized and instructors must make sure that there is no confusion in terms of the course requirements. The students felt that the overall quality of the course met their expectation better for online classes. This is a very positive finding suggesting that the quality of the online classes in terms of meeting expectation were higher than face to face classes. However the students' felt that the course activities met their expectations in face to face classes better. These findings suggest that online course design and delivery is still not very matured and needs lot more work from educators albeit there is some strength in online classes.

Online teaching and learning responds to changing needs and abilities of students. Online classes have the potential to enhance student centered learning experience and can better respond to individual students. Such classes open up new opportunities by saving costs for both the universities and students. They expand market reach globally as well as locally and enhance competitiveness. The results of this study based on preliminary data analysis suggest that online classes have huge potential in Business education particularly in the area of Decision Science. However, it is important to understand the challenges in online classes to make sure that they are mitigated. It is also important to bring the best experiences of a face to face class in an online class through better use of technology. In this endeavor technical support for educators will be a very important factor.

In future we want to expand this research by performing more advanced statistical analysis on the student perception data. We also want to study if there is any difference in student perceptions based on age and gender. Finally, we also want to evaluate student learning outcomes and compare the two delivery mechanisms. Our goal is to come up with strategies to design better courses to improve the learning experience for our students.

ABSTRACT

Upon incorporating price and advertising into a well-known diffusion model for subscription services, optimal dynamic marketing–mix variables over time are characterized qualitatively. A monopolistic market is analyzed for which customers' disadoption, discounting of future profit streams and service cost learning are allowed. The analytical findings indicate that the marketing – mix policies of the firm could be very different in the presence of customers' disadoption than their counterparts in its absence. Static optimization techniques are employed to examine the sensitivity of the optimal solution to a change in customers' disadoption at the steady state.

KEYWORDS*:* Marketing-mix, Diffusion models for subscription services, Optimal control theory

INTRODUCTION

With the development of new technologies and the deregulation of several industries, the number of suppliers of subscription services has grown significantly during the last two decades (Libai et al., 2009; Fruchter and Sigué, 2013). The importance of studying subscription services becomes self-evident in light of the fact that, at present, about every household in a western country is involved, in one way or another, in these services. Examples of subscription services include fixed-line phones, cable or satellite television, health clubs and the internet (Mesak and Darrat, 2002; Fruchter and Sigué, 2013).

New subscription service innovations need to be introduced into their markets with appropriate marketing strategies. The most important marketing variables that affect the diffusion of new subscription services are price and advertising. This paper seeks to qualitatively characterize optimal pricing and advertising policies the service provider should pursue over time. The problem is defined in a continuous-time frame to take advantage of the powerful optimal control methodology.

The extant research focuses on consumer churn occurring when a competitor acquires an existing customer. However, a customer can also disadopt and leave the service category altogether as illustrated in previous research (Reichheld and Schefter, 2000; Meuter et al., 2005). Thus the attrition rate is the sum of the churn plus the disadoption rate (Libai et al., 2009). Three of the major challenging questions that marketing academicians and managers face are (1) How to price and advertise subscription services over time? (2) How the marketing mix policies of the firm differ in the presence and absence of an attrition rate? and (3) When the market gets stabilized in terms of the number of subscribers, how a service provider would change the marketing-mix policies in response to an increase in the attrition rate to mitigate its adverse impact on profit? The answers to the above three research questions that have not been fully addressed in the literature constitute the main contributions of the present study. The above research questions are relevant as managing services is different from managing goods, due to long-recognized differences between the nature of services and the nature of

goods. Services are usually highly intangible (cannot be seen, handled, smelled, etc.), heterogeneous (customized making its mass production difficult), perishable and are produced and consumed simultaneously (lack of transportability) (Zeithmal and Bitner, 2003). Unlike the diffusion of durable goods, the growth of a subscription service does not only depend on the number of adopters each period but also on the number of subscribers who renew the subscription in ensuing periods. When the simultaneous presence of the acquisition and attrition processes stabilizes the number of subscribers for a sufficiently large planning horizon, static optimization techniques, according to Feinstein and Luenberger (1981) and Haurie (2002) as well as others could be employed to characterize the optimal solution at the steady state.

The analytical modeling effort employed in this study considers the learning cost curve and the discount rate. More specifically, the model incorporates the key marketing-mix variables of price and advertising into the diffusion model of services articulated by Libai et al. (2009) and thus it explicitly considers the customer attrition rate. The price variable is represented by the subscription fee. Other charges such as that related to usage are not considered. This situation is relevant to a variety of subscription services such as cable television, health clubs and the internet, to name a few. In addition, subscription services for which advertising is a main source of revenue instead of being an instrument for generating subscriptions such as newspapers, magazines and contemporary electronic media (internet websites) are beyond the scope of the present study. Kumar and Sethi (2009) provide a review of this particular literature.

The second section provides a related literature review. The third section outlines a general dynamic diffusion model for new subscription innovations, formulates the problem and presents the solution method. The fourth section characterizes the optimal marketing-mix policy for the general diffusion model as well as specific diffusion models in a dynamic setting. The last section summarizes and concludes the study. The derivation of key formulas and proofs of all reported propositions are included in separate appendices available from the authors upon request.

LITERATURE REVIEW

Notable early examples of diffusion models for subscription services that have used the Bass (1969) model include Dodds (1973) who presented an early diffusion model of cable TV services, Kim et al. (1995) who modelled the diffusion of cell phone services and Rai et al. (1998) who studied the diffusion of the internet. More recent articles that aimed at forecasting the service growth in some sectors such as telecommunications include Islam and Fiebig (2001), Lee and Lee (2009). Additionally, studies have modelled diffusion in social networks, wireless voice/data services, and gaming consoles. (Susarla, et.al., 2012; Niculescu and Whang, 2012; Altinkemer and Shen, 2008).

In the above references, the models did not account for the influence of marketing mix variables in the diffusion process. A few researchers (e.g., Fruchter and Rao, 2001; Mesak and Darrat, 2002) have examined specific aspects of subscription service dynamics in relation to usage and/ or access fees whereas Mesak and Clark (1998) considered both optimal dynamic pricing and advertising. The above studies treat subscription services as if they were durable goods. However, services diffusion differs from durable goods diffusion by the presence of two processes - the adoption process and the retention process.

Libai et al. (2009) were probably the first to incorporate customer attrition into the Bass diffusion model. They showed that customer attrition affects considerably the market growth of a new service. However, their modeling framework did not incorporate marketing-mix variables. Based

on the Libai et al. (2009) diffusion model for services, Fruchter and Sigué (2013) model optimal dynamic pricing decisions for subscription services whereas Mesak et al. (2011) model optimal dynamic advertising decisions for such services that consider service cost learning. Empirical research related to the diffusion of subscription services that incorporate marketing-mix variables is scarce. Employing a logistic model for which market potential is price dependent, Bagchi et al. (2008) examine the impact of price decreases on land telephone and cell phone diffusion. Using a modified Bass (1969) model that does not incorporate attrition, Mesak and Darrat (2003) show that price affects both the innovation and imitation coefficients. Mesak and Clark (1998) conclude that price affects the coefficient of imitation and advertising affects the coefficient of innovation. Employing a modified Libai et al.(2009) model that includes advertising, Mesak et al. (2011) find out that advertising affects the coefficient of innovation. With the initial intent of empirically examining how price and advertising affect the diffusion of a multi-generational cellular phones service model in Europe that incorporates attrition, Danaher et al. (2001) conclude that advertising has an insignificant effect whereas the interaction in price response across generations is significant.

The above brief literature review suggests that (i) there is a belief that marketing-mix variables do affect the diffusion process of new subscription services, (ii) the substance of these effects is basically an empirical question, and (iii) the literature lacks the examination of a general price-advertising dynamic diffusion model for new subscription service innovations.

GENERAL MODEL FORMULATION AND SOLUTION CONCEPT

Let us consider the adoption of a new subscription service in a monopolistic market. A firm manipulates its service charge P_t and advertising expenditure U_t (both assumed to be bounded from above) at each time t over a fixed planning period T, $0 \le t \le T$. The monopoly assumption may seem reasonable in situations in which the firm enjoys a patent protection, a proprietary technology, or a dominant market share. A general service diffusion model is given by

$$dN_t / dt = \dot{N}_t = f(N_t, P_t, U_t),\ N_0 \ge 0 \text{ and fixed}, \tag{1}$$

where N_t and $\dot{N}_t$ represent the number of subscribers at time t and its rate of change at t, respectively. Expression (1) suggests that the current subscription rate is related to the current number of subscribers and the current rate of the marketing variables. Function f is assumed to be twice differentiable with the following properties related to the marketing variables where a subscript on a variable denotes partial differentiation with respect to that variable:

$$f \ge 0;\ f_P < 0;\ f_U > 0;\ f_{PU} \le 0;\ f_{PP} < 0;\ f_{UU} < 0;\ \text{and } f_{PP}\, f_{UU} - f_{pU}^2 > 0. \tag{2}$$

The inequalities (2) imply that the subscription rate is non-negative (new customers' adoption rate is at least equal to customers' disadoption rate), decreases with an increase in the subscription charge, increases with an increase in advertising and is concave in both marketing variables. Inequality (2) further asserts that price may interact with advertising in affecting the subscription rate f and the nature of the interaction is non-positive. The last inequality is stated to ensure that one of the sufficiency conditions of optimality is satisfied (details are found in an Appendix).

We introduce next a cost learning curve by assuming that marginal costs, denoted by C, depend on the number of subscribers such that marginal costs decrease with increasing the number of subscribers (experience) (Chambers and Johnson, 2000; Boone et al., 2008),

$$C_t = C(N_t),\ dC(N_t)/dN_t = C'(N_t) \leq 0. \quad (3)$$

Note that marginal costs could be constant ($C' = 0$). C_t is mainly a function of efforts related to service activation (e.g., installation) and account maintenance (e.g., billing, computer server space, and help provided by the service firm).

For a firm that aims to find the optimum trajectories P_t^* and U_t^* to maximize the discounted profit stream over the planning period T, the problem is formulated as follows for a discount *rate* $r \geq 0$:

$$\underset{P_t,\ U_t}{Max} \int_0^T [(P_t - C(N_t))\ N_t - Q(U_t)]\ dt, \quad (4)$$

subject to $\dot{N}_t = f\ (N_t, P_t, U_t)$, and the initial number of subscribers $N_0 \geq 0$ is fixed and N_T is free.

In expression (4), $P_t\ N_t$ represents the total revenue generated from subscribers and $C(N_t)\ Nt$ is the related total variable cost. In expression (4), $Q(U_t)$ is the advertising cost function assumed to be non-negative and convex with respect to its argument with the properties $Q' > 0$ *and* $Q'' \geq 0$ (Piconni and Olson, 1979). As in earlier monopolistic models (Dockner and Jørgensen, 1988a; Thompson and Teng, 1984; Kalish, 1985), we assume no salvage value for the final number of subscribers at time T. Dockner and Jørgensen (1988b) assert that this assumption is particularly plausible when the firm is more concerned with its profits stream over the planning period than profits to be made after instant T. This assumption also makes results for new subscription services readily comparable with their counterparts related to new products.

The optimal control problem (4) can be solved by applying Pontryagin's maximum principle optimization technique (Pontryagin, 1962). To apply the maximum principle, we start by forming the current value Hamiltoian (Sethi and Thompson, 2000)

$$H_t\ (P_t, U_t, N_t) = (P_t - C(N_t))\ N_t - Q(U_t) + \lambda_t\ f(N_t, P_t, U_t), \quad (5)$$

where λ_t is a costate variable that must satisfy the ensuing requirements:

$$d\ \lambda_t / dt = r\ \lambda_t - \partial H_t / \partial\ N_t\ ,\ \text{and the transversality condition } \lambda_T = 0. \quad (6)$$

An economic interpretation of λ_t is found in Sethi and Thompson (2000). Briefly, λ_t has the interpretation of a *shadow price* of the stock of subscribers N_t. In this paper, as in Dockner and Jørgensen (1988a), we consider admissible controls that are twice differentiable in t and satisfy $P_t \geq 0$ and $U_t \geq 0$ for all relevant t. (In what follows, the time argument is eliminated to minimize confusion and improve clarity). Confining our interest to admissible controls, the partial derivatives of the current value Hamiltonian with respect to P and U along the optimal trajectories, as in Feichtinger (1982), must satisfy the following conditions for an interior solution for which $0 \leq \underline{P} \leq P \leq \bar{P}$ and $0 \leq \underline{U} \leq U \leq \bar{U}$:

$$\partial\ H / \partial P = 0,\ \partial\ H / \partial U = 0, \quad (7)$$

where $\underline{P}$ and $\bar{P}$ are the lower and upper bounds of P, $\underline{U}$ and $\bar{U}$ are the lower and upper bounds of U, and

Matrix **HM** is negative definite, (8)

such that **HM** is non-singular Hessian matrix of the second partial derivatives of the Hamiltonian H, and

$$\boldsymbol{HM} = \begin{bmatrix} \partial^2 H/\partial P^2 & \partial^2 H/\partial P \partial U \\ \partial^2 H/\partial U\,\partial P & \partial^2 H/\partial U^2 \end{bmatrix}. \quad (9)$$

It is noted that the last three inequalities in (2) guarantee that the elements lying on the diagonal of matrix ***HM*** are negative and ***HM*** is negative definite. Conditions (6) and (7) are the necessary conditions of optimality. The last condition (8) is one of several sufficiency conditions of optimality implying that the Hamiltonian *H* is jointly concave in the control variables *P* and *U* together with the state variable *N* (Seierstad and Sydsaeter, 1977). If a sufficiency condition is violated (e.g., $\partial^2 H/\partial P^2 > 0$) the optimal pricing policy would be either the constant $\underline{P}$ or the constant $\overline{P}$. By substituting into the Hamiltonian *H*, the constant that maximizes it would be chosen as P_t^* (Teng and Thompson, 1985 p. 192).

MARKETING-MIX STRATEGIES

This section starts first by analyzing the situation of the general diffusion model (1) followed by an analysis related to a specific diffusion model for subscription services.

Analysis of the General Diffusion Model

Using conditions (7) in conjunction with expressions (5) and (6), it can be shown that the first derivative of the optimal trajectories P^* and U^* with respect to time *t*, represented by a (2 x 1) column vector ***DER***, are uniquely determined by the equations written in a matrix format

$$\begin{bmatrix} dP/dt \\ dU/dt \end{bmatrix} = \boldsymbol{DER} = -\boldsymbol{HM}^{-1}\,\boldsymbol{CV}. \quad (10)$$

In (10), $\boldsymbol{HM}^{-1}$ is the inverse of the (2 x 2) matrix ***HM***, and ***CV*** is the (2 x 1) column vector

$$\boldsymbol{CV} = \begin{bmatrix} f + N(f_N - f f_{PN}/f_P) - f_P(P - C - NC_N) + r\lambda f_P \\ -Q'(f_N - f f_{UN}/f_U) - f_U(P - C - NC_N) + r\lambda f_U \end{bmatrix}. \quad (11)$$

Substituting ***HM*** given by (9) and ***CV*** given by (11) in (10) produces

$$\begin{bmatrix} dP/dt \\ dU/dt \end{bmatrix} = \frac{1}{\Delta}\begin{bmatrix} -\partial^2 H/\partial U^2 & \partial^2 H/\partial U \partial P \\ \partial^2 H/\partial P \partial U & -\partial^2 H/\partial P^2 \end{bmatrix}\begin{bmatrix} f + N(f_N - f f_{PN}/f_P) - f_P(P - C - NC_N) + r\lambda f_P \\ -Q'(f_N - f f_{UN}/f_U) - f_U(P - C - NC_N) + r\lambda f_U \end{bmatrix}, \quad (12)$$

where $\Delta = (\partial^2 H/\partial P^2)\,(\partial^2 H/\partial U^2) - (\partial^2 H/\partial P \partial U)^2 > 0$, given the last condition in (2).

It is observed from (12) that *dP/dt* would possess the same sign as that related to the sign of the first entry of the column vector in (11) and *dU/dt* would possess the same sign as that related to the sign of the second entry of the column vector in (11) for $\partial^2 H/\partial P \partial U = \partial^2 H/\partial U \partial P = 0$. That is, the qualitative characterization of the optimal pricing policy for a model that includes also advertising would be similar to that for a model that includes price alone. Similarly, the qualitative characterization of the optimal advertising policy for a model that includes also price would be similar to that for a model that includes advertising alone. For $\partial^2 H/\partial P \partial U \neq 0$, on the other hand, the sign of *dP/dt* in the presence of advertising, could be different from its univariate counterpart and the sign of *dU/dt* in the presence of price, could be different from its univariate counterpart. In short, for the latter case ($\partial^2 H/\partial P \partial U \neq 0$), the qualitative characterization of the

two optimal policies of price and advertising are said to be i*nterdependent*. Policy interdependence occurs when price and advertising interacts in affecting the subscription rate *f*. That is when $f_{PU} \neq 0$ (details are found in an Appendix available from the authors upon request).

Based on the necessary conditions (6) and (7) and the general specification of the subscription rate (1), the following proposition is introduced:

Proposition 1. *With subscription rate given by (1) and a presence of a service cost learning the following relationship holds at any point in time along the optimal trajectories of the marketing variables for new subscription services: The ratio of the advertising elasticity of the subscription rate ($\xi = Uf_U/f$) to its price elasticity ($\Lambda = -Pf_p/f$) is equal to the ratio of advertising to sales revenue (U/NP), multiplied by the marginal cost of advertising (Q´).*

The above result, in essence, is the well-known theorem of Dorfman and Steiner (1954), for a monopolist facing a price and advertising–dependent static demand for a product, and a linear advertising cost function *Q*, generalized to a dynamic setting for a subscription service. When both price (service charge) and advertising elasticities are constant, the above proposition provides a defense for an advertising policy based on a percentage of sales revenue since (*U/NP*) becomes a constant for a linear advertising cost function. Based on the general expression (12), two propositions are presented below.

Proposition 2. *For a considerably large interest rate and in the presence of service cost learning, optimal service charge decreases over time whereas optimal advertising increases over time.*

Proposition 2 implies that a myopic service provider interested in maximizing short-term profit because of high uncertainty in the market (Bayus,1994) would be inclined to decrease the service charge and increase advertising over time.

Proposition 3. *For r = 0, presence of cost learning curve and subscription rate given by (1) such that* $f + N(f_N - f f_{PN}/f_p) \geq 0$, $f_N - f f_{UN}/f_U \geq 0$,
(i) Optimal subscription fee is increasing over time.
(ii)Optimal advertising is decreasing over time.

Proposition 3 asserts that it would be *sufficient* that both the price elasticity of the subscription rate and the advertising elasticity of the same to decrease with the number of subscribers *N* for the optimal subscription fee to be increasing over time and optimal advertising to be decreasing over time. It is noted here that $\frac{\partial}{\partial N}(-f_p P/f) \leq 0$ implies that $f_N - f f_{pN}/f_p \geq 0$ and $\frac{\partial}{\partial N}(f_U U/f) \leq 0$ implies that $f_N - f f_{UN}/f_U \geq 0$. Continuous improvement of the quality of subscription services is the rule rather than the exception. For example, a provider of cable TV is inclined to modify the service (cable channels) to meet consumer needs better (Gatignon and Robertson, 1985; Mesak et al., 2011). Parker (1992) asserts that such continuous improvement in quality can result in greater perceived need and may, therefore, explain a decline in price elasticity. Similar arguments can be made to explain a decrease in advertising elasticity. Plausible examples of specific service diffusion models that satisfy the above two properties are demonstrated in Propositions 4, 6(a) and 7(a). As the interest rate measures how profits at present are preferred to those earned in the future, a low interest rate (r = 0) could be a sensible approximation when the planning period is short or in a low growth economy that approaches disinflation. Since expression (12) does not clearly characterize the trajectories of the marketing variables P_t^* and U_t^*, a diffusion model of a specific functional form is analyzed next.

Analysis of a specific Diffusion Model

The original Bass model (1969) as modified by Libai et al. (2009) to represent the diffusion of new subscription services in continuous time that explicitly considers customers' disadoption is given by the following expression:

$$d N_t/ dt = p (M – N_t) + q (1 – \delta) (N_t/ M) (M – N_t) – \delta N_t , \quad (13)$$

where N_t is the number of subscribers at time t, M is the market potential, p is the coefficient of innovation, q is the coefficient of imitation, and δ is the disadoption rate. The Bass model (1969) for the diffusion of new durable goods is obtained from (13) upon putting $\delta = 0$. The above authors assume that only those who did not disadopt spread positive word-of-month communications about the service. Therefore, the level of word-of-mouth promotion by retained customers remains the same (q), but its effective impact is reduced due to disadoption from [$(qN_t)/M$] to [$q (1 – \delta) N_t/ M$]. As disadopters consider readoption, the remaining market potential is $M – N_t$ and is not affected by the disadoption process (Libai et al., 2009). Using diffusion data related to cell phones, cable television and online banking in the US, Libai et al. (2009) show that their service diffusion model is empirically appealing for the above service categories. The authors also illustrate that the following relationship among the parameters of their model holds:

$$q (1 – \delta) – p – \delta > 0. \quad (14)$$

The inequality (14) is influential in arriving at a proof of an ensuing proposition. Whenever a parameter or quantity in the Libai et al.(2009) model is assumed to depend on one or more of the marketing variables, this parameter or quantity is simply multiplied, as appropriate, by one or more of the functions *w(P)* which is a pricing response function, *h(U)* which is an advertising efficiency function, or both. These functions are envisioned to possess the following properties:

$$w > 0; h > 0; w' < 0; h' > 0; w'' < 0 ; h'' < 0. \quad (15)$$

The results obtained upon analyzing a diffusion model for which price affects market potential (Bagchi et al., 2008) and advertising affects the coefficient of innovation (Mesak et al., 2011) is introduced in Propositions 4.

Proposition 4. *For a low interest rate, presence of service cost learning, and a service diffusion model* $d N_t/ dt = ph (wM – N_t) + q (1 – \delta) (N_t/wM) (wM – N_t) - \delta N_t$,
(ai)For $\delta = 0$, *optimal subscription fee is increasing over time.*
(aii) For $\delta = 0$, *optimal advertising is decreasing over time.*
(bi) For $0 < \delta < 1$, *optimal subscription fee is increasing (or increasing first then decreasing later).*
(bii) For $0 < \delta < 1$, *optimal advertising is decreasing (or decreasing first then increasing later).*

Proposition 4 demonstrates that the optimal pricing and advertising policies of the service firm in the presence of customers' disadoption [parts (bi) and (bii)] could be different from their counterparts in the absence of the same [parts (ai) and (aii)].

STEADY STATE STATIC OPTIMIZATION

The optimal control problem analyzed thus far is "autonomous". It is said to be autonomous as time enters only through the discount rate. In this regard, Kamien and Schwartz (1981, p.159)

mention that “In infinite horizon problems, a transversality condition needed to provide a boundary condition is typically replaced by the assumption that the optimal solution approaches a steady state. This assumption is plausible since one might expect that, in the long run, the optimal solution would tend to “settle down” since the environment is stationary by hypotheses”.

Considering a stable equilibrium at the steady state, this section is mainly preoccupied with developing and applying an analytical structure that aims at assessing the sensitivity of the optimal steady state marketing-mix variables *U* and *P* together with the corresponding optimal steady state profit rate π to a change in the disadoption rate δ.

The steady state number of subscribers *N* is obtained from (1) upon putting $dN_t / dt = 0$ and solving afterwards $f(N_t, P_t, U_t)$ for *N* to become a function of *U* and *P* and other pertinent parameters. For $r = 0$, the integrand of the objective functional in (4) takes on the following form:

$$\pi = (P - C)\, N(U, P) - Q(U). \tag{16}$$

To make the analysis simple, no cost learning is assumed to exist at the steady state so that the marginal cost C becomes a constant quantity independent of *N*. To maximize the steady state profit π, the necessary conditions of optimality leads to the following two expressions:

$$\Psi = \partial\pi/\partial U = (P - C)\, N_U - Q_U = 0. \tag{17}$$
$$\Phi = \partial\pi/\partial P = (P - C)\, N_P + N = 0. \tag{18}$$

From (17), one obtains upon differentiation with respect to δ
$d\Psi / d\delta = (\partial\Psi/\partial U)(\partial U/\partial\delta) + (\partial\Psi/\partial P)(\partial P/\partial\delta) + (\partial\Psi/\partial\delta) = 0$, *resulting upon minor arrangement of terms in the following:*

$$[(P - C)\, N_{UU} - Q_{UU}](\partial U/\partial\delta) + [N_U + (P - C)\, N_{UP}](\partial P/\partial\delta) = -(P - C)\, N_{U\delta}. \tag{19}$$

From (18), one obtains upon differentiation with respect to δ
$d\Phi / d\delta = (\partial\Phi/\partial U)(\partial U/\partial\delta) + (\partial\Phi/\partial P)(\partial P/\partial\delta) + (\partial\Phi/\partial\delta) = 0$, *resulting upon minor arrangement of terms in the following:*

$$[(P - C)\, N_{PU} + N_U](\partial U/\partial\delta) + [(P - C)\, N_{PP} + 2\, N_P](\partial P/\partial\delta) = -(P - C)\, N_{P\delta} - N_\delta. \tag{20}$$

Using matrix notation, one can write (19) and (20) as follows:

$$\begin{bmatrix} (P - C)N_{UU} - Q_{UU} & N_U + (P - C)N_{UP} \\ (P - C)\, N_{PU} + N_U & (P - C)\, N_{PP} + 2\, N_P \end{bmatrix} \begin{bmatrix} \partial U/\partial\delta \\ \partial P/\partial\delta \end{bmatrix} = \begin{bmatrix} -(P - C)\, N_{U\delta} \\ -(P - C)\, N_{P\delta} - N_\delta \end{bmatrix}. \tag{21}$$

It is noted that the 2 x 2 square matrix in (21) is not but the Hessian matrix H of second order partial derivatives shown below

$$\boldsymbol{H} = \begin{bmatrix} \partial^2 H/\partial U^2 & \partial^2 H/\partial U\partial P \\ \partial^2 H/\partial P\,\partial U & \partial^2 H/\partial P^2 \end{bmatrix}.$$

The sufficient conditions of optimality imply that $\partial^2 H/\partial U^2 < 0$, $\partial^2 H/\partial P^2 < 0$, *and* $(\partial^2 H/\partial U^2)(\partial^2 H/\partial P^2) - (\partial^2 H/\partial U\partial P)^2 > 0$.

Substituting from (17) and (18), $P - C = Q_U/N_U = -N/N_P$ into (21) and solving for the vector $[\partial U/\partial\delta \;\; \partial P/\partial\delta]'$ afterwards, one obtains the following:

$$\begin{bmatrix} \partial U/\partial \delta \\ \partial P/\partial \delta \end{bmatrix} = (1/D) \begin{bmatrix} (-NN_{PP} + 2N_P^2)/N_P & -(-NN_{PU} + N_P N_U)/N_P \\ (-NN_{PU} + N_P N_U)/N_P & (Q_U/N_U)\, N_{UU} - Q_{UU} \end{bmatrix} \begin{bmatrix} Q_U\, N_{U\delta}/N_U \\ NN_{P\delta} - N_\delta\, N_P)/N_P \end{bmatrix}, \quad (22)$$

and the determinant $D = \{(-NN_{PP} + 2N_P^2)/N_P\}\{(Q_U/N_U)\, N_{UU} - Q_{UU}\} - (-NN_{PU} + N_P N_U)^2/N_P^2$

Expression (22) represents a general analytical framework for obtaining the comparative statics (sensitivities) of optimal steady state marketing mix policies for any service diffusion model. To operationalize expression (22) for alternative service diffusion models based on the Libai et al. (2009) model represented by (13), one needs to first obtain the steady state *N*. This quantity is obtained from (13) upon putting $d N_t/dt = 0$ and solving the quadratic equation for *N* to obtain the unique solution

$$N = \frac{q(1-\delta) - (p+\delta) + \sqrt{(q(1-\delta) - (p+\delta))^2 + 4pq(1-\delta)}}{2q(1-\delta)/M}. \quad (23)$$

Except for parameter *δ*, when one of the parameters *p*, *q,* or *M* is assumed to depend on one or more of the marketing mix variables, this parameter is simply multiplied by the pricing response function *w(P)*, the advertising efficiency function *h(U)*, or both. Functions *w* and *h* satisfy the properties depicted in (15). It is also noted that the first derivative of the right-hand side of (13) with respect to N is negative. This implies that the solution of (13) is asymptotically stable (Fruuchter and Sigué, 2013, p. 2186).

We are now in a position to report the comparative statics $\partial U/\partial \delta$ and $\partial P/\partial \delta$ for the service diffusion models shown in Table 1.

Table 1 Comparative statics at the steady state for selected diffusion models

Diffusion models	N	$\partial U/\partial \delta$	$\partial P/\partial \delta$

In Table 1 where d is a constant parameter, models M1 through model M6 represent mixed effect models where both the external effect (process of innovation) and the internal effect

(process of imitation) are present ($p > 0$ and $q > 0$). Models M7 through M10 are external effect models where diffusion is mainly attributed to innovators ($p > 0$ and $q = 0$). Models M11 through M14 are internal effect models where diffusion is mainly attributed to imitators ($p = 0$ and $q > 0$). For a few diffusion models, advertising would decrease in response to an increase in the disadoption rate. Though such a finding appears counterintuitive, it should be noted that a decrease in advertising cost could moderate the impact on profit. The comparative statics reported in Table 1 reveal that how the marketing-mix variables would change in response to a change in the disadoption rate is basically an empirical question. The answer of such a challenging question depends on whether the diffusion process is of the mixed effect type, the external effect type, or the internal effect type. Furthermore, the answer to the question is also dependent on how the marketing-mix variables are included in the diffusion model. We are now in a position to introduce one more proposition.

Proposition 5. *For r = 0 and a constant marginal cost, irrespective of the type of the diffusion process or how the marketing-mix variables affect the Libai et al. (2009) service diffusion model (13)*
(i) For a given adverting U and price P, an increase in the disadoption rate δ leads to a decrease in the steady state number of subscribers N, and
(ii) An increase in the disadoption rate δ decreases the optimal steady state profit π.

Proposition 5 indicates that doing nothing in response to an increase in the disadoption rate results in a decrease in the number of subscribers and its stabilization together with related profit at lower levels. Responding optimally by making appropriate changes in the marketing-mix variables would also lead to a decrease in profit. In order to remain profitable, service providers have to limit customer attrition actively (Bolton, 1998; Musalem and Joshi, 2009).

SUMMARY AND CONCLUSIONS

This section summarizes the main theoretical and empirical findings of the study, highlights managerial implications, and proposes directions for future research. The diffusion models analytically explored in this article represent a unique attempt in the literature that aims at deriving optimal pricing and advertising policies for new subscription service innovations.

Our approach considers demand dynamics, learning curve, and discounting that are managerially relevant. Demand dynamics are reflected in the differential equation of the diffusion model through incorporating saturation, word of mouth and disadoption effects. In introducing new subscription service innovations, the decision maker may not be interested in setting the pricing and advertising policies in isolation, but rather he or she would be more satisfied by considering the interactive influence of such policies upon the subscription rate.

This study addresses such concern by recognizing the simultaneous impact of the studied two marketing variables on the diffusion process. The analytical findings of the study summarized in Propositions 3 and 4 generally argue in favor of increasing the subscription fee for new subscription services overtime, perhaps followed by a period in which the fee may be decreasing when disadoption is significant, and decreasing the advertising expenditure, perhaps followed by a period in which advertising is increasing when disadoption is significant to win back customers who disadopted the service. Proposition 5 indicates that customers' disadoption, in the long-run, has an adverse effect on profitability and therefore it must be controlled. For example, long-term contracts are common in the American mobile telecommunications market and contract-bound customers incur high procedural and financial swiching costs for breaking or modifying a contracted agreement (mesak et al., 2011).

The dominant policies of increasing price and decreasing advertising for new subscription service innovations are interesting and deserve an explanation. The service provider charges a low fee and advertises heavily at the beginning to generate positive word of mouth, speed up the learning of the service provider offering and build a large base of consumer adopters who keep on repurchasing the service upon their satisfaction with their initial experiences, causing the perceived value of the service to get enhanced over time. Also, because revenues of a subscription service in a given time period are not solely generated from new adopters during that period but also from adopters in previous periods, subscription fee is motivated to increase and advertising is invigorated to decrease in order to increase profits (Nagle, 1987; Mesak and Darrat, 2002).

The modeling effort developed here is exploratory revealing many possibilities for future research. First, one would consider optimal pricing and advertising of a "secondary" subscription service that is contingent on the subscription of a "primary" subscription service (e.g., a customer cannot subscribe to a secondary pay service such as HBO unless he or she is a subscriber to the primary basic cable service). The study of Fruchter and Rao (2001) is useful in this respect.

A plausible second direction for future research is to incorporate service bundling in the modeling effort (Guiltman, 1987). For example, a cable TV provider may expand the business by providing internet access services together with telephone services. Whether to use a mixing bundling strategy or a pure bundling strategy (i.e., selling the bundle only) is an interesting research topic (Ansari et al., 1996).

Third, other marketing mix variables such as service quality (Rust, et al., 1995; Van Mieghem, 2000), service guarantees (Fruchter and Gerslner, 1999; Kumar et al., 1997) and distribution (Jones and Ritz, 1991; Bronnenberg et al., 2000) could be considered endogenously to enrich the modeling effort.

Fourth, this article assumes that the market has only one service provider operating (as in the case of cable TV). An interesting direction for future research is to characterize optimal pricing and advertising policies under the threat of competitive entry (Gupta and Di Benedetto, 2006). Alternatively, competition could be modeled in a (non-cooperative) game- theoretic framework within the same industry (Thompson and Teng, 1984; Dockner and Jørgensen,1988b, Prasad et al. 2012), or between industries such as cable TV and satellite dish (Ross, 1999).

A fifth direction for future research is to extend the modeling effort to consider different generations of the new service innovation. The notable studies of Danaher et al. (2001) and Danaher (2002) should be particularly informative as they provide lucid reviews of research undertaken in this area. Addressing the above research issues, and perhaps several others, should be beneficial to both academicians and practitioners in the service sector.

ABSTRACT

In this paper, we study a unique large-scale, green lunch box delivery system of Mumbai, and identify that it is further possible to improve the collection and delivery processes by following new routes and evenly distributing the loads. We suggest implementing multiple depots vehicle routing concept for this purpose. Using a real-coded simulated annealing algorithm, we propose new routing and collection load decisions. Suggested improvements are shown with the help of a case example.

KEYWORDS: Transportation, Lunch Box Delivery, Multiple Depots Vehicle Routing Problem.

INTRODUCTION

The lunch box delivery system (LBDS) of Mumbai is considered as a classical example of a very large scale, green transportation management problem (Baindur & Macário, 2013). There are approximately 0.2 million lunch boxes transported from household to offices, and the same number of empty boxes are returned from offices to households every day. The LBDS created in Mumbai has many unique features concerning its operations, services, management practices, and overall business model. It is a wonder to both academic and corporate worlds that how such a vast system operates almost perfectly with the help of the illiterate or semi-literate workforce (an average literacy standard is 8th grade in school) without the use of any sophisticated technology. They have shown to the corporate world that the system in place is more critical than the workforce for achieving astonishing results. The accuracy of delivery is Six Sigma certified. The accuracy level is no less than that achieved by Motorola or GE (Mallik Mukherjee, 2007).

Unfortunately, the problem has not been studied extensively. The literature reports only a limited number of studies on this topic. Only a handful number of research articles are available in the literature (Mallik & Mukherjee, 2007; Pathak, 2010; Baindur & Macário, 2013; Chakraborty & Hargude, 2015). A few case studies also appear in the literature (Ravichandran, 2005; Thomke, 2012). In these works, authors have critically examined the system and tried to find out success factors, and the possibility of replicating it to similar situations of any other part of the world.

Some cases are also taught at the world's top B-Schools to understand how a simple operating process leads to such a superior level of service.

In this work, we review the LBDS of Mumbai and identified that the better collection and delivery routing decisions are possible. We formulate the collection and delivery processes as a multiple depots vehicle routing problem (MDVRP). With the help of a numerical example, we find that it is possible to reduce collection and delivery times by following better routes. A simulated annealing algorithm is used for arriving new routing decisions. Therefore, it is possible to bring improvement into an existing world-class system.

LUNCH BOX DELIVERY SYSTEM OF MUMBAI

This massive system which is existing now has its origin way back in 1890. It has started with one lunch box carrier delivering lunch to one person who was a bank employee during the British era in India. The service has grown and sustained over the last 128 years. The number of lunch box carriers has reached to around 5000 in 2017. Their collective efforts are nearly US$12 million annually.

The lunch box carriers are the smallest and the most important units of the system. They provide this service on all working days throughout the year. They start their operations by reaching to residential areas (RA) to collect boxes either by walk or by using bicycle. Each of them is responsible for collecting 35-40 boxes from pre-specified locations. The collection of lunch boxes is completed between (8:30 – 9:00) AM. After collecting the boxes, they reach the designated railway station. Another set of chosen carriers wait at the station for sorting the boxes. A unique coding system is used for this purpose. Immediately after the sorting, lunch boxes are bundled into groups as per their destinations. Designated carts are used for this purpose. This part of transportation is managed by selected carriers in a pre-determined railway station. Another round of sorting is done after the lunch boxes reach destination railway stations. A new set of carriers performs this task and complete the delivery to the respective customers. This process is completed before 01:00 PM. The collection of empty lunch boxes from offices and delivery to the respective households are done following an exact reverse process. This process is completed before 05:30 PM. The railway extends its support by providing areas required for shorting of 'Dabbas' at platforms as well as by running trains having special compartments suitable for loading carts containing lunch boxes during (10:00 – 11:30) AM in the south Mumbai direction.

The efficient running of the system is largely credited to a simple and visual coding structure appropriate for the illiterate or semi-literate carriers. As the lunch boxes are transported through suburban railway network, the coding structure must suitably relate railway stations. These two major concerns are very well incorporated while designing the coding structure. Figure 1 shows the lunch boxes with codes on the lid of each lunch box.

Figure 1: Coding structure of lunch box delivery system of Mumbai Dabbawalas

(Source: Linderman, 2011)

IMPROVING THE EFFICIENCY OF COLLECTION AND DELIVERY PROCESSES

There are two similar problems related to the collection and delivery processes of LBDS. The first problem is concerned with the collection of lunch boxes from individual houses located at residential areas adjacent to different railway stations by the carriers and accumulate them in respective stations. The other problem is concerned with the delivery of lunch boxes to offices after the collection from different railway stations. The transportation problem for both the processes considered for the entire network can be mapped to multiple depots vehicle routing problem (MDVRP) (Montoya-Torres et al., 2015). We consider the case of collection process for illustration. The delivery process can similarly be illustrated.

The mathematical model of the problem can be written as follows:

$$\min: \sum_{i=1}^{n+m}\sum_{j=1}^{n+m}\sum_{k=1}^{K} d_{ij}\, y_{ijk} \tag{1}$$

Subject to

$$\sum_{i=1}^{n+m}\sum_{k=1}^{K} y_{ijk} = 1, j = 1,2,\dots,n \tag{2}$$

$$\sum_{j=1}^{n+m}\sum_{k=1}^{K} y_{ijk} = 1, j = 1,2,\dots,n \tag{3}$$

$$\sum_{i=1}^{n+m} y_{ihk} - \sum_{j=1}^{n+m} y_{hjk} = 1, k = 1,2,\dots,K; h = 1,2,\dots,n+m \tag{4}$$

$$\sum_{i=1}^{n+m} Q_i \sum_{j=1}^{n+m} y_{ijk} \le P_k, k = 1,2,\dots,K \tag{5}$$

$$\sum_{i=1}^{n+m}\sum_{j=1}^{n+m} d_{ij} y_{ijk} \le T_k, k = 1,2,\dots,K \tag{6}$$

$$\sum_{i=n+1}^{n+m}\sum_{j=1}^{n} y_{ijk} \le 1, k = 1,2,\dots,K \tag{7}$$

$$\sum_{j=n+1}^{n+m}\sum_{i=1}^{n} y_{ijk} \le 1, k = 1,2,\dots,K \tag{8}$$

$$x_i - x_j + (m+n) y_{ijk} \le n + m - 1, \forall i,j \in [1,n], i \ne j;\ k \in [1,K] \tag{9}$$

$$y_{ijk} \in \{0,1\}, \forall i,j,k \tag{10}$$

In this formulation, y_{ijk} is the binary decision variable to be equal to 1 if the arc connecting (*i*, *j*) is served by the lunch box carrier *k* and 0, otherwise. The objective function (1) minimizes the total distance travelled, constraints (2) and (3) ensure that each RA is served by one lunch box carrier, constraint (4) represents continuity of routes, constraint (5) represents the collection capacity of lunch box carriers, constraint (6) represents the restriction on route cost, constraints (7) and (8) represent the availability of lunch box carriers, and constraint (9) represents the condition fir eliminating sub tours. It is assumed that availability of lunch boxes at each node does not exceed the carrying capacity of each carrier.

NUMERICAL EXAMPLE

We consider an instance of collecting 370 lunch boxes from 31 RAs located around the Boriville railway station in Mumbai. At the end of collections, lunch box carriers will bring them to the same railway station. Table 1 represents the longitude, latitude, number of lunch boxes available for collection at RAs (2 to 32). The railway station is denoted by 1.

Table 1: Lunch box collection related data

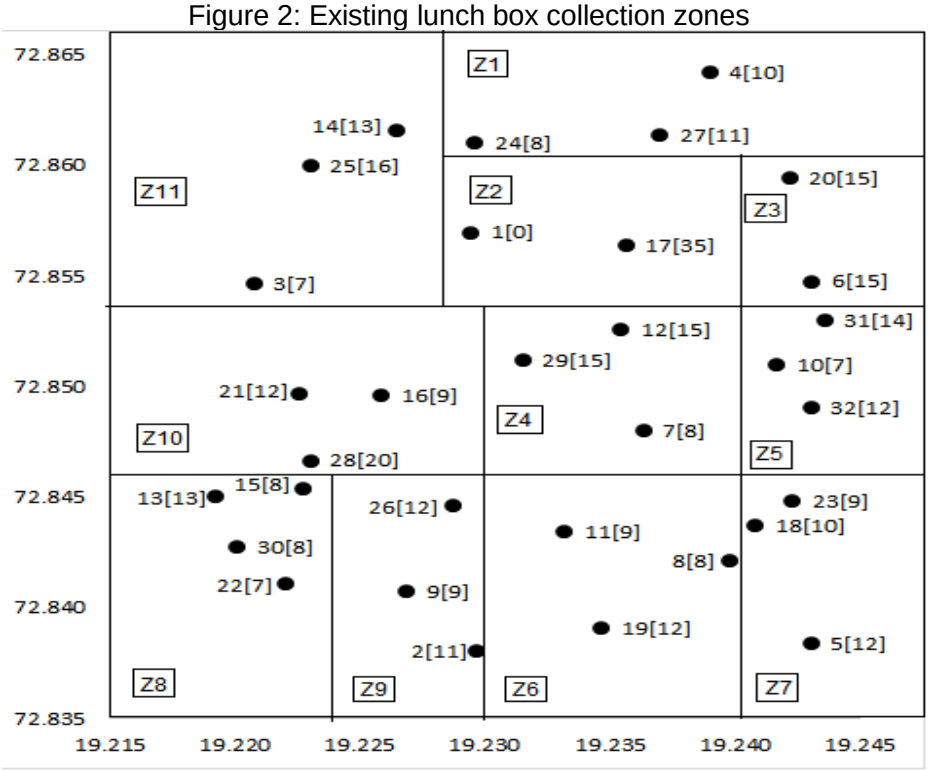
Number	Longitude	Latitude	# Lunch boxes available for collection
1	19.229389	72.856998	0
2	19.229587	72.838105	11
3	19.220730	72.854694	7
4	19.238912	72.864214	10
5	19.242959	72.838453	12
6	19.243015	72.854779	15
7	19.236298	72.848048	8
8	19.239732	72.842170	8
9	19.226823	72.840754	9
10	19.241580	72.851033	7
11	19.233122	72.843478	9
12	19.235389	72.852582	15
13	19.219192	72.845072	13
14	19.226405	72.861590	13
15	19.222681	72.845413	8
16	19.225826	72.849635	9
17	19.235619	72.856406	35
18	19.240763	72.843777	10
19	19.234617	72.839127	12
20	19.242121	72.859455	15
21	19.222511	72.849721	12
22	19.221976	72.841156	7
23	19.242214	72.844861	9
24	19.229522	72.861034	8

25	19.222981	72.860013	16
26	19.228668	72.844680	12
27	19.236964	72.861369	11
28	19.222998	72.846692	20
29	19.231496	72.851250	15
30	19.220080	72.842804	8
31	19.243523	72.853008	14
32	19.242987	72.849063	12

RESULTS AND ANALYSIS

At present, RAs around the Boriville railway station are divided into few zones. One carrier is responsible for collecting boxes from each zone. The zones are shown in Figure 2.

Figure 2: Existing lunch box collection zones



In the Figure 2, longitudes are shown along the x-axis, and the latitudes are shown along the y-axis. For the considered case example, a real-coded simulated annealing (SA) approach is used, which is coded in MATLAB. A comparison of the existing and suggested solutions is presented in Table 2.

Table 2. Existing and proposed routes

Existing Routes			SA Routes		
Route/Zone	# Lunch box collected	Distance Travelled (km)	Route	# Lunch box collected	Distance Travelled (km)
1	29	2.85	1	37	1.97
2	35	1.39	2	40	4.24
3	30	3.47	3	37	2.87
4	38	2.58	4	39	4.81
5	33	3.80	5	36	3.93
6	29	4.55	6	38	4.96
7	31	5.08	7	36	4.10
8	36	4.10	8	36	3.52
9	32	4.15	6	35	1.39
10	41	2.71	10	36	3.38
11	36	2.61	Total	370	35.16
Total	370	37.29			

The existing solution shows the requirement of 11 lunch box carriers, one for each zone. However, the suggested solution shows the requirement of 10 lunch box carriers. The total distances traveled along all the routes are 37.29 km and 35.16 km, respectively. This implies that the proposed approach suggests a saving of 5.71% in terms of distance traveled. The lunch box carriers follow an extremely busy schedule during their hours of operations. The reduction in distance traveled will provide some space for them. It will be even more effective for the elderly lunch box carriers. In terms of carrying the number of boxes, the suggested solution is more rational.

CONCLUSIONS

We reviewed the LBDS of Mumbai from the transportation aspects and investigated its vast scale of operation, environment friendliness, cost efficiency, supervision of the system at different nodes of operations. It is observed that the accuracy of delivery of lunch boxes is near perfect and may not be possible to improve further. The coding structure followed in the system is a major constituent for the success of the overall transportation process. The role of semi or illiterate lunch box carriers is extremely important for the accurate delivery and optimum functioning of the transportation system. We identified an area where improvement is possible. It is regarding the routes followed during the collection and delivery processes of lunch boxes. The results indicate the possibility of reducing the collection time by about 6% compared to the existing one.

ABSTRACT

This research documents the process of developing a performance dashboard system for one university's career services center to overcome challenges including lack access to relevant information, stakeholders not taking advantage of what is being offered, students' anxiety about not being able to find a job, and strategic planning. Through theory foundation grounded on the literature, the research aims to integrate data into actionable information, to present the right information to the right user at the right time, to provide a platform for communication between all stakeholders, and to improve stakeholder satisfaction through self-serve ad-hoc reporting.

KEYWORDS: Performance Dashboards, Higher Education, Data Visualization

I. INTRODUCTION

Recent developments in higher education have spurred the need for more effective planning and management (Duffy, 2005) . With pressure to become active, innovative, results-oriented and effective, universities to operate strategically (Kassahun, 2010). Higher education institutions are transforming into entrepreneurial enterprises in which performance is linked to various university strategies (Nayeri et al., 2008). Some of the challenges that universities face include a tighter job market, competition among schools for applicants, rising tuition, concerns regarding return on investment, relationships with employers, economic volatility and the need for a common platform to communicate with all stakeholders.

A performance dashboard builds on business intelligence (BI) platform to provide interactive visual display of data to effectively measure, monitor and manage business performance of an organization toward predefined goals (Eckerson, 2010; Min, 2015, Lea, Yu, & Min, 2018). With the self-service business intelligence (BI) capbability to deliver the right information to the right users at the right time, a performance dashboard presents opportunities for universities to improve their institutional operation and strategic management capabilities.

This study documents design, development, and implementation of a performance dashboard for a career opportunities and employer relations center (referred as COER hereafter) to overcome challenges and to support the strategic management at a university located in Midwest of U.S.A. The proposed literature review shows how higher education institutions can recreate their strategies and business performances to adapt with the changing environment and to become more technologically advanced. A performance dashboard is proposed as a novel approach to achieve this goal.

This paper first reviews the literature concerning performance dashboards, career services in higher education, and the use of performance dashboards in higher education. Then, the research method will be explained, including the creation of a performance dashboard prototype. The paper will conclude with a summary of the findings, recommendations, contributions and directions for future research.

II. LITERATURE REVIEW

With nearly 15 million students who need assistance in determining their career paths and finding employment (Felix, 2006), career services impact the key aspects of student lives and career plans/opportunities in higher education institutions. Research has shown that the degree of satisfaction of students and parents is directly proportional to the reputation of the university, the placement rate and the expected income after graduation (Zhen, 2004). Therefore, offering students better and effective career assistance can increase the university's reputation and attract more students (Kerr, 1993). In addition to students and their parents, employers, alumni, and faculty of various academic departments are key stakeholders of career service center at a university (Yi & Rui, 2009).

Apart from on-campus placement activities, career services often include providing personality development workshops, mock interviews, resume critiques, job search training, employer information sessions and much more. Universities typically fund career services to make students more marketable (McCorkle et al., 2003) as a result of pressure from competitive job market (McGrath, 2002), high competition for applicants among universities (Howard-Vital, 2006; Garver et al. 2008), higher ROI expectation from higher tuition (Snow, 1995; Domino et al., 2006; Garver et al. 2008), the need for better employer relationship (McGrath, 2002), demand for well-rounded student candidates (Garver et al, 2008), and the use of placement statistics as a measure of educational quality and value (Garver et al., 2008)

Accurate, easily accessible information leads students to make better career choices and benefits the economy (Mayston, 2002), so universities thrive to provide accessible career services centers that provide the stakeholders with good information about various career services programs, events and classes. Lalande and Huston (2005) identified three priorities for measuring stakeholder outcomes from services provided by a career center: implementing an efficient communication strategy with stakeholders, clarifying desirable outcomes for career development practices and developing a system for archiving and easily obtaining information about the career center. Increased importance has been placed on career-related information and guidance, thus pressuring career services to explore better ways to disseminate information to their stakeholder (Grubb, 2022). Higher education institutions across the world have found various ways to disseminate information including individual or group career advising (Maguire & Killeen, 2003; Mayston, 2002), technology enabled self-service (Grubb, 2002), published statatistics amd reports (Spradlin et al., 2010), and consultation and promotion management (Mayston, 2002).

A performance dashboard is a multilayered interactive visual display mechanism built on a business intelligence and data integration infrastructure that conveys key performance information at a glance to allow users to effectively measure, monitor, and manage business performance of an organization toward predefined goals (Lea, et. al., 2018; Lea and Nah, 2013; Eckerson, 2010; Lea, 2011 Few, 2006). A performance dashboard often presents information in three different

layers including a summarized graphical layer, a multidimensional data layer, and a detailed transactional data layer to support its monitor, analysis, and management functions effectively (Eckerson, 2010, Lea, 2011). As a result, performance dashboards are gaining popularity as information delivery mechanism at different organizational levels, as achieved by integrating various data sources and utilizing different information layers to display and communicate data effectively.

Performance dashboards are typically classified into strategic dashboards, tactical or analytical dashboards, and operational dashboards (Eckerson, 2010, Few, 2006). A strategic dashboard aims at assisting top management in charting progress of an organization's strategy execution (Eckerson, 2010; Lea, 2012) and in providing high-level business performance overview. A tactical or analytical dashboard focuses on operational and tactical aspects of an organization and utilizes descriptive, predictive, and prescriptive analytics that allow users to interact with the data needed to understand the context. An operational dashboard focuses on monitoring daily transactions and real-time events that are constantly changing and requiring timely attention and thrives on providing most granular reports and live operational data (White, 2006) to accountability through tangible evidence and its impact on corporate goals (Miller & Cioffi, 2004).

Performance dashboards are designed to serve as a self-service business intelligence (BI) tool with an intuitive and user-friendly interface that require minimum or no user training.to deliver the right information to the right users at the right time. The reported advantages of performance dashboard adoptions include enhanced operational efficiency (Lea, 2011, White, 2006), optimize decision making (Eckerson, 2010, Lea and Nah, 2013), improve data visibility, process transparency, and strategy communication and alignment (Lea, et., al. 2018; Eckerson, 2010), reduce costs and resources required to prepare performance reports and management business (Eckerson, 2010; Few, 2006), and improve profitability.

III. Case Description

The case studied in this research is a career opportunities and employer relations center (COER) at a highly reputed STEM-focus university located in the Midwest. The goal of COER is to help students develop their careers and reach their professional goals while maintaining partnerships with diverse employers and university department staff. Education plays a significant role in students' career success in life, and COER helps to make the most of educational opportunities by helping students find full-time employment, summer internships and cooperative education experiences, thus bridging the gap between students and employers.

COER uses a database to post job opportunities for students. It is very important for COER to make its services and statistics easily accessible so that external and internal stakeholders can utilize them and enrich their educational experience. However, COER faces various challenges in reaching its stakeholders and user groups. One challenge is that students do not take advantage of all the resources that COER provides. Unfortunately, most students do not realize the potential opportunities that they can take advantage of by utilizing COER services that are tailored to meet students' job search and career development demands. Another challenge COER battles is the lack of access to sophisticated software tool and expertise to appropriately market and present the university's recruitment statistics and trends, which could serve various user groups by helping relieve their questions and doubts.

Currently, COER disseminates information mainly through published reports and handouts on their web sites and in office, as shown in Figure 1. These static reports are published on the web site annually, but do not have drill-down or drill-across capabilities to provide customized

report or deliver right information to right user at right time. The lack of interactive and accessible statistics leads to insufficient or outdated information provided to departments, faculty and staff and often resulted in time consuming and manual process information requests from COER's stakeholders. For example, when a department asks for a report or statistics, COER staffs must manually develop the report according to the unique requirements of the different departments. This task is time consuming and requires a great deal of manual intervention. Due to the lack of technology proficiency among COER staffs, user groups such as parents and employers are not involved heavily in the process of students' career and professional development.

- 49% response rate to post-graduation plans survey
- 49% of graduating students remained in MO
- 51% of graduating students moved outside MO

IV. Solution Approach

This study proposes to adopt a strategic planning process and a performance dashboard to address challenges faced by COER. The study is grounded on literature review of performance dashboards implementation in higher education and utilized surveys, interviews, prototyping,

and statistical analysis to validate findings. Software development Life Cycle (SDLC) was utilized in the proposed dashboard prototype development to incorporate theories and best practices from the literature review and the unique challenges faced by COER.

Effectiveness of a dashboard is the extent to which the intended goals of the dashboard through the implemented dashboard functionalities. In-person, email, and web conference interviews were conducted with COER staff and selected stakeholders to understand COER processes and how reports are developed in its current environment. The interview utilized a semi-structured approach that enabled interviewees to speak freely and ask questions. Figure 2 illustrated sample documentation from activity analysis and measures and dimension analysis from the structured and semi-structured interview process. Meeting records were kept and reviewed regularly to revise or validate project scope and timeline. The interview process helped to clarify various rules and definitions used in the process.

	Type of internship / co-op offered	Paid, non-paid, for credit hrs
	Number of employers who return for next career	Semester, year

Strategic planning process was incorporated into the performance dashboard development process. The project team worked with COER staffs to draft mission, vision and value statements

relevant to the business and its organizational chart. The next step involved identifying performance measures, which focus on business performance. Once the performance measures were defined, they were classified into four perspectives including included value creation, stakeholder, and internal process using a Balanced Scorecard approach. Next, strategic objectives and corresponding goals were defined. In this study, to address the strategic objective of enriching the student experience, COER's goal was to expand and increase the quality of the resources, facilities, programs and personnel focused on teaching, learning and the student experience. After these processes are structured, a strategic map was developed that demonstrates the various objectives and their associated goals from different perspectives that influence the business process.

After reviewing the literature and studying COER's challenges, the implementation of a tactical dashboard prototype is proposed to tailor COER's specific performance measures to provide actionable information to internal and external stakeholders and to eventually benefit the university as a whole. A tactical dashboard aims to assist managers in monitoring and tracking performance and progress towards the targets of their functional areas. Furthermore, tactical dashboards give managers deeper insight into the data to identify the root causes of problems and trace the history behind and reason for their occurrence, which helps managers to take corrective actions to improve the situation (Kaplan & Norton, 2004). These business tactics help to align and optimize actual balanced performance with planned performance (White, 2006). The tactical dashboard analyzes business performance over a period of days, weeks or months (White, 2006).

Data were collected from COER legacy database and its custom job database. Data cleansing, which encompasses both data validation and data cleaning, was the most important and time-consuming part of the project. Data cleansing identified inaccurate and incomplete data and then improves its quality by correcting the detected errors through format checks, completeness checks, checks for the use of special characters, and duplicate removal.

Once data were cleaned and initial dashboard functionalities were determined, the data warehouse technical framework using a star schema was developed and implemented using the SAP business warehouse (BW). Queries were than created per COER requirements to publish the dashboard visuals.

Rapid prototyping methodology was adopted to create a portion of the dashboard's solution to COER's challenges in order to demonstrate its functionality and make necessary refinements before the deployment. The project team provided dashboard prototype demonstrations to the COER staffs and selected stakeholders to solicit feedbacks and address concerns on the agreed milestone dates or at least once a month. This methodology proved useful in confirming understandings of COER's requirements and ensuring consistency between the proposed solution and business expectations throughout the entire dashboard development iterations.

Dashboard prototype validation involved checking the data for accuracy and validating it against COER reports. COER staffs conducted a comprehensive and detailed cross verification of the dynamic reports produced by the dashboard prototype to confirm data accuracy. At this step, COER had another the opportunity to use and check the functionalities of the dashboard prototype before the deployment. Modifications were made based on COER feedback in an iterative process that continued until COER approved the prototype's release for production.
After confirmation from COER, the dashboard prototype was published on the official COER's university web site. Once published on the website, all the users, such as students, employers,

and parents, were able to access the new, interactive performance dashboard to analyze the various statistics and reports.

A feedback survey was designed and deployed to identify realized benefits and advantages the dashboard from various COER stakeholders. It also served as a means by which to communicate with stakeholders to learn improvements to the dashboard and additional types of information and dynamic reports users would like to have on the dashboard. The survey instrument was approved by the Institutional Review Board (IRB) to ensure that the survey involving human subjects met the requirement of the U.S. Department of Health and Human Services (HHS). The feedback survey was incorporated into the dashboard prototype and announcements were published in newspaper for both students and employees and sent to COER's employer list, COER's corporate advisory board, Provost and his cabinet, department chairs, presidents of Undergraduate and graduate student councils, president of staff council, and selected parents and alumni.

V. Dashboard Prototype Implementation

This section documents design and key user-centered design principles used in the proposed tactical performance dashboard. The dashboard's functionalities and how its functionalities helps to solve COER challenges and can be used by various COER stakeholders, is described.

5.1 Design for Dashboard Functionalities

The proposed COER performance dashboard prototype intends to help various stakeholders to perform their tasks, such as finding and analyzing department and university statistics, understanding job employment data and career fair statistics, and comparing statistical trends for different job types. Through analysis of peer institutes, COER staff activity reports, stakeholders, and key performance indicators and dimensions, the dashboard's content is divided into three tabs: Major Statistics, Job Statistics, and Recruitment.

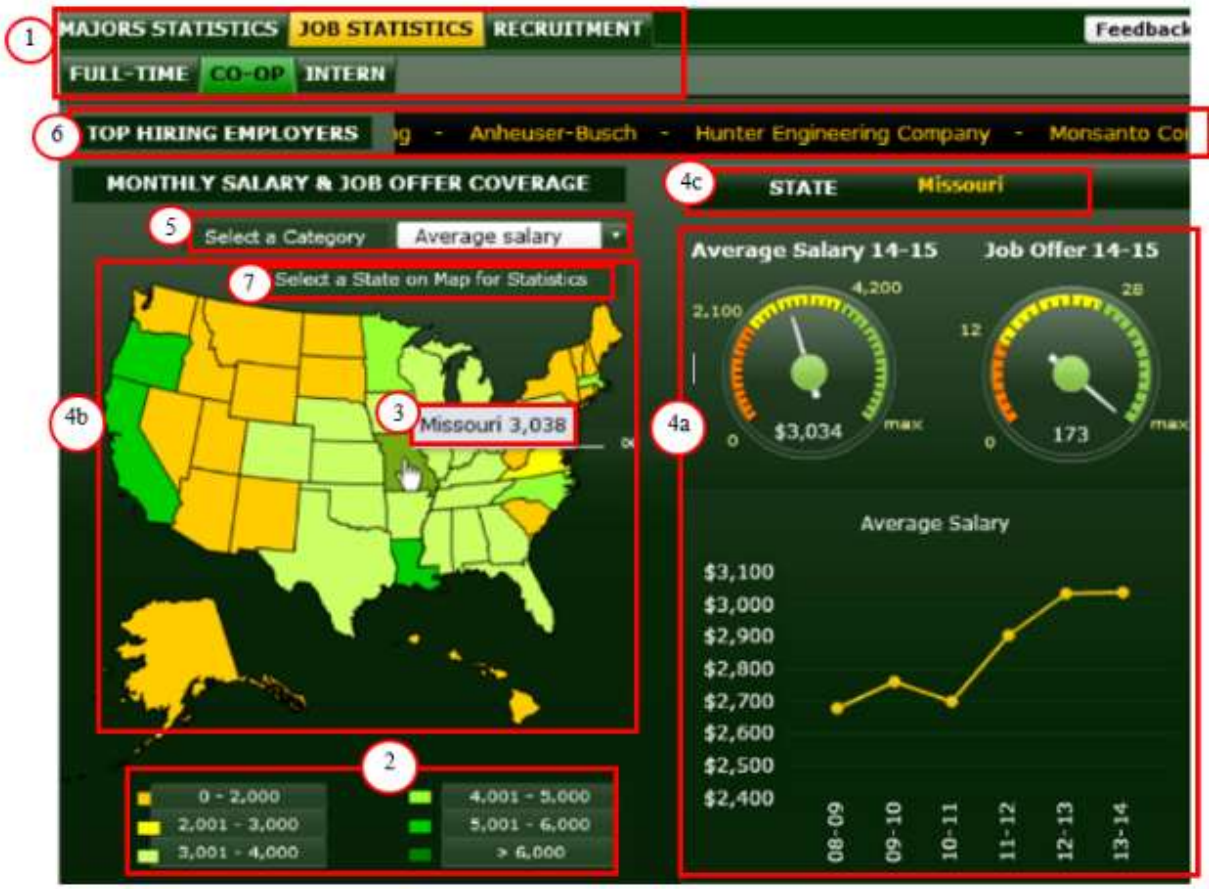
The job statistics tab is used to illustrate Key functionalities. It is deigned to help students to understand the differences that exist between different states' average salaries, which helps them know what to expect in terms of salary when they receive a job offer. This tab also helps COER staffs, faculty, university management, and other stakeholders to understand from which states its students are receiving job offers and that could help them strategize to expand their relationships with employers in other states.

The design of major statistics tab is provided below and is illustrated by Figure 3:

(1) The job statistics are further divided into three tabs according to job type: full time, co-op and intern. The default view is the full-time job statistic. The co-op view is used for illustration, but the format of the data and screen design remains the same for the full-time and internship positions.
(2) The drop-down menu, denoted as 1 in Figure 3, allows the user to select either the average salary or job offer category to display the statistics on the U.S. map, denoted as 2a in Figure 3. The interactive map offers a geographic visualization of the selected category. To help users visualizing the geographic distribution of job offers and average salaries across the country, the color-coding scheme is listed at the bottom of the map, denoted as 3 in Figure 3.
(3) Once a user clicks to select a state on the map, the two dials gauges show the current year's average salary and number of job offers for the selected state on the top of area 2b in Figure 3. The 5-year average salary trend of the selected state is also provided.

(4) The ticker text box shows the current year's top hiring company for co-ops, denoted as 3 in Figure 3.

Figure 3. Job Statistics Screen Design



5.2 Design Principles for intuitive and user-friendly Interface

The benefit of information disseminated depends on the user's sophistication in accessing and comprehending it and on the degree of its sufficiency for making appropriate decisions (Grubb, 2002). Accessibility refers to all users having easy access to information and services, taking into account their different requirements. As performance dashboards are often used by executives and users who are not necessarily technology savvy, it is important for the dashboard to have a user-friendly and intuitive interface. Lichiello and Turnock (2005) indicated that a performance dashboard has a user-friendly interface when it defines and selects the performance measures that are meaningful, relevant and that best allow users to find solutions to their questions. Cowart (2008) indicates that a dashboard is easy to understand because of its bright colors, consistent format, and easy interpretation of complex integrated data, which helps to catch the user's attention. The proposed dashboard prototype utilizes principles learned from the literature to design an intuitive and user-friendly interface as summarized below and illustrated with Figure 3

1. ***Information categorization***: Information is broken down into different tabs, which are organized into a meaningful order and hierarchy, as in examples denoted as 7 in Figure 3.

2. ***Color Coding***: Color coding is used to represent the geographic distribution of job offers and average salaries, making it easier for the user to understand the system, as in the examples denoted as 2 in Figure 3.
3. ***Dynamic information tip***: Placing the cursor over the state gives the statistics for that state, as in the example denoted as 3 in Figure 3.
4. ***Use of common charts and diagrams***: The dashboard is easy to operate because it uses common graph types and gauges, clickable geographic maps, and clearly labeled sections, as in the examples denoted as 4a and 4b in Figure 3.
5. ***Drop-down menus:*** Common drop-down menus are utilized to allow users to select desired a information category or function. For example, a user can select to view average salary or job offer category from a drop-down menu as denoted as 5 in Figure 3.

These interface design features offer users various ways to find information and the ability to scan the dashboard at a glance rather than reading through dense text, which makes it user friendly.

5.3 Design Principles for Learnability

Learnability is an aspect of usability (Nielsen, 2003; Casaló, et. al., 2008) and refers to the ease with which new or occasional users may accomplish certain tasks, including how quickly users are able to understand the components and navigation options and to use them to locate the desired information. That is, learnability refers to the capability of the software to enable the user to learn how to use it and becomes a major concern when designing a software tool.

A dashboard is used to display information for various user groups and each user group has a different set of information requirements, so users must learn how to operate the dashboard in order to find their required information. Kassahun's (2010) indicated that dashboards are easy to learn and easy to operate as they guide different user groups with different sets of data for analysis. The dashboard becomes easier to learn because of its use of charts to compare measures to benchmarking values and its compelling presentation that directs users to the information they are seeking (Stewart & Carpenter-Hubin, 2001). When adopting the performance dashboard, users can develop agility and quickly learn to operate the dashboard to better anticipate and respond to the changing needs of the business (Brudan, 2005). Principles used to design an easy-to-learn dashboard are summarized below.

1. ***Organize the information*** to support its meaning and use: A screen is typically divided into multiple sections and each section displays related and meaningful information for analysis. For example, there are three related information sections on the major statistics screen. The top section displays current year salary by department, the bottom left section displays the five-year salary trend of a user selected department, and the bottom right section displays the five-year university salary trend, denoted as 1, 2, and 3 respectively in Figure 3.
2. ***Use of labels***: Short and self-explanatory labels are provided for various sections, as examples denoted as 7 in Figure 3 respectively.
3. ***Consistent layout design***: The dashboard's format remains consistent throughout all the tabs, making it easy for users to follow the design and to predict the effect of their actions.

Denoted as 3 in Figure 3, the Major Statistics tab and Job Statistics tab have the similar format of displaying Full-time, co-op and intern data. Also within these three sub-categories, the graphical display remains the same.

4. ***Use of instructions***: Clear information is provided where users must select an option to display the information pertaining to that option, denoted as 7 in Figure 3.

VI. Deployment and Assessment

The section is to assess the design aspects and to examine benefits gained by COER after implementing a performance dashboard. The data were collected from the target users through the feedback survey described in the solution approach section. The responses were analyzed to validate designs and the realized benefits of using performance dashboards in higher education systems.

Of eighty-nine responses received in the first two weeks of dashboard deployment, thirty-one were females, forty-one were males, and two were "do not wish to disclose. Seventy-six percent of respondents used the dashboard prototype for the first time, 20% of respondents used the dashboard prototype two to five times, and 4% of respondents used the dashboard prototype six to ten times. About 91% of respondents indicated that they have spent less than an hour, 6% of respondents spent between one and two hours, and 3% of respondents spent between two and five hours in using the dashboard prototype at the time of taking survey.

Researchers have shown that "perceived ease of use" influences "perceived usefulness" and adoption and actual usage of a software system ((Davis, 1989; Davis, et. al., 1989; Venkatesh and Davis, 2000; Lea and Nah, 2013). Therefore, the proposed dashboard prototype is analyzed for the "perceived ease of use" dimension using the following survey statements and hypotheses:

1. The graphs, charts and maps provided by the new dashboard system are easy to understand
2. The new dashboard provides a user-friendly interface
3. I can learn to operate the new dashboard system easily
4. I can easily find university outcome data using the new dashboard system
5. I can easily find services provided by Career Opportunities & Employer Relations (COER) using the new dashboard system

For each survey statement, scale 1 represents strongly agree, 2 represents agree, 3 represents neutral, 4 represents disagree, and 5 represents strongly disagree. As shown in Figures 4, results indicated strong positive for all five "ease of use" dimensions.

In this study, effectiveness refers to user satisfaction in terms of ease of use, usefulness of results, and meeting user requirements and is measured by the degree to which the system enables a user to achieve his or her goal through performing required tasks. Therefore, following survey statements were developed to examine typical tasks performed by staff and stakeholders of a career services center:

1. I can clearly identify my department outcome data using the new dashboard system
2. As an employee at the XX (the case university name), I can use the new dashboard system to obtain statistics, charts and reports that are needed for my department and/or students
3. The new dashboard system could help me to review and compare recruitment

4. The new dashboard system could help me to review job status (full time, co-op, intern) statistics
5. The new dashboard system could help me to obtain career fair statistics
6. The new dashboard system could help me to understand job employment data (number of jobs, salary, etc.) with respect to geographical location
7. The new dashboard system could help me to analyze department recruitment statistics

For each survey statement, scale 1 represents strongly agree, 2 represents agree, 3 represents neutral, 4 represents disagree, and 5 represents strongly disagree. As shown in Figures 5, all dashboard functionality dimensions were positively received by the survey respondents.

Researchers have shown that “perceived ease of use” influences “perceived usefulness” and adoption and actual usage of a software system ((Davis, 1989; Davis, et. al., 1989; Venkatesh and Davis, 2000; Lea and Nah, 2013). Therefore, the proposed dashboard prototype is assessed for the “perceived usefulness” dimension using the following survey statements:

1. Usefulness in interpreting data and results
2. Usefulness in visualizing data
3. Usefulness in assisting the university with publicity
4. Usefulness in analyzing trends
5. Creating additional charts, reports and statistics
6. Usefulness in helping the university with continuous improvement
7. Usefulness in providing timely information
8. Usefulness in providing different details for different users for different purposes

The same 5-point Likert scale was used with a 1 represents very useless and a 5 represents very useful. As shown in Figure6, respondents show strong positive support for the usefulness of dashboard in all nine dimensions.

Figure 4. Ease of Use Survey Response

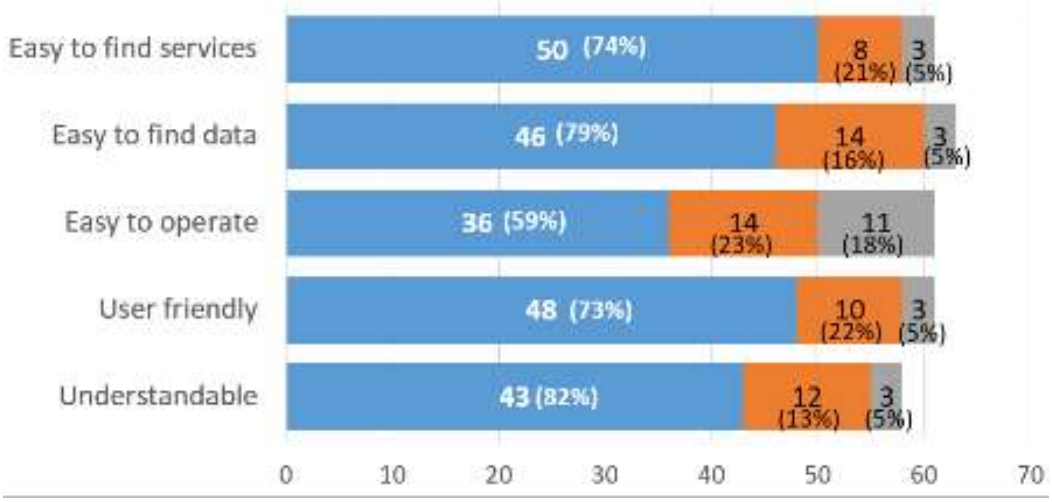


Figure 5. Task Functions Survey Response

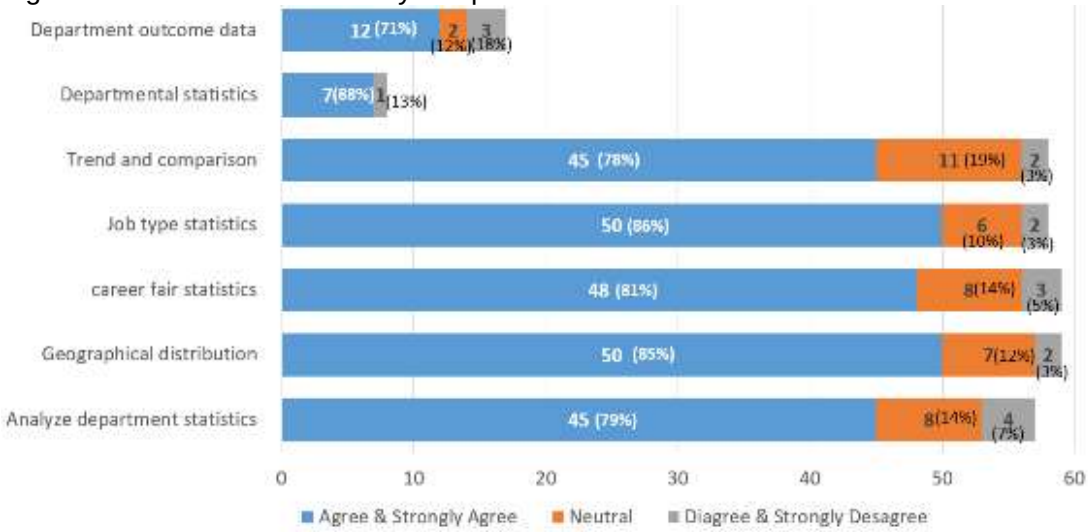

Figure 6. Survey Results on Perceived Usefulness

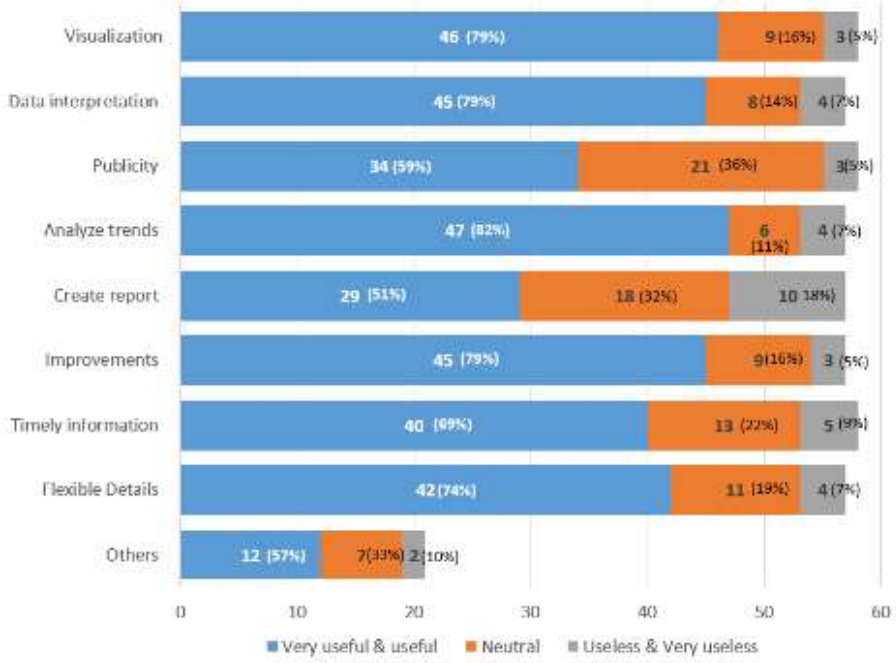

VII. Research Contributions, Implications, Limitations, and Future Research Directions

The objective of this research was to investigate if performance dashboards can be applied to overcome challenges faced by institutions of higher education aiming to measure and manage performance. The dashboard was implemented to support the career service center COER to communicating its recruitment statistics and services at the case university. The assessment results indicated the proposed performance dashboard provides a useful, common platform for communicating with various stakeholders. It provides an interactive platform that users can use to analyze and to facilitate decision-making. The dashboard gives university executives a higher-level picture of business performance and previous statistical trends that can be helpful for predictive analyses.

The results of this research revealed that implementing a performance dashboard offered significant improvements for COER and its stakeholders, allowing users requirements to be addressed through self-service on a timely manner. The proposed interactive dashboard addressed challenges faced by institutions of higher education, such as lack of access to information, stakeholders failing to take advantage of what is being offered, and students' anxiety about not being able to find a job and strategic planning. The dashboard prototype feaures a user-friendly interface with which to access the system easily, allow new or occasional users to adjust to their operation easily and quickly and help users to perform tasks effectively. The results from a feedback survey validated dashboard functionalities. The assessment results further support the fact that dashboards help in presenting the right information to the right users at the right time (Lea, 2011).

One of limitations faced the study was a concern for security and privacy. The career service center COER at the case university did not want to create reports and statistics because of the confidential data housed in the database. Respecting this concern has limited the development of some functionalities and reports that could have been embedded in the dashboard for better performance improvements. The second limitation was time constraints. The survey has not sufficiently reached some stakeholders, such as parents and department chairs, so analyses could not be performed from their perspective. Furthermore, the survey is still on-going and that limited data points for a more in-depth analysis.

Future research includes adopting Kaplan and Norton's Balanced Scorecard framework (1992, 1996) at COER for performance management. The novelty of balanced scorecards in higher education systems provides a rich opportunity to utilize this tool in a wide range of applications. Furthermore, a Balanced Scorecard based dashboard system allows additional strategic planning and alignment of strategies (Lea, et. al., 2018).

ABSTRACT

Phubbing is pervasive across cultural entities, but there is little insight of phubbing behavior. There is an urgent need for understandings into phubbing culture in cultural contexts. This study sought answer to three questions: what social factors account for phubbing? What cognitive factors motivates phubbing? And, what cultural factors discourage phubbing? A grounded theory methodology approach was adopted for the study. We used Grounded Theory because it allows for empirical theory-creation. Findings indicated three motives for phubbing in the context of nonwestern societies: social, cognitive, and cultural.

KEYWORDS: Phubbing, Smartphone addiction, Techno-Snubbing, Phubbing Theory, Phubbing Non-Western Context

INTRODUCTION

With increasing diffusion of smartphone and handheld devices and the numbers of people adopting, and using smartphones globally, the problem of phubbing is becoming more pervasive (Qian, Z. 2014; Relling, B. A. 2014; and Pheeraphuttharangkoon, S. 2015). Studies have been undertaken with a view to having a better understanding on phubbing culture. Although, extant studies are beginning to provide insights on phubbing phenomena, such studies are limited. The scarcity of studies on phubbing culture is even more limited in the context of nonwestern societies.(Simon, L. 2017; Dilonardo, M. J. 2018). No systematic account exists that explains what phubbing is, how it is practice, why it is practice and the perceptions of people in the context of non-western culture. (Davey, S. 2018; Chotpitayasunondh and Douglas, K. M. 2016). The objective of this paper is to report the result of empirical inquiry that attempt to offer a theoretical model of phubbing in the context of developing countries, case study of Kaduna, Nigeria. This study adopted grounded theory methodology to explore phubbing culture which

refers to the act of snubbing someone during conversation by focusing on smartphone. Grounded theory, was advanced by Glaser and Strauss (1967) has provided us with a frame for advancing a theory on phubbing behavior. This paper is the first part in a series of 4 part articles reporting findings on the complex social and cultural determinants of phubbing and smartphone addiction in the context of non-western societies.

LITERATURE REVIEW

Smart Phone

Over the year's smartphones have become indispensable in modern society. (Barnes, E (2017; Muhammad, S. and Soomro, T. R. 2013). Smartphones has the advantage of being portable and is used for chatting, internet browsing, watching movies, and texting (Fortunati, 2002). Smartphone has become cheap and affordable (Acharya et al. 2013; Leung 2008). Smartphone is changing lives in many societies including Africa where it is used in health care systems to improve health and wellbeing (Apple 2013; Annika 2016; Chen and Katz, 2009). Smartphones have been shown to promote deeper intimacy between family and friends (Campbell and Ling, 2009). Closely related to the use of smartphones for improved wellbeing is the challenges brought about by the improved diffusion, adoption, and use of smartphones. For instance, smartphone related mishaps are common as a result of text driving (Harwood et al. 2014).

Smartphone: The Challenge of Phubbing

Phubbing is a major challenge brought about by the improved diffusion, adoption, and use of smartphone. Phubbing refers to the act of snubbing someone by using smartphone during conversation (Angeluci, 2016). The term phubbing is a combination of the words "phone" and "snubbing", and describes the act of snubbing directly in one's company (Haigh, 2012). This term was originally coined to represent a growing problem of smartphone misuse in social situations (Pathak, 2013). In a social interaction, a "phubber" can be defined as a person who is engage in the practice of phubbing his or her companion(s), and a "phubbee" is a person who is a recipient of phubbing behavior. Phubbing has been shown to undermine relational closeness (Przybylski and Weinstein, 2012; Misra et al., 2014). Smartphones is considered as a medium that disconnects conversational partners since one might feel left out as the other person is intensively absorbed with his or her smartphone. Phubbing result in distraction during conversation and it usually provoke negative feelings (Hart et al., 2004). Studies indicate that smartphone use can lead to addiction as owners of smartphone experience urge to peep at smartphone technology (Harwood et al. 2014). Studies found that smartphone owners peep through smartphones over thirty times in a single day (Lee et al. 2014). The increasing urge to peep through smartphone result in phubbing. The consequence is that individuals may be near to each other physically, but they are more focused on their smart devices (Stop Phubbing 2014).

METHODS

This study adopted Grounded Theory methodology to explore phubbing culture which refers to the act of snubbing somebody in a communal setting by focusing on smartphone. Grounded Theory (GT), was advanced by Glaser and Strauss (1967) has provided us with a frame for advancing a theory on phubbing. In line with the GT methodology, this study is framed within qualitative research paradigm. Qualitative research methodology refers to the method of inquiry employed to gather an in depth understanding of human behavior and the reason that governs the behavior (Musa 2013). Qualitative research methods are known to be best suited for studies

whose purpose is to learn from participants about their experiences, opinion and perception within their social and cultural context (David 2012). The purpose of the study is to gain deeper understanding about the social, cognitive and cultural motives of phubbing and the experiences, perceptions or feeling about the people who engaged in phubbing when or during conversation. Purposive sampling is suited for this study, as it offers a frame for selecting participants with phubbing experiences. Participants from this study were selected using criterion sampling. Therefore, to be included as a respondents for this study, the participants most meet the following criteria: Must be a student, must be between the ages of 17-25 years, must own a smartphone for at least three years, and must have internet access at least 5 days in a week. Based on the criteria listed 15 respondents who met the study criteria were interviewed for the study.

Data Collection

Data collection is the process that enables the researcher to systematically gather relevant answers to research questions (Milanzi, 2009). The data required for achieving the objectives of this study were collected using in-depth interview. Thus, the interview was designed for collecting data on phubbing from the social and cultural setting. Phubbing: Towards a Theory of Techno-Snubbing. The interview session began with the explanation about the purpose and objectives of the research and also solicited participants' permission to voluntarily participate in the interview. The researchers followed research protocol by informing participants that their participation in the research is voluntary and were given informed written consent indicating their consent to partake in the study. Permission were asked for responses to be recorded and participants were informed of the anonymity and confidentiality of their responses. Participants were also informed of their right to withdraw from the study at any time during the interview process. Each participant wasprovided with an opportunity to ask question before the commencement of the interview.

The interview took place in five locations within the study setting. At the onset of the interview, the researchers conceptualized phubbing to each of the respondent. A smartphone was then turned on and the in-depth individual interview commenced. Each interview lasted for up to 40 minutes. The interviews were conducted between April 2018 and May 2018 by the principal investigator and co-investigators and 5 research assistance. All the interviewers were trained and experienced interviewers.

During the interviews the researchers used probing technique to solicit for in-depth information and obtain situational data to build on their responses. By the time 15 participants were interviewed, the data was saturated. Marshal (2006) explains data saturation as the point when there are no new categories, themes, or explanation is emerging. To get responses in respect to research question 1 (what are the social motives for phubbing?) The researchers asked respondents the following sub-questions: Share with me your feelings when you phubbed someone? Describes factors that encourage you to phub? Share with me your perceptions on people when you see them phubbing? Share with me any existing rule of behavior on phubbing? Similarly, to get response in respect to research question 2 ((what are the cognitive motives for phubbing?). The following sub-question was asked: Share with me occasions in which you use smartphones to get clarification during discussion with someone? In the same vein, to get response in respect to research question 3 (what cultural factors discourage phubbing?) the following sub-question was asked: share with me circumstances that will prevent you from phubbing?

Data Analysis

The data received from respondents were audio taped and then transcribed for analysis. Data from this study were analyzed using inductive analytical process (Cresswell, 2013; Graneheim and Lundman, 2004). Inductive approach is a process of condensing raw textual data into a brief summary format and establishing clear links between the research objectives and the summary findings (themes) that are derived from the raw interview data. The process of inductive analysis followed three step process of open coding, axial coding, and selective coding. These three stps process were expanded into series of steps as suggested by Graneheim and Lundman (2004) and adopted in this study.

The steps are as follows.

1. Transcribe interview verbatim
2. Read the transcribed interviews to get an overall insight of its content: To accomplish this stage the investigators together with research assistants read and re-read interview transcripts and underlined words phrases that best answer the three research questions (open codes).
3. Establish meaning units and initial codes. This was achieved collapsing open codes into categories according to similarities and differences.
4. Classifying the initial codes inductively into comprehensive emergent categories: This was done by condensing codes into themes.

Interview Analysis

Data in the form of phrases and sentences about phubbing were collected from 15 respondents in five locations within the study setting representing a diversity of voices on phubbing. The selected respondents provided multiple views and insights into the complex nature of phubbing culture. Each of the 15 interviews was transcribed read, examined, and re-examined using an analytic inductive process described by Graneheim and Lundman (2004); as well as Creswell (2013), wherein the “researcher works back and forth between the themes and the database until the researcher has established a comprehensive set of themes” (p. 186). While reading the transcribed narratives, the principal researcher, co-researchers, and research assistance highlighted sentences, phrases, and passages that dealt with phubbing culture. All the 15 interview narratives explaining phubbing culture were highlighted and recorded in Microsoft Excell spreed sheet. An iterative analysis method informed by Krathwohl (1998) and Graneheim and Lundman (2004) employed a series of steps for coding the highlighted narratives. Following these steps, the principal researcher, with the help of co-researchers, and research assistants read through the data looking for variances and similarities in the narratives.

Rigor

Three steps processes helped ensure the credibility of the analysis. First, each interview was facilitated by two persons. With the consent of the participant each interview was recorded and notes were taken. The interview notes were compared with the transcribed audio recording. This procedure has helped in establishing data credibility. Second, a triple coding was done in which the researchers work in three teams during the analysis of the transcribed data. The purpose is to check for consistency during the coding process. Each of the three teams coded the transcribed interviews on three separate occasions (triple - coding) and drafted an initial coding frame. Both teams (“peer debriefers”) identified key themes. The three coding teams made separate memos and converge to discuss the developing coding frame. Third, interview continued until emerging theory adequately reflect the data and that theoretical saturation was achieved after the researchers conducted fifteen interviews.All this is to ensure Ultimately,

credibility is about creating a coherent narrative that stands up to challenges and brings fresh ideas. Mcniff, K. 2017 and Korstjens, I & Moser, A. (2018).

RESULTS

Findings for this study are provided in this section, and are presented by research questions. The 3 research question are: What social factors account for phubbing? What cognitive factors motivates phubbing? And, what cultural factors discourage phubbing?

Descriptions of Emergent Categories

Research Question One: What social factors account for phubbing behavior?
In response to this question seven categories emerged depicting social reasons for phubbing in the study setting. These are: (1) Phubbing is normal acceptable behavior (2) I feel bad to see people phubbing (3) I phubbed when I am bored and not interested in discussion (4) I phubbed to check for important massage (5) I phubbed because I am addicted to smartphone (6) Those who phubbed are uncivilized (7) No rule exist on phubbing behavior. Each of the seven category is explain below:
Phubbing isnormal acceptable behavior. Phubbing is normal acceptable behavior is a category depicting phubbing practices as common and normal in the context of the study setting. Beck, (2016). A participant observed that there is nothing wrong in phubbing, “I feel normal when someone is phubbing during discussion”. In the same vein, another respondent stressed that “I feel comfortable when I see someone phubbing”
I feel bad seeing people phubbing. Contrary to the explanation by respondents that they see phubbing as normal, this category comprises explanations by participants explaining that even thou they considered phubbing as normal they nonetheless hate to see others engaged in phubbing. A participant noted, “I don’t like it. I hate to see people chatting when they are conversing with others, you may miss an important point”.
I phubbed when I am bored and not interested in conversation. This category suggests that participants engaged in phubbing when they are either bored or when they are not interested in an on-going conversation. This category explains the factors that let people to practice phubbing, as revealed by these respondents: “I practice phubbing usually when am bored in a conversation” Furthermore, another respondent expressed that, “only when am not interested in a discussion that is when I practice phubbing”. Similarly, a respondent observed that I engage in phubbing “when I lose interest in a discussion” Another respondent stated that “I use to practice phubbing when the discussion is not important” similarly, another respondent revealed that, “I phubbed when conversation is boring or annoying”
I phubbed to check for important massage. This category depicts responses of respondents as to the reasons why they engaged in phubbing practices. They noted that phubbing is inevitable on instances in which a person is expecting important message. A respondent stressed, I phubbed “to check an important email”. Another respondent stated that, “I do phubbing when checking important massage on WhatsApp”. Others stated, “I phubbed when I am expecting massages or when I am expecting a parcel from online shopping”. This category explains the desire to read important messages as a reason for engaging in pubbing behavior among respondents. A respondent stressed “I phubbed in order to confirm or to check credit alert transfer into my account”

I phubbed because I am addicted to smartphone to Interact with loved ones: Accounts of being addicted to smartphones are indicated as reasons for engaging in phubbing practices. Many respondents indicated that they are addicted to smartphone. A respondent noted that he is so much used to being with smartphone and cannot help to peep through the phone during conversations to interact with loved ones. This category also explained instances in which people practiced phubbing in their desire to keep in touch with loved ones. A respondent observed "I chat with my kids when am in the lecture hall, especially if the lecture is boring" Another respondent stated that: "I practice phubbing because am addicted to it

Those that practice phubbing are considered as uncivilized. This category comprises narratives revealing participants' perceptions on other people when they see them phubbing, as described by these respondents: "when I see some people phubbing I use to say they are villagers…not civilized". Another participant stated that: "it is funny when I see people phubbing during discussion" "it also annoying when I see someone phubbing in public"

No existing rule on Phubbing. This category contains participant's response on whether there is existing law on phubbing in their society. These are some of the responses: "I don't think there is any law regarding phubbing". "There is no any existing rule for phubbing". "I am not aware of any law on phubbing"

Table 1: Social Motives for phubbing behavior

Research Questions	Emergent categories
What factors account for social motives for phubbing?	(1) Phubbing is normal acceptable behavior (2) I feel bad to see people phubbing (3) I phubbed when I am bored and not interested in discussion (4) I phubbed to check for important massage (5) I phubbed because I am addicted to smartphone (6) Those who phubbed are uncivilized (7) No rule exists on phubbing behavior.

Research Question 2: What cognitive factors account for phubbing behavior?

This question sought to determine the cognitive motives for phubbing behavior. Analysis of interview data revealed one recurring topic as classification category depicting cognitive motive for phubbing in the study setting (Table 2: Cognitive motives for phubbing). This is explained below:

People engaged in phubbing during classes or when seeking for specific information online: This category comprises narrations revealing instances in which people are engaged in phubbing to get clarifications or further information using their smartphones. One respondent stated that "I always use my smartphone in the lecture room or when I am receiving lectures" Another respondent stated that, "I use it in a lecture hall when I want to search for a specific information" or "during scholarly argumentation in the lecture hall with my friends".

Table 2: Cognitive Motive for Phubbing	
Research Question 2	Emergent categories
What are the cognitive motives for phubbing?	When receiving lectures or when searching for specific information during conversation

Research Question 3: What cultural factors account for phubbing behavior?
In regard to the third research question 2 recurring topics were identified as classification category (Table 3: cultural factors that discourage phubbing) depicting cultural factors that discourage phubbing in the study setting. This are explained.

I do not phub when discussing with my superior. This category provides explanations from participants' about the cultural motives for phubbing. It explains the circumstances preventing people from phubbing. A respondent observed, "I do not phub if I'm discussing with my superiors". In the same another respondent states, "If I'm talking with my boss at work I don't phub"

I do not phub when interacting with parent and elders. This category also contains narratives about the situations that prevent people from phubbing as describes from the following respondents: "If I'm talking with my parents or an elderly person I found it difficult to use my smartphone." Similarly, another respondent notes, "When I am engaged in serious discussion especially with parent or when I am conversing with the aged I do not use smartphone"

Table 3: Cultural factors discouraging phubbing	
Research Question 3	Emergent categories
What are the cultural factors discouraging phubbing?	(1) I do not phub when discussing with my superior (2) When receiving lectures or when searching for specific information

TOWARDS A THEORY OF PHUBBING BEHAVIOR: THEORETICAL PREPOSITIONS AND DISCUSSION

Arising from evidence collected from this study seven theoretical prepositions on techno-snubbing (phubbing) behavior (TofPB) is presented. The seven theoretical prepositions are as presented below together with their corresponding expositions.

Preposition 1:Those who considered phubbing as pervasive are likely to practice phubbing. Individuals are socially motivated to phubbed when they consider phubbing as common. This denote that there is a strong desire by individuals to phubbed when they discovered that peers, relations, acquaintances, family members also practice phubbing. Under this circumstances the individual believes that since everyone else in the community considered phubbing as ubiquitous it is fine for them to do so. In this circumstances individuals believed that taking a moment to peep through one's smartphone during conversation is largely conceived as acceptable.

Preposition 2: Individuals who consider smartphones as conjoined partner are more likely to practice phubbing. Individuals are likely to phubbed if they consider smartphones as a companion that should be carried all the time, all day, and every day. Individuals who believe smartphones as inseparable companions are social and therefore maintaining timely connections with online friends is crucial and indispensable.

Preposition 3: Individuals who consider smartphones as learning device are likely to engage in phubbing. Individuals are likely to phubbed if they consider smartphones as a learning gizmo. They do so by checking emails and short service massages, and by chatting. The main objective of phubbing is primarily cognitive with the intention to seek information considered critical. For this category of individuals, peeping through one's smartphone during communicative action is purely cognitive and done on impulse.
Preposition 4: When individuals are bored/uninterested during conversations they are likely to engage in phubbing behavior. Individuals are likely to phubbed if they are engaged in discussions that is boring and/or uninterested. In this circumstances, individuals are engaged in phubbing principally seeking for exciting information as a means to escape a conversation that is considered bored. For this category of individuals, peeping through one's smartphone during communicative action is deliberate and not necessarily on impulse.
Preposition 5: Individuals who practiced phubbing and considered phubbing as pervasive considered phubbing as uncivilized and therefore do not like to be phubbed. Those who practice phubbing disliked to be phubbed by others, despite the fact that they practice phubbing and they consider phubbing as ubiquitous.
Preposition 6: Individuals are unlikely to engage in phubbing practices when they are conversing with parents, elders, and respected personalities. Those who phubbed are unlikely to do so while they are with parents, elders, and persons they accorded much respect. In this situation smartphone addiction, expecting critical/vital information, or being bored during conversation has no place, because respect for elders, personalities, and parents overshadows cognitive and social benefits of phubbing.
Preposition 7: Those who practice phubbing are not aware of formal or informal rule on phubbing. There is lack of common rule, norms, and value systems in regard to phubbing.

DISCUSSION AND CONCLUSIONS

The seven theoretical propositions of the Theory of Phubbing Behavior (TofPB) discussed above highlights the social, cognitive, and cultural dynamics of phubbing in the contexts of everyday life. However, the 7 prepositions of TofPB should not be understood as an effort to generate a wrong contrast between phubbing in the context of nonwestern culture and western societies because phubbing behavior across culture may be identical in some instances. Generally defined, the proposed theory of TofPB refers to the tendency of individuals to peek at smartphones and other handheld devices during conversation. Consulting smartphones and other handheld devices occur as a result of conversation being bored or uninterested, or the desire to access information that is considered critical. Phubbing also occurs out of the belief that everyone else does it.
Phubbing is associated with differing situations and contexts. For example, in the classroom during learning, with peers during conversations, or with significant others and loved ones. Phubbing behavior is shaped by factors such as the person(s) being phubbed, length of conversation, personality of conversation partners, and the topic of discourse. However, these factors are not solitary to explain phubbing culture. The prepositions of the TofPB attempt to offer broad principles for phubbing culture why it is done, and why it is done in the context of non-western setting.

DECISION SCIENCES INSTITUTE

Possible Impact of Adopting Information System Management in the States of Under Developing Country of Africa

Habib Ullah Khan
College of Business and Economics
Qatar University, Doha, Qatar/ Walden University, USA
Email: habib.khan@qu.edu.qa

ABSTRACT

The local government of Ifako Ijaiye in Lagos state of Nigeria was considered to be a candidate for automation that will implement an information management system. In automating their processes the voluminous records stored in the numerous filing cabinets within its offices shall need to be digitized and made available by using computer based tools. However, during the course of the study several realizations should have been taken into consideration first. It was determined that the area where the local government of Ifako Ijaiye is located does not have the infrastructure needed to successfully implement an information management system. It was also determined that the employees of the local government of Ifako Ijaiye do not have sufficient computer literacy or have any computer training that is at a level required for the successful implementation of an information management system. The survey that was given to the employees of the local government of Ifako Ijaiye revealed the desire of the employees for a better system that would allow them to provide quality customer service to the clients of the local government office. Taking into consideration these factors, an analysis of the deficiency as enunciated by Mr. Dapo Okeniran have been studied. Possible solutions and strategies have also been studied to resolve the issues presented that impede or hinder not only the implementation of an information management system but also the development of Ifako Ijaiye in general.

KEYWORDS. IS Management, Technology Adoption, Under Developing Countries

INTRODUCTION

The the depth and breadth of the proposed Information System Management that will be implemented in Ifako Ijaiye as a representative local government within in Lagos State. An Information System Management has several different components and each component has their own unique impact to the different sectors of the organization where it will be rolled out (Haag & Cummings, 2009). From hardware to the different modules of the sys-tem that will be installed, different reactions emanating from various stakeholders is worthy of an investigation. The same goes with the department that will be tasked to manage the information system's infrastructure.

To illustrate: an Information System Management would include a Process Flow Management System that will automate and track each of the transactions of the individual processes of Ifako Ijaiye's local government's operation. An example is the business permit processing which would include tax mapping of the business, financial assessment and economic impact assessment of the business. Another local government unit pro-cess is the request and release of funds for local project. These processes are actually the ones that generate most if not all of the documents stored in the cabinet of the local government.

An information system management system shall also include the digitization of the documents generated over the years from the various local government units operations. And to be truly paperless, the ISM in fact includes an email system that would enable the various departments of the local government units to communicate with each other. The three systems is a start that will make the operation of the local government of Ifako Ijaiye truly paperless. Further along, to provide Ifako Ijaiye with a good decision support sys-tem an Enterprise Resource Management system with a financial system module capable of handling government accounting can also be installed and used to manage its finances for a more transparent operation.

The impact to the organization comes in several different ways. The psychological impact pertains to the effects on the confidence, motivation and the dynamics or the relationship of each personnel in the organization with each other (Evans & Yen, 2005). Efficiency impacts the process flow itself and the performance of the organization including its service level. Cost impacts the operating expenses related in the maintenance of the Information System Management. It should be noted that the different levels of the organization are also affected at different levels. To illustrate: City or municipal officials are affected differently from that of the ordinary local government employee. The fear of losing a job due to the automation process or the fear of being replaced by a computer is a com-mon fear associated with computerization.

Consequential impact also considered as over-all impact to the organization includes an increase or decrease in the collection of taxes, provisioning of basic services to a wider or narrower constituency likewise deserves attention and investigation. These impacts are emanating from the perception of the clients of the organization. The different permutations and combinations of the above mentioned impacts also affect each level of the organization. The impact is considered myriad because of the different stake and vested interest each level has in the implementation of the Information System Management. The implementation process in itself is categorized as pre-implementation, implementation and post implementation and each category has its own impacts on the organization (Arwidmark & Nystrom, 2010). The process of implementing the information system management also transform the perspective of each employee within the organization thus the dynamics and the relationships of each of the permutation changes above shall also change.

Tallon and Kraemer (2003) in a similar study investigated the relationship between strategic alignment and the benefits there of. An analysis was carried out on sur-vey data from over sixty (60) companies and the study revealed the existence of a significant link between strategic alignment and the benefits from IT irrespective of the company's strategic orientation or the focus of their IT units. The authors also noted that despite the strive for strategic alignment for IT business value, executives have been cautioned to enforce this principle with care as it may lock the organization into inflexibility and will have difficulties in reacting to environmental issues.

This paper shall study the impact of implementing an information system in Ifako Ijaiye particularly the impact to the employees and the local government's clients. By projecting the effects of an automation system to the operation of the local government this paper shall be able to determine the added efficiency that will be achieved by the automated system. Taking into considerations the requirements of having an information system installed, its maintenance and operation also impact the organization.

The adoption and implementation of an Information System will digitize the documents currently stored in the numerous filing cabinets. The system hopefully will lower the turn-around time in the retrieval of pertinent records essential in the operation of the local government departments. Although there will be several technical professional who will be hired to administer and manage the system from an IT perspective. The system will actually be used by the employees themselves, thus retooling the current regular employees is an essential part of the project.

However, the ultimate aim of the Information System is to aid the local government to manage its internal processes and provide all stakeholders (customers) with an improved efficient service. This would translate to the installation of a process flow system that will keep track of all transactions. The changes that will be triggered by the information sys-tem are in the area of customer satisfaction that would include the businesses and the other different department of the government. With this parameter the impact of the proposed changes amongst the employees or to the organization itself shall be assessed and a survey shall be used to determine the impact to the employees. Face to face interviews with questionnaires shall also be used to validate the results.

An assessment of the skill set of the employees will be conducted with the use of surveys. The surveys will ascertain the resiliency of the employees to change, their current ability to accept change and the level of readiness of the employees to change. The sur-vey will be conducted on site. This project will address three areas of concern in implementing an Information Management System. The first area of concern shall be the infrastructure needed in order for an information management system shall prosper. The second area of concern is the actual implementation strategy that will be adopted including the possible systems that could be implemented that will form part-and-parcel of the Information Management Sys-tem Infrastructure (Vengurlekar, Vallath, & Long, 2007). The third and last area of concern is the human factor that will consist of the acceptability and resiliency of the prospective users to change and the new technology. These three areas are the drivers of information management system implementation and without there will be failure in the implementation.

REVIEW OF LITERATURE

Lagos is Nigeria's financial, commercial and industrial centre (Lagos State Government, 2011) boasting of over 2,000 manufacturing industries, more than 200 financial institu-tions (Banks, Insurance companies etc) and the nation's stock exchange, the Nigeria Stock Exchange. The nation's monetary authority, the Securities and Exchange Commis-sion and the Central Bank of Nigeria (CBN) is in Lagos State. The State alone holds 60% of the Federation's total industrial investments including foreign trade while attracting 65% of Nigeria's commercial activities. It equally accounts for more than 40% of all labour tax-es. Various international companies have offices in Lagos State that would include Unile-ver, John Holts, BEWAC/VYB, Leventis, Churchgate, Chevron, Shell and ExxonMobil.

Nigeria particularly Lagos State is in a stage of its economic development that automating the operation of its Local Government would tremendously help its turnaround time in providing local government services to multi-national companies wanting to invest in the area and benefit Lagos State as a whole. However, an in-depth study of the factors that affect automation should be considered since it is dependent on several factors such as the organization's culture, business environment, technology and the type of service (David Skyrme Associatioes, 1999). It is also suggested that in implementing information technology not only should the organization itself desiring to be automated should be examined but rather holistic views should be adopted to determine the organization's inter and intra communication to determine its overall impact (Francalanci, 2010).

It should be noted however, that automation is not a matter of providing a number of programs and a number of computers in the department (Galup, 2009). The automation should start with the examination of all the organization's processes since automation is not only automating the processes for the sake of automating the process (Laudon & Traver, 2009). The automation should also mean improving the processes to make the job of the process owners not only easier but also efficient (Heizer & Render, 2009). The concept of the automation is to ensure that all aspect of the organization is anylzed including its resiliency (Oerlemans, 2005).

In order for the Ifako Ijaiye local government to compete with the rest of its neighbouring local governments in Lagos State, it is imperative that it modernises its operations to en-sure that potential investors will not be discouraged by the slow processing of transac-tions. Nonetheless, before any computerization is commenced, an in-depth study of its feasibility and viability should first be conducted.

Foremost, among the requirements of automation is the infrastructure where the hard-ware that will host the software shall reside. Infrastructures such as clean and reliable power source is an important factor to ensure that the equipment that support the infor-mation management system will not be subjected to adverse condition that will have an impact on its performance. The sensitivity of the equipment cannot be underscored and the energy that provides the power to make the system work at its optimum should be at the very least reliable.

Another factor to consider is a reliable telecommunication infrastructure that will enable the system to communicate to the satellite offices within the local government of Ifako Ijaiye. Most if not all multi-national companies communicate through the internet and not being at par with the technology of these companies would make any office in Ifako Ijaiye isolated. Support for the hardware and more importantly, the software component should also be considered and the presence of the vendors will make the implementation of an information management system feasible.

Preventive Maintenance Planning Using Group Technology

Farouq Alhourani
University of Tampa
Email: falhourani@ut.edu

ABSTRACT

Preventive Maintenance plays a critical role in any manufacturing environment to avoid any possible machine breakdowns which can lead to serious interruptions in the production and customer dissatisfaction. This research explores the use of similarity coefficient method in Group Technology that considers machines reliability to form virtual machine cells.

KEYWORDS: Maintenance Planning, Group Technology

INTRODUCTION

The competitiveness power of any industry is affected directly or indirectly by the effectiveness of the maintenance strategy they use (Almomani *et al*., 2012). Preventive maintenance is necessary in production since it helps to reinforce machine efficiency and extend the useful life of a system. All types of complex systems, ranging from manufacturing machines to computer network systems need to have prescribed maintenance schedules. A good preventive maintenance program can prevent equipment failures by sensing an imminent failure and fixing the equipment before it causes any damage (Kister and Hawkins, 2006). With the increased use of Flexible Manufacturing and Just-In-Time systems in today's manufacturing, preventive maintenance has become critical issue in the manufacturing environment to avoid any possible machine breakdowns in the production lines or manufacturing cells that can lead to delays and interruptions in the production which will also cause a dramatic increase in the cost and customer dissatisfaction. Preventive maintenance activities generally consist of inspection, cleaning, lubrication, adjustment, alignment, and/or even replacement of components (Moghaddam, 2015).

LITERATURE REVIEW

Several multi-criteria decision-making approaches have been developed in the pursuit of an optimum maintenance strategy, including analytical hierarchy process (AHP) and Technique for Order Preference by Similarity to Ideal Situation (TOPSIS; Sharma *et al*., 2011; Shyjith *et al.,* 2008). Different algorithms and techniques were proposed to schedule preventive maintenance activities. Alardhi *et al.* (2007) used mixed integer programming model, where Sitompul and Aghezzaf (2011) used integrated aggregate production and maintenance planning together. In other models, the system failure probability is integrated with the maintenance cost to determine the time interval between preventive maintenance activities (Kardon and Fredendall, 2002). Talukder and Knapp (2002) created a heuristic method to group equipment for the application of preventive maintenance overhauls within a series system.

The models that uses Group Technology (GT) methods to plan preventive maintenance are very limited in the literature. GT method can be used to form virtual machine cells that contain machines with similar maintenance needs. By performing similar activities of preventive

maintenance on different machines in the virtual cells, one can avoid time wasted in changing from one unrelated task to another and leads to standardization of the maintenance processes, tools and maintenance materials used, and allows the work to be done by a small group of workers which avoids duplication of effort and saves time Abdelhadi *et al.* (2015). Abdelhadi (2010) developed a platform for the planning of preventive maintenance actions that uses the concept of GT to establish preventive maintenance virtual cells for equipment/machines based on the type and/or severity of failures that the equipment/machines encounter. Almomani *et al.* (2012) presented a case study on the use of similarity coefficient method in GT for creating preventive maintenance virtual cells. Abdelhadi *et al.* (2015) studied the impact of applying the GT method for preventive maintenance on stockroom operational costs. They showed that preventive maintenance programs can be enhanced by applying the concept of GT in the formation of the virtual preventive maintenance cells in manufacturing. Abdelhadi *et al.* (2015) also showed that a significant cost savings that can be obtained by applying the GT method to the activity of preventive maintenance using a simulation study based on real-life manufacturing.

GROUP TECHNOLOGY METHOD

GT is a philosophy that identifies and exploits the sameness among the attributes of a set of objects. (Ballakur and Steudal, 1987). This philosophy is used in practice to design Cellular Manufacturing Systems. This requires identification of groups of machines that can produce parts with similar processing requirements. Each dedicated cell with dissimilar machines process a family of parts, in which the parts in each cell are processed with minimum moves into other cells.

Mathematical programming models are mainly used to solve the cell formation problem in GT. NP-hard problems usually take very large amount of computational efforts and time to solve the problem when classical optimization methods are used, especially for large-sized problems (Chung, Wu, and Chang 2011; Jouzdani *et al.* 2014). On the other hand, procedures using the similarity coefficient method (SCM) are more flexible in incorporating various important production data and can be used easily in the computer applications (Alhourani and Seifoddini 2007; Yin and Yasuda 2006). Furthermore, the optimal solution methodology fails to solve larger instances of problems (Islam & Sarker, 2000).

Similarity Coefficient Method in GT

Jaccard's similarity coefficient is the basic similarity coefficient equation that uses 0–1 binary data to calculate the similarity between machines. Jaccard's similarity equation calculates the similarity based on the number of part types that visit the machines. McAuley (1972) defined the similarity between a pair of machines as follows:

$$S_{il} = \frac{A_{il}}{A_{il} + B_i + C_l} \quad (1)$$

Where:

S_{il} similarity coefficient between machines i & l
A_{il} number of part types processed by both machines i & l
B_i number of part types processed by machines i
C_l number of part types processed by both machine l

Almomani *et al.* (2012) used this basic similarity equation to calculate the similarity between machines based on the types of failures that occur in these machines. To the best our knowledge this is the only research that appeared in the literature that utilized the similarity coefficient method in GT to form preventive maintenance virtual cells. Almonami *et al.* (2012) ignored other important production factors such as machines reliability. It is important to consider this factor when forming the virtual machine cells since each machine has a different reliability and therefore, preventive maintenance for each machine is needed at a different times.

NEW SIMILARITY COEFFICIENT CONSIDERING MACHINE RELIABILITY

A common way of dealing with machines reliability concern in the design phase of a manufacturing system is by the evaluation of the quantities of the mean time between failures (MTBF).

Therefore, the above similarity coefficient can be modified to incorporate this important factor:

$$S_{il} = \frac{A_{il}}{A_{il} + B_i + C_l} * R_{il} \qquad (2)$$

R_{il} ratio of the two machines' reliabilities

CLUSTERING ALGORITHM

McAuley (1972) proposed the use of single linkage clustering algorithm (SLINK). It assigns the largest value of the similarity coefficient possessed by a pair of machines from the two groups as the coefficient value for the two groups. SLINK may identify two groups as candidate for the formation of a new group at a certain threshold value, although several machine pairs possess significantly smaller similarity coefficient. This results in ‘‘chaining’’ problem among the groups of machines. Seifoddini (1988) suggested the use of average linkage clustering (ALINK) to reduce the chaining problem. ALINK assigns the average of similarity coefficients for all pairs of machines in the two groups as their similarity. Gupta and Seifoddini (1990) used the complete linkage clustering (CLINK) which assigns the smallest value of the similarity coefficient possessed by a pair of machines from the two groups as the coefficient value for the two groups. CLINK clustering is expected to result in more closely bonded groups due to the fact that each machine pair possesses similarity coefficient higher than the similarity coefficient for the two groups (Gupta & Seifoddini, 1990). Alhourani and Sefoddini (2007), Alhourani (2013), and Alhourani (2016) used their developed similarity coefficient equation to calculate the similarity between the formed machine cell and other machines. Their algorithms do not assign the smallest, largest, or average value (SLINK, ALINK, or CLINK) of the similarity coefficient possessed by a pair of machines.

CONCLUSIONS

Group technology can be used for preventive maintenance planning in the manufacturing environment. Machines can be grouped into machine cells where each machine cell contains machines with similar maintenance needs. Machines reliability should be considered when forming the virtual machine cells. Machines have different reliabilities and therefore their maintenance needs will be different. Incorporating this factor will make the problem more complex but more realistic. Similarity coefficient equation method in group technology is easier

to use and incorporate the important factors than the mathematical programming models that require a lot if computational efforts.

ABSTRACT

Many of the thousands of MBA courses offered online are developed haphazardly and without reference to learning design principles. This paper describes the challenges encountered by graduate faculty at a public university as it used instructional design principles to develop and implement online, hybrid, and traditional courses in its MBA Program. Adjustments to teaching methods, assignment structures, student interactions, and teaching assistant integration are described, and case studies of fast-paced, large online classroom environments are presented.

KEY WORDS: MBA Programs, Online MBA Programs, Course Design Principles

INTRODUCTION

In 2018, 450 online MBA programs are now offered in the United States. The majority of these programs co-exist with on-the-ground MBA programs, which share the same curriculum and learning goals. However, the growth in scale of MBA programs has raised questions about the instructional quality of online delivery. An examination (Margaryan, Bianco, & Littlejohn, 2015) of a random sample of 76 massive open online courses (MOOCs) indicated that the majority of the courses scored poorly on most instructional design principles. Only organization and presentation of course material of the courses examined received higher ratings. Although the Margaryan, Bianco & Littlejohn (2015) study focused on MOOCs, the results have implications for the design of online MBA programs, as well.

This paper examines the course design characteristics of the launch of an accelerated online MBA program in 2016 in the context of a synthesis of effective contemporary instructional design principles (Merrill, 2002, 2009, 2013; Margaryan, Bianco, & Littlejohn, 2015; Collis, Margaryan, & Amory, 2005; Frick et al., 2010; Gardner, 1999, 2011; Margaryan & Collis, 2005). Between August, 2016 and August, 2018, the number of students in the online version grew exponentially--from 100 students to 620 students. Due to the rapid enrollment growth, class sizes increased from an average of 65 to 245 for approximately one year before structural adjustments could be made to reduce class sizes to a more manageable level.

The paper begins with background on the development of the ten-principle framework for effective course design that was extended from Merrill's "First Principles of Instruction" (2002), and tested and validated by Margaryan, Bianco, & Littlejohn (2015); followed by case studies that detail how this framework was consulted and integrated into the development of courses for the MBA program of interest in this paper.

THEORETICAL BASIS FOR MERIILL'S FIRST PRINCIPLES OF INSTRUCTION

The flourishing of the demand for, and the availability of, online MBA programs presents the challenge of developing courses, methods and materials that are based on relevant instructional design principles. As pointed out in an article by Phan and Hoover (2014), many online MBA programs are put together in a haphazard manner, without consideration for current instructional theories and principles. The importance of theory-based instructional design was also recognized a few years earlier by David Merrill, who developed the First Principles of Instruction after extensive examination of contemporary instructional design theories (Merrill, 2002, 2009, 2013). The First Principles of Instruction include a problem-centered approach, activation of prior knowledge and skills, demonstration of new skills to be developed, and the integration of new skills/knowledge into the learner's skill set. It should be noted that Merrill's work was not specifically focused on online course delivery, but Merrill argued that this set of principles was applicable and valuable in any learning setting. Margaryan, Bianco, & Littlejohn (2015) more recently confirmed the validity and reliability of these principles and their usefulness in evaluating online courses. In developing his First Principles of Instruction, Merrill referenced several prominent instructional design theories, which are briefly described in the following paragraphs.

Vanderbilt learning technology center's star legacy (Schwartz et al., 1999)

(Schwartz et al., 1999) proposes a learning cycle that includes looking ahead to provide a learning context and learning goals; a progression of increasingly challenging problems to be solved; generating ideas that facilitates interaction among learners about their challenge-related experience; and multiple perspectives in which students compare their view of possible problem solutions with that of other students and the instructor. The research and revise phase engages students in the application of various solutions to the problem. Students get feedback on their ideas from others before final sharing of their ideas. Students are then ready to go public to demonstrate their solutions and defend their ideas. Finally, in the reflect back phase, they review the learning activities they have just completed.

4-Mat model (McCarthy, 1987; McCarthy & McCarthy, 2006)

McCarthy (1987; McCarthy & McCarthy, 2006) proposes an explicit learning cycle. She recognizes that, although learners may have preference for various approaches to learning, effective instruction should involve them in the whole cycle of learning activities. The first phase of her theory engages students in sharing information of past experiences and finding meaning in new material. Phase two is the demonstration phase, in which students acquire new knowledge and relate it to their prior knowledge. In phase three, application, students use their new knowledge to make something or develop a new idea. In phase four, they integrate their new knowledge into their knowledge/skill set.

Instructional episodes model (André, 1986, 1997)

According to André, (1997) an instructional episode has three phases. First, the activation phase; then the instructional phase, which includes presentation, discovery, and practice; and third, the feedback phase. André argues that identifying problems, searching for solutions, and presenting results give the learner many opportunities to integrate new knowledge.

Multiple approaches to understanding model (Gardner, 1999)

Gardner's (1999) performance approach to understanding emphasizes understanding content, such as "important questions and topics of the world" (73), rather than problem solving. He argues that evaluating learning must involve demonstrations “that can be observed, critiqued, and improved" (73). Gardner’s theory includes three phases. First, entry points are used to activate students and engage them in a topic, in one or more of the following ways: through narration, or quantitative, numerical, foundational, existential, aesthetic, hands-on, or social activities. In the second phase, telling analogies, students must demonstrate their new knowledge. The third phase, approaching the core, includes demonstrating and applying the new knowledge in a number of ways to show how they have integrated it into their skill/knowledge set.

Collaborative problem solving (Nelson, 1999)

Nelson's (1999) theory emphasizes critical thinking, creativity, and complex problem solving as well as social interaction skills. She presents guidelines that are organized under nine process activities: (1) build readiness, (2) form and norm groups, (3) determine a preliminary problem definition, (4) define and assign roles, (5) engage in an iterative collaborative problem-solving process, (6) finalize the solution or project, (7) synthesize and reflect, (8) assess products and processes, and (9) provide closure.

Constructivist learning environments (CLE) (Jonassen, 1999)

Jonassen's (1999) CLE theory places major emphasis on problem solving, which, he argues, drives learning. “Students learn domain content in order to solve the problem, rather than solving the problem as an application of learning" (218). Jonassen recommends using a progression of problem-solving tasks. "Start the learners with the tasks they know how to perform and gradually add task difficulty until they are unable to perform alone" (235).
He argues that demonstrations/related examples can be used to scaffold students’ existing knowledge by providing representations of new experiences or skills. Experts should demonstrate activities carefully, emphasizing how to perform activities and explaining the reason behind each activity. Students should have opportunities to perform the activities, first by imitating the expert, gradually developing skills, and then exhibiting original use of the skill to show they have integrated it into their skill set. "Coaches should “monitor, analyze, and regulate the learners' development of important skills" (233).

Learning by doing (Schank, Berman, & Macpherson,1999)

Shank, Berman, l Macpherson’s (1999) model is problem-focused and emphasizes the application phase of instruction. In GBSs [goal-based scenarios], students are engaged in learning-by-doing simulations in which they practice target skills and use relevant content knowledge to achieve a goal. A GBS includes seven phases: learning goals, mission, cover story, role, scenario, operations, resources, and feedback. First, a goal is determined, then a background story line establishes the need for the mission to be accomplished, and a role defines whom the student will play within the cover story. Stories provide content that extends

what the student already knows. In the scenario phase, experts scaffold the student through tasks and application, and in the operations phase, students work toward the mission goal, demonstrating integration of new skills in the process.

Categories of learning theory (Gagné, 1985)

Gagné argues that the different types or levels of learning require appropriate instructional goals and procedures. Learning is facilitated when the practice used is consistent with the learning goal. Gagné identifies five major types of learning: verbal information, intellectual skills, cognitive strategies, motor skills and attitudes; and nine instructional events and corresponding cognitive processes that can provide the necessary conditions for learning: (1) gaining attention (reception) (2) informing learners of the objective (expectancy) (3) stimulating recall of prior learning (retrieval) (4) presenting the stimulus (selective perception) (5) providing learning guidance (semantic encoding) (6) eliciting performance (responding) (7) providing feedback (reinforcement) (8) assessing performance (retrieval) (9) enhancing retention and transfer (generalization).

Four-component instructional design model (4C/ID) (van Merriënboer, 1997)

Van Merriënboer's (1997) model provides detailed instructional sequences to use with problem-based approaches, based on current understanding of cognitive processing. His whole-task practice approach includes the use of increasingly complex versions of a skill. "While learners practice simple to complex versions of a whole task, instructional methods that promote just-in-time information presentation are used to support the recurrent aspects of the whole task while, at the same time, instructional methods that promote elaboration support the non-recurrent aspects of the task" (10).

Elaboration theory (Reigeluth, 1999)

According to elaboration theory, the most effective learning occurs when instruction is organized in increasing order of complexity. With each succeeding lesson, the student should be reminded of all versions taught so far. Students should be guided to develop a meaningful context into which subsequent ideas and skills can be assimilated. Elaboration theory proposes seven major strategy components: (1) an elaborative sequence, (2) learning prerequisite sequences, (3) summary, (4) synthesis, (5) analogies, (6) cognitive strategies, and (7) learner control. The elaboration approach has been praised for facilitating more stable cognitive structures, and better retention and transfer of knowledge, increased learner motivation, and the provision of information about the content that allows informed learner control.
Merrill found commonalities among these instructional design theories and models that helped to confirm the integrity of his First Principles of Instruction, which are presented in more detail below.

A TEN-PRINCIPLE FRAMEWORK FOR EFFECTIVE COURSE DESIGN

As stated earlier in this paper, Margaryan, Bianco, & Littlejohn (2015) examined the design and structure of MOOC courses. Merrill's (2002, 2009, 2013) five First Principles of Instruction were used as criteria for rating the courses, and Margaryan & Collis (2005) also included five additional principles from the instructional design literature (Margaryan & Collis, 2005)—the development of collective knowledge, learner collaboration, differentiation of learning activities to fit learner needs, authentic (real-world) resources, and feedback. These additional five criteria were combined with the five First Principles of Instruction to create a ten-principle framework

(See Table 1.), which was validated in more than one hundred online corporate courses to test its ability to measure online course design quality (Margaryan, 2008; Margaryan & Collis, 2005). When employed as criteria of effective instruction in the MOOC study, Margaryan, Bianco, & Littlejohn's (2015) ten principle framework revealed that, except for organization and presentation of course material, the majority of MOOC courses were significantly lacking in all aspects of effective course design and learning environment that were measured, including problem-centered approach, activation of existing experience, demonstration of new skills, opportunities for learners to apply their new knowledge or skill to solve problems, facilitation of learner integration of the new knowledge, development of collective knowledge, collaborative learning, support for the learning needs of diverse learners, real-world course materials, and expert feedback to learners. These results highlight the importance of effective, theory-based online course design.

The following section presents more in-depth descriptions of Merrill's First Principles of Instruction and the five additional principles added by Margaryan & Collis (2005) to create the Ten Principles of Effective Course Design.

Table 1: Ten Principles of Effective Course Design	
First Principles of Instruction (Merrill, 2002, 2009, 2013)	
Problem-Centered	Learners acquire skill in the context of finding solutions for real-world problems that are representative of real-world issues.
Activation	Learning is promoted when learners activate existing knowledge and skills, relate and apply these to what they will learn in the course; and develop mental models and schemes.
Demonstration	Learning is promoted when learners observe a demonstration of the skill to be learned and are shown how to apply it in new situations.
Application	Learning is promoted when learners apply newly acquired skill to solve problems, with scaffolding gradually diminished.
Integration	Learning is promoted when learners reflect on, discuss, and defend newly acquired skills.
Five Additional Principles (Margaryan & Collis, 2005)	
Collective Knowledge	Learning is promoted when learners contribute to, and have access to, the collective knowledge.
Collaboration	Learning is promoted when learners collaborate with other learners.
Differentiation	Learning is promoted when different learners are provided with different avenues of learning, according to their need.
Authentic Resources	Learning is promoted when learning resources are drawn from real-world settings.
Feedback	Learning is promoted when learners are given prompt expert feedback on their performance.

Merrill's first principles of instruction (Merrill, 2002, 2009, 2013):

Problem-centered

Learning is promoted when learners acquire skill in the context of real-world problems. Many contemporary learning theories and instructional models such as constructivism, authentic learning, cognitive apprenticeship, situated learning, problem-based learning, and expansive learning, have as a premise, the idea that humans learn better when they are engaged in solving problems and building knowledge than when they are presented with information they are required to memorize. Problems refer to 'a wide range of activities, the most critical characteristic being that the activity is a whole task rather than only components of a task. and that the task is representative of those the learner will encounter in the world following instruction (Merrill, 2002, 45). In contrast to topic-centered instruction, where a subject is taught in isolation from the real-world tasks, problem-based instruction focuses on working through a progression of interrelated tasks, from the least difficult to the most difficult, that reflect the complexity of real-world settings.

Activation

Learning is promoted when learners activate existing knowledge and skill as a foundation for new skill. Instructional effectiveness of a course will increase if the course includes learning activities that help learners to recall and describe their relevant previous experiences, and to relate and apply these to what they will learn in the course. If learners have not had relevant experience, a course should begin by helping learners acquire such experience by, for example, providing real-world or simulated examples that learners can use as a foundation for their new learning. However, activation requires more than enabling learners to recall or build relevant experience; activation also requires learning activities that stimulate the development of the mental models and schemes that can help learners to incorporate the new knowledge or skill into their existing knowledge.

Demonstration

Learning is promoted when learners observe a demonstration of the skill to be learned. This principle highlights the importance of showing learners what they could do to apply the new information or skill in new situations rather than merely presenting them information about what to do. Effectiveness of a course is enhanced, firstly, when learners are shown examples of both poor and good practices; secondly, when the demonstration is consistent with the type of knowledge or skill being taught; and, thirdly, when learners are guided to relate general information or an organizing structure to specific instances of the knowledge or skill being taught.

Application

Learning is promoted when learners apply their newly acquired skill to solve problems. There is widespread agreement among contemporary learning theories that applying new knowledge or skill to real-world tasks is a necessary condition for effective learning. This principle emphasizes that applying knowledge to a single problem is insufficient for learning and that a course must provide multiple opportunities for learners to apply their new knowledge or skill to a wide range of real-world problems. A key corollary to the application principle is appropriate learner guidance, through diminishing coaching or 'scaffolding'. The basis to this corollary is the observation shared by many learning theories that while in the early stages learners may need considerable support, as learners progress this support is gradually taken away, with more control shifted to the learner to help build their independence. A key mechanism of scaffolding is feedback and most learning theories have long recognized feedback as the most important form of learner guidance.

Integration

Learning is promoted when learners reflect on, discuss, and defend their newly acquired skill. Learners have integrated new knowledge and skill into their everyday life when they are able to demonstrate change in behavior or modification of their existing mental models and, when challenged, are able to defend their new knowledge or skill. Therefore, the effectiveness of a course is enhanced when, first, learners are provided with opportunities to reflect on what they have learned in order to revise, synthesize, recombine and modify their new knowledge or skills; and, second, when learners are required to demonstrate and defend their new knowledge or skill to peers and others.

A meta-review (Merrill, 2002, 2013) indicated that these fundamental principles underpin all contemporary instructional design models and theories. Several aspects of the above five principles are worth noting. First, they are "relationships that are always taken to be true under appropriate conditions, regardless of program or practice" (Merrill, 2002, 43). Second, they "can be implemented in any delivery system or using any instructional architecture" (Merrill, 2002, 44). Third, "learning from a given program will be promoted in direct proportion to its implementation of these principles" (Merrill, 2002, 44). Fourth, the principles are "design-oriented and prescriptive, rather than learning-oriented or descriptive - they relate to creating learning environments and products rather than describing how learners acquire knowledge and skills" (Merrill, 2002, 44).

Additional principles of instructional design in the framework (Margaryan & Collis, 2015)

The five items below are additional principles of instructional design which Margaryan & Collis (2005) gleaned from the literature and included in the Ten-Principle Framework.

Collective knowledge

Learning is promoted when learners contribute to, and have access to, the collective knowledge. The interactive process of collective knowledge construction occurs when a group of individuals creates new knowledge by recombining the contributions of others to form new insights (Lave & Wenger, 1991). As a result, a group of learners as a whole develops and constructs new knowledge, and participants also individually advance and refine their own knowledge (Kimmerle, et al., 2015).

Collaboration

Learning is promoted when learners collaborate with other learners. Educators have long recognized the crucial role of dialogue and social interaction in learning (Vygotsky, 1978; Lave & Wenger, 1991). The collaboration that is part of learning in an online course facilitates the development of critical thinking skills, co-creation of knowledge and meaning, reflection, and transformative learning (Vygotsky, 1978; Lave & Wenger, 1991).

Differentiation

Learning is promoted when learners are provided with different avenues of learning, according to their need. Educators and instructional designers must be aware of students' individual differences, such as cognitive and learning styles, prior knowledge, and cultural differences. Field dependent learners and learners with low prior knowledge may need more attention and support from instructional designers, while other learners may be able to work independently in web-based learning systems. Adaptability is important in the design of web-based learning

systems to enable a variety of individuals to use the system successfully in learning environments (Alomyan, 2003).

Authentic resources

Learning is promoted when learning resources are drawn from real-world settings. Applications of theoretical material in real-life situations make content more relevant and easier to understand. Recent literature on brain function and learning indicates that existing knowledge forms the foundation for incorporating new information into more complex and sophisticated schemas (Theall, 1999; Keller, 2008).

Feedback

Learning and student engagement are promoted when learners are given expert feedback on their performance. In order to be beneficial to learners, feedback must enhance learning, be timely, clearly communicated to students, consistently delivered, and have consistent quality. (Black & William, 1998; Falchikov, 2001; Gibbs & Simpson, 2004).

DESIGN OF ONLINE MBA COURSES BASED ON THE 10-PRINCIPLE FRAMEWORK

With a commitment to developing courses which reflect the best practices of instructional design identified in the ten-principle framework, the administrators and faculty responsible for the online MBA described in this paper consulted the framework and employed principles from it to guide the development of the two courses described below.

Case Study #1: CIS 601: information systems and technology

Course description

CIS601 is the information technology-focused course offered in the MBA. This course concentrates on the strategic use of information systems, with emphasis on the Information Systems Strategy Triangle, which relates business strategy with IS strategy and organizational strategy. The underlying theme of this course is that, with information systems at the heart of virtually every business interaction, process, and decision, managers can no longer abdicate participation in decisions regarding their company's use of information systems. Managers must become knowledgeable participants in information system decisions. CIS601 is designed to build the knowledge and skills business managers need to make strategic decisions about information technology, as well as to introduce them to the use of digital visualizations with software like Tableau. Course topics include the Information systems strategy triangle, strategic use of information resources, organizational strategy and information systems, digital systems and the design of work, information systems and business transformation, architecture and infrastructure, security, the business of information technology, governance of the information systems organization, information systems sourcing, managing information technology projects, business intelligence/knowledge management/analytics, and privacy and ethical considerations in information management.

Adaptation of CIS 601 for online delivery

CIS601 had been offered for many years as a face-to-face course, but the growing digital presence of the RCOB's MBA necessitated offering the course online. The course was offered online for a couple of years, serving mostly local and area students. All assignments were

posted and submitted online. Students were required to take exams on campus, or to arrange for an approved local proctor to administer the exam to them.

With the move to a totally online MBA, the course now serves an unlimited number of students, with enrollments from around the world and around the nation. The spring, 2018 the course had an enrollment of 250 students. This newly increased enrollment necessitated major changes in how the course is run. First, the MBA Program is now working with Instructional Connections, LLP, which provides instructional support services to colleges and universities that offer online programs (http://instructionalconnections.com/). Instructional Connections supplies well-qualified academic coaches to support the instructor and the students. For a class with 250 students, for example, the resumes of potential academic coaches are offered, and the instructor can determine how many coaches are needed as well as which coaches have the most appropriate background for a particular course. The instructor provides detailed instructions to the coaches, regarding assignments, projects, procedures, and grading rubrics, as well as a table of responsibilities—those of the instructor, the coaches, and the students. For this eight-week course with an enrollment of 250 students, four coaches were assigned, with each coach being responsible for a portion of the students. The coaches provide updates to the students, reminders of due dates, and encouraging messages to them. They also grade assignments and projects, using guidelines and rubrics provided by the instructor, and in close consultation with the instructor. Throughout the course, when a student has a question about course content or other issue that the coaches believe can be better and more thoroughly answered by the instructor, the coaches forward the questions to the instructor. All questions are answered immediately or as soon as possible.

Consideration of psycho-social factors of online learning

The expanded enrollment has also necessitated consideration of several psycho-social factors related to student learning online that are relevant to large enrollment courses. These factors are widely discussed in the MOOC (massive open online course) literature, and many of them are relevant to large enrollment courses in general. As the following discussion points out, these factors are consistent with the ten criteria for effective instruction based on key instructional design theories and models[i] (Merrill, 2002, 2009, 2013; Margaryan & Collis, 2005) that were discussed above.

First, research has found that most online learners need to feel “teacher presence” throughout a course in order to feel confident and able to succeed in a course (Garrison & Anderson, 2003). This factor is addressed in CIS601 by the use of academic coaches, each of whom is assigned a portion of the students to manage, and by the prompt addressing of issues and questions by the instructor, updates and deadline reminders, and other encouraging emails. Prompt, consistent feedback to students (Margaryan & Collis, 2005) provides scaffolding that supports the learning experience and builds students’ confidence in the application of new knowledge (Merrill, 2002, 2009, 2013).

Second, online learners can differ across many dimensions, such as skills (digital and participatory), preferences, learning styles, motivation, engagement, and the context of learning (Terras & Ramsay, 2014). To the extent possible, an online course should address learner differentiation (Margaryan & Collis, 2005) and diversity and provide structure that facilitates a high-quality learning experience for diverse learners. CIS601 addresses individual differences in background/experience/preferences by, to the extent possible, giving students choices in project topics. All assignments are problem-centered and require students to analyze and develop solutions to real-world issues (Merrill, 2002, 2009, 2013; Margaryan & Collis, 2005). A project that focuses on the impact of new IT initiatives includes the choice of either writing about an on-the-job project or about a fictitious IT initiative. A second project, an article review, gives students the choice of a number of different articles from prominent journals, each related to a

particular chapter in the text. Students can choose an article, based on interest or relevance to their experience, thus underscoring the importance of activation, in which students activate existing knowledge and skills as a foundation for new skills. The coursework also includes a hands-on component, in the form of two projects that involve students in learning the rudiments of Tableau software. The goal is to introduce them to data visualization and provide practice exercises that build their skills and confidence and demonstrate how powerful and insightful data visualizations can be. It should be noted that some students had difficulty using Tableau on their particular computer systems. In the few cases in which students found it impossible to complete the Tableau exercises, an alternative assignment was given which involved reviewing an article about Tableau and detailing how the student believes that data visualizations could be useful in his/her given field/position.

Third, another aspect of online learning that is relevant to online MBA courses is the finding that discussion and interaction with others are paramount to achieving higher-level learning (Ferschke et al., 2015). This issue is important for MBA students, who, one can assume, are mature and deal with complex, real-world issues daily. Weekly discussion board assignments involve CIS601 students in sharing their opinions and commenting on the postings of other students. This process widens their horizons as they share their own ideas and peruse the experiences and perspectives shared by a diverse group of learners. Students have an opportunity to get to know each other through the first week of the course's discussion board, which requires them to share their educational and work experience, and how they feel information technology fits into their current work and future career goals. These activities involve application of newly acquired skills and the integration of new skills through reflecting on, discussing, and defending newly acquired skills (Merrill, 2002, 2009, 2013).

Fourth, active engagement of students in the learning process is also key to a successful learning experience (Harasim, 2012). The table of responsibilities of instructor, academic coach, and students that is listed on the class syllabus provides students a clear idea of their role in the course. Students are also engaged through weekly discussion board interactions with other students, in which many assignments call for their opinions on various topics and they are required to respond in detail to the opinions of other students on the same topics.

The author has found that the eight-week format for the online course significantly limits the depth into which it is possible to go on the many important topics included. Going forward, CIS601 will be offered in fall, 2018, in a semester-long face-to-face format as well as the eight-week online format. The decision to offer two formats addresses the issue of learning preferences and learning styles, as some students, depending on their geographic location and work schedule, will have the option of choosing the format that best fits their learning style and preferences. The face-to-face format will also make it possible for the instructor to go into greater depth on the Tableau data visualization portion of the course and to offer hands-on experiences with SAP/ERP/Sim software.

Management 611: leadership skills and innovation online

Course overview

Management 611: Leadership Skills and Innovation is an MBA course that addresses leadership in the business context to prepare students for a future of rapid change and increasing complexity. The skills developed in this course include project management, change management, critical thinking, effective decision-making, developing others to improve work engagement, disciplined execution, developing business models, conducting a leadership audit, conducting an innovation audit, and pitching an idea. This course has been taught on campus full-term, hybrid full-term, and online full-term, but the most profound learning curve occurred in delivering this broad scope of topics in an online accelerated (8-week) term to 235 students.

Teaching a large section of an online MBA course can profoundly impact instructional effectiveness both in the classroom and online because it forces examination of three important course elements: content, design, and feedback.

Course content

Most college faculty maintain the intellectual and interpersonal abilities to gain the affection and admiration of their students in the classroom regardless of their teaching skills. However, students taking MBA courses online are primarily concerned with how the content of the course will help them be more effective in their careers. The intellectual prowess of the instructor is far less important than the extent to which the topics covered in the course are practical, engaging, and valuable. Therefore, these three criteria were the lens through which course topics were selected.

As this course is in the core of the MBA program, there is great diversity among the students in the course in terms of background, profession, and years of experience. Students did not self-select into the course based on experience or interest, but rather were required to take it for the degree which poses quite a challenge for faculty teaching courses in the MBA core. In light of this, the chosen course topics were broadly applicable across industry segments and levels of career experience. While each topic was not expected to appeal to every student given the population diversity, carefully selecting broadly applicable content was an essential element to appeal to a majority of the students.

Once the course topics were identified, the same criteria (i.e., practical, engaging, and valuable) were used for content selection, which was vastly underwhelming, as the experiential methodology is nascent relative to the discipline. As a result, custom materials (e.g., readings, simulations, and videos) were curated and/or created to accomplish the course objectives and appeal to the student population. In addition to content, customized presentations, quizzes, and assignments were created for each module. The upfront workload of this approach was high, but the reward paid excellent dividends in student experience and engagement. The results from a survey from 221 students in the online accelerated section of this course indicated that 90.95% felt the course was very practical, 89.59% felt the course was engaging, and 87.78% felt the course was valuable. Furthermore, 91.39% indicated this course was intensive so the rigor of the course was very high from the students' perspective and numerous favorable comments were offered with regard to course quality and impact.

Course design

The format of a course (i.e., online or in-person) should never dictate the learning objectives, but almost always influences the course design. When dealing with large online class sizes, there are several practical course design elements to maintain consistency and improve effectiveness. Practices that were valuable in building a scalable course include: 1) creating grading rubrics in the learning management system (e.g., blackboard) for each assignment to assist with grading consistency, 2) organizing content into modules rather than task type, 3) outlining the module learning objectives on each module folder in the LMS, 4) using thread box via voice thread to facilitate connections and build a sense of community among students, 5) using online video conference office hours via zoom, and 6) organizing module folders consistently (e.g., module instructions and attached documents - module presentation – quiz to assess content coverage – submission folder for assignment documents).

While some of these practices apply to all course formats, they become profoundly more important for large online courses. 100% of survey respondents indicated the LMS site was easy or very easy to navigate, and the module requirements were easy to understand.

Furthermore, while consistency is key in LMS formatting, differentiating assignment types (Merrill, 2002) engages different student strengths and provides diverse pathways for success. Because online MBA students are keenly sensitive to how their learning will impact their life, course assignments were designed to help them discover how much they need the information before they receive it. For example, when students ran simulations in the course, they first completed a practice run with only instruction on the mechanics of the simulation. Because they were taking actions without a conceptual framework or understanding the theory behind making effective decisions, their performance quickly illustrated their need for knowledge they did not maintain. The subsequent debrief covered content relevant to the simulation as well as reflection on how that information would alter their decisions in the simulation. Students then ran the simulation again and achieved profoundly better results.

This approach is consistent with the *problem-centered* criterion for effective instruction (Merrill, 2002) as it focuses students' attention on solving the problem at hand, rather than memorizing information for an ambiguous situation they may encounter at some point in their life. This approach has been more effective than simply telling students why the topics they study are important because once they are hungry for the information, they place value on it and receive it with excitement. They see it as keys to success rather than information to be memorized for an assignment or exam.

The *application* criterion for effective instruction (Merrill, 2002) was built into each module assignment as students applied the content to a scenario in their work-life. This facilitated the transfer of training and made the material high-touch in a real and experiential way. This reflection/application component highlighted the impact the content had on students' lives and helped integrate them as co-creators in the learning process.

This course design was adapted from the scaffolding model which follows an I do – We do – You do approach that helps learners perform a task that would be difficult independently (Gašević, et al., 2015). The scaffolding methodology facilitates experiential learning without overburdening the instructor because students have a frame-of-reference to reflect on when applying the content to themselves or a situation. This approach emphasized the *demonstration* component of effective instruction (Merrill, 2002) as examples of unsatisfactory, satisfactory, and excellent performance were presented as well as the assignment instructions and completion process for each assignment.

Course feedback

Social presence (i.e., the ability of students to share their personal characteristics and present themselves to others as real people) has been found to relate positively to the ability to construct meaning from course interactions (Lee, 2014). Voice thread boxes were effective tools to elicit social presence as students shared presentations and ideas with peers and received feedback from them. This built a sense of community to help them feel connected to one another, the university, and the instructor. Students in this course introduced themselves by posting their leadership journey in a thread box which accomplished two things: (1) eliciting social presence, and (2) creating student awareness that they have a foundation on which to build with this course material, which aligns with the *activation* component of effective instruction (Merrill, 2002). Furthermore, the expert feedback (Merrill, 2002) they receive from emails and graded assignments allows students to experience high teacher presence as well. With large sections, clarifying responsibilities of faculty, teaching assistants, and students was also very helpful way to convey teacher presence and elicit higher-level learning.

Course feedback in this online course appeared superior to on campus sections in some ways. For instance, communication is an essential leadership skill and presenting to peers provides valuable practice for the learner. However, audience feedback during live student presentations is limited by class time, but this constraint does not exist online. Online presentations can be

paused, restarted, and watched again so feedback can be deeper and more constructive. Similarly, peer engagement in online discussion boards is often greater than in-class discussions due to higher perceptions of psychological safety which allows for a free-flowing exchange of ideas. Furthermore, student interactions in this course aligned with the *integration* component of effective instruction (Merrill, 2002) as students reflected on, discussed, and defended their acquired skills which elicited social presence and provided valuable feedback to the learner.

Online education is not ideal for every instructor or learner, but selecting content relevant to the student population, using a scalable/appropriate design, and creating feedback interactions which contribute to social and teacher presence are excellent ways to appeal to this segment of learners.

DISCUSSION AND CONCLUSIONS

Table 2 presents a summary of ways in which design elements in MBA courses CIS601 and MNGT611 have addressed the ten principles of effective course design developed by Merrill (2002, 2009, 2013) and expanded by Margaryan and Collis (2005).

The goal of this paper was to use these principles as a guide in the development of MBA courses that reflect the best practices of instructional design and provide a means of evaluating the achievement of this goal. Adjustments to teaching methods, assignment structures, student interactions, and teaching assistant integration were made to facilitate fast-paced, large online classroom environments.

This paper is limited, of course, by the inclusion of only two courses. Further research will expand to include all MBA courses in the college's MBA Program. A tool will be developed to evaluate MBA courses on their implementation of the ten principles, based on the tool used by Margaryan and Collis (2005). An additional tool will be developed to measure student perception of the course's coverage of the ten principles, using Margaryan and Collis' (2005) tool as a starting point. Both tools will be administered for several semesters/years to determine trends; and based on the results, any needed adjustments will be made to courses.

Meanwhile, efforts will be made to provide both synchronous and asynchronous communication channels for students in all courses, in order to facilitate student-to-student and student-instructor interaction. Additionally, to facilitate knowledge sharing, an area will be provided where assignment answers can be shared, after the due date has passed. More provisions will also be made to accommodate the needs of diverse learners. According to Rolfe (2015), when an online course is available to learners around the world, it is important to address the needs of a geographically, culturally, and academically diverse participant group, as well as special needs students. This is particularly important for the MBA Program discussed in this paper, which has students in remote locations, international students, and special needs students.

Table 2: Coverage of the ten course design principles in CIS601 and MNGT611		
Course Design Elements	**CIS601**	**MNGT611**
Problem-Centered	Real-world case analyses and article reviews	Problems introduced first to set the stage for material
Activation	Students use prior experiences to analyze new information and build on these to develop new skills.	Students use prior experiences to analyze new information and build on these to develop new skills.
Demonstration	Cases and articles demonstrate both best practices and challenges.	Scaffolding methodology is used to teach material and clarify assignments.
Application	Students are required to apply new skills to real-world situations.	Assignments exclusively use real-world scenarios.
Integration	Students required to demonstrate new knowledge and understanding.	Students required to demonstrate new knowledge and understanding.
Collective Knowledge	Students share ideas in discussion boards.	Students share ideas in voice threads and discussion boards.
Collaboration	Students critique and learn from each other.	Collaboration occurs via voice thread presentations and discussion boards.
Differentiation	Assignment options provide diverse pathways for success.	Assignment options provide diverse pathways for success.
Authentic Resources	Exclusive use of real-world scenarios.	Exclusive use of real-world scenarios.
Feedback	Coaches instructor, peers provide prompt feedback.	Occurs via peers, academic coaches, and instructor.

Public acceptance of commercial drone deliveries:
A case study in developing a marketing research measure with the Rasch model

Garret Marshall
University of Toledo
Email: garret.marshall@utoledo.edu

ABSTRACT

This paper will detail the development of a measurement scale designed to profile the extent to which the public would be willing to accept commercial deliveries by drones. The survey items for this instrument were generated through the use of focus groups, guidance from experts of the technology, backward translation and extensive piloting and calibration using the Rasch model.

KEYWORDS: Drones, drone delivery, Rasch, acceptance survey, survey development, focus groups, backward translation

INTRODUCTION

Drones are a hot topic. They are in the news, shown in movies, given as toys for children, used by hobbyists for shooting videos and the government for surveillance. They are becoming part of our culture. Some are eager to find new commercial applications for drones, and the most obvious possibility would be for package delivery. Yet, as with all changes in culture, there is resistance – particularly when it comes by way of a new technology. Those that are less eager ask if these changes are happening too rapidly. The online retailer Amazon.com doesn't think so. They, and other firms, have spent untold millions of dollars developing such programs, and to them, it's merely a matter of time.

Strangely, very little academic research has been devoted to business models involving drones. Most of the material discussing drones has been published in trade journals, or as news articles related to some specific development - nearly all of which focuses on either the feasibility or inevitability of drone package delivery. Almost no one is asking if potential customers would actually want such a service. This paper details the development of an instrument for the measurement of public acceptance of drone deliveries.

The method used in this development is centered around the use of the Rasch model. While the Rasch model is used extensively in educational and psychological research, it is rarely used to explore business related issues. This is truly unfortunate as many areas of business research rely upon psychographic data gathered largely through surveys. The data from surveys is typically categorical, or at best ordinal, and difficult to analyze without a number of dubious assumptions. The Rasch model (or simply Rasch) was designed specifically to analyze such data and would be extremely useful to business researchers – particularly in marketing. Therefore, this paper has two purposes. The details behind the development of the proposed measure are presented not only to demonstrate the application of specific methodology, but also to serve as an ambassador for Rasch to business academia.

The paper begins with a brief overview of the publications related to drone delivery. The theoretical framework suggested in the literature serves as valuable guidance for the generation of survey items in this study. The development itself is broken into process sections. The pre-pilot section discusses how the initial ideas for survey items were generated and tested with Rasch. The focus group section introduces a more structured approach to refining survey

items. The primary testing section details a large scale test of the proposed measurement instrument. The Rasch analysis section discusses a few difficulties encountered during the analysis. A final section offers advice for the deployment of the measure as a market research tool.

LITERATURE REVIEW

As of this writing, there are only two publications of academic value directly related to public acceptance of drone deliveries. In October of 2016, the Office of Inspector General for the United States Postal Service published "Public Perception of Drone Delivery in the United States". This report details the results from a nationwide online survey in which participants were asked how they might prefer to receive their mail. The survey also gathered a great deal of demographic information through which a number of conclusions were drawn. They divided the respondents by generations of Millennials, Generation X, and Baby Boomers. Millennials were found to be significantly more knowledgeable, open, and positive towards the idea of drone delivery than older generations, though all generations seemed to feel that it may be "too soon" for drone delivery.

According to this report, men were more aware of the idea of drone delivery and more accepting of the prospect. They also observe that those who rely primarily on postal deliveries would feel less positive towards the USPS if it offered the service today compared with those who frequently use ecommerce channels. There appeared to be no significant difference in awareness of the drone delivery concept across geographic regions. The concept was viewed most positively by Western residents and least liked by Midwestern residents, with Southern and Northeastern residents somewhere between.

Surprising for a government report, a relatively detailed description of their methodology was included along with a list of the questions posed. One limitation noted by the authors was the use of quota sampling. Strictly speaking, this non-probabilistic method restricts the generalizability of the findings, though they point out that it is used extensively in marketing research. They also note that rural residents were overrepresented in the sample.

The biggest limitation in the USPS report was in the design itself. The questions posed were largely written in the context of mail delivery. Respondents were asked how they felt about the USPS in comparison to other commercial entities such as FedEx or Amazon, and while these other firms are prohibited from delivering mail, it was clear that the focus was to gauge the public attitude toward the prospect of the USPS entering the future ranks of drone-capable delivery services. In fact, an internal memorandum from the vice president of operations attached to the report notes the importance for the USPS to remain competitive. This is noted here as a limitation because the conclusions drawn by the report were tailored very specifically for the USPS, and while they may be interesting, they are not likely to be of direct use by private firms.

The other relevant publication was a 2017 article by Ramadan, Farah and Mrad entitled "An adapted TPB approach to consumers' acceptance of service-delivery drones". In this article, the authors attempt to draw a parallel between consumer acceptance of other business-to-customer technologies (such as ATMs) and drone deliveries through a framework based on the Theory of Planned Behavior (TPB). Similar in structure to the Technology Acceptance Model, though the TAM antecedents *perceived usefulness* and *perceived ease of use* are generalized to the TPB variables *functional benefits* and *relational attributes*. In this conceptual article, these proposed variables, along with *risks*, are antecedents to *attitude toward using drones*, which in turns leads to *intention to use drones*. The authors offer propositions that link perceived risk, drone performance and "personification" with the likelihood of acceptance.

The inclusion of perceived risk and drone performance are certainly reasonable (and somewhat obvious), though the notion of personification is quite interesting. By this, the authors refer to the "consumer's need for human interaction". While noting that this need has often been an inhibitor of acceptance for other technologies, the possibility that a single firm (such as Amazon.com) might gain enough of a lead in the implementation of drones that the service itself may become part of their brand identity. This brand-consumer relationship, along with the sheer novelty of the drones, may lead to some level of anthropomorphic attachment. No empirical evidence was offered, but the linkages between benefits, risks and intentions were set on a firm theoretical foundation.

The primary idea behind TPB is that an individual's perception of the outcomes of performing a certain behavior influences their attitude towards the related behavior (Fishbein and Ajzen, 1975). By extension, TAM argues that the *perceived usefulness* of a technological adoption is relevant in terms of improving one's job performance and thereby may influence attitudes towards the intention to use the technology (Davis, Bagozzi, and Warshaw, 1989; Porter and Donthu, 2006). TAM also suggests that the *perceived ease of use* of technology influences the decision regarding how and when the technology might have the greatest impact. While TAM was intended to model workplace behavior, Ramadan, Farah and Mrad (2017) would argue that issues such as concerns over privacy, susceptibility to subversion or mere malfunctions are legitimate risks in the eyes of potential users and thereby would have the same impact on their intention to choose drone delivery.

OVERVIEW OF THE RASCH MODEL

To motivate the use of the Rasch model, consider how most empirical research is conducted in business academia. The point of most empirical models is to establish a causal relationship between higher order latent constructs. Each of the underlying first order constructs would be defined by a number of survey items – each of which would be related to a particular aspect. In terms of measurement, having a single survey item to measure an idea would be analogous to a ruler with a single tick mark. If the research objective is merely to establish relationships between constructs, then the true degree of covariation between items may not be as important as the specification of the model itself.

On the other hand, if the research objective is to develop a rigorous measure of a latent construct through the gathering of psychographic data, a ruler with more than one tick mark is needed. This would certainly be the case in marketing research, in which researchers wish to generate a demographic profile of attitudes toward a product or brand. The Rasch model is ideal for the development of such measurements.

The primary idea behind using multiple survey items to build a single measurement scale is based on the notion that each question should present a different level of difficulty for someone of a set view to agree. For example, imagine a respondent that is positively disposed toward, but not completely in agreement with the idea of drone delivery. Such a person might readily agree that drones would work well in situations of low-risk with packages of minimal value. However, as the concerns increase, this person might find it harder to agree with the assertion that drones would work well. In this way, a carefully crafted series of questions that spanned the range of benefits and concerns could gauge the extent to which a respondent would be willing to accept the idea of drone package delivery.

The difficulty lies in developing survey items that, as a whole, are unidimensional, adequately cover the extremes (easy to agree and hard to agree) of the range, and form a coherent narrative from which a marketing profile might be inferred.

DEVELOPMENT OF THE PRE-PILOT SURVEY INSTRUMENT

The Initial Brainstorming Session

The initial survey items were developed during a classroom discussion of new product development in an undergraduate operations management course. Though the discussion was not specifically intended to be part of a research project, a number of interesting insights were revealed regarding the concerns over drone package delivery. By the end of the class period, a number of specific survey items were proposed. Appendix 1 contains a list of these initial questions. From these questions, three primary themes emerged: impact, benefits and trust. While the survey items are not ordered according to these themes, they could be grouped as follows:

The general idea behind the theme of impact is to measure how respondents view the effect of drones on the welfare of society. Items 4, 5, 6, 7, and 16 were intended to address this issue. Because of the very general nature of such questions, it was decided to ask about societal impact and the impact on families in both positive and negative forms. Reasoning that the absence of a threat does not imply a benefit, Item 7 was given as the negation of Item 5. Similarly, Item 6 is the negation of Item 16.

The theme of benefits is fairly straightforward. The focus group identified speed and potentially lower costs as the primary incentives to request drone delivery. Items 21, 23, and 24 were included to address these features.

The benefit theme was also intended to explore the limitations of drone technology. It has been suggested that a delivery drone may not be able to reach all residents. For example, a customer may live in a high-rise apartment building with no suitable drop zone. In such cases, a customer may have to retrieve their package from a common drop point. Item 10 was included for this purpose.

Further concerns regarding the limitations of drones include the impersonal nature of the system and the worry that a drone might drop their package in the wrong location. Items 20 and 26 were intended to address these concerns. The inclusion of such items may serve to identify possible deficiencies that may need to be addressed. For example, if a large enough percentage of respondents answered strongly agree to Items 20 and 26, retailers might consider a new marketing campaign to change public perception.

Given the historical use of drones, the bulk of the items were related to trust. The focus group identified a number of possibilities related to trust. Chief among these issues is safety. Items 1, 9, 15, 17, 18, and 19 address the specific concerns discussed.

In addition to personal safety, concerns were also raised regarding the safety of the cargo. Item 3 is related to the fragility of packages, while Items 2 and 13 are related to valuable or confidential cargo.

The small remainder of items are all related, if somewhat tangentially, to one or more of these themes. For example, Item 12 touches onto issues of trust and benefit. To date, no grocer has expressed interest in pursuing drone delivery, if perishable food were ever to be delivered by drone, pizza would likely be the first to fly.

Rasch Analysis of the Pre-pilot survey

The items proposed in Appendix 1 were assembled into a pre-pilot instrument and tested on a different class section with 42 students. The characteristics of the survey instrument fits the Rasch rating scale measurement model, and was analyzed with the Winsteps program (version 3.74.0). The analysis and consequent revisions were arranged in the order of scale, dimensionality, item, and people. The initial results are shown in Figure 1.

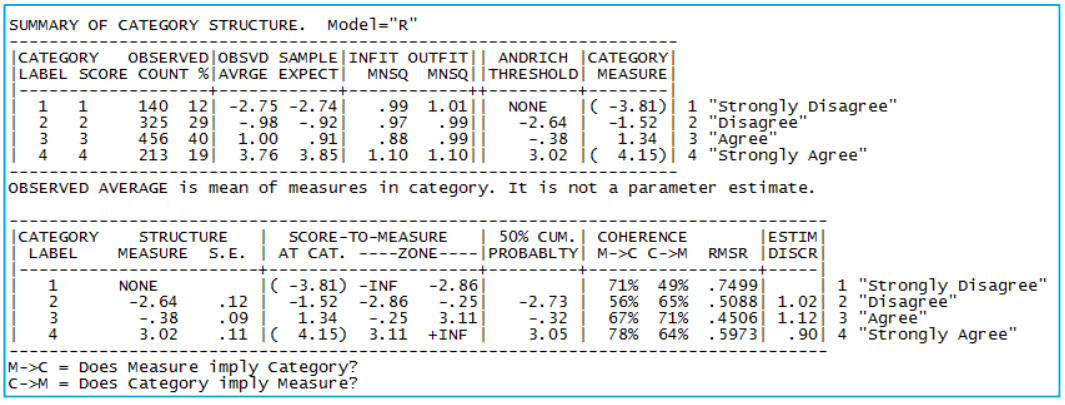
Figure 1

The analysis shows a 5.81 separation between people (potentially 7 distinct groups), and a 4.07 separation between items (5 or 6 groups). The survey also appears to exhibit a high level of reliability, but as with the other statistics, a word of caution is advised. The same group that helped write the survey also served as the sample for this pilot study. Hence, this may constitute a significant bias. This type of convenience sample may not be as much of a problem for the pilot study, but this limitation must be kept in mind throughout the evaluation process.



SUMMARY OF CATEGORY STRUCTURE. Model="R"

CATEGORY LABEL	SCORE	OBSERVED COUNT	%	OBSVD AVRGE	SAMPLE EXPECT	INFIT MNSQ	OUTFIT MNSQ	ANDRICH THRESHOLD	CATEGORY MEASURE

C->M = Does Category imply Measure?

Figure 2

The results in Figure 2 suggest that the 4-point Likert scale chosen for the survey performed well. The rating scale structure, parameterized with the Andrich Threshold, is monotonic and increasing with threshold separations of at least 1.4. Likewise, the category probability plot in Figure 3 exhibits a strong relationship between a person's logit score and the difficulty of the item.

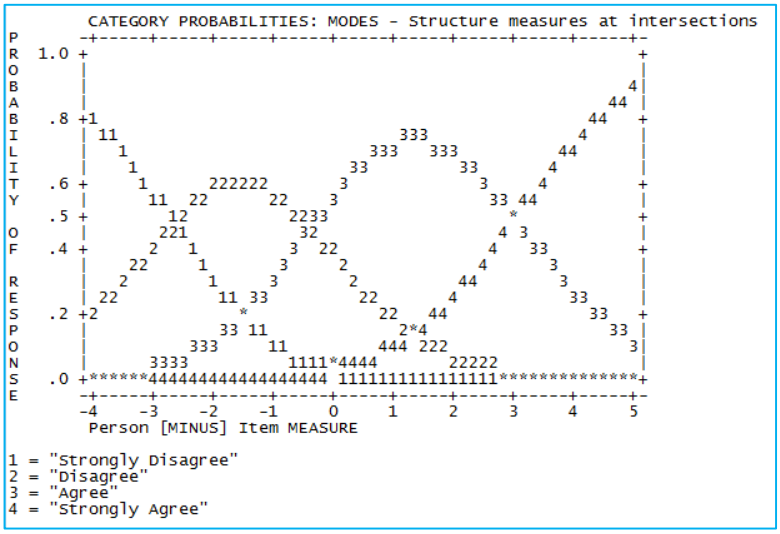

Figure 3

Sometimes, the appearance of perfection disguises problems. Without any revisions, the survey instrument already exhibits large threshold separation. This may suggest that the category structure may be "too broad" – that is, a scale with more categories might have captured more information. Through this analysis, scale can be collapsed, but not expanded. This issue will be revisited after the revisions are made.

The output shown in Figure 3 suggests that the instrument is reasonably unidimensional. The raw empirical variance explained by measures should exceed 60%. The percentage found in the initial analysis estimate the percentage to be 65.6%. Furthermore, no contrast contributed unexplained variance greater than 3.6% - well below the standard of 5%. The items with loadings outside of the (-0.4, 0.4) interval did not appear to be grouped in any particular pattern.

Table of STANDARDIZED RESIDUAL variance (in Eigenvalue units)

		-- Empirical --		Modeled
Total raw variance in observations	=	78.4 100.0%		100.0%
Raw variance explained by measures	=	51.4 65.6%		64.7%
Raw variance explained by persons	=	32.1 41.0%		40.4%
Raw Variance explained by items	=	19.3 24.6%		24.2%
Raw unexplained variance (total)	=	27.0 34.4%	100.0%	35.3%
Unexplned variance in 1st contrast	=	2.8 3.6%	10.5%	
Unexplned variance in 2nd contrast	=	2.7 3.5%	10.1%	
Unexplned variance in 3rd contrast	=	2.3 2.9%	8.3%	
Unexplned variance in 4th contrast	=	2.1 2.6%	7.6%	
Unexplned variance in 5th contrast	=	1.9 2.5%	7.2%	

Figure 4

The item analysis begins with an examination of the misfit order rankings in Figure 5. Item 11 exhibits large infit and outfit statistics, as well as a low point-biserial estimate. Perhaps this is not surprising as it was the only item to which no respondents chose *strongly disagree*. Acceptable infit and outfit statistics should fall within a range of 0.6 to 1.4. The point-biserial should be positive, and preferably above 0.3. When these statistics do not agree, the point-

biserial is considered to be more predictive. At this point, item 11 is the only item with a point-biserial below 0.3 and is a good candidate for removal.

Figure 5

Further examination of misfit order is shown in Figure 6. The measures of average ability should be monotonic, yet items 4, 11, 21 and 25 are not. In themselves, these estimates are not necessarily cause for removal, but upon closer review, each of these items appear to be mismatched in the context of the whole survey. The double-barreled nature of item 21 ("*I would choose drone delivery if it was more expensive, but much faster, than conventional delivery*") is likely causing a misfit and was later removed.

Figure 6

After a number of successive trials, a total of five items were removed from the survey.

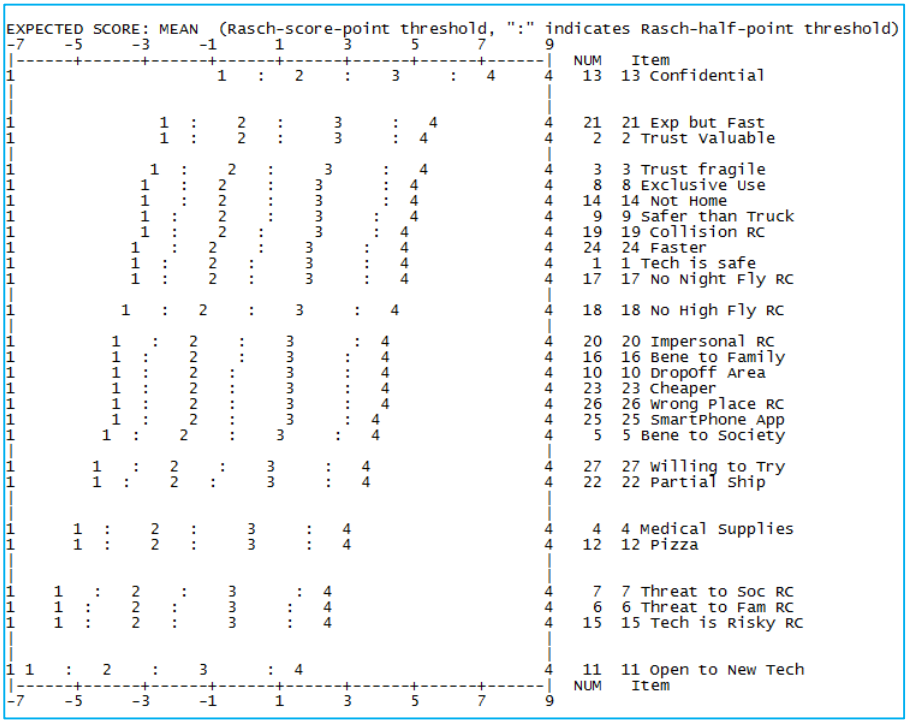

Figure 7

The *diagnostic keyform* table in Figure 7 appears to show significant "stacking" in the center of the item distribution. Ideally, a truly linear measure would disperse the items evenly throughout the domain, though the sort of distribution shown in Figures 7 and 8 are not uncommon.

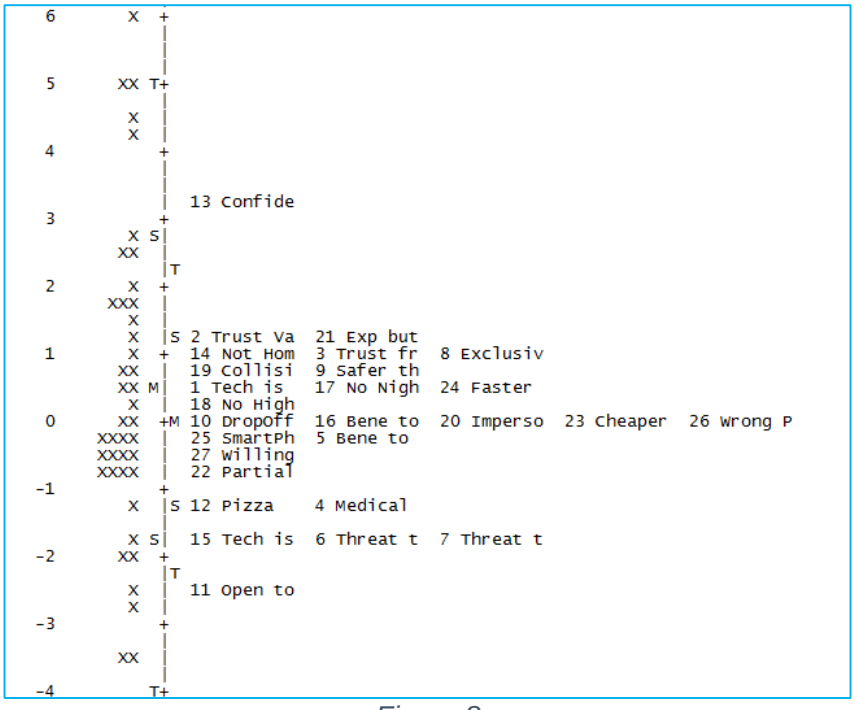

Figure 8

Figure 8 shows why this lack of dispersion may be a problem. While the distributions of items and people may be evenly centered, there is little to measure respondents with "extreme" logit scores – particularly at the higher end. This might suggest that some of the respondents were excited about the possibility of drones beyond that which was prompted by the survey items. This may not be surprising. Consider the sample. Youngsters in American society tend to be very "gadget-focused" and therefore might have answered positively to almost anything. But that is an inference of intuition. From a purely measurement view, the instrument scale should be able to account for these individuals.

The analysis of people begins with the output shown in Figure 9. In this figure, the misfit order of people suggests that persons 2, 35 and possibly 6 may be a problem. The standards for infit, outfit and point-biserial statistics are the same as they were for items, and all of these respondents exhibit high outfit statistics. Most striking is the point-biserial for person 2. It is hard to say exactly why person 2 would have this score - except to say that he or she was *moving in another direction*, as it were. This person was removed from the sample.

Person STATISTICS: MISFIT ORDER

Figure 9

While statistics for persons 35 and 6 were suspicious, their removal was shown to have no positive effect on the reliability of the instrument, and were left in.

While the resulting instrument exhibited a number of positive characteristics, it was also clear that a further grounding in theory might serve to improve the unidimensionality of the measure. However, to do this, a more structured approach toward item development needed to be adopted. The pre-pilot described above, aligned well with the propositions offered in Ramadan, Farah and Mrad (2017), though the issue of personification was not fully explored.

USE OF FOCUS GROUPS FOR SURVEY ITEM DEVELOPMENT

Using insights gained in the development of the pre-pilot, a series of structured discussion points were assembled for use with a number of focus groups. Greenbaum (1988) was used extensively in the design and execution of this phase of the project. A general outline of the methodology is as follows:

- Define the data-gathering objectives
- Define the parameters of the situation, stimuli to be used, and discussion points
- Define the group composition
- Arrange for a suitable location
- Prepare for unexpected group dynamics

In the USPS report, a great deal of attention was paid to demographics. If the ultimate objective of the project was to develop a demographic profile of likely acceptance of drones, then the group composition should be stratified as specified in the report: by generation and gender. In this way, the specific objective of the groups would be to assemble a series of survey items that accurately reflected the perceived benefits and concerns of commercial drone delivery.

The program for the focus group would proceed as follows. First, group members would be shown four still pictures of drones: a military drone, a surveillance drone, a hobbyist's drone equipped with a camera, and a small toy drone being operated by a child. Members would be asked to write down four words to describe their reaction to these images. These responses would then be discussed.

Next, an early commercial produced by Amazon.com would be shown to the members. This video contains no dialogue, but follows a buyer placing an order online, the items being picked in a distribution center and loaded onto a drone, and the arrival of the package at the buyer's home. This time, members would be asked to write down three positive words to describe what they viewed and two negative words. This would be followed by a discussion in which members would be asked to imagine that they were part of a marketing team that wanted to debut the new service. They would then be asked about specific concerns that they might need to address.

Finally, a second Amazon.com video would be shown to the group members. This video was a humorous, fully-fledged commercial intended to highlight the benefits of the service. This time the members would be asked to write down two positive words and three negative words in reaction to the video. The final discussion would ask the members to suggest possible survey items.

The original plan was to hold seven separate focus group sessions with the following compositions. Each group would consist of eight members. Three session of millennials – one all girl, one all boy, and one mixed. Two groups of Baby Boomers – one all women, one all men. Finally, there were to be two additional Baby Boomer groups with mixed genders, but arrangements could not be made within the time allotted.

The primary concern in screening the potential group members was to ensure that friends were not in the same group. The idea is to encourage all members to speak freely, and this become more difficult when there are such preset subgroups. Likewise, the moderator had to be prepared to handle members that dominated the discussion or those that were reluctant to speak at all. Fortunately, having taught a number of undergraduate courses in business, the moderator was well-aware of these issues of group dynamics and was prepared.

In total, five focus groups were assembled and the program was executed perfectly during the month of March, 2018. The Millennial groups were assembled from volunteers at the University of Toledo and the Purdue Fort Wayne campus. The Baby Boomer groups consisted of volunteers from various administrative departments from Purdue Fort Wayne.

During these sessions, the idea of personification was explored in terms of brand recognition. Both videos were produced by Amazon.com and they have managed to dominate much of the discussion regarding the future of drone use. Yet, only a single group member expressed any tendency to associate this new service with any vendor.

Backward Translation

The questions listed in Appendix 2 were assembled after careful review of the group recordings. A number of the questions from the pre-pilot were close enough to what had been suggested in the group sessions that the wording survived the revision.

A technique called *backward translation* was used to ensure that the questions retained their intended meaning when read by respondents of differing cultural contexts. A list of

proposed questions was given to a student at Purdue Fort Wayne that was fluent in German for written translation. The German text was given to a graduate student at the University of Toledo to translate back into English.

Of the 16 questions translated, none had lost their original meaning. The grammatical structure of three sentences were altered, though this did not change the intended message. In all three cases, the questions were shortened and given back to the second translator. In each case, the reduced length returned the structure to its exact original form.

RASCH ANALYSIS OF THE PRIMARY SURVEY INSTRUMENT

The summary statistics for the revised survey instrument included in Figure 10. Of particular interest is the Person Separation value of 5.74. In Rasch, *separation* suggests the extent to which one set of parameters of a group can be estimated separately from another. Person Separation implies the number of distinct groupings of respondents with commonalities (Bond and Fox, 2015). Here, a value of 5.74 suggests that the analysis found six distinct groups within the sample. Often such analyses find only three or four. Finding more than four is very encouraging for this sample size.

Figure 10

The effect of the revisions on these statistics was marginal, but interesting. The item separation increased from 4.07 to 4.29, and the item reliability increased from 0.94 to 0.95. A hit was taken on person separation (decreased from 5.81 to 5.74), but as seen in Figure 11, there was an improvement in dimensionality. The raw empirical variance explained by measures increased from 65.6% to 69.1%.

```

    Unexplned variance in 5th contrast =          1.7   2.4%   7.7%
```

Figure 10

However, Figure 12 shows that the concern regarding the category structure may have been justified.

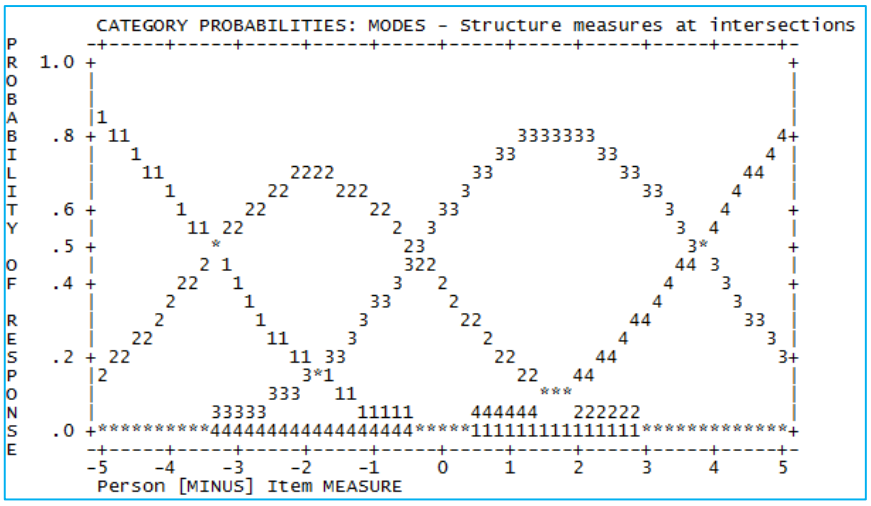

Figure 11

The structure shows Andrich threshold separation of roughly 3 with the probability curves at or approaching 80%. In retrospect, the scale could have included more categories. The decision to use a 4-point scale was based on the agree/disagree nature of the scale. If an odd-numbered scale is to be avoided, how would a 6-point scale be worded?

Strongly Disagree	Disagree	Mildly Disagree	Mildly Agree	Agree	Strongly Agree

This scale seemed likely to cause confusion as respondents might not be able to distinguish between the pairs on either side of the middle.

12	63	22	1.14	.43	1.22	.8	1.25	.8	K .73	.57	59.1	68.7	12
15	61	22	.79	.42	1.19	.7	1.25	.8	L .41	.57	54.5	66.6	15
1	84	22	5.72	.62	1.06	.3	1.24	.5	M .35	.45	86.4	85.2	01
4	71	22	2.70	.45	1.18	.7	1.21	.7	N .33	.58	63.6	72.0	04
40	52	22	-.69	.40	1.18	.7	1.09	.4	O .57	.59	54.5	64.6	40
16	50	22	-1.00	.39	1.13	.5	1.13	.5	P .54	.60	59.1	65.5	16
28	82	22	5.08	.53	1.08	.4	1.06	.3	Q .38	.47	81.8	77.1	28
13	62	22	.96	.42	1.04	.2	1.07	.3	R .48	.57	63.6	67.8	13

Figure 12

As mentioned, it was decided that persons 35 and 6 were not to be removed. This decision is bolstered by the results shown in Figure 13. After the removal of person 2, person 35 was still suspect, but made little difference.

Lastly, an advantage of Rasch over traditional methods is the manner in which the analysis can be used to address how the construct being measured speaks to the underlying theory. Using a more structured, theoretical approach made significant improvements in the performance statistics of the survey instrument.

DISCUSSION AND CONCLUSIONS

Iacobucci and Churchill (2015) draw a distinction been *marketing* research and *market* research. The former establishes the relationship between specific potential customers (often in terms of demographics) and product concepts. An important end product of marketing research is a customer profile by market segmentation. This profile serves as a basis to project likely market reaction (and sales) to a given product. The data used in marketing research is nearly always through primary means (surveys, focus groups, etc.) and is typically proprietary. Whereas, market research looks at specific markets (typically geographic locations) through secondary data. A customer profile can then be applied to the market in question to predict likely sales. The measurement instrument developed here was specifically intended to help firms generate customer profiles by gender and generation.

Unlike surveys intended to support a theoretical model with a series of hypotheses, the instrument developed here is a pure measurement tool. Just as the Wechsler Adult Intelligence Scale is used by researchers in psychology, this measurement of drone acceptance could be used in the analysis of a specific market. Where customer satisfaction measurements (such as the CSAT or NPS) are more general tools, this measurement scale is tailored specifically on a single issue and was intended primarily for primary market research.

The revised survey instrument appears to function reasonably well, but cannot be rigorously validated until certain issues are addressed. First, a much wider sample must be taken. One possible method might be through the use of Amazon's Mechanical Turk program. This program was designed to survey customers after they have made a purchase. The reported response rates from this program are claimed to be "much higher than traditional survey methods". Every survey is different, and it's hard to see how such a claim could be

made. However, this method has the advantage of reaching the very audience intended in the first stage of this study.

Second, consider expanding the category structure. To stay with the rating scale model, each step difficulty would have to be the same – otherwise the model would have to switch to a partial credit or ranks model. Therefore, it would be best to use the same category structure throughout the survey, but it need not be in the form of *agree*/*disagree*. An alternate structure might take the *too little*/*just right*/*too much* form.

Finally, items should be developed to fill the gaps in the measurement scale. It was postulated that some respondents may be so willing that they'd agree to *anything*. If this is true, it might be well to exclude these individuals from a subsequent sample. They might be included in a report of counts, but their inclusion in the analysis does not further the research interest at issue. They were not excluded from this pilot study, in part, due to the limited sample size.

APPENDIX 1

Pre-pilot Survey Questions

Respondents were asked to indication the extent to which they agreed or disagreed with the following statements:

1. This technology is safe.
2. I would trust a drone to carry something of value.
3. Drones are no more likely to damage fragile packages than a delivery truck.
4. Drones would be a good way to deliver emergency medical supplies.
5. This technology is beneficial to society.
6. This technology is threatening to my family and me.
7. This technology is threatening to society.
8. I would be willing to order from a company that exclusively used drones for deliveries.
9. This technology is as safe, or safer, than other technologies that perform the same task.
10. I would be willing to go to a designated drop-off area.
11. I am open to new technologies.
12. I would have a drone deliver a pizza.
13. I would trust a drone to carry confidential information.
14. I would be willing to have a drone deliver a package when I am not home.
15. This technology is risky.
16. This technology is beneficial to my family and me.
17. Drones should be restricted from flying at night.
18. Drones should not be allowed to fly above a certain height.
19. If delivery drones became very popular, then dangerous collisions would be likely.
20. Delivery drones would be too impersonal.
21. I would choose drone delivery if it was more expensive, but much faster, then conventional delivery.
22. If a drone could only carry part of my order (other parts were too heavy), I would still prefer drones to deliver as much as they could.
23. I would choose drone delivery if it was cheaper than traditional delivery.
24. I would choose drone delivery if it was faster than traditional delivery.
25. All drone deliveries should work with a smart phone app.
26. I am concerned that the drone would deliver my package to the wrong place.
27. I would be willing to try drone delivery.

APPENDIX 2

Primary Survey Questions
Respondents were asked to indicate the extent to which they agreed or disagreed with the following statements:

1. Drones would be fast.
2. I would trust a drone to carry something of value.
3. Drones should be restricted from flying at night.
4. Drones would be safe.
5. Drones should not be allowed to fly above a certain height.
6. Deliveries would be environmentally friendly.
7. Drone deliveries would be worth an extra expense.
8. Drones might be used in a way that invades my privacy.
9. Drones would give me more control over where I receive my package.
10. Drones would have no place to land at my residence.
11. Drone might deliver my package to the wrong place.
12. The package it's carrying might be stolen.
13. Drones might malfunction and damage the package they're carrying.
14. Drones would give me more control over when I receive my package.
15. I would be willing to have a drone deliver a package when I am not home.
16. I would be willing to go to a designated drop-off area.

Quantitative Models of Supply Chain Risk Management: A Systematic Review of Literature

Attique ur Rehman
Email: attique@uvas.edu.pk

ABSTRACT

This paper is aimed at reviewing the literature in the domain of quantitative models in supply chain risk management. Screened papers from 2008 to 2018 are analyzed and classified based on the nature of modeling technique being used and the key dimension of supply chain being discussed. We found out that stochastic models are used widely to explain demand uncertainties whereas simulations are used in various manners to explain supply chain network designs. This paper provides a methodical review of journal articles in the domain of quantitative models in supply chain risk management.

KEYWORDS: Supply Chain Risk Management, Modeling Techniques, Supply chain strategy

INTRODUCTION

Academic and industry practitioners have become seriously interested in supply chain risk over the past decade, attributed to supply chain disruptions caused by natural disasters or intentional or unintentional human actions (Snyder et al., 2016). Supply chains, globally are becoming more vulnerable with large unanticipated events (Craighead, Blackhurst, Rungtusanatham, & Handfield, 2007). Supply chain disruptions have deeply impacted firms' performance in recent years (Ho, Zheng, Yildiz, & Talluri, 2015). A number of broad models have been suggested for recognizing and weighing supply chain risks including cause and effect diagrams, social network theory, interpretative network modeling, FMEA, identifying interdependent enablers of risk mitigation and Risk Priority Number analysis (Kim, Choi, Yan, & Dooley, 2011; Lin & Zhou, 2011; Nishat Faisal, Banwet, & Shankar, 2006; Pfohl, Gallus, & Thomas, 2011; Tuncel & Alpan, 2010). Some quantitative and sophisticated models include analytical models (deterministic and stochastic), simulations, AHP, fuzzy set theory, multi-echelon, Linear programming and Integer linear programming models.

In the last decade, four articles were published on supply chain risk management review. 55 articles published between 1994 and 2010 were reviewed by Colicchia and Strozzi (2012) revealed the trend and evolutionary patterns in the field of SCRM. Rao and Goldsby (2009) reviewed 55 journal articles and established a typology of various risk factors. O. Tang and Musa (2011) reviewed 138 journal articles and identified and classified various risks associated with information, financial and material flows. Sodhi, Son, and Tang (2012) formulated their own perception of diversity in SCRM by reviewing 31 journal articles.

Earlier research works have primarily focused on particular topics of SCRM such as risk classification or risk factor analysis or risk gap identification. None of the earlier research works have discussed categorization of quantitative modeling in supply chain risk management. In order to fill this gap, this paper presents a comprehensive review of all quantitative articles from specified journals published between 2008 and 2017 undertaking a classification scheme.

Classical categories of supply chain risk have been proposed by Beamon (1998). He makes a distinction between deterministic analytical, stochastic analytical, economic and simulation models. Another classification scheme provided by R. S. Gaonkar and Viswanadham (2007) focused on the dimensions of supply chain risk based on deviations in sourcing strategies, demand uncertainties and supply chain network.

We will be using these baseline classification schemes to categorize various supply chain risk management models in the literature.

LITERATURE REVIEW

In supply chain risk management literature, the differentiation between risk and uncertainty is not clear. Supply chain risk can be referred to the events that have small possibility but may occur abruptly and such events can have substantial negative consequences on the system (O. Tang & Musa, 2011). Supply chain risk can occur at any stage in the whole supply chain. Supply chain is a complicated production system. It is an integration of different processes instead of individual functions. Issues of supply chain risk are evident at sourcing, operations and customer service levels in a typical supply chain.

Sourcing strategies have gained importance, since the supply chains have become globally dispersed. Supply chains, globally are becoming more vulnerable with large unanticipated events (Craighead et al., 2007). Snyder et al. (2016) explained that academic literature on supply chain disruptions has increased significantly since 1994. The interest of academics in supply chain risk has amplified based on a number of reasons. First, several high-profile events like September 11 attack, hurricanes like Katrina in 2005, Tsunami in 2004, Thai flood in 2011 have aggravated the need of literary work in supply chain risk management. Another reason for growing importance of supply chain risk is the phenomena of global supply chain. Firms' supply chain partners are located across the world and increased lead times have raised issues in supply chain risk. Even a small disruption in supply chain can have devastating impact throughout the supply chain for example, in 1998, 100 part plants were shut down as a result of knock on effect of strikes at two parts plants at General Motors. It further led to closure of 26 assembly plants, leaving dealers vacant for months (Simison, 1998). The examples just discussed show that supply disruptions could result from major event but might also be attributed to less severe, less global events. There are different studies that have evaluated the performance of various sourcing strategies to counter disruption. For instance, Berger, Gerstenfeld, and Zeng (2004) modeled a decision making process of identifying number of suppliers in the presence of risk. Ruiz-Torres and Mahmoodi (2007) proposed a deterministic model where probability of failure of suppliers in delivering the product is tested. Meena, Sarmah, and Sarkar (2011) developed and tested a stochastic model to determine optimal number of suppliers considering different failure probability, capacity and compensation. Multi-sourcing is a better strategy than single or dual sourcing under supply chain disruptions (Meena et al., 2011). Anupindi and Akella (1993) developed a model when demand is stochastic and continuous distribution. There are numerous studies that model sourcing in different analytical ways.

While sourcing is important to manage depending on supply chain risk, demand uncertainties can affect customer service levels. The complex a supply chain is, the more difficult it becomes to cope with uncertainties. Schmitt (2011) modeled a multi-echelon system where disruption can occur at any stage and they evaluate multiple strategies to protect customer service if in any case disruption occurs. They found out that a two-stage multi-echelon system is the simplest of all. Such type of system was used by Bollapragada, Rao, and Zhang (2004) and Qi, Shen, and Snyder (2009) to consider uncertain lead time due to capacitated supply and maintain focus on service levels in the network. Inventory was allowed to be held on lower echelon and disruptions are allowed at other locations. A close form solution was developed approximating the cost function.

Covering the above discussed ends of supply chain i.e., sourcing and customer service level, supply chain network also encompasses manufacturing sub-systems. SC network design is the basic decision of supply chain management. Operational decisions, such as operational

inventory holding and transportation costs are the key decisions in supply chain network design. Baghalian, Rezapour, and Farahani (2013) advanced a stochastic mathematical formulation to design a supply chain network of multi-product supply chains spanning different production facilities, distribution centers and retailers under uncertainty.

THEORETICAL DEVELOPMENT/MODEL

The purpose of literature reviews is to aim and map body of literature focusing on potential research gaps and highlighting boundaries of knowledge (Tranfield, Denyer, & Smart, 2003). Systematic literature reviews ae completed through an iterative process of identifying the appropriate literature through keywords (Saunders, Lewis, & Thornhill, 2007). We used the key terms “Supply chain risk”, “Quantitative models in supply chain risk” and “techniques in supply chain risk management”. Various academic databases were explored like emerald, Taylor and Francis, ScienceDirect, Springer, IEEExplore and Wiley. The key words returned a total of 324 articles. Trend showed that over the past decade, the supply chain risk management has been an area of interest for the researchers.

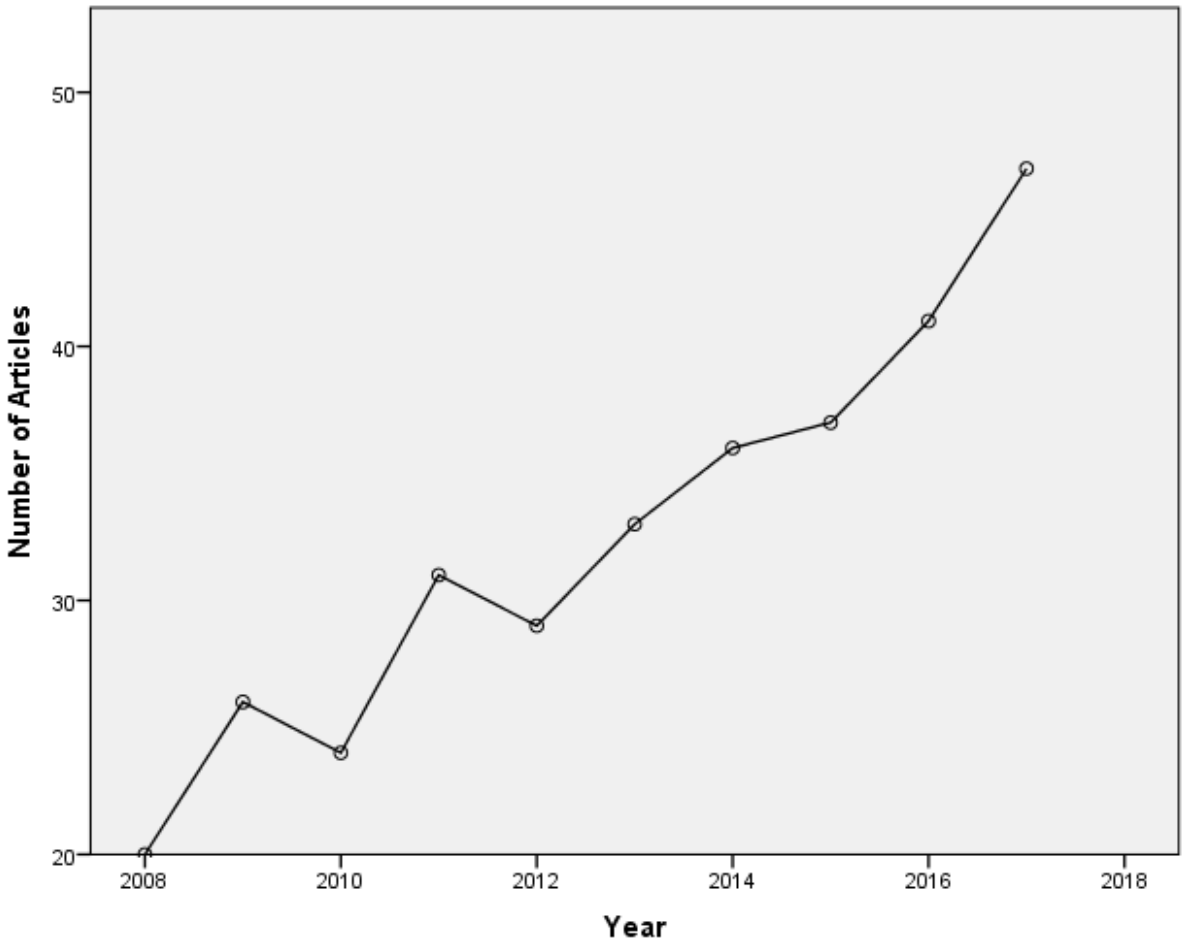

Fig 1

We screened 38 articles (Appendix A) for relevance in terms of specific models to be discussed as per our classification scheme explained below:

Suitable Framework for Development and Classification of Models in Supply Chain Risk Literature:

Within Supply Chain Risk management, there are hardly any frameworks that classify modeling techniques. R. Gaonkar and Viswanadham (2004) provided a broader framework of supply chain uncertainty: Deviation, Disruption and Disaster. Deviations refer to variations in demand, supply or in any other supply chain related process like procurement, costs and production. In a further refined work, R. S. Gaonkar and Viswanadham (2007) divided the risk management process between inbound logistics, operations and outbound logistics. Inbound logistics tackles the concern like sourcing strategies. Outbound logistics is concerned with demand and service level uncertainties and operations are mainly concerned with supply chain network design (SND) issues as supply chain network design is considered to be the most important step for decreasing the overall cost or increasing the overall profits of the chain (Simchi-Levi, Kaminsky, & Simchi-Levi). Another framework by Beamon (1998) categorizes supply chain design and analysis into four types of models (1) Deterministic analytical (2) Stochastic analytical (3) Economic models and (4) Simulation models.

Deterministic Analytical Models:

Based on our classification scheme as discussed above, we evaluated deterministic analytical models based on mathematical programming including “linear programming, non-linear programming, mixed-integer non-linear programming and multi-objective programming”. Mathematical modeling can have either deterministic or stochastic parameters. Various deterministic analytical models have been formulated in discussing sourcing strategies, demand uncertainties and supply chain network designs.

Chen and Yano (2010) provided a model that discussed weather-linked rebate for a manufacturer in order to increase profits. The basic model includes a retailer and a manufacturer that sells seasonal goods under demand uncertainty. The ultimate goal was to improve the coordination in supply chain thus improving profit allocation between two parties. Similarly, Schmitt and Singh (2012) stressed the importance of network utilization and proactive planning I a multi-echelon supply chain under disruption risk. Firm’s resilience to disruption in supply chain largely depends on the measures they have taken in the system by using different models to evaluate impact of risk (C. S. Tang, 2006).

Sourcing strategies have also beein thorouhgly investigated using different mathematical models under deterministic parameters. Yu, Zeng, and Zhao (2009) obtained an objective function to measure the expected profits of two different sourcing modes in the presence of supply chain risk. They also measured the sensitivty of buyer’s expected profits to various inputs with differnet examples. It is believed that multiple sourcing has proven benefits over single sourcing in terms of cost, quality and profits (Silbermayr & Minner, 2014).

Mathematical programming models with deterministic parameters have also been used to evaluate supply chain network designs of organizations under supply chain risk. Huang and Goetschalckx (2014) developed mathematical formulation based on mean-standard deviation for robust supply chain design as the set of all pareto optimal configurations. Wang, Lai, and Shi (2011) developed a multi-objective optimization model that can be used as an effective tool towards green supply chain management.

Stochastic Analytical Models:
Stochastic programming is a framework for modeling optimization problems with the inclusion of uncertainty. Stochastic distribution is widely used to measure demand uncertainties (Hamdi, Ghorbel, Masmoudi, & Dupont, 2018). Taskin and Lodree Jr (2010) assumed that demand is uniformly distributed in modeling variability. A stochastic model was developed by Xanthopoulos, Vlachos, and lakovou (2012) to capture trade-off between inventory policies and disruption risks in a dual sourcing supply chain based on normal distribution of demand. Retail firms also face a demand with uniform pattern Zhu and Fu (2013) based on a newsboy model. Song, Dong, and Xu (2014) developed stochastic model for multiple uncertainties such as production time, variable demands of customers and uncertain raw material supplies. They formed the problem based on multiple suppliers.

Similarly, Sawik (2014a) developed a stochastic mixed integer programming model to integrate supplier selection and customer order scheduling in presence of supply chain disruption risk. Apart from sourcing strategies, stochastic models have also been studied in supply chain network designs. Ramezani, Bashiri, and Tavakkoli-Moghaddam (2013) developed a multi-objecive stochastic model for forward/reverse logistics network design to evaluate systematic supply chain configuration. The focus was on maximizing profits and improving customer responsiveness and quality. A fuzzy inference system was developed by Paul, Sarker, and Essam (2017) to predict changes in future demand over base forecasr using a stochastic model.

As discussed above, demand uncertainties have been widely measured using stochastic models. Baghalian et al. (2013) developed a stochastic model for designing muli-product supply chain based on different production sites. This work extended the earlier work of El-Sayed, Afia, and El-Kharbotly (2010) who developed a multi-echelon forward/reverse logistics network design under risk.

From the discussion above, it is noted that stochastic models have been widely used for different supply chain dimensions under risk like sourcing strategies, network designs and demand/service uncertainties levels. Demand uncertainties have been widely discussed using stochastic models.

Simulation:
Simulation is a process of imitating a system or a real-world situation. Virtually, simulations are being used in every field such as performance optimization, safety engineering etc. Simulation allows us to study a system without building it (Hamdi et al., 2018). Simluation also allows us to find key soultions for uexpected scenarios. In our review, we find some key supply chain decisions based on simulations. Klibi and Martel (2012) used Monte Carlo approach to create plausible future scenarios for supply chain networks. Schmitt and Singh (2012) quantitatively analyzed disruption risk in multi-echelon supply chains using simulations. They showed that in order to control downside risk, a systematic approach is required. Simulations are majorly used in supply chain nerwork designs and sourcing strategies in contrast to stochastic models which are majorly used to meaure demand uncertainties. Costantino and Pellegrino (2010) proposed a real option approach for valuing probabilistic benefits of multiple sourcing. Wu (2012) simulated different interactions of prices, service, sales decision and performance in a multi-echelon supply chain.

Govindan and Fattahi (2017) simulated different situations in a glass supply chain under risk to come up with most effective decision under demand uncertainty.

Table 1 summarizes a 3 X 3 matrix against the two classification schemes discussed:

	Deterministic Analytical	Stochastic Analytical	Simulation
Sourcing Strategies	Silbermayr and Minner (2014) Yu et al. (2009) Li, Wang, and Cheng (2010) Kirytopoulos, Leopoulos, Mavrotas, and Voulgaridou (2010)	Sawik (2014a) Sawik (2014b) Iakovou, Vlachos, and Xanthopoulos (2010) Taskin and Lodree Jr (2010) Xanthopoulos et al. (2012)	Fang, Zhao, Fransoo, and Van Woensel (2013) Costantino and Pellegrino (2010)
Demand/Service uncertainties	Federgruen and Yang (2009) Schmitt (2011) Comes, Hiete, Wijngaards, and Schultmann (2011) Amin and Zhang (2013)	Sawik (2013) Xiao and Yang (2008) Baghalian et al. (2013) Song et al. (2014)	Schmitt and Singh (2012) Wu (2012)
Supply chain network design	Huang and Goetschalckx (2014) Chen and Yano (2010) Wang et al. (2011) Rezapour, Farahani, and Pourakbar (2017) Paul et al. (2017) Hasani and Khosrojerdi (2016)	Oliveira, Gupta, Hamacher, and Grossmann (2013) Goh, Lim, and Meng (2007) Azaron, Brown, Tarim, and Modarres (2008) Hahn and Kuhn (2012) Pishvaee and Torabi (2010) Ramezani et al. Table 1

CONCLUSION

In this systematic literature review, we have presented a classification scheme based on Beamon (1998) and R. S. Gaonkar and Viswanadham (2007). There are four broad categories of models in supply chain namely (1) dterminisitc (2) stochastic (3) simulations and (4) economic model.s We used three categories out of the four mentioned under the classification process.
R. S. Gaonkar and Viswanadham (2007) divided supply chain risk management under three main processes of value chain i.e., inbound logistics, outbound logistics and operations. We discuss three main areas of supply chain risk (1) sourcing strategies (2) Supply chain network design (SND) and (3) Demand/service uncertainties. Based on the two classification scheme mentioned, we pursued a 3X3 matrix to come up with nine different categories of quantitative models in supply chain risk.

Initially, supply chain risk modeling was used as a key word to figure out various scientific research articles published in various academic databases. A total of 324 articles were screened to find out 38 most relevant articles falling under the classification scheme discussed. We found that stochastic models have been widely used to model demand uncertainties whereas simulations are majorly used for sourcing strategies and supply chain network designs.

15	(Govindan & Fattahi)	Investigating risk and robustness measures for supply chain network design under demand uncertainty: A case study of glass supply chain	2017	IJPE	Stochastic / simulation	Supply chain network design	Performance of stochastic model is investigated. Simulation is used to compare different decision making situations.
16	(Silbermayr & Minner)	A multiple sourcing inventory model under disruption risk	2014	IJPE	Deterministic	Sourcing Strategies	Dual sourcing generates better result as compared to single sourcing.
17	(Wu)	Price and Service competition between new and remanufactured products in a two	2012	IJPE	Simulation	Multi-echelon service level	A model is developed with a common retailer and two manufacturers. Profits of supply chain

		echelon supply chain					members are estimated by different interactions of price and service, sales decisions and performance.
18	(Sawik)	Joint supplier selection and scheduling of customer orders under disruption risk: single vs dual sourcing	2014	Omega	Stochastic	Sourcing Strategies	A stochastic mixed integer programming model is developed to integrate supplier selection and customer order scheduling in presence of supply chain disruption risk. Based on the model, risk neutral and risk-averse solutions against average worst-case performance of a supply chain are compared for single and dual sourcing strategy.
19	(Wang et al.)	A multi-objective optimization for green supply chain network design	2011	DSS	Deterministic	Supply Chain Network Design	A model is developed for effective strategic planning in supply chain
20	(Yu et al.)	Single or dual sourcing: decision making in the	2009	Omega	Deterministic	Sourcing strategies	Expected profit functions of two sourcing modes in the

		presence of supply chain disruption risks					presence of supply chain disruption risks are obtained and compared. Sensitivity analysis of buyer's expected profits are also examined
21	(Pishvaee & Torabi)	A possibilisitc programming approach for closed loop supply chain network design uncertainty	2010	Fuzzy Sets and Systems	Possibilisiitic	Supply chain network design under uncertainty	A possibilsitc mixed integer programming model is developed for closed loop supply chain network design problems
22	(Amin & Zhang)	A multi-objective facility location model for closed-loop supply chain network under uncertain demand and return	2013	Applied Mathematical Modeling	Deterministic	Demand uncertainty	A mixed integer linear programming model is proposed that minimizes the total cost in a closed loop supply chain network
23	(Pishvaee et al.)	A robust optimization approach to a closed loop supply chain network design under uncertainty	2011	Applied Mathematical Modeling	Deterministic/Simulation	Supply chain network design	A deterministic mixed integer programming model is developed for designing a supply chain network design. A robust counter-part model is also developed by extending optimization theory. Both models are compared under different test problems
24	(Ramezani	A new multi-objective	201	Applied	Stochastic	Supply chain	A multi-echelon

	et al.)	stochastic model for a forward/reverse logistic network design with responsiveness and quality model	3	Mathematical Modeling		network design	stochastic multi-objective model is developed to evaluate systematic supply chain configuration focusing on maximizing profits, improving customer responsiveness and quality
25	(Li et al.)	Competition and cooperation in a single retailer two supplier supply chain with supply disruptions	2010	IJPE	Deterministic	Sourcing strategies	Sourcing strategies of the retailer are characterized in a centralized and a decentralized system. A coordination mechanism is devised to maximize profits for both suppliers.
26	(Xiao & Yang)	Price and Service competition of supply chains with risk averse retailers under demand uncertainty	2008	IJPE	Deterministic	Demand uncertainty	A price-service competition model for two supply chains is developed to find out optimal decision under demand uncertainty. High risk sensitivity leads to lower optimal service level and prices. Higher service investment efficiency of one retailer leads to a lower optimal service and price of

							the rival.
27	(Rezapour et al.)	Resilient supply chain network design under competition	2017	EJOR	Deterministic	Supply chain network design	A mixed integer non-linear model is developed to find out most profitable network and risk mitigation strategies
28	(Baghalian et al.)	Robust supply chain network design with service level against disruption and demand uncertainties: a real life case	2013	EJOR	Stochastic	Demand uncertainties	A stochastic mathematical formulation is devised for designing a network of multi-product supply chain comprising of several production sites. A transformation based on piecewise linearization method is created to solve the model.
29	(Paul et al.)	A quantitative model for disruption mitigation in a supply chain	2017	EJOR	Deterministic/Stochastic	Supply chain network	A three stage supply chain network is considered and three different approaches are developed. A fuzzy inference system is developed to predict changes in future demand over base forecast. A quantitative model for revising production is

							also developed in reactive mitigation planning.
30	(Sawik)	Optimization of cost and service level in the presence of supply chain disruption risks: Single vs multiple sourcing	2014	Computer and Operations Research	Stochastic	Sourcing Strategies/Service level	A combinational stochastic optimization problem is formulated as a mixed integer program. The objective was either to minimize worst case cost or worst case service level.
31	(Costantino & Pellegrino)	Choosing between single and multiple sourcing based on supplier default risk: A real options approach	2010	JPSM	Simulation	Sourcing strategies	A real options approach is proposed for valuing the probabilistic benefits of multiple sourcing. Results showed that multiple sourcing is better in risky environment. Sensitivity analysis allowed identifying the most important transactional parameters of the two sourcing strategies.
32	(Hasani & Khosrojerdi)	Robust global supply chain network design under disruption and uncertainty	2016	Transportation Research Part E	Deterministic	Supply chain network design	A mixed integer, non-linear model is developed for robust supply chain network

		considering resilience strategies: A parallel memetic algorithm for real life case study					design. Six resilience strategies are proposed and a parallel Taguchi based memetic algorithm is also designed. The model is solved for real life case of manufacturer of medical devices
33	(Iakovou et al.)	A stochastic inventory management model for a dual sourcing supply chain with disruptions	2010	International journal of systems science	Stochastic	Sourcing strategies	A single period stochastic inventory decision making model is proposed that allows capturing the trade-off between inventory policies and disruption risks for an unreliable dual sourcing supply chain network.
34	(Kirytopoulos et al.)	Multiple sourcing strategies and order allocation: an ANP-AUGMECON meta-model	2010	SCM	Deterministic	Sourcing strategies	The paper provides a meta model for supplier evaluation and order quantity allocation based on different mathematical models. The model allows manager to actively evaluate the suppliers while minimizing the cost and mean delivery

							times
35	(El-Sayed et al.)	A stochastic model for forward-reverse logistics network design under risk	2010	Computer and Industrial Engineering	Stochastic	Network design	A multi-period multi-echelon forward–reverse logistics network design under risk model is developed. Problem is developed based on stochastic mixed integer linear programming and objective was to maximize profit.
36	(Taskin & Lodree Jr)	Inventory decisions for emergency supplies based on hurricane count predictors	2010	IJPE	Stochastic	Sourcing strategies	A control policy is developed for stocking decisions based on hurricane forecast model using stochastic programming model. The proposed model specifies cost minimizing inventory strategies for simultaneously meeting stochastic demands.
37	(Song et al.)	Integrated inventory management and supplier base reduction in a supply chain with multiple	2014	EJOR	Stochastic	Demand uncertainties	A stochastic model is developed to cater for multiple production times, uncertain demands subject to

		uncertainties					supply and production capacity constraint. The model further enables us to quantitatively achieve the trade-off between the supplier base reduction and the supplier capability improvement.
38	(Xanthopoulos et al.)	Optimal newsvendor policies for dual-sourcing supply chains: A disruption risk management framework.	2012	Computer and Operational Research	Stochastic	Sourcing strategies	A generic, single period model is developed for capturing the trade-off between inventory policies and disruption risk in a dual sourcing supply chain network. Model is developed for both risk neutral and risk-averse managers under various types of disruptions.

ABSTRACT

Visual analytics dashboards or storyboards are attractive reporting tools getting more popular by analytics users who need to convey business insights to audience effectively. But when presented with a data analysis dashboard or storyboard, how can we be sure that the dashboard or storyboard addressed all the important questions that should have been asked out of the dataset? The goal of this paper is to propose a framework that will help business analytics users to ask the right questions and work as a visual tool to represent an extent a typical analytics has addressed in a given business problem space.

KEYWORDS: Data Analytics, Dashboard, Story Board, Knowledge Space, Problem Space, Agile Management

INTRODUCTION

Visual analytics dashboards or storyboards are attractive reporting tools getting more popular by analytics users who need to convey business insights to audience effectively. But when presented with a data analysis dashboard or storyboard, how can we be sure that the dashboard or storyboard addressed all the important questions that should have been asked out of the dataset? Considering the vastness and intricacies of a business environment, can we say confidently that: 1) a data analyst presenting a dashboard does have all the necessary domain knowledge to come up with all the relevant questions?; and 2) even if he/she knows the business, how do we know the extent the presented insights in storyboards cover with respect to the entire information domain?

Availability of large data and powerful visual analytics tools in conjunction with agile management practice present a great potential for organizations to become highly flexible and effective in decision making. But at the same time, they pose some challenges at the same time. For example, let's assume that an organization has created autonomous agile teams comprised of members from different business units. All these teams have access to the same data sources to come up with business solutions. Since it's not practical on a regular business scenario to arrange data expert or significantly experienced personnel in the overall business domain for each team, it can be assumed that none of the teams will have superior skill of asking right questions that lead to getting relevant business answers from the large set of available data. At the current moment, there are no systematic methods or tools to facilitate business analytics teams to develop necessary questions to lead their analytics investigation.

Now businesses are well aware of the power of big data and the exponential benefit that can be derived by utilizing big data via various data analytics tools. However, even though both the data and analytics tools are readily accessible, businesses still struggle to take the best advantage out of the available data. Moreover, big data analytics investment may result in less than expected ROI (return on investment) if such investments are pushed only by either analytics vendor or data scientists driven by their eagerness of running analyses on businesses' inside data rather than the desire to address business need (David Court, Jesko Perrey, Tim McGuire, Jonathan Gordon, & Dennis Spillecke, 2015). This shows that there is a problem in considering data analytics in seclusion of the business process. This problem can be discussed further in the light of the concept of modern trinity of information as discussed by Dr. Barry Devlin in his book 'Business Unintelligence'. Where he explained how information, process, and people are the three core components of a successful information revolution and how these must be reinvented and restructured to deliver the value expected from big data analytics (Devlin, 2013). Emphasizing only on analyzing data and creating information ignoring the people and process component is destined to be unsustainable.

But in dealing with the 'people' component a challenge lies in the unavailability of people having a combination of domain knowledge and advanced data analysis skills. The best kind of people to deal with the data analytics in a firm are the ones who are not only good at advanced data analysis skills but also great at speaking the language of business and helping business leaders reformulate their challenges in a way that big data can tackle (McAfee & Brynjolfsson, 2012). But people with such level of cross-domain knowledge and expertise is very hard to find (Thomas H. Davenport & D.J. Patil, 2012).

To counter this scenario there have been discussions about incorporating analytics in the business process rather than implementing it as a role of a secluded team of experts (David Court et al, 2015). In this process business users who have the domain expertise are empowered with data analytics tools that are intuitive and do not require a significant level of acquisition of new technical skills such as coding. Intuitive and less-technicality-driven data analytics tools such as Tableau and Rapidminer have delivered the power of visual analytics and modeling to the regular business users who have their domain expertise but lack technical analytics skill sets. This trend of empowering business users with data analytics tools is liberating and has an immense opportunity of adding value to the overall business output. Moreover, such empowerment also opens opportunities to experiment with emerging management techniques such as agile management in a more effective and productive way.

Agile has been widely used process in information technology and software industry but recently it has been considered as a radical alternative to the 'command-and-control-style-management' across different types of industries and at a different level of organizational command level (Darrell K. Rigby, Jeff Sutherland, & Hirotaka Takeuchi, 2016). Having business domain experts from different business units empowered with data analytics skills can improve the performance of agile teams. But for this new type of data users, who are less savvy with the hard skill of data analytics but have the soft skill of business understanding, is there any structure to guide them in their exploration for insights from a bulk of data?

In a regular organizational setup, data analysis process represents the inductive research method. Which follows inductive reasoning process of creating general conclusion from observations of specific phenomena (Uma Sekaran & Roger Bougie, 2016). In the field of inductive research, the concept of Exploratory data analysis (EDA) provides with a guideline on how to approach a dataset and come up with insight. Jeroen de Mast and Benjamin P. H. Kemper proposed a three-step model of EDA where the three steps are as follows (Jeroen de

Mast & Benjamin P. H. Kemper, 2009): 1) Display of the data; 2) Identification of the salient features; and 3) Interpretation of the salient features.

PROBLEM STATEMENT

EDA model provides with a general approach towards data analysis but still, it does not address the issue of the versatility of human pattern recognition (Jeroen de Mast et al, 2009). This means in the context of agile management, different groups would come up with a various set of insights on the same problem by analyzing the same dataset. That pose challenges for the top management team. It is because once they are presented with different analyses from different agile teams there are no ways in practice that link such insights coherently. Moreover, it is not possible for the top management to know how much of the total problem space was considered to derive the insights. This keeps the top management team in dark about how much the presented solutions address the problem space both individually and collectively and how big the area of the unexplored space is.

In summary, business analytics practitioners and users lack a systematic approach to address these issues:

1) What is the totality of a problem space which will work as the source of the related questions?
2) How much of the problem space does a business intelligence dashboard cover and what is yet to be covered?

PROPOSED FRAMEWORK: "QUESTION BREAKDOWN STRUCTURE (QBS)"

As a way of addressing the issues above, we propose a 'Question Breakdown Structure (QBS)'. It is a structure that is similar to the Work Breakdown Structure (WBS), a widely used tool in the project management field. In QBS, the whole business domain is broken down into independent knowledge blocks. This detailed layout of the business domain visually represents the problem space and gives a direction about the range of possible questions that can be asked during an analysis.

QBS can be developed by breaking down the whole business domain into its pieces to represent specific knowledge segments in the business and there could be different approaches that can be developed. When all the bottom level knowledge blocks are summed up, they should represent the entire business domain or knowledge space, which analytics users try to explore for questions. For example, as shown in Figure 1, if a business domain is broken down to pieces using a firm's organizational structure, the resulting knowledge blocks at the lowest level should represent the entirety of the business information from that firm. In the next section, we will use how such QBS is used as a way of demonstrating the proposed QBS framework.

Figure 1 shows the total business domain in the organizational structure format, presenting different packages of potential business knowledge groups at different levels. Breaking down the business domain on different layers should stop where the individual knowledge components are sufficiently detailed enough for future analytics to zoom in. Different knowledge nodes at the bottom layer of the QBS represent very specific individual potential knowledge blocks that can be used that need to be explored and questioned during the analytics process.

This is a significant static structural representation in which the business domain is broken down to potential question-related knowledge blocks that need to be addressed by analytics teams.

This gives us a visual representation of the entire problem space. This works as the source of the possible questioning during the analysis phase. Moreover, once an analytics is done in the form of dashboards and storyboards, the analytics results as answers can be connected to the individual knowledge blocks or nodes in the QBS model as a visual problem space documenting tool. This connection between the knowledge blocks and questions addressed in storyboards are shown as lines in Figure 1. The QBS therefore can display how much of the problem space has been explored by the analytics teams and how much of the problem space has yet to be explored.

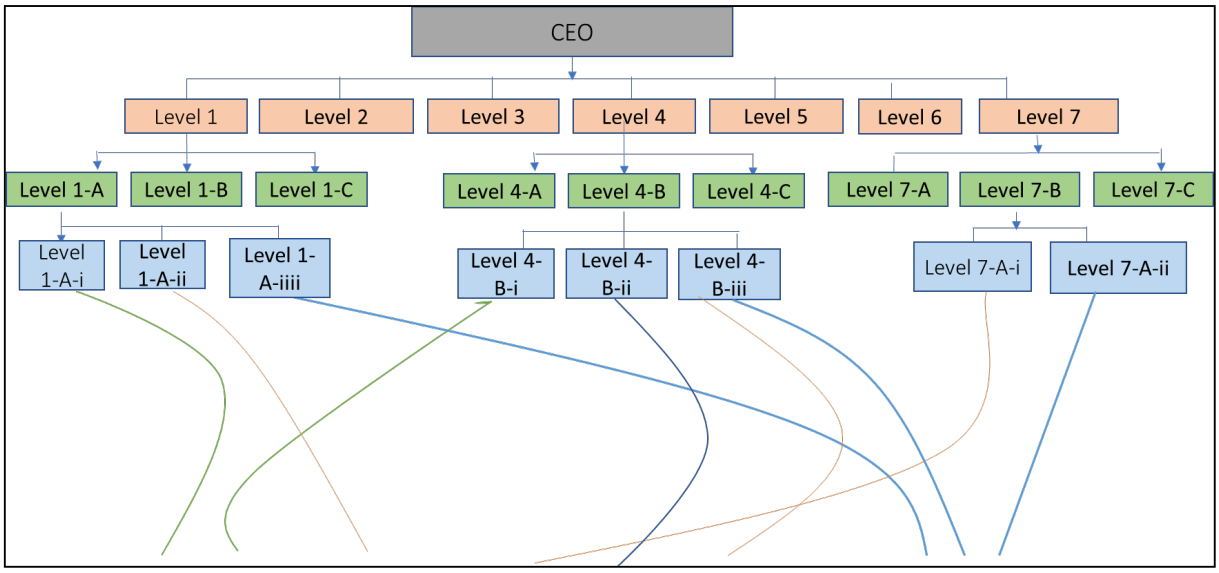

Figure 1. Question Breakdown Structure (QBS) using Organization Structure

CASE

To discuss a use case of our proposed QBS model let's first detail a scenario. Let's assume that a commercial bank has decided to increase its revenue in the coming quarter. To get ideas about ways to generate more revenue, the bank has decided to apply agile management techniques to form 3 agile teams consisting of members from different business units of the bank. All these three teams have access to the same dataset. As found in a regular business setting, we assume that all the members of the teams come from a diversified business domain and thus have a good grasp over the particular function that they work on but not much beyond their areas.

In this scenario, we use the dataset that contains general information about clients (age, job, etc.) as well as more specific information about the current insurance sell campaign (communication, last contact day) and previous campaigns (attributes like previous attempts, outcome). This dataset is from Kaggle.com, an open community of data analysts and data scientists, where it was originally shared by the Data Mining Cup organizing authority from Technical University of Munich (Technical University of Munich, 2017).

As the first step, for this scenario, we developed a QBS for the entire bank as shown in Figure 2 using the functional organizational structure or often called 'U form structure' which is defined as 'an arrangement based on the functional approach to departmentalization' by Griffin (Griffin,

2013). In this QBS, people and units in an organizational process are grouped under functional departments such as finance, supply chain and so on.

Since the dataset provides data that only relates to the consumer banking products and customers, the only related knowledge block in the developed QBS is the consumer and community banking. Therefore only the knowledge areas related to consumer banking activities have been detailed out into different layers and sublayers while keeping the other blocks aggregated.

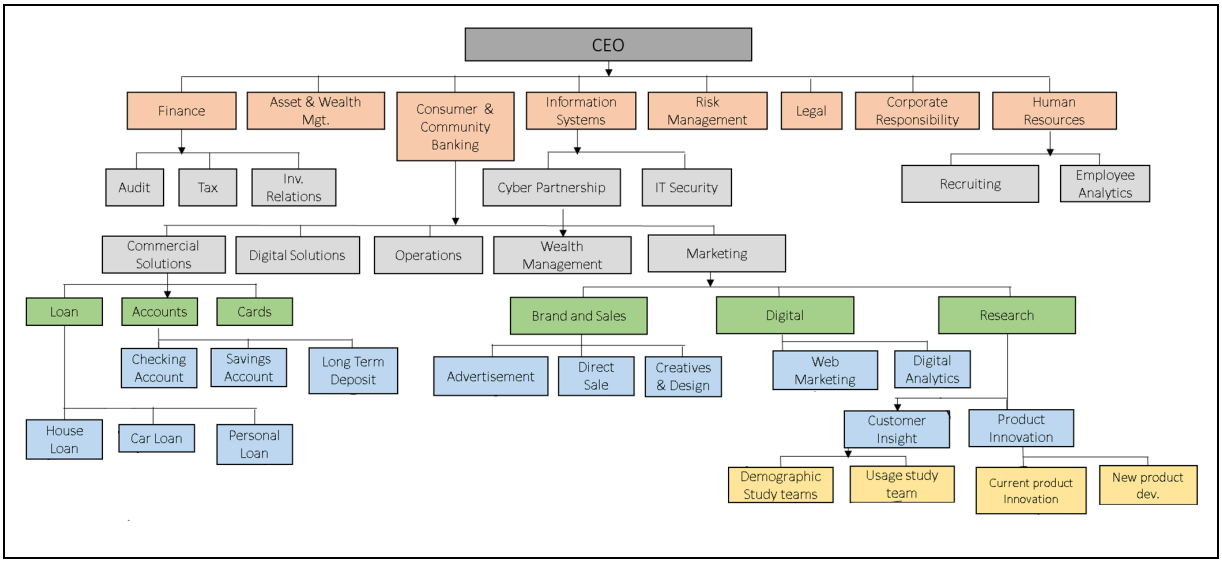

Figure 2. QBS of a Commercial Bank Case

Going back to our scenario of three agile teams looking for ways to increase revenue, we assume that these three teams have differences in their perspectives about increasing revenue. There are different ways that a company can increase its revenue such as by increasing number of customers for existing products, or by reducing cost, or by introducing new products, or by making existing communication more efficient so that maximum number of conversion can be achieved at the lowest cost, or by expanding the operation of the organization in different location and so on. To mimic the reality of having different insights from different teams, we assume that the teams would approach their data analysis from their own perspectives. These perspectives will direct the key questions that they will try to find answers for from their analyses. Table 1 shows these different perspectives and the derived key questions to start off their analytics operations.

Table 1 Team Perspectives and Questions for Analytics Operations

Team no.	**Perspective**	**Question**
01	Increasing number of customers for existing core business	Who should we target for more deposit?

02	Finding out new market for new product	Who should we target for insurance product?
03	Increasing effectiveness of the marketing efforts	How can we make our campaigns more successful?

Based on these key questions, each team approaches the dataset and comes up with storyboards showing their analysis results. Here, by storyboards we mean the data analysis presentation feature available in visualization analytics tools such as Tableau where key findings from analytics operations are presented along with the insights as a series of connected business information found from data.

Story Board 01: Who should we target to gather more deposit?

This team starts with the existing regular banking customers who keep their deposit in the bank. Their prepared data analysis story has four core messages as presented below and available in the visual graphs in Appendix-A:

1. The highest percentage of customers have deposits of less than $1000.

2. Once the customers are clustered based on their account balance, it is seen that customer cluster 02 (balance between $1887 and $6060) and cluster 03 (balance between $6101 and $14144) consist lower share in the total number of customers but the highest share in total dollar value of the deposit.

3. Among the customers from cluster 2 and 3 blue-collar, management, housemaid and technicians have the highest percentage of the total number of customer in these clusters.

Considering all these findings, team 01 proposes customers having a balance between $1000 and $14000 should be prioritized so that they continue their account and professionals from the working areas of management, blue collar, housemaid, and technicians should ger priority when new customers are searched to increase bank deposit.

Story Board 02: Who should we target for insurance products?

This team concentrates on the non-conventional products offered by the bank such as house and car insurance. Their presented data analysis story has four core findings as detailed below and visually presented in Appendix-B:

1. There are slightly more house insurance customers than car insurance customers.

2. Car insurance customers' age varies more widely compared to the age of house insurance customers.

3. Based on 'marital status' doesn't show any significant change in the purchase behavior in neither of the house and car insurance.

4. There are more highly educated customers in car insurance buyers than house insurance buyers.

Considering all these findings, team 02 proposes that comparatively older customers having a university education are the better market to target for car insurance than house insurance.

Story Board 03: What should we do to make our campaign more successful?

Team 03 concentrates on the cold call result and previous campaign data to check which factors make sales call campaigns more successful. Their presented analysis has three core findings as detailed below and visually presented in Appendix-C:

1. The month of May historically has the highest number of attempts but in terms of success ratio June, July and August have had better success.

2. No particularly distinct trend has been observed in terms of success ratio based on day of the week.

3. Customers who accepted previous offer tend to accept a current offer more often than customers who never accepted an offer.

Overall, they propose that Summer time (June, July, and August) provides the best conversions and customers who have accepted previous offers pose a greater chance of accepting the new offer.

Connecting Storyboards to QBS

Although the dataset the teams used for their analyses was same, different teams concentrated on different areas of the dataset that suited their key questions. If we put their areas of interest in the QBS model that we built in Figure 2, we can see that different analyses touched at different knowledge blocks as shown in Figure 3. Table 2 below summarizes how these analyses relate to the different knowledge blocks in the QBS.

Table 2 Relations between analyses and QBS

Analysis Story Board No.	Addressed Knowledge Blocks in QBS
Story board 01	Savings account, Demographic study
Story board 02	Demographic study, Usage study, Current product innovation
Story board 03	Advertisement, Direct sales

In a usual scenario, however, once these three analyses are presented, they are not coordinated with each other and thus don't give any clear picture of how much complete these analyses are with respect to the entire knowledge space of the project they were engaged in. In other words, when the top management team is presented with these analyses, they cannot immediately see which areas of the problem space have been addressed and not addressed by the analyses of the teams.

However, the QBS model connected with the storyboard slides can clearly provide us with information on how much complete the analyses are and a further need of future analyses that have not been done currently.

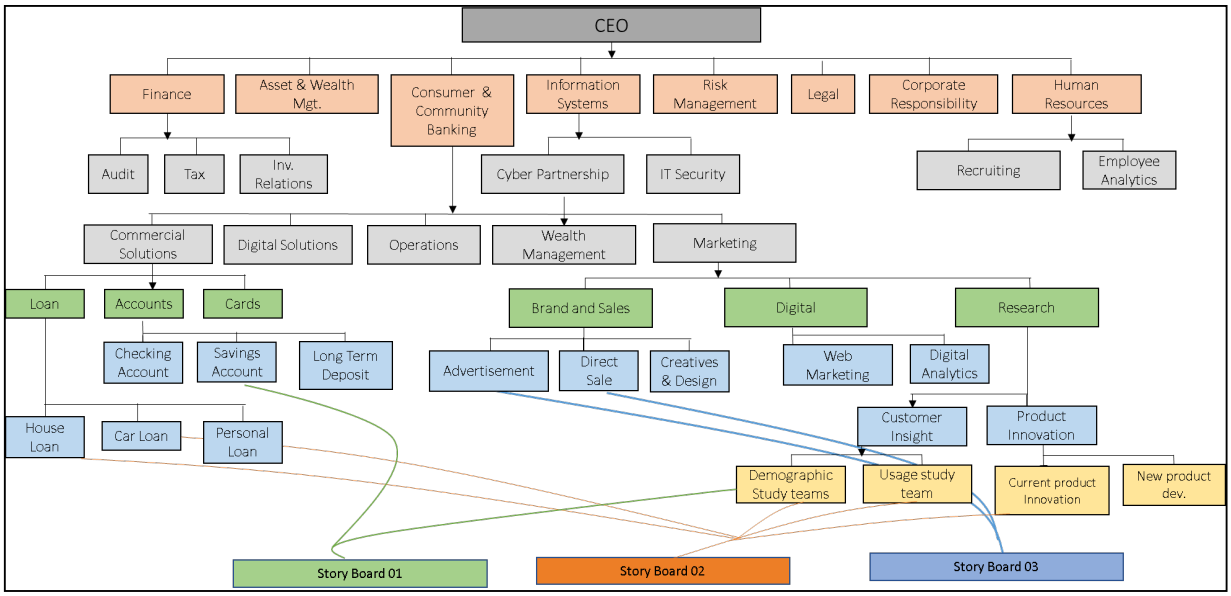

Figure 3. QBS Connected with Teams' Storyboards

DISCUSSION

From Figure 2, we can see that our QBS model produced total 15 knowledge blocks at the last layer while the teams' analyses addressed only total 8 of those blocks. All the three analyses combined cover 53.33% of the problem space considering the unique knowledge blocks that they touched upon. The other 47% of the problem space is not addressed at all by the agile teams. And if we consider the team's contribution separately, the coverage ratio goes even lower as shown in Table 3 below.

Table 3 Percentage of problem space coverage by each analysis

Story Board No.	Addressed areas	Total areas	% of coverage
Story Board 01	2	15	13.33%
Story Board 02	5	15	33.33%
Story Board 03	2	15	13.33%

We get a picture of how the agile teams' analyses, either combined or separately, give a small fractional view of the overall problem space in only one broad vertical of the banking business (consumer banking). If other verticals are considered then the problem space would grow much bigger and eventually the coverage ratios will potentially go down even further. But still, by creating the QBS model of the problem space linked with the analytics storyboards we can get a visual picture of how broad our problem at hand is and how much of it is covered by the analyses presented to us. This give us not only an idea about our scope of understanding on the overall problem but also a direction for further future analysis.

LIMITATION

Application of QBS has its limitations. Some of the limitations are:

- The success of QBS model depends largely on the method used for question breakdown structure. Here organizational chart has been shown as a possible solution. But in different cases different ways of breaking down the business knowledge space may make it more effective.
- A QBS model provides a guideline for the analysts to come up with questions and thus provide a visual representation of the overall coverage of the problem space. It does not provide definitive answers to business questions.
- Application of QBS models will be most effective in cases where a high-level understanding of a problem and knowledge of the limitations or scope of the solutions presented are crucial for the non-technical agile teams and management.

CONCLUSION

This paper addresses one of the challenges that comes along with the incorporation of data analytics in the business process:

1) “How do we know that the analytics teams ask the necessary and relevant questions?; and

2) “How do we know that a presented storyboard from the analytics operation has addressed the problem space properly and by how much?”

The proposed QBS framework can be applied in the business firms who are trying to implement data analytics as a part of their business process. The framework can work as a supportive tool in the successful integration of data driven decision in the regular business process. However, more research is needed in terms of how the QBS is developed other than from an organization structure and various ways of using QBS to improve the analytics operations and documentation.

ABSTRACT

This paper investigate whether the increasing adoption of electronic tax filing technologies has inadvertently resulted in corresponding growth in Tax Identity Theft. Data was extracted from Identity Theft complain reports maintained by U.S. government agencies. Our results indicated that, after controlling for general Identity Theft, number of Individual Tax Returns, and Total Refunds, Tax Identity Theft was still positively associated with E-filing and this relationship was mediated by Self-e-filing and Direct Deposit adoption. These findings suggest that the key risk gateways in the Tax Identity Theft process are at self-e-filing and at the direct deposit points.

KEYWORDS: Tax Identity Theft, Risk gateways, e-filing, Technology adoption, Unintended consequences

INTRODUCTION

The Information Age has brought technological innovations that have given consumers new options. Key among these innovations is the Internet, which has changed the way consumers conduct business. Governments are also using the Internet to provide services to citizens. This study will focus on the unintended consequences of the introduction of electronic tax filing by the US govern and subsequent efforts to encourage the citizens to move from manual tax filing to electronic filing (E-filing). Individual taxpayers can now file their own taxes instead of depending on the more expensive tax filing agencies. The adoption of electronic technology in tax filing process has improved the accuracy of tax filing process, reduced the cost for the government and taxpayers, and shortened the lead-time of receiving individual tax refunds (Edwards-Dowe, 2008).

Unfortunately, the U.S. has also seen a dramatic increase in tax related identity theft with the menace becoming the number one scam in the last couple of years (US Internal Revenue Service, 2014). The total amount of refunds issued to fraudulent tax return totaled $5.2 billion in 2010 and is projected to reach $21 billion in the next five years (US Treasury Inspector General for Tax Administration, 2012). If Taxpayer Identity Theft continues to rise at the present trend, the abovementioned gains from e-filing will be in serious jeopardy. This call for an investigation into the relationship between the two occurrence and identification of possible solutions.

This paper examines the increased adoption of new technologies in e-filing and their unintended consequences as a potential explanation for the rise in Tax Identity Theft. Specifically, we asked the questions: Does the increased adoption of technology in individual tax filing contribute to the proliferation of Tax Identity Theft and, if so, how does it contribute to this proliferation?

Answers to these questions will help stakeholders better understand the trend of Tax Identity Theft and devise effective ways to mitigate such threats.

This paper is organized as follows. We first provide a literature review of the advantages and progress made with the adoption of e-filing technologies followed by a review of the growth of Tax Identity Theft. We then develop hypotheses on the relationship between the two and identify possible mitigating factors on the relationship. We present the data gathered and the statistical models developed to test our hypotheses in the methodology section, followed by the results analysis presented in the data analysis and results section. We conclude with the discussion section with interpretation of results found and their implications. Several recommendations are suggested followed by limitations of the study.

LITERATURE REVIEW

Identity theft involves "*stealing of another person's personal identifying information such as social security number, date of birth and mother's maiden name, and then using the information to fraudulently establish credit, run up debt or take over existing financial accounts*"(US Government Accountability Office, 2002). The Identity Theft and Assumption Deterrence Act of 1998 makes it a crime to "*knowingly transfer or use, without lawful authority, a means of identification of another person with the intent to commit, or to aid or abet, any unlawful activity that constitutes a violation of Federal law, or that constitutes a felony under any applicable State or local law" ("The Identity Theft and Assumption Deterrence Act of 1998*", 1998).

Tax Identity Theft is one form of identity theft that involves the illegal use of a potential taxpayer's identity to fraudulently file a tax return and claim a refund (US Internal Revenue Service, 2013b). For several years, Tax Identity Theft has risen over the years and remained the top scam in the "Dirty Dozen Tax Scams" list maintained by the IRS (US Internal Revenue Service, 2010, 2011, 2012, 2013a, 2014, 2016b). The increase is reflected in both the numbers of incidents per year and the monetary loss. The rising trend in these reports suggests that Tax Identity Theft is set to continue topping the list unless significant changes are made. As a first step, we seek to understand the Tax Identity Theft threat in the next few paragraphs.

There are many variations of Tax Identity Theft. Typically Tax Identity Theft starts when a criminal acquires a victim's social security number and electronically files for a tax refund, often early in the tax season to get a head start against the genuine owner of the social security number (Weisman, 2015). The criminal submits false information on the income earned in the year, taxes paid and claim eligibility for various tax credits (e.g., earned income tax credit), all with the aim of maximizing the total tax refund. The criminal then requests IRS either to deposit the refund amount into a direct deposit bank account, or to mail a prepaid card or check. Oftentimes, the IRS issues the refund only to discover the refund was fraudulent when it receives a second tax return filing from the actual owner of the stolen social security number (victim) later in the season. By this time, the criminal will have withdrawn the refund and disappeared (Weisman, 2015).

Despite the public attention on the rise of Tax Identity Theft, peer-reviewed literature on Tax Identity Theft was relatively sparse. Much of the extant literature examined the general identity theft and related frauds, while few focused on Tax Identity Theft. Several reasons may explain this void. First, the study of Tax Identity Theft is relatively new. Its prevalence and severity to society relative to the other forms of identity theft may just be becoming apparent to researchers. Second, different stakeholders do not even seem to agree on a standard name for

Tax Identity Theft. This has created challenges for researchers to collaborate and build on prior works and data sources. This study uses the name "Tax Identity Theft" to emphasize the fact that we are only focusing on the subset of identity theft involving tax returns. Lastly, credible statistics on Tax Identity Theft is lacking. IRS, the authority that keeps all tax data and pays the fraudulent claims, does not seem to know the total number of fraudulent tax returns or the approximate cost of Tax Identity Theft. This lack of information created hurdles for researchers to analyze Tax Identity Theft trends and contributing factors.

Fortunately, the Federal trade commission keeps a database of the identity theft complains annual reports in the US and gives the percentage of the complaints that are tax/wage related (US Federal Trade Commission, 2015). We used the later as a proxy for the number of customers affected by Tax Identity Theft as a way of overcoming lack of actual published statistics on Tax Identity Theft (US Federal Trade Commission, 2015). The next section reviews the increasing adoption of e-filing then investigate whether there is a link of this growth with the rising Tax Identity Theft and the risk gateways being exploited.

THEORETICAL DEVELOPMENT/MODEL

Tax Identity Theft and Growth of E-Filing

Most U.S. taxpayers look forward to filing their taxes and receiving refunds in each tax season. In 2016, Internal Revenue Service (IRS) gave tax refunds totaling $279.857 Billion to 102,424,000 taxpayers; an average tax refund of $2,732 per taxpayer (US Internal Revenue Service, 2016a). This is a significant sum for many households, considering that the 2013 U.S. median household income is $52,250 (US Census Bureau, 2014).

Though many enjoy their tax refund, probably few enjoy the process of filing their taxes. Filling taxes manually is laborious and prone to inaccuracies (Edwards-Dowe, 2008). Besides, the government spent large amount of resources in printing the tax forms and distributing them to the taxpayers.

To ease the burden on the taxpayer, the government has spent the last two decades promoting the adoption of electronic tax filing. The IRS has been encouraging all taxpayers to file their taxes electronically and by the end of 2015 tax season (May 2016), 140,258,000 individual tax returns had been received out of which 123,737,000 which is 88.2% were filed electronically (US Internal Revenue Service, 2016a).

E-filing has several advantages over manual filing systems (Edwards-Dowe, 2008). First, e-filing is convenient to the taxpayer as they can e-file from anywhere at any time resulting in increased customer satisfaction. Second, e-filed submission is delivered instantly to the IRS and a receipt confirmation is made immediately to the taxpayer. This is followed by a quick decision on whether the returns have been accepted by the tax authority or not and associated reasons if not accepted. Third, e-filing enables the reuse of previously entered data such as name, address and other tax entries of the taxpayer, resulting in significant time saving. Finally, the fact that all data is entered via keyboard electronically rather than hand written manually reduces errors, and the electronic system enables data validation and detection of major discrepancies before actual submission (Edwards-Dowe, 2008).

However, the use of new technology can bring unintended consequences. The Internet brings several benefits but also brings into play its dark side which include hacking and identity theft

(Won Kim, Ok-Ran Jeong, Chulyun Kim, & Jungmin So, 2011). Because of its ability to accumulate and disseminate vast amounts of information electronically, the Internet may make theft of personal or financial identity easier (Milne, Rohm, & Bahl, 2004). More specifically, three aspects of e-filing that contributed to its rising popularity, namely simplified electronic data entry, remote filing, and shortened lead time on refund, can also contribute to the prevalence of Tax Identity Theft. This is because a criminal can file many tax returns in a short time (simplified electronic data entry) remotely from anywhere including foreign countries without revealing their identity and with lower risk of apprehension and prosecution.

The large trove of electronic data collected in the tax filing process may become a magnet for data thieves and can be stolen and reused to file fraudulent tax returns. There is already anecdotal evidence to suggest that this is already happening: The Utah tax commission in 2015 noticed a rise in suspicious tax returns (Krebs, 2015). The above examples suggest that the factors that contribute to the increasing adoption of e-filing will also contribute to the growth of Tax Identity Theft and leads to the following hypothesis:

H1: Tax Identity Theft growth is positively associated with e-filing growth

Mediating Effect of Self-E-Filing

Self-e-filing is the submission of income taxes electronically by individual taxpayers instead of going to professional tax preparers, such as H&R Block. In the early days, taxpayers would go to professional tax preparers who were experienced, trained, and with the necessary software tools to do tax returns. However, part of the IRS strategy to increase e-filing involved encouraging tax software companies like Intuit, H&R Block, TaxACT to provide tax e-filing software that is easy to use and affordable (10-30$ range) to individual taxpayers (Yakal, 2015). This resulted in more individual taxpayers using software to file taxes by themselves instead of relying on tax preparation professionals. As competition among these companies intensified, several companies even started providing free online software to qualified individuals (US Internal Revenue Service, 2015b). These factors have driven more individuals to filling their own taxes using these software tools and thus increased individual self-e-filing.

However, the fact that more individuals are self-e-filing also means that it is much easier for an identity thief to self-e-file fictitious taxes using same software products. Previously, filing tax return with help of a professional tax preparer meant that a professional would look at the taxpayer's data in details and verify the numbers from original documents like employee W2 and benefits statements. Thus, it was much harder for an identity thief to present fictitious figures without supporting documents. Also, with self-e-filing, identity thieves can file hundreds of tax returns from the comfort of his/her house without prying eyes. The above rationale lead us to the following hypothesis

H2: The positive relationship between Tax Identity Theft growth and e-filing growth is mediated by self-e-filing growth

Mediating Effect of Direct Deposit

Among the electronic technologies adopted in automating the tax refund process is the use of direct deposit refunds. Tax refund through direct deposit is the electronic transfer of tax refund payments from IRS directly to the taxpayers' bank account. Direct deposit of tax refunds electronically takes less processing time than the traditional process, which involves physically

printing, mailing, depositing, and processing refund checks. Though direct deposit process has a higher upfront setup cost compared to the traditional process, it has a much lower unit processing cost because it eliminates the printing, mailing, and processing costs associated with physical checks. It also eliminates the hassle for taxpayers to deposit and wait for the check to be cleared. Thus, as more individuals turns to e-filing because of these benefits, we expect that more taxpayers will opt to have their refund checks deposited directly to their bank accounts instead of having a check mailed.

While direct deposit process eliminates risks of identity theft associated with the traditional process, it is open to other risks that contribute to the increased Tax Identity Theft. The method eliminates the use of the physical address as a detection point. Mailing a check to the taxpayer's address, means that the taxpayer or a representative must be living on that physical address to pick the check and then deposit it to the bank. However, with direct deposit, a criminal can give a fictitious address without much repercussion, as the money will still be debited to the bank account. The abovementioned rationale suggests that the increased use of direct deposit contribute to Tax Identity Theft growth.

H3: The positive relationship between Tax Identity Theft growth and e-filing growth is mediated by direct deposit growth.

Though the rise of Tax Identity Theft coincided with the increasing adoption of tax filing technology, it is possible that the rise in Tax Identity Theft is unrelated to technology adoption in tax filing process but due to other factors that have become more significant over the recent years. For example, the Tax Identity Theft growth trend may simply be attributed to the growth of individual tax return filed, annual refunds approved. Alternatively, Tax Identity Theft growth may be a natural consequence of increasing popularity of identity theft. As such, we include the annual total number of individual tax returns filed (Individual Tax Returns), annual total number of refunds issued, and count of identity theft complaints (Identity Theft) as control variables in our regression models.

RESEARCH METHODOLOGY

Data Description

In order to test the hypotheses developed, we retrieved archival data from various government agencies to be used in the regression models presented in the Statistical Models section. The dependent variable, Tax Identity Theft, is the count of Tax Related Identity Theft complaints received by FTC in a given year. We use this as a proxy for the count of actual tax return identity theft cases in the U.S. since the latter is not known. The US Federal trade commission has been releasing annual reports of all the consumer complaints that it has received since 2006 (Sentinel Annual Data-Book) comparing the annual counts by year (US Federal Trade Commission, 2015). These complaints include General Identity Theft (Identify Theft) and the percentage of General Identify Theft complaints that is tax/wage related fraud for each year. Thus, we derived the Tax Identity Theft count each year (the dependent variable) based on the number of identity theft complaints for that year multiplied by the given percentage that is tax fraud related in that year. This study used identity theft complaints over the last eleven years (2004-2014) as reported. General Identity Theft count from each year (Identify Theft) was used as a control variable.

We retrieved values of independent variable (E-filing) and the mediating variables (Self-e-filing and Direct Deposit) from the IRS' filing season statistics archive covering years 2009 to 2015 (US Internal Revenue Service, 2015a). E-filing is the count of individual taxpayers who filed their personal taxes electronically in a given year. Self-e-filing is the count of individual taxpayers who personally filed their taxes electronically. Direct Deposit is the count of individual taxpayers who had their tax refund deposited directly into their bank account. We also retrieved value of Individual Tax Return, the count of taxpayers who filed their personal taxes in a given year, and Total Refund, the count of total refund issued in a given year, from the same source, to be used as control variables.

Statistical Models

Three sets of regression models are necessary to test the mediation effects of self-e-filing and direct deposit on the relationship between e-filing and Tax Identity Theft.

Model 1: *Tax Identity Theft* (y) = β_0 + β_1*Identity Theft* + β_2*Individual Tax Return* + β_3*Total Refund* + β_4*E-filing*

Model 2A: *Self-e-filing* (y) = β_0 + β_1*Identity Theft* + β_2*Individual Tax Return* + β_3*Total Refund* + β_4*E-filing*

Model 2B: *Direct Deposit* (y) = β_0 + β_1*Identity Theft* + β_2*Individual Tax Return* + β_3*Total Refund* + β_4*E-filing*

Model 3: *Tax Identity Theft* (y) = β_0 + β_1*Identity Theft* + β_2*Individual Tax Return* + β_3*Total Refund* + β_4*E-filing* + β_5*Self-e-filing* + β_6*Direct Deposit*

The mediating effects of self-e-filing and direct deposit are established (Baron & Kenny, 1986) if:
(1) The independent variable affects the dependent variable in the first regression model (Model1)
(2) The independent variable affects the mediating variable in the second set of regression models (Models 2A and 2B).
(3) The effect of mediating variable on dependent variable must remain significant in the third model and the effect of the independent variable on dependent variable must weaken relative to the first regression model.

DATA ANALYSIS AND RESULTS

Multiple Regression Analyses

The results of multiple regressions analyses are presented in Table 1. Four regression models were tested, and they were organized into three groups. Models 1 examined the effects of E-filing (independent variable) on Tax Identity Theft (dependent variable), respectively. Models 2A and 2B examined the relationships of E-filing with Self-e-filing (Model 2A) and Direct Deposit (Model 2B), respectively, where Self-e-filing and Direct Deposit were the mediating variables. Finally, Models 3 examined the effects of E-filing, Self-e-filing, and Direct Deposit on Tax Identity Theft.

These results indicated that (1) there was a significant relationship between the independent variable and the dependent variable (Model 1), (2) there was a significant relationship between the independent variable and each of the mediating variable (Models 2A and 2B), and (3) the mediators were significant predictors of the outcome variable in an equation including both the mediator and the independent variable (Model 3) and the effect of the independent variable on dependent variable was weakened relative to when the mediator is excluded (comparing results

from Model 3 with that from Model 1). Thus, taken together, these results suggested that self-e-filing and direct deposit mediated the relationship between e-filing and Tax Identity Theft.

Table 1: Multiple Regression Analysis Results

	DV: Tax Identity Theft	DV: Self-e-filing	DV: Direct Deposit	DV: Tax Identity Theft
	Model 1 (β[a])	Model 2A (β[a])	Model 2B (β[a])	Model 3 (β[a])

DISCUSSION AND CONCLUSION

The findings from this study provide practical implications for Tax Identity Theft mitigation and contribute to the state of the art in technology acceptance research. Our results indicated that, after controlling for Individual Theft, Individual Tax Return, and Total Refund, Tax Identity Theft was still positively associated with E-filing adoption and this relationship was mediated by Self-e-filing and Direct Deposit adoption, as hypothesized earlier. These findings confirmed that the growth in Tax Identity Theft did not just happen because of increased tax return filing or increased general Identity theft but was, at least in part, caused by the increased adoption of e-filing technology. Furthermore, the results suggest that the increased e-filing adoption contributed to the growth of Tax Identity Theft through increased adoption of self-e-filing and direct deposit.

The findings shed light on the mechanism of how the adoption of technology in tax refund process influence Tax Identity Theft. Economic principles dictate that resources are scarce and great effort should be taken to make sure that the available resources are used in the most efficient and effective way possible (Samuelson & Nordhaus, 2009). Thus, better understanding of Tax Identity Theft mechanism will allow stakeholders to focus on these vulnerability points with all available resources instead of spreading them across the organization.

The best way to address information security problems is through a risk-based approach (Shameli-Sendi, Aghababaei-Barzegar, & Cheriet, 2016). This require conducting a risk analysis and identifying risks gateways and then designing a security defense (Boyle & Panko, 2015). The findings from this study suggest that the key risk gateways in the Tax Identity Theft process are at self-e-filing and at the direct deposit points. The knowledge of these risk gateways allows security engineers to implement smart security instead of brute force security in that

countermeasure are only placed at key strategic points instead of placing them in every possible terminal end point.

Our findings also support treating direct deposit as a key detection point in the process. The use of direct deposit allows criminals to bypass security detection mechanism such as bank tellers matching a customer's ID with his or her facial physical features. While we are not suggesting IRS should discourage the use of direct deposit, measures should be set up to detect fraudulent direct deposit requests.

While this study yielded interesting results, it is not without limitations. As reported earlier, our identity theft data is based on counts of reported General identity theft complaints rather than counts of actual identity theft events. This is common in identity theft research as real data on identity theft is often difficult to obtain and investigators must rely on reported incidents. Furthermore, the reported complaints likely represent lower bounds for the actual cases. Still, there is a chance that this limitation may affect the finer relationship among the variables in our models. We do not expect the main effects to be different but it is hard to be 100% certain unless actual identity theft data is available. We leave this for future research hoping the IRS can avail this data.

Research Methodology for Healthcare Productivity Studies

Timothy L. Smunt
University of Wisconsin – Milwaukee
Email: tsmunt@uwm.edu

ABSTRACT

We present a multi-phase methodology for productivity studies in a large hospital setting. The illustration shown in this paper is based upon an initial study to understand the implementation of a Computerized Physician Order Entry (CPOE) system at an academic medical center. CPOE is a major facet of electronic health records (EHR), and it is hypothesized that CPOE implementation may increase both productivity and patient safety. This paper presents the methodology used in this study in order to provide guidance for future research on viable, scientific methods for testing hypotheses for process and information system improvements in a complex healthcare environment. Some initial results that help illustrate the benefit of the methodology are also provided.

KEYWORDS: healthcare, methodology, process mapping, work sampling, electronic health records

INTRODUCTION

We present multi-phase methodology for productivity studies in a large hospital setting. The illustration shown in this paper is based upon an initial study to understand the implementation of a Computerized Physician Order Entry (CPOE) system at an academic medical center. The medical center was interested in understanding the potential increased productivity over the life cycle of a patient's stay in the hospital, especially since there was some resistance by medical care providers to utilize the CPOE system. Reports of previous resistance to utilizing CPOE by physicians at other medical centers heightened the concerns of the medical center's administrators.

For these reasons, the medical center requested a structured methodology that was evidence based and statistically sound that would provide clear substantiation to both the medical care providers and administration. This paper will mainly present the methodology used in this study and will also present some results that help illustrate the benefit of the methodology. The main methodologies used are geographical mapping, process mapping, and work sampling.

LITERATURE REVIEW

Efficiency Analysis

Process mapping has been widely used in many industrial settings, including in healthcare. The use of process mapping in healthcare typically is initiated through lean manufacturing and Six-Sigma programs. For example, see Savory & Olson, 2001, for a list of guidelines provided for process mapping use in hospitals.

Work sampling studies have been used extensively in manufacturing for decades but are now starting to enter the healthcare sector. Ben-Gal, et al., 2010, present the use of work sampling for determining physician staffing at hospitals, and Upenieks, 1998, provides a discussion on how this method can be used to assess nursing efficiency.

CPOE

Numerous articles have been written over the past 20 years that discuss the need for CPOE, as well as the challenges that exist in implementing CPOE in hospital settings. One of the main stated benefits of CPOE is increased patient safety, since CPOE is a part of an electronic health records (EHR) system, that not only includes reported data on the patient, but also uses sophisticated decision support systems to ensure that prescribed medications are called for by a physician in acceptable protocols and do not negatively interact with other medications or specific patient allergies. Berger & Kichak, 2004, discuss these issues in detail. Devore & Figlioli, 2010, and Khanna & Yen, 2014, further elaborate on lessons learned and various hospital experiences with implementing CPOE.

It is important to note that actual experiences in CPOE implementations indicate difficulties of many types, including resistance by physicians to use the technology as well as productivity reductions and information errors.

Due to the known and expected hurdles in the CPOE implementation associated with this article, the CPOE champions and hospital administrators decided to determine how both short-term and long-term productivity levels could be methodically assessed and requested the author to design a multi-phase approach for this purpose.

PROCESS MAPPING PHASE

The objective of process mapping phase was to observe various physicians, nurses, and pharmacists to determine the work processes these healthcare providers perform throughout their work shifts. Based on these observations, the research team, which including the author and three graduate students, created process maps (also called flow charts) to illustrate the detailed work flows. These process maps were later used as the basis for the Task Lists for the the work sampling studies.

The goal of this project was to obtain a baseline reference on the work processes of various healthcare providers before CPOE was implemented throughout the medical center. We found, however, that approximately 80% of the General Internal Medicine (GIM) patients were CPOE patients, that is, that the orders for these patients were entered using CPOE whenever appropriate. Some orders, such as those for MRIs, could not be entered using CPOE and must either have a written order submitted or a phone order. None of the patients for Cardiac Care Unit (CCU) and General/Trauma Surgery (G/TS) were CPOE patients. The pharmacy received orders by CPOE and also by phone and fax, which are the two common methods for sending prescriptions from non-CPOE implemented units.

Traditionally, each patient has a record that contains information on his or her symptoms, diagnosis, vitals, and progress. This information is collectively called the patient's chart and is kept in a 2-inch binder. However, for CPOE patients, much of this information, such as vitals, is recorded in the computer, which is a database that contains all of the patient's computerized

information at the medical center. Other information, such as progress notes continued to be stored in a patient's binder that held paper-based forms. Patients' information, whether it be held in a paper form in a binder or in electronic form still called "the chart".

Geographical Maps

Ideally, all patients assigned to a particular service would be located in designated areas reserved for that service. At the time of this study, however, the medical center was operating at full capacity. Therefore, many patients were placed into rooms as the beds became available and a physician team's patients would be located on multiple floors. Figure 1 shows a "geographical map, which is a process map that shows typical movements of a physician throughout the facility.

It became evident when reviewing various geographical maps that physicians would often be walking to other locations, sometimes to different buildings in order to complete their tasks. Movement tasks clearly would need to be an essential part of the productivity studies.

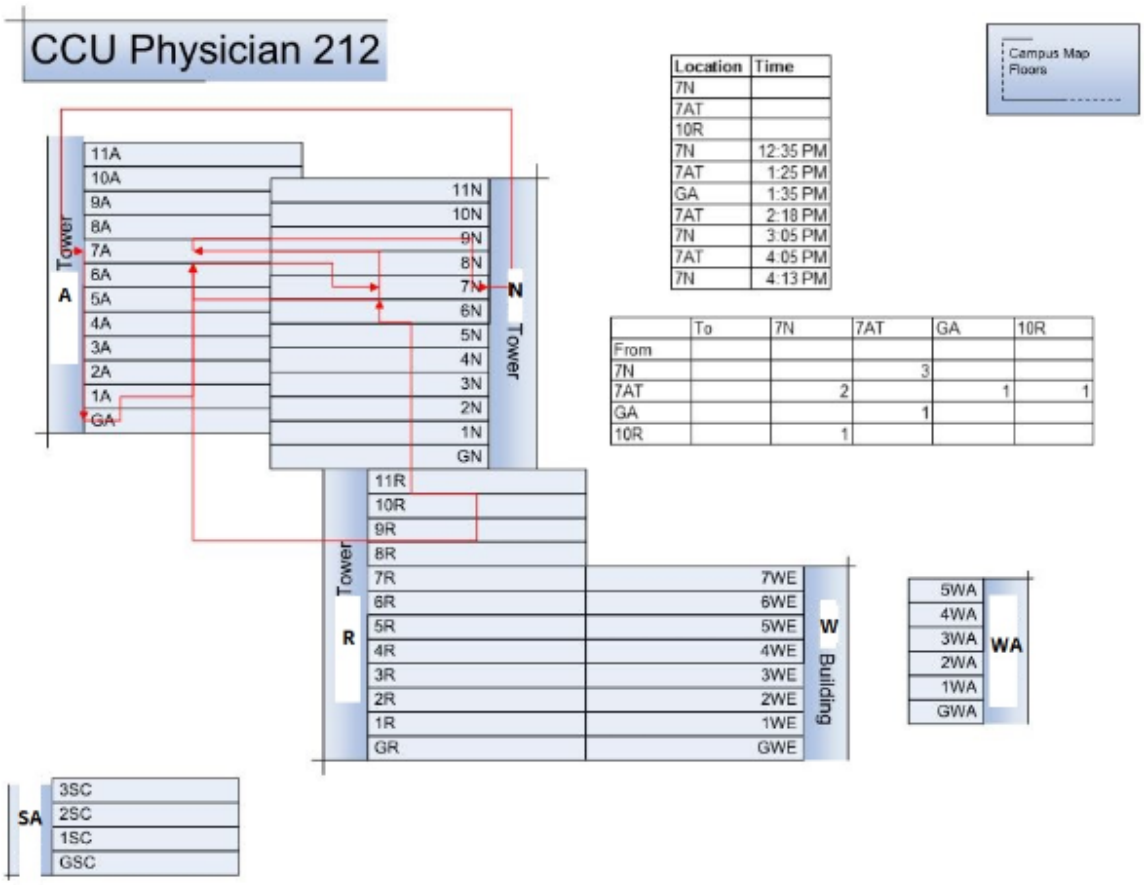

Figure 1: Geographical Map of a CCU Physician

Nursing Process Map

Since this article's main objective is to present a multi-phase methodology for use in EHR productivity studies, only the nursing main process map and descriptions are provided. Figure 2 provides the graphical view of the nursing process map.

Nurses are assigned to a specific floor, which generally corresponds to a specific service, like GIM. Nurses are assigned to a block of patient rooms. The number of patient rooms varies, depending on the service. There is at least one medication (med) cart for each block of rooms, except in the CCU where there is one med cart for each patient. The med cart contains medicines for all patients in the block except for those medicines kept in an AcuDose machine or in a refrigerator. Medicines kept on the med cart are separated by patient. AcuDose machines are located in every unit and contain IV fluids, expensive medicines and controlled substances. Pharmacy technicians periodically deliver medicines to the med carts, AcuDose machines, and refrigerators throughout the day.

The nurses have a set of six primary activities that occur in a relatively random fashion throughout the day. Almost all of the nursing activities fall into one of these six primary categories. These six categories are: administer medications; check for new orders; communicate; admit, discharge, and transfer patients; documentation of given care; and patient care.

Administer Medications

Administering medications involves a significant portion of a nurse's day. Most medications are administered at Standard Medication Administration Times (SMAT), such as 8:00 am, 12:00 pm, or 4:00 pm. However, not all medications are given at these times, as a patient may receive a dose every four hours, six hours, twelve hours, twenty-four hours, or as needed. Additionally, some medications cannot be given at the same time without the risk of an adverse reaction. Therefore, although the nurse will have many medications to give at SMAT, he or she will also give single doses of medications throughout the day.

The nurse begins the medication administration process by looking up a patient's medication list in either the information system or on the Medication Administration Guide (MAG). The medications are entered into the information system regardless of whether a patient is in CPOE. Thus, any nurse can obtain the patient medication list through this outlet. However, the MAG is not used on floors that have CPOE. As the nurse reviews the medication list, he or she determines whether a medication is in the patient's bin on the nursing cart in the hallway or in AcuDose. If the medication is in AcuDose, the nurse must walk to the AcuDose machine and go through the verification process to obtain the medication. This subprocess generally takes 1-5 minutes, as opposed to 10-30 seconds to get a medication from the patient's bin on the medication cart. In order for a nurse to administer a chemotherapy or insulin medication, he or she must have another nurse verify the dose. This additional step requires another 1-5 minutes of nurse time.

Before the nurse administers medications to a patient, he or she completes an assessment. The assessment includes checking the patient's vitals and, if necessary, the blood-sugar level or other relevant levels. After the assessment, the nurse administers the medications and charts those medications in the information system. If the nurse is also using a MAG, then it is

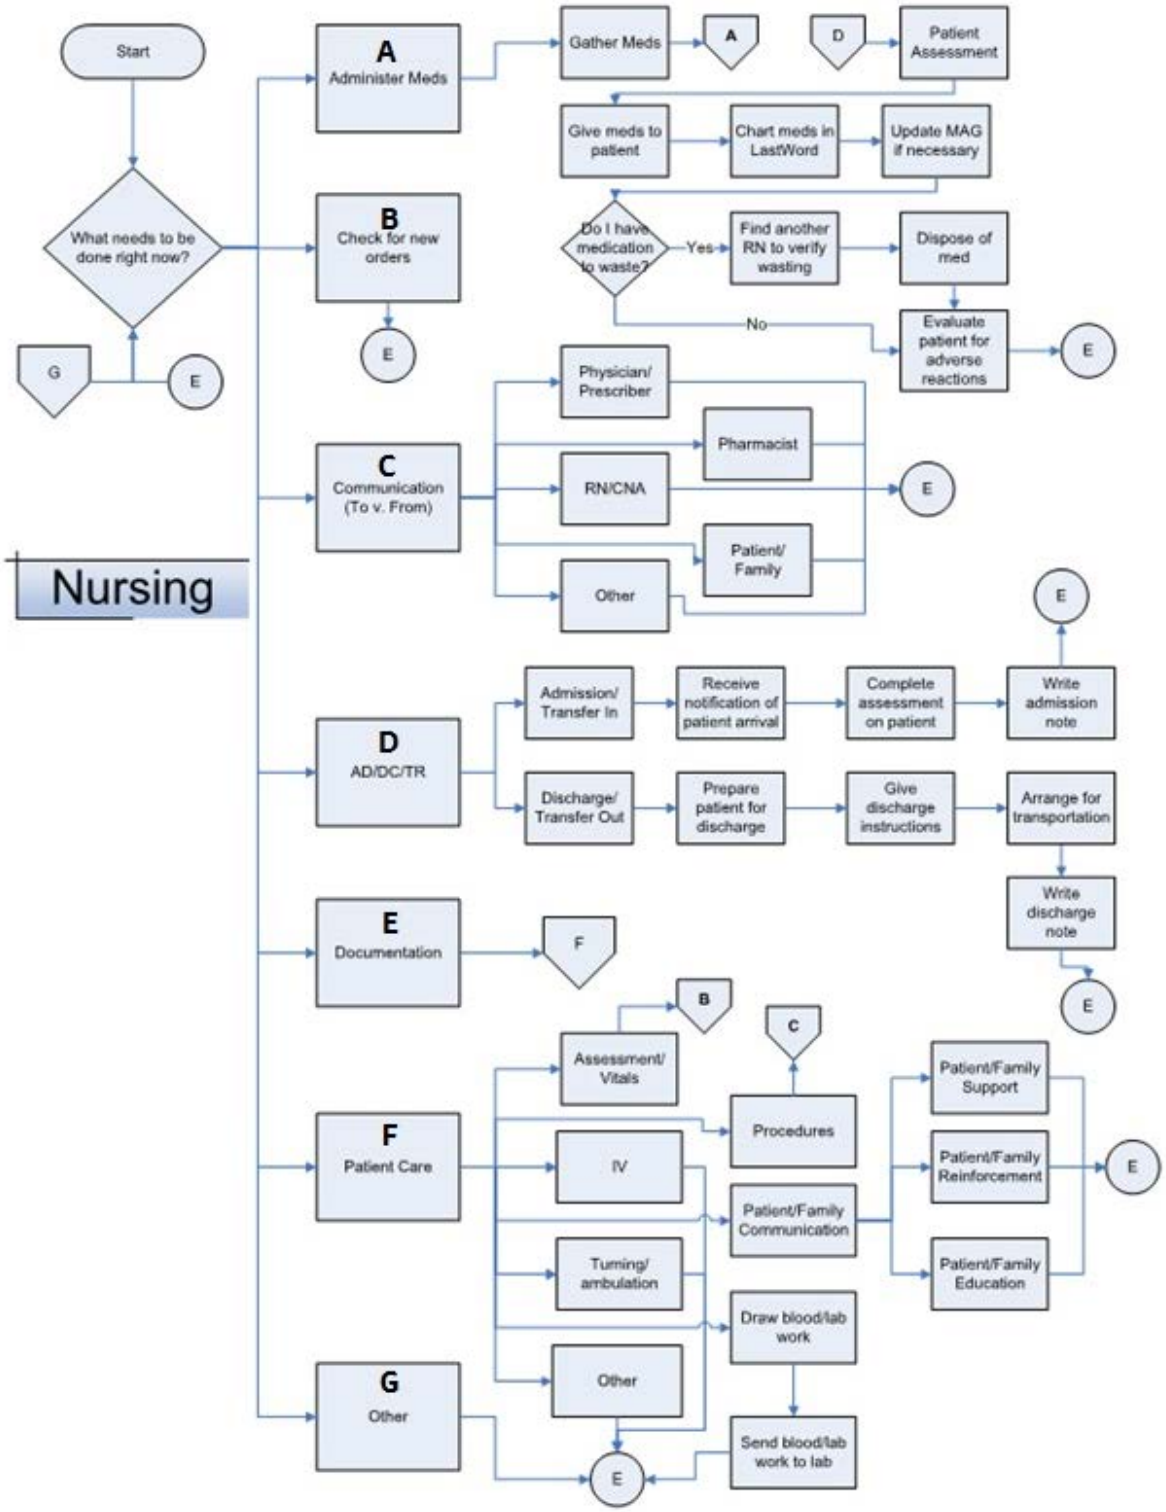

Figure 2: Nursing Process Map

updated at the same time. When there is excess medicine that cannot be saved for the next dose, the nurse must "waste" the medication, and another nurse must witness and verify that this is done. The final step in administering medications is for the nurse to evaluate the patient for any adverse reactions. The entire medication administration process usually takes about 5-20 minutes per patient, depending on the number of medications the patient must receive.

Check for New Orders

Throughout the day, nurses must check for new patient orders. On a CPOE floor, the nurse may search the record in the information system. On a non-CPOE floor, nurses must look to the patient's paper binder of records. Depending on the unit, this is either kept at the nurses' station or outside of the patient's room. The new order is usually "flagged" by placing it in the binder so that it protrudes from the top. Additionally, the unit secretary may give a carbon copy of the order to the nurse. Note that a new order does not necessarily require immediate attention; the order may be for medication to be administered several hours later.

Communication

A good portion of the nurses' day is spent communicating with others. Nurses commonly speak with: physicians and other prescribers; pharmacists; other nurses and CNAs; patients and their families; and other healthcare providers. The communication may be initiated by the nurse or the other party and may take place at any time. Topics may include, but are not limited to, patient updates; informal notification on new orders; questions about the patient's status; or non-business-related discussions. Note that communication here is distinguished from communication with the patient, or the patient's family regarding the patient's care (e.g. support, reinforcement and education) that is considered part of the Patient Care process.

Admit, Discharge, and Transfer Patients

While any given floor may have 0-8 admissions, discharges, or transfers into or out of the unit, during a day, we observed that one nurse will usually not have more than three or four of these events over two days. The process for both a new admission and a transfer into the unit is the same, as is the processes for a discharge and a transfer out of the unit. When there is a new admission or a transfer, the unit secretary will receive notification. The unit secretary will alert the charge nurse, who then makes the decision of in which room to place the patient. The charge nurse then informs the nurse assigned to that room.

Upon the patient's arrival, the nurse performs an assessment on the patient. The thoroughness of this assessment varies depending on whether the patient is a new admission or a transfer. A new admission requires a more complete assessment since there is no documentation tracking the patient over time. After completing the assessment and ensuring that the patient is settled, the nurse writes an admission or transfer note and places it in the chart. This subprocess requires approximately 20-45 minutes of the nurse's time.

For a discharge or a transfer out, the nurse prepares the patient for departure. This involves getting the patient dressed if he or she is leaving the hospital as well as securing all IV lines for transfer or removing them for discharge, among other tasks. If the patient is being discharged, the nurse goes over the discharge instructions. These instructions inform the patient of how to take any required medications at home, any physical therapy instructions, dietary instructions,

wound care instructions, and activity guidelines. It takes the nurse 5-15 minutes to go through the discharge instructions with the patient. Regardless of whether the patient is being discharged or transferred, either the nurse or unit secretary must arrange for transportation.

Finally, the nurse writes a discharge or transfer note after the patient leaves. The entire discharge or transfer out process takes about 15-45 minutes.

Documentation of Care Provided

Documentation is a ubiquitous task throughout the nurse's shift. Four primary areas of documentation were noted. First, all phone or verbal orders must be documented. Second, any patient care should be documented, such as changing dressings, adjusting IVs, and the patient's condition. Third, charting is considered documentation; charting includes recording that medication has been given, refused, or was not available, as well as a patient's vital signs. Finally, other miscellaneous documentation is required, such as accident reports and discharge papers.

Patient Care

The patient care process includes a broad array of tasks and can take a significant portion of the nurse's shift. There are six major categories of patient care: physical assessment/vitals, procedures, IV care, patient/family communication, turning/ambulation, and blood/lab work. To perform a complete assessment, the nurse performs a physical exam on the patient in addition to checking vitals. When the nurse begins a shift, he or she performs a complete physical exam on each patient. After this initial assessment, the nurse will perform many additional assessments throughout the day, which we observed to be less thorough. For example, the nurse checks vital signs on all patients throughout the day, but this process takes only 1-2 minutes, including the charting.

While the nurse is completing a physical assessment, he or she may make pre-charting notes of important information. These notes are informal and serve as a resource when the nurse does the formal charting. Formal charting either in the paper chart or in LastWord is the last step of the assessment process. Overall, the entire assessment process takes approximately 1-30 minutes, depending on the thoroughness of the assessment.

A nurse may be involved in procedures in several ways. Most frequently, the nurse preps the patient for a procedure that will occur at another location within the hospital. This includes arranging for transportation, securing all IVs and lines for transport, and sometimes accompanying the patient to or during the procedure. Nurses are required to accompany patients on procedures when the patient is deemed by a physician to be incapable of moving to the procedure room on his or her own. Additionally, the nurse may assist with routine and scheduled procedures or emergency procedures within the patient's room. In these cases, he or she may gather supplies, call a lab technician or other healthcare provider, confer with or assist a physician, or assist another nurse. While the procedure process generally takes 5-30 minutes, it can take much longer if the nurse accompanies a patient throughout a procedure or for emergency procedures.

If a patient has an IV, the nurse provides various kinds of care for it throughout the day. He or she checks it to make sure that it is open and clean. Also, the nurse may need to change the

line during the day. IV care is a relatively small part of a nurse's day, as it requires only 5-10 minutes of time. Similarly, turning and ambulation are quick processes. If a patient is confined to the bed, the nurse will turn him or her throughout the day. If the patient can get out of bed, the nurse will help the patient move within the room, such as from the bed to a chair. A physical therapist may come to help the patient with any further ambulation. Turning and ambulation requires approximately 1-5 minutes.

The nurse provides patient care through patient and family communication in three ways: support, reinforcement, and education. Patient and family support involves psychological support. Reinforcement are reminders as to what the patient needs to be doing to improve his or her health, as originally determined by a physician or other healthcare provider. Finally, education entails activities such as informing the patient and family about a medication that the patient is taking or explaining a procedure that the patient will have. Overall, patient and family communication lasts about 1-20 minutes on each occasion.

The final major category of patient care is blood and lab work. We observed that the majority of patients need lab work completed at least once every day, while many patients require multiple labs per day. This is especially true of patients who take medications whose dosage depends on the patient's blood levels immediately prior to medication administration. Although a lab technician will generally draw the labs, the nurse must ensure that this is completed when scheduled. We also observed that the nurse sometimes draws the labs. For example, if a physician orders a STAT lab, the nurse will draw the blood and send it to the lab through the tube system. Drawing and sending labs takes 5-20 minutes. Finally, the nurse checks all of the completed labs as the results return. If any results are abnormal, the nurse must decide whether to alert the physician. Generally, it only takes the nurse 1-5 minutes to check lab results.

WORK SAMPLING PHASE

The second part of the improvement analysis focused on a work sampling study designed to determine 1) if the observed tasks and task lists were sufficient and 2) the proportion of time spent by the health care providers on each of the tasks. The work sampling study allowed the subjects to record the activities that were being performed at random times during their work shift.

We used the information provided by the detailed process mapping phase to determine a "task list" that would be used in a work sampling study. The task list for nurses is provided below.

Nurse Task List Description

The Nurse Task List consists of seven major categories: Administer Meds, Review Orders, Communication, Admission/Discharge/Transfer Patient (Pt), Pt Care, Documentation, and Other.

Administer Meds

The five subcategories for Administer Meds correspond to the five primary tasks completed by nurses during the process of administering medications to patients: Gather & Prepare Meds, Physical Assessment, Give Meds, Chart Meds, and Waste Meds. Gather & Prepare Meds is

the process of collecting medications from AcuDose machines, the medicine refrigerator, and the nursing cart and preparing the medications for administration, such as removing pills from wrappers. A Physical Assessment of the patient is given by the nurse prior to drug administration. Give Meds is the act of administering the medications, such as hanging IV bags and watching the patient swallow oral medications. Chart Meds documents the administration of the medications. Waste Meds occurs when the nurse must document the accidental wasting, e.g. the drug needed to be disposed of due to accidental breakage of the container, of an expensive medication or controlled substance.

Review Orders

The Review Orders category is divided according to the medium of the order: Paper Order and CPOE Order.

Communications

The Communication subcategories correspond to the methods by which a nurse may communicate: Place Call/Page, Received Call, and Face-to-Face. Each of these subcategories is divided according to whom the nurse is communicating: another Nurse/CNA, Doctor/Prescriber, Pharmacist, Pt/Family, and Other. Furthermore, Doctor/Prescriber is divided by the topic of conversation: Verbal Order or Other. The Pt/Family item is for general communications with a patient or patient's family, such as directions to the cafeteria. Communications specific to patient care is found in the Pt Care category (described later) under Pt/Family Communication. The Other item refers to other people to whom the nurse may speak, including a respiratory therapist or a nutritionist.

Admit/DC/Transfer Pt

The Admit/DC/Transfer Pt is for patient movement into and out of the unit or floor. The two subcategories are Admission/Transfer In and Discharge/Transfer Out. Tertiary items for these subcategories represent the typical tasks required for the patient movement. For Admission/Transfer In, the tertiary items are: Notified of Incoming Pt, Settle Pt, Orient Pt, Write Admission Note, and Other. Notified of Incoming Pt indicates that the nurse is notified by the unit secretary that either a newly admitted patient or will be arriving on the unit or floor or a patient will be transferring in from another unit. Settle Pt refers to moving the patient into the room and perform other tasks required for having the patient stay on the floor, such as connecting IV tubes, oxygen flow monitors, and heart monitors. Orient Pt refers to describing information necessary for the patient's stay, such as hospital rules and how to use the television remote.

For Discharge/Transfer Out, the tertiary items are Prepare Pt, Review Meds/Orders with Pt, Arrange for Transportation, Collect Pt's Documents, Write Discharge Notes, File Pt's Documents, and Other. Prepare Pt refers to preparing the patient for departure, including disconnecting IVs, closing off the oxygen flow, and disconnecting a heart monitor. Review Meds/Orders with Pt means discussing the physicians discharge orders and what medicines to take when at home and how often. Arrange for Transportation refers to the nurse telling the unit secretary to call for someone to assist the discharged patient to the hospital door. Collect Pt's Documents refers to collecting and preparing the patient's documents, such as teaching notes and plan of care, for departure. Write Discharge Notes refers to writing final progress notes in

the patient's chart or plan of care. File Pt's Documents refers to putting all of the patient's documents into the patient's chart.

Patient Care

The Patient (Pt) Care subcategories pertain to the tasks associated with general patient care. They are Physical Assessment/Vitals, Pt/Family Communication, Procedures, Turning/Ambulation, Inspect IVs, Draw Blood/Lab Work, and Other. Pt/Family Communication refers to imparting information specific to the patient's care to the patient or family. Examples of this type of information include reminding the patient of how to perform breathing exercises or how to care for surgical incisions at home. There are three types of care specific information which corresponds to the tertiary categories: Support, Reinforcement, and Education. Tertiary categories for Procedures are: Wound Care, Prepare Pt for Procedure, Perform Emergency Procedure, and Perform Routine/Scheduled Procedure. Prepare Pt for Procedure refers to task associated with preparing the patient for a procedure that may performed either in the patient's room or off the floor. These tasks include gathering equipment or supplies, such as a mobile heart monitor or gauze pads and syringes. Perform Routine/Scheduled Procedure refers to procedures that the nurse performs, such as removing a sheath from a patient after a stent is implanted.

Documentation

Subcategories of Documentation are: Charting, Pt Care, Telephone/Verbal Orders, and Other. Charting refers to documenting the patient's vitals and other standard patient items, such as the cleanliness of the patient's IV location and the patient's assessment of his or her level of pain. Pt Care refers to writing notes related to patient care, such as daily plan of care updates and progress notes. Documentation of a Telephone/Verbal Order includes completing a Nursing/Pharmacy Communication Form.

Other

Subcategories under Other consist of: Stock Cart, Personal Time, and Other. Stock Cart entails gathering supplies from the Par Stock room and stocking the nursing cart.

<u>WorkStudy+ Software</u>

Handheld devices were loaded with a software program called WorkStudy+ created by QueTech. Preliminary tests were performed with a subset of subjects in order to determine the best settings and presentation features for this sampling study. One program feature was the random timer with an alarm that could be set over a range of time with a uniform distribution. Graphical analysis of the subset data, confirmed that the random alarms occurred as expected.

Another setting tested by the team with a subset of subjects was the random timer alarm. The alarm could be set for several different audible rings or one vibrate setting. The research team concluded that the vibrate setting did not adequately notify the user of the pending observation as it could not be felt to be vibrating within the user's pocket consistently. The team also discovered that the alarm was designed with a window of opportunity to record observations. That is, when it was time to make an observation, the device would power on. After ten seconds, the alarm would ring and continue ringing for a set period or until the user began

recording the observation. If the subject did not record the observation within the set period or if the subject began to record the observation but did not complete the recording by the time the window closed, the program recorded a missed observation.

Lastly, the research team experimented with the layout of task list activities on the device. There are several layout options. The device task list activities could be arranged in a table that could be arranged with any combination of two, four, or eight rows and one, two, or three columns. The row heights could also be set to a dynamic setting that would adjust the row heights as necessary but to no smaller than the initial number of rows. The limitation was that the table settings would be same for all screens, no matter the number of activities to be listed. For example, if the first screen held a three by three table to accommodate nine options, but a second screen only required a table of four options, the box size of those options for the second screen would be equal to the box size for the three by three table. The research team determined that, based on the initial version of the physician task list, a table of four rows and two columns was ideal. This effectively limited the number of categories to be listed on any one screen to eight options.

We performed a usability test of the devices with two volunteers. They were each given a device to carry as they worked in the hospital. The random timer was set for a range of twenty to thirty minutes with an average of twenty-five minutes. Another setting was a window of opportunity of sixty seconds. The hospitalists carried the devices for approximately four hours. The hospitalists were asked to focus on the usability of the device, such as the alarm beeping and the window of opportunity, as well as the veracity of the items on the task list. Feedback indicated that the window of opportunity needed to be extended to longer than sixty seconds as the volunteer subjects were being timed out of the window of opportunity before being able to complete the observation recording. Other feedback indicated that the time range was adequate, the beeping was not very intrusive, and the task list items were accurate. In response to the window of opportunity, we extended it to ninety seconds.

Prior to the approval of the Physician Task List, a preliminary version of the list was loaded onto the devices using WorkStudy+ template in Microsoft Excel. When the final version of the Physician Task List was approved, that list was uploaded onto all devices. This cycle was repeated during the approval process for each of the task lists.

All participants were personally instructed by a member of the research team on the use of WorkStudy+ immediately prior to the commencement of their participation in the work sampling study. They were also given a hardcopy of the relevant task list and the contact number for one of the members of the research team.

COLLECTION OF WORK SAMPLING RESULTS

Once all data was collected from the subjects, we analyzed the means and performed Tukey range tests. In Figure 3, we list a partial set of nurse work sampling information. This information was considered extremely enlightening by the medical center's administration, and would inform the design the CPOE system, as well as other design decisions for the medical center's operations.

Figure 3: Representative Work Sampling Data

TUKEY STATISTICAL TESTS

Figure 4 provides a small subset of the work sampling results to illustrate the final step of the productivity analysis phases. Here, we see that nurses in GIM spend significantly more time administering medications than do nurses in CCU and G/TS. Recognition of this difference can provide insights into prioritizing electronic health record applications like CPOE, since the use of CPOE in GIM will likely have the potential to increase nurses' productivity there as compared to the other two services, especially CCU.

c. Alpha = .05.

FIGURE 4: Representative Tukey Range Tests

CONCLUSION

A comprehensive approach to studying productivity issues due to CPOE implementation was illustrated. A multi-phase approach was utilized, starting with observations of healthcare providers, then moving onto geographical and process mapping. Based upon the detailed process information learned, a work sampling study was designed and executed with commercially available software, WorkStudy+.

The data gathered from WorkStudy+ was then statistically analyzed to better understand where differences in work efforts occurred. It can be seen that the number of volunteers in each provider category were limited due to the difficulty of performing such a study in a working health care environment. Ideally, it would be beneficial to increase the number of study participants, and, therefore, the number of observations in order to increase the reliability of the results. Nevertheless, it can be observed that even with limited number of participants, relatively good statistical results were obtained.

Such a systematic approach to obtaining data in a complex, real-life service setting provided the constituents reliable information for determining design decisions related to the use of electronic health records. With increasing complexity of medical treatments, insurance and regulatory reporting requirements, and internal information needs, it will become even more important to analyze the current and proposed designs of electronic health record systems. A systematic approach using the operations management and industrial engineering methods applied in manufacturing settings will likely substantially improve both efficiencies and effectiveness in the health care arena.

FUTURE RESEARCH

This study was conducted at a single facility with a particular set of operating and information designs in place. Future research needs to expand the number of health care facilities tested in order to provide more generalizable results. In addition, testing more comprehensive improvements to electronic records systems in a longitudinal setting can provide organizations with a better understanding of the startup time required to see benefits across a variety of design options.

DECISION SCIENCES INSTITUTE
Resource Dependence Driving Deficiency Premiums in B2B Supply Chains in the Bop

Raja Usman Khalid
Information Technology University
Email: usman.khalid@itu.edu.pk

ABSTRACT

Purpose
The paper comments on resource dependence dynamics of inter-organizational relationships in base of the pyramid (BoP) markets and elaborates related deficiency premiums.
Design/methodology/approach
The data was collected as field observations. Resource dependency theory is employed to analyze findings of the study.
Findings
The results of the study show that the financially poor micro-entrepreneurs remain on the losing edge in B2B supply chains in BoP markets.
Research limitations/implications
The qualitative findings of the empirical research need further validation using quantitative research designs.
Originality/value
With earlier empirical works in BoP literature mainly focusing business-to-customer linkages, the extent paper will further enrich the understanding of B2B business environment at the BoP.

KEYWORDS: Supply Chain Management, Business-to-Business, Base of the Pyramid, Field Observations, Resource Deficiency Premiums.

INTRODUCTION

Development through commerce agenda for those making the bottom tier of the world income pyramid put forward by Prahalad and colleagues (Prahalad, 2006; Prahalad and Lieberthal, 2003) have succeeded in gathering notable attention from concerned scientific community (Kolk *et al.*, 2014; Khalid and Seuring, 2017). The foremost BoP literature either tried to problematize BoP case or tended to stir multinational corporations' (MNCs) attention to start commerce in potentially lucrative informal markets of BoP (Prahalad, 2006; McMullen, 2011). While the BoP research stream has gradually developed from a consumer oriented (Ahlstrom, 2010; Weidner *et al.*, 2010) through a producer oriented (Agnihotri, 2013) to a partner oriented (Simanis *et al.*, 2008) inclusive business domain, business relationships and issue of poverty premiums was mainly dealt with from a business-to-consumer (B2C) perspective in extant literature (Karnani, 2007). Indeed, humble consumers are exploited on hands of the local businesses who while offering mainly utility items do charge certain price premiums. However, the consumer centered justifications for this malpractice in B2C supply chains are far diverse than ones presented by BoP researchers so far. The BoP literature in simplistic terms considers illiteracy, weak purchasing power and inconsistent and unreliable sources of income as prime causes forcing consumers to pay poverty premiums (Agnihotri, 2013). The respective literature has however not yet investigated the B2B dimension of the malpractice and therefore has yet to explore if relationships further up a supply chain remain a cause of the phenomenon. Instead of having a holistic end-to-end supply chain perspective, BoP literature by far has focused on a bifurcated,

localized and a more consumer centered B2C perspective in order to analyze case of premiums in subsistence markets.
Individual businesses today are considered as nodes forming a wider supply chain network, with core assumption implying 'each node of the chain effects others'. The indigenous entrepreneurs working in subsistence markets remain not an alien to the fact. Not only that the supply chain actors working up a supply chain can be prone to same malpractices happening down the chain but can also be a cause of downstream challenges.
In such a context the study aims to explore how inter-organizational relationships in BoP frame advent of poverty premiums. The study while analyzing business relationships using resource dependency theory (RDT) as theoretical lens, incorporates B2B dimension in a largely B2C centered poverty premium discussion. While doing so the paper presents the case of the indigenous entrepreneurs. The paper argues that not only the consumers but also the humble local businesses in peculiar informal market setting of BoP are paying premiums to their relatively advantageous suppliers. Furthermore, the paper while also maintaining in-line with the core understanding of supply chain management literature elaborates on how the B2B practices have an impact on B2C domain of respective supply chain. The extent paper therefore maintains that challenge of premiums cannot be tackled by solely aiming at B2C focused interventions converging on final consumer empowerment strategies.
Furthermore, while relating empirical findings with RDT, the paper also analyses highly dependent indigenous micro-entrepreneurs' relationship with their immediate suppliers. We are of the view that RDT while talking about causes of a dependent relationship between organizations, its' respective pros and cons and strategies that can help businesses reduce interdependency, can provide valuable insights to peculiar situation of indigenous business in resource scarce business environments. At the theoretical level, the paper thereby tries to incorporate RDT in a highly concrete BoP debate (Halme *et al.*, 2012). The paper in the context of RDT will also open a new theoretical window to better analyze an asymmetric B2B supply chain in BoP.
The rest of the paper is structured as follows. The next section presents a brief overview of the concerned published literature. Following section introduces the reader with the methodology employed. Findings of the study are presented in the next section. Last but not least a discussion is presented after findings and a brief conclusion makes the concluding section of the paper.

LITERATURE REVIEW

Base of the Pyramid (BoP)

Since the earliest publications of Prahalad and Lieberthal (1998), Prahalad and Hart (1999) and also Prahalad, (2006), people making up the bottom tier of world income pyramid and largely dependent on informal market economy for their subsistence (Arnold and Williams, 2012) are referred to as BoP in management related literature (Kolk *et al.*, 2014). The terms subsistence markets (Elaydi and Harrison, 2010), subsistence consumers (Weidner *et al.*, 2010), subsistence businesses and subsistence entrepreneurs (Toledo-López et al., 2012) have been used by researchers to refer to the fragile nature of economic activity at the BoP. Furthermore, the very use of the term "subsistence" while referring to BoP in general, points to the critical nature of financial capital in the particular settings. While lack of financial capital resources remain a defining characteristic of BoP (Kistruck et al., 2011), literature presents and comments on different types of capital resources that remain vital for doing business in BoP (McMullen, 2011).
Over the years the BoP debate has gradually developed from a consumer and marketing centered call of market intervention for MNCs to a partner and capability nurturing notion for

sustainable development of BoP through promoting business related activities (London *et al.*, 2010; Calton *et al.*, 2013). The BoP literature in general considers slow economic activity in BoP markets, a result of varied number of reasons from illiteracy to absence of logistical and institutional infrastructure. Therefore, a sundry of proposals to kick start economic activity at the BoP focusing both business model and product innovations have been presented by BoP researchers over the years (Hall *et al.*, 2012; Kistruck *et al.*, 2013; Hall *et al.*, 2014; Fawcett and Waller, 2015).

An examination of the earliest published BoP literature reveals that devising mechanisms to lower down the poverty premiums, remains one among the core foundations of whole premise of the research stream (Prahalad, 2006; Karnani, 2007). BoP scholars argue that MNCs are well able to reduce poverty premiums while earning decent profits by offering their products and services to BoP after reconfiguring their products and pricing strategies (Agnihotri, 2013). This should lead to the creation of win-win scenario for both MNCs and poverty stricken inhabitants of resource scarce business environments (Viswanathan *et al.*, 2009; Van den Waeyenberg and Hens, 2012). Since the seminal BoP literature was largely consumer focused and scholars have primarily dealt with B2C issues, the poverty premiums are mainly understood and dealt with from a consumer oriented perspective (Acosta *et al.*, 2011; Kolk *et al.*, 2014). While, indigenous BoP businesses remain part and parcel of the same resource scarce communities, little effort has yet been undertaken to study the advent of the premium phenomenon in B2B market interactions. The apparent research gap has not only baffled our wholesome understanding of the issue, but has also contributed towards positing consumer focused and rather “incomplete” solutions to the challenge (Agnihotri, 2013). Furthermore, the actor based viewpoint of BoP literature (focusing either consumers or producers) has contributed towards dealing with poverty premiums in a relatively narrower actor focused rather than in a more holistic supply chain perspective.

Though the absence of logistical infrastructure has been highlighted, and strategies to address related challenges have been presented earlier (Vachani and Smith, 2008), over the time concerned researchers have started viewing the BoP in a broader supply chain perspective (Sodhi and Tang, 2016; Khalid and Seuring, 2017). Calls for redesigning supply chains to address the unique challenges of BoP and involving the disadvantaged supply chain actors in value creating activities along the supply chains have emerged (Hall and Matos, 2010; Fawcett and Waller, 2015). Sodhi and Tang (2014, 2016) argue that the BoP market is different from the formal markets on account of two main challenges to deal with. First, challenge being lowering down high transaction costs arising from dealing with a large number of small transactions. Second, insuring the fair distribution of rents generated by supply chains among the advantaged and disadvantaged supply chain actors. Since both of these issues are supply chain related we think that examining BoP related issues in an overarching supply chain perspective instead of localized actor based view can be a potential way forward. By supply chain perspective we mean the basic understanding of the concept, viewing individual businesses as segments (nodes) of a wider and more complex network with activities happening in one part of the chain effecting or traveling to other parts.

Having said that, we argue that the issue of poverty premiums also needs to be studied in a wider supply chain perspective. Examining the structure and inter-organizational relationships upward a BoP supply chains can enrich our understanding of resource scarce business environments while providing new insights to deal with associated challenges. Given the scarcity of resources in BoP, the RDT can offer a theoretical background for analyzing the question taken up in the extent paper.

THEORETICAL DEVELOPMENT/MODEL

Resource Dependency Theory (RDT)

Since the influential work of Pfeffer and Salancik (1978), RDT has been widely employed to suggest and explain strategies employed by organizations to reduce "environmental interdependence and uncertainty" (Hillman *et al.*, 2009). "Rooted in an open system framework" (Barringer and Harrison, 2000), RDT talks about *why* and *how* organizations work to reduce other's power, meanwhile establishing their own supremacy. Power*,* understood in terms of control over fundamental resources thereby builds a core construct, RDT uses to explain interdependence in inter-organizational relationships along a supply chain (Bode *et al.*, 2011; Drees and Heugens, 2013). It must be kept afore that RDT is distinct from resource based view presented by e.g. Barney (1991). While the resource based view focuses on internal firm resources, RDT talks about the external environment of an organization influencing it. RDT considers organizations not to be autonomous entities rather constrained by their external business environment therefore in order "to understand the behavior of an organization (one) must understand the context of that behavior – that is, the ecology of the organization" (Pfeffer and Salancik, 1978, p. 1). The social context of the organization thereby is considered imperative for understanding organizational behavior. Core assumptions of RDT can be summarized as follows:

1. To a large extent organizations are not internally self-sufficient with respect to strategic resources (Heide, 1994; Paulraj and Chen, 2007).
2. To get access to respective strategic resources organizations are dependent upon other firms (external environment).
3. Organizations intentionally establish "formal and semiformal links with other firms" in order to "reduce uncertainty and manage dependence" (Ulrich and Barney, 1984; Paulraj and Chen, 2007)
4. While managing dependencies for the sake of their personal (corporate) benefit "organizations must acquire control over critical resources in an effort to decrease dependence on other organizations" (Barringer and Harrison, 2000).
5. Furthermore, organizations must "acquire control over resources that increase the dependence of other organizations on them" (Barringer and Harrison, 2000).

RDT thereby considers firms to be inherently resource scarce. Moreover, in a wider perspective the theory also assumes firms to be operating in an uncertain and resource scarce business environment (as the external organizations focal firm is interacting with remain also not self-sufficient). Business entities thereby lacking in one or the other resources needed to run their normal business operations have to interact to fulfill each other's needs. The inter-organizational interaction gives rise to a whole range of relationship continuum from transactional associations to strategic alliances. Though, the interaction among the organizations on one hand serves to provide respective firms with the needed resources and thereby mitigate associated uncertainty, however, on the other hand it creates dependencies. RDT posits that inter-organizational interactions do remain prone to opportunistic intentions of interacting firms, who purposefully structure these relationships to manage dependencies in their own favor. Inter-organizational relationships therefore remain one among the different options employed by firms to manage interdependencies in an uncertain business environment (Barringer and Harrison, 2000). It should be kept afore that RDT considers relationships among organizations only a mean to acquire critical resources, possession of whom is considered a source of power.
This paper will use RDT to analyze inter-organizational relationships in a highly social, volatile and resource scarce business environment i.e. BoP markets.

RDT and Inter-organizational Relationships

Inter-organizational relationships help firms achieve their business objectives by integrating otherwise segregated physical and intellectual resources. As mentioned earlier, in an open market environment firms engage with each other to get accesses to critical resources they lack otherwise (Pfeffer, 1972). This need to obtain resources creates dependencies among firms. Based on the concept of interdependence (Paulraj and Chen, 2007), the basic arguments of RDT and its perspective on inter-organizational relationships are summarized by Pfeffer (1978, pp. 26-27) as:

1. The fundamental units for understanding intercorporate relations and society are organizations.
2. These organizations are not autonomous, but rather are constrained by a network of interdependencies with other organizations.
3. Interdependence, when coupled with uncertainty about what the actions will be of those with which the organizations interdepend, leads to a situation in which survival and continued success are uncertain
4. Organizations take actions to manage external interdependencies although such actions are inevitably never completely successful and produce new patterns of dependence and interdependence.
5. These patterns of dependence produce inter-organizational as well as intra-organizational power, where such power has some effect on organizational behavior.

Focusing “on control, power, and vulnerability” (Bode *et al.*, 2011), RDT asserts that firms by establishing inter-firm relationships tend to reduce uncertainty in their external resource requirements. Firms are therefore inclined to manage the resource provision uncertainty in their external business environment by increasing depth and breadth of their supply chain relationships. A reciprocal relationship therefore can be imagined between environmental uncertainty and inter-organizational relationships (strategic relationships) (Paulraj and Chen, 2007). In line with the said argument and while considering the strength of relationships from an intensity of information exchange perspective Bode *et al.*, (2011) maintain that “the more environmental uncertainty a firm face, the more information it needs to gather and process to achieve a given level of performance”. Relying on the logic it can therefore be anticipated that frequent exchange of information and extensive relationships among supply chain actors will be highly evident in a volatile and uncertain business environment.

Furthermore, RDT talks about the power factor in inter-organizational relationships especially when these relationships are asymmetric and dependent. RDT theorists maintain that, firms while decreasing their dependence upon external environment, simultaneously increase dependence of external business entities upon themselves (Pfeffer and Salancik, 1978). RDT thereby considers inter-organizational relationships a tool used by business organizations to increase their market power relative to other businesses, by getting hold on complementary assets. Access to critical resources is pursued as a strategy to counteract business ambitions of other supply chain actors particularly competitors (Barringer and Harrison, 2000).

RDT thereby attempts to provide theoretical foundations explaining the complex setting of inter-organizational relationships in an uncertain external environment, where strategic relationship building and opportunistic intentions go hand-in-hand. The guiding principle in relationship building remains the maximization of focal firm’s business interests.

RDT and BoP

RDT has been rarely used to analyze the case of the BoP. For example, though Schuster and Holtbrügge (2014) have used RDT to elaborate market entry strategies for foreign firms in BoP,

the theoretical framework has yet to be used to study the relationships among the indigenous firms operating in a resource scarce business environment.

RDT provides valuable insights about the interaction of firms with their external environment while also trying to explain how the firms can better deal with the respective challenges effecting their business outcomes. Considering firms to be operating within the constraints imposed by provision of restrained/controlled means of production, resource dependence perspective intends to elucidate the strategies that can help firms guard their business interests in a limited resource environment. In context of resource scarce and volatile business environments of BoP, inter-organizational relationships not only function to get access to otherwise lacking resources but also to compensate for institutional voids. The concerned literature considers institutional voids as among the prime factors responsible for the poor market performance in particular and underdevelopment of BoP in general (Parmigiani and Rivera-Santos, 2015). BoP researchers therefore, consider inter-organizational relationships with traditional and non-traditional stakeholders (social capital) as a means to compensate for institutional voids and therefore essential for successfully operating in BoP (Web *et al.*, 2010). Bridging institutional voids and gathering capital resources for developing operational capabilities of BoP entrepreneurs, therefore can be regarded as the core functions firms try to pursue through establishing external relationships. Firm's relationships in BoP in context of fulfilling dual objectives of resource provision and institutional voids can thus potentially be a special case for analysis using the theoretical lens of RDT.

BoP literature while highlighting the need for firms operating in peculiar informal business environments to strengthen their internal resource base, acknowledges the role of external stakeholders in providing the respective business entities with capabilities they otherwise lack (Calton *et al.*, 2013; Hahn and Gold, 2014). Table 1, categorizes the different types of capital resources literature suggests firms need to have to survive in the volatile business environment of BoP.

Table 1: Capital resources in BoP markets

RESOURCES	EXPLANATION		REFERENCES
Social capital	Relational capital	Trust, identification and obligatory traits among organizations	(Wagner, 2011; Ansari *et al.*, 2012)
	Cognitive capital	Shared ambition, vision, and values	
	Structural capital	Strength and number of ties between actors	
Financial capital	Financial resources a firm can leverage upon to build its competitive advantage		(McMullen, 2011; Kistruck *et al.*, 2011)
Human capital	Human resources enabling firm to achieve its strategic objectives		(Bardy *et al.*, 2012)

BoP literature also highlights the variation among different firms in terms of capital resources to operate in BoP. While some of the firms operating in BoP are reported to be rich in social capital, they usually lack in terms of financial and human capital (Ansari et al., 2012). Absence of ample financial institutions and uneducated/untrained labor force remain prime reasons for lack of both of the respective capitals with indigenous firms. On the other hand, certain BoP firms (MNCs) appear to be rich in financial and human capital, lack in social (Ghauri et al., 2014). Thereby, making it difficult for them to comfortably operate in a highly social business environment. The capital resources therefore appear to be a limiting factor both for indigenous and foreign firms in BoP.

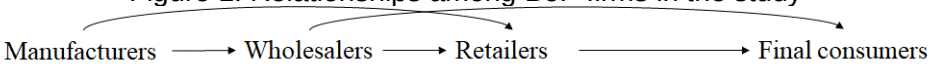
The issue of resources thus appears to be a point of convergence between BoP and RDT. While possession of resources (Table 1) potentially defines the existence of a firm in BoP markets, the RDT elaborates how one can access these resources. One should keep afore that the RDT theorists propose inter-organizational relationships as one among the different strategies that firms can employ to get access to deficient resources and thus decrease the supply related uncertainty in their external business environment (Barringer and Harrison, 2000). Corresponding to the propositions of RDT inter-organizational relationships in BoP may serve to compensate for the lacking capital resources i.e. financial and human capital for indigenous firms (filling institutional voids created by absent financial and education/training institutions) and social capital for MNCs (London and Hart, 2004). The apparent theoretical synergies among the relatively mature RDT and still evolving BoP research stream point to the fact that the argumentation of the former can be used to serve the purpose of later.
The extent paper tends to further explore this convergence of RDT and BoP on capital resources. RDT will be taken as the theoretical underpinning to analyze how inter-organizational relationships to get access to critical resources lead to generation of premiums in BoP markets. Since RDT considers firm power to be dependent upon the possession of critical resources. Firm relationships in human and financial resource sensitive BoP markets can be expected to be power based or opportunistic in nature. Firms can be imagined to be competing for the possession of the respective resources, as they remain relatively more inadequate than social resources (social capital) in BoP markets.

METHODOLOGY

Data Collection

The paper presents qualitative findings of an empirical study conducted in Pakistan during 2015-2016. While the data for the principal study was gathered using a structured questionnaire, the qualitative findings of the survey presented in this paper were collected as field observations to further enrich the principal quantitative findings. Qualitative data thus gathered helped better understand the interviewee and BoP business environment in a B2B context. The target population was indigenous micro-entrepreneurs operating with in a B2B business domain. Respondents were predominantly involved in manufacturing (suppliers) and retail (buyers) businesses. The retailers in this case were kiosks getting their supplies from manufacturers and wholesalers and selling it to final BoP consumers. Their merchandise consisted of various utility items from food and garments to stationary and basic electric equipment. Since the wholesalers doing business in the study area were found to be relatively “big” and couldn’t be regarded as micro-entrepreneurs, none of them was part of the sample and thereby included in the study.
The sample was drawn using snow-ball and convenience sampling techniques. The core criteria used to define micro-entrepreneurs (respondents) was number of employees (being 1-5) and subjective observation of the premises of the respondent’s workplace. The said data collection

Figure 1: Relationships among BoP firms in the study



techniques were specifically warranted in our context, since no reliable database was available to draw sample from. The respondents were usually either the owners of the businesses or general managers responsible for running the whole business independently. A pilot study was conducted with 10 respondents beforehand to identify potential avenues of improvement of data collection instrument. After completion of pilot study 50 face-to-face interviews were conducted

while not specifying any particular industrial sector. The strategy provided liberty to gather opinions from a very diverse business community representing various industrial sectors. A typical interview took approximately 45 minutes and were primarily conducted at the respondent's work premises and in regional language (i.e. Punjabi the mother tongue of the first author). While the interviews were audio-recorded, the filed observations are recorded in black and white. Furthermore, follow-up questions were asked during the course of interview to better understand the context and further enrich qualitative findings.

Data Analysis

The process of analyzing the data for this study started with transcribing the interviews and field observations. The transcription involved not only 'decoding' audio-recorded data in black and white and further streamlining filed observations, but also translating the respective data from regional language into English. While the field observations remained the prime source of qualitative data, on certain occasions data from structured interviews was consulted for better comprehension of the context.
RDT asserts that nature of the firm relationships are very much dependent upon and framed by its external environment. Since the research question taken up for the study remains enquiring how inter-organizational relationships in BoP frame advent of poverty premiums, it was deemed relevant to not only assess the general B2B business environment of BoP for indigenous micro-entrepreneurs, but also, the nature of dyadic buyer-supplier relationships focusing B2B supply chain. Having the qualitative data transcribed, the next step was unitizing the now relatively ordered filed observatory data into categories. The two respective categories were developed and titled as *B2B business environment at the BoP* and *nature of dyadic B2B relationships*. The process of grouping the data in categories was once revised in order to increase the reliability of coding process.

Qualitative data corresponding to the category 'B2B business environment at the BoP' was mainly inductively analyzed. Analytic induction procedure corresponds to intensive examination of strategically collected data to understand a specific phenomenon and establish its causes (Saunders *et al.*, 2006, p. 498). However, RDT was primarily employed to analyze the data pertaining to the category 'nature of dyadic B2B relationships'. It remains worthwhile mentioning that the results of analytic induction helped better understand the context and thereby make sense of B2B relationships assessed in context of RDT. The study therefore helped further establish relevance of yet another long-sought theoretical infrastructure to evaluate and tackle with BoP proposition and challenges, particularly those related to development and functioning of inter-organizational relationships (Ansari *et al.*, 2012; Schuster and Holtbrügge, 2014). The insights related to the B2B business environment yielded by inductive analysis of the qualitative data and nature or inter-organizational relationships in BoP studied in background of argumentation of RDT are presented in the next section.

Validity and Reliability

Credibility of the responses has been established by engaging the researcher (first author) native to the particular societies for data collection and prolonged engagement with the respondents. The two factors enabled develop familiarity with their cultural, social settings, and interests, and further, allowed to define the scope of interview. Additionally, through persistent observations follow-up questions were asked, which provided depth to the interview and proffered authors with relevant information for the findings of the study. Similarly, through the implementation of thick description technique, transferability of the study findings has been increased (Holloway, 1997).

Through the inductive analysis of B2B business environment and employing RDT argumentation for assessing inter-organizational relationships in BoP, theoretical triangulation of the study findings has been warranted. Theoretical triangulation allows the researchers to use multiple theoretical perspectives to interpret the data (Patton, 2001). The technique is often employed to establish conformability of the data in qualitative research. Therefore, the theoretical background applied in the study corroborates the consistency of findings.

FINDINGS

As has been highlighted earlier in the previous section that the qualitative data has been evaluated in backdrop of the two research objectives, the findings of the study will therefore be presented accordingly.

BoP Business Environment in B2B Context

To assess the general B2B business environment in BoP the respondents have been asked about the challenges and comforts of doing business in their peculiar informal market environment. The particular issues brought to light by the respondents are detailed below.

Physical Infrastructure

In the context of the acute power crises Pakistan was facing at the time of data collection, power shortage issue was most frequently mentioned challenge micro-entrepreneurs were dealing with. However, in line with what has been documented earlier under notion of missing infrastructure in BoP related literature (Berger and Nakata, 2013; Arnold and Valentin, 2013), we maintain that given the relaxation of magnitude of problem, power shortage issues are not unique to area under investigation. Having said that, the power shortage came up as one of the main obstacles hindering the respondents achieve their optimum performance potential.
Missing or absent logistical infrastructure has been presented as one of the striking characteristics of BoP markets in related literature (Vachani and Smith, 2008), however, while mainly speaking in context of B2C business environment. Surprisingly logistical issues were not regarded as a bottleneck by the respondents of this study. The micro-entrepreneurs seemed to have developed certain indigenous strategies to deal with missing logistical infrastructure e.g. using three-wheelers (auto-rickshaws) to transport relatively small batch sizes.

Institutional Voids

Having said about the business supporting physical infrastructure, respondents also mentioned how institutional voids are restricting their business growth (Parmigiani and Rivera-Santos, 2015). Absence of ample financial institutions to fulfill the working capital needs of indigenous businesses has been highlighted during survey (Akula, 2009). Furthermore, some respondents also pointed towards the corrupt and exploitative practices of officials of the few micro-finance institutions doing business in the region.
It has been further revealed that, though, to a large extent micro-entrepreneurs want to pay tax and thereby become formalized, astronomical tax rates and prevalent corruption of tax officials often keeps them from becoming part of the formal economy. The respondents seemed unanimously acknowledge the fact that illiteracy and absence of efficient judicial and other regulatory institutions remains the prime cause of exploitation of micro-entrepreneurs by opportunistic public and private officials (Van den Waeyenberg and Hens, 2012).

Micro-entrepreneurs as Lenders

It has been pointed out earlier by Weidner *et al.* (2010, p. 561) that "owners of small businesses in these markets (BoP markets) often play the role of lender", however while talking in perspective of B2C transactions. The qualitative findings of the study have concluded that the narrative stands true also for B2B market transactions (dyadic buyer-supplier transactions between retailers and manufacturers respectively in our case). Not only micro-entrepreneurs themselves lend their produce to their customers but also get their supplies on a deferred payment mode. The respondents have highlighted that a major part of B2B business transactions materialize on a deferred payment mode, with no guaranteed payback time negotiated or followed. Sometimes these deferred payments account for more than two-third of total business transactions.
While the deferred payments provide a financial life line to micro-entrepreneurs and enable them run their businesses during hard times, fraudulent practices remain common. Institutional voids further encourage black sheep exploiting their lenders. The intensity of such malpractices is so wide spread that most of the respondents have put the lost or deferred payments as second most cited challenge indigenous micro-entrepreneurs have to deal with. One can imagine the plight of affectees if one also takes into perspective the institutional voids in BoP. Furthermore, it has also been reported that relatively stronger suppliers use to lend supplies to their disadvantageous customers as part of an exploitative business strategy. While knowing that with meager financial capital at their disposal, the humble business customers are unable to get raw material, suppliers provide them with vital supplies on above market rates thereby charging them a capital deficiency premium. The modest business earnings, deferred payments and fraudulent practices in market keeps buyers from clearing the exorbitant bills with their suppliers. Relatively advantageous suppliers thereby gradually succeed in building a 'loyal' customer base to whom they can sell their output while charging a certain deficiency premium. The exploitative practice not only restricts business growth in BoP but also dictates nature of inter-organizational relationships which will be discussed in more detail later on.

Skilled Labor

While it is presumed that an abundant rather over supply of labor has paved the way for use of labor intensive technologies in BoP (Ray and Ray, 2010), the availability of skilled labor remains scarce. The third most mentioned challenge micro-entrepreneurs were facing after power shortage and lost payments was thereby related to human capital. The advantages of a trained labor force for businesses have been highlighted earlier in the BoP literature (Arnould and Mohr, 2005). However, the respondents of the study maintained unavailability of sufficiently skilled labor force as a major efficiency draining factor for their businesses.
Having said that we maintain that provided the general shortage of a trained labor force, inadequate human capital is effecting both financially strong and poor actors in BoP market.

China Factor

Indigenous micro-entrepreneurs in BoP due to their scarce resources usually remain unable to achieve economies of scale and scope (Karnani, 2007; Elaydi and Harrison, 2010) and thereby compete with big international players. "Due to China's rapid growth and integration with global markets, Southeast Asia's poorer economies are losing comparative advantage in labor-intensive manufacturing" (Coxhead, 2007). Inflow of relatively cheap alternative products in local markets has further made life difficult for respondents of this study. The micro-entrepreneurs have pointed towards lack of willingness of regional and national governments to keep a check

on imported items to safeguard local industry. Though few respondents manufacturing certain traditional and localized products remained neutral, majority reported losing business to Chinese products despite of the gigantic size of the BoP market. The owner of a small workshop employing 6 workers and manufacturing handmade shoes mentioned;
"it is becoming difficult to sustain the business with every passing day, before there were the big market players with heavy pockets who established big factories and snatched away our workers and now the influx of machine made cheaper Chinese shoes have made it difficult for us to compete ……. buyer in our market is always searching for cheaper products".

Obsolete Technology

In line with what has been reported earlier for telecom and automotive sector of India by Ray and Ray (2010; 2011), indigenous manufacturers have found to be using outdated technology. The vast majority of manufacturers realize the dire need to update their machinery however capital constraints and illiteracy restricts them to do so. Respondents of the study acknowledged that illiteracy impedes them from getting know how of latest technological advancements in manufacturing industry. A respondent manufacturing handles for electric irons in his house mentioned;
"you can see how we are making them (handles) by using this manually operated press. It requires good amount of muscle power and we know we are not efficient. The automatic press costs about Rs. 1,00,00,00 (US$ 9900 approx.) it's more efficient and gives quality output but we cannot afford it"
The phenomenon being general in nature for the BoP markets needs policy initiatives to be taken at national level in order to educate indigenous manufacturers and provide them with needed finances for technological upgrading.

Nature of Dyadic B2B Relationships in BoP

Having commented on the B2B business environment of BoP, this section will mainly deal with findings of the study related to dyadic buyer-supplier relations of indigenous micro-entrepreneurs in BoP. Furthermore, it is worthwhile mentioning that the respondents have been asked about three aspects pertaining to nature and strength of inter-organizational relationships i.e. frequency of contact, medium of contact and quality of relationships.

Frequency of Contact

Corresponding to what have been reported earlier in the BoP related literature, the respondents of the study were found to remain in frequent contact with each other (Hill, 2010; Hahn and Gold, 2014). It has been reported that the frequency of contact largely, however, not solely remains dependent upon the intensity of business transactions. Frequency of dyadic contacts though increases during high season, it does not entirely fade away during times of low business activity. The social bonds also make it possible for micro-entrepreneurs to keep seeing each other at different social gatherings. The micro-entrepreneurs contact each other sometimes just to convey the message 'I am still around'. One of the reasons justifying frequent contact with other businesses in BoP has been elaborated by one respondent as:
"In a dynamic business environment like BoP, with businesses appearing and disappearing quite recurrently, 'the call' is essential to keep other party aware of one's presence"
Furthermore, micro-entrepreneurs being devoid of formal organizational structures evident in large business organizations, the contacts are developed and managed mainly by owners of respective businesses.

Medium of Contact

Responding to question related to channel of contact, the micro-entrepreneurs were found to be mostly using mobile phones to communicate with other supply chain actors. Extensive geographical coverage of telecommunication technology and its affordability has made it possible for micro-entrepreneurs to expand their businesses (Van Sandt and Sud, 2012). Furthermore, it was also reported that visiting work premises of each other, meeting on various communal and social gatherings and discussing general life related issues apart from business was a common practice.
The informal nature and frequency of inter-organizational interactions highlight the much advocated social aspect of business relationships in BoP literature.

Quality of Relationships

When asked about the nature of relationships with their suppliers/customers (depending on if the respondent was manufacturer or retailer), the replies poised a complex picture of inter-organizational relationships in BoP. In spite of being in frequent informal contacts with each other generally the micro-entrepreneurs doubt the healthy nature of these relationships for their businesses. Relatively smaller businesses were found to be suspicious about the opportunistic intentions of relatively stronger business affiliates. They commonly believe bigger players doing business only for sake of their vested benefits and disregarding the general business interests of other supply chain actors. Though a very few of suppliers also appeared to be standing on the losing side, normally buyers were found to be weaker than their respective suppliers. Lack of sufficient working capital, weak purchasing power, selling in small quantities on deferred payments (while charging poverty premiums) and illiteracy remain the prime causes of relatively weaker financial position of buyers in dyadic relationships. Suppliers (manufacturers) while having relatively sound working capital to leverage upon, selling in large quantities (while charging poverty premiums) normally were found to be financially better-off then their business customers (retailers). In spite of the unhealthy nature of relationships the financially poor retailers intend to keep these associations to ensure a continuous supply of raw material in context of the dynamic and uncertain nature of external business environment (consider for example issue of lost or deferred payments touched earlier). On the other hand, financially strong suppliers appeared to ‘invest’ (by lending supplies) on buyers, in order to capitalize on business associations so developed by building a loyal customer base. The respective dyadic relationships among micro-entrepreneurs thereby appeared to be of opportunistic in nature. The next section will elaborate further on the dyadic inter-organizational relationships in BoP in context of argumentation of RDT.

RDT and Inter-organizational Relationships in BoP

An uncertain external business environment remains one of the defining characteristics of BoP (Hall *et al.*, 2014) . RDT asserts that firms in such a volatile business environment are inclined to interact with other supply chain actors in order to gather maximum information pertaining to their external environment (Paulraj and Chen, 2007). An increase in depth and breadth of inter-organizational relationships will therefore be evident in such a scenario as is depicted by the findings of this study. Furthermore, RDT proposes that firms by establishing such relationships will try to decrease their dependence on external environment while increasing dependence of external business affiliates upon themselves. While managing external dependencies firms produce new patterns of interdependencies subject to their social context Pfeffer and Salancik (1978, pp. 26-27). Corresponding to arguments of RDT one can anticipate that the unique

business environment of BoP relative to formal markets warrants exclusive modes of inter-organizational relationships.

It seems worthwhile highlighting here again that the respondents of this study regarded financial capital as the source of power. The claim appears justified when seen in context of arguments presented in BoP literature, considering social capital vital for BoP firms, regardless of their size and position in the supply chain (Ansari *et al.*, 2012; Reficco and Márquez, 2012). The fact can therefore be conveniently appreciated that the indigenous firms doing business in BoP must have accumulated social capital enabling them pursuing their business activities. Furthermore, the respondents of this study regardless of their role (buyers or suppliers) frequently highlighted how the underdeveloped human capital is effecting their business performance. The observation seems in accordance with BoP literature regarding issues like illiteracy and untrained labor force among the prime causes of underdevelopment of these regions (Kistruck et al., 2013; Shivarajan and Srinivasan, 2013). Social and human capital thereby appear as "constants" in this study since one (social capital) remains prime requirement of doing business for various indigenous BoP firms and second (human capital) is effecting all the business entities in BoP. With two types of resources remaining constant for respondents of this study, presence of financial capital stands out as the only type of resource determining power of the respective BoP actors.

An powerful actor in a dyadic relationship is thereby considered as one having more financial capital to leverage upon relative to other. While both the financially strong and poor actors in a dyadic relationship try to reduce uncertainty and manage interdependencies, their approach to achieve the objective differs. We have found that in context of BoP, financially strong actor naturally tends to pivot more on the financial power it enjoys to mould relationships in its own favor. On the other hand, financially poor actor tries to protect its business interests by focusing more on relationship building activities in order to showcase its trustworthy stature. Furthermore, respondents reported to be trying to increase dependence of other actors upon themselves while pursuing unique business strategies crafted in their respective internal and external resource provision environment (Lusch and Brown, 1996). In line with arguments of RDT, resources, may they be financial or another can thus be seen as being exploited by firms to manage interdependencies leading to maximize their respective market power relative to other supply chain actors (Caniëls and Gelderman, 2007; Boons *et al.*, 2012) . Analyzing exhibit of power by relatively financially strong actors or their trustworthy stature by financially poor actors in their mutual effort to decrease uncertainty and manage interdependencies can help better understand B2B business environment and inter-organizational relationships in BoP.

Financially Strong Suppliers in BoP

RDT asserts that the power is a consequence of access to or ability to leverage upon the resources a firm needs to run its business operations (Hillman *et al.*, 2009). Working (financial) capital remains one of the prime resources an entrepreneur needs to run its business operations. Not only the monetary capital is a resource in its own capacity but it also enables a firm to get access to other resources it needs to run its business. The formal markets have developed the necessary institutional infrastructure to provide businesses with the needed finances not only to manage their running business expenditures but also to fulfill their business growth needs. Defined by the lack of their monetary capital, importance of financial resources increases manifold in BoP (Kistruck *et al.*, 2011). Resource scarce BoP firms not only require financial resources to furnish their working capital needs but also to get access to other supplies which they need to run their business operations.

Likewise, the respondents of the study understood the market power in resource (financial) scarce business environment of BoP to be a consequence of strong financial resources of respective firms. The results of the study depicting suppliers to be enjoying a relatively powerful

and thereby an advantaged position in inter-organizational relationship in BoP mirror their sound financial position. Furthermore, in context of uncertain business environment of BoP, building and maintaining a loyal consumer base could help suppliers defuse external risks. The business strategy of BoP suppliers, in context of buyer-supplier relationships and postulates of RDT will thereby be focused at achieving three objectives. First, ensure a strong financial performance to uphold their market power. Second, build and maintain a loyal customer base, to reduce market related environmental uncertainty and boost financial performance and third, increase dependence of buyers upon themselves.

It has been observed that BoP suppliers succeed in achieving these objectives mainly by using their financial power. Financially poor buyers facing capital constraints normally approach advantaged suppliers via certain 'common friends' or other social contacts. Suppliers having known the destitute financial position of their 'new' customers, offer them to purchase goods on a deferred payment mode (lending). In return of their 'courtesy' suppliers charge above market price for their merchandise, a fragility/resource deficiency premium indeed. It should be kept afore that, business being relationship driven in BoP, the common friends or other social contacts play the role of guarantor for materializing such transactions. The suppliers in this case like vicious money lenders, try to keep an equilibrium whereby financially poor buyers while remaining unable to clear their bills in one go, continue to purchase goods on above market prices. Furthermore, it was also observed that each supplier depending upon its financial position decides for himself how much capital he can afford to 'block' in market, for building such a customer base suiting to his opportunistic intentions.

The business strategy thereby in accordance with postulates of RDT enables financially strong suppliers; (1) to decrease down external uncertainty by building a loyal consumer base (2) build their power by making financially poor buyers dependent upon them (3) maintain their power (financial resources) by charging above market rents and building a customer base and (4) decrease their own dependence upon external business actors (buyers).

Financially Poor Buyers in BoP

Financially poor buyers try to reduce environmental uncertainty and manage interdependencies as poised by RDT, while pursuing a business strategy crafted in their own specific context and different from that of relatively financially strong suppliers. From an RDT perspective the supply related uncertainties could occur as a consequence of "(1) lack of superior relational aspects or (2) power imbalance in favor of the supplier firm" (Pfeffer and Salancik, 1978; Paulraj and Chen, 2007). As has been mentioned earlier the financially poor buyers due to their weak financial resources have thin financial capital cushion to leverage upon. Buyers therefore appeared to focus more on relationship building (social capital). Building a trust worthy stature of themselves for their suppliers and extending their supplier base were found to be core pillars of their external business strategy in wake of volatile business environment of BoP. It is worthwhile noting that their efforts related to building social capital remain primarily supplier focused.

To manage uncertainties and decrease their dependence upon other actors (suppliers in this case), buyers tend to extend and diversify their supplier base. Though streamlining firm's supply base by reducing number of suppliers remains the popular notion of modern supply chain management literature targeting formal market scenarios (Lemke *et al.*, 2000), vice versa is believed to be a constructive and thereby practiced business strategy by indigenous businesses in BoP. Respondents of the study mentioned that the financially poor buyers are inclined to increase their supplier base for two main reasons. First, to increase their 'working capital' (in form of raw material). One should keep afore that normally these supplies are received on a deferred payment and thereby are kind of lent/borrowed from suppliers. In this way financially poor buyers by using their business relationships and social contacts become able to get access to financial capital needed to expand their business. Social capital therefore can be seen

as a mean to get access to financial capital. Second, to ensure a continuous supply and avert any supply related risks (e.g. in case any of the supplier stops supplying goods due to any potential disputes developed on payment related issues). Thereby reducing supply related uncertainty in precarious business environment of BoP. The two mentioned reasons partially explain cause of consent of financially poor buyers to pay above market rents for getting their supplies. Having said that we think that, the extent to which the supplier extension and lending strategy remains beneficial for businesses in BoP needs careful scrutiny. As pointed out earlier in the relationship driven business context of BoP, extending the supplier base remains dependent on the social contacts. Financially poor buyers therefore reported to care more and spend substantial part of their off-work time in relationship building.

It was learned that financially poor buyers also use supplier relationships to offset competition and thereby increase their power. Having secured their supply base, the buyers try to increase breadth of relationships in their effort to strike some exclusive business deals. Social capital gradually maturing into exclusive business partnerships helps buyers defuse competition and thereby gain upper hand in their local markets.

The financially week buyers by virtue of their relationship building efforts and in accordance with propositions of RDT become able to (1) decrease supply related and financial uncertainty by extending their supply base (2) decrease dependence on suppliers by building a diversified supplier base (3) increase their power by diffusing competition via entering into exclusive partnerships with their suppliers. Relationship building thereby plays crucial role in realizing business interests of buyers in uncertain markets of BoP as proposed by RDT.

Table 2: Resources and business strategies in BoP

RESOURCE	FIRM IN POSSESSION	FIRM LACKING RESOURCE
Financial capital	Use financial capital to get access to other resources and thereby manage dependencies in their own favor	Diversify and extend relationships with direct and indirect business actors
Social capital	Use relationships to get access to other resources and thereby manage dependencies in their own favor	Get access to financial resources to manage dependencies or face market exclusion

DISCUSSION

Functioning institutions remain primitive for markets to function and play their part in development of societies. While institutional infrastructure is “taken for granted as a passive background” in formal markets, their absence results in market exclusion (Mair *et al.*, 2012; Reficco and Marquez, 2012). Devoid of formal institutions (i.e. formal laws and regulations and the corresponding enforcing apparatus, communication and transport infrastructure related elements providing society’s basic needs and encouraging economic activity and capital markets), informal institutions (i.e. values, relationships, beliefs, norms) derive markets in BoP (Kistruck *et al.*, 2011). Respective scholars have commented extensively on how informal institutions can substitute for formal institutions in running markets in BoP (London and Hart, 2004). The extent paper tends to enrich the concerned literature by presenting empirical evidence showing how the informal institutions in form of relational capital decreases exclusion in B2B markets. Furthermore, using the arguments presented by RDT it also tends to highlight the power factor at play in BoP business relationships and its side effects on financially week actor in context of buyer-supplier relationships.

Using argumentation of RDT Schuster and Holtbrügge (2014) have commented on strategies that can help foreign firms enter into and operate in BoP markets. However, in this paper we

have used logic of RDT to look more into relationships among local BoP business actors. In line with the popular opinion of BoP scholars, we maintain that the informal institutions in form of relationships remain a business qualifying criteria in BoP. The relationship based business environment of BoP can be justified theoretically by taken into account the resource dependency argument. In a resource scarce business environment like BoP, extensive relationship building with a wide array of direct and indirect business actors is not only meant to get access to internally deficient resources but also to bridge institutional voids. Trust based relationships with intermediaries compensate for formal institutions in developed markets to link together and create “spaces for interaction” (Schuster and Holtbrügge, 2014) among buyers and suppliers in BoP. Furthermore, the relational capital is also used to get access to critical business resources as has been presented in the case of the financially poor buyers in the paper.

Having said that the findings of the paper suggest the power of respective actors playing crucial role in defining the nature of BoP relationships. RDT theorists propose power to be a product of access to resources a firm need to run its business operations. Inability of firm to internally furnish all of its resource needs compels it to interact with its external business environment which creates dependencies. More dependent an organization is on its environment to get its resources, less power it enjoys and vice versa (Pfeffer and Salancik, 1978). The extent paper identifies two resources i.e. financial resources and relational resources simultaneously at play in defining power and nature of buyer-supplier interaction in BoP. Characterized by its poverty the respective scholars acknowledge the financial resource scarcity of BoP actors. However, the respective literature by mainly encouraging MNCs to start business operations in BoP, has seldom considered monetary capital a resource in its own capacity compelling firms to interact with external environment for its possession in BoP markets (Kolk *et al.*, 2014).

Direct and indirect relationships are vital to operate in relationship driven business environment of BoP (Arnould and Mohr, 2005). With social capital being a business qualifying criteria, importance of monetary resources in a financially deprived business environment increases manifold. One should keep afore the institutional voids to provide businesses with the needed capital in BoP. Power in such a context and as has been reported by the respondents of the study, is largely defined by the financial capital a firm has on its disposal. The study therefore in context of BoP buyer-supplier interactions considers, powerful firms as the ones with relatively more financial resources in BoP. Table 2 in line with the findings of the study presents different strategic options employed by BoP firms with in context of varying financial and relational resource possessions.

One among the core arguments presented by the seminal advocates of BoP in favor of the foreign business interventions in marginalized societies was to reduce down poverty premiums (Prahalad, 2006). Since the original BoP literature remains consumer oriented, the poverty premium issue was mainly dealt within a likewise context. BoP literature since its inception remained overshadowed by works either highlighting the issue of premiums or presenting business strategies to reduce it, however, mainly dealing with it in a B2C market context (Agnihotri, 2013). Correspondingly the approach posed by the respective scholars to address the challenge of premiums was consumer focused and mainly incorporated such strategies as consumer education, running ethical marketing campaigns and encouraging business competition in BoP (Arnold and Valentin, 2013). The very disposition of seminal BoP literature led to concentrate more on B2C issues while overlooking B2B challenges in BoP. Likewise, little effort has been undertaken to explore B2B market transactions and trace back the roots of premiums further up a supply chain.

The extent study intends to fill the apparent research gap by looking more into B2B market transactions in BoP. During the course of investigation, it was learned that premiums remain a common practice in B2B markets. Extending the poverty premium debate, we maintain that the malpractice not only remains a practiced reality in B2B transactions but it also travels further

down respective supply chain. The poverty premium charged by businesses in B2C markets is thereby partially if not solely a result of the trickledown effect of what is happening up a supply chain within B2B business domain. Analyzing the premium issue using the theoretical lens of RDT, we consider the premium in B2B markets as a resource deficiency premium charged from the business actors enjoying relatively disadvantageous position (less power).
In light of the results of the study we think that employing a localized actor based (consumer) perspective and focusing only B2C markets might not be enough to address the challenge of poverty premiums. Analyzing BoP markets within a holistic supply chain wide perspective can help better address the challenge. The study has elaborated on the role of power and dependence in developing relationships in uncertain business environment of BoP. RDT considering power and dependence as the underlying forces shaping the inter-organizational relationships in volatile business environment, can prove to be a helpful tool for future researchers working to address the premium issue.

CONCLUSION

The paper presents qualitative findings of an empirical study focusing dyadic buyer-supplier relationships among indigenous micro-entrepreneurs in BoP. The findings of the study have then been evaluated using inductive analysis and in light of arguments presented by RDT. The study revealed that in accordance with published BoP literature the business in BoP is relationship driven. Indigenous micro-entrepreneurs appeared to prefer doing business with 'known ones'. However, in absence of market regulating institutions to overlook these business relationships and resulting business transactions, business interactions appeared to be opportunistic in nature. Furthermore, market power is generally perceived as an outcome of financial capital. Firms with relatively stronger financial muscle are perceived as enjoying advantageous position in the dyadic interactions.
Powerful supply chain actors, mostly, however, not solely being suppliers in our case, appeared to use their financial resources to mould inter-organizational relationship in their own favor. While doing so, financially strong actors try to increase dependence of other organizations upon themselves and decrease their own dependence upon them. Furthermore, while managing these interdependencies, care is taken to sustain and build power securing resources on sustainable basis. However, the strategy employed by respective business entities to achieve the three objectives i.e. maintain and increase their power, decrease their dependence on external businesses and increase dependence of other actors upon themselves, differs depending upon their respective role in market/supply chain.
The study further revealed that in wake of power and dependence driven dyadic relationships relatively financially poor actors are paying a deficiency premium. The deficiency premium thereby denotes the insufficient/deficient financial capital of respective firm. The extent paper augments B2C centered poverty premium argument back to B2B interactions in BoP. BoP scholars thus also need to consider and trace the source of poverty premiums further upward a supply chain. It can be the case that a retailer charging a poverty premium to its already destitute customers, himself is paying the deficiency premium to its suppliers. Poverty premiums in B2C market therefore can also be seen as a trickledown effect of B2B transactions and not something novel introduced solely by retailers serving final consumers in BoP.
The paper also tries to extend the scope of largely B2C centered BoP literature while moving into domain of B2B interactions. Responding to call of Ansari *et al.* (2012) for employing diverse theoretical infrastructure to analyze the case of BoP, we have used RDT to examine inter-organizational relationships in our case. Though the arguments of RDT are mainly employed to analyze the dyadic interaction between manufacturers (suppliers) and retailers (buyers) in this paper, we are confident that the theory can be used to look into more diverse business interactions in BoP.

ABSTRACT

Analysis of the responses of 166 hackers reveals that moral affect mediates the effect of perceived intensity of emotional distress on responsibility assessment only in an ill intention systems security breach, and consideration of consequences strengthens the relationship between moral affect and responsibility assessment only in a good intention breach.

KEYWORDS: Hacker, Moral affect, Moral intensity, Consideration of consequences, Responsibility assessment, Intent, Information security breach

INTRODUCTION

Modernity creates liquid online relationships where one's life and identity are choices that depend on how one seeks pleasure, creates identities, engages with others, and solves problems (Coulthard & Keller, 2012). This liquid modernity allows a voluminous amount of information exchange via social media (e.g., Facebook, Twitter, and Instagram), e-commerce, and online banking which raises concerns about information security (Benson, Saridakis, & Tennakoon, 2015) and privacy (Garg & Camp, 2015) because users may have little understanding of how information systems operate (Ben-Asher & Gonzalez, 2015). Thus, users may be clueless about what could happen to their personal information, pay little attention to information security, and put their trust in the competency of security service providers (Alsmadi & Prybutok, 2018). Users' ignorance of the important implications of an information security breach provides an opportunity for hackers to breach into information systems, leading to increased number of reported information security breaches (PricewaterhouseCoopers, 2017). Users may be victims of information security breaches and suffer emotional distress (Elhai & Hall, 2016). Even if users have not been victims of an information security breach, they might be able to make inferences about the victims' situation and experience similar emotions as the victims (de Melo et al., 2014; Parkinson, 2011). While emotional distress may motivate users to use information system with precaution (Burns et al., 2017; Mamonov & Benbunan-Fich, 2018), users may feel overwhelmed with precautionary efforts, decrease their intention to engage in precautionary behavior (van Schaik et al., 2017), and pay little attention to information security issues. Thus, user efforts alone may not be sufficient for combating the issue of information security incidents. We add contribution to the literature by examining the information security issue from the perspective of hackers to enhance understanding of security breach. This insight may assist regulatory authorities and information security professionals develop effective strategies for handling the security issue.

Hackers break into information systems in an unauthorized manner with one or more of the following intentions: increase security, improve technology, protect privacy, monetary purposes, or release anger and frustration (Chiesa, Ducci, & Ciappi, 2009). Hacking is a violation of criminal law regardless of a hacker's intentions because it involves unauthorized access to a system (National Institute of Justice, 2000). Morality research (e.g., Bandura, 2001; Fida et al., 2016; Haidt, 2003) asserts that individuals engage in an action only when they perceive the action to be morally right. However, the moral perspective of perceived right versus wrong may be different from that of the legal perspective. For example, some individuals use pirated software because they believe this does not cause any harm to the companies and they may even feel that such action is morally right (Bhal & Leekha, 2008) even though it is illegal to do so (Menell, 2018). Thus, individuals may focus on moral values instead of the legality of an act when they decide to engage in an act. This study aims to shed light on whether moral values explain hackers' engagement in information security breaches.

Hackers may possess moral beliefs that are incongruent with their out-groups (Chiesa, Ducci, & Ciappi, 2009; Pieters & Consoli, 2009). According to The Hacker Manifesto: The Conscience of a Hacker (The Mentor, 1986), hackers constantly look for challenges and are passionate about breaking limits. They search for inadequacies and vulnerabilities in information systems so that they can direct the attention of system developers to potential threats and vulnerabilities. They believe that such an act suggests good moral values and sense of responsibility if they fully and privately disclose on a timely basis to developers and organizations so that the problem is taken care of before anyone could actually engage in malicious exploitation of the vulnerability (Chiesa, Ducci, & Ciappi, 2009). However, if the problem remains unsolved for a specific period of time, hackers might disclose the system vulnerabilities to the public. Kapustkiy and Kasimierz hacked an Indian embassy website located in seven different countries (Switzerland, Italy, Romania, Mali, South Africa, Libya, and Malawi) in November 2016 (Bonderud, 2016), and left a note alerting the embassy about the vulnerabilities; however, this notice was ignored. Subsequently, the breached data were announced publicly. The event drew the attention of the Indian embassy and the developers were instructed to fix the problem immediately with the assistance of Kapustkiy and Kasimierz. After the breach, the Indian embassy thanked Kapustkiy and Kasimierz for breaking into the website to draw their attention to the vulnerabilities. This breach is a good example of the hackers' moral values and sense of responsibility. Kapustkiy indicated later that he believed his act was morally right because the vulnerabilities were fixed with little data leakage (Patterson, 2017).

The information system environment facilitates increased abstract representation of actions which trigger utilitarian moral judgment (Barque-Duran et al., 2017) where the perceived benefits and costs determine the morality of an act (Bartels, 2008; Mill, 1861/1998). While harming someone is a moral dilemma, this act may be acceptable if it increases the well-being of a large number of people (Conway & Gawronski, 2013). This suggests that Kapustkiy's act (discussed earlier) may be morally acceptable if the perceived benefit (e.g., improving information systems security) is greater than the perceived cost (e.g., the victims' emotional distress). A perpetrator's intent determines the extent of one's perceived benefits versus costs; specifically, compared to an act with ill intention, an act with good intention is likely to be perceived as more beneficial and elicit positive feelings (Martin & Cushman, 2016). This study examines the intent of a hacker to promote understanding of whether hacking is morally acceptable.

Hackers may break into systems to release anger and frustration with the intention to cause damage to others (Chiesa, Ducci, & Ciappi, 2009). For example, a hacker known as "Peace"

stole and attempted to sell at least 200 million Yahoo's user data on the black market which devastated users and caused them to change their Yahoo's account information (BBC News, 2016). Selling personal data on the black market has a negative impact on the victims and such an act reflects the perpetrator's ill intention. Hackers may also engage in information security breaches without the intention to harm anyone but to improve security, enhance technology, or protect privacy (Chiesa, Ducci, & Ciappi, 2009). However, hacking with a good intention can still elicit unpleasant feelings. While Kapustkiy and Kasimierz breached the Indian embassy's websites to force the embassy to take information security seriously without any intention to cause damage, the breach caused anxiety to the embassy because it involved sensitive data that could be used for cyber espionage campaigns (Kumar, 2016). Hackers may not be aware that security breaches can cause emotional distress to a victim; especially when they believe that they have a good intention. Hence, increasing the awareness of hackers about the victims' emotional distress may lead them to become cognizant of the implications of information security breaches from the victims' perspective.

The purpose of this study is to investigate whether hackers react differently to information security breaches when a perpetrator possesses either an ill or good intention. To our knowledge, limited research is available for promoting understanding of whether intent induces different levels of moral affect (i.e., perceptions of the extent of a perpetrator's feelings of regret, sorrow, guilt, and shame) explains the effect of perceived intensity of emotional distress on responsibility assessment. Further, research is sparse on enhancing understanding of whether the nature of a perpetrator's intent affects the moderating role of consideration of consequences in the relationship between moral affect and responsibility assessment. This study attempts to shed light on these important issues. Increased understanding of the relationships among the intent of an act, moral affect, consideration of consequences, and responsibility assessment of an information security breach from the hackers' perspective may shed light on their continued engagement in the act despite the disapproval of society. The findings can help inform future research on development of effective strategies for dealing with the vulnerability issue.

We posit that moral affect explains the effect of perceived intensity of emotional distress on responsibility assessment (i.e., mediating hypothesis) and consideration of consequences strengthens the impact of moral affect on responsibility assessment (moderating hypothesis) regardless of the intent of an act. We recruited hackers from two major hacker conferences. They completed a questionnaire containing items which assessed their perceptions of the intensity of the victims' emotional distress, moral affect, consideration of consequences, and responsibility assessment of a breach. Analyses of the usable responses of 166 hackers support the mediating hypothesis in the case where a perpetrator harbors an ill intention; this effect is not observed when the perpetrator has a good intention. The results also support the moderating role of consideration of consequences in the relationship between moral affect and responsibility assessment when a perpetrator has a good intention. This suggests that hackers disapprove of an act with an ill intention without considering the consequences of the act. When a perpetrator engages in an act with a good intention, hackers tend to perceive the act to be morally acceptable after they consider the consequences of the act.

The remainder of this paper is organized as follows. The next section reviews the relevant literature and develops the hypotheses. Then, the research method and results are presented. Finally, the findings of this study, its limitations and suggestions for future research are discussed.

LITERATURE REVIEW

Moral Intensity

Moral intensity theory states that each act has a certain degree of moral intensity and the degree of intensity needs to reach a certain threshold before one can recognize an act as a moral issue and see a need for a moral response (Jones, 1991). The degree of moral intensity may vary based on six characteristics: magnitude of consequences, probability of consequences, temporal immediacy, proximity, and concentration of effect (Jones, 1991). Prior research (Jordan et al., 2012; McMahon & Harvey, 2007; Robertson et al., 2010) suggests that it may not be necessary for all of these components to be present for the formation of perceived moral intensity of an act. We focus on magnitude of consequences, probability of consequences, and temporal immediacy because these components are appropriate for the information security incidents examined in this study.

Magnitude of consequences refers to all the harm caused to the victims of a moral act in question (Jones, 1991). An act that causes the death of a human is of greater magnitude of consequences than an act that causes a person to suffer a minor injury (Jones, 1991).

Probability of consequences is defined as a joint function of the probability that an act actually occurs and causes the predicted harm (Jones, 1991). For example, selling a gun to a known armed robber has greater probability of harm than selling a gun to a law-abiding citizen (Jones, 1991).

Temporal immediacy is the length of time between the present and the onset of consequences of a moral act (Jones, 1991). For example, releasing a drug that causes an acute side effect has greater temporal immediacy than releasing a drug that causes a side effect after 20 years (Jones, 1991).

Moral intensity is perceived to be high when one believes that a victim suffers severe harmful consequences (magnitude of consequences), actually experiences the harmful consequences (probability of consequences), and suffers from the immediate consequences (temporal immediacy) (Jones, 1991). When an act is perceived to have high moral intensity, one may consider the act as involving a moral issue and engage in moral behavior (Frey, 2000; Jones, 1991). However, moral behavior may not occur when perceived moral intensity is below one's threshold (Barnett & Valentine, 2004; Jones, 1991). Suppose an employee installed a company's licensed software onto his or her home computer against his or her colleagues' suggestion to purchase a separate license for personal use. This act may elicit high moral intensity because the harmful consequences (negative emotions such as disgust and anger) are immediate and has actually occurred, leading to the perception of the act as morally unacceptable (McMahon & Harvey, 2006). Now, suppose one's colleagues have mixed opinions on use of the company's licensed software for personal purposes. This situation may not elicit high moral intensity because the colleagues' mixed opinions dilute perceived harmful consequences; therefore, the act may be perceived as less morally unacceptable (McMahon & Harvey, 2006). Elicitation of moral behavior may necessitate increased awareness of the harmful consequences which accentuates the victims' well-being and propel a need for restoring justice for the victims (Greene et al., 2008).

Moral Affect

Moral affect (i.e., regret, sorrow, guilt, shame, and anger) elicits intuitive and automatic emotions in response to an act that violates a person's moral beliefs, even though the act may harm others rather than that individual (Haidt, 2007; Janoff-Bulman & Carnes, 2013; Tangney, 1991). Moral affect entails implicit reactions to an act because of one's concern about the interests or welfare of the victims or society at large (Gray & Schein, 2012; Haidt, 2003).

Individuals' desire for belongingness to their social group (Baumeister & Leary, 1995) may cause them to monitor and constrain their own behavior when they encounter a moral violation by exhibiting a prosocial behavioral in response to a situation (i.e., a desire to restore justice or reciprocate an act of kindness) (Ford et al., 2018; Haidt, 2003). Emotions such as shame, guilt, sorrow, and regret may be elicited to assist individuals to cope with a specific situation that fits in with their social groups (Haidt, 2003; Leyens et al., 2000). Individuals may attempt to help, comfort, or alleviate the suffering of the victims (Stellar et al., 2015) to convey the perception that they are concerned about the well-being of others and to mitigate concerns about the uncertainty of their helping behavior (Grant & Gino, 2010).

Moral affect is critical when an act involves a conflict between one's good intention and the resultant harmful consequences of the act (Greene, 2008). For example, in a trolley problem, one has to decide between (a) pulling a switch to divert a runaway boxcar headed toward five agents to one agent on a side track, and (b) abstaining from pulling a switch to leave the runaway boxcar headed toward one agent while five agents were on a side track. The findings suggest that abstaining from pulling a switch is perceived to be morally wrong to a greater extent than pulling a switch (Hauser et al., 2009; Navarrete et al., 2012). Individuals' need for engagement in a prosocial behavior may be so strong that they cannot ignore or do nothing to help regardless of the number of victims involved (Greene et al., 2001; Hauser et al., 2007; Navarrete et al., 2012).

Although prior research indicates that moral affect may be invariant across groups (Hauser, 2006), it may differ across groups for an act involving in-group norms (Rutland et al., 2010) because of society's influence on their moral beliefs (Haidt & Graham, 2007) which lead them to side with a perpetrator of the act rather than the victims. When individuals perceive their group to be superior to other groups, their moral affect may favor their own group instead of their outgroup (Leyens et al., 2000).

Intent versus Consequences of an Act

The consequences of an act, commonly used to judge a perpetrator's wrongdoing in the legal systems, is a critical factor for assessing responsibility (Miller et al., 2014). While thoughts about an illegal act without actual commitment of the act may go unpunished, killing someone without an ill intention may be punishable (Miller et al., 2014). Further, punishment for an attempt to kill someone may not be as severe as actually killing a person. Individuals may consider a perpetrator's intent and the consequences of an act when they address the moral issues of the act (Cushman, 2008; Killen & Smetana, 2015). They may attempt to understand a perpetrator's mental states (desires, motives, beliefs, or intent and how these relate to what actually occurred) before forming a conclusion on the consequences of the act (Cushman & Young, 2011).

Both the intent and consequences of an act influence assessment of the moral implications of the act (Miller et al., 2014). Two theories can be used to explain the relationship between the

intent and consequences of an act. Blame blocking posits that harmful consequences cause one to focus more on the consequences of an act instead of a perpetrator's intent (Cushman, 2008). For example, shooting but missing a victim may be viewed to be less wrongful than shooting a victim who happened to be struck and harmed by a lightning instead of the shooting. Although the victim's injury is not a direct consequence of the perpetrator's act, individuals may link the consequences to the perpetrator and conclude that this would not have occurred if the perpetrator had not shot the victim. According to two-process theory, individuals generally engage in a single-process by considering only the consequences when assessing the morality of an act (i.e., the harmful consequences of the immoral act regardless of intent); however, unintended harmful consequences create a cognitive conflict which may cause individuals to blame a perpetrator for the harm but not blame the perpetrator for causing the harm because it is unintended (Cushman, 2008). When individuals experience this conflict, they may utilize a two-process model where the consequences of an act are assessed and a perpetrator's mental state is analyzed to evaluate the wrongfulness of the act (Cushman, 2008). Unintended harmful consequences that result from a good intention remind individuals of alternatives that a perpetrator could have chosen without causing any harm; hence, an act may be judged as wrongful, suggesting that a perpetrator's good intention may not mitigate the resultant harm (Cushman, 2008). While one may focus on a perpetrator's mental state or the consequences of an act (Cushman & Greene, 2012), an act with harmful consequences may cause one to focus more on the consequences rather than the mental state of the perpetrator (Young & Saxe, 2011).

HYPOTHESES DEVELOPMENT

The Mediating Role of Moral Affect

Suppose someone hacks into a system and obtains the confidential information of customers. This perpetrator might engage in this activity to steal information or test the security of the system. Regardless of the perpetrator's intention, the victims are likely to suffer emotional distress because their personal information is stolen. We posit that our hacker participants may believe that the victims actually and immediately suffer severe harmful consequences (i.e., stolen personal information). That is, the victims would not have been harmed if the act had not occurred. Therefore, perceived intensity is expected to be high, leading to judgment of the act as a moral issue (Jones, 1991). Once an issue is perceived as a moral issue, our hacker participants may utilize moral reasoning, engage in moral behavior, (Brandon et al., 2007; Jones, 1991), and hold a perpetrator responsible for the act.

The victims' emotional distress experienced as a result of an act either with an ill or good intention suggests an unpleasant situation that lead our hacker participants into the belief that the perpetrator should have feelings of regret, sorrow, shame, and guilt for causing emotional distress to the victims (de Graaff et al., 2016). This reaction provides a basis for intuitions about the degree of morality of an act (Haidt, 2008). Since emotional distress is an undesired emotion, it is likely to influence hackers to judge the perpetrator's act as morally unacceptable. Specifically, our hacker participants may be motivated to behave in a prosocial and equitable manner because they are concerned about the welfare of the victims (Haidt, 2003; Killen & Smetana, 2015; Wright et al., 2017). Hence, they may hold a perpetrator responsible for an information security breach regardless of whether the act has ill or good intention. The above discussion suggests that moral affect mediates the impact of perceived intensity of emotional distress on responsibility assessment, regardless of a perpetrator's intent, leading to the first hypothesis as follows:

H1: Moral affect explains the effect of perceived intensity of emotional distress on responsibility assessment, regardless of the nature of the perpetrator's intention.

The Moderating Role of Consideration of Consequences

An information security breach perpetuated either with an ill or good intention elicits a moral affect which accentuates a need for concerns about the victims' well-being (Haidt, 2003; Killen & Smetana, 2015). Hackers might engage in a good deed to restore the victims' welfare to maintain their moral values (Wright et al., 2017). Hackers may hold a perpetrator responsible for causing emotional distress to the victims regardless of the intent (ill or good) of the information security breach. When prompted to consider the consequences of a breach either with an ill or good intent, hackers may focus on the harm caused to others which elicits a negative emotional response (Bucciarelli et al., 2008) that increases responsibility assessment. Hackers may believe that the victims would not have been harmed if the breach had not occurred even if a perpetrator does not have any intention to cause harm to others. Hence, consideration of consequences is predicted to direct attention to the harmful consequences caused to the victims regardless of the perpetrator's intent, increasing the strength of the negative emotional response. To restore equity for the victims, hackers may assign increased responsibility to a perpetrator. We propose that Consideration of consequences may enhance the impact of moral affect on responsibility assessment. Finally,

H2: Consideration of consequences strengthens the impact of moral affect on responsibility assessment, regardless of the nature of the perpetrator's intention.

METHOD

Research Instrument

We develop two hypothetical scenarios describing different information security incidents in a business context based on court documents available on the U.S. Department of Justice website, and reports published by the Bureau of Justice Statistics, Computer Security Institute, and media. One scenario discussed an incident with an ill intention while the other scenario described an incident with a good intention. The materials reveal that taking revenge on corporations, stealing confidential information for financial purposes, and destroying corporate systems are common examples of incidents with an ill intention in corporate system intrusions. Revenge is used to represent ill intention in this study because it occurs frequently in intrusion reports. Corporate systems may also be intruded with the intent of helping to improve systems security. Helping behavior (i.e., testing security measures for detecting and mitigating weaknesses) is utilized to represent a perpetrator's good intention in this research. The information provided in the scenarios is adapted from actual computer incidents in the court documents.

Pretest

The research instrument was pretested with 28 senior accounting students and improved based on the feedback received from these participants.

Task

Participants read two hypothetical scenarios, answered questions pertaining to the scenarios, and provided demographic information. All participants received a T-shirt in for their voluntary participation in this study. The order of the scenarios was not randomized. Our participants may be less vulnerable to order effect because they relied on their personal moral beliefs rather than external factors such as information from other cases when they evaluated cases involving moral issues (Wright, 2010). In addition, the pretest results indicated that the order of the scenarios did not have an effect on the participants' responses.

Participants

We recruited hackers at two major hacker conferences. The Mahalanobis distance test reveals that 15 out of 181 responses had probability values below 0.001, suggesting lack of representativeness of the sample examined in this study. Therefore, the responses of 15 participants were excluded from analysis, resulting in 166 usable responses. The hackers' age ranged between 18 and 63 years and the mean was 34. About 94% were males and 76% worked in the field of information systems (e.g., system engineers, systems security professionals, programmers, and consultants). Except for six participants, all hackers engaged in hacking activities ranging from one to 45 years and the mean was 10.49 years. The participants' demographic information (age, work experience, and hacking experience) did not have an impact on our results.

Measurement of Variables

Intensity of Emotional Distress

Our three-item perceived intensity of emotional distress scale is adapted from moral intensity theory (Jones, 1991; Singhapakdi et al., 1996). Participants responded (on a 7-point scale with 1 = strongly disagree and 7 = strongly agree) to questions assessing their perceptions of the magnitude (the victims would suffer serious emotional distress), probability (the victims would definitely suffer emotional distress), and temporal immediacy (the victims would immediately suffer emotional distress) of the consequences in the ill or good intention scenario.

Moral Affect

The literature on moral affect (e.g., de Hooge et al., 2011; Ghorbani et al., 2013; Tangney et al., 1996) suggests that emotions such as guilt, shame, sorry, and regret are activated when individuals evaluate an act that causes harmful consequences to the victims. We use a four-item moral affect scale to assess (on a 7-point scale with 1 = strongly disagree and 7 = strongly agree) the participants' perceptions of whether the perpetrator in the hypothetical scenarios should feel guilty, shameful, sorry, and regret for engaging in the act.

Responsibility for an Act

Our dependent variable (on a 7-point scale; 1 = strongly disagree and 7 = strongly agree) measures the hackers' assessment of the perpetrator's responsibility for the breach.

Consideration of Consequences

We measure consideration of consequences (on a 7-point scale; 1 = strongly disagree and 7 = strongly agree) via the hackers' assessment of the perpetrator's responsibility for the consequences.

RESULTS

Measurement Model

The measurement models for the ill and good intention scenarios are used to assess the psychometric properties of two latent variables – perceived intensity of emotional distress and moral affect.

Confirmatory Factory Analyses

The measurement model fit indices (χ^2 = 0.000; CFI = 1.000; RMSEA = 0.000; SRMR = 0.000) are acceptable for perceived intensity of emotional distress for the ill and good intention scenarios. The measurement model is just-identified because this construct has three items. The factor loadings of the perceived intensity of emotional distress construct are acceptable for the ill (0.678-0.834) and good (0.707-0.838) intention scenarios.

The measurement model fit indices (χ^2 = 1.419; CFI = 1.000; RMSEA = 0.000; SRMR = 0.012) and factor loadings (0.742-0.899) for the moral affect construct are acceptable for the ill intention scenario. The measurement model fit indices (χ^2 = 0.276; CFI = 1.000; RMSEA = 0.000; SRMR = 0.004) and factor loadings (0.787-0.939) for the moral affect construct are also acceptable for the good intent scenario.

Table 1: Loadings, Cross-Loadings, and AVEs for Multi-Item Constructs

Panel A: Ill Intention			
	Factor Loadings Distress	*Factor Loadings* Affect	AVE
Magnitude of consequences (The victims would suffer serious emotional distress as a result of hacker's action)	**0.727**	0.247	0.553
Probability of consequences (The victims would definitely suffer emotional distress as a result of hacker's action)	**0.834**	0.362	
Temporal immediacy (The victims would immediately suffer emotional distress as a result of hacker's action)	**0.678**	0.192	
Regret (The hacker should regret the act)	0.147	**0.742**	0.709
Sorry (The hacker should feel sorry for the act)	0.296	**0.852**	
Guilty (The hacker should feel guilty about the act)	0.328	**0.864**	

Table 1: Loadings, Cross-Loadings, and AVEs for Multi-Item Constructs			
Panel A: Ill Intention			
	Factor Loadings Distress	*Factor Loadings* Affect	AVE
Ashamed (The hacker should feel ashamed of the act)	0.302	**0.899**	
Panel B: Good Intention			
	Factor Loadings Distress	*Factor Loadings* Affect	AVE
Magnitude of consequences (The victims would suffer serious emotional distress as a result of hacker's action)	**0.707**	0.013	0.592
Probability of consequences (The victims would definitely suffer emotional distress as a result of hacker's action)	**0.794**	0.008	
Temporal immediacy (The victims would immediately suffer emotional distress as a result of hacker's action)	**0.838**	-0.050	
Regret (The hacker should regret the act)	-0.030	**0.931**	0.775
Sorry (The hacker should feel sorry for the act)	0.040	**0.787**	
Guilty (The hacker should feel guilty about the act)	0.073	**0.820**	
Ashamed (The hacker should feel ashamed of the act)	-0.004	**0.939**	
Distress = Intensity of Emotional Distress, Affect = Moral Affect			

Reliability Tests

Table 2 shows that the Cronbach's alpha and composite reliability of the perceived intensity of emotional distress construct are 0.793 and 0.792, respectively, for the ill intention scenario; and 0.808 and 0.816, respectively, for the good intention scenario. These results indicate acceptable reliability for the items in the perceived intensity of emotional distress construct.

Table 2 also indicates that the Cronbach's alpha and composite reliability of the moral affect construct are 0.898 and 0.906, respectively, for the ill intention scenario; and 0.927 and 0.932, respectively, for the good intention scenario. These results suggest acceptable reliability for the items in the moral affect construct.

Validity Tests

The average variance extracted (AVEs) of the perceived intensity of emotional distress construct are 0.553 and 0.592 for the ill and good intention scenarios, respectively, indicating convergent validity. Table 2 shows that the squared root values of the AVEs are larger than the

correlation between the perceived intensity of emotional distress and moral affect constructs for both the ill and good intention scenarios, suggesting discriminant validity.

The AVEs of the moral affect construct are 0.709 and 0.775 for the ill and good intention scenarios, respectively, suggesting convergent validity. Further, the square root values of AVEs are greater than the correlation between the perceived intensity of emotional distress and moral affect constructs, indicating discriminant validity.

Table 2: Reliability and Inter-Construct Correlations

Panel A: Ill Intention				
	Cronbach's Alpha	Composite Reliability	Inter-Construct Correlations	
			Intensity	Affect
Distress	0.793	0.792	**0.744***	
Affect	0.898	0.906	0.491	**0.842***
Panel B: Good Intention				
	Cronbach's Alpha	Composite Reliability	Inter-Construct Correlations	
			Intensity	Affect
Distress	0.808	0.816	**0.769***	
Affect	0.927	0.932	0.533	**0.880***

Square root of average variance extracted (AVEs)
Distress = Perceived Intensity of Emotional Distress, Affect = Moral Affect

Test of Mediating Effect (Hypothesis 1)

We test the mediating hypothesis using the causal indirect effect approach (Muthen, 2011; VanderWeele & Vansteelandt, 2009). The results reveal that moral affect mediates the effect of perceived intensity of emotional distress on responsibility assessment (β = 0.187 [all the coefficients were unstandardized coefficients.], p = 0.002, Table 3, Panel A), providing support for hypothesis 1 for a breach with an ill intention. However, moral affect does not mediate the relationship between perceived intensity of emotional distress and responsibility assessment (β = -0.046, p = 0.267) for breach with a good intention.

Table 3: Results of Hypotheses

Panel A: Test of Mediation										
	IV	MV	DV	1) IV→MV		2) MV→DV		3) IV+MV→DV		Mediation
				β	p-value	β	p-value	β	p-value	
Ill intention	Distress	Affect	Resp	0.375	0.000	0.499	0.000	0.187	0.002	Supported
Good intention	Distress	Affect	Resp	0.618	0.000	-0.082	0.297	-0.051	0.286	Not Supported

Panel B: Test of Moderation					
	IV	DV	IV→DV		Moderation
			β	p-value	
Ill intention	AffCon	Resp	-0.110	0.457	Not Supported
Good intention	AffCon	Resp	0.118	0.008	Supported

IV=Independent Variable, MV=Mediating Variable, DV=Dependent Variable
Distress=Perceived Intensity of Emotional Distress, Affect=Moral Affect, Resp=Responsibility
AffCon=Moderation between Moral Affect and Consideration of Consequences

Test of Moderating Effect (Hypothesis 2)

Hypothesis 2 states that consideration of consequences strengthens the effect of moral affect on responsibility assessment, regardless of the nature of the perpetrator's intent. Since the fit indices (i.e., χ^2, CFI, RMSEA, and SRMR) are not available for the moderated mediation analysis, we use the Akaike Information Criterion (AIC) (Brown, 2006; Byrne, 2011) to assess the model fit. AIC is a comparative fit measure which suggests that a model with a smaller value has a better fit. This study examines two models: the first model comprises only the main effect of the moderating variable on the dependent variable (responsibility assessment), and the second model consists of both the main effect and the interaction between moral affect (mediator) and consideration of consequences (moderator) on responsibility assessment. The AIC value of the model without the interaction term is 4457.310. When the interaction term is included, the AIC value decreases to 4456.963, indicating that the model with the interaction term has a better fit. The results ($\beta = -0.106$, $p = 0.468$) do not support hypothesis 2 for an information security breach with an ill intention.

In the case of a breach with a good intention, the AIC value of the model without the interaction term is 4534.789. This value decreases to 4527.577 after the interaction term is introduced, suggesting improved model fit. The results indicate that consideration of consequences strengthens the relationship between moral affect and responsibility assessment ($\beta = 0.118$, $p = 0.008$, Table 3, Panel B), supporting hypothesis 2 for a breach with a good intention.

Conclusion

Discussion of Findings

This study uses two hypothetical scenarios suggesting an information security breach either with an ill or good intention to examine hackers' responsibility assessment of the breach. The findings show that hackers recognize the emotional distress of the victims when a perpetrator harbors ill intention. The victims' emotional distress elicits moral affect (i.e., feelings of regret, sorrow, shame, and guilt), causing our hacker participants to view the information security breach as unacceptable and holding the perpetrator responsible for the breach. This is consistent with prior research (e.g., Buon et al., 2013; Martin & Cushman, 2016; Phillips & Shaw, 2014) findings on judgment of an act as morally unacceptable and punishable when a perpetrator harbors an ill intention which causes harmful consequences to the victims. Our

hacker participants may consider a breach with an ill intention as an out-group act and deem such an act as undesirable (Bissett, 2003; Chiesa et al., 2009). In the case where a perpetrator has a good intention for engaging in a breach, the extent of their moral affect is attenuated, leading to reduced responsibility assessment, despite awareness of the victims' emotional distress. In the absence of an intention to cause harm to a victim, hackers may view a perpetrator's act as an in-group act and consider the breach as morally acceptable (Bissett, 2003; Chiesa et al., 2009). Therefore, hackers are less likely to hold a perpetrator responsible for a breach with a good intention. Further, our hacker participants' moral affect (i.e., feelings of regret, sorrow, shame, and guilt) may be attenuated when they evaluate a breach without any intention to cause emotional distress to the victims. Hence, accentuating our hacker participants' focus on a perpetrator's good intention may mitigate perceptions of the harmful consequences of a breach. Hackers may also focus on the potential benefits of a breach with a good intention (e.g., improving systems security) which may outweigh the harmful consequences of the breach. Subsequently, they are less likely to hold a perpetrator responsible for the breach despite their awareness of the victims' emotional distress.

Additionally, our findings reveal that the ill intention of a breach is more important than consideration of consequences of a breach with an ill intention in our hacker participants' responsibility assessment. This observation is consistent with prior research (e.g., Monroe & Reeder, 2011). Hackers may recognize the victims' emotional distress and become motivated to behave in a prosocial and equitable manner when a perpetrator harbors an ill intention (Haidt, 2003; Killen & Smetana, 2015). In the case of a breach with a good intention, consideration of consequences directs the hackers' attention to the victims' emotional distress. While a perpetrator may not have any intention to cause harmful consequences to the victims, the act causes emotional distress to the victims (Cushman, 2008). Direction of attention to the victims' emotional distress results in increased responsibility assessment (Young & Saxe, 2011).

Contributions

Our research shows that the nature of a perpetrator's intention for engaging in an information security breach determines our hacker participants' response to the breach. While hackers may not approve of a perpetrator's engagement in a breach with an ill intention, they may be tolerant of a perpetrator engaging in a breach with a good intention. Thus, effective handling of information security breach issues requires discernment of an act either with an ill or good intention. Lack of a conflict between an act with an ill intention and the consequences of the act suggests lack of a valid justification for making such an act morally acceptable. In the case of a breach with a good intention, hackers may believe that they engage in the activity to help improve systems security; subsequently, they are likely to perceive this activity as morally acceptable and continue to engage in the act. Directing attention to the victims' emotional distress due to an information security breach might help to discourage this behavior.

Limitations and Suggestions for Future Research

This study has some limitations. First, we use one question to measure our hacker participants' consideration of consequences and responsibility assessment, respectively. Future research can develop comprehensive measures of these constructs to examine whether similar results are obtained. Second, since this study involves a survey, future work can design an experimental study to enhance understanding of the process of and factors influencing the hackers' responsibility assessment of information security breaches. Third, this study examines only one type of consequences; that is, the victims' emotional distress. Future research can

investigate hackers' reaction toward an information security breach that leads to disastrous financial consequences. Research can also provide insight into evaluators' (hackers or jurors) responsibility assessment of a company in an information security breach. Finally, future work can shed light on whether hackers assess responsibility in favor of their in-group (i.e., a breach with a good intention) and explore whether consideration of consequences may attenuate the effect of in-group bias on moral judgment.

ABSTRACT

Using a value-based definition of organization culture, a relationship between culture and strategy is supported based on the qualities of strategy being reflective of values, shared by the collective and distinguishing one organization from another. The history and corporate actions of Uber is presented to motivate and illustrate the relationship.

KEYWORDS: Organizational Culture, Strategy

INTRODUCTION

During a tumultuous 2017, Travis Kalanick, the co-founder and CEO of Uber, resigned leadership of the ride sharing service company (Reilly, Fortune, 2018). Under Kalanick's leadership, Uber was the target of sexual harassment allegations, a negative social media campaign, and a U.S. Department of Justice criminal investigation. Dara Khosrowshahi took over as CEO of the technology giant and began a deliberate effort to reverse the negative perceptions of the brand. In a television advertisement airing mid-2018, Khosrowshahi made the following statement:

"I want you to know just how excited I am to write Ubers next chapter with you. This begins with new leadership and a new culture and you're going to see improvements to our service with better pickups and ride quality for both riders and drivers. One of our core values as a company is to always do the right thing and if there are times when we fall short we commit to being open taking responsibility for the problem and fixing it."

-- Dara Khosrowshahi, CEO, Uber

A key point of this statement is the focus on changing the *culture* of Uber. Under Kalanick's leadership, the culture of Uber has been described as entrepreneurial, or a growth at all costs (Khosrowshahi, Uber, 2018). This is consistent with the aggressive growth strategy pursued by the firm since inception. However, while Khosrowshahi has discussed the culture change of the firm several times, the strategy of the firm has not been addressed. How will a shift in culture affect the strategy of the firm? Is a strategy change necessary to affect culture?

These questions motivate a much broader topic – what is the relationship between organizational culture and strategy? Khosrowshahi himself argues the “forward-leaning, fearless approach” type of culture has contributed to the success of the aggressive growth strategy. In this example, it appears the culture directly influences strategy.

However, it may be argued that the strategy of the firm determines the culture. A key component of strategy is the impact the strategy has on resource allocation (Bourgeois & Brodwin, 1984). If the company hopes to implement a diversification strategy and diverts additional resources to R&D, then the strategy has signaled a high value ranking of innovation. The value of innovation then may craft a culture of teamwork and collaboration. Alternatively, if a company implements an aggressive growth strategy, then resources may be diverted to meeting short-term sales targets. This resource allocation may lead to an organizational culture that is less concerned with long-term consequences.

In this paper, we will discuss the concepts of organizational culture, strategy, and the relationship between culture and strategy in terms of shared values. We seek to open a discussion of how these concepts can be used to assess or leverage one another.

LITERATURE REVIEW

Organizational Culture

Culture is defined as “the collective programming of the human mind that distinguishes the members of one human group from those of another. Culture, in this sense, is a system of collectively held values.” (Hofstede, 1980; p. 24). Organizational culture is the culture specific to an organization and it enables “the differentiation of organizations along the lines of dominant values guiding organizational behaviors” (Leidner & Kayworth, 2006; p. 360). This description suggests organizational culture is not only a set of values important to a group, but a combination of these values to distinguish one group from another.

The term "organizational culture" (also referred to as "corporate culture") entered the research field in 1965 in textbooks by both Bass and Schein independently (Schein, 1996). While the early measurement of organizational culture had been focused primarily on individual characteristics and how they matched or conflicted with the social norms of the organization, the research evolved to include more intergroup phenomena and leadership implications (Schein, 1996). The concept of organizational culture was advanced significantly by Geert Hofstede in the early 1980s through the extensive study of culture, at both the national, organizational and individual levels. Hofstede defines culture as "the collective programming of the human mind that distinguishes the members of one human group from those of another. Culture, in this sense, is a system of collectively held values." (Hofstede, 1980; p. 24). A value is "a broad tendency to prefer certain states of affairs over others" (Hofstede, 1980; p. 19).

This view of a value-based organizational culture definition is supported in prominent management research. Straub and colleagues (2002) postulated shared values were the central and distinguishing characteristic of culture. In 2006, the organizational culture construct was reviewed through a meta-analysis conducted by Leidner and Kayworth (2006). This seminal work describes organizational culture as enabling “the differentiation of organizations along the lines of dominant values guiding organizational behaviors” (Leidner & Kayworth, 2006; p. 360).

This description supports the concept that organization culture is not simply a list of values the group may hold, but a ranking of those values. Certain organizational culture values may be hidden, even from the group itself, until there is a conflict in which the group participants must choose between two mutually exclusive values. This conflict can arise between stakeholders and technology (Leidner & Kayworth, 2006; Kappos & Rivard, 2008). For example, an organization may value both security and cooperation as part of the organizational culture. However, if a technology, such as an intranet, which is designed to encourage collaboration and information sharing amongst departments, is presented, the technology may be contrary to the value of security. Therefore, the values of security and cooperation are pinned against each other, meaning the organization must rank one of these values as higher than the other in the face of this new technology.

Strategy

Strategy has been defined by multiple researchers in several different contexts. In the field of business management, Henry Mintzberg (1987) defined strategy as a plan, a ploy, a pattern, a position and a perspective. The notion of strategy as perspective suggests a relationship with organizational culture. In Mintzberg's perspective definition, strategy is how the organization perceives the world and the organization's role in the world. He likened the strategy of an organization to the personality of an individual. In this way, the strategy of an organization is "built right into it". The character of an organization leads the organization to act and respond in a certain way to stimuli. Mintzberg noted that other fields have used other concepts to capture this notion. In particular, sociologists refer to the "ideology" of a society, military theorists refer to the "grand strategy" of armies, and anthropologists refer to the "culture" of a society.

This organizational personality embodies the organizational culture and values of the collective (Mintzberg, 1987). For example, if a company values innovation and the first-mover advantage, then the company may be an aggressive risk taker and devote resources and attention to research and design. Another example is if a company values safety, then the company may accentuate safe working environments and infrastructure.

Chen, Mocker, Preston, and Teubner (2010) adopted the perspective definition when defining strategy as, "a shared organizational perspective on setting and meeting organizational goals" (Chen et al., 2010, p. 236). Following these researchers, strategy is defined as the shared organizational perspective on setting and meeting organizational goals based on the organization's culture and values.

Relationship between organizational culture and strategy

Following Husted and Allen (2007), classic literature (Child, 1972; Hambrick & Mason, 1984; Prahalad & Bettis, 1986; Andrews, 1987) and the more contemporary theory, the resource-based view (RBV) of the firm (Barney, 1991), elicit a relationship between strategy and organizational culture. This relationship is based on the qualities of strategy as: 1) reflective of values, 2) shared by the collective, and 3) distinguishing one organization from another.

<u>Reflective of Values</u>

Corporate values historically have been listed as a fundamental pillar of corporate strategy (Andrews, 1987), but these values were later de-emphasized by other researchers (Porter, 1979). The RBV presented by Barney (1991) brought values back into the spotlight by linking

strategy and values through the concept of organizational culture. Barney specifies the strategy of a firm is formed by the external perception of the business environment and the internal resources of the organization. One of the key resources of the organization, in the fact that it is valuable and difficult to imitate, is organizational culture, which is rooted in the dominant values and beliefs of the organization (Barney, 1991).

Strategic choices are made through an evaluative process (Guth & Tagiuri, 1965; Child, 1972; Hedberg & Johsson, 1977, Prahalad & Bettis, 1986, Geletkanycz, 1997). The decision maker considers his or her cognitive base (perceptions about the future, alternatives, or consequences) and his or her values (Hambrick & Mason, 1984). As Hambrick and Mason (1984) point out, values are an important element in organizational strategy; “a decision maker can arrive at a set of perceptions that suggests a certain choice, but discard that choice on the basis of values” (Hambrick & Mason, 1984; p. 195). Therefore, a strategy is derived partially from the consideration and ranking of values. This value ranking is reflective of the value ranking within the organizational culture.

The connection between values and strategy has been empirically supported as well (Geletkanycz, 1997; Kotey & Meredith, 1997; Husted & Allen, 2007). Geletkanycz (1997) tested the effects of managerial values on the strategic choices for an organization. He found the national cultural values of individualism and short-term orientation covary with certain strategic decisions and policies. Kotey and Meredith (1997) tested a similar relationship between values and strategy when they focused on the link between managerial values and organizational strategies. Kotey and Meredith (1997) measured the personal values of small business owners, in terms of entrepreneurial and conservative values, and found specific strategies, in terms of proactive or reactive strategies, are associated with these values. Husted and Allen (2007) found similar results by looking at the corporate responsibility values of a firm and the strategy of the firm. Husted and Allen (2007) use the RBV to hypothesize the relationship between strategy and values and found the organizations with a high value for social responsibility were much more likely than other firms to engage in a socially responsible strategy.

Guth and Tagiuri (1965) summarize the relationship between values and strategy best by stating, "It is quite clear, on the basis of both observation and of systematic studies of top management in business organizations, that personal values are important determinants in the choice of corporate strategy" (p. 123). This concept is consistent with the values-based definition of organizational culture. Strategy is indicative of organizational values and are therefore related to organizational culture.

Shared by the Collective

According to the shared perspective view of strategy, a key component of strategy is the collective feature of strategy. Following this definition, the strategy cannot only be dictated to the organization from the board room, but, in fact, is shared by the members of the organization. Mintzberg (1987) describes this well when discussing the concept, "Strategy is a perspective shared by the members of an organization, through their intentions and/or by their actions. In effect, when we are talking about strategy in this context, we are entering the realm of the collective mind – individuals united by common thinking and/or behavior" (p. 17). Mintzberg is not alone in specifying strategy as collectively shared; Guth and Tagiuri (1965) define strategy as shared when they say strategy is, “an explicit and shared set of goals and policies defining what the company is to achieve and become in the future and how it must operate in order to reach its goals” (p. 127).

The cultural model of strategy formation, offered by Bourgeois and Brodwin (1984), further supports the shared perspective view strategy. Bourgeois and Brodwin (1984) provided the metaphor of upper management playing a coaching role in the organization. The coach may give general direction but then the strategy is taken up by the members of the organization to fulfill the goal. The shared by the collective component of strategy is supported later by Hart (1992) in the discussion of strategic vision and shared values. While top management motivates and inspires the strategy, the strategy centers on the shared perspective and values of organizational members.

By defining strategy as a group-level phenomenon, researchers must consider the perceptions of strategy by organizational members to assess the strategy, and therefore the values of an organization. Perceptions are how individuals assign meaning to their environment (Taylor & Fiske, 1978), so organizational members' perceptions of strategy indicate the way members assign meaning to the strategy of the organization.

Distinguish an Organization

Organizational culture is defined as shared values that distinguish one group from another (Hofstede, 1980; Leidner & Kayworth, 2006). Shared values are ranked according to priority, creating a unique value hierarchy that distinguishes one organization from other organizations with different value hierarchies. As Hedberg and Johsson (1977) discussed, one of the purposes of a strategy is to be an ordering system that maps information into perspectives or worldviews. Roth, Schweiger, and Morrison (1991) posited these worldviews are the dominant general management logic, based on the schemas of the top managers. The schemas are unique to each manager but are reflective of the values, theories, and propositions of the managers.

Empirical research supports the concept that the strategy of an organization differs from another organization in terms of values. For example, in the empirical work of Kotey and Meredith (1997), two distinct strategies were measured, proactive strategies and reactive strategies. Proactive strategies involve initiative-taking and value more integration and risk. Reactive strategies tend to follow the market leaders and do not value innovation greatly. The researchers admit the activities involved with each strategy may intermingle, but a "proactive-reactive continuum" (Kotey & Meredith, 1997; p. 39) exists, which is used to distinguish organizations.

The idea of strategy distinguishing an organization is revisited by Mahoney and Pandian (1992) in their discussion of the RBV and strategic management. As the RBV explains, the strategy of the firm is the distinctive competencies of the organization. These competencies are defined by the rules and routines of the organization and may be based on the values of the organization. The idea of strategy distinguishing the organization is particularly true when considering the information technology (IT) capability of an organization. Bharadwaj (2000) discusses IT capabilities under the RBV lens and finds organizations differentiate themselves on the basis of their IT capabilities. An organization that values IT capabilities, and the strategic value IT provides for the organization, employs a superior IT capability strategy. The superior IT capability strategy is consistent with the value placed on IT and is shared by the collective. Bharadwaj found that organizations may be identified and differentiated based on strategy, such as a superior IT capability strategy.

CONCLUSION

The discussion above supports a relationship between organizational culture and strategy, but the nature of the relationship is still unclear. For example, recall the case of Uber. The aggressive growth strategy was necessary for the firm to survive in the competitive industry of mobile applications, where buyer power is high and the threat of newcomers to the industry is high (Standard & Poor, 2018). This strategy may have attracted, or nourished, a “Hobbesian environment… in which workers are sometimes pitted against one another and where a blind eye is turned to infractions from top performers.” (Isaac, New York Times, 2018). The culture, therefore, reflected the value ranking of growth and revenue targets above integrity.

Yet, one may also argue the culture of the firm led to the aggressive strategy of the firm. Uber was founded by Travis Kalanick and Garrett Camp, who were described as serial entrepreneurs that needed to rebuke conventional wisdom regarding consumer transportation to be successful. As reported by CNN Money, the company was threatened with legal action in several cities during the expansion (Petroff, 2017) forcing the owners and employees to challenge existing market structures. It is possible the organizational culture, which highly ranked the value of innovation, led to an aggressive strategy.

While previous literature can be used to support the relationship between organizational culture and strategy, more research is needed identifying the nature and strength of this relationship. This conceptual understanding is the first step toward understanding the phenomenon of the culture-strategy relationship. Thoughtful, deliberate research design and modeling is necessary to further a consistent theory of systematic effects on organizational culture and strategy.

DECISION SCIENCES INSTITUTE

Risk Assessment of Small Unmanned Aircraft System (sUAS) Operations

Dothang Truong
Embry-Riddle Aeronautical University
Email: truongd@erau.edu

ABSTRACT

The rapid growth of the Small Unmanned Aircraft System sector raises questions about the risk of accidents and incidents in National Airspace System (NAS). The purpose of this research is to propose a process to analyze the Federal Aviation Administration (FAA)'s UAS sighting data using cluster analysis to classify sUAS encounter incidents into different groups based on a set of selected variables. The identified clusters help researchers understand the nature, characteristics, and risk factors of incidents, based on which a risk assessment model can be developed to predict the risk of incidents and collision in NAS.

KEYWORDS: Small Unmanned Aircraft System, risk assessment, cluster analysis, National Airspace System, safety

INTRODUCTION

Small Unmanned Aircraft System (sUAS) is an emerging sector of the aerospace industry and the sUAS market was projected to reach $1.61 billion in 2015 (Visiongain, 2015). The Federal Aviation Administration (FAA) defines sUAS as "a small unmanned aircraft, weighing less than 55 pounds, and equipment necessary for the safe and efficient operation of that aircraft" (FAA, 2016a, p. 42065). sUAS can be used either for recreational or business purposes. The demand for sUAS has grown rapidly. As of September 2016, the FAA has granted the exemption for more than 5500 petitions to allow sUAS to be used for non-recreational purposes, and more than 406,000 people have registered to use sUAS for hobby; and the number will continue to grow (FAA, 2016b). The FAA expects about 1.9 million additional sUAS to be used for hobby in 2016 (FAA, 2015).

In June 2016, the FAA issued the new Small UAS Rule (part 107), which requires sUAS to be registered and sUAS pilots to have the remote pilot airman certificate and pass the FAA approved test if the sUAS is used for business or work. If used for recreational purposes, the sUAS over 0.55lbs must be registered but the operator does not need any permission from the FAA to fly (FAA, 2016c). In order to ensure the safety of sUAS operations in National Airspace System (NAS), the FAA explicitly requires sUAS to stay under 400 feet above ground level (ABL), at speed of no faster than 100 mph, away from airports, and operate during daylight hours. When a sUAS is flown within 5 miles of an airport, the operator must provide the airport and air traffic control tower with prior notice (FAA, 2016a).

Safety of integrating UAS into NAS is one of the FAA's top priorities (FAA, 2016b). Despite strict procedures and regulations issued by the FAA, not all UAS operators adhere to these rules. There have been a number of incidents, in which manned aircraft's pilots and air traffic controller reported their encounters with sUAS in the restricted airspace. Specifically, the UAS sighting report shows that there is 1346 UAS encounter incidents reported from November 2014

to January 2016 (FAA, 2016d). This high number of sightings of sUAS violating the FAA-defined regulations raises questions about the reliable separation of sUAS and manned aircraft needed to ensure safety in the NAS (Gettinger & Michel, 2015).

When a sUAS operates above 400 feet AGL, intentionally or unintentionally, it increases the risk of collision between the sUAS and manned aircraft. Similarly, the collision may occur when a sUAS operates near airports, in which manned aircraft fly at low altitudes while on final approach and during take-off (Gettinger & Michel, 2015). While this risk can be mitigated by methods such as see-and-avoid, in most circumstances flying sUAS below 400 feet AGL or flying more than 5 miles away from an airport will provide necessary separation and consequently avoid the risk of collision (Logan, Bland, and Murray, 2011).

As the number of sUAS used for hobby continues to grow, the number of sightings of violating sUAS will likely to increase; on average, the FAA receives more than 100 incident reports per month (FAA, 2016d). The higher the number of sUAS encounter incidents, the higher the risk of collision in NAS. This raises some important questions: What happens? How do these incidents happen? Why do they happen? How to prevent them from happening again? While the use of sUAS for non-recreational purposes can be controlled at some extent, it is much harder to enforce the rules to individuals using sUAS for fun since they are not required to go through any safety training, to pass any test, or to get the permission from the FAA to fly. Accordingly, in order to find the solution for this problem, it is critical to have a deeper understanding in similarities and differences of these violations and how they occurred.

The purpose of this research is to propose a process for identifying risk factors for sUAS operations in NAS. Specifically, this process can be used to analyze the FAA's UAS sighting data using cluster analysis to classify sUAS encounter incidents into different groups based on a set of selected variables in the dataset. First, data will be collected from the FAA's UAS sighting database. Then, even narratives will be coded into specific variables using two coders with expertise and experience in sUAS and aviation safety, followed by the reliability and validity assessment to ensure the quality of the data. In the next step, a two-step cluster analysis will be performed to classify sUAS encounter incidents into different clusters; each cluster represents a group of incidents sharing common characteristics and risk factors. These clusters will be interpreted, compared, and profiled to provide more details of these risk factors.

LITERATURE REVIEW

The rapid growth of the sUAS sector attracts more attention from the industry. However, the literature on sUAS operations in NAS is limited and inadequate, especially from the recreational sUAS perspective. There seem to be two major trends in sUAS literature. The first trend focuses on see-and-avoid methods. In a NASA research project, McAdaragh et al. (2014) highlighted the importance of the human element in visual line-of-sight operation, which is critical for sUAS not equipped with altitude reporting devices to comply with altitude restrictions. In another study, Williams and Gildea (2014) also emphasized the importance of altitude estimation by a visual observer and how this visual observer could help avoid mid-air collisions between a sUAS and manned aircraft. Loffi et al. (2016) tested the ability of manned aircraft's pilots in visually detecting the distance with a sUAS in visual meteorological condition (VMC) and the time needed to avoid a collision. The results showed that pilots overestimated their distances to a sUAS and did not have adequate time to recognize and respond to the sUAS.

The second trend focuses on risk assessment aspect of sUAS operations in NAS. Atkin (2010) studied risk minimization for sUAS in urban regions. Major causal factors are identified including lost link, in-flight upset, loss of sense-and-avoid, loss of operator situational awareness, and component failure. In another study, Awad (2013) developed crash models for UAS in two scenarios: mid-air collision and ground collision. The mid-air collision model evaluates the impact of VMC at day and night time on the collision incidents. The ground collision model evaluates the effects of factors such as aircraft failure rate, aircraft wingspan, glide angle, and population density on the risk likelihood. However, the study does not differentiate between sUAS and regular sized UAS. Similarly, Sahawneh (2016) developed mathematical models for collision detection and risk estimation for sUAS equipped with a sense-and-avoid system. While the models are proven to be working, the study is limited to the sense-and-avoid technology that can keep the sUAS remain clear and avoid collision with other air traffic.

Overall, although these studies provide interesting findings in the safety of sUAS operations in NAS, they are limited to see-and-avoid methods by the pilots or sense-and-avoid technology. In addition, risk assessment models are developed to predict the collision likelihood for very specific and controlled scenarios, in which sUAS are assumed to have already violated the altitude restriction and entered the restricted airspace. What missing in the literature is the classification of sUAS encounter incidents and how to prevent them from happening again.

There are only two industrial reports that analyzed the UAS sighting data. Gettinger and Michel (2015) analyzed 921 sUAS incidents using descriptive statistics and showed that 90.2% of sUAS encounters occurred above 400 feet AGL and 58.8% of sUAS encounters occurred near airports where UAS operations are prohibited. The Academy of Model Aeronautics (AMA) conducted a similar analysis of UAS sightings, using 582 reports of UAS encounters between August 2015 and January 2016. The report indicated only 3.3% of sUAS encounters were considered “near misses” or “close call”. In addition, the report also noted that the data contained reports of objects other than sUAS, including balloons, birds, or jet pack (AMA, 2016). While these reports provide an overview of UAS encounter incidents using simple descriptive statistics for single variables, they do not establish classification of these incidents based on a variety of related variables and develop profile for each group, a needed base to identify causes and develop effective mitigation strategies.

METHODOLOGY

In order to meet these objectives, this research proposes the following steps in data collection and analysis to ensure the validity of the results.

Data Collection and Preparation

Data will be collected from the FAA’s UAS sightings reports between October 2016 and September 2017 (FAA, 2018). The total sample size is 2094 cases. The data includes four variables: event date and time, city, state, and event report narrative. The report narrative is qualitative data presenting observations by pilot, air traffic controller and citizen in regard to sUAS encounters with manned aircraft, helicopters, and airports (FAA, 2016b). The data is anonymous and has no personal or identification information of the individuals reporting the incidents. Hence, there is no concern of ethical issues.

Two data sets will be combined into one data file and sorted by date and time. MS Excel will be used for data exploration and preparation purpose. In order to ensure the usability of the data, the data will be examined carefully to identify unusable or irrelevant data including

- False alarm events are events in which the encounter with sUAS was reported but then marked false alarm. These events will be deleted from the data.
- Since this research focuses on sUAS, any sightings of other objects will be deleted.
- Any reports that have too much missing information, which make them less meaningful, will be deleted.

Data Coding

Since even narratives in the sighting data are qualitative and unstructured, it is important to filter the data and code it into separate variables for the analysis purpose. First, event narratives will be examined carefully to identify important variables for analysis. Second, the data will be coded to these identified variables.

A preliminary analysis of the data suggests the following variables. The list of variables will be examined and validated before the coding process.

- Incident date
- Incident time
- Incident location
- UAS type
- Number of involved UAS
- UAS color
- Type of incident
- Violation detail
- Injury or hazards
- Incident altitude
- Airport
- Distance from airport
- Type of manned aircraft
- Manned aircraft operation
- Distance from manned aircraft
- Evasive action
- Law enforcement notification

Code Reliability and Validity Assessment

Since the data is coded from event narratives, it is important to ensure the reliability and validity of the data. Data reliability refers to the extent to which data consistently represents what is intended to measure (Hair et al., 2010). In order to test the reliability, a second coder will be asked to recode a sample of data randomly selected from the dataset (Bazeley, 2013). The coders must have understanding of sUAS operations and aviation safety. Then the codes will be compared, and Cohen's Kappa coefficients will be used to evaluate the inter-coder reliability of the codes (Landis and Koch, 1977; Cohen, 1960; Fleiss, 1981; Gwet, 2014). Kappa coefficients will be interpreted following the general guidelines by Fleiss (1981). Specifically, a Kappa coefficient above 0.75 indicates an excellent level of agreement; a coefficient between 0.4 and 0.75 indicates a fair to good level of agreement; and a coefficient below 0.4 indicates a poor level of agreement. If the inter-coder reliability is not satisfactory, the codes will be revised and the reliability assessment will be repeated.

Data validity refers to the extent to which data correctly represents what is intended to measure (Hair et al., 2010). The validity will be assessed through the auditing process, in which a set of criterion codes will be set in advance. Then the actual codes will be compared with the criterion codes, and Kappa coefficients will be used to evaluate the agreement between these codes

(Crittenden and Hill, 1971; Bazeley, 2013). The process will continue until the validity is satisfactory.

Additional Data Collection

In order to identify clusters, additional information may be needed, for example, the size of the airport, size of manned aircraft, color, and operation type, etc. The data will be useful for cluster comparison and cluster profiling. Based on the name of the airport and aircraft type indicated in the report, these additional data will be collected from external sources.

Data Analysis

Variable Selection

Classification of sUAS encounter incidents will be performed based on their commonalities in various variables. Based on the literature review, a selected set of variables will be identified for this purpose. A preliminary list of these variables includes incident altitude, distance from manned aircraft, distance from airport, airport size, manned aircraft size, etc. The variables will be reviewed and finalized by subject matter experts in sUAS and aviation safety.

Cluster Analysis

Cluster analysis is a multivariate statistical technique that classifies objects based on a set of user-selected variables (Hair et al., 2010). First, missing values and outliers will be examined and handled. And then, the multicollinearity assumption will be evaluated to meet the requirement of the test, and the data will be standardized as needed. Cluster analysis will be performed in two steps.

At Step 1, a hierarchical cluster analysis will be conducted using SPSS 24 to identify the number of cluster based on the selected variables. Hierarchical cluster analysis is a stepwise clustering procedure that combines the objects into clusters. The result is the dendrogram showing the formation of the clusters. In this step, the Ward's method will be used as the clustering algorithm to generate clusters that are homogenous and relatively equal in size, and squared Euclidean distance will be used to measure the similarity (Milligan, 1979; Jain et al., 1999; Hair et al., 2010).

At step 2, a non-hierarchical cluster analysis will be conducted to fine-tune the cluster solution identified in step 1. Non-hierarchical method has an advantage of being able to "better optimize cluster solutions by reassigning observations until maximum homogeneity within clusters is achieved" (Hair et al., 2010, p.531). K-means algorithms will be used to partition data into "a user-specified number of clusters and then iteratively reassign cases to clusters until a numerical goal related to cluster distinctiveness is met" (Hair et al., 2010, p.485).

Cluster Validation

The cluster validity will be assessed by comparing the clusters based on variables that have a theoretically based relationship to the clustering variables but are not included in the cluster solution. MANOVA test will be used for this purpose. First, the criterion validity variables will be selected as dependent variables (for example, incident time of day, hazard, location, etc.). Second, assumptions for MANOVA (independence, homoscedasticity, normality, linearity and

multicollinearity) will be tested. Then, the multivariate and univariate testing will be performed to compare group differences in regard to the criterion validity variables. If the results show the effect of cluster solution on these dependent variables, then it can be concluded that there is enough evidence of criterion validity.

Cluster Profiling

The meanings of clusters will be interpreted by analyzing the cluster size and the pattern of cluster means and mean-centered values of selected variables including characteristic variables and risk factors. These groups will be presented with selected names and characteristics; each group represents incidents with common characteristics and risk factors. Qualitative data will be examined to provide further explanation for the cluster results.

CONCLUSIONS

This research promises both theoretical and practical contributions to the field of sUAS operations and safety. From the theoretical perspective, the proposed process fills the gap in the literature by identifying risk factors for sUAS operations in NAS. The research will use the FAA's UAS sighting data, which takes into account the large number of sUAS used for hobby; something has been missing in the current sUAS literature. The cluster analysis will classify sUAS encounter incidents into groups based on their common characteristics and risk factors, which provide a big picture of what violations and how they happen as a high number of sUAS integrate into NAS.

From the practical perspective, the results of this process will provide the FAA and stakeholders a clear picture of safety concerns when more users purchase and fly sUAS for hobby. The high number of sightings of sUAS violating the FAA's sUAS procedures and regulations may increase the risk of collision in NAS. The clusters will allow the FAA to understand the nature, characteristics, and risk factors for each group of incidents, based on which they develop necessary mitigation strategies to prevent further violation of the FAA's sUAS rules and regulations. They can also be used as the base to identify causes of sUAS encounter incidents and develop a risk assessment model to predict the risk of incidents and collision in NAS.

DECISION SCIENCES INSTITUTE
Risk Management for Funds: A Decision Theoretic Approach

Michel Verlaine
Michel.verlaine@icn-artem.com

ABSTRACT

The aim of this paper is to develop an integrated portfolio optimization framework that is consistent with empirically documented investor behaviour as well as market practice in the asset management industry. We develop a top-down approach where risk measures as well as benchmarks of investment funds can be linked to features of behavioural theories such as Prospect Theory. We show how a risk budgeting and risk management process that is consistent with Behavioral Portfolio Theory can be developed.

KEYWORDS:: Risk Management, Portfolio Selection, Decision Theory.

JEL classification: G11, D81, C11.

INTRODUCTION

In theory, investors knowledgeable of their risk aversion should choose their portfolios by either maximizing return for a given risk or minimizing risk for a target return. Within the standard portfolio framework, risk is typically measured with the standard deviation of returns. There are two issues with this approach. First, empirical evidence points out that investors' behaviour is not consistent with Expected Utility. Research by (Bruhin et al, 2010) indicates that 80% of individuals distort probabilities as suggested by (Kahneman & Tversky, 1979;1992). This behaviour is also in line with recent decision theoretic research on behaviour under ambiguity, when there is uncertainty concerning the probabilities (Gilboa & Schmeidler, 1989; Schmeidler, 1989). Second, in practice, most of the investments are managed by asset management companies that act as agents for the investors. This creates a layer of asymmetric information, as the investor does not directly observe, neither the skills, nor the effort of the asset manager. Issues related to fund delegation problems and asymmetry of information are closely related (Stracca, 2005) to the current EU regulation for mutual funds, where the board is responsible for the supervision of the risk management process and the contracts with the service providers of the fund.

In principle, the Board members should devise rules that are consistent with preferences exhibited by the investors. This implies that they have to develop risk management principles and compensation rules. Risk principles are discussed in (CMRA, 2008). Besides broad governance principles and the focus on non-market risks (operational, etc.), the document indicates that the main risk consists in deviations of the fund's performance from client expectations. In principle, the benchmark return of the fund should be in line with client expectations as well as the risk profile of the fund. The asset manager's task is then to limit downside risk with respect to the benchmark.

There is also a greater awareness that risk management should be integrated with portfolio optimization (CMRA, 2008). In a sense, risk management generates alpha. This implies that the risk budgeting process should be integrated with the portfolio optimization. In the standard mean-

variance framework, a benchmark is selected on the efficient frontier, and the manager has a constraint on the tracking error variance (TEV). The manager has a constraint on the TEV and is supposed to maximize alpha under this constraint (Berkeelar et al, 2006). The Risk Management department also fixes limits on the Value at Risk (VaR). Again, there are a few issues with this approach. First, as shown by (Admati & Pfleiderer, 1997) the existence of a benchmark is inconsistent with expected utility. Second, returns are not normally distributed (Embrechts et al, 2002).

Research in Decision Theory and Behavioural Economics documents that individuals evaluate risk with respect to a subjective reference level. Experimental evidence by (Kahneman & Tversky, 1997;1992) suggests that investors analyse losses and gains with respect to a benchmark in a non-linear way. Moreover, investors are loss averse which implies that losses with respect to the reference level are penalized heavily. Moreover, investors transform the so-called objective probabilities in an inverse S-shaped way (Prelec, 1998; Bruhin et al*,* 2010). Finally, investors consider different asset classes as individual portfolios, a phenomenon called Mental accounting. This is an instance of the heuristics used by individuals (Gilovich et al, 2008). (Shefrin & Statman, 2000) develop a framework that is consistent with empirically documented investor behaviour. Their framework rationalizes the existence of different asset classes and investment styles. Moreover, return distributions are analysed along three dimensions: Security, Aspiration and Potential. Aspiration indicates what the investor expects. Security, implies limits on losses and potential indicates that an investor pays for small probabilities of very high payoffs.

The aim of this paper is to develop an integrated risk management framework that is consistent with empirically documented investor behaviour. Within our framework, a subjective benchmark is determined by the subjective reference level of the investors. The subjective benchmark is then mapped on risk factors to determine the relevant market or return-based benchmark. The setting of risk limits can then be set as a function of the loss aversion of investors. Constraints are typically set in terms of VaR, but recent evidence points out that expected shortfall is more robust and reduces the incentives for the managers to take extreme risks not measured by VaR (Basak & Shapiro, 2001). Moreover, VaR is not sub-additive which is an issue essentially when different sub-compartments of the fund are managed by different managers. Sub-additivity, of course, depends on the type of portfolio considered and can be tested by econometrically analyzing the tails of the distributions (Garcia et al*,* 2007).

Risk decomposition is typically implemented through a marginal risk decomposition. First, note that VaR has the property that if each subposition is multiplied by a given constant , then the total VaR increases by this given constant. This property based on Euler's law enables us to measure marginal (sometimes called incremental) contributions by portfolio positions (Tasche, 2008; Kalkbrener, 2005). If we evaluate the derivative of VaR with respect to each portfolio position and weigh the latter by the respective position, we get the total value of VaR. We can thus evaluate the portfolio adjustments that respect the VaR constraints and determine the respective contributions to VaR. For simple frameworks with a few assets the marginal VaR calculations are straightforward, but for realistic environments a risk mapping has to be implemented. The latter consists in mapping risk properties on representative asset classes.

Although the risk budgeting approach is well-known and is part of market practice, recent developments that suggest approaches consistent with return statistics are less known. As already alluded to, when the tails of the return distributions are too heavy, VaR is not sub-additive and cannot be used in the risk budgeting process. In that case coherent risk measures such as shortfall measures (Acerbi, 2002) can be used to develop a coherent risk budgeting process (Dorfleiter et

al, 2008). Such an approach can then be used to develop an integrated risk management and portfolio optimization process that is consistent with leptokurtic return distributions.

In our framework, risk will be analyzed in terms of deviations with respect to a benchmark, the latter being either return-based or model-based. The measures that will be considered are actually deviation measures as the reference level is not fixed. There is, however, a clear and simple mapping between deviation measures and risk measures. Bertsimas *et al* (2004) have suggested shortfall measures as risk measures to be used in an optimizing framework. Shortfall measures evaluate deviations with respect to the benchmark under extreme market movements. We show how that measure can be used as a risk management tool and in the risk budgeting process.

Risk budgeting presumes that risk can be consistently aggregated. The total risk measured has to equal the sum of the different measured risks of the sub-components taking into account diversification effects (Kalkbrener, 2005). In order to be effective in a risk aggregation process, a measure needs to respect some of the coherence axioms (Atzner et al, 1999), notably positive homogeneity and sub-additivity. The Euler principle can then be used to measure the marginal contributions to risk of the different sub-components (Tasche, 2008). The shortfall measure is sub-additive and positively homogeneous and there thus exists a linear diversifying capital allocation. These characteristics enable the board to set a top-down risk management process making the sure the total risk budget is respected.

Our roadmap is the following. We start with a short overview of experimentally documented investor behaviour. We then analyse the portfolio delegation problem of the investor, which is an institutional feature of the asset management industry. This leads to the conclusion that the choice of the benchmark is an important risk management that can be linked to investors' subjective aspiration levels. We then discuss the types of measures to be used to create a top-down risk budgeting approach that is consistent with an investor's aggregate risk target. Finally, we discuss the application of the top-down optimization process.

INVESTOR BEHAVIOUR

Standard Markowitz portfolio theory presumes that investors are EU maximizers with a concave Bernouilli utility function. The decision theoretic and behavioral economics literature, however, highlights that most individuals' behavior is not consistent with the EU hypothesis. Recent experimental evidence is provided in (Bruhin et al, 2010). (Kahneman & Tversky, 1979; 1992), document that individuals evaluate gains and losses with respect to a subjective reference level. Their so-called value function is concave on gains and convex on losses. Moreover, investors are strongly averse to losses. This has led to the following well-known specification:

$$v(w-\overline{w}) = \begin{cases} (w-\overline{w})^{\alpha} & if \quad w \geq \overline{w} \\ -\lambda(w-\overline{w})^{\beta} & if \quad w < \overline{w} \end{cases} \tag{1}$$

Where *w* and $\overline{w}$ respectively denote the realized wealth and the subjective reference wealth level. λ is the loss aversion parameter and is typically calibrated to 2.25. α and β are generally calibrated to 0.88.

Investors also transform observed probabilities and the way these probabilities are distorted is well-documented (Tversky & Wakker, 1995; Wakker, 2010; Prelec, 1998). Investors typically apply inverse S-shaped functions, called probability weighting functions, to the cumulative probability distribution. Recent research indicates that such behavior could stem from a kind of ambiguity aversion. Frameworks to treat ambiguity have been developed by (Gilboa & Schmeidler, 1989;

Schmeidler, 1989). Those authors suggest that DMs maximize EU under the worst case scenario given sets of probability distributions. (Schmeidler, 1989) shows that relaxations of the independence axiom lead to a preference representation with respect to a non-additive set measure. This model is known as the Choquet Expected Utility (CEU) model. (Ghirardato et al, 2004) suggest to model behavior in the face of ambiguity with a weighted $(\alpha, 1-\alpha)$ combination of the worst and the best scenarios. This has led to the $\alpha - MEU$ approach where α is interpreted as a parameter of ambiguity aversion. Recently, (Amarante, 2009) shows that $\alpha - MEU$ can be mapped on CEU representations. Finally, a last dimension that is often forgotten in the literature, is that DMs also typically consider prospects in different mental accounts. This opens the door for multiple investment styles and funds. This provides an explanation of the asset Allocation Puzzle (Canner et al, 1997). The academic literature, however, has faced difficulties to integrate those behavioral aspects into an operational portfolio optimization framework and this is the task we try to solve here.

(Shefrin & Statman, 2000) develop a portfolio optimization approach that is consistent with empirically documented behavior. They argue that there are three dimensions that matter for the DM: *potential*, *aspiration* and *security*. *Aspiration* indicates the level of wealth expected or desired by the DM. *Security* refers to the desire to limit losses with respect to the aspiration level. Finally, *potential* indicates that DMs want to invest a fraction in assets that have a very small probability of very high payoffs such a lottery tickets. This is in line with the well-documented fact that DMs buy insurance as well as lottery tickets. The three dimensions are linked to different behavioral aspects of prospect theory. Besides behavioral aspects, institutional features are also important to take into account and are actually conditioned by behavioral features. (Verlaine, 2016) provides a detailed analysis of this topic. As investors are deviating from the standard rationality paradigm, they are not investing their money directly but delegate the investment to managers, an issue analyzed in the next section.

THE PORTFOLIO DELEGATION PROBLEM

As the optimal contracts with the asset managers bear a close relationship with the risk management of the fund, behavioral aspects also influence the optimal contract. There has been an interest, quite recently, in the delegation issues in portfolio management. For a good overview consult (Stracca, 2005). The delegation problem is typically modelled through a Principal-Agent relationship. The investor is the Principal and the Agent is the Asset Manager. The portfolio delegation literature focuses on contractual issues. In a first step, the investors face a set of Managers and have to select the good ones that have the skills to generate outperformance. In a second step, the contract and the compensation rules have to incentivize the Manager to spend maximal effort to generate outperformance. The investors are thus supposed to structure the contract in such a way that 3 conditions be respected. First, the managers with superior skills are selected. Second, the contract incentivizes the Asset Manager to generate risk-adjusted outperformance once the contract is signed. Finally, the risk-sharing between the investor and the Asset Manager should also be optimal.

Formally, the maximization problem takes the following form.
In the first order the Principal maximizes his expected utility given by :

$$\begin{aligned} &Max_f\, EU\big((1+R) - f(R)\big) \\ &with\ R = w\big(S(e)\big)R_p \end{aligned} \tag{2}$$

He thus maximizes expected utility of gross return minus the fees. But in order to hire a manager he also needs to be sure that the expected utility of the return is higher than what he gets if he simply invests in a passively managed fund. Hence, the following participation constraint:

$$EU\left(1+R-f\left(R\right)\right)\geq EU\left(1+R_u\right) \tag{3}$$

So basically, the EU of the gross net of fees return has to be higher than what the investor gets when he invests in an Exchange Traded Funds, for instance.
The manager also maximizes utility and faces a participation contraint.

$$e,w\left(S\right)=\arg\max\left[EU\left(f\left(R\right)\right)-h\left(e\right)\right] \tag{4}$$

So the manager chooses an optimal effort level and portfolio combination so that he maximizes EU of fees perceived minus his disutility of effort *h(e)*. However, the following participation constraint

$$EU\left(f\left(R\right)-h(e)\right)\geq U^{*} \tag{5}$$

indicates that he is only working for the investors if the expected utility of the fee minus disutility of effort is higher than the utility he gets in another job.
Different fee functions have been suggested, but they all face the drawback that, due to the fact that there is no direct relationship between effort spent by the manager and portfolio return, it is extremely difficult to make sure the manager spends effort and that the returns are due to luck or hidden risks. Basically, there are two types of contracts, linear and non-linear, which we analyse below.

The linear compensation contract takes the following form:

$$\begin{aligned} &f\left(R\right)=C+B\left(R-b\right)\\ &with\ C,B>0 \end{aligned} \tag{6}$$

b is a subjective benchmark that is known in advance and it can be either stochastic or fixed. Our approach implies the evaluation of this subjective benchmark for a prospect theory type decision maker and then the choice of a investment fund becnhmark that has the same expected return. Typically Mutual Funds are benchmarked with a stochastic market based benchmark, generally given by an index that reflects the strategy of the fund. Hedge Funds, however, are mostly benchmarked with an absolute target which is given by the Hurdle rate. Hedge Funds often also have so-called High-water mark clauses which specify that past losses with respect to the benchmark have to be made up before the variable fees are paid. As shown by (Brown & Goetzmann, 2003) this creates path dependent option like features which are difficult to analyse within this framework. Within the linear contract framework, a higher B induces the manager to spend more effort but also to take more risk which will increase the required flat payment C.

In the standard agency setting, there is a trade-off between risk sharing and effort inducement.
However, in a portfolio delegation framework this kind of contract doesn't induce the manager to work harder. The manager has complete control over his response to signals (his information). This is known as the 'irrelevance result'. This result holds irrespective of whether the contract contains a benchmark. A benchmark, unless it is the optimal conditional portfolio, is a distorting factor.

The non-linear compensation contract has also been suggested as an optimal compensation rule:

$$f(R) = C + B(R-b)^2 \quad with \quad C, B > 0 \tag{7}$$

Here, compensation depends in a quadratic way on the relative performance compared to a benchmark. It can induce the manager to undertake more effort. However, if the manager is allowed to respond to the signal in a nonlinear way, the 'irrelevance result' still holds. Hence, restrictions have to be imposed on the manager's trading set. This is an interesting result in terms of industry regulation.
Finally, linear vs. non-linear asymmetric contracts

$$f(R) = \begin{cases} \mathrm{C} + \mathrm{B(R - b)} \text{ if } \mathrm{R} > \mathrm{b} \\ 0 \text{ if } \mathrm{R} < \mathrm{b} \end{cases} \tag{8}$$

Symmetric contracts penalize negative outcomes in the same way as they reward positive outcomes, while for convex contracts the marginal reward is higher the better the performance compared to a benchmark. Symmetric linear contracts are typical of the (regulated) hedge fund industry, whereas call-option contracts are more widespread in the hedge fund industry.

The irrelevance result and the fact that restrictions on the trading set have to be imposed rationalizes the recourse to risk management and risk limits. The Board's responsibility in terms of risk management is thus to select a benchmark that is in line with the risk profile of the fund and determine the risk limit or limits of the fund or positions. The foregoing developments imply that the Board has to develop a top-down approach to the risk management and measurement and this is the issue that we aim to address.

The function of the benchmark is also to distinguish performance related to systematic risk factors from performance due to superior selection skills. From an operational viewpoint, the role of the benchmark is also to control the deviation of the portfolio with respect to the benchmark. As pointed out in (CMRA, 2008), the main risk is that the performance will fall short of the benchmark. Finally, benchmarks are also often used to compare fund performance to the benchmark. Correct benchmarking is an issue and (Sensoy, 2009) suggests that approximately 35% of benchmarks are not in line with the risk profile of the fund.

Deviations from the benchmark are typically controlled through the trading error variance (TEV). This is in line with the quadratic compensation rule above. If we apply the expectation operator to the quadratic compensation rule we get:

$$\begin{aligned} E[f(R)] &= C + BE\left[(R-b)^2\right] \\ &= C + B \times TEV \end{aligned} \tag{9}$$

And the compensation thus depends on the TEV. Even though this approach is quite used in practice, the TEV evaluates positive and negative deviations from the benchmark in the same way.

We argue that the benchmark selection should be integrated with the risk management process and be linked to empirically documented risk behavior. As the benchmark measures risk-adjusted performance, the benchmark should be in line with the reference risk measure and be used to determine the global risk exposure of the fund. For instance, if the global exposure of the fund is measured with the Value at Risk (VaR, henceforth), then the benchmark's expected return should be in line with the risk implied by the VaR. The expected return of the benchmark will be

determined by an equilibrium asset pricing model. If returns are normally distributed, the VaR being the product of volatility with a multiplying factor, the benchmark could be selected by construction of an efficient frontier in the mean-variance space and by determining the equilibrium expected return for the respective volatility of the funds risk profile.

The multivariate normality of returns, however, has been questioned by Embrechts *et al.* (2002). This has led to the application of new risk measures, notably VaR and Expected Shortfall (ES). The benchmark should thus be deduced from equilibrium relationship between return and one of the chosen risk measures. The choice of the risk measure, however, depends on the aggregation properties and here the notion of coherency of the risk measure plays a major role.

RISK MEASURES AND AGGREGATION

(Artzner et al., 1999) derived the axioms that a well-behaved risk measure should respect. . A coherent risk measure $\rho(X)$ is a real valued function defined on the space of real-valued random variables which satisfies the following axioms:

- Translation invariance: $\forall c \in \Re, \rho(X+c) = \rho(X) - c$
- Sub-additivity: $\forall X, Y \ \rho(X+Y) \leq \rho(X) + \rho(Y)$
- Positive homogeneity: $\forall \lambda \geq 0, \ \rho(\lambda X) = \lambda \rho(X)$
- Positivity: $X \geq 0, \ \rho(X) \leq 0$

All those axioms have a specific interpretation. Translation invariance, also called cash-invariance, implies that the risk can be interpreted in terms of capital requirements. If an investor puts the amount $\rho(X)$ of cash in the portfolio, the portfolio becomes riskless given the risk measure used ρ. Positivity, of course, just implies that a higher payoff profile has less risk. A measure that satisfies both axioms is called a monetary measure of risk (Föllmer & Scheid, 2008). Positive homogeneity means that an increase in all the portfolio positions by λ also leads to a linear increase in the risk involved. This axiom has actually been questioned on the grounds of liquidity risk. Finally, sub-additivity which is probably the most important axiom implies that the risks of a portfolio are less than the sum of individual risks. A well-behaved risk measure should thus model diversification effects.

This last property is actually important to decentralize the task of managing the risks arising from a collection of different positions. Separate risk limits can be set for different positions or sub-compartments making sure that the risk of the aggregate position is bounded by the sum of individual risk limits. With that respect, it is well-known that VaR defined as

$$VaR_{\alpha}(X) = \inf\left\{m \in \Re \middle| P[X+m] < 0 \leq \alpha\right\} \tag{10}$$

is not sub-additive.
Expected shortfall given by

$$ES_{\lambda} = \frac{1}{\lambda}\int_0^{\lambda} VaR_{\alpha}(X)d\alpha \tag{11}$$

is a coherent risk measure and can be used as an effective risk measure to set decentralized risk limits. ES also has other interesting properties in terms of manager control and robustness. As highlighted by (Basak & Shapiro, 2001), risk limits in terms of VAR may lead to portfolio concentrations and increases of extreme risks. ES measures can also be deduced from robust decision making in the face of uncertainty (Föllmer & Schied, 2004). The development of coherent

risk measures has also led to research on coherent capital allocation which is of particular interest here.

Coherent capital allocation has been a research topic since the seminal work of (Artzner et al, 1999). The first major contribution to the issue of coherent economic capital allocation was provided by (Denault, 2001). More exactly, the problem addressed is the following. Adding different business units or sub-portfolios leads to diversification effects, thus the sum of the risks of the subcomponents is larger than the risk of the sum of the subcomponents. However, the benefits of risk reduction due to the portfolio composition have to be divided among the different subcomponents. Denault applied concepts from cooperative game theory to a coherent approach to the allocation of risk capital.

(Kalkbrener, 2005) develops an axiomatic approach based on subadditive and positively homogeneous risk measures. The suggested axiomatization presumes that the risk capital allocated to a subportfolio *i* depends exclusively on the distribution of *i* and the distribution of the whole portfolio, not on the decomposition of the rest. The axiomatization of Kalkbrener is based on the assumption that capital allocated to subportfolio P_i only depends on P_i and the aggregate portfolio *P*, but not on the decomposition of the rest of the portfolio.

$$P - P_i = \sum_{i \neq j} P_j \tag{12}$$

The capital is thus represented by a function $\Lambda(P_i, P)$. If we consider an aggregate risk measure $\rho(P)$, fixed by a decision maker for instance, then Λ is a capital allocation with respect to $\rho(P)$ whenever

$$\Lambda(P, P) = \rho(P) \tag{13}$$

hence when the capital allocated to the aggregate portfolio equals the risk capital of the aggregate portfolio.

Kalkbrener suggests three axioms for capital allocations. First, linear aggregation makes sure that the sum of the risk capital of the sub-portfolios equals the risk capital of the aggregate portfolio. Second, there are some diversification effects. Third, continuity ensures that small portfolio adjustments have a limited impact of the risk capital of the sub-portfolios. Those axioms uniquely characterize capital allocations. Also, for a given risk measure ρ there exists a capital allocation Λ_ρ that satisfies the linear aggregation and diversification axioms if and only if ρ is sub-additive and positively homogeneous, that is ρ satisfies:

$$\begin{aligned} \rho(P_i + P_j) &\leq \rho(P_i) + \rho(P_j) \\ \rho(\alpha P_i) &= \alpha \rho(P_i), \ \forall \alpha \geq 0 \end{aligned} \tag{14}$$

Kalkbrener proves that the existence of directional derivatives of ρ at a portfolio *P* is a necessary and sufficient condition for Λ_ρ to be continuous at *P*.

Kalkbrener then shows that:

- If there exists a linear, diversifying capital allocation Λ with respect to ρ, then ρ is positively homogeneous and sub-additive.
- If ρ is positively homogeneous and sub-additive then Λ_ρ is a linear, diversifying capital allocation with respect to ρ.

One of the challenges is to develop a top-down risk management process consistent with institutional features and loss aversion as well as probability weighting. For this, specific properties of the risk measures are needed.

PREFERENCES AND SHORTFALL MEASURES

The foregoing developments warrant the recourse to alternative risk measures such as expected shortfall. Although this type of measures have been known for some time, they have not been used in practice till recently. (Bertsimas et al, 2004) were the first to analyse the use of shortfall measures in an optimizing framework. Recall, that our aim is to develop a portfolio optimization approach that is consistent with investor behaviour exhibiting loss aversion and probability weighting. As discussed earlier, (Shefrin & Statman, 2000) suggest that such an investor maximizes his portfolio along three dimensions *potential*, *aspiration* and *security*. *Aspiration* indicates the level of wealth expected or desired by the DM. *Security* refers to the desire to limit losses with respect to the aspiration level. Finally, *potential* indicates that DMs want to invest a fraction in assets that have a very small probability of very high payoffs such a lottery tickets. Note that the *potential* dimension can be implemented through Core-Satellite approaches, where most of the investments are concentrated in a standard fund and a very small fraction of the investment is invested in satellites of Hedge Funds. We thus concentrate on the *aspiration* and *security* dimension. *Aspiration* then determines the benchmark of the fund, while *security* implies downside restrictions of deviations with respect to the benchmark.

Let's now consider a vector of returns R, with mean

$$E(R) = \mu \tag{15}$$

and a vector of portfolio weights **ω**. As we will concentrate on risk measurement, the mean return will be fixed at a target aspiration rate.

$$E\left[R^T \omega\right] = R_p \tag{16}$$

We could now minimize over **ω** the (1-α) confidence level

$$VaR_\alpha(\omega) := \mu^T \omega - q_\alpha\left(R^T \omega\right), \ \forall \alpha \in (0,1) \tag{17}$$

where $q_\alpha\left(R^T \omega\right)$ is the α-quantile of the distribution of the portfolio return $R^T \omega$. A natural approach of portfolio optimization would thus consist in maximizing VaR_α as a function of portfolio weights. As VaR_α is not a convex function of portfolio weights this leads to computational difficulties (see Lemus *et al.* (1999)).

Issues with sub-additivity also lead us to use shortfall to impose limits on deviations with respect to the benchmark. We thus suggest to minimize the shortfall at the risk level α:

$$s_\alpha(\omega) := \mu^T \omega - E\left[R^T \omega \middle| R^T \omega \le q_\alpha\left(R^T \omega\right)\right], \ \forall \alpha \in (0,1) \tag{18}$$

$s_\alpha(\omega)$ basically measures the expected losses below the expected return that might occur whenever the portfolio drops below the α-quantile. Given those results we are led to focus on shortfall minimization.

It is interesting to discuss the properties of the shortfall risk measure. As shown by Bertsimas *et al.* (2004) whenever returns are elliptically symmetrically distributed, the shortfall measure is proportional to the standard deviation. It is thus equivalent to minimize volatility or shortfall.
As discussed in the next section shortfall measures have "good" aggregation properties that can be used in a risk budgeting process.

RISK BUDGETING PROCESS

The risk measure originally introduced by (Artzner et al,. 1999) was not expected shortfall but Tail Conditional Expectation

$$TCE_\alpha(\omega) = -E\left[R^T\omega \middle| R^T\omega \le q_\alpha\left(R^T\omega\right)\right] \tag{19}$$

Which is a coherent risk measure.

As shortfall is to be used in portfolio optimization it integrates the expected return and shortfall can be expressed as the following way:

$$s_\alpha(\omega) = \mu^T\omega + TCE_\alpha \tag{20}$$

Due to this mean-adjustment expected shortfall violates translation invariance and positivity.
Shortfall also has very useful mathematical properties. Most notably, an important issue for portfolio optimization is that it is convex in the portfolio weights ω.
Moreover:

- $s_\alpha(\omega) \ge 0\ \forall\omega and\ \alpha \in (0,1)$. $s_\alpha(\omega)$equals 0 for some ω and α if and only $R^T\omega$ is constant with probability 1.
- $s_\alpha(\omega)$is positively homogeneous : $s_\alpha(\lambda\omega) = \lambda s_\alpha(\omega),\ \forall\lambda \ge 0$
- If the density of returns is continuous: $\nabla_\omega s_\alpha(\omega) = \mu - E\left[R \middle| R^T\omega \le q_\alpha\left(R^T\omega\right)\right]$

Those are actually the properties needed to develop a linear diversifying capital allocation process. The properties are also useful to optimize portfolios.

Shortfall can be estimated quite easily. Consider a sample of T returns of the portfolio ω. The return at date t is given by $r_t(\omega)$and the returns can be sorted in increasing order:

$$r_1(\omega) \le r_2(\omega) \le \ldots \le r_T(\omega) \tag{21}$$

Consider $K = [\alpha T]$, the number of returns below a certain level, the non-parametric estimator of $s_\alpha(\omega)$can be represented thus:

$$s_\alpha(\omega) = \omega^T\mu - \frac{1}{K}\sum_{j=1}^{K} r_{(j)}(\omega) \tag{22}$$

Sometimes α is too small and extreme value theory (EVT) can be used to extrapolate outside the observed sample. In order to optimize the portfolio the following mean-shortfall optimization can be solved.
Minimize $s_\alpha(\omega)$
subject to $\omega^T\mu = r_p\ and\ e^T\omega = 1$
where e is a column vector of ones.
Bertsimas et al. (2004) show that the minimum α-shortfall frontier is convex. In presence of a riskless asset the minimum shortfall is defined from:
Minimize $s_\alpha(\alpha)$
Subject to $\omega^T\mu + (1 - e^T\omega)r_f = r_p$

(Tasche, 2000) has shown that the minimum shortfall frontier in the $(r_p, s_\alpha(\omega))$ space, with $r_p \geq r_f$, is a ray starting from the point $(r_f, 0)$ and passing through the particular point $(r_p^*, s_\alpha^*(\omega))$ with $r_p^* \geq r_f$.

The optimal solution satisfies

$$\mu_j - r_f = \beta_{j,\alpha}(\omega_\alpha)(r_p - r_f), \quad j = 1,...,n \tag{23}$$

With

$$\begin{aligned} \beta_{j,\alpha}(\omega) &= \frac{1}{s_\alpha(\omega)} \times \frac{\partial s_\alpha(\omega)}{\partial \omega_j} \\ &= \frac{\mu_j - E\left(R_j \middle| \omega^T R \leq q_\alpha(R^T\omega)\right)}{\omega^T \mu - E\left(\omega^T R \middle| \omega^T R \leq q_\alpha(R^T\omega)\right)} \end{aligned} \tag{24}$$

$\beta_{j,\alpha}$ is called the shortfall beta and can be interpreted as the relative change in shortfall when varying the weight of asset j. Note that as with the standard beta.

$$\sum_{j=1}^{n} \omega_j \beta_{j,\alpha}(\omega) = 1 \tag{25}$$

This is a very useful property as it gives a decomposition of the portfolio shortfall into individual assets' contributions. Note that $\beta_{j,\alpha}$ depends on α and this may be used to quantify the empirically observed fact that components of the market or portfolio become more dependent on the market when the latter is more volatile.

OVERVIEW OF THE TOP-DOWN RISK MANAGEMENT PROCESS.

Consider a board of directors that supervises the management of a fund with different asset classes. These asset classes can be managed by different asset managers. As discussed in section 4 and 5, the first foremost element of the risk management process is the right choice of a benchmark. Typically, the board then chooses either a market index that is the most representative of the aggregate investment strategy of the fund, or a return-based benchmark. For Mutual Funds different models could be used, but market standard has become the (Carhart, 1997) 4-factor or (Fama & French, 1993) 3-factor model. Carhart's model is used extensively as it encompasses the Fama-French model. The specification is the following:

$$r_{it} = \alpha_i + \beta_{rm,i} rm_t + \beta_{hml,i} hml_t + \beta_{smb,i} smb_t + \beta_{pr1y,i} pr1y_t + \varepsilon_{it} \tag{26}$$

Where smb and hml denote returns on portfolios that proxy for common risk factors associated with size and book-to-market, respectively. The term pr1yt is the return difference between stocks with high and low returns in the previous year. This term accounts for passive momentum strategies. r_{it} is the fund's before-expense return in month t in excess of the 30-day risk-free interest rate. The alpha is supposed to capture the fund's before-fee risk adjusted performance. Of course, the benchmark would be given by an expected return with zero alpha.

The benchmark expected return can now be used to determine the expected return $\mu(\omega)$ of the shortfall measure

$$s_\alpha(\omega) = \mu(\omega) - E\left[R^T\omega \middle| R^T\omega \leq q_\alpha(R^T\omega)\right] \tag{27}$$

We write the expected return as a function of the portfolio weights rather than $\omega^T \mu$ as in our delegation framework the expected return is not directly a function of our portfolio but is indirectly related to the risk of the fund. Once the benchmark is chosen the board has to fix a confidence level α for the calculation of the TCE. The confidence level could actually be related to behavioural aspects such as the security dimension of (Shefrin & Statman, 2000). The weights of the "portfolio" are given by the weights of the respective asset classes of the fund. The board can now fix a shortfall target and given the positive homogeneity and sub-additivity properties as well as the continuity of the shortfall measure, we can apply Euler's (Tasche, 2008) Theorem to the measure to deduce:

$$s_\alpha(\omega) = \sum_{j=1}^{n} \omega_j \times \frac{\partial s_\alpha(\omega)}{\partial \omega_j} \tag{28}$$

More exactly:

$$\mu\ (\omega) - E\left(\omega^T R \middle| \omega^T R \le q_\alpha\left(R^T \omega\right)\right) = \sum_{j=1}^{n} \omega_j \times \left[\mu_j - E\left(R_j \middle| \omega^T R \le q_\alpha\left(R^T \omega\right)\right)\right] \tag{29}$$

The shortfall is thus given by the weighted sum of the different asset classes' shortfall contributions. This implies that the Board can now fix a target shortfall and determine the portfolio weights and shortfall risk limits for the different asset classes. Shortfall can thus be used as risk budgeting tool. The total risk budget is fixed by the Board in terms of shortfall, then the different risk budgets can be determined for the different asset classes, making sure the sum of the risk budget equals the target risk budget.

The notion of shortfall beta is also very useful. The property that

$$\sum_{j=1}^{n} \omega_j \beta_{j,\alpha}(\omega) = 1 \tag{30}$$

is actually a direct result of the Euler property. As shortfall beta measures the marginal contribution to risk compared to total risk, it can be used as a performance attribution tool and integrated to portfolio optimization as we can relate estimates of alpha to marginal contributions to risk.

CONCLUSION

This paper develops a portfolio optimization framework that is consistent with recent evidence concerning investor behavior. The approach developed in the paper is also consistent with practice in the Asset management industry, namely the existence of benchmarks and risk management constraint. The shortfall measures discussed could in principle be calibrated for different degrees of loss aversion. The aggregation properties enable us to fix a target on the shortfall and then risk budget different asset positions. The existence of shortfall betas provides a tractable way to optimize the portfolio. Future research will focus on implementations and calibrations for investor behavior.

ABSTRACT

The 2-bin inventory model has been well-known as a visual version of the basic (Q, r) model for inventory control. Visual control has been a hallmark of the JIT movement in industry toward simplification and transparency. The equal bin variation of the 2-bin idea, although prevalent in application, has not been thoroughly analyzed in the research literature. We provide a complete analysis of 2-bin Kanban and derive a simple closed form expression for the minimum total cost bin size subject to a specified customer service level, and extend it to the case of n-equal-bins, n>2.

KEYWORDS: Inventory management and coordination, Health care operations

INTRODUCTION: THE TRADITIONAL 2-BIN (Q, r) APPROACH

The scientific literature on inventory management typically describes 2-bin systems as a special case of the well-researched (*Q, r*) system; e.g., see Miltenburg and Wijngaard (1991) and the texts from leading authors such as Silver, Pyke, and Peterson (1998, p. 238, p. 363) and Starr (2004, pp. 533-534). Given an expected demand rate of *D* units/period, an order of quantity *Q* is placed whenever the inventory reaches the reorder point, *r*. As described by these (and other) authors, the 2-bin system is a "visual" version of (*Q, r*) with two bins: the first bin (called the working bin) of capacity *Q*, and the second bin (called the reserve bin) of capacity $r = DL + ss$, where *L* is the lead time until the order is received, and *ss* is the desired safety stock. We assume here throughout that safety stocks are computed in the conventional manner; i.e., given the distribution of demand during lead time, $F(\cdot)$, and a desired customer service level, *CSL*, we choose *ss* so that $F(DL + ss) \geq CSL$.

This control policy specifies that when the working bin is depleted, an order is issued to replace it and is expected to arrive *L* periods later. The quantity of the working bin is fixed, possibly set to the *EOQ* quantity; the reserve bin quantity is set to *r*, the estimated expected demand during lead time, *DL*, plus any planned safety stock, *ss*. When the replacement order is received, the reserve bin is to be filled (to level *r*) and the remaining received quantity is to be placed into the working bin. This approach has long been touted for its visual simplicity (e. g., see Brown, 1977, pp. 250-254; Welch, 1983).

This 2-bin approach is recommended only when lead time *L* is sufficiently short or *Q* is sufficiently large, i.e., only when $DL = r \leq Q$ holds. Otherwise, we cannot guarantee that the received quantity will replenish total inventory above the reorder point. As Silver et al. (1998) point out, a possible procedure then would be to reorder when the *inventory position* reaches level *r*. Here inventory position at time *t* is defined as on-hand inventory plus open orders minus

backorders as of time *t*. Although monitoring inventory position solves the problem, it introduces more complexity by requiring continuous monitoring of open replenishment orders, mitigating the desired visual simplicity. Thus, the recommendation typically has been to limit 2-bin systems when lead times are sufficiently short.

LITERATURE REVIEW: 2-BIN KANBAN

For decades, the so-called 2-bin inventory system has been a well-known replenishment system for high volume, low cost components in manufacturing (e.g., see Brown, 1977). More recently it has become popular in hospitals for controlling the inventory of disposable incidentals (see Landry and Beaulieu, 2013 for a historical perspective). It is also seen in the retail trade in the stocking of displays of items for sale. It is widely popular because it requires no sophisticated information system and no perpetual inventory record keeping, and is consistent with the fundamental principles of JIT: it is simple, functional, and visually intuitive.

Whereas the scientific literature describes 2-bin systems as having two unequal sized bins as specified above, there is a great deal of empirical evidence (case studies like Bélanger, Beaulieu, Landry, and Morales , 2018, and web sites, as listed below), that shows the prevalent simplification found in practice is to have both bins contain the same quantity. Such “2-equal-bin” systems have been commonly referred to as “2-bin Kanban” systems (Landry and Beaulieu, 2013; Moons, Waeyenbergh, and Pintelon, 2018). Evidence of the widespread adoption of this “2-equal-bin” interpretation in industry can be found in Oracle Corporation’s support literature for their worldwide MRP users (See Oracle ***MRP User's Guide*****,** Release 12.1.) Another industrial example is found in the case study by Childerhouse, Aitken, and Towill (2002) of a UK Lighting manufacturer. Their study examined how the subject company reorganized its logistics chains whereby high volume suppliers were managed via a 2-bin Kanban approach.

The growing attention given to logistics process improvements for hospitals is well documented (e.g., see Denton, B.T. (ed.), *Handbook of Healthcare Operations Management*, and Hall, R. (ed) *Handbook of Healthcare System Scheduling*). The popularity of the 2-bin Kanban approach in hospitals can be found in the health care trade literature (e.g., Kaczmarek, 2015) and verified at a number of web sites used by hospitals to train their medical staffs. Notable examples include:

1. “2 Bin Training Video” https://www.youtube.com/watch?v=WULe9bg31ps
2. “ Two Bin Supply System at St Clair Hospital" https://www.youtube.com/watch?v=yjSwwPF5BUU
3. “Inventory Management Solutions: 2-Bin Kanban - Cardinal Health” https://www.youtube.com/watch?v=bRgcMaTmHCU
4. “Kanban Training: What is the Two Bin Kanban?” https://www.youtube.com/watch?v=I3bURj1oM_k
5. “Martin Health System - Blue Bin Demand Flow Process” https://www.youtube.com/watch?v=A5Y_3NuN5Ng

In viewing these training videos, it becomes apparent that these hospitals have changed the traditional 2-bin (Q, r) approach by making the size of both bins equal. In a recent study by Rosales, Magazine, and Rao (2015), the authors describe how the 2-equal-bin approach is prevalent in hospitals where large numbers of medical supplies need to be efficiently (and simply) managed. Other case studies describing 2-bin Kanban implementations in hospitals

include Landry and Beaulieu (2010) and Landry, Beaulieu, Roy (2017) who describe a Canadian hospital's logistics improvements including an $850,000 2-bin Kanban system, Aguilar-Escobar, Bourque, and Godino-Gallego (2015) who describe operations improvements (including 2-bin Kanban) in a Seville hospital, and Persona, Battini, and Rafele (2008) who describe 2-bin Kanban application by two hospitals in Italy.

But Why Two Equal Bins?

In hospital settings, medical supplies are typically withdrawn from stock and reordered by medical technicians who are not necessarily trained in inventory management, making simple visual control systems appropriate. Implementing the aforementioned (Q, r) version of the 2-bin approach runs the risk that when a replenishment order is received, the reserve bin, due to worker error, is not replenished but rather all of the replenishment is assigned to the working bin. Replenishing the reserve bin to its full value might also be complicated by the need to count remaining quantities which introduces additional labor cost and also becomes a source of error. Such mistakes increase the risk of stocking out in the next cycle. The 2-equal-bin interpretation eliminates the need to refill the reserve bin each time a replacement is received. We simply continue using the bin in use until it empties. Here the order quantity and reorder point are identical, so when a delivery arrives, the container in which it arrives can automatically serve as the second bin. In a 2-equal-bin system the two parameters r and Q are the same; when the quantity on hand reaches level B (the bin quantity), an order for B units is placed. The equal-bin approach thus further simplifies implementation because there is now only a single parameter. Moreover, it facilitates first-in-first-out cycling of inventory (important in hospitals and whenever items are perishable).

As mentioned above, the 2-equal-bin approach is typically appropriate in both manufacturing and health care applications (hospitals) for managing the point-of-use (POU) inventory of supply items. In manufacturing, the point of use may be an individual work center; in a hospital, it would be an individual nursing unit. Typically, SKUs are held in a central storage facility and disbursed to the individual POUs by a material handling staff; or the SKUs may be supplied directly from an outside vendor as in the "stockless delivery" approach described by Rivard-Royer, Landry, and Beaulieu (2002). The material handler(s) tour the facility, visiting POUs, delivering replacement stock, and noting empty bins. Thus, once a bin becomes empty the total lead time to replenish it includes the time until it is first recognized (by the handler) as empty, plus the time for the handler to return to central storage, pick the SKU from stock, and finally deliver it to the POU. Modern applications of this model are now able to reduce this lead time through use of RFID technology (See Landry and Beaulieu, 2010, for detailed description of how this technology is being applied to complement 2-bin systems.)

MOTIVATION

All of the empirical evidence cited above confirms the wide usage of 2-equal-bin inventory control systems in practice. Yet the issue of how to set these (equal) bin sizes has been only seldom raised and never resolved. As Rosales et al. (2015) point out in their study of the hospital environment, the bin quantity for a given SKU was determined by applying a management-defined target level of inventory turns given estimated mean demand. Bin quantity determination was not in the scope of their investigation; but as they conclude, this would be an important issue for further research. Olson (2014) draws a similar conclusion in his study of the 2-bin Kanban implementation at the Walter Reed National Military Medical Center, where he concludes that an economic analysis similar to EOQ might be worthy of future research. The

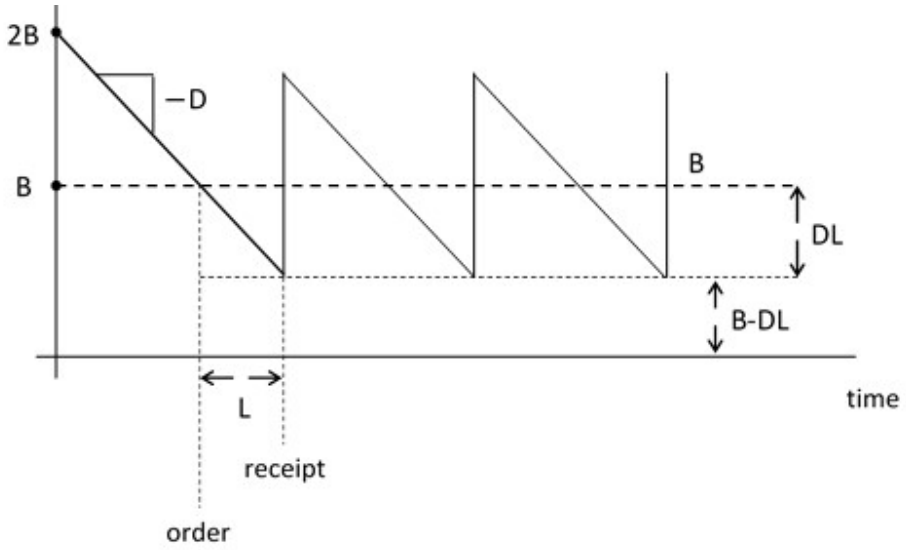
notion of setting bin quantities according to some target level of inventory turns is also reported by Miltenburg et al., (1991, p.118) as they write, "*The order quantity is an amount sufficient to satisfy x weeks of usage, where x is specified by management*." A possible alternative would be to set the order quantity to the familiar economic order quantity (*EOQ*). We show here that setting bin quantities in either of these ways is an unnecessary over-simplification and will lead to higher-than warranted total cost. We provide an analysis showing how the economic lot quantity concept can be applied when the order point and replenishment quantities are made identical to the bin quantity. The impact of efficient inventory management of disposable SKUs for hospitals is not trivial; they constitute as much as 17% of total expenses (Olson, 2014; Patrick, 2014), and it is not uncommon for hospitals to manage hundreds of such items and to distribute them to numerous nursing units across different departments (Rosales, Magazine, and Rao, 2015). Providing an understanding of the effect of bin sizes and a complete economic analysis is the motivation for this study.

The rest of this work is organized as follows. The next section develops the economic bin quantity for the 2-bin Kanban model comparing its total cost to the traditional (Q, r) 2-bin approach. As shown, the total cost of 2-bin Kanban is higher than that achieved with the traditional model. One can interpret this as the added cost for the improved simplicity and reduction of the risk for errors that it provides. The following section extends the analysis to the case of n bins, $n \geq 2$. Having more than two bins may often be more suitable when the item takes up excessive space and/or when the lead time is relatively long (i.e., when $L > B/D$). (Typically, shorter lead times occur when the source of supply is an internal central stockroom as opposed to an outside supplier.) Next we provide numerical examples illustrating how the various results can be applied, and a straight-forward procedure for management for determining bin quantities and number of bins when a visual equal bin approach is desired. The final section summarizes and identifies potentially fruitful further research.

THEORETICAL MODEL: THE ECONOMIC 2-BIN KANBAN MODEL

Figure 1 plots the average inventory behavior of a 2-bin Kanban system. As the figure shows, after an initial setting of *2B* units, inventory depletes at an expected rate *D* until inventory level *B* is reached at which time an order for *B* units is placed and expected to arrive *L* time units later.

Figure 1: Average Inventory Behavior under a 2-bin Kanban System



After this first cycle, the system converges to the steady state behavior whereby the expected value for minimum inventory is $MinI = B - DL$, and the expected value for the maximum inventory is $MaxI = B + B - DL = 2B - DL$, so that the mean inventory can be computed by

$$\text{Average Inventory} = \frac{MinI + MaxI}{2} = \frac{(3B - 2DL)}{2}.$$

Let *S* denote the fixed cost to replenish a bin, *c* be the unit cost, and *h* the periodic percent inventory holding cost. (S is assumed non-trivial. When the supplier is an outside vendor, transport and handling costs will be incurred; if replenishment comes from a storage facility, labor cost for replenishment workers is incurred.) Given these parameters, we can express the expected value of total relevant cost for the 2-equal-bin system, TC_2, as a function of *B*:

$$TC_2(B) = \frac{(3B - 2DL)}{2}ch + \frac{DS}{B}, \qquad (1)$$

where the first term on the rhs of (1) represents average periodic inventory holding cost (including holding the implicit safety stock of B-DL units) and the second term is the average periodic fixed replenishment costs. In addition, we have the constraint $B \geq DL + ss$ to assure that the appropriate customer service level (CSL) is met. Assuming normally distributed periodic demand with standard deviation σ, z_α is the point on the standard normal distribution such that $P\{Z > z_\alpha\} = \alpha$, and recalling that L is the lead time until delivery, yields $ss = z_{CSL}\sigma\sqrt{L}$. Thus, when $B > DL + ss$, the 2-bin Kanban approach affords the added stockout protection of $B - DL - z_{CSL}\sigma\sqrt{L}$ units of safety inventory. Note that the comparable expected total periodic cost for the (*Q, r*) model (including a safety stock of *ss*) is

$$TC_{Q,r}(Q) = \frac{Q}{2}ch + \frac{DS}{Q} + (ss)ch. \qquad (2)$$

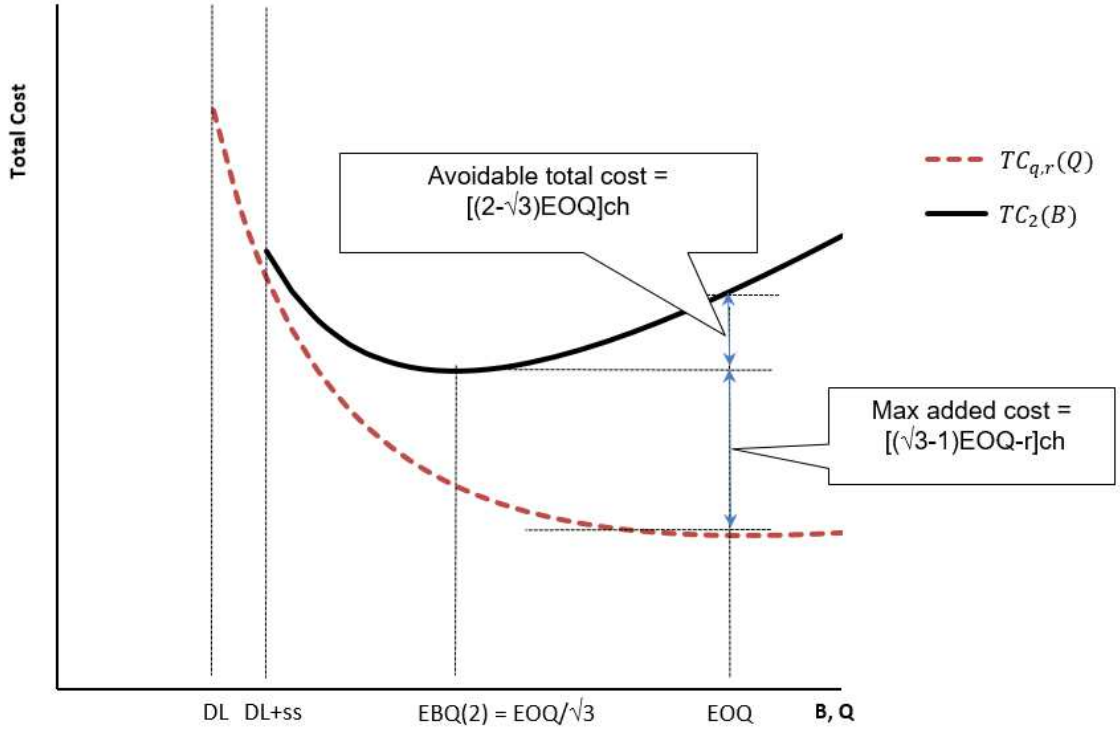
Taking the first derivative of (1) and setting it to zero yields the economic bin quantity for the 2-bin Kanban system, $EBQ(2)$:

$$EBQ(2) = \sqrt{\frac{2DS}{3ch}}. \quad (3)$$

Since $\frac{d^2TC_2}{dB^2} > 0$, $EBQ(2)$ is the value of *B* which minimizes average total relevant costs. Note this is $1/\sqrt{3} \approx 0.577$ as much as the traditional $EOQ = \sqrt{\frac{2DS}{ch}}$ derived by finding the value which minimizes $TC_{Q,r}$ in equation (2).

As shown in Figure 2, selecting the bin size to *EOQ* (and not *EBQ(2)*) can incur avoidable total cost, which is obviously parameter dependent. The conclusion here is that given that we are using a 2-bin Kanban system, then setting *B = EOQ* leads to avoidably excess total cost.

Figure 2: The Economic Bin Quantity (EBQ) Cost Model



The figure illustrates that the $TC_{Q,r}$ cost curve is only relevant for $Q \geq DL$ and that the TC_2 total cost curve is only relevant for $B \geq DL + ss$. Thus, because of the convexity of $TC_2(B)$, whenever $EBQ(2) < DL + ss$, the lowest cost choice for *B* is $DL + ss$. As a result, the appropriate specification for selecting the optimum bin size, *B*, is

$$B = \max\{EBQ(2), DL + ss\}. \quad (4)$$

Remark 1: If the objective is to minimize inventory (without regard for fixed costs to order) then we set $B = DL + ss$.

This would be appropriate in manufacturing when JIT is the goal and setup costs are minimal. Given the limited alternatives offered in the literature, a materials manager may easily be tempted to choose a bin size equal to the economic order quantity. See, for example, Rossetti, Buyurgan, and Pohl (2012, p.257). The next remark quantifies the economic implication of using $B = EOQ$ instead of $B = EBQ(2)$ as a bin size in a 2-bin system.

Remark 2: The avoidable total cost shown in Figure 2 can be computed by

$$TC_2(EOQ) - TC_2\big(EBQ(2)\big) = \left\{\frac{3ch}{2}\sqrt{\frac{2DS}{ch}} + DS\sqrt{\frac{ch}{2DS}} - DLch\right\} - \left\{\sqrt{6DSch} - DLch\right\}$$
$$= \big(2-\sqrt{3}\big)\sqrt{2DSch}$$
$$= (0.268)TC_{EOQ,DL}(EOQ), \qquad (5)$$

which may also be expressed as $(0.268)EOQ \cdot ch$. In equation (5) the value $\sqrt{2DSch}$ is equation (2) evaluated at $Q = EOQ$ with $ss = 0$. The implication here is clear: in deciding to use the visual 2-bin Kanban system, setting the bin quantity to the traditional *EOQ* leads to significant excess total cost (over 25% of the relevant total cost in the traditional EOQ model).

Remark 3: Assume that $EBQ(2) \geq DL + ss$. Then using the conventional 2-bin (Q, r) configuration with *EOQ* and a safety stock *ss* is always less costly than using a 2-equal-bin configuration.

This follows by noting that the 2-equal-bin configuration is the conventional 2-bin (Q, r) configuration with the constraint $Q = r$.

Remark 3 tells us that the total cost of inventory using a 2-bin Kanban system is always greater than using the conventional (Q, r) 2-bin model. The maximum cost difference is $TC_2 - TC_{Q,r} = \big[\big(\sqrt{3}-1\big)EOQ - r\big]ch > 0$. This assumes no operational errors (as described earlier). One can think of this as the added cost for system simplification and stock keeping error reduction.

EXTENDING TO n EQUAL BINS

The analysis provided above shows that it is not necessary to limit application of 2-equal-bin systems to cases when lead times are "short;" i.e., when $L < {}^{(EBQ(2)-ss)}/_{D}$. Rather than resorting to tracking inventory position, we can simply set $B = \max\{EBQ(2), DL + ss\}$ and continue having a fully visual system. But there is also another option, which will be shown in the section to follow to be economically optimal if $EOQ > (DL + ss)/\sqrt{2}$.
Rather than increasing B to at least $DL + ss$, we can maintain visual control (i.e., avoid tracking inventory position) by increasing the number of bins. It is equivalent to tracking inventory position because an empty (missing) bin represents an open replenishment order. Additionally, in many cases it may be more practical to set the bin quantity B based on efficient container quantity for transport. With more bins we can tolerate longer lead times and smaller bin sizes, but at the cost of more inventory.

Optimum Bin Quantity Given the Number of Bins

We can generalize the analysis for the 2-bin Kanban case to the case $n > 2$ to determine the optimum bin (container) quantity as follows. Note that an order will be placed every time a bin is emptied which is exactly the same moment that the inventory position reaches $(n-1)B$. Therefore, the expected value for minimum inventory is $MinI = (n-1)B - DL$, and the expected value for the maximum inventory is $MaxI = B + (n-1)B - DL = nB - DL$. The mean inventory can be computed by

$$\text{Average Inventory} = \frac{MinI + MaxI}{2} = \frac{((2n-1)B - 2DL)}{2}. \quad (6)$$

Thus total relevant cost is then

$$TC_n(B) = \frac{((2n-1)B - 2DL)}{2}ch + \frac{DS}{B}, \quad (7)$$

which upon setting the derivative with respect to *B* equal to zero yields the economic bin quantity given n:

$$EBQ(n) = \sqrt{\frac{2DS}{(2n-1)ch}} = \frac{EOQ}{\sqrt{(2n-1)}}. \quad (8)$$

A check of the second derivative will confirm that this is a global minimum for $TC_n(B)$ in (7).

Since every order is placed when the inventory position is at $(n-1)B$, it is necessary that $(n-1)B \geq DL + ss$ in order to meet the CSL. As a result, the appropriate specification for selecting the optimum bin size, *B*, is

$$B = max\left\{EBQ(n), \frac{DL + ss}{(n-1)}\right\}, n \geq 2. \quad (9)$$

In order to understand how to find the optimal number of bins and bin sizes for a given problem efficiently, it is first necessary to investigate the total cost functions given in expression (7) and their minima. The next theorem shows that if $B = EBQ(k)$ for some *k* (*i.e.*, $EBQ(k) > (DL + ss)/(k-1)$, implying that $EBQ(k)$ is feasible), then $B = EBQ(m)$ is feasible for all $m \geq k$.

Theorem 1: Assume that $EBQ(n) \geq \frac{(DL+ss)}{n-1}$. Then $EBQ(n+1) \geq \frac{(DL+ss)}{n}$.

Proof: The expression $EBQ(n) = \sqrt{\frac{2DS}{(2n-1)ch}}$ implies that

$$EBQ(n+1)\sqrt{\frac{2n+1}{2n-1}} = EBQ(n) \geq \frac{(DL + ss)}{n-1}$$

where the inequality holds by hypothesis. Multiplying this expression by $\frac{n-1}{n}$ yields

$$EBQ(n+1)\left(\frac{n-1}{n}\right)\sqrt{\frac{2n+1}{2n-1}} \geq \frac{(DL+ss)}{n}.$$

Since $\left(\frac{n-1}{n}\right)\sqrt{\frac{2n+1}{2n-1}} < 1$ for $n \geq 1$,

$$EBQ(n+1) > EBQ(n+1)\left(\frac{n-1}{n}\right)\sqrt{\frac{2n+1}{2n-1}} \geq \frac{(DL+ss)}{n},$$

as was to be shown.

Two immediate consequences of this theorem are given by the following corollaries. The first corollary uses the result in Theorem 1 to determine when $EBQ(n)$ is feasible for any number of bins, $n \geq 2$. The second corollary uses the result in Theorem 1 to show that if $EBQ(n)$ is feasible for some n, then the difference in the minimum total cost decreases monotonically to 0 as the number of bins increases.

Corollary 1: If $EBQ(2) \geq DL + ss$, then expression (9) reduces to

$$B = EBQ(n), \qquad n \geq 2, \tag{10}$$

that is, whenever $EBQ(2)$ is feasible, then so is $EBQ(n), n > 2$.

Corollary 2: If $EBQ(n) \geq \frac{DL+ss}{n-1}$, then

$$TC_{k+1}(EBQ(k+1)) - TC_k\big(EBQ(k)\big) = \left[\sqrt{2k+1} - \sqrt{2k-1}\right]TC_{EOQ,DL}(EOQ), k \geq n. \tag{11}$$

This shows that $TC_{k+1}(EBQ(k+1)) - TC_k\big(EBQ(k)\big)$ monotonically decreases to 0 in *k*.

According to expression (9), if $EBQ(n) < \frac{DL+ss}{n-1}$, then $B(n) = \frac{DL+ss}{n-1}$. Substituting this into $TC_n(B)$ yields

$$TC_n\left(\frac{DL+ss}{n-1}\right) = \frac{DLch}{(2n-2)} + \frac{(2n-1)}{(2n-2)}ch(ss) + \frac{(n-1)DS}{(DL+ss)}. \tag{12}$$

Equation (12) is useful in proving the following, which shows how to select an optimum number of bins in the case that $EBQ(k) < \frac{DL+ss}{k-1}, 1 \leq k \leq m$, for some *m*.

Theorem 2: $TC_{n+1}\left(\frac{DL+ss}{n}\right) > TC_n\left(\frac{DL+ss}{n-1}\right)$ if and only if $EOQ > \frac{DL+ss}{\sqrt{n(n-1)}}$.

Proof: $TC_{n+1}\left(\frac{DL+ss}{n}\right) - TC_n\left(\frac{DL+ss}{n-1}\right) > 0$ implies from (12) that

$$-\frac{ch(DL+ss)}{2n(n-1)} + \frac{DS}{(DL+ss)} > 0.$$

This can be rewritten as

$$\frac{2DS}{ch} > \frac{(DL+ss)^2}{n(n-1)}.$$

Taking the square root of both sides and recognizing the left hand side as the *EOQ* completes the proof. The proof of the converse is similar.

Noting that in Theorem 2, the sequence $\frac{1}{\sqrt{n(n-1)}}$ is monotonically decreasing in *n* leads to the following.

Corollary 3: If $EOQ > \frac{DL+ss}{\sqrt{n(n-1)}}$, then

$$TC_n\left(\frac{DL+ss}{n-1}\right) < TC_{n+1}\left(\frac{DL+ss}{n}\right) < TC_{n+2}\left(\frac{DL+ss}{n+1}\right) < \cdots.$$

We can now state our main result: there are only two candidates for n for the n-equal-bin quantity.

Theorem 3: The least cost equal-bin solution occurs at either $EBQ(2)$ or $\frac{DL+ss}{n-1}$ for some $n \geq 2$ which satisfies the condition of Corollary 3.

Proof: Theorem 1 implies that there is a smallest *n* for which $EBQ(n)$ is a feasible equal-bin solution, and thus partitions the set $\{EBQ(k), k \geq 2\}$ into the set of infeasible equal-bin values, $\Gamma = \{EBQ(k), 2 \leq k \leq n, n \geq 1\}$, which is null if $n = 1$, and the set of feasible equal-bin values, $\{EBQ(k), k \geq n+1, n \geq 1\}$. Because of the convexity of $TC_n(B)$ in equation (7), the optimum equal-bin values are $\frac{DL+ss}{k-1}$ for $2 \leq k \leq n$. By Corollary 2, $TC_n\big(EBQ(n)\big) < TC_k(EBQ(k))$ for $k > n$. Consequently, if $EBQ(2)$ is a feasible equal-bin value, then it is the least cost equal-bin solution. Thus if we can show that

$$TC_n\left(\frac{DL+ss}{n-1}\right) < TC_{n+1}\big(EBQ(n+1)\big), \tag{13}$$

for $n \geq 2$, then the theorem will follow.

Let N be the largest value of n such that $EBQ(N) \in \Gamma$, implying that $EBQ(N) \leq \frac{DL+ss}{N-1}$, and $EBQ(N+1) \geq \frac{DL+ss}{N}$. Upon substitution of the values of $EBQ(N)$ and $EBQ(N+1)$ from equation (8), these two constraints can be rewritten as

$$\frac{(2N+1)}{2N^2}\frac{(DL+ss)^2 ch}{D} \leq S \leq \frac{(2N-1)}{2(N-1)^2}\frac{(DL+ss)^2 ch}{D},$$

or more simply as

$$S = c_1 \frac{(DL+ss)^2 ch}{D}, \tag{14}$$

where

$$LL = \frac{(2N+1)}{2N^2} \leq c_1 \leq \frac{(2N-1)}{2(N-1)^2} = UB, \tag{15}$$

and LL (UL) indicates the lower (upper) bound. Define

$$f(N) = TC_N\left(\frac{DL+ss}{N-1}\right) - TC_{N+1}\big(EBQ(N+1)\big)$$

$$= \left(\frac{2N-1}{2N-2}\right)(DL+ss)ch + \frac{(N-1)DS}{(DL+ss)} - \sqrt{2(2N+1)DSch}, \tag{16}$$

Substituting S in equation (14) into (16) yields

$$f(N) = \left[\left(\frac{2N-1}{2N-2}\right) + c_1(N-1) - \sqrt{2(2N+1)}\sqrt{c_1}\right](DL+ss)ch, \tag{17}$$

so that the sign of $f(N)$ will be negative when

$$f(N) = \left[\left(\frac{2N-1}{2N-2}\right) + c_1(N-1) - \sqrt{2(2N+1)}\sqrt{c_1}\right] < 0, \tag{18}$$

or equivalently

$$f(N) = (N-1)^2c_1^2 - (2N+3)c_1 + \left(\frac{2N-1}{2N-2}\right)^2 < 0. \tag{19}$$

The zeros of $f(N)$ are real, distinct, and occur at

$$c_1 = \frac{2N+3}{2(N-1)^2} \pm \frac{\sqrt{4N+2}}{(N-1)^2}. \tag{20}$$

Some algebra shows that the lower zero, $c_1 = \frac{2N+3}{2(N-1)^2} - \frac{\sqrt{4N+2}}{(N-1)^2}$, is smaller than LL in expression (15) while the upper zero, $c_1 = \frac{2N+3}{2(N-1)^2} + \frac{\sqrt{4N+2}}{(N-1)^2}$, is greater than UL in expression (15). As a quadratic function of the artificial variable c_1, $f(N)$ achieves a minimum between the zeros in expression (20), and therefore $f(N) < 0$ for all $LL \leq c_1 \leq UL$. By Corollary 2,

$$TC_N\left(\frac{DL+ss}{N-1}\right) < TC_{N+1}\big(EBQ(N+1)\big) < TC_{N+2}\big(EBQ(N+2)\big) < \cdots,$$

and Theorem 3 follows. The next corollary shows how to determine the optimal number of bins when $EBQ(2)$ is not feasible.

Corollary 4: If $EBQ(2) < DL+ss$, then the optimum number of bins, n_{opt}, can be determined from Theorem 3 by

$$n_{opt} = \left\lceil \frac{1+\sqrt{1+4((DL+ss)/EOQ)^2}}{2} \right\rceil, \tag{21}$$

where $\lceil\cdot\rceil$ is the ceiling function.

Optimum Number of Bins Given the Bin Quantity

Whenever the bin quantity is predetermined, say B_0, the minimum number of containers, n_{min}, can be selected so as to minimize inventory (and therefore total cost) subject to assuring a desired level of customer service, CSL. Assuming that lead time demand follows a normal distribution, with mean *DL* and variance σ_L^2, the value of $n \geq 2$ can be easily determined by

$$n_{min} = \left\lceil \frac{DL + ss}{B_0} + 1 \right\rceil = \left\lceil \frac{DL + \mathrm{F}^{-1}(CSL)\sigma_L}{B_0} + 1 \right\rceil, \tag{22}$$

where $\mathrm{F}(\cdot)$ denotes the cumulative probability distribution for a standard normal distribution.

ILLUSTRATIVE EXAMPLES

In order to demonstrate the use of these results, consider a decision maker who wishes to use n-equal-bins to achieve a visual system. The mean daily demand is $D = 8$ units with a standard deviation of daily demand $\sigma_D = 3.12$ units, the lead time $L = 3$ days, and the CSL is to be at least 90%. The cost structure includes a unit cost of $c = 300$ dollars, an annual holding cost of $h = 12\%$ of the unit cost to hold a unit for a 365 day year, and a fixed order cost of $S = 3$ dollars.

The decision maker would first check to see if $EBQ(2) > DL + ss$. Since $EBQ(2) = 12.74$ and $DL + ss = 8(3) + 6.93 = 30.93$, $EBQ(2)$ is not a feasible 2-bin Kanban quantity, and so equation (21) can now be used to determine the optimum number of bins

$$n_{opt} = \left\lceil \frac{1 + \sqrt{1 + 4((DL + ss)/EOQ)^2}}{2} \right\rceil = \left\lceil \frac{1 + \sqrt{1 + 4\left(\frac{24 + 6.93}{12.74}\right)^2}}{2} \right\rceil = \lceil 1.988 \rceil = 2,$$

which yields the optimum bin size of $\frac{DL+ss}{1} = 30.93$.

Table 1 shown below contains relevant data supporting this decision for $2 \leq n \leq 7$.

Table 1: Example Computations for the n-Equal-Bins Problem

n	EBQ(n)	$(DL + ss)/(n-1)$	B	$(DL + ss)/\sqrt{n(n-1)}$	Annual Total Cost
2	12.74	30.93	30.93	21.87	2.734
3	9.87	15.46	15.46	12.63	3.308
4	8.34	10.31	10.31	8.93	4.179
5	7.35	7.73	7.73	6.92	4.949
6	6.65	6.19	6.65	5.65	5.638
7	6.12	5.15	6.12	4.77	6.267

We have already determined that $EBQ(2) < DL + ss$ as shown in the first row of this table where $n = 2$. Now noting that $EOQ = 20.06$, the smallest value of n for which Corollary 3 holds is $n = 2$. As can be seen, this is also where the annual cost is minimized.

To demonstrate the impact of lead time on the optimal number of bins given the same cost structure as described above, Table 2 shows the values of $(DL + ss)/\sqrt{n(n-1)}$ as lead time varies from 1 day to 15 days.

Table 2: Values of $(DL + ss)/\sqrt{n(n-1)}$ for Selected Lead Times

	n						
L	2	3	4	5	6	7	8
1	8.48	4.90	3.46	2.68	2.19	1.85	1.60
2	15.31	8.84	6.25	4.84	3.95	3.34	2.89
3	21.87	12.63	8.93	6.92	5.65	4.77	4.13
4	28.28	16.33	11.55	8.94	7.30	6.17	5.34
5	34.61	19.98	14.13	10.94	8.94	7.55	6.54
6	40.87	23.59	16.68	12.92	10.55	8.92	7.72
7	47.08	27.18	19.22	14.89	12.16	10.27	8.90
8	53.25	30.74	21.74	16.84	13.75	11.62	10.06
9	59.39	34.29	24.25	18.78	15.34	12.96	11.22
10	65.51	37.82	26.74	20.72	16.91	14.30	12.38
11	71.60	41.34	29.23	22.64	18.49	15.62	13.53
12	77.68	44.85	31.71	24.56	20.06	16.95	14.68
13	83.73	48.34	34.18	26.48	21.62	18.27	15.82
14	89.77	51.83	36.65	28.39	23.18	19.59	16.97
15	95.80	55.31	39.11	30.30	24.74	20.91	18.11

To determine the optimal number of bins for a given lead time, say $L = 6$, Theorems 2 and 3 along with Corollary 3 indicate that the decision maker should find the first value in the corresponding row that is smaller than $EOQ = 22.06$. For $L = 6$, this occurs in the column for $n = 4$. For each lead time, the optimal number of bins is indicated by the shaded selection.

To determine the optimal bin size, the result is $(DL + ss)/(n-1)$ for $n \geq 3$. In the special case of $n = 2$, it is also necessary to determine if $EBQ(2) > DL + ss$. If so, $EBQ(2)$ is the optimal quantity; otherwise $(DL + ss)/(n-1) = DL + ss$ is optimal.

Confirmation of the optimal number of bins is shown in Table 3 where the total cost of Equation (7) is computed for each combination of lead time and bin number. The minimum cost value for each lead time is once again indicated by the shaded selection. These are exactly the same selections made in Table 2.

Table 3: Total Annual Cost Behavior for Selected Lead Times

	n						
L	2	3	4	5	6	7	8
1	2.980	4.076	4.968	5.738	6.427	7.056	7.638
2	2.734	3.308	4.179	4.949	5.638	6.267	6.849
3	2.984	2.998	3.520	4.169	4.849	5.478	6.060
4	3.361	2.975	3.246	3.682	4.183	4.718	5.271
5	3.786	3.069	3.158	3.447	3.816	4.226	4.659

13	7.464	4.747	3.977	3.693	3.603	3.611	3.675
14	7.926	4.984	4.130	3.797	3.673	3.653	3.693
15	8.386	5.222	4.286	3.906	3.749	3.704	3.722

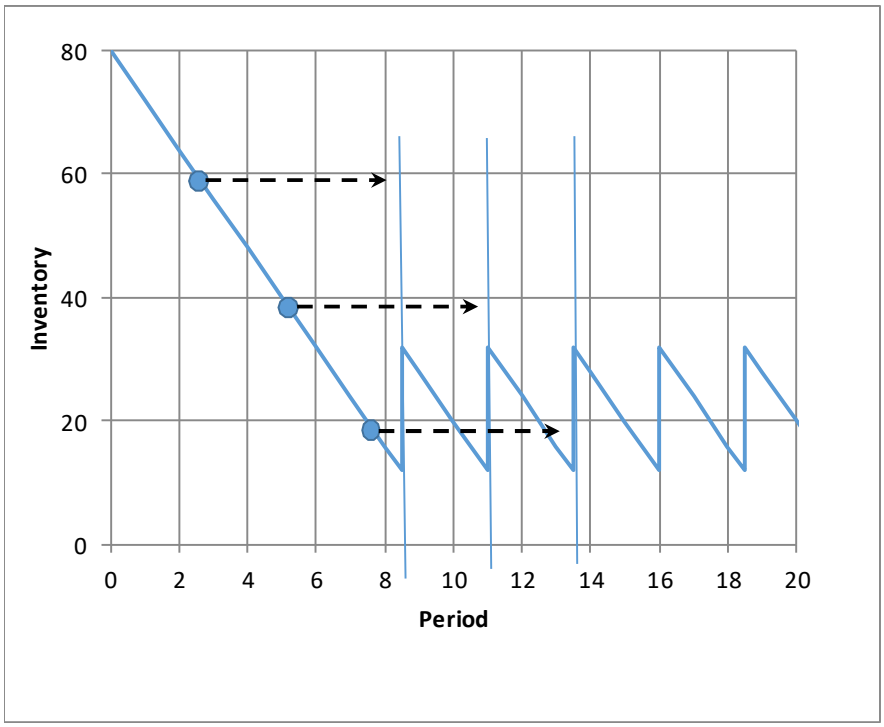
The choice of using n-bins instead of 2-bins will be the optimal economic choice if $EOQ > (DL + ss)/\sqrt{2(2-1)} = (DL + ss)/\sqrt{2}$; however, the inventory on hand will appear to be a 2-bin Kanban system to workers using a visual system, as described next.

In order to illustrate the expected inventory behavior of an n-equal-bin system, Figure 3 shows the expected inventory level over time for the 4-equal-bin system in the preceding example with $L = 6$. Beginning with inventory of four bins of 19.25 units, when the first bin empties at time $t = 2.5$ a replacement bin of 19.25 units is ordered arriving 6 periods later at time 8.5. Subsequent bins are emptied and reordered every 2.5 periods. The equilibrium average inventory is $\frac{((2n-1)B-2DL)}{2} = 22$ units. In general, the inventory level for an n-equal-bin system can be expressed using the floor function $\lfloor \cdot \rfloor$ as:

$$I(t) = nB - Dt + \max\left\{0, B\left\lfloor \frac{t-L}{\frac{B}{D}} \right\rfloor\right\} \tag{23}$$

Figure 3 also demonstrates that the inventory on hand will typically appear to be a 2-bin Kanban system to workers using a visual system. The unseen inventory position fluctuates between $(n-1)B$ and nB.

Figure 3: On Hand Inventory Behavior for a 4-Bin Visual System



DISCUSSION

It is frequently suggested that so-called "C items," often referred to as the "trivial many," represent the appropriate target class of items for applying a visual system approach for controlling inventory. C items are often described as those whose annual usage dollars (AUD) reside in the lowest quintile with respect to AUD for all stock keeping units (SKUs), yet often comprise up to 50% of the total number of SKUs. We would not recommend automatically designating a 2-bin Kanban approach for all C items or limiting the approach to only C items. The central assumptions validating the analytical results here are continuous, constant and stationary expected demand. Consistent with the recommendation of Bijvank and Vis (2017), our recommendation is to use the 2-bin method only for non-bulky multi-usage disposable supply items. For hospitals, this would exclude perishable items such as blood and medicines, and non-disposable items such as surgical instruments. Basic inventory management approaches for such cases can be found for example in Federgruen, Prastacos, and Zipkin (1986), Katsaliaki .and Brailsford (2007), and Prastacos (1984)

Finally, note that the typical recommendation for applying the 2-bin model (the Q,r version) has been to limit it to items with short lead times. We have shown here that this is not necessary; one can accommodate long lead times either by increasing the bin size or the number of bins.

Based on the results derived here, we provide a straight-forward procedure for determining bin quantities and number of bins when a visual equal bin system is desired. After calculating $EBQ(2)$ from Equation (3) or simply $EBQ(2) = .577EOQ$.

1. *If a 2-equal-bin system is desired, then set* $B = max\{EBQ(2), DL + ss\}$ *to achieve minimum total cost.*

2. *If a specific bin quantity* B_0 *is desired, then to achieve minimum total cost set* $n = \left\lceil \frac{DL+ss}{B_0} + 1 \right\rceil$.

3. *If a least cost n-equal-bin system is desired, then:*
   3.1 If $EBQ(2) \geq DL + ss$, *then*
   set $B = EBQ(2), n = 2.$
   3.2 If $EBQ(2) < DL + ss$, *then*
   set $n = \left\lceil \frac{1+\sqrt{1+4((DL+ss)/EOQ)^2}}{2} \right\rceil$ *and*
   set $B = \frac{DL+ss}{n-1}$.

It is advisable to periodically review all the firm's inventory items to see if those currently controlled via a 2-bin system should remain so and if the 2-bin approach should be applied to any new items.

FINAL REMARKS

In this paper we have examined the 2-bin Kanban model for inventory control, a special case of the well-known (Q, r) system with two bins. A total cost model was developed that includes holding and replenishment costs. The minimum total cost bin size/reorder point was derived subject to a specified customer service level to constrain backorder costs. An extension of the problem to the case of n-equal-bin, n > 2, was then provided. Somewhat surprisingly, it was shown that in the general n-equal-bin system that the optimum bin size can occur at only two possible values, which may be easily computed based on problem parameters. Simple conditions were then given that describe which of these two values is optimum, thus completely solving the general problem.

As we have shown, there is significant empirical evidence that the 2-bin Kanban model is widely used in hospitals as well as in industrial settings because it removes the chance of worker error in replenishing the reserve and working bins. In spite of this popularity in practice, the 2-equal-bin system has not been analyzed in the research literature, implying that this is a situation where practice has led research. This paper has provided the practice of inventory management a straightforward comprehensive approach on how to specify bin-based visual control systems.

Future Research

The 2-bin Kanban inventory control system has an interesting similarity to the familiar Kanban system for production control. Both systems make use of fixed batch transfer quantities. The major difference is that Kanban is a procedure for controlling production when we have a series of capacitated resources. An interesting and perhaps productive line of future research would be to apply an analogous economic approach (as described here for EBQ) for the production coordination problem addressed by Kanban systems.

Single-Point Manufacturing Resilience: A Simulation Study and Initial Results

Timothy L. Smunt
University of Wisconsin – Milwaukee
Email: tsmunt@uwm.edu

ABSTRACT

There have been numerous studies related to supply chain multi-point network fluctuations in response to real or perceived demand shocks in the system. Starting with the classic work in the bullwhip phenomenon, it is well known that poor visibility of downstream demand can cause increasing fluctuations in orders upstream. Many researchers have followed this initial work with increasingly complex studies to determine optimal remediation strategies. There has also been considerable research related to improving a single manufacturing facility, one of the many points in a typical supply chain network. However, there is little work performed on determining the impact of demand shocks for a single facility. While there has been an attempt to determine optimal mitigation strategies for shifting bottlenecks, or for scheduling a bottleneck resource, there are no known studies that test the resiliency of a set of processes within a single operations facility, whether manufacturing or service. This paper uses a complex simulation approach to model various types of single point manufacturing facilities with different sets of typical operating attributes. The results indicate how quickly a manufacturing facility can return to steady state conditions after a one-time, limited duration, demand increase. Such infrequent shocks can be the result of marketing promotions, short-term pricing discounts, weather phenomenon, or even disruptions caused by terrorist attacks on another similar facility.

KEYWORDS: manufacturing, resilience, simulation, demand variability

INTRODUCTION

The main objective of this paper is to provide the foundation for understanding the effects of short-term demand shocks in a single-point manufacturing facility across a spectrum of operating attributes. While there have been numerous studies and articles related to supply chain networks with multiple points and the effect of fluctuations in response to real or perceived demand shocks in the system, there is little work done on such fluctuations within a single manufacturing facility. We note that in the classic work in the bullwhip phenomenon, sometimes called “system or industrial dynamics,” it is well known that poor visibility of downstream demand can cause increasing fluctuations in orders upstream. (See Forrester (2007) for a review of the past literature). Many researchers have followed this initial work with increasingly complex studies to determine optimal remediation strategies.

Considerable research exists that focuses on improving a single manufacturing facility. However, there is little work performed on determining the impact of demand shocks for a single facility. While there has been an attempt to determine optimal mitigation strategies for shifting bottlenecks, or for scheduling a bottleneck resource, there are no known studies that test the resiliency of a set of processes within a single operations facility, whether manufacturing or

service. This paper uses a complex simulation approach to model various types of single point manufacturing facilities with different sets of typical operating attributes.

We note that infrequent shocks can be the result of marketing promotions, short-term pricing discounts, weather phenomenon, or even disruptions caused by terrorist attacks on another similar facility.

The objective of this study is to lay the groundwork for future studies of increasing complexity in various types of settings, both manufacturing and services. In particular, this study examines the impact of single demand shocks on a single operating facility for short period, with various operating conditions tested. We look for the overall impact of the delays caused by the shock, as well as the length of time required for an operating system to recover.

In the manufacturing arena, short-term demand shocks on a factory due to weather related issues can cause spikes in demand, like for portable power generators immediately before and after major storms. Analogies in the service sector also exist. For example, the resilience of an emergency department of a hospital is of high interest and importance, since major events may cause long back-ups to providing needed treatments to injured or ill patients. Beyond the necessary use of triage to prioritize the incoming patients, there can be other remediation methods used to reduce the return to steady state operations, as well as initial design decisions that increase resilience. This initial study provides some insight into those design decisions.

LITERATURE REVIEW

There is much literature that focuses on the performance of manufacturing systems under different design parameters. Additionally, there is a good deal of literature that addresses supply chain network resilience. However, a major gap exists in the literature for resilience at single-point manufacturing facilities. In the following sections, a sample of the relevant literature is presented.

Resilience in the Supply Chain

The earliest work that can be attributed to the concept of supply chain resilience is Jay Forrester's work on Industrial Dynamics, later called System Dynamics. (See Forrester, J., 1961.) Forrester provides a detailed perspective on related work over the next fifty years in Forrester, 2007.

There have been number articles and studies that refer specifically to supply chain network resilience in recent years. Scholten & Schilder, 2015, for example, discuss the importance of collaboration for high performing and resilient supply chains. Supply chain readiness and recovery is further discussed by Chowdhury & Quaddus, 2016. Birkie,et. al, 2017, specifically address how to mitigate disruptions in the supply chain and the importance of resilience capabilities in mitigating disruptions. Their research indicates that supply chain complexity can be helpful in mitigating disruptions.

Process Design Attributes

Manufacturing systems with high flow dominance have been extensively analyzed from both an assembly line perspective, and batch production perspective, the latter sometimes called flow shops. Bitran, G. & Dasu, S.,1992, provide a comprehensive review of open queueing network models of manufacturing systems.

Hillier and Boling, 1967, developed analytic models for studying the performance of assembly lines when no setup times occurred during production. They considered lines composed of up to five sequential machines, using exponential service times and finite buffer capacity. They were the first to consider limited buffer capacity in these scenarios and showed that a “bowl phenomenon” existed for optimal assignment of service times to machines. They determined that optimal assignment of tasks should result in higher task times in the earlier and later machines in the line.

Smunt and Perkins, 1985, later showed that the improvements in output rate from using the bowl service time distribution degraded rapidly once task time variance was reduced to more realistic levels, and, thus, practically, balancing assembly lines was still the best approach in practice.

Considerable research followed on production processes that were in-between pure flow lines and random job shops. The intent of this research and practice was to reduce random flows found in job shops by grouping machines together in a quasi-assembly line, called cells. The intention is to allow the production of small batches of many products with reduced setup times. See Wemmerlov & Hyer,1989, for a survey of cellular manufacturing users in the U.S. Suresh and Meredith, 1994, provide a comprehensive understanding of cellular manufacturing systems and the use of remainder cells, which are machines that are left over from the cellular design.

In the random job shop area, Jackson, 1957, 1963, provided the first analytic approaches for studying dynamic job shop performance. A comprehensive review of queuing models analyzing job shop performance can be found in Bitran and Dasu,1992.

The implementation of cellular manufacturing results in process configurations that share design characteristics common to both flow shops and job shops. Garza and Smunt,1991, measured of flows between cells and illustrated the negative impact of variations from purely sequential flows on system performance. Monahan and Smunt, 1989, studied processes with nearly sequential routings under a variety of product-process characteristics. Smunt & Ghose, 2016, presented a way to measure flow dominance on a continuum from 0.0 to 1.0, which was not scale dependent. They illustrated comparative performance for a wide variety of process scenarios across the continuum of this flow dominance measure.

While these past studies have addressed either multi-point network resilience or single-point manufacturing performance, there is little discussion in the literature that focuses on how a single manufacturing facility may respond to short-term demand shocks. The research presented here provides some preliminary results for understanding single-point manufacturing resilience.

DEVELOPMENT OF THE MANUFACTURING MODEL AND EXPERIMENT

Manufacturing system performance has mainly investigated two extremes of flow dominance, i.e. the routes taken by a job through the factory for complete processing. Purely sequential routings and totally random routings are the extremes. With increasing use of automated manufacturing technology and cellular manufacturing, we see that it is now possible to realize many of the efficiencies of flow lines for the production of low-to- medium volume products. The result is a process design that has characteristics of both a flow shop and a job shop. We define our experimental characteristics in the next section.

Process Characteristics

Four characteristics of a manufacturing process are considered, including flow dominance (FD), operation time utilization (UTIL), setup time (SU), and job size (JS).
Flow dominance is defined as the proportion of jobs going from one machine to another. A high level of flow dominance characterizes flow lines - all jobs follow the same routing through the process. At the other extreme, job shops typically have low flow dominance since jobs may have many different routings. When flow dominance is low, it is more likely that short-term bottlenecks will occur since the routing is more random. We utilize a measure described in Smunt & Ghose, 2016, to specify flow dominance based upon entropy theory.

It is well-known that setup time influences system performance. High machine setup times tend to increase the severity of bottlenecks. Low setup times, resulting from faster changeovers, worker method improvements, or dedicated equipment to produce families with similar processing requirement (cellular manufacturing), results in the ability to economically produce a large variety of parts without the need for large finished-goods inventory.

Job sizes interact with setup times since lower job sizes require more setups, thus increasing total system utilization.

Finally, we use operation time utilization to vary the load on the process. When operation time utilization is lower, the impact of setup times and other disruptions should have less impact than when the operation time utilization is higher.

Demand Characteristics

Demand stability refers to the consistency of the overall load on the system. We model unstable demand by temporarily increasing the load, a situation we refer to as a demand shock. Demand shocks may be the result of marketing promotions, short-term pricing discounts, weather phenomenon, or even disruptions caused by terrorist attacks on another similar facility.
We are particularly interested in the system's ability to return to its steady state condition following a demand shock that causes an overload in capacity utilization. A short-term shock resulting in less than 100% utilization would produce a relatively quick change to another steady state level, and is, therefore, of less interest to us. Rather, we are concerned with the process attributes that effect long response times under short-term, high-load conditions.

In this experiment, we use two different levels of shocks – 133% of the normal demand level for two periods and 200% of the normal demand level for two periods.

Simulation Experiment – Design

A comprehensive factory simulation model was developed and coded in SIMSCRIPT. (More detailed information for the base simulation model design can be seen in Smunt an Ghose, 2016.) Using this model, we conducted an initial experiment to determine the impact of a demand shock and the resulting resilience of the manufacturing facility based upon the time for the mean flow time (MFT) of the production to return to steady state levels.

The experimental product-process factors and their levels are shown in Table 1. The experiment utilized a full factorial design and allowed demand to experience periodic shocks.

Ten (10) repetitions of each combination of factor levels each were tested for a total of 9,000 runs. To eliminate transient state effects, the simulation for each combination was initialized for 5,000 hours of simulated factory time. Following initialization, performance statistics were gathered for forty periods of 320 hours each, so that a time series of performance measures could be observed. Additional intervals between the batches were not utilized in this experiment because serial correlation is of interest in this setting. Since we want to test the ability of the system to return to steady-state conditions after the demand shock, it is important to track performance criteria as they first increase and then decrease.

In this experiment, we define utilization from three perspectives: 1) operation utilization - the percent of machine time spent producing units, 2) setup utilization - the percent of machine time that is nonproductive due to required changeovers between production of different product types, and 3) total utilization - operation utilization plus setup utilization. We set average operation utilization at 60% and 70%. Total utilization varied with job size and the setup time. (We verified that operation utilization of either 60% or 70% was a steady-state condition after 5,000 simulated hours.) At 60% operation utilization, the manufacturing process' total utilization ranged from 70% to 90% - typical values in practice and in prior research studies of job shops. These total utilization levels result in interesting and realistic conditions. For example, total utilization levels reaching into the high 90's percentages result in a near-explosive queueing condition, thus the system will exhibit increasing flow times that would not be acceptable in real world applications. Below a total utilization level of 70%, the system has a large capacity to take on additional demand input, so testing lower utilization levels is not needed or interesting. However, we did observe that at a 70% operation utilization, the total utilization reached 100% in some situations. Note that for every combination of factor levels tested, the operation utilization remains at either 60% or 70% for each work center.

Setup times are deterministic and are specified in terms of the setup ratio, which we define as the ratio of the desired setup time to a base setup time. Pilot experiments revealed that a base setup time of 3.0 hours yields reasonable levels of total utilization.

Each job requires six separate tasks for completion. Jobs are processed in shortest operation time priority, with no capacity limit on the WIP inventory that may develop ahead of each work center.

FACTOR	Level 1	Level 2	Level 3	Level 4	Level 5
FD (Flow Dominance)	0.00	0.23	0.50	0.76	1.00
SU (Setup Time)	0.25	0.50	0.75	-	-
UTIL (Operation Utilization)	60%	70%	-	-	-
JS (Job Size)	25	100	175	250	-
DS (Demand Shock)	1.33	2.00			

Table 1: Simulation Experiment Factor Levels

Example routings for the products produced on the simulated factory for the high and intermediate flow patterns can be seen in Smunt & Ghose, 2016.
In the high dominance case (FD = 1.00), each product type starts at work center 1 and ends at work center 6 after sequentially using each work center in between.

At the other extreme, the low flow dominance case (FD = 0.00) has twelve work centers. We originally set the routings so that each product type uses six of these work centers in random order. Each work center is used as the first, second, etc. task in the sequence. A work center is used only once for each product type.

The intermediate flow dominance levels are variations of the FD=1.00 case. Intermediate conditions may occur as firms move from a process layout to more automated manufacturing. It is unlikely that a firm will completely change its flows from a jumbled order to a pure flow shop in one step.

For any combination of factor levels, job arrival rates are adjusted so that operation utilization remains at either 60% or 70%.

RESULTS

Results of initial experiments that test a single-point manufacturing facility's resilience are discussed in this section. Demand is increased by either 1.33 or 2 times the steady-state demand for two periods, which effectively overloads the facility during this time.
Figure 1 shows the Mean Flow Time (MFT) longitudinal results for the five levels of flow dominance tests, from 0 to 1, where 0 represents a pure job shop (low flow dominance) and 1 represents a pure flow shop (high flow dominance). In these experiments, there was unlimited buffer capacity between the work centers and the average operation utilization (UTIL) is set at 60%. We can see that the systems with the most random flows, FD =0.00, the effect of a demand shock is most apparent when looking at the peak MFT. The ability of the systems to return to steady state, however, is the same for all FD levels.

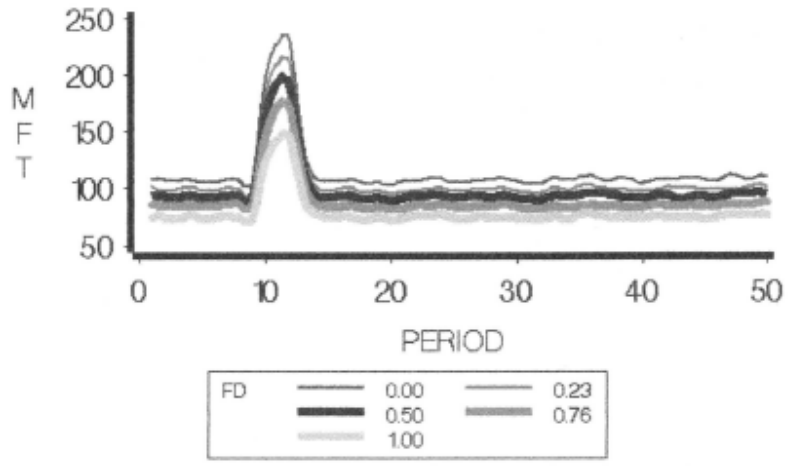

Figure 1: MFT Resilience – By Flow Dominance; DS = 1.33; UTIL = 60%

The longitudinal results for MFT in Figure 2 use the same parameters as in Figure 1, except that the demand shock (DS) is at the higher level of 2 times the average demand. The MFT peak is much higher with this increase surge level, and most FD levels experience approximately the same peak. It is also seen that the time to respond to steady state is longer with the higher surge level.

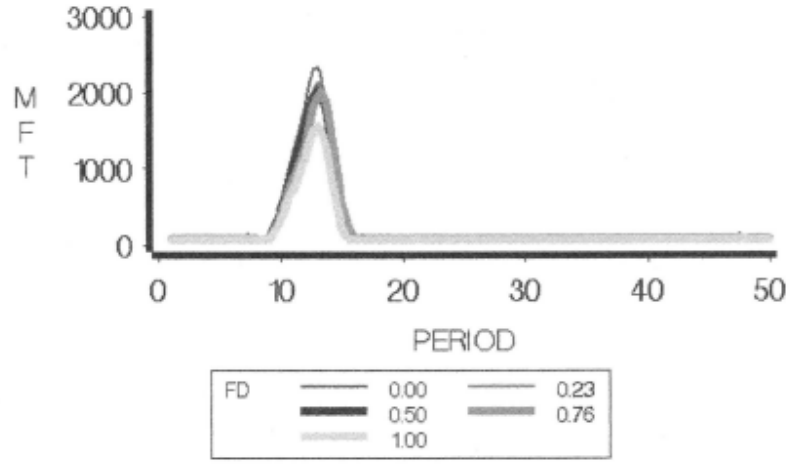

Figure 2: MFT Resilience – By Flow Dominance; DS = 2.00; UTIL = 60%

Figure 3 plots the MFT results over time for the lower levels of DS and UTIL. The impact of increasing setup times in the system is significant. Both steady state and peak MFTs are much larger as the setup times increase. The ability of the system to return to steady state levels with high setup times is less, thus high setup times reduce resiliency. The impact of flow dominance is also interesting to note since the peak MFTs are lower for higher flow dominance conditions.

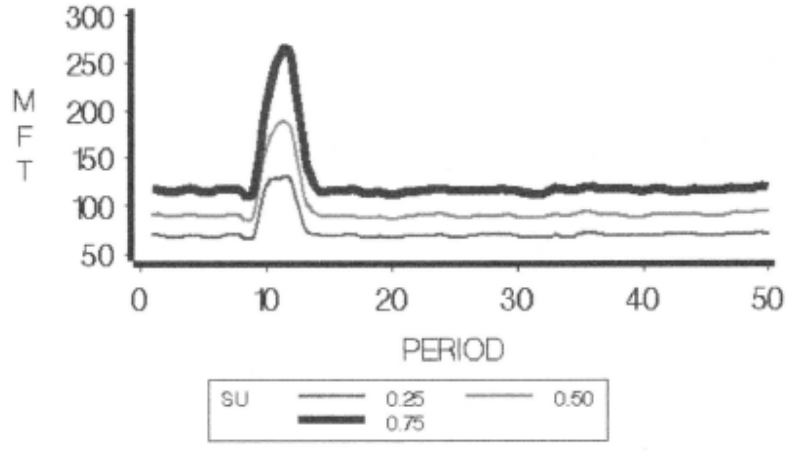

Figure 3: MFT Resilience – By Setup; DS = 1.33; UTIL = 60%

Figure 4 shows similar MFT results to Figure 3, except that DS = 2.00. The impact of increasing the short-term total utilization level results in greatly increased peak MFTs for all setup levels. Differences in peak MFT due to setup levels are now minimal, since it is the increased total utilization percentage caused by the higher demand shock dominates the systems' (non) resilience.

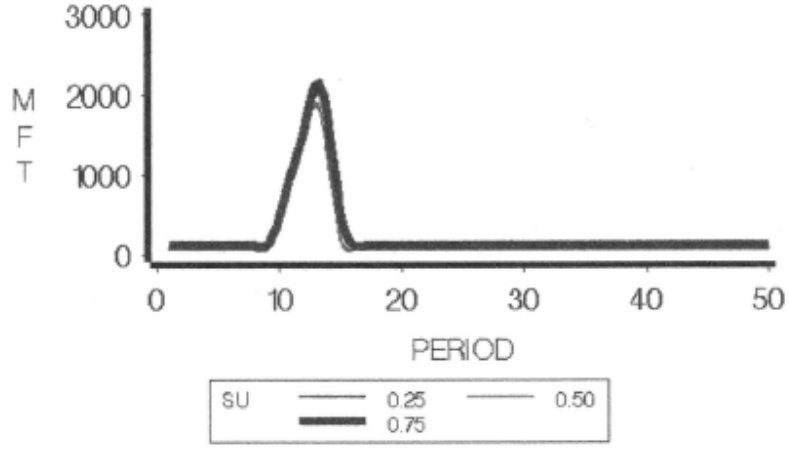

Figure 4: MFT Resilience – By Setup; DS = 2.00; UTIL = 60%

Figure 5 presents the MFT resilience perspective for various levels of job sizes. While it is true that both steady state and peak MFTs are larger as job size increases, there appears to be no relative negative impact on resilience to operating a system with higher job sizes. In fact, the marginal increase in MFT for the peak is lower for large job sizes than for low job sizes.

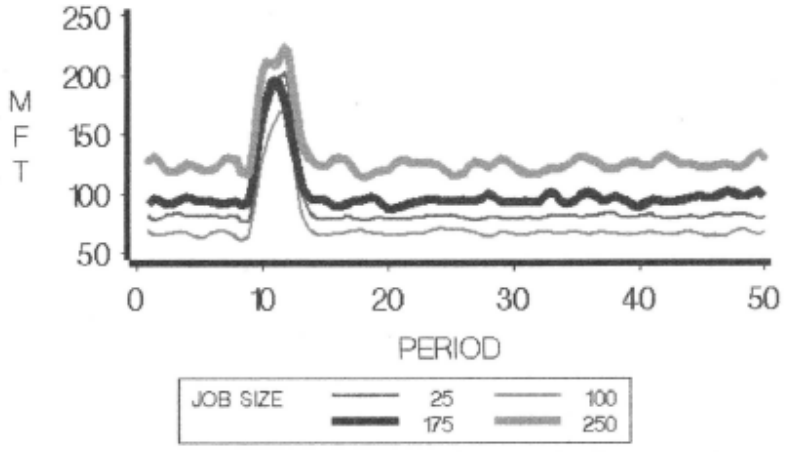

Figure 5: MFT Resilience – By Job Size; DS = 1.33; UTIL = 60%

When increasing DS to 2.00, the effect of job sizes is minimal. MFT peaks are much higher for all levels of job sizes.

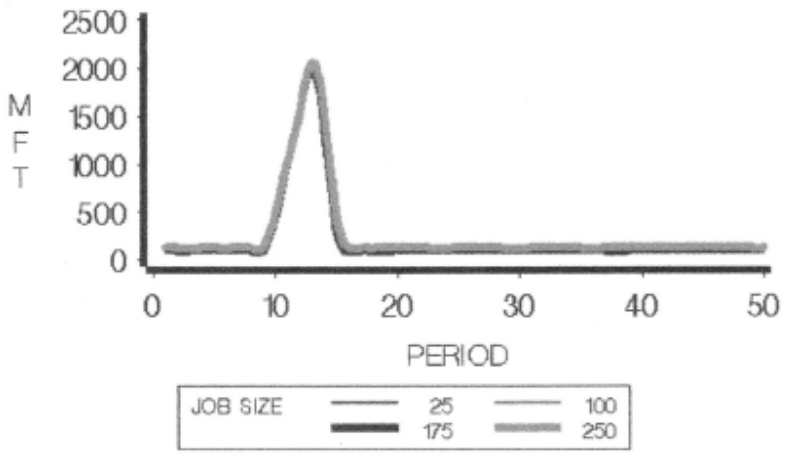

Figure 6: MFT Resilience – By Job Size; DS = 2.00; UTIL = 60%

Finally, in Figure 7, we look at the double impact of high levels of DS and UTIL across all levels of FD. What can be seen is that the systems essentially explode with the higher demand surge and overall operation utilization levels, and never return to steady state during the 50 periods of the simulation.

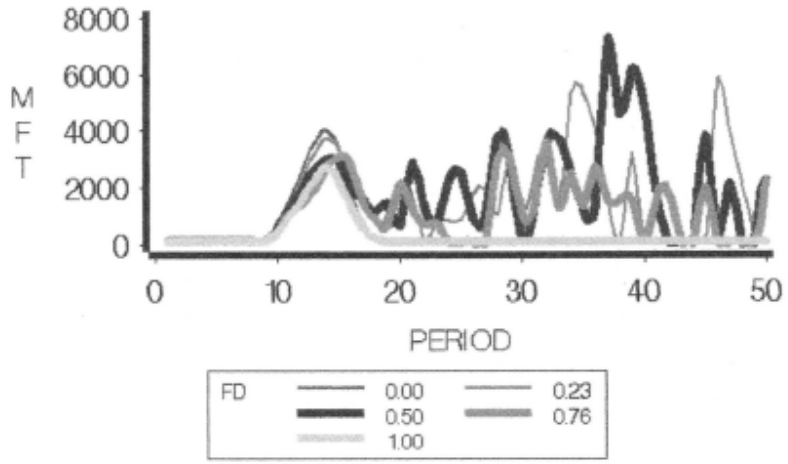

Figure 7: MFT Resilience – By Flow Dominance; DS = 2.00; UTIL = 70%

CONCLUSIONS AND FUTURE RESEARCH

A comprehensive simulation experiment was conducted to investigate factors that affect resilience of single-point manufacturing facilities. The results indicate how quickly a manufacturing facility can return to steady state conditions after a one-time, limited duration, demand surge and potential design factors to consider for adding resilience to systems.

While these results are mainly focused on manufacturing operations, especially due to the testing the impact of setup times in a batch manufacturing mode, similar experiments can be designed to determine resilience in service settings. Designing resilient emergency departments, for example, should be of great interested due to high likelihoods of external events that may cause huge surges in capacity needs.

Future research will encompass additional testing of operating conditions and various other structures of demand surges. One important design consideration is the amount of buffer inventory available within the manufacturing system. The study discussed here allowed unlimited buffer capacities, but modern production systems are moving towards very low levels of work-in-process inventory. It is likely that limited inventory buffers will exacerbate system resilience. Future experiments will also need to examine various levels of demand surges, as well as the length of time of such surges. Finally, modifications to provide ways to increase resilience will need to be tested, for example, the use of parallel processing capabilities or smart control systems.

ABSTRACT

Research has shown that people use smartphones in a way that encourages constant multitasking. While previous studies have determined that multitasking with technology has a negative impact on performance of a primary task, we examine how constant task switching specifically with mobile devices affects users. Our experiment examines discretionary task interleaving with smartphones and the effects this has on performance. The results demonstrate that while any amount of multitasking negatively affects performance on a primary task, these effects are lessened when switching at a breakpoint between subtasks rather than during a subtask.

KEYWORDS: Multitasking; Smartphones; Breakpoints

INTRODUCTION

Multitasking can be categorized in two different ways: internal versus external. External interruptions cause someone to switch tasks due to an interruption in the environment (Miyata & Norman, 1986), such as receiving a text message. In contrast, internal interruptions, occur when someone is interrupted due to their own thought processes (Miyata & Norman, 1986), for example someone remembers to respond to an outstanding email. An internal interruption is "a self-initiated switch away from a task prior to its completion" (Jin & Dabbish, 2009). These are also referred to as "voluntary, discretionary task interleaving between independent tasks" (Payne, Duggan, & Neth, 2007). External interruptions and internal discretionary task switching occur at about the same frequency (Gonzalez & Mark, 2004).

People are constantly multitasking whether at work or at school. Employees switch tasks often, and experience internal and external interruptions at about the same rate (Czerwinski, Horvitz, & Wilhite, 2004; Gonzalez & Mark, 2004; Dabbish, Mark, & González, 2011). Dabbish et al. (2011) found that in the workplace the organizational environment, individual differences, and external interruptions explain self-interruptions. Studies focusing on multitasking with technology have also largely focused on students. Surveys of college students have found that multitasking with technology including emailing, texting, and social networking is widespread during classroom and study time (Jacobsen & Forste, 2011; Junco, 2012; Junco & Cotten, 2012). These results have also been supported through direct observation. Despite the presence of an observer, middle school, high school and college students were found to remain on task for an average of ten minutes total out of fifteen, and were on task without a break for an average of just 5.61 minutes at a time (Rosen, Carrier, & Cheever, 2013).

Recent studies have shown that the timing of external interruptions may have different effects on performance of the primary task depending on when the interruption occurs (Adamczyk & Bailey, 2004; Iqbal & Bailey, 2005; 2007; 2008). Some studies have tried to mitigate the negative impacts of interruptions by placing them at breakpoints (Iqbal & Bailey, 2008; Okoshi, Ramos, Nozaki, Nakazawa, Dey, & Tokuda, 2015a).

Although there has been recent research examining the effects and prevalence of multitasking with technology in general, fewer studies have specifically studied multitasking with mobile devices. However, people are using these devices and they are being used in a way that encourages multitasking behaviors (Oulasvirta, Tamminen, Roto, & Kuorelahti, 2005; Böhmer, Hecht, Schöning, Krüger, & Bauer, 2011; Oulasvirta, Rattenbury, Ma, & Raita, 2012). Multitasking on mobile devices has received some research attention in recent years (Ho & Intille, 2005; Okoshi, Ramos, Nozaki, Nakazawa, Dey, & Tokuda, 2015b; Okoshi et al., 2015a). Users download numerous apps on their smartphones and some are constantly interrupting users (Ho & Intille, 2005). Performance effects of multitasking on mobile devices may not be the same as computer-based multitasking. Adepu and Adler (2016) found that users performed the same task better on desktop computers than on smartphones, though they preferred their smartphones for that task. Larger screen sizes can enhance performance.

In addition to receiving interruptions which force a user to multitask, often people choose to multitask from one app to another. However, research in the area of discretionary multitasking has received less attention. Similarly, while computer-based multitasking has been studied, less research has focused on mobile-based multitasking and its performance implications. This research examines the timing and performance effects of discretionary task interleaving on smartphones.

LITERATURE REVIEW

Performance Effects of Multitasking

Hembrooke and Gay (2003) found that multitasking with laptops during a classroom lecture negatively impacted performance. A later study expanded on that concept and examined how multitasking with different technologies affected an assessment of a series of three typical lectures (Wood, Zivcakova, Gentile, Archer, De Pasquale, & Nosko, 2012). This study found that social based technologies, such as Facebook and instant message, had the most negative impact.

The negative effects of multitasking with some technologies may fluctuate with their popularity. For example, one study found instant messaging to be a popular form of multitasking which led to negative effects (Levine, Waite, & Bowman, 2007). Later studies performed after instant messaging was no longer popular did not find the same negative effects, but found multitasking with other forms of technology that were used more often, and for social purposes to be harmful. For example, surveys of college students have found that multitasking with Facebook or texting is negatively correlated with GPA (Jacobsen & Forste, 2011; Junco, 2012; Junco & Cotten, 2012). Similarly, another study found that students who texted or accessed Facebook at least once during the fifteen minutes they were observed were more likely to have a low GPA (Rosen et al., 2013).

Bowman et al. (2010) did not find that multitasking with technology negatively impacted the

performance of a primary task. However, they did find that multitasking increased the length of time to complete the task. These findings were contradicted by Adler and Benbunan-Fich (2012). Their study found that medium levels of multitasking helped participants finish a larger amount of the primary task, but that any amount of multitasking negatively impacted accuracy on the primary task. This may be due to the fact that in the study by Adler and Benbunan-Fich (2012) the primary task was timed, while the experiment performed by Bowman et al. (2010) was untimed.

A person's perception of task importance can also affect performance when multitasking (Coens, Reynvoet, & Clarebout, 2011). Participants in this study who were told that the secondary task was more important performed better on the secondary task than on the primary task. Participants who were told that both tasks were equally important performed better on the secondary task than participants who were told that the primary task was more important. Janssen et al. (2012) also found that people perform differently depending upon the priority of the tasks.

When Do People Multitask and its Performance Implications

Many studies that have examined when people multitask have not focused on discretionary multitasking, which involves task switches prompted by the user, but rather they focus on external interruptions (Dabbish et al., 2011). However, some experiments involving external interruptions can help predict when people are most likely to multitask when given a choice.

McFarlane (2002) compared four methods of interruption: immediate, negotiated, mediated, and scheduled. Participants in the immediate category received interruptions immediately when they occurred. Participants in the negotiated category were given control over when they would respond to the interruptions. Participants in the mediated category were interrupted at times of lower workload as judged by the application. Participants in the scheduled category received interruptions every 25 seconds. The negotiated category was the most successful category. Although the timing of the task switches was not recorded, the fact that it led to the best performance suggests that people waited for an opportune time to respond to interruptions.

Salvucci and Bogunovich (2010) determined that people tended to respond to interruptions at a moment of lower workload when given a choice. A time of lower workload is a point in the primary task when the participant would not need to remember any information about the primary task when returning after an interruption.

In one study where participants were allowed to multitask at their own discretion, people preferred to switch at subtask boundaries (Payne et al., 2007). Participants were presented with two similar tasks with hard and easy versions. People in this experiment preferred to switch tasks at the completion of a subtask.

Several experiments have been done to determine the most opportune time to interrupt people who are using technology. These studies have all demonstrated that interruptions at breakpoints are the least disruptive to the user by comparing the cost of disrupting participants at different points in a task (Adamczyk & Bailey, 2004; Iqbal & Bailey, 2005; 2008). These experiments have involved users completing a task on a computer, and being disrupted at predetermined best times (at breakpoints between subtasks), at predetermined worst times (during a subtask), and at random times.

Adamczyk and Bailey (2004) report that participants experienced more frustration and annoyance when the interruptions were at random and worst times. Participants also rated these disruptions as less respectful of their primary task than disruptions at best times. However, differences in resumption lag (the time between responding to the interruption and resumption of the primary task) were not significant. Iqbal and Bailey (2005) contradict the previous findings about resumption lag. In their experiment, resumption lag was significantly higher for random and worse cases than for best cases.

Iqbal and Bailey (2007) divide breakpoints into three categories: coarse, medium, and fine. For example, in a task involving document editing, “Fine may be switching paragraphs; medium may be switching documents; and coarse may be switching to an activity other than editing.” Iqbal and Bailey (2008) interrupted participants at coarse, medium, and fine breakpoints with interruptions related to the primary task and interruptions unrelated to the primary task. Participants reported preference for related material at fine and medium breakpoints and unrelated material at coarse breakpoints. They also reported that resumption lag differed based on the relevance of the interruption content. Furthermore, they found that scheduling notifications at breakpoints, rather than having them occur immediately, reduced frustration and reaction time.

Other research has found that the timing of an interruption can affect the length of time it takes to complete the interrupting task. Fischer et al. (2011) interrupted users using their phones in natural environments throughout a two week period and found that interrupting tasks take longer to acknowledge and complete when participants were interrupted at a random time rather than at the end of another task (such as after hanging up from a phone call). Their findings did contradict Iqbal and Bailey (2008) in that their participants did not give random interruptions a worse rating than interruptions at the end of another task.

How Mobile Devices are Used

Several studies have demonstrated that people use mobile devices in a way that is habit forming and facilitates multitasking. When navigating typical urban environments, people pay attention to their mobile devices in short bursts of four to eight seconds (Oulasvirta et al., 2005). Smartphone use throughout the day is more spread out, with one study finding participants spending an average of 59.23 minutes on their mobile devices per day and each session lasted an average of 71.56 seconds (Böhmer et al., 2011).

Smartphones are also used for a longer portion of the day than laptops. Oulasvirta et al. (2012) found that people use smartphones for an average of 160 minutes per day as opposed to 87 minutes per day on a laptop. They also found that unlike laptops, smartphone usage is habit forming. This study looked for smartphone usage sessions that qualify as Short Duration and Reward Based (SIRB). This is defined as a session that is less than 30 seconds in duration that provides some emotional reward. Smartphone sessions were found to be significantly more likely to qualify as SIRB than laptop sessions, which lead to habit forming behaviors. Oulasvirta et al. (2012) suggest that this is because smartphones are more readily available than laptops. They found several characteristics of habitual smartphone use. These habits increase the overall time spent using smartphones because they lead to other smartphone based activities.

More people are now becoming distracted with their smartphones. This can occur in many situations, such as in the classroom (Bradstreet Grinols & Rajesh, 2014). With interruptions from phones becoming normal occurrences, designers need to think about ways to manage these

interruptions (Tolmie, Crabtree, Rodden, & Benford, 2008). Böhmer et al. (2014) found that a multiplex design, where people can be alerted to a call through a small partial-screen notification while working on their primary task worked best. Nagata (2003) found that anticipated interruptions led to better performance in web-based tasks, particularly on a mobile device.

Many websites that were once used solely on computers now have mobile versions or apps. Kalkbrenner and McCampbell (2011) conducted a survey comparing smartphone use vs. standard phone use and found that 88% of respondents felt that smartphones led to an increase in their productivity compared with 42.8% of regular phone owners. Having many apps on one's phone increases people's multitasking. As computers became faster, cheaper, and more powerful, user multitasking occurred more frequently. Similarly, smartphones are become more commonplace and people can open multiple apps simultaneously and task switch.

While multitasking can occur between smartphones and other media and multitasking is prevalent with smartphones when driving (Liu, Cao, Tang, He, & Wen, 2017), we concentrate exclusively on multitasking on mobile devices from one smartphone-based app to another in order to a) compare the results to computer-based multitasking and b) understand more about the ways in which people multitasking on a mobile devices and its effects on performance.

HYPOTHESES

When given a choice about when to respond to an interruption, people tend to choose a time in between subtasks when they will not need to remember information about the primary task (Salvucci & Bogunovich, 2010). People also experience frustration when forced to task switch during a subtask instead of in between subtasks (Adamczyk & Bailey, 2004). People perform better with negotiated interruptions (McFarlane, 2002). If given a choice, people will prefer to switch tasks at a time that is more convenient, such as during a breakpoint rather than during a subtask. Therefore, we hypothesize:

H1: People will have more task switches at breaks between subtasks than during subtasks on mobile devices.

Multitasking has been demonstrated in various studies to negatively impact performance on a primary task. Some studies have found a negative correlation between GPA and multitasking in class or while completing school work (Jacobsen & Forste, 2011; Junco, 2012; Junco & Cotten, 2012; Rosen et al., 2013). Other studies have found that multitasking has a direct impact on performance of the primary task (Hembrooke & Gay, 2003; Adler & Benbunan-Fich, 2012; Wood et al., 2012). Although these studies have not specifically focused on the effects of multitasking with mobile devices, other studies have shown that smartphones are used in a way that specifically encourages multitasking habits and behaviors (Oulasvirta et al., 2005; Böhmer et al., 2011; Oulasvirta et al., 2012). Therefore, we predict:

H2: People who multitask with mobile devices will have worse performance on the primary task than those who do not multitask.

As mentioned above, task switches negatively impact performance on a primary task. This impact can be affected by several factors, including the timing of the task switch. While using technology, interruptions during a subtask can be more detrimental than interruptions in between subtasks (Adamczyk & Bailey, 2004; Iqbal & Bailey, 2005; 2008). When people are

interrupted at a subtask, they experience less frustration (Adamczyk & Bailey, 2004) and less time lag when returning to the primary task (Iqbal & Bailey, 2005). Similarly, with discretionary task interleaving there can be better and worse times to choose to interrupt oneself. Therefore, we propose:

H3: Task switches during a subtask on a mobile device will negatively affect performance on the primary task more than task switches in between subtasks.

MATERIALS AND METHODS

In order to examine when people task switch and its effects, we created a primary task and secondary task that participants were able to choose to switch to.

Primary Task

For the primary task we created an app-based math puzzle called Math Squares. The puzzle consisted of a grid of three rows and three columns of the numbers that formed equations using addition and subtraction. Each of the numbers one through nine was used in the grid exactly once. At the start of the puzzle, the answers to each of the equations were displayed at the end of each row and column. The goal of the task was to fill in the numbers on the grid to create accurate equations. Three numbers were displayed by default to help participants get started. See Figure 1 for a screenshot of the Math Squares puzzle.

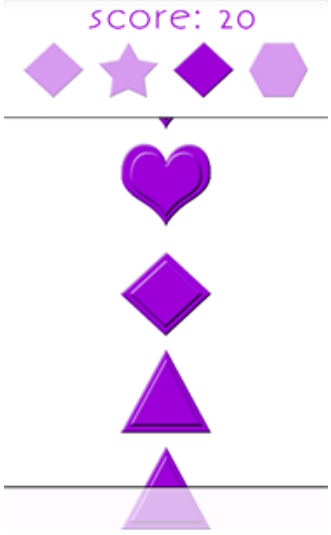
The Math Squares puzzle was designed as the primary task for several reasons. The puzzle requires concentration to find the correct answer, but only involves basic skills like addition and subtraction. Multiple puzzles could be completed in the ten minute time limit so that participants would be able to task switch both in the middle of completing a puzzle and in between puzzles.

Figure 1: Screenshot of Math Squares Puzzle

Secondary Task

For the secondary task, we created an app-based game called Match-It. At the top of the phone screen, four shapes were displayed in a row. Other shapes scrolled down the middle of the screen. The goal of the game is to tap the scrolling shapes in the order of the pattern at the top of the screen. See Figure 2 for a screenshot of the Match-It game.

Figure 2: Screenshot of the Match-It game



The Math Squares puzzle was designed as the primary task since it requires concentration to find the correct answer similar to performing some kind of homework related task. The Match-It game was designed as the secondary task because of its similarity to popular games available in the Google Play store that can be played quickly. Our goal was to mimic the user who is working on something, such as homework, but switches to play a game as is common nowadays.

Participants

Participants were recruited through Amazon's Mechanical Turk, an online platform that allows task creators (known as requesters) to pay workers to complete online tasks known as Human Intelligence Tasks (HITs). Requesters are able to hire a large number of workers from around the world for relatively low pay. This allows researchers using Mechanical Turk to inexpensively recruit more participants from a diverse pool of candidates (Horton, Rand, & Zeckhauser, 2011; Berinsky, Huber, & Lenz, 2012; Mason & Suri, 2012). Research has shown that although workers are paid small amounts of money for doing short tasks, they are often intrinsically motivated and complete the HITs for personal enjoyment (Buhrmester, Kwang, & Gosling, 2011). The reliability of research using Mechanical Turk has been found to be on par with research conducted using traditional methods. In fact, Mechanical Turk participants performed better on online attention checks in three different studies when compared with an undergraduate subject pool of students (Hauser & Schwarz, 2015). Studies can also be done using a wider and more diverse pool of candidates than recruitment on college campuses (Buhrmester et al., 2011; Horton et al., 2011; Berinsky et al., 2012; Mason & Suri, 2012). For

better accuracy of results, the requester can also specify qualifications for completing a HIT, such as the number of HITs a worker has previously completed, and their prior approval rating. Requesters can choose to reject a HIT and not pay the worker if the HIT was not completed accurately (Mason & Suri, 2012).

For this study, a HIT was created on Mechanical Turk. $1.00 payment was given for approximately twenty to twenty-five minutes of work on the experiment. To incentivize accurate results, the person with the highest score was given an additional reward of $5.00. Participants were given forty minutes to complete the HIT so that they would not feel rushed. In order to ensure that our participants would take the tasks seriously, workers had to have previously completed at least 500 HITS at 95% approval rate by the previous requesters. Because the directions were written in English, participation was also restricted to English speaking countries.

After accepting a consent form, participants were given a link to access the experiment via an Android phone. After installing the app and beginning, participants were given a questionnaire regarding their demographic information. Participants were then presented with tutorials for the primary and secondary tasks. Both tutorials included written instructions for how to complete the task as well as two minutes of practice time for each of the tasks.

After the tutorials, instructions were provided to explain the rules of the experiment. The directions were as follows:

1) You will be given ten minutes to complete the math puzzle as many times as you can.
2) After you submit each completed puzzle, a new puzzle will appear. You will not find out your score until the end of the experiment.
3) Your goal is to complete as many puzzles as you can accurately. The participant with the highest number of complete wins will receive an additional $5.00.
4) You may switch to the Match-It game at any time. You can play the Match-It game as often as you want.
5) Please do not use a calculator.
6) Please do not close this app, or engage in any other activities during the ten minutes. If you receive a phone call, please do not answer it. If this app is closed, you will not be able to continue with the experiment, and you will not be paid.

In the experiment itself, participants had ten minutes to complete a primary task and were given the opportunity to switch to a secondary task at any time. Once the experiment was completed, participants were given a post-questionnaire regarding their performance during the experiment.

One hundred and eighty three participants completed the experiment. Two participants were not able to complete the experiment due to technical difficulties with their phones and had to be removed. One additional participant was removed who had 53 switches. We chose to remove this participant, since the range of switches for all other participants was between 0 and 13, and 53 was way above the average and not representative of typical participants but an outlier. The data of the remaining 180 participants (108 male and 72 female) was analyzed.

Since the experiment was through Mechanical Turk and therefore remote (we could not see the participants), a few safeguards were put in place to ensure that participants were not switching to other apps on their phone and were completing the experiment with full concentration and commitment:

1) The app was designed so that if the participant attempted to navigate away from the app

on their phone, they were prompted to abandon the experiment or to continue. After abandoning the experiment, the app was made inaccessible.
2) The post-experiment questionnaire asked participants if they had used a calculator, left the experiment at any time and asked them to self-rate their effort on a scale of one to five. The directions in the questionnaire ensured participants that they would be paid regardless of their answers.

No participant reported using a calculator. Four participants (2%) reported leaving the experiment at some time, and six participants (3%) rated their effort as a one (from a scale from 1 – 5), which we felt indicated they did not put in much effort to try and complete the task with the best results possible. We considered removing these 10 participants, but removing them from the results did not change the significance of the analysis so we left them in.

We also allowed users to leave comments, many of which indicated that they enjoyed the experiment and put effort into completing it. Some comments include: “It was awesome playing the puzzle”, “I wanted to do as best I could on the math game so I could win the bonus.”, “Nice game. Hope you release it for Android.”, and “good hit..brain heating”.

Pre- and Post-Questionnaires

Participants were given a pre- and post-questionnaire on their smartphone before and after the experiment. Since the experiment as well as the questionnaires was completed on a smartphone we asked mostly closed-ended questions with choices to limit the amount of typing on the phone that would be necessary.

In the pre-questionnaire, participants were asked questions related to their frequency of game use and multitasking patterns on phones. In the post-questionnaire they were asked the questions described previously on their effort, whether they used a calculator, and left the experiment at any point.

Experiment

For ten minutes, participants played the Math Squares puzzle as many times as possible. Underneath the puzzle there was a button to submit a puzzle and receive a new one, a button allowing the participant to switch to the Match-It game, and a timer showing the remaining time. Each Math Squares session had to take a minimum of thirty seconds to keep participants from randomly filling in the grid and submitting. If the user attempted to close the app by clicking on the home or recent apps buttons, a popup would appear asking the user to confirm their desire to abandon the experiment. This was done to prevent people from using other applications on their phones instead of participating in the experiment. Participants could switch to the Match-It game at any time. During the Match-It game, the timer was stopped to ensure that everyone would spend ten minutes playing the Math Squares puzzle in order for performance to be compared accurately.

Measures

During the experiment the following data were captured:

1) *Complete Wins*: The number of Math Squares puzzles completed correctly, with all six numbers filled in accurately.

2) *Total Switches*: The number of times that the user switched from the Math Squares puzzle to the Match-It game.
3) *Between Switches*: The number of times the user switched to the Match-It game in between finishing one Math Squares puzzle and starting the next puzzle.
4) *During Switches*: The number of times the user switched to the Match-It game after starting a Math Squares puzzle but before submitting the puzzle.
5) *Average Score per Match-It Game*: Participants were given one point each time they tapped the correct shape. The total number of points was recorded and averaged together.
6) *Average Seconds per Match-It Game*: The total number of seconds played for each Match-It game was recorded and averaged at the end.

RESULTS

Participants

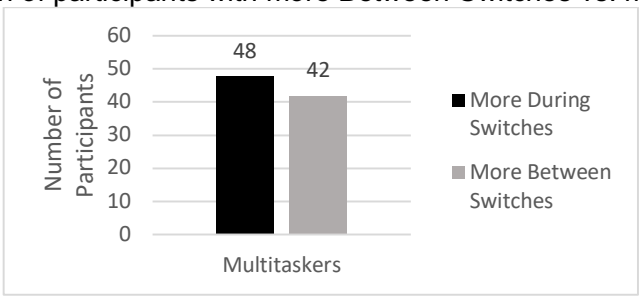
The 180 participants' data was analyzed for demographic information. In regards to ethnicity: 111 (61.67%) were Caucasian, 38 (21.11%) were Asian/Pacific Islander, 14 (7.78%) were Hispanic/Latino, 13 (7.22%) were Black/African American, 3 (1.67%) were Middle Eastern, and 1 (0.56%) identified as "other". The breakdown of age is as follows: 106 (58.89%) were 18-30, 54 (30%) were 31-40, 15 (8.33%) were 41-50, 2 (1.11%) were 51-60, and 3 (1.67%) were 61 or older.

Of the 180 participants, 78 (43.33%) of the participants were monotaskers, participants who did not switch during the experiment, while 102 (56.67%) were multitaskers, participants with at least one switch. The number of switches among multitaskers ranged from one to thirteen with a mean of 2.9. Of the multitaskers, 32 (31.37%) switched only one time while the remaining 70 participants (68.63%) had two or more switches. Participants completed an average of 5.8 Math Squares puzzles, and had an average of 3.07 Complete Wins. Participants spent an average time of 16.43 seconds on each Match-It game and 119.17 seconds on each Math Squares puzzle.

Test of Hypothesis 1

In order to determine whether participants would choose to task switch more frequently at breakpoints between subtasks rather than during a task, we compared Between Switches and During Switches for the 102 multitaskers. 42 participants had more Between Switches than During Switches, and 48 had more During Switches than Between Switches (see Figure 3). There were 12 participants who had an equal number of Between Switches and During Switches. A sign test shows that there were no significant differences between the number of Between and During Switches for participants ($z=0.63$, $p=0.53$), therefore H1 is not supported.

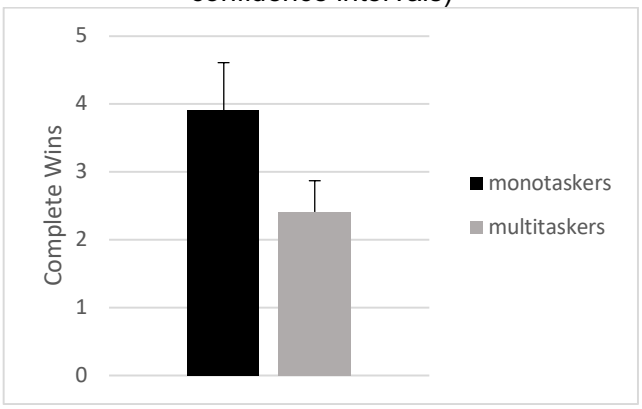
Figure 3: Comparison of participants with more Between Switches vs. more During Switches



Test of Hypothesis 2

To determine whether participants who multitask on mobile devices have lower performance on the primary task than those who do not multitask, we compared the performance on the Math Squares puzzle for multitaskers (102 participants who had at least one switch) and monotaskers (78 participants who had zero switches). The measurements used to gauge performance on the Math Squares puzzle (the primary task) was Complete Wins. The range of Complete Wins was zero to twelve, and the overall mean of Complete Wins was 3.067. As shown in Figure 4, there was a significant difference in the performance for monotaskers (M=3.92) over multitaskers (M=2.41), t(178)=3.79, p=0.0002. These results suggest that switches in general may negatively impact performance of a primary task.

Figure 4: Comparison of Complete Wins for monotaskers and multitaskers (error bars = 95% confidence intervals)



Furthermore, results of a Pearson correlation indicate that there is a significant and negative association between Total Switches and Complete Wins (ρ=-0.22, p=0.003). These results suggest that there is a negative relationship between people switching away from the primary task and their performance. Therefore, H2 was supported.

In addition to analyzing the effect of Total Switches on performance of the primary task, we also examined the amount of time spent on the Match-It game. A correlation shows a negative relationship between the average time spent playing the Match-It game and Complete Wins

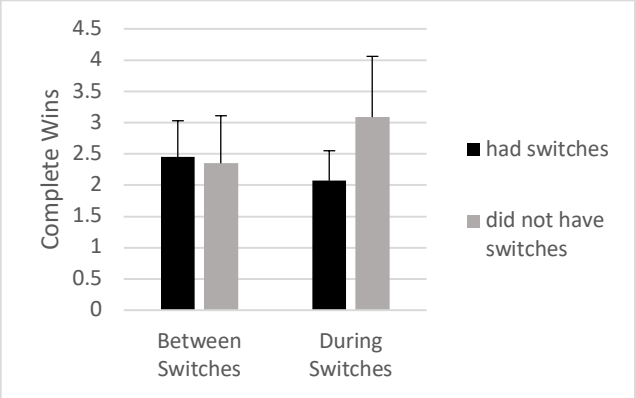
(ρ=-0.17, p=0.019). Even though the timer on the primary task was stopped and all participants spent the same ten minutes working on the primary task, the more time away from the task the lower the users performance. This suggests that the number of switches is not the only factor affecting performance on the primary task. The amount of time spent away from the primary task before returning may also impact the results.

Test of Hypothesis 3

To analyze whether task switches during a subtask negatively affect performance on the primary task more than task switches between subtasks, we examined the data for multitaskers (N=102) and explored the performance effects of During Switches and Between Switches.

For all multitaskers, a t-test showed that participants who had During Switches had significantly fewer Complete Wins than participants who had no During Switches, t(100)=2.13, p=0.036. However, performance for participants who had Between Switches was not significantly different from participants who did not have Between Switches, t(100)=-0.20, p=0.843, see Figure 5. Therefore, H3 was supported.

Figure 5: Performance differences between participants who had and did not have During Switches and participants who had and did not have Between Switches (error bars = 95% confidence intervals)



For multitaskers, we also computed a correlation comparing Complete Wins with During Switches and Between Switches. There is a significant negative relationship between Complete Wins and During Switches (ρ =-0.22, p=0.027), but no significant relationship between Complete Wins and Between Switches (ρ=0.06, p=0.545). These results suggest that switches during a subtask negatively affect performance on a primary task, while switches in between subtasks do not have a significant negative effect.

We also examined the difference in performance among those who had only Between Switches, only During Switches, both During and Between Switches, and no switches at all (Table 1). An ANOVA shows that there is no significant difference between those with no switches and those with only Between Switches (F(1, 110)=1.88, p=0.1728), but there is a significant difference between those with no switches and those with During Switches (F(1, 113)=7.80, p=0.0061). Furthermore, while there is no significant difference between those with only During Switches and those with both During Switches and Between Switches (F(1, 66)=1.63, p=0.2068), there is a significant difference between those with Between Switches and both During and Between

(F(1, 63)=5.77, p=0.0192). This suggests that the harmful effect of task switching is worse when those switches are During Switches, rather than Between Switches.

Table 1: Complete Wins and Switches

Complete Wins	**N**	**Switches**
3.92	78	No Switches
3.09	34	Only Between Switches
2.35	37	Only During Switches
1.74	31	Both During and Between Switches

DISCUSSION

In this experiment, there were no significant differences between the number of people who had more During Switches and the number of people who had more Between Switches. This seems to contradict previous studies that have determined that people prefer to task switch at breakpoints (Payne et al., 2007) and that when given a choice about when to respond to an interruption, people prefer to wait for a break between subtasks (Salvucci & Bogunovich, 2010). Similarly, Katidioti et al. (2014) found that participants preferred to switch at a moment of lower workload even in situations where they were able to switch completely at their own discretion. Our results also seem to contradict previous studies in the interruption literature that people prefer to task switch in response to an interruption when the interruption comes at a breakpoint (Adamczyk & Bailey, 2004; Iqbal & Bailey, 2005; 2008; Bogunovich & Salvucci, 2011; Borst, Taatgen, & Rijn, 2015).

There are a few possible reasons for this discrepancy. There may be factors that we are not accounting for such as the difficulty of the primary task. People may switch more/less depending on the difficulty level of the task. It is also possible that had we examined between switches not after completion of a puzzle but between-row or between-column switches vs. during-row and during-column switches we may have had different results. Finally, the low number of switches in our experiment may have led to the different results. Since participants were allowed to switch to the Match-It game as many or as few times as desired, some preferred to switch only once or not at all. Out of 180 participants whose data were analyzed, only 102 (56.67%) had any switches at all, and 32 (17.8%) had only one switch during the ten minutes. Leiva et al. (2012) found that people do not switch apps on their smartphones very often. It is possible that if participants were required to switch a fixed number of times (with the timing still at their discretion), that a clearer pattern would emerge.

Similar to previous studies (Hembrooke & Gay, 2003; Adler & Benbunan-Fich, 2012), we have found negative results when multitasking with technology. Specifically, our research demonstrates that these negative effects are also found when people multitask with smartphones. There was a strong negative relationship between primary task performance and any amount of switching.

In addition to the number of switches, we also found that time away from the primary task lowered performance. When participants in our experiment switched to the Match-It game the timer on the Math Squares puzzle was stopped, so all participants spent the same ten minutes

on the primary task. Despite this, there was a significant negative relationship between time away from the primary task and number of Complete Wins. The more participants were away from the primary task, the lower their performance. This supports previous research by Hembrooke and Gay (2003) who found that time away from the primary task had more of a negative impact on performance than the content of the interruption.

The data in this research also supports Hypothesis 3 that switching in the middle of a subtask on mobile devices is more detrimental to performance on a primary task than switches in between subtasks. This suggests that the negative effects on performance can result from the amount of time it takes to remember information about the primary task after the end of an interruption. This supports previous research that found a time lag after interruptions from the primary task (Iqbal & Bailey, 2005). When the task switch occurs at a breakpoint there is no need to remember information and the primary task can be resumed immediately. In this research, participants who switched during the Math Squares puzzle would have to remember their thought process and strategy when returning to the task which negatively affected their performance.

While there were no significant differences between those who monotasked and those who switched in between subtasks, performance was significantly lower for those who switched during the subtask than those with no switches. This implies that some switching may not be detrimental if it is between subtasks and not during the task.

Implications

Previous research has shown that there are negative consequences to multitasking with technology in general (Hembrooke & Gay, 2003; Adler & Benbunan-Fich, 2012). Since smartphones in particular are used in a way that facilitates multitasking that can become habit forming (Oulasvirta et al., 2005; Böhmer et al., 2011; Oulasvirta et al., 2012), it is important to understand the effects of multitasking with smartphones specifically. Previous research has shown that performance on smartphones can be lower than on desktops, yet people still prefer smartphones (Adepu & Adler, 2016). This research has demonstrated that similar to computer-based multitasking, multitasking with smartphones negatively affects performance on a primary task. In addition, the more time away from the primary task, the lower users' performance. Furthermore, this research suggests that there are smarter ways to multitask which can lessen these negative effects. While previous literature discusses breakpoints in terms of external interruptions, we found that task switches during breakpoints can minimize the negative effects of multitasking. People who task switch can wait for a natural breakpoint in their primary task to switch to a secondary task. This will allow them to continue their multitasking behavior while minimizing negative effects on performance of their primary task.

Limitations and Future Research

Although Mechanical Turk provides many benefits to researchers, there are some limitations as well. Because participants completed the experiments on their own, it is possible that they experienced other distractions in their environment other than the Match-It game. It is also possible that participants left the experiment for part of the ten minute time limit. However, these limitations may be balanced out by the benefits of Mechanical Turk, which allowed us to recruit a larger and more diverse group of participants than we could have recruited on a college campus.

Another limitation in our research was the low number of participants who chose to switch to the secondary task. It is possible that we would have gotten better results had there been more of an incentive to switch to the secondary task. Requiring participants to multitask a fixed number of times while still allowing them to switch at a desired time, might give a clearer picture of when people are more likely to multitask. Data from participants who only switched a couple of times may not provide enough information to determine when they may have switched when constantly multitasking.

Future research may also look at the amount of time spent away from the primary task in between subtasks and during a subtask. In this experiment, only the average amount of time per Match-It game was recorded, and a negative relationship between Average Time per Match-It game and performance on the Math Squares puzzle was found. It would be interesting to see if total time spent on the Match-It game in the middle of a puzzle had a worse effect than total time in between puzzles.

CONCLUSION

People multitask constantly in multiple environments such as the workplace and school. Multitasking with technology is very common, and is especially pervasive when people are using mobile devices. Prior research has established the negative effects of multitasking when using technology in general. This research focuses on smartphone-based multitasking and found negative consequences of multitasking on smartphones. Furthermore, the more time participants spent away from the primary task, the lower their performance. While this study did not find any difference between the number of people who multitasked in between subtasks and during a subtask, the difference in performance between these two groups was significant. Switches during a subtask had a significant negative effect on performance, while switches in between subtasks did not have a significant effect. This suggests that the negative effects of discretionary task interleaving can be lessened by the timing of the switch. Waiting to switch to a different task at a natural breakpoint can reduce the negative consequences of multitasking on mobile devices.

ACKNOWLEDGEMENTS

We would like to thank Northeastern Illinois University Committee on Organized Research grant for funding this research.

Smart Phone use - The effect of Economics and Culture

(Full Paper Submission)

David M. Simmonds
Savannah State University
simmondsd@savannahstate.edu

ABSTRACT

The use of Smart phones for economically motivated activities, is examined against Hofstede dimensions of culture using 4 macro-economic indicators and the proportion of smartphone use for activities related to the cultural dimensions. Results suggest that this technological extension to human hands, is mirrored somewhat in the collective socio-economic soul of a country.

KEYWORDS: Smartphone, Apps, Satisfaction, Culture, Economics , Hofstede

INTRODUCTION

Smartphones have been steadily increasing in resolution and are at the point where they rival 60” TV screens in a 5” space. Bandwidth available has also increased exponentially and easily rivals home-internet, with dozens of Mb per second, even over cellular connections., making the loading of rich, complex knowledge sources, very commonplace. Smartphones represent a convergence of information & communication technology, facilitating many modes of communication and knowledge transfer. The extent of computing power which has now gone into Smartphones phones prompted vice president of Nokia, William Plummer to remark that "There used to be a computer industry, and there used to be a consumer electronics industry, but it's all the same thing now" (CIO, 2008). They now come with a plethora of apps which are expected to be almost seamlessly fast even over the internet (Djerv & Malla, 2012).

In this paper, we examine how national culture and economics influences smart phone use for a range of economic activities facilitated by ICT. We examine the relationship between New Business Density percent, and the Ratio of Searched_jobs/Finance_activities in the presence of Uncertainty Avoidance. Also, how GINI drives Ratio of Searched_Travel_holidays/Used_shopping_coupons in the presence of Power Distance. We also look at how Manufacturing percentage of GDP is related to the ratio of Listened_music/Played_games in the presence of Individualism/Collectivism. Gender-Parity-of-Employers is a growing concern and we see whether it is connected to the ratio of Accessed_social_network /Sent_read_email in the presence of Masculinity/Femininity

LITERATURE REVIEW

Culture is the way groups of peoples have configured the behavior which they share and learn in order to form a cohesive whole (J. A. Lee, Garbarino, & Lerman, 2007). It differentiates them from other peoples (I. Lee, Choi, Kim, & Hong, 2007). It is the content and set of values and thought-processes which are created and passed along in order to shape fellow human beings into functioning members of society (I. Lee et al., 2007). “Culture is the collective programming of the mind which distinguishes the members of one group of people from another” (Hofstede,

1991, p. 5). National culture is the values and beliefs which people adopt early in their lives (Lim, Leung, Sia, & Lee, 2004) and drives the outcomes at a national level, as well as affecting their attitudes to and contentment with those outcomes.

Hofstede's Dimensions of Culture

In the 1960s and 70s, famous a Dutch anthropologist Geert Hofstede used IBM employees in 53 countries to determine the common components of culture (Hofstede, 1980, 1991). His studies led him to differentiate cultures into four dimensions initially, and ultimately six. These dimensions of culture while attracting criticism are the landmarks with regard to viewing the collective behavior of nations and have been broadly applied in studies of culture. They include Uncertainty Avoidance, Individualism versus Collectivism, Masculinity versus Femininity and Power Distance. Temporality and Indulgence later rounded out the six and added value in differentiating between, for example, Western Cultures which tend to have a right-now mentality versus much older cultures which take a long-view of results.

Masculinity vs. Femininity

Not surprisingly, a study done by a patriarchal figure in the 60s would necessarily differentiate personalities by gender and top it off by linking the dimension to achievement and success. And so, Masculinity vs Femininity is unfortunately, as sexist as it sounds. Naturally, the feminine side would be described as being relationship focused. While the purpose of this study is not to critique Hofstede's work, certainly a modernized, progressive discussion human development needs to make clear the distinction between gender-traits and gender-abilities. Most modern re-readings make the distinction more in terms of the different approaches to doing things and not whether an individual has higher standards or works less than others (Lemish & Cohen, 2008; Palen, Salzman, & Youngs, 2000; Totten, Lipscomb, Cook, & Lesch, 2005).

Uncertainty Avoidance

Hofstede described socially driven levels of anxiety, fear of failure and unwillingness to take chances as Uncertainty Avoidance. A preponderance of innovation is not the strength of an Uncertainty Avoidant culture since they avoid the possibilities that come with adventure, in favor of the evils they know. Uncertainty avoidance is not the same as fear that comes from a threat someone knows about and understands (I. Lee et al., 2007; Marcus & Gould, 2000). Uncertainty Avoidant cultures fear uncertain situations and will focus on the possible losses that may ensue.

Individualism vs. Collectivism

People in an individualistic society tend to go it alone, preferring loosely coupled relationships which serve their individual interest. Property is seen as more personal than communal (Jhangiani & Smith-Jackson, 2007; J. A. Lee et al., 2007). Each person is responsible for themselves or those of their inner circle only (Marcus & Gould, 2000). In situations involving conflict between the wider community and personal goals, in an individualistic society, the personal goal will usually take precedence (Srite & Karahanna, 2006).

Power Distance

Power distance represents the extent to which people accept differences in power levels within a society (Marcus & Gould, 2000). Large power distance societies are marked by a sense that everyone has a 'rightful' place in society. Old age and status are respected tremendously and status is put on display to demonstrate power (de Mooij, 2000)

Smartphones and Productivity

In addition to being the state-of-the-art in communications technology, Smartphones are challenging PCs for dominance in daily computer use. Smartphones have the major advantage over office computing devices in that they can be used literally anywhere—if internet service is available (Van Biljon & Kotzé, 2007). Due to massive availability of user installable applications on Android from Google Play and iOS from the Apple Store. The amounts and kind of tasks that can be accomplished using a smartphone has increased. All these features available on a smartphone means that the gap between computer and smartphone usability is being reduced constantly by the advances in smartphone capabilities and especially the leaps and bounds being made in increasing their technical capabilities. So, the technical drivers of usage should become less important and give way to more deeply held human qualities and stable qualities such as national culture.

Mobile hotspots included as part of many cellular mobile plans, is now an every-day reality. Purchasing car parts, Booking Vacations, applying for jobs, reserving movie tickets and playing games is now unremarkable, High-end smart phones have screen resolutions, processors, memory, and storage that rival laptop computers. Smartphones can be taken anywhere and wherever there is network access, which tends to be everywhere on the beaten path. It allows you to perform internet-based activities throughout the day, not only while sitting at a desk or at home. However, comparing information is more difficult on a smartphone even though the newer smartphones allow users to use 2 apps side by side. to directly compare information about two products, services or activities. Incompatible data formats can also a problem since not all file formats are available, especially in an editable mode on a smartphone. This can make saving and retrieving information more difficult.

Naturally their ubiquity as tools of knowledge acquisition, development, accomplishment, connectivity, commerce and progress, all come at a price. Psychiatrists such as Lin and Chang, have investigated and established the existence of 'smartphone addiction, and in the process, created the Smartphone Addiction Scale (SPAI), using the Chen Internet Addiction Scale (CIAS) (Lin et al., 2014) as their point of departure. PTSD severity and impulsivity in smartphone use, linked to addictive behaviors have also been validated using the PTSD Checklist for DSM-5 (PCL-5) and Kwon et al. (2013)'s Smartphone Addiction Scale- Short Version (SAS-SV) (Contractor, Weiss, Tull, & Elhai, 2017). Smartphones also act as a tether, keeping employees working outside normal hours. This according to (Cole & Cole, 2016) reduces their ability to recover from the stress of work.

HYPOTHESES

Use of Smartphones for Uncertainty Avoidant activities reflected in Entrepreneurship

New businesses require investment which implies financial planning to maximize currently held resources to acquire the capital to start a business. Starting one, while promising the possibility of great reward, does simultaneously carry a lot of risk (Yang, 2004). This is countered by a focus on gaining employment from an existing employer. Uncertainty avoidance will determine the extent to which prospective entrepreneurs will embrace the risk of opening their own business versus continuing to be employed by existing businesses (I. Lee et al., 2007; Marcus & Gould, 2000). Customers now have instant access to their bank balances and get notifications of purchases, minutes ago on their smartphones, thanks to apps available from every major financial institution. Job search apps for companies like Indeed, Monster and Glass-Door, have become a staple for on-the-go job application, so critical in today's competitive job market where being one of the first resumes available to an employer is vital to getting an interview.

Hypothesis 1: New-Business-Density is related to ratio of smartphone use for Searched_jobs/Finance_activities moderated by Uncertainty Avoidance.

Use of Smartphones for Power Distant activities reflected by GINI

Income inequality is reflected in the flamboyant lifestyles of the rich, mirrored in the scraping for existence by the poor. Travel holidays are one of the reflections of discretionary income and the freedom of time and movement, the ability to "drop everything and go". They also reflect a level of exposure to the finer things in life and the emphasis on higher order self-development, as witnessed by social media postings in which the traveler emphasizes how many cities they have visited. This is important in Power Distant society where it becomes imperative to show you are one of the "haves" (de Mooij, 2000). On the flip side, shopping coupons while also used by some rich people, are mostly a reflection of someone's s need to economize and stretch their dollars, instead of flaunting success. Both activities are done on Smartphones, which allow ubiquitous levels of activity in either, allowing Smartphones to be used at every point of sale, and vacation plans to be constantly refined.

Hypothesis 2: GINI is related to Smartphone use for ratio of smartphone use for Searched_Travel_holidays /Used_shopping_coupons in the presence of Power Distance.

Use of Smartphones for Individualistic activities reflected by Manufacturing

Manufacturing as rethought by Adam Smith, and constantly reimagined by entrepreneurs, involves the solitary activities in which the individual carries out tasks which have been very neatly subdivided by individual skill required and specific contribution to the value generation process (Yeniyurt & Townsend, 2003). Agricultural societies, especially subsistence-based economies, as reflected in the family approach where children are an integral part of the process and sometimes removed from school

to focus on the planting and reaping of crops to boost the family income, is a very participative activity. This is necessary as it is highly (cheap) labor intensive, as activities such as weeding are difficulty to automate. In many societies it even pulls in the wider community which is on no-questions-asked standby to help reap a crop when the weather, especially flooding, poses a threat to a farmer's ability to bring a crop to market (Jhangiani & Smith-Jackson, 2007). This is reflected in the individuality/collectivist construct which drives the focus on the group versus the individual (J. A. Lee et al., 2007). Smartphone use should mirror this contrasting approach to economic activity.

Hypothesis 3: Manufacturing percentage of GDP is related to the ratio of Smartphone use for Listened_music/Played_games in the presence of Individualism/Collectivism.

Use of Smartphones for Feminine activities reflected by Gender equality of Female businesses

While Hofstede needs a rethink to indicate that contributions of men and women are equal in value, even if diverse--bringing the richness and various strengths to the mix, ensuring that the process and product benefit from the best of our different approaches and styles. Gender parity does not mean that we all look or act like the same person, but that the contributions of each gender play an equally valuable role in business and society. Social media allows the more feminine quality of relationship building to shine through over the cut-and-dry approach to basic information seeking and dissemination which is allowed by email (Lemish & Cohen, 2008; Palen et al., 2000; Totten et al., 2005). The Femininity/Masculinity aspect of national culture will determine the extent to which the two different approaches are combined and balanced, reflected in the use of smartphones for either activity.

Hypothesis 4: Gender-Parity-Employers is related to the ratio of Smartphone use of Accessed_social_network/Sent_read_email in the presence of Masculinity/Femininity.

Data

Dependent Variables

Socio-Economic indicators were acquired from World Bank, OECD, OurWorldinData.org, PewGlobal.org, Gallup Polls and UNDP.

Independent Variables

Data for smartphone use was taken from Google's Our Mobile Planet for years 2011 and 2012 which were averaged. The dataset covers 40 countries which correspond to the top 40 countries with significant, comprehensive use of smartphones. This dataset remains unique, and has never been replicated to any significant level. Each country data point represents between 500 and 1000 respondents. In some cases, the survey questions such as how often the respondent uses social networking on their smartphone allowed several responses. In this case, valid responses were: "Daily", "Weekly", "Monthly", "Less than Monthly" and "Never". To derive a country-level score, the results were converted to a log-based Likert-scale weighted average.

For example, the country score for this variable was calculated as (7 x Daily + 5 x Weekly + 3 x Monthly + 1 x Less-than-Monthly + 0 x Never) / Total-Responses

Hofstede culture data was derived from https://www.hofstede-insights.com/product/compare-countries/ and represents culture data as at 2001 which has not changed significantly in the intervening years.

RESULTS

Hypotheses were tested using linear regression in R. All models included a Hofstede dimensions of Power-Distance, Uncertainty-Avoidance, Individualism_Collectivism and Masculinity_Femininity. They also included: GDP_PerCapita, Population_perc65over, GP_PostSecondary, Happiness_2010, Used_Application and Browsed_Internet as control variables.

Model-1: New-Business-density & Uncertainty-Avoidance …

Independent Variables	Beta	t	p-value	
Used_Application	0.392836	1.593	0.1456	
Browsed_Internet	-0.57705	-2.423	0.03841	*
GDP_PerCapita	-0.00045	-2.108	0.06429	.

adj R^2 = 0.5451				
p = 0.0414				
** p < 0.05, ** p < 0.01, *** p < 0.001*				

Hypothesis-1 suggested that countries with a higher level of Entrepreneurship as reflected in the rate of New-Business-density, would make greater use of Smartphones in job searches compared to use for Finance_activities. And also, that this effect would be increased by the Uncertainty Avoidance of the country. Overall model-1 was significant ($f = 3.397$, $p = 0.0414$) and so Hypothesis-1 was supported, since the ratio of Smartphone use in job searches to Finance_activities was significant the ratio of job-searches to Finance_activities was significant ($\beta = 81.3400554$, $t=2.478$, $p=0.03512$). However, Uncertainty Avoidance was not significant ($\beta = 0.392966$, $t=1.83$, $p=0.10045$) but the interaction variable between them was significant ($\beta = -1.2099495$, $t=-2.744$, $p=0.0227$).

Model-2: GINI & Power-Distance …

adj R^2 = 0.7423				
p = 0.0004956				
** p < 0.05, ** p < 0.01, *** p < 0.001*				

Hypothesis-2 suggested that countries with a higher level of Income-Inequality as reflected in their GINI, would make greater use of Smartphones for Searching_Travel_holidays compared to use for shopping_coupons. And also, that this effect would be increased by the Power Distance of the country. Overall model-2 was significant (f =8.04, p =0.0004956) but Hypothesis-2 had limited supported, since the ratio of Smartphone use for Searched_Travel_holidays compared to Used_shopping_coupons was not significant (β= -9.07E+00, t=-1.476, p=0.163748), even though Power Distance was significant (β= -5.31E-01, t=-2.296, p=0.038941) and the interaction variable between them was significant, but only at the 0.1 level (β= 1.96E-01, t=1.874, p=0.083612).

Model-3: Manufacturing & Indvidualism_Collectivism …

Independent Variables	Beta	t	p-value	
Used_Application	0.01235	0.036	0.97203

adj R^2 = 0.2896				
p = 0.1392				
** p < 0.05, ** p < 0.01, *** p < 0.001*				

Hypothesis-3 suggested that countries with a stronger manufacturing focus as reflected in the Manufacturing-percentage-GDP, would make greater use of Smartphones for Listening_music compared to use for Playing_games. And also, that this effect would be increased by the Individualism of the country. Overall model-3 was not significant ($f = 1.951$, $p = 0.1392$) and so Hypothesis-3 was not supported, since the ratio of for Listening_music to Playing_games was not significant ($\beta = -4.18E+01$, $t = -0.788$, $p = 0.44582$). Neither was Individualism significant ($\beta = -6.76E-01$, $t = -0.718$, $p = 0.48638$) nor was the interaction variable between them ($\beta = 5.07E-01$, $t = 0.557$, $p = 0.588$).

Model-4: Female-Businesses & Masculinity_Femininity …

Independent Variables	Beta	t	p-value	
Used_Application	-0.7931	-1.501	0.18391	
Browsed_Internet	0.7813	1.442	0.1995

Masculinity_Femininity	-6.458	-3.47	0.0133	*
SPRatioColumn1_MF:Masculinity_Femininity	5.297	3.349	0.01544	*

f-statistic = 8.139
R^2 = 0.9243
adj R^2 = 0.8107
p = 0.009492
** p < 0.05, ** p < 0.01, *** p < 0.001*

Hypothesis-4 suggested that countries with a higher level of Gender-Parity-in-Employers as reflected in the Employers_percFemale, would make greater use of Smartphones for Accessing-social-network compared to use for Sending_reading_email. And, that this effect would be increased by Femininity (the negative of masculinity in the model) of the country. Overall model-4 was significant ($f = 8.14$, $p = 0.009492$) and so Hypothesis-4 was supported, since the ratio of Smartphone use in job searches compared to Finance_activities was significant ($\beta = -2.34E+02$, $t = -2.901$, $p = 0.0273$), Femininity (-ve masculinity) was significant ($\beta = -6.46E+00$, $t = -3.47$, $p = 0.0133$). However, the interaction variable between them was significant, but correlated with masculinity, not femininity ($\beta = 5.30E+00$, $t = 3.349$, $p = 0.01544$).

DISCUSSION

Entrepreneurs look for dramatic change to life financial strength rather than incremental improvements (CITE). Hypothesis-1 supports the notion that this Entrepreneurial spirit is captured in the differences between different country's use of smartphones. With countries that are more entrepreneurial favoring job-searches on smartphones over doing finances with said smartphone. Even though Uncertainty Avoidance itself was not significant in model-1, the significance of the interaction with the smartphone-use ratio was significant. However, the interaction is negative, indicating that Uncertainty Avoidance flips the relationship to favoring doing finances over searching for jobs. This is not all that surprising since Uncertainty Avoidance can play out in the maximization of the current job instead of wanting to explore new avenues.

In Power Distant countries, people with wealth will do their best to flaunt it in order to demonstrate that they have more status than people who are trying desperately to make ends meet. Unsurprisingly, Power Distance was significant with GINI—but very unexpectedly, the relationship was negative. The use of smartphones for luxury spending on vacations versus the survival driven use for shopping coupons, was not significant. There are several possible explanations, the first being that vacations are not so much a way to flaunt one's status and draw envy. This is hardly likely since nobody has a shortage of Facebook friends posting pictures of their vacation to show how well-traveled and exposed they are, in the process becoming the day's like-leader. The other possibility is that Smartphones are not considered a great way to search for vacations, which would not be surprising since the small screens would not be best for choosing your next vacation that is going to draw the most envy on Instagram. The interaction term was only significant to the 0.1 level. The more likely explanation here being that power distance reduces use for shopping coupons (the denominator in the ratio), because no self-respecting elite would be caught trying to save $2.

According to Hofstede, in Masculine countries, men are the bread-winners and by extension, the employers of bread-winners. Women on the other hand are supposed to be nurturers who maintain relationships. It was hypothesized that in more feminine countries, there should be less Gender-Inequality as far as economic power is concerned. Model-4 supports the idea that Femininity (the opposite of masculinity) is related to higher percentages of Female business owners through the negative relationship between Masculinity and percentage of Female-business ownership. However, the negative relationship between % of female-led businesses and the use of social media over emails was not expected. But it is possible that the notion that countries that are more feminine would favor social media is possibly as sexist as the very existence of a construct which says that productivity is a masculine construct, implying very politely that women should stay at home. It could be that with more feminine countries, women are too busy running those business using email, to waste time on social media. The interaction variable between these two was positive, suggesting that masculine countries where there is a tendency towards social-media instead of emails actually have higher percentages of female owned business. The implication of this is that the use of social media is a tempering of the masculine side which allows for the rise in female owned businesses.

CONCLUSIONS

The results of this study are important for several reasons. They confirm that there is a significant pattern in the way countries make use of smartphones for socio-economic activities, based on culture, which is moderated by the economic structure of the country. Also, that these smartphone uses do conform to some intuitive norms – such as social-networking (relationship maintenance) being a feminine activity.

Additionally, it was confirmed that Hofstede culture is related to socio-economic activity, for example Power Distance being related to Income Inequality, but interestingly, not in the way initially hypothesized. This would seem to suggest Power Distance is not important to people with unchallengeable economic power. It is possible the do not feel the need to flaunt their power to make themselves heard and be taken seriously, allowing them to focus on getting the best out of the people surrounding them. Financially powerful people may feel a lesser need to flaunt their power because they are more secure in their power and more focused on gaining more power by surrounding themselves with colleagues who create instead of drones who toe the line. This is reflected in the rise of Silicon Valley Billionaires showing up for work in jeans and t-shirt, in contrast to traditional managers just a few levels above, who donned pin-stripe suits to display their difference in status. These disparate ways in which power is shown is certainly consistent with the idea that by melding with staff, you get the best creativity out of them, versus drawing clear and distinct lines between them in order to establish command and control.

The other contribution of this study is the surprises found in the interactions and a few of the cultural effects. Some of the unexpected relationships suggest that technology doesn't necessarily follow cultural signals faithfully, and by its nature may flip culture on its head sometimes. We need to rethink some of the ways culture plays out in the economics and technology use of a country. Technology can be a game-changer which brings out the true nature of people when they feel freer to express themselves using tools such as mobile devices which extend their reach and give them a bigger platform, limited only by the importance of what they have to contribute.

The results of this paper will help people who design and market Smartphone apps to figure out the role that smartphones actually play among groups of countries and among groups within these countries. It is important to understand the wording, features and interface that apps should use – driven by culture - which will best appeal to prospective users in order to maximize usefulness and appeal. This will affect the layout and prominent features of apps, example, for banking compared to job search apps – across cultures. By understanding how the users of these apps vary by country, will help to optimize the way the apps are presented, the complexity of features and simplicity of use, the wording and positioning of advertising for these apps, and so on. Added to macro-economic indicators, the cultural indicators of a country will guide the design of effective apps which can translate to higher overall satisfaction with social media apps, e-mail apps, travel-search apps, shopping apps and so on.

By customizing the apps to fit the cultures and work-styles of the citizens of a country, they will ensure the smoothest and most enjoyable experiences for the users, ensuring that users derive the maximum satisfaction from using their smartphones and driving engagement, sales and customer loyalty to the institutions represented by these apps.

ABSTRACT

This paper discusses the functionality of social media in Higher Education (HE). The aim of the research reported in this paper was to identify the main factors and problem areas in the use of social media in HE. Our study included a survey involving students of Information Technology and Information Systems in Greece. The Honeycomb model and the theory of external and internal motivation were applied for this study.

The results showed that understanding content sharing is the most important issue in the planning of learning/teaching activities based on social media. We also found that conversations are less significant in HE context. Based on the analysis guidelines for planning social-media-based learning activities are proposed. Indications of further work complete the paper.

KEYWORDS: Social media, ICT/IS education, functionality, and honeycomb

INTRODUCTION

Communication, collaboration and content sharing are the foundation of social media. The term social media is interchangeable with the terms Web 2.0 and social software (Dabbagh & Reo, 2011). In recent years technology enhanced learning has become a fundamental part of Higher Education (HE) (Siakas et al., 2011). Rapid advances in Information and Communication Technologies (ICTs) have initiated fast and easy access to new electronic learning environments. In particular, Social Media Platforms (SMPs) have become an integral part of modern society. In the last 5 years they have been established both in academic and public use. They have completely changed the way we communicate, share and co-create information. Social networking is accomplished through a bottom-up approach and crowd-sourcing (Siakas et al., 2014). Engagement in SMPs, when used in education, usually means that students become active participants to a higher degree. This is partly due to the fact that learning becomes fun and is akin to leisure activities that these young people participate in, as opposed to remaining as spectators. The objective of motivating students to actively participate in their learning process is increased since students engage in all forms of social discourse by multi-way communication and action.

The aim of this study is revealing to show what aspects of SMPs can provide support for HE. In this way we can find two kinds of benefits for the future development regarding use of SMPs:

- in what way can an instructor use SMPs in teaching activities, and

- what are current deficiencies of SMPs.

We also clarify the use of SMPs in the light of motivation. Our analysis covers both external and internal motivation.

In the next sections, we present the background of this study including the honeycomb model and the motivation model. This is followed by research questions and methodology, results of the study and the discussion.

ASPECTS OF SOCIAL MEDIA USE

Kaplan and Haenlein (2010) have defined social media as a set of Internet-based services which are based on Web 2.0 ideology and technologies. These applications enable user-oriented content creation and sharing.

The honeycomb of social media is a useful tool for defining the role of a social media application in a certain context (Kietzmann et al., 2011). The honeycomb includes the following elements:

- presence;

- sharing;

- relationships;

- conversations;

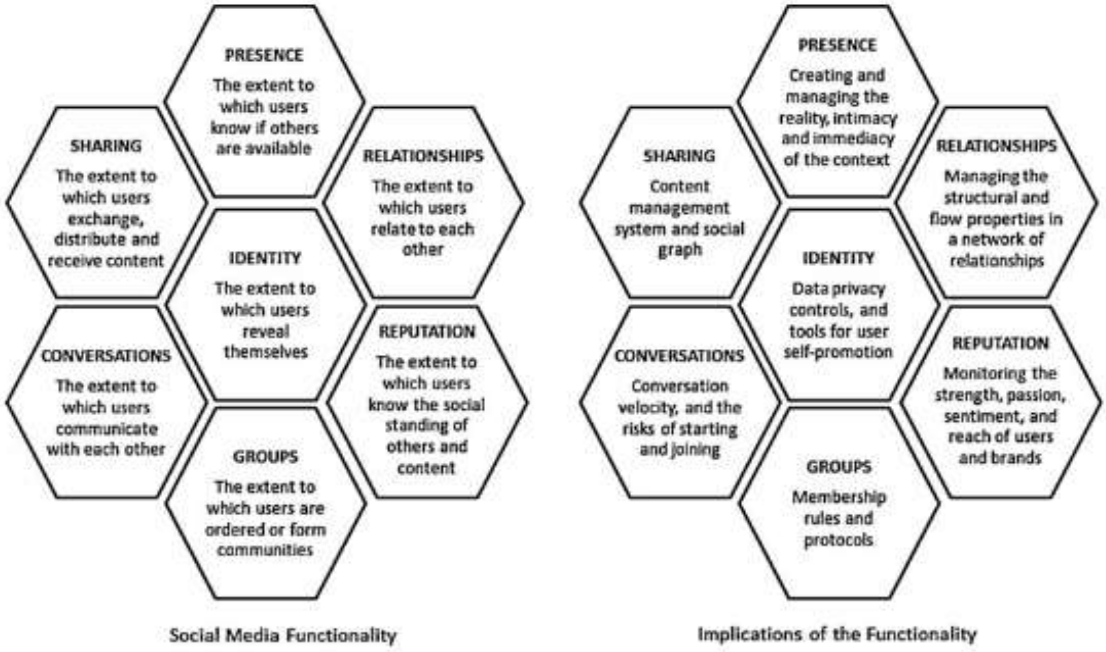
- reputation;

- groups;

- identity as the core item.

Figure 1 (see next page) demonstrates how the honeycomb can be used in analyzing social media use. First in this figure the honeycomb has been applied for the functionality of social media and then for the implications of social media.

Figure 1: Honeycomb for analyzing social media (Kietzmann et al., 2011)



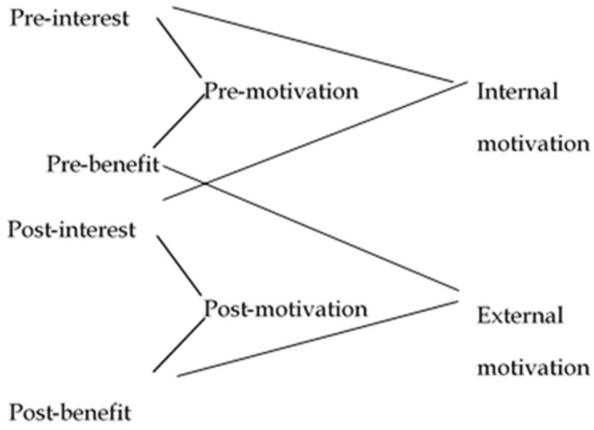
ENGAGEMENT AND MOTIVATION

Evaluating motivation is important from the perspective of our research context, because many problems in regard to learning the basics of informatics occur. Romano and Balthazard (1993) have summarized the problems. These include limited individualized attention, “cyberphobia”, in other words a fear of computers, a lack of interest in the subject matter, limited or no access to interactive learning software, and information overload leading to failure to make associations. These issues are relevant in the current era of web 2.0 and social media.

According to Schunk (1990), “motivation refers to the process whereby goal-directed behavior is instigated and sustained”. Most commonly in learning from text, motivation is understood both internally and externally (Biggs, 1984; Biggs, 1985; Entwistle & Ramsden, 1983; Linnakylä, 1988). Internal (intrinsic) motivation reflects a student's own interest in regard to espousing new knowledge. It is associated with a human's high-level need such as self-actualization. External (extrinsic) motivation reflects the need to reach goals set by others. This is connected to a human's low-level needs such as security and survival.

Motivation regarding learning from text can be evaluated as shown in figure 2 (see next page).

Figure 2: Motivation of learning from text (Linnakylä, 1989)



Pre-motivation is the sum of pre-interest and pre-benefit. Post-motivation is the sum of post-interest and post-benefit. Internal motivation is the sum of pre-interest and post-interest. External motivation is the sum of pre-benefit and post-benefit (Linnakylä, 1989).

OUR STUDY

In our study and this paper we explored what is important to the use of social media in education based on students' views. The aim was to find out what instructors should look at especially when creating social media based learning activities for their students. In this it is important to know what promotes the use of social media and what impairs.

Derived from the honeycomb model and the motivation model the major variables were:

- presence;

- sharing;

- relationships;

- conversations;

- reputation;

- groups;

- identity as the core item;

- internal motivation;

- external motivation.

Forty students from Alexander Technological Education Institute in Thessaloniki (Greece), 11 females and 29 males, whose mean age was 26 years (range 18-46 years), participated in our online Survey on Webropol platform. The respondents rated each item of five most significant social media tools on a scale of 1 to 5 where (1= not significant and 5=significant). The tools were Facebook, Twitter, LinkedIn, Pinterest, and Instagram from the list provided by Pew Research (Greenwood et al., 2016).

Each social media feature of each tool variable was merged into a one sum variable representing one feature of social media. The mean values of each sum variable were compared in order to analyze how well different honeycomb features of social media support learning. Statistical analysis was made by using SPSS.

ANALYSIS OF DATA

Table 1 shows the frequencies of the responses concerning the honeycomb variables of the study.

Table 1: Honeycomb frequencies (means)						
Presence	Sharing	Relationships	Conversations	Reputation	Groups	Identity as the core item
2.89	3.37	2.58	2.28	2.75	2.55	2.68

Table 2 shows the frequencies of the responses concerning the motivation variables of the study.

Table 2: Motivation frequencies (means)	
Internal motivation	External motivation
3.09	2.95

The Kolmogorov test showed that the data based on the responses of the students concerning the variables in our study did not agree with the normal distribution. Thus, the Mann-Whitney was appropriate for statistical analysis of the data when comparing the means of variables.

Concerning the honeycomb use model of social media we found significant differences (as all p values were less than .05) between the main variables as shown in Table 3 (see next page).

Table 3: Mann-Whitney results showing significant between the variables studied				
Variable 1	Variable 2	p value	Positive observation	Negative observation
Presence	Sharing	p=.014	Sharing is important	Presence is less important
Presence	Relationship	p<.001	Presence is important	Relationship is less important
Presence	Conversations	p=.002	Presence is important	Conversations are less important
Sharing	Relationship	p<.001	Sharing is important	Relationship is less important
Sharing	Conversations	p<.001	Sharing is important	Conversations are less important
Sharing	Reputation	p=.003	Sharing is important	Reputation is less important
Sharing	Groups	p=.001	Sharing is important	Groups are less important
Sharing	Identity as the core item	p=.004	Sharing is important	Identity as the core item is less important
Conversations	Reputation	p=.012	Reputation is important	Conversation is less important
Conversations	Identity as the core item	p=.042	Identity as the core item is important	Conversations is less important

The results show that sharing of content is the most important factor in the use of social media in HE, followed by internal and external motivation. The users of our sample did not prefer conversation on social media and instead they used other ways of communicating.

In addition, we evaluated motivation. We did not found significant difference in the Mann-Whitney test between internal and external motivation (p=0.396).

DISCUSSION

Different cultural contexts bring about differences in assumptions about learning and the expectations that participants have regarding learning and teaching, the teaching model and the relationships between educator and learner, the way the technology itself is experienced, the pedagogical aspect, the design of online courses and the way in which individuals and groups communicate and respond to their environment. New trends in teaching and learning, including social media learning environments, require a shift from instructor/educator-centered to learner-centered learning. A paradigm shift embracing active learning and knowledge sharing is needed. Participative learning is not only imperative but also made possible. The pedagogical trend today focuses more on learning than on teaching and calls for flexibility in teaching and assessment methods. To this respect, the nature of new technologies (ICTs) helps considerably (Siakas & Economides, 2012).

According to our results, social media shows its power regarding content sharing. Educators should look at this when applying social media in education. Our results also show that conversation is less important in the use of social media in education. This result may be caused by the fact that our data for this study has been collected in Greece. Because of this we will analyze the results from a cultural viewpoint referring to four main work-related cultural values described by Hofstede (2001) and the corresponding scores for Greece shown in table 4. Originally the scores were to be a continuum between 0 and 100, but when some countries were added after the formula had been developed scores greater that 100 became possible.

Table 4: Hofstede's cultural dimensions and their scores for Greece

Dimension	Description	Hofstede's Scores
Power Distance	The extent to which a society accepts the fact that power is distributed unequally among individuals	60
Uncertainty Avoidance	The extent to which a society feels threatened and tries to avoid ambiguous situations by rules	112
Masculinity vs. Femininity	The relationship between masculine assertiveness vs. feminine concern for social well being	57
Individualism vs. Collectivism	The relationship between the individual independence and the collective interdependence of a group	35

Below we discuss each dimension separately. This provides deeper view concerning what we have found in this study.

Power Distance: Greece scores 60 on the Power Distance dimension, which means that Greece is a country characterized as high Power Distance. The educational system in high Power Distance countries is teacher centered; anticipate teacher-student inequality with little questioning of authority (Hofstede, 1986; Spencer-Oatey, 1997). Students depend on teachers, who are considered to be gurus transferring personal wisdom. The quality of learning depends on the excellence of the teacher. The teachers, who are not questioned nor contradicted, initiate communication and the students speak up only when invited to do so. High Power Distance countries use less technology than low Power Distance countries, they have higher expectations on benefits of technology and in general they maintain a less critical attitude towards technology (Hofstede, 2001). Students in high Power Distance countries often feel role ambiguity and expect to be told what to do (Siakas & Mitalas, 2004).

Uncertainty Avoidance: Greece has the highest Uncertainty Avoidance score (112) of all the countries Hofstede used for his study (2001). The level of Uncertainty Avoidance determines the requirements of structures in the teaching and learning process. Students from high Uncertainty Avoidance cultures prefer structured teaching methods, tasks with clear outcomes, precise objectives, detailed assignments and no risks. They like to follow instructions and to have a strict timetable. They are motivated by security, fear of failure and they expect to be rewarded for accuracy. Self-efficacy is usually rated low (Hofstede, 2001). Students from high Uncertainty Avoidance societies also expect their teachers to be experts knowing the right answers (Hofstede, 2001; Hoppe, 1990). Teachers, who use cryptic academic language, are respected.

Masculinity vs. Femininity: Greece scores 57 on the Masculinity Femininity dimension, which means that Greece can be considered to be a Masculine society (Hofstede, 2001). In Masculine societies teachers' academic reputation and students' academic performance and excellence are dominant factors. Curriculum choices are guided by perceived career opportunities. Students try to make themselves visible in the class and compete openly with each other. The best student is considered to be the norm. Good students are awarded. Performance is usually overrated by the students themselves and the self (ego) boosted (Siakas & Mitalas, 2004). Students try to make themselves visible in the social media by posting and sharing knowledge and information. On the other side they also compete openly with each other and for that reason they may hide and obscure information and knowledge in order to be unique and get higher grades

Individualism vs. Collectivism: Greece scores 35 on the Individualism Collectivism dimension, which means that Greece is a collectivistic county (Hofstede, 2001). Purpose of education in the collectivist society is learning how to do in opposite to learning how to learn. Students' individual initiatives are discouraged. Students associate according to pre-existing in-group ties (in-group vs. out-group distinction). Teachers also deal with students as a group and students expect preferential treatment by teachers from their in-group. Students do not speak up in class or large groups and maintenance of 'face'[1] is important. Harmony should be maintained in the class and conflicts should be avoided (Siakas & Mitalas, 2004). Due to the collective characteristics of the Greek culture we believe that conversation is needed more in conventional ways such as talking face-to-face. If the social media is used by and in-group the sharing will be natural, otherwise it may need some time to build up the feeling of 'we' in the social media group.

Concluding we try to understand the power of each dimension on the opinions of the students. The Uncertainty Avoidance Dimension seems to be the most dominating dimension in the Greek culture due to the high score (112). It is likely that 'sharing' of material is considered the most important use of social media in HE due to the fact that social media provide a familiar forum with clear rules. We also need to take into consideration the free nature of social media. Due to the persisting financial crises (Dudin et al., 2016), students are looking for ways of finding material for free. Nowadays even the university libraries find it difficult to finance new resources. Another fact is that many students have to work simultaneously with their studies for financial reasons. This has led to the fact that many students due to lack of time practice surface learning instead of deep learning. Deep learning requires a willingness to thoroughly engage a topic or situation through a learning approach that is deep, opposed to surface learning that aims to get a degree, through a learning approach that is shallow and superficial. The need for students to develop critical thinking skills is indisputable, and the technological advantages of the information age have made information instantly available and readily accessible. Students know how to sift through large volumes of data in increasingly knowledge rich environments. Finding the "correct" or "best" information can, however, be problematic due to time needed, information clutter or insufficient sifting, sorting, or evaluation (Meeks et al., 2013). If the presence of the educator is obvious (needed in High Power Distance cultures) and enough time is given to the group using Social Media in HE in Greece for effective team building (in-group feeling needed in collectivistic cultures) the results are likely to be better. The

[1]Face is lost when the individual, either through his action or that of people closely related to him, fails to meet essential requirements placed upon him by virtue of the social position he occupies.

role of the educator is particularly important in Greece due to high power distance (top-down hierarchy) and uncertainty avoidance (structure needed) values.

Implications of Social Media functionality regarding sharing will be demonstrated below by an example of how an educator can initiate and motivate students to share educational content on social by media for improved learning and increased student satisfaction. In three of the modules at the department of Informatics of Alexander Technological Education Institute an experiment was introduced for investigating the outcomes of a different pedagogical approach. The students could voluntary choose to perform eight group-work assignment instead of final written exams. The groups that consisted of two-three students were asked, with clear rules and detailed instructions about the process, to investigate different subjects within the module curriculum. The students shared learning material and sources on social media, such as Google+, Dropbox and Facebook. The university annual internal assessments and interviews with students have shown that the students are very satisfied with the experiment of content and knowledge sharing. Also the average grades of the students that participated in the experiment were higher than the grades of those students that did not participate in the experiment. The students in the experiment considered that they get a deeper and wider insight in the subject under consideration. '*When reading for exams you read and try to figure out what exam questions there may be in the exams in order to pass the exam – by investigating in depth a certain subject and by sharing content you discover different viewpoints and as a natural outcome the subject become interesting*'. The experiment regarding functionality of social media in HE and sharing in particular proved that the students who participated in the experiment were more satisfied with the learning approach, they developed a higher level of critical thinking, they improved collaboration, sharing and presentation skills, hence, learning as an outcome was increased.

CONCLUSIONS AND FURTHER WORK

This paper discussed the adoption and use of social media in Higher Education (HE). The aim of the study reported was to identify the main factors and problem areas in the use of social media in HE, in particular functionality of Social Media in HE was analysed. Our study included a survey involving students of IT/IS in Greece. The Honeycomb model and the theory of external and internal motivation were identified to be suitable underlying theories for the study. The results showed that understanding content sharing is the most important issue in the planning of learning/teaching activities based on social media.

In the next phase of our research we are going to compare this data collected from Greece to data collected from Finland. In this way we can find the practices and recommendations for different cultures regarding the use of social media in education.

ABSTRACT

This research focuses on the use of social media (SM) by first-generation college students and their peers, and compares how the SM use affects the digital competence of these two groups. To do so, we collected survey data from a sample of 106 students in a 4-year public university in the United States. The data analysis showed that overall, an increase in the SM use time had a positive effect on digital competence. However, findings are different between first-generation college students and their peers in that their digital competence is affected differently by SM access frequency and duration time.

KEYWORDS: Social Media, Digital competence, Digital literacy, First-generation students, Regression

INTRODUCTION

The stagnant upward mobility and postsecondary educational success of first-generation students have been a prevalent issue in the United States, especially during a time of booming economic growth and innovations in the science, technology, engineering and mathematics (STEM) field. First-generation students are undergraduates whose parents' highest level of education is a high school diploma or less (Nunez & Cuccaro-Alamin, 1998). This population of college students face economic, social, and cultural challenges in their college education. As first-generation students are from challenging economic backgrounds and are the first in their family to attend a postsecondary educational institution to attain a bachelor's degree, they are more likely to drop out of college compared to their better-equipped peers. For example, the 2008 Center for Education Statistics' Beginning Postsecondary Study revealed that "[l]ow-income, first-generation students were nearly four times more likely - 26 to 7 percent - to leave higher education after the first year than students who had neither of these risk factors" (Engle & Tinto, 2008, p. 2). The large difference in dropout rates conveys the disparity between first-generation students and their peers and brings to attention the need to put more focus into the research on strategies to support first-generation students' persistence and success in their college educational journeys.

With the numerous challenges that first-generation students face, several possible solutions have been proposed to promote educational success for these students, including the use of an early rigorous curriculum, providing financial aid for college, and encouraging engagement on the college campus (Eagle & Tinto, 2008). In recent years, with the increasing reliance on smart phones and computers for communication and collaboration, researchers are turning their attention toward social media as a factor in influencing a first-generation student's education success. For example, researchers from Royall & Company found that underrepresented student groups are more likely to rely on social media channels in their college search, with 27 percent of first-generation students selecting a college through online sites such as Facebook, Snapchat, and Instagram compared to only 17 percent of non-first-generation students (Kelly, 2017). In addition, researchers from Prairie View A&M University (Rahman, Ramakrishnan, & Ngamassi, 2017) have studied the impact of social media use on college students' learning and found evidence to show the positive impact of using social media on student learning outcomes.

We refer to the collection of information and communication technology for social media platforms as social technology, which is defined as "any technology that facilitates social interactions and is enabled by a communications capability, such as the Internet or a mobile device" (Gartner, 2017; p. 1). Similarly, we refer to the skills and knowledge that correspond with using the social media technology as digital competence.

Since social media is playing an increasing role in the educational success of first-generation students, there is an opportunity for colleges to improve their social media resources and investments. However, not much is known about how the use of social technology affects the digital competence of first-generation students.

To fill in the gap, in this study, we attempt to address the following two research questions: (1) What are the determinants of digital competence of first-generation college students? (2) What is the relationship between first-generation students' use of social media and their digital competence?

To answer the research questions, we collected survey data from a sample of 106 students in a 4-year public university in the United States. To develop the hypotheses, we drew upon digital literacy research (e.g., Dabbagh & Kitsantas, 2011; Ng, 2012) and studies of first-generation students (e.g., Engle & Tinto, 2008; Nunez & Cuccaro-Alamin, 1998). Our quantitative data analysis showed that overall an increase in the social media use in terms of duration time had a positive effect on the digital competence of the college students. However, findings are different between first-generation and their peers: the duration time on social media had a positive effect on the digital competence of first-generation students, but the frequency of social media access had a positive effect on their peers, those who are not first-generation students. In addition, household income and age were significant factors in the first-generation student data sample, but gender was significant in the non-first-generation students' data sample.

This paper is organized as follows. In the next section, we develop our hypotheses. Following that, we present the research methodology and our preliminary findings. We conclude the paper with discussion and implications.

LITERATURE REVIEW AND HYPOTHESIS DEVELOPMENT

Digital literacy is broadly defined as individual ability to embrace information and communication technologies (ICT), in particular the use of mobile phones and social media technology (Ng,

2012). Possessing a certain level of digital literacy is essential for success in the college education. The study of undergraduates at a university in Australia suggested that in general, college students are able to use a wide range of computer information technologies, including desktop computers, laptops and mobile technologies for texting, capturing information, researching on the Internet, and downloading music and video files, but it is important for higher education institutions to provide them with opportunities to use the technologies for meaningful purposes (Ng, 2012).

In this paper, we focus on individual ability to use social media technologies and platforms and tools, and define a person's ability to efficiently utilize social media technology for certain tasks such as gathering information or collaborating on projects as digital competence. Social media, one major component of digital technology, is important to students "as a channel for communication, collaboration, and creative expression" (Dabbagh & Kitsantas, 2011, p.3). Through the use of social media, students will become more familiar with navigating through online sites and posts. Furthermore, as a tool for the interconnectedness and expression of a multitude of different people, social media will provide students with exposure on how to use digital technology to access educational opportunities and keep up with important current events. Therefore, we hypothesize that:

Hypothesis 1: Use of Social Media has a positive effect on users' digital competence.

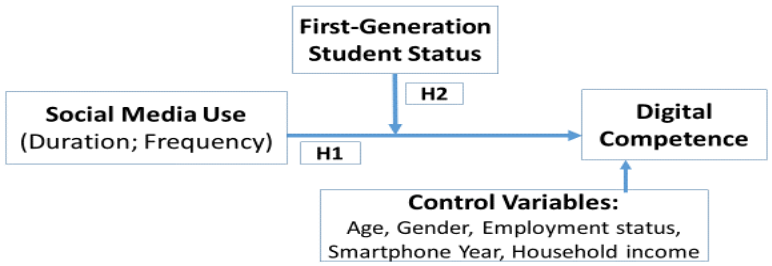
Social media is a great tool for students when searching for educational opportunities and being connected with others. Furthermore, it is beneficial in improving a student's familiarity with the uses of digital technology such as online collaborative projects and presentations. However, social media use can have a larger influence on a first-generation student's digital competence compared to those who are not first-generation students. This is because students that are not first-generation students may already have access to other resources for educational purposes such as their parents, tutors, or peers.

In contrast, first-generation students often encounter more barriers in their college education than their peers: they lack financial support from their family and have multiple obligations beyond their college responsibilities. Nunez & Cuccaro-Alamin (1998) outlined some of the barriers students face when completing their degrees: "poor academic preparation, family responsibilities, and full-time work, for instance, can pose severe challenges to a student's ability to integrate into postsecondary institutional life" (p.2). Although these factors are influential in determining a student's success in college, other factors that may often be overlooked are a student's experiences prior to postsecondary education, such as extracurricular activities and social experiences (Engle & Tinto, 2008). By missing out on such experiences, these students eventually lacked the necessary preparation and social exposure that would usually foster success in college. Since they often lack these resources, they often rely on self-regulated learning, the learning enabled by a student's ability to independently and proactively engage in self-motivating behavioral processes and aimed at attaining goals (Zimmerman, 2000). Such self-regulated learning relies greatly on social media use and digital competence. Thus, we hypothesize that:

Hypothesis 2: The relationship between social media use and digital competence is moderated by the status of first-generation students; the effect is bigger when users are first-generation students than those who are not.

Both hypothesis 1 and 2 are depicted in the research model in Figure 1 below.

Figure 1: Research Model



METHODS

Research Site and Data Collection

The research site is a four-year public, urban university located in the west region of the United States. As an ethnically and economically diverse university, the campus recently reports that 61% of its student population identify themselves as the first in their families to go to college. The survey was conducted online in November 2017 by freshmen who were expected to complete the survey in 10 minutes. The survey asked the students to identify themselves as "first-generation college students" or not. In addition, respondents to the survey were ensured that no names or personal identity information would be collected to protect their confidentiality. The survey included questions about their social media usage behavior, such as time spent on social media, frequency of using social media, and the list of social media accounts they have.

Table 1: Demographic Characteristics of Participants

		Non-FirstGen (n=18)	FirstGen (n=88)	Grand Total (n=106)
	Total	**17.0%**	**83.2%**	**100.00%**
Gender	Female	12.26%	62.26%	74.53%
	Male	4.72%	18.87%	23.58%
	Gender Non-Conforming	0.00%	1.89%	1.89%
Ethnicity	American Indian or Alaskan Native	0.0%	0.9%	0.9%
	Asian or Pacific Islander	3.8%	1.9%	5.7%
	Black or African American	3.8%	6.6%	10.4%
	Hispanic or Latino	4.7%	72.6%	77.4%
	White / Caucasian	4.7%	0.9%	5.7%
Employment Status	Employed full-time	0.9%	1.9%	2.8%
	Employed part-time	5.7%	19.8%	25.5%
	Not employed	10.4%	61.3%	71.7%
Household Income	1_Less than $25,000	5.7%	39.6%	45.3%
	2_$25,000 - $49,999	2.8%	34.0%	36.8%
	3_$50,000 - $74,999	5.7%	4.7%	10.4%
	4_$75,000 - $99,999	0.0%	1.9%	1.9%
	5_$100,000 or more	2.8%	2.8%	5.7%

The table below summarizes the demographic characteristics of the survey participants. A total data sample of 106 participants is analyzed and reported in this article. The majority of the 106 students surveyed, 83 percent, are first-generation students. 62.26 percent of all students are female and first-generation students. 72.6 percent of those students are Hispanic or Latino and first-generation students. 61.3 percent of those students are unemployed and first-generation students. 39.6 percent of those students have a family income of less than $25,000 and are first-generation students. 34 percent of those students have a family income between $25,000 and $49,999 and are first-generation students. All the percentages are based on the grand total of 106 respondents.

Model

The two items for digital competence are adopted from Ng (2012); the items were measured by using the 5-likert scale. These two questions are "*I can learn new social media technologies easily"* and *"I have the technical skills I need to use social media technologies for learning and to create artifacts (e.g., videos, digital stories, wikis, and blogs)"*. For each dimension, we code "strongly agree" as 5, "agree" as 4, "neutral" as 3, and "disagree" as well as "strongly disagree" as 2 and 1. As a result, the total rating for each measure ranges from 1 to 5. We took the average of the two items to measure an individual's overall digital competence.

We then measure social media use by access Frequency (*Frequency*) and use duration time (*Duration*). Our main model is Equation (1), which is estimated using the ordinary least squares (OLS) model for all students or for only the first-generation students. In the model, the control variables are Age, Gender, Employment Status, Years of having a Smartphone, and Household income.

$$\text{Digital Competence} = ß_0 + ß_1\, Frequency + ß_2\, Duration + ß_3\, Age + ß_4\, Gender + ß_5\, Employment + ß_6\, SmartPhoneYr + ß_7\, Household\_Income + \varepsilon \quad (1)$$

RESULTS

Descriptive Statistics

Distribution of Social Media Accounts by Participants

83.02% of all students own an Instagram. 68.87 percent of all students own an Instagram and are first-generation students. 82.1 percent of all students own a YouTube. 67.9 percent of all students own a YouTube and are first-generation students. 45.3% of all students own a Facebook. 35.8 percent of those students own a Facebook and are first-generation students, and 47.2 percent of those students don't own a Facebook and are first-generation students. In total, 87.7 percent of all students own a Snapchat. 73.6 percent of all students own a Snapchat and are first-generation students.

42.5 percent of all students own a Twitter. 32.1 percent of all students own a Twitter and are first-generation students. Only 16.0 percent of all students own a Pinterest. 11.3 percent of all students own a Pinterest and are first-generation students. Finally, 3.8 percent of all students own a LinkedIn. 2.8 percent of all students own a LinkedIn and are first-generation students. The distribution of social media account ownership is summarized in the table below.

Table 2: Distribution of Social Media Accounts by Participants (n=106)				
Social Media Account	Ownership?	Non-FirstGen	FirstGen	Grand Total
(1) Snapchat	YES	14.2%	73.6%	87.7%
	NO	2.8%	9.4%	12.3%
(2) Instagram	YES	14.1%	68.9%	83.0%
	NO	2.8%	14.2%	17.0%
(3) YouTube	YES	14.2%	67.9%	82.1%
	NO	2.8%	15.1%	17.9%
(4) Facebook	YES	9.4%	35.8%	45.3%
	NO	7.5%	47.2%	54.7%
(5) Twitter	YES	10.4%	32.1%	42.5%
	NO	6.6%	50.9%	57.5%
(6) Pinterest	YES	4.7%	11.3%	16.0%
	NO	12.3%	71.7%	84%
(7) LinkedIn	YES	0.9%	2.8%	3.8%
	NO	16.0%	80.2%	96.2%
Grand Total		17.0%	83%	100%

Percentages in this table and in tables 3&4 are based on the grand total of 106 respondents.

Among all these social media accounts, the three most popular types of social media are Snapchat, Instagram and YouTube with 87.7 percent, 83 percent and 82.1 percent respectively. The two least popular types of social media are Pinterest and LinkedIn with 16.0 percent and 2.8 percent respectively.

Social Media Use Patterns among Participants

Among all the first-year college students, the majority used social media every 2-3 hours (33.0 percent), followed by every 1 hour (23.6 percent). For the first-generation students, the pattern is similar with the majority using social media every 2-3 hours (27.4 percent), followed by an equal percent of first-generation students using social media every 1 hour and every 4-6 hours (17.0 percent). The distribution of social media access pattern is summarized in the table below.

Table 3: Patterns of Social Media Use by Participants (n=106)			
	Non-FirstGen	FirstGen	Grand Total
By Social Media Access Frequency			
Frequency1_Every 30 minutes	0.9%	15.1%	16.0%
Frequency2_Every 1 hour	6.6%	17.0%	23.6%
Frequency3_Every 2-3 hours	5.7%	27.4%	33.0%
Frequency4_Every 4-6 hours	3.8%	17.0%	20.8%
Frequency5_Every 7 hours +	0.0%	6.6%	6.6%
By Social Media Use Duration			
Duration1_Less than 1 hour	3.8%	17.0%	20.8%
Duration2_1-2 hours	5.7%	20.8%	26.4%
Duration3_3-4 hours	4.7%	21.7%	26.4%
Duration4_5 hours or more	2.8%	23.6%	26.4%
Grand Total	17.0%	83%	100%

As shown in the table above, the different amount of time students spend on social media is equally proportioned between 1-2 hours, 3-4 hours, and 5 hours or more (26.4 percent) and a

smaller percent of students using social media for less than 1 hour (20.8 percent). The pattern for first-generation students is slightly different with the largest percent using social media for 5 hours or more (23.6 percent).

Self-Assessment of Social Media Skills and Usage

Both first-generation students and non-first-generation students have about the same evaluations on how easily they can learn social media technologies. However, more non-first-generation students strongly believe that they have the technical skills to use social media technologies for learning than first-generation students with 27.8 percent and 21.6 percent respectively. These patterns in participants' self-evaluation are shown in the table below.

Table 4: Participants' Self-Assessment of Social Media Competence (n=106)			
	Non-FirstGen	FirstGen	Grand Total
Response to the statement: "I can learn new social media technologies easily.			
Agree	50.0%	42.0%	43.4%
Agree strongly	22.2%	27.3%	26.4%
Disagree strongly	0.0%	1.1%	0.9%
Neutral	27.8%	29.5%	29.2%
Grand Total	100%	100%	100%
Response to the statement; "I have the technical skills I need to use social media technologies for learning and to create artifacts (e.g., videos, digital stories, wikis, blogs)."			
Agree	27.8%	29.5%	29.2%
Agree strongly	27.8%	21.6%	22.6%
Disagree	0.0%	8.0%	6.6%
Neutral	44.4%	40.9%	41.5%
Grand Total	100%	100%	100%

Spearman Correlation

We have examined the spearman correlations for the variables used in our analysis. The highest correlation we observed is 0.21 between employment status and age, which does not raise any multicollinearity concerns for our regression model.

Main Results

Our main results are given in Table 5, Table 6 and Table 7. Table 5 is based on the first competence measure. Table 6 uses the second competence measure while the average of the two measures is considered in Table 7. Each table presents three sets of results: full sample, first-generation, and non-first-generation.

Table 5 demonstrates that when we focus on the full sample (again, based on the first competence measure), age is negatively associated with digital competence (-0.25, $p < 0.05$) and the duration time of using social media is positively related to digital competence (0.21, $p < 0.01$). When we look at the findings of the first-generation students, the results are similar to those in the full sample. However, when we switch our focus to the non-first-generation student group, gender (male compared to female, coefficient is 1.25, $p < 0.05$) and social media usage frequency (-0.44, $p < 0.10$) become the only two significant factors. However, given the small sample size of this group, this result needs to be interpreted with caution.

Table 5: Main Results based on the First Competence Measure			
	Full Sample	First-Gen	Non-First-Gen
Intercept	7.89*** (2.29)	9.05*** (2.81)	1.90 (4.72)
Gender_Male	-0.05 (0.18)	0.00 (0.2)	1.25** (0.41)
Age	-0.25** (0.13)	-0.34** (0.16)	0.12 (0.27)
Employed	0.13 (0.17)	0.10 (0.20)	0.29 (0.38)
SmartPhoneYear	0.05 (0.05)	0.08 (0.05)	0.08 (0.14)
Household_Income	0.05 (0.07)	0.11 (0.09)	-0.06 (0.15)
Social Media Frequency	-0.09 (0.07)	-0.04 (0.07)	-0.44* (0.20)
Social Media Duration	0.21*** (0.07)	0.21*** (0.07)	0.14 (0.21)
N	106	88	18
Adj R^2	0.11	0.11	0.45

Standard errors are in parenthesis, * $p < 0.10$, ** $p < 0.05$, *** $p < 0.01$

We next turn our attention to the second measure and the aggregate measure of digital competence. The results are presented in Table 6 and Table 7 respectively.

Table 6: Main Results based on the Second Competence Measure			
	Full Sample	First-Gen	Non-First-Gen
Intercept	4.85 * (2.65)	7.54 ** (3.27)	2.58 (4.47)
Gender_Male	0.32 (0.21)	0.20 (0.24)	0.74* (0.39)
Age	-0.11 (0.15)	-0.27 (0.18)	0.13 (0.25)
Employed	-0.03 (0.20)	-0.01 (0.23)	0.29 (0.36)
SmartPhoneYear	0.06 (0.06)	0.04 (0.06)	-0.14 (0.14)
Household_Income	0.11 (0.08)	0.21* (0.11)	0.02 (0.14)
Social Media Frequency	-0.06 (0.08)	0.02 (0.09)	-0.42 * (0.19)
Social Media Duration	0.17** (0.08)	0.16 * (0.09)	0.19 (0.2)
N	106	88	18
Adj R^2	0.05	0.05	0.21

Standard errors are in parenthesis, * $p < 0.10$, ** $p < 0.05$, *** $p < 0.01$

First, our main results regarding the positive association between social media duration time and digital competence hold in both the second measure and the aggregate measure under the full sample and the first-generation group. In addition, the negative association between social media usage frequency and digital competence for the non-first-generation group also holds in both Table 6 and Table 7. We discuss the implications of these findings in the next section.

Table 7: Main Results based on the Aggregate Competence Measure			
	Full Sample	First-Gen	Non-First-Gen
Intercept	6.37 *** (2.21)	8.30*** (2.73)	2.58 (4.47)
Gender_Male	0.13 (0.17)	0.1 (0.2)	0.74 * (0.39)
Age	-0.18 (0.12)	-0.31 ** (0.15)	0.13 (0.25)
Employed	0.05 (0.17)	0.05 (0.19)	0.29 (0.36)
SmartPhoneYear	0.05 (0.05)	0.06 (0.05)	-0.14 (0.14)
Household_Income	0.08 (0.07)	0.16 * (0.09)	0.02 (0.14)
Social Media Frequency	-0.07 (0.07)	-0.01 (0.07)	-0.42 * (0.19)
Social Media Duration	0.19 *** (0.07)	0.18 ** (0.07)	0.19 (0.2)
N	106	88	18
Adj R^2	0.09	0.11	0.21

Standard errors are in parenthesis, * $p < 0.10$, ** $p < 0.05$, *** $p < 0.01$

Overall, the main results from the regression analysis supported the first hypothesis on the positive role of social media use on digital competence, based on the duration time of social media use, as shown in the results of the full sample in Tables 5-7. This positive relationship holds in the sample of first-generation students (column 2, Tables 5-7), but not in the non-first-generation student sample (column 3, Tables 5-7). These results provide evidence to show that first-generation students benefit more from social media use in improving their digital competence, thus supporting the second hypothesis.

DISCUSSION

This research sought to investigate the behaviours and competence levels of social media use in first-generation college students and their peers, mostly at the age of 18 in their freshman year at college. The research findings indicate that social media use is pervasive among college students, regardless of their first-generation student status. More than eighty percent of the survey participants own the three most popular social media accounts: Snapchat, Instagram, and YouTube. About 4 out of 10 survey participants (39.6%) reported accessing social media every one hour or every 30 minutes, and half of the participants (52.8%) reported spending three or more hours daily on social media.

Participants in our survey provided us some examples on how they utilize social media platforms to search for educational resources online and to communicate with their classmates to share course-related information. These types of social media enabled activities were found beneficial to the college students in our study, as they explained:

> *Using social media is helpful to my study, because you can find videos and peoples experiences in certain areas that you're study. For example my disability class focuses a lot on films and social media.*

> *I will say social media helps because if the person is stuck on something, they can talk to one of their classmate or look up on YouTube on how to solve the problem they are stuck on.*

These responses by the students suggest that it's important for college students to develop skills in using social media. However, our study shows that only half of the participants (51.8%) in our data sample were confident about their competence in using social media technologies for educational purposes such as creating videos, digital stories, wikis, or blogs. On the other hand, 41.5 percent of the participants took a neutral stand on their competence in using digital technology (See Table 4). Participants in our study are first-year college students with ages between 17 and 21, with an average age of 18.1. They are all born after 1995; they are from the Generation Z, the segment of the population born between 1995 and 2010. Growing up in a world of smartphones and free Wi-Fi, young adults of this generation are assumed to be equally Internet-savvy and proficient in information and communication technology, especially those social networking applications such as Facebook, YouTube, Twitter, Instagram, and LinkedIn (Priestley, 2015). Our study shows that not all of the Generation Z college students are equally competent at using social media technologies for academic work. However, the regression analysis in our study has provided sufficient evidence to show the more time spent on social media, the more the digital technology competence of young adults' would improve.

Another important finding is that the social media access frequency is negatively associated with digital competence, and this negative effect is significant for the non-first-generation students (e.g., -0.42 at $p<0.1$ in Table 5, column 3). This may be partially explained by the distraction caused by frequent access to social media for entertainment purposes instead of educational purposes. Such uses of social media for entertainment purposes are reflected in the instances below:

> *I believe there may reach a point where social media interactions would become distracting. For example, if a student has many friends and all want to talk.*

> *I think that they are a good use to communicate with friends or professors, but there are times where social media could be distracting*

As social media use becomes pervasive among young adults, Generation Z, it is important for them to not only develop their competence with digital technology, but also to use that competence for meaningful activities that support their educational growth. The findings of this study suggest that it is time for higher education institutions to consider incorporating social media tools and platforms in the academic program design (e.g., course delivery channel, instructor feedback mechanism) to take advantage of the students' digital competence and to benefit from the technological affordances for communication and collaboration. For college students, they should focus on their purposeful use of social media to capitalize on an important educational resource.

Our finding may be limited by the organizational characteristics of the research site, the economically-diverse urban public university with majority of students are undergraduate students of first generations. Thus, the findings of this study should be applied to other types of higher education institutions with caution.

CONCLUDING REMARKS

Developing competence with social media technologies is important for the college students, especially first-generation college students who lack educational resources at home or in their own community. One Forbes article noted, “As a digital generation, Generation Z expects digital learning tools such as these to be deeply integrated into their education. For them, technology has always been a fully integrated experience into every part of their lives” (Kozinsky, 2017). One promising direction for future research is to conduct a longitudinal study to examine the role of social technology competence on the college persistence of first-generation students. Dennis and colleagues (2005) have suggested that support from peers, such as sharing notes, studying in groups, sharing learning strategies, made the biggest impact upon first-generation college students’ success in college. With such a widespread use of social media in today's society, social media platforms may provide a convenient tool for first-generation students to access and mobilize resources made available by their peers or teachers.

ABSTRACT

This paper analyzes the spatial distribution and socio-economic determinants of social media utilization in 3,109 counties of the United States in 2012. A theory of determinants is presented that is modified from the Spatially Aware Technology Utilization Model (SATUM). Socio-economic factors including demography, economy, education, innovation, and social capital are posited to influence social media utilization dependent variables. Spatial analysis is conducted including exploratory analysis of geographic distribution and confirmatory screening for spatial randomness. The determinants are identified through OLS regression analysis. Findings for the nation indicate that the major determinants are demographic factors, service occupations, ethnicities, and urban location. Further subsample analysis is conducted for the U.S. metropolitan, micropolitan, and rural subsamples. The subsamples differ most evidently in effects of ethnicities and construction occupations, and there are inverse effects of social capital at the micropolitan and rural levels. Exploratory spatial analysis generally indicates similar geographic patterns of use of social media nationally. We find that Twitter users are more heavily concentrated in southern California and have strong presence in the lower Mississippi region, while Facebook users are highly concentrated in Colorado, Utah and adjacent Rocky Mountain States. Social media usage is lowest in the Great Plains, lower Midwest, and South with the exceptions of Florida and the major southern cities such as Atlanta. The overall extent of spatial agglomeration is very high and is examined in detail for the nation and subsamples. The paper concludes by discussing the policy implications of the analysis at the county as well as the national levels.

KEYWORDS: Social media, spatial analysis, United States, counties, regression, spatial autocorrelation, and policy
